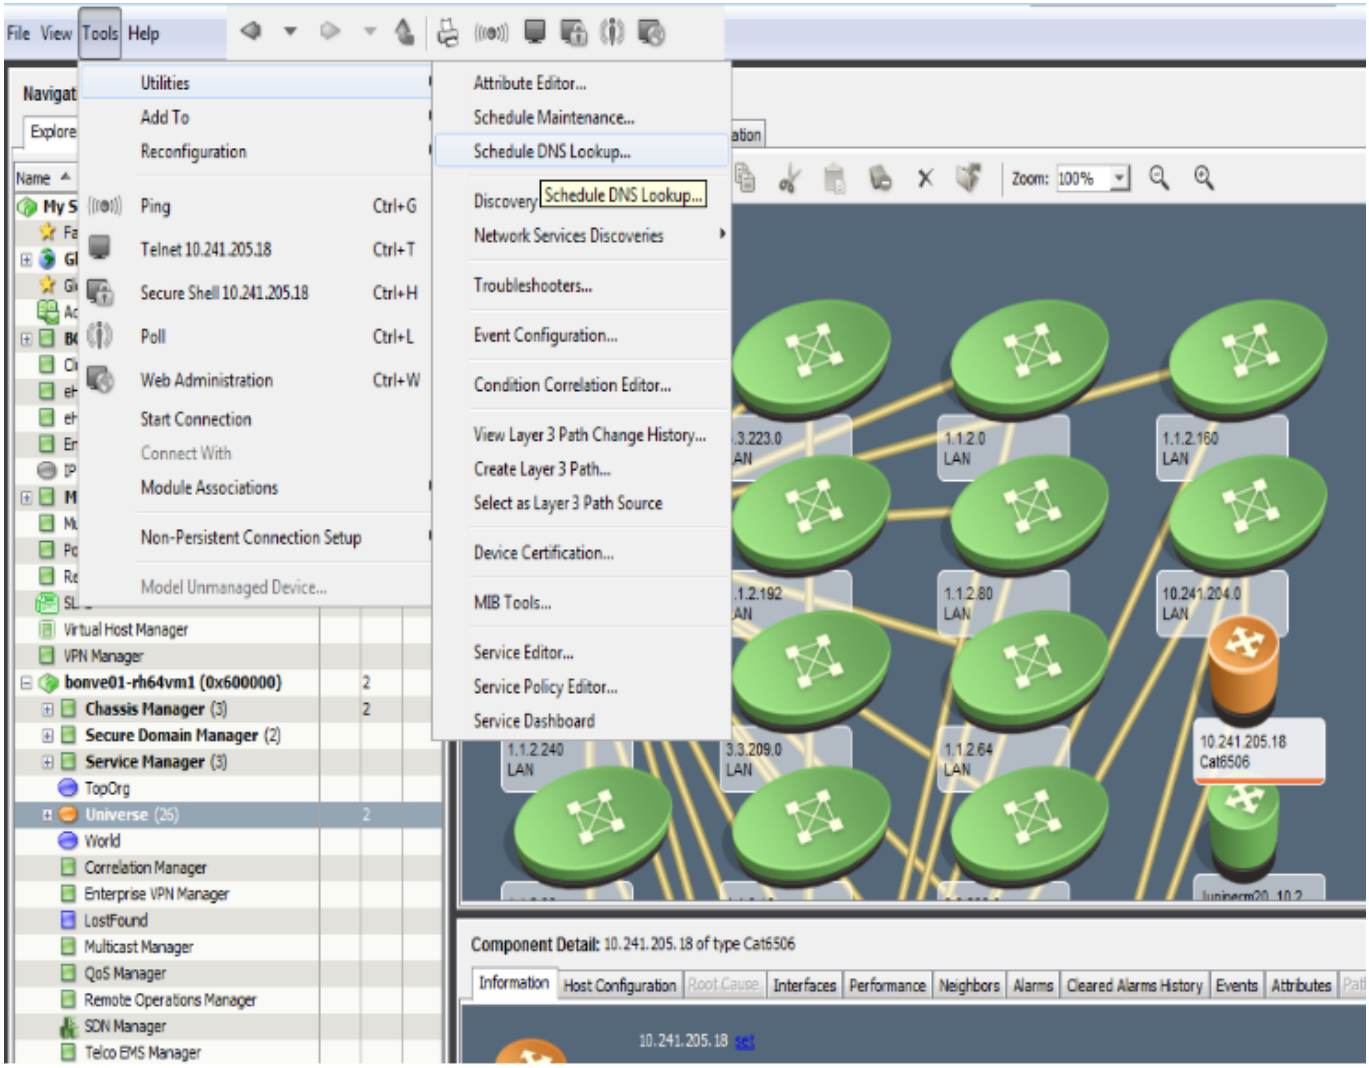
Schedule DNS Lookup

The Schedule DNS lookup is created to perform DNS lookup at a specified date and time. The DNS lookup is triggered only for the models having ' *do_dns_lookup*' attribute value set to yes, as part of the schedule.

Follow these steps to schedule a DNS lookup:

1. Log in to OneClick console.
2. Click the Explorer tab.
3. Select the device model on which you want to create a schedule for the DNS lookup.
4. Navigate to **Tools**, **Utilities**, **Schedule DNS Lookup**.



5. Select from the **Available Schedules** or create **New** schedules.
   Available recurrences are **Daily**, **Weekly**, **Monthly**, **Yearly**.
   (The time that is specified is relative to the 'SpectroSERVER's local time zone).
   After the schedule is created and attached to a model or group of models, the DNS Lookup is performed on those models when the schedule goes active.
6. To see the models that are associated to a DNS schedule, navigate to **Locater, Schedules, All Schedules**, **Information Tab** and expand **Items Scheduled for DNS Lookup** subview.

Events for DNS Lookup

The following events are generated, when a DNS schedule is associated and disassociated:

- 0x11005 - (DNS Schedule is associated)
- 0x11006 - (DNS Schedule is disassociated)

The following event is generated, when the IP changed after the DNS lookup.

- 0x11007

Enable and Disable Event Logging

To enable event logging, from the command-line interface, run the following command:

```
update action=0x10803 mh=<model handle of the model for which logging has to be enabled>
```

To disable event logging, from the command-line interface, run the following command:

```
update action=0x10804 mh=<model handle of the model>
```

The disable command disables the logging irrespective of the model for which the logging is enabled.

You can find the above events that are captured as part of logging into VNM.OUT.

Single Sign-On

Single Sign-On is the authentication scheme for DX NetOps Spectrum and all supported data sources. Once they are authenticated to DX NetOps Spectrum, users can navigate the console and registered data sources without signing in again.

Enabling the navigation of multiple product interfaces ensures a seamless drilldown experience for operators analyzing performance and status data. For example, if a user logs in to DX NetOps Spectrum and follows a drilldown path to the data source interface, that the user does not log in again.

DX NetOps Spectrum uses a distributed architecture. The Single Sign-On website is automatically installed on every server where a supported data source or DX NetOps Spectrum is installed. The distributed architecture lets users log in to data source products by logging in to the servers where these products are running.

SAML2 Authentication in DX NetOps Spectrum

You can authenticate users with SAML 2.0 through your organization's Identity Provider (IdP). DX NetOps Spectrum now supports Security Assertion Markup Language (SAML) 2 authentication as a single sign-on login standard for this purpose. SAML is a standard for logging users into applications based on their sessions in another context.

SAML2 authentication in DX NetOps Spectrum supports the following IdPs:

- Auth0
- Okta
- Onelogin
- Microsoft Azure Active Directory (Azure AD)
- Any Other SAML2.0 IdP

Enable Single Sign-On

The following procedure lists the steps to integrate DX NetOps Spectrum with the identity provider server.

Follow these steps:

1. Enable SSL in DX NetOps Spectrum OneClick Server.
2. Configure the IDP server - Create DX NetOps Spectrum app in Identity Provider (IdP) Server.
3. Create DX NetOps Spectrum users for Single Sign-On.

   NOTE
   The **IdP usernames** and **DX NetOps Spectrum usernames** must match, else the authentication fails.
4. Download the IdP Server x509 certificate and Import the certificate into KeyStore of DX NetOps Spectrum OneClick Server.

5. Configure the fediz_config.xml file.
   a. Open the `fediz_config.xml` file located in the `<SPECROOT>/tomcat/conf` directory.
   b. Update the following fields:
      - **audienceItem**
        Specifies the Audience URI. For example, https://spectum_host/spectrum/

        NOTE
        Audience URI: The application-defined unique identifier that is the intended audience of the SAML assertion. This is most often the SP Entity ID of your application.
      - **Issuer**
        Specifies the IdP Single Sign-On URL. For example, https://oneclickhostname.broadcom.net:8443/spectrum/

        NOTE
        Single Sign-On URL: https://oneclickhostname.broadcom.net:8443/spectrum/ The location where the SAML assertion is sent with an HTTP POST. This is often referred to as the SAML Assertion Consumer Service (ACS) URL for your application.
      - **realm**
        Specifies the IdP Audience URI. For example, https://spectum_host/spectrum/

        NOTE
        The **audienceItem** and **realm** parameters must have the same value.
      - **(Optional) reply**
        Single Sign-On URL: https://oneclickhostname.broadcom.net:8443/spectrum/ The location where the SAML assertion is sent with an HTTP POST. This is often referred to as the SAML Assertion Consumer Service (ACS) URL for your application.
   c. Update the Keystore file location in the following parameters values:
      - certificateStores
      - signingKey
      - tokenDecryptionKey
   d. **Retain the default values for all other parameters.**
   e. Save and close the file.
6. Configure Basic Authentication for other product integrations.
   DX NetOps Spectrum SAML Authentication supports web browser single sign-on. Some integration clients like the ones listed below are not browser-based applications:

   - Spectrumgtw probe - UIM Integration
   - DX NetOps Spectrum - DX OI Connector
   - Other clients which use Rest API's to communicate with DX NetOps Spectrum.

   For such clients, DX NetOps Spectrum allows the user to communicate using the basic authentication.
   To configure basic authentication, follow the below steps:

   1. Open the `non-saml-config.xml` file from the `<SPECROOT>/tomcat/conf` directory.
   2. Set the `allowBasicAuthentication` parameter to true.
      ```
      <allowBasicAuthentication>true</allowBasicAuthentication>
      ```
   3. Specify the spectrum user name which is used for integrations. You can use only the listed users in this configuration.
      ```
      <userName>spectrumUser1</userName>
      <userName>spectrumUser2</userName>
      ```
   4. Save and close the file.
7. Enable SAML Authentication.
   a. In the OneClick Web interface, click the **Administration** tab.
   b. Click the **Single Sign-On Configuration** link.

c. Select SAML as SSO option.
d. In case the tomcat does not restart automatically, manually restart the tomcat.
e. Stop the tomcat and start the tomcat.
For more information, see Start and Stop the OneClick Web Server from the command-line.
The changes are applied after the tomcat server restarts.

Disable Single Sign-On

You can disable the SAML authentication when it is not required. You can use the DX NetOps Spectrum administration UI to disable SAML. In case, you did not create the IdP user in DX NetOps Spectrum and enabled SAML, you can disable SAML using the command line.

Disable SAML using GUI

Follow these steps:

1. In the DX NetOps Spectrum, navigate to Administrator, Single Sign-On Configuration.
2. Select **No Single Sign-On.**
3. Save and confirm save at the prompt.
4. Restart the Tomcat server.

Disable SAML using Command Line

Follow these steps:

1. Open the `context.xml` file from the `<SPECROOT>/tomcat/conf/` directory.
2. Change the value from `com.aprisma.tomcat.authenticator.Saml2FederationAuthenticator` to `org.apache.catalina.authenticator.BasicAuthenticator`.
3. Save and close the file.
4. Open the `web.xml` file from the `<SPECROOT>/tomcat/webapps/spectrum/WEB-INF/` directory.
5. Change the value of the `<auth-method></auth-method>` parameter from WSFED to BASIC.
6. Save and close the file.
7. Restart the Tomcat server.

Integrating with CA Embedded Entitlements Manager

About the DX NetOps Spectrum Integration with CA Embedded Entitlements Manager

Single Sign-On is a separate component that uses the CA Embedded Entitlements Manager (CA EEM) solution. It is not configured as part of the DX NetOps Spectrum installation. Instead, you must activate it after you install DX NetOps Spectrum by modifying configuration settings from the Administration pages on the OneClick server.

Intended Audience

The How to Configure DX NetOps Spectrum/CA EEM Integration section is intended for administrators who want to set up authorization access for DX NetOps Spectrum with CA EEM. The DX NetOps Spectrum integration with CA EEM addresses the need for fine-grained access control to DX NetOps Spectrum enterprise applications and other applications integrated with DX NetOps Spectrum.

Before using this section to integrate DX NetOps Spectrum with CA EEM, you should have knowledge about DX NetOps Spectrum user management and you should be familiar with the OneClick Administration pages. No special knowledge of CA EEM is required to specify integration parameters from the DX NetOps Spectrum environment. However, some

knowledge of user management such as user creation and integration with LDAP (for registering DX NetOps Spectrum users in CA EEM) is required in the CA EEM environment.

How to Configure the Integration

Follow this process to configure the integration of DX NetOps Spectrum and CA EEM:

1. Install CA EEM.

   NOTE
   For more information, see the *CA EEM* documentation. We recommend that you install CA EEM on a separate machine.
2. Register DX NetOps Spectrum users with CA EEM.
3. Configure the CA EEM server for single sign-on in OneClick:
   a. Configure CA EEM server connection parameters.
   b. Test connectivity to the CA EEM server.
   c. Save connection parameters settings.

Register DX NetOps Spectrum Users with CA EEM

After installing CA EEM, register DX NetOps Spectrum users in CA EEM before you configure Single Sign-On (SSO) settings for them.

Follow these steps:

1. Open a browser and navigate to the CA EEM home page.
2. Log in as the CA EEM administrator.
   Default: EiamAdmin.
3. Click the Manage Identities tab.
4. Click the New User icon in the Users panel.
5. Add the DX NetOps Spectrum user to the CA EEM system by supplying values in the fields provided.

   NOTE
   You can point CA EEM to an LDAP or Active Directory server from the Configure tab. CA EEM 12.0 and later can point to more than one LDAP or Active Directory server. For more information, see Support for Multiple Active Directory Domains.

Create DX NetOps Spectrum Users for Single Sign-On

Creating user accounts in DX NetOps Spectrum requires entering a password manually. This step may not be possible if DX NetOps Spectrum is integrated with CA Embedded Entitlements Manager for Single Sign-On. But if DX NetOps Spectrum is integrated with an LDAP server, you can create users with blank passwords. The LDAP server then handles user authentication.

NOTE

Integrating DX NetOps Spectrum with LDAP is not mandatory. However, the integration simplifies user creation with blank passwords in DX NetOps Spectrum.

If your DX NetOps Spectrum deployment requires you to use SSO through CA EEM, and if EEM is integrated with an LDAP server, configure the LDAP server in DX NetOps Spectrum, create the users in DX NetOps Spectrum and then configure SSO settings to integrate with CA EEM.

NOTE

- Configure EEM with the LDAP server first, then configure DX NetOps Spectrum, create user accounts and integrate with CA EEM.
- When CA EEM points to an AD for SSO, DX NetOps Spectrum supports only the user accounts in that AD. Do not use group names for SSO.

Follow these steps:

1. Log in to the OneClick Web Console.
2. Configure the Web Console with your LDAP server as described in the OneClick Administration Pages section.
3. Launch the OneClick Console.
4. In the Users tab of the Navigation panel, select the top-level Users node and click Creates a New User.
   The Create User dialog opens.
5. Create a user account, but leave the password blank. Save the user account.
6. Repeat the previous steps to create all required DX NetOps Spectrum users.
7. Close the OneClick Console.
8. In the OneClick Web interface, click the Administration tab.
9. Click the Single Sign-On Configuration link.
10. Complete DX NetOps Spectrum configuration with EEM.
11. Restart the Tomcat server on the OneClick Web server host for the changes to take effect.

Now LDAP users can log in to DX NetOps Spectrum and can be authenticated using the EEM Server.

Configure OneClick to Connect to the CA EEM Server

Follow these steps:

1. Log in to the OneClick web server.
2. Click Administration in the menu bar on the OneClick home page.
   The system verifies your administrator credentials.
3. Click Single Sign-On Configuration in the Administration Pages panel on the left.
   The Single Sign-On Configuration page opens.
4. Select CA EEM in the Choose SSO Option section.
   The CA EEM Single Sign-On Configuration section opens.
5. Specify the following parameters for connecting with the CA EEM server in the CA EEM Server Connectivity section:
   - **CA EEM Server Hostname**
     Specifies the host name of the CA EEM server you want to connect to.
   - **OneClick Server Domain Name**
     Specifies the domain where the OneClick server resides (for example, ca.com).

     NOTE
     If you are trying to inter-operate between eHealth and DX NetOps Spectrum using CA EEM or CA SiteMinder®, a second-level domain or greater is required for the cookie domain.

     Cookies are restricted to a certain domain level for security reasons. According to "RFC 2901" and "RFC 2965", cookies cannot be set to a top-level domain (such as .com, .org, .gov). A minimum of second-level domain is required. For more information, consult the RFC documentation.
     If a domain name ends with a two letter country code, a minimum of a third-level domain is required. A cookie that is set to a second-level domain is visible at all of its third-level domains. However, a cookie that is set to a third-level domain is not visible at its parent second-level domain or at other sub domains. If no domain name is specified when a cookie is written, the cookie domain attribute defaults to the domain name where the application resides.
   - **Spectrum Application Name in CA EEM**
     Specifies the name of the DX NetOps Spectrum application in CA EEM, enabling you to set up rules in CA EEM. Enter *spectrum* in this field. This is not a mandatory field.
   - **Proxy URL**

Specifies the URL to be used for proxy connectivity.

6. Select Yes in the Authentication Logging section to enable logging to either the Tomcat log or to a specified log location for debugging connectivity issues.
7. (Optional) Perform the following steps to test the configuration:
   a. Complete the Test Username field and the Test Password field with appropriate credentials for testing the connection to the CA EEM server.
   b. Click Test.

   The OneClick Console notifies you when proper authentication occurs.
8. Click Save.
   DX NetOps Spectrum verifies whether the CA EEM single sign-on conflicts with any other SiteMinder single sign-on option. If a conflict is detected, you see an error. Otherwise, a dialog asks you to restart the web server.
9. Click OK.
10. The system saves the information to an eem-sso.conf configuration file in the Tomcat directory. You can find the file at the following location: *$SPECROOT*/custom/sso/eem-sso.conf
11. Restart Tomcat to let the changes take effect.
    OneClick is configured to connect to CA EEM server.

Support for Multiple Active Directory Domains

DX NetOps Spectrum leverages the multiple Active Directory domains feature of CA EEM to authorize users from multiple domains. CA EEM 12.0 and later versions support this feature.

For example, User1 and User2 are two users belonging to different domains, "Domain1.com" and "Domain2.com" respectively. With this feature, user1 and user2 can connect to OneClick. When you create these users in OneClick, supply user names that are identical to the principal names of these users in CA EEM.

- If the principal name of "User1" of "Domain1.com" in CA EEM is "Domain1.com\User1", in DX NetOps Spectrum create this user as "Domain1.com\User1".
- If the principal name of "User2" of "Domain2.com" in CA EEM is "Domain2.com\User2", in DX NetOps Spectrum create this user as "Domain2.com\User2".

Two users with the same user name can exist in more than one domain. Include the domain prefix for such identical users during the OneClick authentication. For example, supply "Domain1.com\User1" and "Domain2.com\User1". When a user with the same user name is not present across domains, during the OneClick authentication domain prefix before the user name is not mandatory.

> **NOTE**
> Do not use the "User@Domain" format to configure principal name in CA EEM, DX NetOps Spectrum supports only the "Domain\User" format.

As a result, when User1 and User2 of two different domains try to access the OneClick, DX NetOps Spectrum sends an authentication request to CA EEM. When CA EEM successfully authenticates these two users by resolving its actual domain, DX NetOps Spectrum authorizes them to access the SpectroSERVER.

CA EEM 12.0 supports the following two configuration types to enable the multiple Active Directory domains feature:

- Active Directory Domain
- Active Directory Forest

For more information about configuring multiple domains in CA EEM, see the CA Embedded Entitlements Manager - Implementation Release 12.51.

How to Disable the CA EEM Integration

To disable the DX NetOps Spectrum and CA EEM Integration, follow this process:

1. Close all the OneClick client consoles.
2. Stop the One Click Tomcat Web Server.
   Windows: Open the Services view and Stop the Spectrum Tomcat service.
   Linux: Run the stopTomcat.sh command from the $SPECROOT/tomcat/bin directory.
3. In the One Click web server, navigate to the $SPECROOT/custom/ directory and rename the sso directory to sso.bak.
4. Edit the web.xml in the $SPECROOT/tomcat/webapps/spectrum/WEB-INF directory:
   a. Change the following entry:
   ```
   <login-config>
   <auth-method> EXTERNALSSO </auth-method>
   <realm-name>SPECTRUM</realm-name>
   </login-config>
   ```
   To become:
   ```
   <login-config>
   <auth-method> BASIC </auth-method>
   <realm-name>SPECTRUM</realm-name>
   </login-config>
   ```
   b. Comment out the following entry that should show at the top of the file:
   ```
   <listener>
   <listener-class>com.aprisma.tomcat.authenticator.ExternalSSOAuth</listener -class>
   </listener>
   ```
   To make it:
   ```
   <!--
   <listener>
   <listener-class>com.aprisma.tomcat.authenticator.ExternalSSOAuth</listener-class>
   </listener>
   -->
   ```
   c. Save the changes made to the $SPECROOT/tomcat/webapps/spectrum/WEB-INF/web.xml file.
5. Go to the $SPECROOT/tomcat/conf/context.xml file.
   a. Add the following line:
   <Valve className="org.apache.catalina.authenticator.BasicAuthenticator" changeSessionIdOnAuthentication="false" /
   ></Context>
   b. Comment out the following line:
   <Valve className="com.aprisma.tomcat.authenticator.ExternalSSOAuth" changeSessionIdOnAuthentication="false" /
   ></Context>
   So that it looks like this:
   <!--
   <Valve className="com.aprisma.tomcat.authenticator.ExternalSSOAuth" changeSessionIdOnAuthentication="false" /
   ></Context>
   -->
6. Save the file changes to the $SPECROOT/tomcat/conf/context.xml file.
7. Start the One Click Tomcat Web Server and attempt to log in with a non LDAP account.

Troubleshooting Integration with CA EEM

This chapter describes how to respond to potential authentication problems with the DX NetOps Spectrum CA EEM integration.

Cannot log in to OneClick web page after CA EEM 12.51 integration

Symptom:

After upgrading to 10.2.1 and enabling the CA EEM 12.51 integration, unable to log in to OneClick web page, keep asking for username and password.

The following error was found in the $SPECROOT/tomcat/logs/sdtout.log file:

<date and time> - SPC-OCA-10486: Error: DX NetOps Spectrum user model not found for user <domain>\<user>.

Example: SPC-OCA-10486: Error: DX NetOps Spectrum user model not found for user ad1.ca.com\user1

The following error is found in the CA EEM debug log:

[2017-07-28 10:14:55.877] [EEMSSOContext::authenticateWithPassword] EEM password authentication successful. [/spectrum/][<user>]

[2017-07-28 10:14:55.877] [EEMSSOContext::authenticateWithPassword] [/spectrum/][<user>] [UserSession;Version-1.0;dd71c8d592f2115a37d1f7826a619a86-597b1913-cc82b00-4] returned.

[2017-07-28 10:14:55.877] [ExternalSSOAuth::authenticate] Successfully authenticated user/pass with SSO Server ["GET /spectrum/"]["0:0:0:0:0:0:0:1"]["<user>"][authenticated="true"][authorized="false"]

[2017-07-28 10:14:55.877] [ExternalSSOAuth::authenticate] usernameFromToken <domain>\<user>

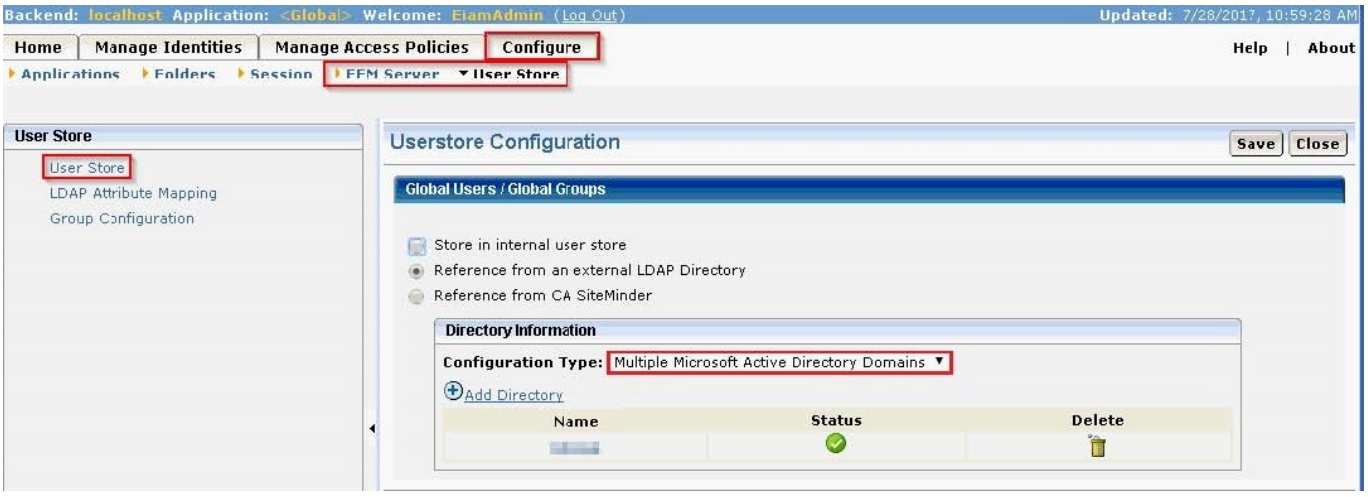
[2017-07-28 10:14:55.892] [ExternalSSOAuth::authenticate] Could not authorize request for resource. ["GET /spectrum/"] ["0:0:0:0:0:0:0:1"]["<domain>\<user>"][authenticated="true"][authorized="false"]

Environment:

CA Spectrum 10.2.x, 10.1.x and CA EEM 12.51

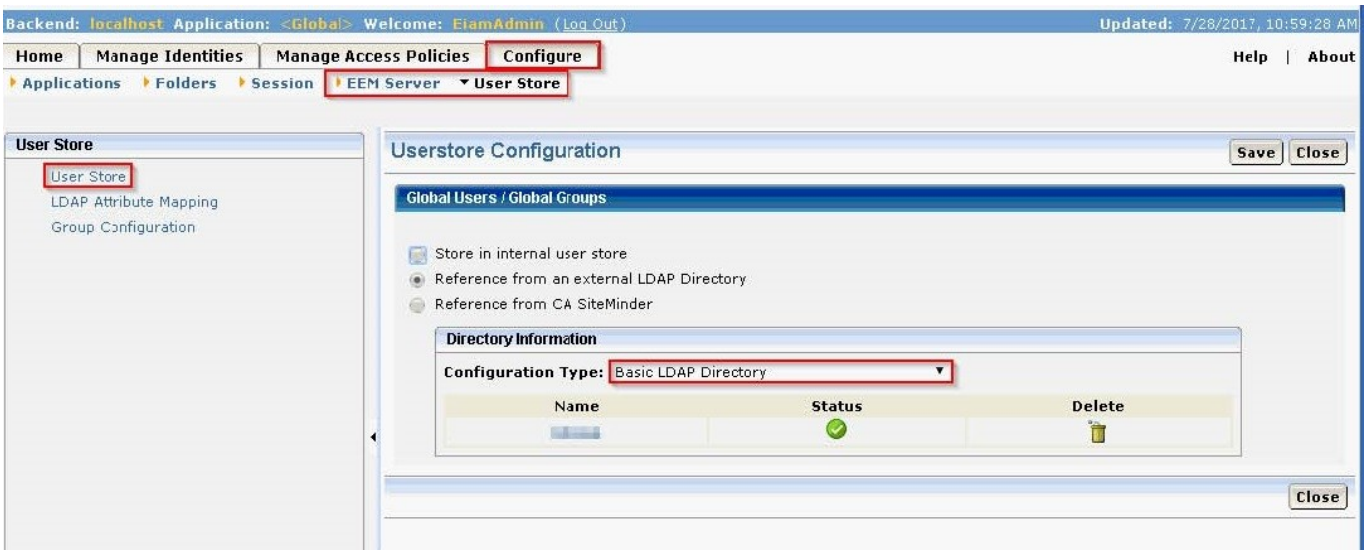
Probable Cause:

If you have configured the CA EEM for Multiple Microsoft Active Directory Domains, but you have only one Active Directory. The CA EEM is appending the domain in the account name, like: ad1.ca.com\user1, instead of only user1.



Resolution:

To resolve this issue, delete the setting for Multiple Microsoft Active Directory Domains and configure for Basic LDAP Directory.



The login is success.

Cannot Log In to DX NetOps Spectrum

Symptom:

User unable to authenticate to DX NetOps Spectrum.

Solution:

Verify that the user name and password have been entered correctly in DX NetOps Spectrum.

Configuration Test Fails

Symptom:

Unable to authenticate with CA EEM though the DX NetOps Spectrum configuration test.

Solution:

Verify that the proper user name, password, server name, and port have been entered.

Managing Client Applications

This section describes how to use OneClick, Alarm Notifier, SANM, Report Manager, and so on.

AlarmNotifier

This section discusses the AlarmNotifier Application, and how it is used for alarm notifications. This section also discusses how alarm notifications can be customized for various requirements of the administrators and troubleshooters.

About AlarmNotifier

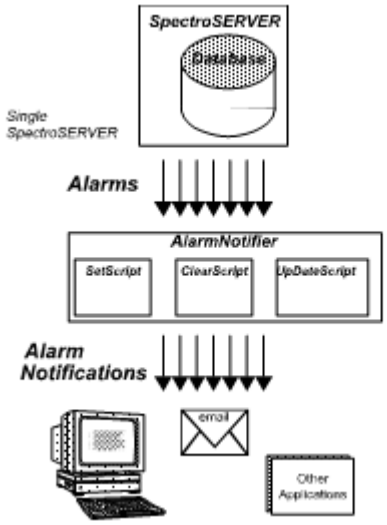
AlarmNotifier is a SpectroSERVER-client application that installs with core DX NetOps Spectrum components. The AlarmNotifier application connects to a single SpectroSERVER and invokes scripts that provide notifications about DX NetOps Spectrum alarm status.

Start AlarmNotifier from a terminal shell command prompt. Once started, it continuously displays output from scripts that are invoked whenever alarms are either set, cleared, or updated. AlarmNotifier provides the following features for DX NetOps Spectrum:

- Single SpectroSERVER alarm monitoring.
- Three scripts that generate alarm information: SetScript, ClearScript, and UpdateScript. These scripts contain settings that can be customized for your environment.
- Resource file parameters that can be configured to modify AlarmNotifier operational features.

Alarm Monitoring Process

AlarmNotifier supplements DX NetOps Spectrum alarm monitoring and notification features. The following diagram illustrates the relationship between AlarmNotifier and DX NetOps Spectrum:



DX NetOps Spectrum performs some alarm functions, while AlarmNotifier performs others. DX NetOps Spectrum polls the modeled network elements and updates the status information about each element that is stored in the SpectroSERVER database.

DX NetOps Spectrum generates an alarm when it receives a trap from the network or when it detects a critical status change in a network-element model. In the OneClick Topology view, the condition of the model icon changes from green to another color to indicate alarm severity. DX NetOps Spectrum posts information about the alarm in the Alarms tab. Event information for the alarm appears in the Events tab in the OneClick Contents panel.

When AlarmNotifier is started, it registers with DX NetOps Spectrum. Then a model named AlarmNotifier of type ClientApp is created. This model is not visible in any of the DX NetOps Spectrum Topology views. However, you can see it in the Events tab. The Events tab displays information such as the application start and stop time for this model.

AlarmNotifier queries the SpectroSERVER and requests information about existing alarms. AlarmNotifier runs scripts and generates notifications about existing alarms.

Each time an alarm is set, cleared, or updated, AlarmNotifier receives information from the SpectroSERVER and invokes the relevant script. AlarmNotifier scripts can initiate email notifications of alarms that are sent to network personnel. They can also transmit alarm information to third-party applications.

Spectrum Alarm Notification Manager (SANM)

Spectrum Alarm Notification Manager (SANM) is an add-on component for DX NetOps Spectrum that can enhance AlarmNotifier features. The SANM Policy Administrator lets you create multiple alarm-filtering policies, which you can associate with uniquely named instances of AlarmNotifier applications. Use these policies to instruct AlarmNotifier to generate notifications only for the alarms that you consider relevant.
The SANM Policy Administrator lets you associate policies with AlarmNotifier applications as required. You can also automate this association process using the Scheduler utility.
With SANM installed, AlarmNotifier offers the following capabilities:

- Distributed SpectroSERVER alarm monitoring
- Additional script parameters that provide more alarm information
- Commands for acknowledging and clearing alarms
- Additional startup options that let you log AlarmNotifier activities and concurrently run multiple instances of AlarmNotifier
- SANM alarm-filtering tools

NOTE

For more information about SANM, see the Spectrum Alarm Notification Manager (SANM) section.

Operating AlarmNotifier

This section discusses how you can operate AlarmNotifier. Operating AlarmNotifier involves starting, viewing alarm notifications, update script parameters, and stopping AlarmNotifier.

Start AlarmNotifier Application

AlarmNotifier is located in the <*$SPECROOT*>/Notifier directory. This directory contains the following files by default:

- .alarmrc
- AlarmNotifier
- ClearScript
- README
- SetScript
- UpdateScript

AlarmNotifier includes the following additional files and directory:

- **AlarmAck**
  Acknowledges an alarm.
- **AlarmClear**
  Clears an alarm.
- **Trace**
  Displays trace files.

To start AlarmNotifier, use the following AlarmNotifier command in the <*$SPECROOT*>/Notifier directory:

```
AlarmNotifier [-r resourcefile] [-n application][-tl summary|details [-tn tracefile] [-ts size]]
```

- **-r *resourcefile***

Lets you specify a resource file other than the default resource file .alarmrc.

- **-n *application***
  Lets you override the application name value that is specified by the APPLICATION parameter in the resource file. You can specify a different name for an AlarmNotifier application instance. This option lets you start multiple instances of AlarmNotifier and associate each of them with a different SANM alarm-filtering policy. If a name is not assigned to the APPLICATION parameter in the resource file, use the -n option at start-up to specify an application name.
- **-tl summary | details**
  Lets you activate tracing at a specified level, summary or detailed. The default format for an AlarmNotifier trace file is the application name together with the date when the trace file was created.
- **-tn *tracefile***
  Lets you specify a trace file name other than the default name, which is provided when only the -tl option is used. Use this option with the -tl option.
  When using the trace file option, the output file is written by default to the <*$SPECROOT*>/Notifier/trace directory. To explicitly name an output file and path, use the [-tn filename] option. If <*filename*> is a relative path, trace output is written to a file that is relative to the current directory. If <*filename*> is an absolute path, trace output is written to the absolute path.
- **-ts *size***
  Lets you specify the number of lines in the trace file. Use this option with the -tl option. The application writes this number of lines to the file and then wraps around to the beginning of the file. Entries are numbered sequentially, and an END OF TRACE line follows the last entry. The default number of lines in a trace file is 10000.

NOTE

If you migrate DX NetOps Spectrum to a higher release, verify the following settings in the ".alamrc" file:

- The paths to the scripts are correct.
- You have all the permissions to the "ClearScript" script.

AlarmNotifier does not start if these settings are incorrect.

Stop AlarmNotifier

Once started, the AlarmNotifier runs continuously. To stop the AlarmNotifier, use the following commands:

- To stop the AlarmNotifier running in the foreground for Windows, run the command:
  ```
  Control-C
  ```
- To stop the AlarmNotifier running in the background for Windows, run the command:
  ```
  $SPECROOT/lib/SDPM/kill - TERM <pid>
  ```

Start AlarmNotifier with the Process Daemon

You can automate the startup of AlarmNotifier processes using processd, the DX NetOps Spectrum process management daemon.

The processd automatically starts during DX NetOps Spectrum installation and whenever the system restarts. Once processd is started, it automatically starts and manages other processes via *.idb ticket files that are located in the **$SPECROOT/lib/SDPM/partslist** directory. For the AlarmNotifier process, processd uses the AlarmNotifier.idb file.

To enable processd to launch and track the AlarmNotifier application, edit the **$SPECROOT/lib/SDPM/partslist/AlarmNotifier.idb** file and change AUTOBOOTSTART to Y.

Follow these steps:

1. Using a text editor, edit the **$SPECROOT/lib/SDPM/partslist/AlarmNotifier.idb** file and change AUTOBOOTSTART to Y:

```
# Processd Install Ticket for Alarm Notifier
PARTNAME;ALARMNOTIFIER;
APPNAME;Alarm Notifier;
WORKPATH;$SPECROOT/Notifier;
LOGNAMEPATH;$WORKPATH/ALARMNOTIFY.OUT;
ADMINPRIVS;y;
AUTORESTART;y;
AUTOBOOTSTART;y;
#STATEBASED;N;
NUMPROCS;1;
RETRYTIMEOUT;6000;
TICKETUSER;<USERNAME>;
RETRYMAX;20;
STARTPRIORITY;30;
#ENV;<var>=<value>;
ARGV;$WORKPATH/AlarmNotifier<CSEXE>; //
```

2. The LOGNAMEPATH parameter specifies the name and path of the log file for the AlarmNotifier application.

   NOTE
   Each time AlarmNotifier starts, a new log file is generated, and a backup of the previous log file is created. However, the SpectroSERVER only stores the two most recent AlarmNotifier log files. To keep more Notifier log files, add this line after the LOGNAMEPATH entry, **LOGBACKUPMAX;10; This will save 10 copies of your Notifier Log file.**

   The value of the TICKETUSER parameter, <USERNAME>, must be the username of a valid DX NetOps Spectrum User Model.
   The SpectroSERVER must be running before AlarmNotifier starts. Therefore, the STARTPRIORITY parameter can be set to 30, indicating that AlarmNotifier is dependent on the SpectroSERVER. For more information, see the Distributed SpectroSERVER Administration section.

Run Multiple AlarmNotifiers

Multiple AlarmNotifiers with different notification policies can be started when DX NetOps Spectrum processd starts. You can enable this setup by creating install ticket files for each new AlarmNotifiers. Perform the following tasks to run multiple AlarmNotifiers:

- Make a copy of the default **$SPECROOT/lib/SDPM/partslist/ALARMNOTIFIER.idb** file and rename the files accordingly. For more information, see Start AlarmNotifier with the Process Daemon. For example: ALARMNOTIFIER_OPERATORS.idb
- Make a copy of the **$SPECROOT/Notifier/.alarmrc** and keep the naming consistent: .alarmrc_operators
- After the install ticket files are created, you can change the values of the install ticket file to start an AlarmNotifier with a preferred notification policy. You can provide the following values:
  - **PARTNAME**

    Identifies a particular process/application with a multi-character string with no spaces. The install ticket for this application has a filename in the form *<PARTNAME>*.idb. *<PARTNAME>* is the process name. For example, if you named the idb file ALARMNOTIFIER_OPERATORS.idb, set this to: PARTNAME;ALARMNOTIFIER_OPERATORS;
  - **APPNAME**

Specifies the name of the application that is created to implement the notification policy. To run the new instance of AlarmNotifier, edit your copied idb file and change this value to the name you would like to see in a process listing. For example: AlarmNotifier_Operators. For more information, see the Spectrum Alarm Notification Manager (SANM) section.

– **AUTOBOOTSTART**

Notifies the process daemon to start a process when processd starts. Set the value to Y.

– **WORKPATH**

Specifies the working path where the application can be found. Leave this set to **$SPECROOT/Notifier;**

– **LOGNAMEPATH**

Specifies the name and path of the log file for the AlarmNotifier application. Change the name of the log to match the APPNAME. For example: **LOGNAMEPATH;$WORKPATH/AlarmNotifier_Operators.OUT;**

NOTE
LOGNAMEPATH must be unique for each instance.

– **ARGV**

Specify the following value using your custom APPNAME:

```
$SPECROOT/Notifier/AlarmNotifier<CSEXE> -r .alarmrc_operators -n <name of the application that you
 specified for APPNAME>
```

For example:

```
$SPECROOT/Notifier/AlarmNotifier<CSEXE> -r .alarmrc_operators -n
 AlarmNotifier_Operators
```

NOTE
Do not copy the AlarmNotifier application and rename it as the copied executable will not be upgraded when you upgrade Spectrum. The best practice is to use the default AlarmNotifier application and provide the new name in both the APPNAME variable and the ARGV variable in your .idb file. This ensures that the AlarmNotifier version will be consistent with the version of Spectrum that you are running.

AlarmNotifier Output

AlarmNotifier invokes the SetScript, ClearScript, or UpdateScript whenever AlarmNotifier detects an alarm that is set, cleared, or updated in DX NetOps Spectrum. Each script generates a notification containing information about alarm status (set, cleared, or updated) and displays it. Each notification contains the parameters that are defined in Script Parameter Definitions.

- **SetScript**
  Invoked for an alarm in the following situations:
  – AlarmNotifier is started and detects an existing alarm. AlarmNotifier invokes SetScript unless the value of GET_EXISTING_ALARMS is set to 'false' in the .alarmrc resource file.
  Default: true.
  – DX NetOps Spectrum generates an alarm while AlarmNotifier is running.
- **ClearScript**
  Invoked when an alarm is cleared.
- **UpdateScript**
  Invoked when an alarm is updated. An alarm is defined as updated in these situations:

- A troubleshooter has been assigned to an alarm, or the troubleshooter name has been changed. The RepairPerson parameter in the scripts represents this troubleshooter name.
- The status of an alarm has changed. Status information for an alarm is entered in the Alarms tab. The AlarmStatus parameter represents status in the scripts.
- An alarm is acknowledged or unacknowledged in DX NetOps Spectrum.
- A new event, or a change to an existing event, occurs on a device that is in an alarm state.

Script Parameter Definitions

You can update the parameters of the AlarmNotifier scripts to customize their functionality. The following list describes the parameters that are available for SetScript, ClearScript, and UpdateScript.

> **NOTE**
> Additional script parameters are available when you use SANM with AlarmNotifier. For more information, see the Spectrum Alarm Notification Manager (SANM) section.

- **Date**
  Specifies the date when AlarmNotifier detects that the alarm is set, updated, or cleared.
  Format: mm/dd/yyyy
- **Time**
  Specifies the time when AlarmNotifier detects that the alarm is set, updated, or cleared.
  Format: hh:mm:ss
- **Mtype**
  Specifies the type of model for which the alarm is set, updated, or cleared.
- **ModelName**
  Specifies the name of the model whose alarm is set, updated, or cleared. If the ModelName contains special characters, pass it to the script as an environment variable to avoid errors. A special character is a character that the command shell interprets as having special meaning such as '$' or '*'.
  To pass the model name as an environment variable, add the attribute ID for ModelName (0x1006e) to the values for the EXTRA_ATTRS_AS_ENVVARS parameter in the .alarmrc file. For more information, see Passing DX NetOps Spectrum Attributes to Scripts and .alarmrc Parameters.
- **AlarmID**
  Specifies the numeric identifier that DX NetOps Spectrum assigned to the alarm.
- **Global AlarmID**
  Specifies a unique numeric identifier that DX NetOps Spectrum assigns to the alarm. Unlike the AlarmID, the global alarm ID is not only unique within the DX NetOps Spectrum environment, but also can be passed as a unique identifier to other environments. Use this value to pass a unique identifier to third-party software. By default, Global AlarmID is commented out in each of the AlarmNotifier scripts. Remove the comment mark (#) to pass this parameter.
- **Severity**
  Specifies the DX NetOps Spectrum severity-level code for the alarm: Critical (Red), Major (Orange), Minor (Yellow), Maintenance (Brown), Suppressed (Gray), or Initial (Blue).
- **ProbableCauseID**
  Specifies the hexadecimal identifier that is associated with the probable cause for the alarm.
- **RepairPerson**
  Specifies the troubleshooter who is assigned to the alarm in the Alarms tab. AlarmNotifier invokes the UpdateScript whenever a troubleshooter is first assigned and each time thereafter.
  The following circumstances determine whether the name of a troubleshooter (a repair person) appears in the notifications that SetScript and ClearScript generate:

  - If a troubleshooter is assigned after AlarmNotifier detects that an alarm has been set, SetScript does not display a name. The UpdateScript and the ClearScript do display a name.
  - If a troubleshooter is assigned before AlarmNotifier detects the set (for an alarm that exists before AlarmNotifier is started), all three scripts display the name of the troubleshooter.

    NOTE
    For more information, see the Using OneClick section.
- **AlarmStatus**
  Indicates the status information for the alarm in OneClick. AlarmNotifier invokes UpdateScript whenever status information is first entered and each time thereafter. Status information typically appears in the notifications that the SetScript and ClearScript generate. The following circumstances are exceptions:
  - If status information is entered after AlarmNotifier detects that an alarm has been set, SetScript does not display the information. The UpdateScript and the ClearScript do display the information.
  - If status information is entered before AlarmNotifier detects the set (for an alarm that exists before AlarmNotifier is started), all three scripts display the status information.

    NOTE
    For more information, see the Using OneClick section.
- **SpectroSERVER**
  Specifies the name of the host for the SpectroSERVER where the alarm has been set, updated, or cleared.
- **Landscape**
  Specifies the handle for the landscape from which the alarm has been set, updated, or cleared.
- **ModelHandle**
  Specifies the handle of the model for which the alarm has been generated.
- **ModelTypeHandle**
  Specifies the handle of the model type for which the alarm has been set, updated, or cleared.
- **IPAddress**
  Specifies the IP address of the network element for which the alarm has been set, updated, or cleared.
- **SecurityString**
  Specifies the security string of the model for which the alarm has been set, updated, or cleared.
- **AlarmState**
  Specifies whether the alarm state is "Existing" or "New."
  The state of an alarm is "Existing" if the alarm is set before AlarmNotifier is started. AlarmNotifier invokes SetScript for an existing alarm if the GET_EXISTING_ALARMS parameter in the .alarmrc resource file is set to true.
  The state of an alarm is "New" if the alarm is generated after AlarmNotifier is started. The alarm state is also "New" when the SpectroSERVER for the AlarmNotifier restores connections to a previously connected landscape where the alarm occurred.
- **Acknowledged**
  Specifies whether the alarm has been acknowledged.
- **UserClearable**
  Specifies whether a user can clear the alarm.
- **DeviceType**
  Specifies the value of the DeviceType attribute on the model for which the alarm has been set, updated, or cleared. For more information, see the Certifications section.
- **Raw Alarm Time**
  The Alarm date and time is available as $DATE and $TIME. To get the unformatted alarm time, you can reference $RAW_ALARM_TIME.

    NOTE
    The unformatted alarm time is the number of seconds that have elapsed since midnight UTC of January 1, 1970.

Persistent and Stale Alarms

When the SpectroSERVER stops and restarts, alarms that were already present continue to exist. These alarms are "persistent" alarms. The persistent alarm feature lets DX NetOps Spectrum retain alarm-related information such as troubleshooter assignments and status when the SpectroSERVER shuts down.

In some cases, the underlying cause of an alarm is resolved between the time that the SpectroSERVER shuts down and restarts. The alarm still appears in the Alarms list in OneClick but is considered to be stale. You can clear all stale alarms (which are also known as "residual alarms") manually.

However, stale alarm information is not forwarded to AlarmNotifier by the SpectroSERVER. Instead, a single *new* alarm that indicates that stale or residual alarms exist on the landscape is generated and sent to AlarmNotifier. When you manually clear a stale alarm, that alarm is also cleared in AlarmNotifier. When the final stale alarm is cleared, a "clear" is issued for the stale alarm notification.

Customizing AlarmNotifier

This section discusses how you can customize AlarmNotifier. Customizing AlarmNotifier involves the following things:

- Modifying scripts
- Limiting script outputs
- Passing DX NetOps Spectrum attributes to scripts
- Sending data to third-party applications
- Customizing the ".alarmrc" resource file

Modifying Scripts

You can modify AlarmNotifier scripts to customize AlarmNotifier actions and output. You can configure the scripts to initiate email notifications to specified recipients. You can also customize scripts to limit the range of information that alarm transition notifications provide, or to integrate with a third-party application.

Enable Email Notifications in a Script

Each AlarmNotifier script includes two parameters (SENDMAIL and VARFORMAIL) that you can configure to enable email notifications to the troubleshooter for an alarm. You can enable email notifications for one or more scripts.

Note: To preserve default script configuration settings in case of accidental loss, make a backup copy of the default script that you plan to edit.

Follow these steps:

1. Navigate to the <*$SPECROOT*>/Notifier directory, or to the directory where the script is saved.
2. Open the script with a text editor.

   NOTE
   All of the scripts are executed serially. Therefore, you can edit a script without stopping the AlarmNotifier.
3. Set the SENDMAIL parameter in the script to True.
4. Set the VARFORMAIL parameter to RepairPerson.
5. Save and close the script.
   Email is sent to the troubleshooter who is assigned to the alarm in the Alarms tab. This person must be an authorized user of (or user model in) the landscape where the alarm originates.

   NOTE
   The value for RepairPerson is established after the alarm has occurred. As a result, mail cannot be sent in response to a set action (using the SetScript). However, if you are also using SANM, you can configure mail

to be sent as a result of a set action. For more information, see the Spectrum Alarm Notification Manager (SANM) section.

Mail Service on Windows Platform

On Windows, use the mail command to enable the mail service so that AlarmNotifier scripts can send email notifications.

Take this step before AlarmNotifier starts. Otherwise, an error message prompts you to configure the mail service and then start AlarmNotifier.

Mail Command Parameters

Several parameters are required when running the mail command from a terminal window. These parameters are as follows:

- **-m**
  Is the Return host name. The Return host is the computer where incoming mail is received.
- **-h**
  Is the Simple Mail Transfer Protocol (SMTP) host, the computer where outgoing email is sent to be processed.
- **-u**
  Is the username.

  NOTE
  AlarmNotifier can send notifications to a pager. We recommend first configuring AlarmNotifier to send notifications to a valid local mail account to test this configuration. You can then reconfigure the Mail Service to send the notifications to the pager.

Configure Mail Service

You can set up the mail service on Windows so that AlarmNotifier can send email notifications.

Follow these steps:

1. Consult with your mail server administrator to verify the correct values of the mail command parameters.
2. Open the bash shell.
3. Enter the following command:
   ```
   mail -m your-company.com -h smtp.your-company.com -u username
   ```
   The command usage list appears once the command has completed successfully.
4. To verify that the configuration is complete, view the registry entries for HKEY_CURRENT_USER/Software/SMail. The hostname, smtphost, and username keys now contain the information that you included in the command string.

Limiting Script Output

You can comment out AlarmNotifier script parameters to reduce the amount of output from a script.

NOTE
Before you modify a script, review the parameter descriptions in Script Parameter Definitions. We recommend a thorough understanding of the information that you are suppressing.

Follow these steps:

1. Close the instance of the AlarmNotifier application that you want to configure.
2. Navigate to the default script directory, <$SPECROOT>/Notifier, or the directory where the script that you want to edit is saved.
3. Open the script with a text editor.

4. Comment out the echo command lines that you want to suppress by typing a pound sign (#) at the beginning of each line. In the following example, the UserClearable parameter is commented out:

```
echo "SecurityString: " $SECSTR
echo "AlarmState: " $ALARMSTATE
echo "Acknowledged: " $ACKD
#echo "UserClearable: "  $CLEARABLE
```

   When this script generates notifications, the information from the parameter that has been commented out does not appear on the screen.
5. Save and close the script.

> **NOTE**
> Do *not* comment out or modify the assignments of the variables themselves or the shift commands. The script does not display alarm information properly if you change these lines.

Passing Product Attributes to Scripts

Attributes of a model with an alarm can be passed to AlarmNotifier. Model attributes can be used as parameters in SetScript, ClearScript, or UpdateScript. Use the .alarmrc parameters EXTRA_ATTRS_AS_ENVVARS or EXTRA_ATTRS_AS_ARGS to pass in attributes. To enable these parameters, set the USE_NEW_INTERFACE .alarmrc parameter to TRUE.

EXTRA_ATTRS_AS_ENVVARS passes attributes to AlarmNotifier as environment variables. EXTRA_ATTRS_AS_ARGS passes attributes as command-line arguments. For most attributes, either of these mechanisms can be used. However, EXTRA_ATTRS_AS_ENVVARS is required in cases where new lines or special characters can cause problems for the script that parses the extra data. When USE_NEW_INTERFACE=TRUE, the environment variable mechanism is used to pass $STATUS, $EVENTMSG, and $PCAUSE to avoid this problem.

In the .alarmrc file, set the appropriate parameter equal to the DX NetOps Spectrum attribute IDs that you want to pass. You can reference the attribute ID either in hexadecimal or decimal notation.

If you pass an attribute as an environment variable using EXTRA_ATTRS_AS_ENVVARS, you reference this variable in a script using the following syntax:

```
$SANM_<attribute_ID>
```

- **<attribute_ID>**
  Specifies the attribute ID of the attribute you are referencing. If you have used hexadecimal notation to call this attribute in the .alarmrc file, hexadecimal notation is also required in the script. If you have used decimal notation to call this attribute in the .alarmrc file, use decimal notation in the script.

  > **NOTE**
  > Windows automatically sets environment variables to uppercase. Therefore, when you reference these variables, use the uppercase format, such as $SANM_0X100C5.

If you use EXTRA_ATTRS_AS_ARGS to pass an attribute as an argument, you can reference this variable in a script by assigning the value to a variable within the script:

```
<variable>=$<x>
```

- **<variable>**
  Specifies the variable that holds the value of the attribute.
- **<x>**
  Specifies the appropriate variable number for the order and number of arguments that you have passed.

Example

The following example shows four sample DX NetOps Spectrum attributes that are passed to AlarmNotifier in the .alarmrc file. The attributes are then referenced in a script.

.alarmrc File Reference

```
USE_NEW_INTERFACE=TRUE
EXTRA_ATTRS_AS_ENVVARS=0x100c5,0x11f84
EXTRA_ATTRS_AS_ARGS=0x110df,0x117dc
```

Script Reference

```
#These lines read 0x110df and 0x117dc into the variables MAC_ADDRESS
#and FIRMWARE_VERSION respectively.
shift 9
MAC_ADDRESS=$1
FIRMWARE_VERSION=$2
#These lines print out the value of each attribute.
echo "The value of attribute 0x100c5 is: " $SANM_0x100c5
echo "The value of attribute 0x11f84 is: " $SANM_0x11f84
echo "The value of attribute 0x110df is: " $MAC_ADDRESS
echo "The value of attribute 0x117dc is: " $FIRMWARE_VERSION
#These lines print out the value of each attribute.(Windows Platform)
#references to environmental variables are in uppercase
echo "The value of attribute 0x100c5 is: " $SANM_0X100C5
echo "The value of attribute 0x11f84 is: " $SANM_0X11F84
echo "The value of attribute 0x110df is: " $MAC_ADDRESS
echo "The value of attribute 0x117dc is: " $FIRMWARE_VERSION
```

Global Alarm Attributes

This section lists the DX NetOps Spectrum Global Alarm attributes and their corresponding attribute IDs. Pass any of these attributes to AlarmNotifier using the method that is described in this article.

- **Acknowledged**
  0x11f4d
- **Alarm_Source**
  0x11fc4
- **Alarm_Status**
  0x11f4f
- **Cause_Code**
  0x11f50
- **Cleared_By_User_Name**
  0x11f51
- **Creation_Date**
  0x11f4e
- **ImpactScope**
  0x1290e
- **ImpactSeverity**
  0x1290d
- **Last_Occurrence_Date**
  0x1321a
- **Occurrences**
  0x11fc5
- **Originating_Event**

0x1296e
- **Persistent**
  0x12942
- **Primary_Alarm**
  0x11f54
- **Severity**
  0x11f55
- **Trouble_Shooter_Email**
  0x12a6c
- **Trouble_Shooter_mh**
  0x11fc6
- **Trouble_Ticket_ID**
  0x12022
- **TroubleShooter**
  0x11f57
- **User_Clearable**
  0x11f9b
- **Customer_Impact**
  0x12bf6
- **Service_Impact**
  0x12bf7

NOTE
Service_Impact does not always reflect the current health of the service. Service_Impact represents the health status of the service at the time when the device alarm was generated. If only the service health changes, Service_Impact is not affected.

Sending Data to a Third-Party Application

You can customize or replace SetScript, ClearScript, or UpdateScript to create an integration with a third-party application.

You can supplement and extend the functionality of SetScript, ClearScript, or UpdateScript. You can also include DX NetOps Spectrum CLI commands in these scripts to retrieve more information from the SpectroSERVER. You can also add code of your own to the script that sends data to a third-party application.

If you do not use the functionality of the existing script, you can direct AlarmNotifier to run your own script or executable. In the AlarmNotifier resource file (.alarmrc), the Set_Script parameter controls the script that runs when an alarm is set. The Clear_Script parameter controls the script that runs when an alarm is cleared, and the Update_Script parameter controls the script that runs when an alarm is updated.

By default, the Set_Script parameter has a value of SetScript, the Clear_Script parameter has a value of ClearScript, and the Update_Script parameter has a value of UpdateScript. You can modify the values of these parameters to launch a different script when an alarm is set, cleared, or updated.

Custom script parameters depend on the data to extract from DX NetOps Spectrum and on the third-party application to which the data is sent. To create your own script or executable, first, understand the arguments that are passed from DX NetOps Spectrum to the receiving script or executable. Your script or executable must receive all of the arguments from DX NetOps Spectrum in the correct order.

Arguments -- USE_NEW_INTERFACE Set to True

The following table shows the number, name, and format of each argument that is passed to each script when the `USE_NEW_INTERFACE` parameter in the `.alarmrc` file is set to TRUE.

NOTE
When USE_NEW_INTERFACE is set to TRUE, the Status argument is sent as an environment variable. The order of arguments is therefore affected.

Argument	Name	Format
1	Date	mm/dd/yyyy
2	Time	hh:mm:ss
3	Model Type	Text
4	Model Name	Text
5	Alarm ID	Integer
6	Severity	Text
7	Cause	Text
8	Repair Person	Text
9	Server	Text
10	Landscape	Hexadecimal
11	Model Handle	Hexadecimal
12	Model Type Handle	Hexadecimal
13	IP Address	xxx.xxx.xxx.xxx
14	Security String	Text
15	Alarm State	Text
16	Acknowledged	Text
17	Clearable	Text
18	Device Type	Text

Arguments -- USE_NEW_INTERFACE Set to False

The following table shows the number, name, and format of each argument that is passed to each script when the `USE_NEW_INTERFACE` parameter in the `.alarmrc` file is set to FALSE.

NOTE
If you are working with a SANM-enabled AlarmNotifier, additional arguments are passed. For more information, see the Spectrum Alarm Notification Manager (SANM) section.

Argument	Name	Format
1	Date	mm/dd/yyyy
2	Time	hh:mm:ss
3	Model Type	Text
4	Model Name	Text
5	Alarm ID	Integer
6	Severity	Text
7	Cause	Text
8	Repair Person	Text
9	Status	Text
10	Server	Text

11	Landscape	Hexadecimal
12	Model Handle	Hexadecimal
13	Model Type Handle	Hexadecimal
14	IP Address	xxx.xxx.xxx.xxx
15	Security String	Text
16	Alarm State	Text
17	Acknowledged	Text
18	Clearable	Text
19	Device Type	Text

Date and Time

The following conditions apply to the Date and Time arguments for the Set, Clear, and Update Scripts:

- **For SETs:** Date and Time are derived from the CREATION_DATE (0x11f4e) attribute. SpectroSERVER sets this attribute when the alarm is created.
- **For CLEARs:** Date and Time are derived from the CLEAR_DATE (0x129af) attribute. SpectroSERVER sets this attribute when the alarm is cleared.
- **For UPDATEs:** Date and Time reflect when the AlarmNotifier received notification that the alarm has been updated. SpectroSERVER does not set this value. Do not rely on this value to determine the exact time that the update occurred.

Customizing the .alarmrc Resource File

The .alarmrc resource file, which is saved in the Notifier directory, includes AlarmNotifier operational parameters. You can modify the resource file in the following ways:

- Specify whether AlarmNotifier processes alarms that DX NetOps Spectrum generated before AlarmNotifier started.
- Specify optional DX NetOps Spectrum attributes to pass to AlarmNotifier.
- Replace SetScript, ClearScript, or UpdateScript with custom scripts.
- Specify the SpectroSERVER to which AlarmNotifier connects.
- Disable the parameters that specify AlarmNotifier actions that you do not plan to deploy, reducing network traffic.

NOTE
Commenting out parameters does not disable them. Instead, their default value is used.

Follow these steps:

1. Navigate to the <*$SPECROOT*>/Notifier directory and make a backup copy of the .alarmrc file.
2. Open the file with your preferred text editor.
3. Edit the file by turning off optional parameters or by entering new parameter values. You can disable a parameter by giving it a value of False or by leaving the value blank.

   NOTE
   Do not disable required parameters or delete parameters.
4. Save and close the file, and then restart AlarmNotifier.
   Your changes go into effect when AlarmNotifier is restarted.

.alarmrc Parameters

The following list describes the resource file parameters that are provided with AlarmNotifier. For more information, see the Spectrum Alarm Notification Manager (SANM) section.

- **LANDSCAPE**
  Identifies the initial SpectroSERVER host to which AlarmNotifier connects. Enter only one name here. If LANDSCAPE is not defined, AlarmNotifier defaults to using the first landscape in the VNM landscape map. An informational window shows the default landscape handle.
- **VNM_MAIL_TIMEOUT**
  Specifies the minimum time that the Mail Service waits for a response from the SpectroSERVER before the request is canceled.
  Default: 60,000 milliseconds (one minute)
- **VNM_CONNECT_TIME_LIMIT**
  Specifies the minimum delay before an initial TCP connect request between AlarmNotifier and a SpectroSERVER times out.
  Default: 60,000 milliseconds (one minute)
- **KEEP_ALIVE_TIMEOUT**
  Specifies the amount of time before a keep-alive request times out.
  Default: 30,000 milliseconds (30 seconds)
- **KEEP_ALIVE_INTERVAL**
  Specifies the amount of time between keep-alive requests that are sent to the SpectroSERVER. A keep-alive request checks to see if the SpectroSERVER is still connected to the AlarmNotifier. If AlarmNotifier does not receive a response to the request, it disconnects from the SpectroSERVER. If your SpectroSERVER is slow to respond to these requests, you can increase this value to prevent the AlarmNotifier from disconnecting from the SpectroSERVER.
  Default: 60,000 milliseconds (1 minute)
- **SEND_ALARM_DELAY**
  Specifies the minimum delay between successive alarm notifications.
  Default: 1,000 milliseconds (1 second)
- **GET_GRAY_INITIAL_ALARMS**
  Specifies whether you want to receive Gray and Initial alarms. If you do not want Gray or Initial alarms, set this parameter to FALSE. This setting reduces the network traffic that AlarmNotifier generates and improves its performance.
- **GET_EXISTING_ALARMS**
  Specifies whether you want to receive reports about the alarms that exist when AlarmNotifier is invoked. Otherwise, you only receive reports of alarms that occur after AlarmNotifier is invoked. The "Waiting for more alarms from the SpectroSERVERs" message appears during any interval between alarm notifications.

Reinstalling or Upgrading the Product

When you reinstall DX NetOps Spectrum or you upgrade the version of DX NetOps Spectrum, the install process automatically saves the SetScript, UpdateScript, and ClearScript to a backup directory. Versions of the default scripts that you have saved under another name, for example SetScript_version1 or UpdateScript_modified, are retained in the <*$SPECROOT*>/Notifier directory. That directory also contains the default scripts that are included with the reinstallation or upgrade.

In addition, the install process saves your .alarmrc file to a backup directory. Versions of the .alarmrc resource file that you have saved under another name, .alarmrc1 or .alarmrc2 for example, are retained in the <*$SPECROOT*>/Notifier directory.

The backup scripts and the backup .alarmrc are saved to the following directory:

```
<$SPECROOT>/Install-Tools/SAVES_<date>/<time>/Notifier
```

WARNING

When using a custom AlarmNotifier, created by using a non default-directory, the AlarmNotifier does not upgrade by the DX NetOps Spectrum migration task and it results in having AlarmNotifier executable files (and modules/libraries) not in sync with the upgraded DX NetOps Spectrum install. This may cause severe issues such as, having the "old_release Notifier" opening a connection to the "new_release SpectroSERVER". In this case you have to manually update the custom AlarmNotifier directory to cover the current release executables/modules.

WARNING

During the DX NetOps Spectrum upgrade process, customization that were made to the default files(shipped with the product) in the $SPECROOT/lib/SDPM/partslist/ location will be lost. It is recommended to preserve these files before starting the upgrade process, and merge them back after the upgrade.

Spectrum Alarm Notification Manager (SANM)

The Alarm Notification Manager (*SANM*) is a DX NetOps Spectrum component that enhances the functionality of DX NetOps Spectrum alarm-processing applications. Multiple alarm-processing applications are available for DX NetOps Spectrum, including AlarmNotifier and Attention! These applications respond to DX NetOps Spectrum alarms by sending email notifications, creating trouble tickets, and more. SANM lets you create and associate alarm notification policies with applications.

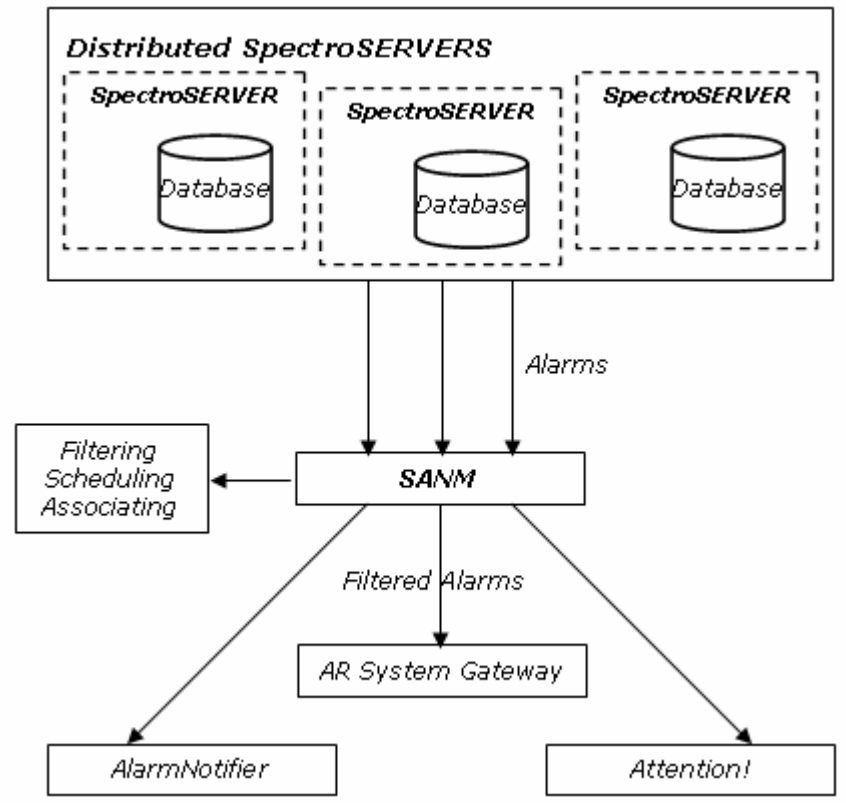
NOTE

From 10.3.1 onwards, SD Notifier (SANM) supports HTTPs.

How the Product Monitors Alarms

DX NetOps Spectrum, alarm-processing applications, and SANM work together in the alarm monitoring process.

The following diagram shows the alarm monitoring process:



The following workflow describes how DX NetOps Spectrum monitors alarms:

1. DX NetOps Spectrum polls the modeled network elements and updates the status of each element in the SpectroSERVER database.
2. DX NetOps Spectrum generates an alarm when it receives a trap from the network, or when it detects a critical status change in a network model. In the OneClick Console, the model icon changes from green to another color that indicates the alarm severity level.
   - DX NetOps Spectrum posts specific information for each alarm on the Alarm Details tab of the Component Detail pane.
   - DX NetOps Spectrum posts alarm event information to the Events tab of the Component Detail panel.
3. Data about alarms that DX NetOps Spectrum has generated is passed to SANM. SANM lets you create and associate alarm notification policies with alarm processing applications. In addition, the SANM Schedule subview lets you schedule application and policy associations and automates the association process.
4. SANM passes the alarm information to alarm processing applications only when the alarm types specified in the policies occur.

AlarmNotifier

Alarms that SANM filters are sent to AlarmNotifier. When both SANM and AlarmNotifier are installed, AlarmNotifier gains some capabilities:

- You can apply the SANM alarm-filtering policies to individual instances of AlarmNotifier.
- AlarmNotifier can generate alarm notifications from all landscapes of a distributed SpectroSERVER environment.
- Additional commands are available to acknowledge and clear alarms from AlarmNotifier.
- A new startup command lets you start multiple instances of AlarmNotifier. You can associate each instance with a different SANM alarm notification policy.
- Other new startup commands let you create a summary or detailed trace files.
- AlarmNotifier scripts include new parameters that contain information about troubleshooting alarms.
- The AlarmNotifier resource file includes new parameters to obtain more information about alarms.
- SANM lets you automatically associate a different policy with AlarmNotifier at a specified time.

Attention!

Attention! is a client-server network monitoring and notification system. The Attention! application alerts system managers to critical system and network events. Supported alert formats include alphanumeric paging, telephone calls, email, PA announcements, electronic message boards, and custom notifications. You can use SANM as a foundation for integration between DX NetOps Spectrum and Attention!.

The Alarm Resource File

The alarm resource file, .alarmrc, contains operating parameters that define SANM defaults. You can modify these parameters to customize SANM alarm management.

You can find the alarm resource file in the <*$SPECROOT*>/Notifier directory. For more information, see the Alarm Notifier section.

If you reinstall DX NetOps Spectrum or upgrade the version, the installation saves your resource file, .alarmrc, to a backup directory. Versions of the resource file that you saved with another name are preserved in the <*$SPECROOT*>/SANM directory. That directory also contains the default resource file that is included with the reinstallation or upgrade.

> **NOTE**
> We recommend creating a backup copy of the file before you modify it.

Create an Alarm Notification Policy

An alarm notification policy specifies the alarm types that an alarm-processing application receives and filters the unwanted alarms. You can create alarm notification policies to determine which applications receive alarms of the types you select.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select All Applications under SANM, and click the search icon 
   The Select Landscapes to Search dialog opens.
3. Select the landscapes to include in your search, and click OK.
   The available applications and the policy that they are using appear in the Contents panel on the right. The policy details appear in the Component Detail panel below the Contents panel.

   > **NOTE**
   > Run AlarmNotifier at least once. Otherwise, the search returns no models. The AlarmNotifier file is located in the <*$SPECROOT*>/Notifier directory.

4. In the Component Detail panel, click the link to create or set policy under General Information.
   The Select Policy dialog opens.
5. Click Create.
   The Create SANM Policy dialog opens.
6. Enter the policy name in the Name text box.
7. (Optional) Create one or more filters to associate with the new policy.

   NOTE
   We recommend assigning policy names that indicate when the policy is used. For example, use a name like 'ciscoRtrPM' so that you can identify Cisco router policies in a collection.
8. Click OK.
   The new policy is created.

Define a Filter For a Policy

You can define alarm notification policy filters that refine notification policies. A filter must be associated with a policy. Filters include parameters to include or exclude alarms by severity and by device type. You can set filters for alarms of specified types, on specified landscapes, or in specified topologies.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select All Applications under SANM and click the search icon 
   The Select Landscape to Search dialog opens.
3. Select the landscapes you want to include in your search and click OK.
   The available applications and the policy they are using appear in the Contents and Component Detail panels on the right.
4. In the Component Detail panel, click the create/set policy link in the General Information subview.
   The Select Policy dialog opens.
5. Click Create.
   The Create SANM Policy dialog opens.
6. Click the Add button.
   The Add Filter dialog opens.
7. Enter the following information:
   - **Name**
     Defines the new filter name.
   - **Notes**
     (Optional) Describes the filter.
   - **Age Time**
     (Optional) Indicates the time for which the filter holds the alarm. The alarm passes to the alarm processing application after the age time.

     NOTE

     If the alarm must pass multiple filters with different ages, SANM uses the shortest, non-zero alarm age interval.
   - **Notification Data**
     (Optional) Defines the data that is sent with the alarm notification.

     NOTE
     DX NetOps Spectrum can differentiate the filter based on Alarm Severity, Landscape, Model Type e.t.c, but can not be differentiated with the Age out time.

For example, If an alarm comes for the same device (modeled on same landscape) with same severity, and if same policy is applied with two different filters, then the alarm passes through the filter with minimum age out and will not pass through the higher age out filters. Since the minimum age out criteria is already met, the higher age out filters are ignored. But DX NetOps Spectrum still collects the notifications from other higher age out filters and sends them to all.

8. Define parameters for your filter:
   a. (Optional) Select the Landscapes tab to define the landscapes for the filter. To define the landscape, select servers in the Include and Exclude lists. You can move servers between the Include and Exclude lists by using the arrow buttons provided.

      NOTE
      OneClick combines the Landscapes and Servers parameters of the legacy SANM UI into a single parameter, Landscapes.
   b. (Optional) Select the Severity tab to define the alarm severity to include or exclude. To define the severity, select alarm severity levels from the Include and Exclude lists.
   c. (Optional) Select the Device Type tab to specify the device types for the filter, as follows:
      - Select an option to see the lists of device types to Include or Exclude.
      - Enter a device type and click Add to add it to the included or excluded list.
      - **Note:** Enter the name of an existing device type, or the name of a device type that you plan to create.
      - Click Browse to select from a list of existing device types.
      - Select a device type and click Remove to remove it from the list.
      - Select a device type and click Modify to edit that device type.
   d. (Optional) Select the Collections tab to specify the collection of policies for the filter. Alarms on devices that are in these collections are filtered. The steps to include, exclude, add, remove, modify, and browse for containers are the same as for the previous tab.
   e. (Optional) Select the Topology tab to specify the topology containers for the filter. Alarms on devices that are in these topologies are filtered. The steps are the same as for the previous tabs.
   f. (Optional) Select the Alarm Type tab to include or exclude alarms of specific types.
   g. (Optional) Select the Model Type tab to include or exclude models of specific types.
   h. (Optional) Select the Location tab to specify location containers for the filter.
      Alarms on devices that are in these locations are filtered.
   i. (Optional) Select the Organization tab to specify the organization containers for the filter.
      Alarms on devices that are in these organizations are filtered.
   j. (Optional) Select the IP Address/Range tab to specify the Internet Protocol (IP) addresses for the filter.
      SANM only passes alarms that are generated within the specified network, subnet, or IP address range to the alarm processing application.
   k. (Optional) Select the Model Name tab to specify the model names for the filter.
9. Click OK.
   The new filter is defined.

   NOTE
   If you create a filter with multiple parameters, you create an AND condition. As a result, all of the parameters must return TRUE for the filter to return any results. To create an OR condition, create two filters, each with a different filter parameter.
10. Enter a name for the new policy in the Name field of the Create SANM Policy dialog, and click OK.

    NOTE
    We recommend assigning policy names that indicate when the policy is used. For example, use a name like 'ciscoRtrPM' so that you can identify Cisco router policies in a collection.

The new policy is created.

Add a Filter to an Existing Policy

You can add a filter to an existing policy.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select SANM, All Policies and click the search icon 
   The Select Landscapes to Search dialog opens.
3. Select the landscapes that you want to include in your search and click OK.
   The existing polices display in the Contents panel on the right.
4. Select the policy for which you want to add a filter.
   The policy details display in the Component Detail panel.
5. Expand the Filters menu under the Information tab in the Component Detail panel.
6. Click the icon 
   Opens a dialog (Add a Filter) to add a filter to this policy.
7. Enter the filter information as explained in Define a New Filter and save the information.
   The filter is added to the policy.

Change the Filter Order

You can change the order in which the filters that are associated with a policy are processed.

This feature applies only to Notification Data. For instance, if Notification Data on filter 1 has jack@xyz.com, and filter 2 has jill@xyz.com, the alarm notifier returns jack@xyz.com:jill@xyz.com. If you change the order, the output is jill@xyz.com:jack@xyz.com.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select SANM, All Policies, and click the search icon 
   The Select Landscape to Search dialog opens.
3. Select the landscapes to include in your search, and click OK.
   The existing policies appear in the Contents panel on the right.
4. Select a policy whose filter order you want to change.
   The policy details appear in the Component Detail panel below the Contents panel.
5. Expand the Filters menu under the Information tab.
6. Click the icon 
   Opens a dialog (Set Order) to set the Notification data order.
7. Select a filter.
8. Use the arrow buttons to move the filter up or down in the order, and click OK.
   The filter is processed according to the new order.

Edit a Filter

Edit a filter to change the values of filter parameters. You can add, edit, and delete the filter parameters.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select SANM, All Policies, and click the search icon  .
   The Select Landscape to Search dialog opens.
3. Select the landscapes that you want to include in your search, and click OK.
   The existing policies appear in the Contents panel.
4. Select the filter in the filter table.
5. Click the icon  .

   Opens a dialog to enable editing of the selected filter.
6. Edit the Name, Notes, Age Time, Notification Data fields as required.
7. Click each parameter tab to add, edit and delete the corresponding parameter values, as explained in Define a New Filter.

   NOTE
   If you delete all values of a parameter, the filter no longer includes that parameter.
8. Select the Show only filtered by parameters check box if you want to view only the parameters included in the filter.
9. Click OK.
   The filter is edited.

Add Filter Parameters

You can add parameters to a filter to increase the level of filtering.

NOTE
You can add a parameter to a filter by adding a value to that parameter. That is, if a parameter was not included when you created the filter, defining a value for that parameter adds that parameter to the filter.

Follow these steps:

1. Open the filter for editing.
2. Click the tab of the parameter that you want to add to the filter.
3. Add one or more values to the parameter, as explained in Define a New Filter.
4. Click OK.
   The parameter is added to the filter.

Delete a Filter

You can delete a filter that is no longer required.

To delete a filter, select the filter in the filter table, and click the delete icon to permanently delete the selected item  .

The filter is deleted.

Add a Model or Alarm to a Policy

You can add a model or an alarm to a policy.

Follow these steps:

1. Click the Explorer tab in the Navigation panel of the OneClick Console.
   The model or alarm details display in the Contents panel on the right.
2. Right-click the model or alarm and select Add to, SANM Policy, Add.
   The Select Policy dialog opens.
3. Select a policy and click OK.
   The Select Write Option dialog opens.

   NOTE
   To remove the item, select Remove.
4. Select an option.
   The model or alarm is added to the selected policy.

Editing an Alarm Notification Policy

You can edit a policy before or after you save it, regardless of whether it is associated with an application. If the policy is associated with an application, SANM begins enforcing the new policy as soon as you save your changes.

WARNING
The Archive Manager must be running and connected to the SpectroSERVER for modified policies to take immediate effect.

The Association Process

After you create an alarm notification policy, you associate the policy with one or more alarm processing applications. An association between a policy and an application remains in effect until you associate another policy with that application or delete the associated policy.

SANM enforces a rule that an application can have only one associated policy at a time. To let an application to process different alarms at different times, associate the policies with the applications manually at run time. Or use the Schedule subview to schedule the associations automatically at a specified date and time. To run the same application with different policies, start multiple instances of the application, each with a unique name. Then associate the different policies with the application instances.

To change the policy that is associated with an application, associate a policy, such as the default policy, with that application. If you instead delete the associated policy, SANM associates the default policy with the application. Editing a policy that is associated with multiple alarm processing applications changes the policy for all of the applications. Reassociating the policy with each application is not required.

The SANM Default Policy

SANM associates a default policy with each application when you start the application for the first time, or when you delete a policy associated with that application. You can also explicitly associate the default policy with an application.

The default policy is a null policy; it does not filter alarms. That is, applications that are associated with the default policy receive all alarm notifications that occur in every landscape in the landscape map of the SpectroSERVER to which SANM is connected.

You can modify the default policy to add filters, but SANM continues to associate it with applications by default.

If you delete a policy that is associated with an application, SANM associates the default policy with that application. Therefore, before you delete a policy, check whether the default policy has been modified. If you delete a policy that is associated with an application, or if you modify the default policy, SANM displays a warning.

You can avoid associating the default policy associated with an application when you delete the associated policy. First associate a different policy with the application. The current policy is automatically deleted.

Associate a Policy with an Application

You can associate a policy with an application in OneClick.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select SANM, All Applications and click
   
   (Launch the selected search).
   The Select Landscape to Search dialog opens.
3. Select the landscapes to include in your search, and click OK..
   The existing applications appear in the Contents panel on the right.
4. Click the Create/Set Policy link.
   The Select Policy dialog opens.
5. Select a policy and click OK.
   The policy is associated with the application.

The Schedule Subview

The Schedule subview automates the association process and lets you implement alarm notification policies according to a schedule. For example, if you want an alarm application to take action in response to an alarm during the evening, you can create a special evening policy and can schedule the association of this policy with the application for 6 PM every day. You can then schedule the association of a different daytime policy with the same application for 7 AM every day. The Schedule subview lets you perform scheduled associations. You can avoid manually associating a new policy each time you want a change in alarm filtering.

You can verify the results of operations that were performed by the Schedule subview on the Events tab in OneClick.

Schedule an Association

You can schedule a policy association with an application in OneClick.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Select SANM, All Applications and click
   
   (Launch the selected search).
   The Select Landscape to Search dialog opens.
3. Select the landscapes to include in your search, and click OK..
   The existing applications display in the Contents panel on the right.
4. Select the SANM application whose policy you want to schedule.

5. In the Component Detail panel, expand the Scheduled Policies menu under the Information tab and click 
(Opens a dialog to schedule a policy to the current policy).
The Select Policy And Schedule dialog opens.
6. Select a policy, select a schedule, and click OK.

NOTE
You can create custom policies and schedules by clicking the Create buttons.

The scheduled policy displays in the Scheduled Policies table.

Additional Utilities

AlarmNotifier includes three utilities that you can use to manage existing alarms:

- assignticket
- clearticket
- updatealarm

assignticket Utility

The assignticket utility is used to populate the Trouble Ticket ID field of an alarm with the name of the person to whom the ticket is assigned.

Run this utility using the following syntax:

```
assignticket modelhandle alarmid assignee [username]
```

- ***modelhandle***
  Indicates the handle of the model where the alarm was raised.
- ***alarmid***
  Indicates the ID of the alarm to which to write.
- ***assignee***
  Indicates the name of the user to whom the ticket is assigned.
- ***username***
  (Optional) Specifies the name of the DX NetOps Spectrum user account to use to connect to the SpectroSERVER.

clearticket Utility

Use the clearticket utility to clear an alarm.

Run this utility using the following syntax:

```
clearticket -mh model_handle -ai alarm_ID -su username
```

- **-mh *model handle***
  Indicates the handle of the model where the alarm exists.
- **-ai *alarm_ID***
  Indicates the ID of the alarm to clear.
- **-su *username***
  Specifies the name of the user account to use to connect to the SpectroSERVER.

updatealarm Utility

Use the updatealarm utility to set the value of any attribute on any alarm.

Run this utility using the following syntax:

```
updatealarm modelhandle alarmid attrid attrvalue [username]
```

- ***modelhandle***
  Indicates the handle of the model where the alarm was raised.
- ***alarmid***
  Indicates the ID of the alarm to which to write.
- ***attrid***
  Indicates the ID of the attribute to which to write.
- ***attrvalue***
  Indicates the value to write to the attribute.
- ***username***
  (Optional) Specifies the name of the user account to use to connect to the SpectroSERVER.

Monitoring SANM Processes

Monitoring SANM processes involves viewing SANM events and tracing policies. This section discusses how you can view the SANM events and the type of trace files available to trace policies.

SANM Events

The Events tab in OneClick lists events that occur on a SpectroSERVER. When a user performs a SANM operation, the results of the operation appear on the Events tab with other DX NetOps Spectrum events. The following information about an event is listed:

- Date and time of the operation
- Application name and policy name
- User's host and user name
- Explanation of the event
- Event code

> **NOTE**
> For more information about using the Events tab, see the Using OneClick section.

SANM Event Codes

Each SANM event code corresponds to a SANM operation. Use the following SANM event codes to locate SANM operation entries or to filter out all entries that are not specific to SANM operation.

- **00d70000**
  Application registered with SANM
- **00d70001**
  Application unregistered with SANM
- **00d70002**
  Association created
- **00d70004**
  Scheduled association created
- **00d70006**
  Policy created
- **00d70008**

Policy modified
- **00d7000a**
  Application created
- **00d7000b**
  Application creation failed

Tracing Policies

To collect information about how a policy is working for a SANM-enabled application, at application startup you can enable the creation of a detailed or summary trace file for that application.

- **Detailed trace file**: Indicates the filters in a policy alarm that did not match when they were evaluated against that policy.
- **Summary trace file**: Indicates the time when an alarm notification is passed to the associated application when that application is started. A summary trace file does not include information about alarms that do not meet the criteria that are specified in a policy.

Use a record of policy-based actions by SANM as a decision-making tool. The results may confirm that you have the correct policy in place for an application, or they may compel you to refine your policy. For example, you can discover that you are inadvertently excluding alarms that should be passed to an application.

The Summary Trace File

The summary trace file includes a summary of all alarm notifications (set, cleared, updated) sent to the application, as follows:

```
05/24/2000 15:48:44 SANM Trace Entry 1
Notification sent to AlarmNotifier for Alarm 52 set on landscape 0x540000
05/24/2000 15:48:44 SANM Trace Entry 2
Notification sent to AlarmNotifier for Alarm 21 updated on landscape 0x540000
05/24/2000 15:48:44 SANM Trace Entry 3
Notification sent to AlarmNotifier for Alarm 26 cleared on landscape 0x540000
```

The summary trace file does not indicate the alarms that failed the policy.

The Detailed Trace File

A detailed trace file includes entries for alarms that meet and that do not meet the criteria of a policy. An alarm entry includes the alarm attribute values, which that are compared to the filter parameter values. An arrow symbol under MATCH between ALARM VALUES and FILTER VALUES indicates a match. The arrow is absent if the values do not match.

The following is an example of a trace file that indicates that an alarm passed a policy:

```
AlarmNotifier Trace Entry 305

Applying first_shift to Alarm 8982 set on landscape 0x540000
Applying Filter 1, tag: Abner or Abbott

   ALARM VALUES              MATCH  FILTER VALUES
   -----------               -----  -------------
   LANDSCAPE                        LANDSCAPE
      0x540000               -->       0x540000
                                       remaining values ignored

   MODEL TYPE                       MODEL TYPE
      Pingable               -->       Pingable
                                       remaining values ignored

   DEVICE LOCATION                  DEVICE LOCATION
      World:USA:NorthEast:   -->       USA

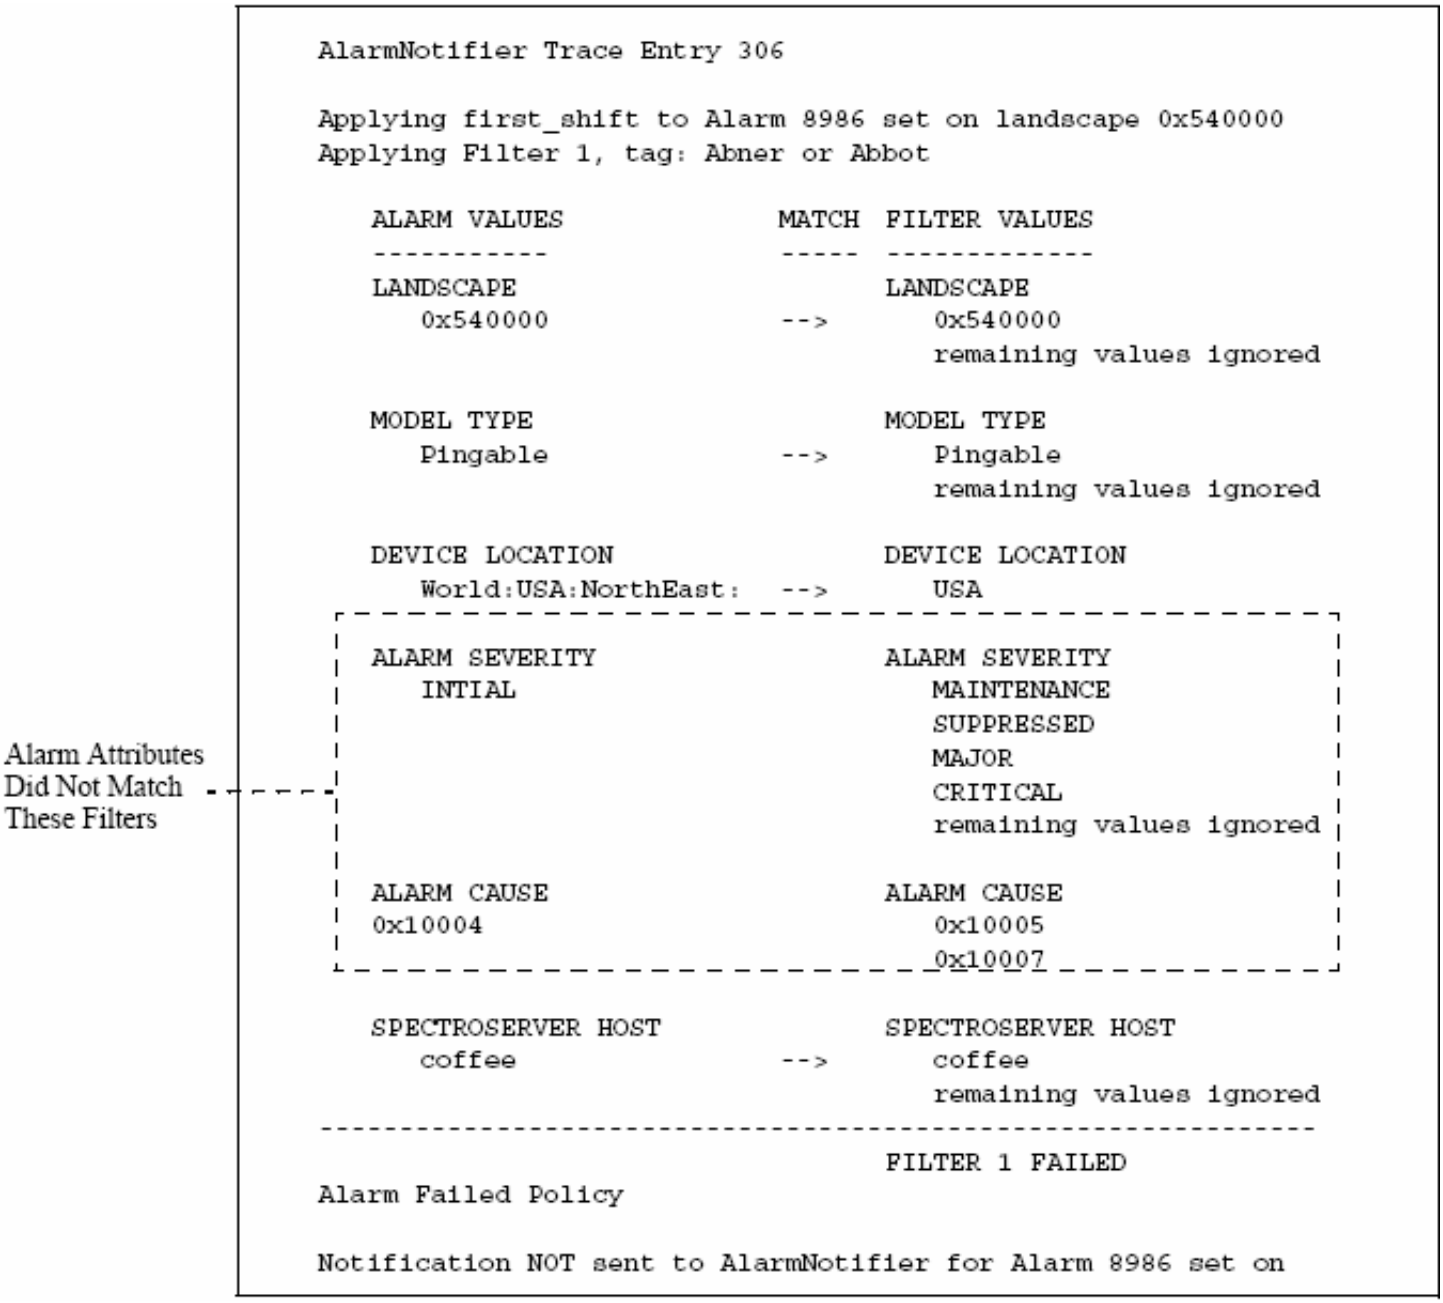
   ALARM SEVERITY                   ALARM SEVERITY
      CRITICAL                         MAINTENANCE
                                       SUPPRESSED
                                       MAJOR
                              -->      CRITICAL
                                       remaining values ignored

   ALARM CAUSE                      ALARM CAUSE
   0x10007                             0x10005
                              -->      0x10007

   SPECTROSERVER HOST               SPECTROSERVER HOST
      coffee                 -->       coffee
                                       remaining values ignored
-------------------------------------------------------------
                                    FILTER 1 PASSED
Alarm Passed Policy

Notification sent to AlarmNotifier for Alarm 8982 set on landscape
0x540000
```

The following is an example of a trace file that indicates that an alarm failed a policy:



SANM and AlarmNotifier

This section discusses how SANM enhances the capabilities of AlarmNotifier.

AlarmNotifier Enhancements

AlarmNotifier gains capabilities when you install SANM on your system. These capabilities include additional startup options for specifying application names and for creating trace files, alarm acknowledge and alarm clear commands, and script and resource file parameters. SANM also lets AlarmNotifier operate in a distributed environment.

Start AlarmNotifier

AlarmNotifier is located in the <*$SPECROOT*>/Notifier directory. This directory contains the following files by default:

- .alarmrc
- AlarmNotifier
- ClearScript
- README
- SetScript
- UpdateScript

AlarmNotifier includes the following additional files and directory:

- **AlarmAck**
  Acknowledges an alarm.
- **AlarmClear**
  Clears an alarm.
- **Trace**
  Displays trace files.

To start AlarmNotifier, use the following AlarmNotifier command in the <*$SPECROOT*>/Notifier directory:

```
AlarmNotifier [-r resourcefile] [-n application][-tl summary|details [-tn tracefile] [-ts size]]
```

- **-r *resourcefile***
  Lets you specify a resource file other than the default resource file .alarmrc.
- **-n *application***
  Lets you override the application name value that is specified by the APPLICATION parameter in the resource file. You can specify a different name for an AlarmNotifier application instance. This option lets you start multiple instances of AlarmNotifier and associate each of them with a different SANM alarm-filtering policy. If a name is not assigned to the APPLICATION parameter in the resource file, use the -n option at start-up to specify an application name.
- **-tl summary | details**
  Lets you activate tracing at a specified level, summary or detailed. The default format for an AlarmNotifier trace file is the application name together with the date when the trace file was created.
- **-tn *tracefile***
  Lets you specify a trace file name other than the default name, which is provided when only the -tl option is used. Use this option with the -tl option.
  When using the trace file option, the output file is written by default to the <*$SPECROOT*>/Notifier/trace directory. To explicitly name an output file and path, use the [-tn filename] option. If <*filename*> is a relative path, trace output is written to a file that is relative to the current directory. If <*filename*> is an absolute path, trace output is written to the absolute path.
- **-ts *size***
  Lets you specify the number of lines in the trace file. Use this option with the -tl option. The application writes this number of lines to the file and then wraps around to the beginning of the file. Entries are numbered sequentially, and an END OF TRACE line follows the last entry. The default number of lines in a trace file is 10000.

  NOTE

  If you migrate DX NetOps Spectrum to a higher release, verify the following settings in the ".alamrc" file:

  - The paths to the scripts are correct.
  - You have all the permissions to the "ClearScript" script.

  AlarmNotifier does not start if these settings are incorrect.

Access Alarm Management Parameters

The Alarm Management view lets you control some aspects of alarm management. Two parameters in this view, Generate Alarm Events and Add Events to Alarms, determine how the SpectroSERVER reacts to alarm updates.

You can view and modify alarm management parameters in OneClick to control some aspects of alarm management.

Follow these steps:

1. Open OneClick.
2. In the Navigation panel, select a VNM model in the Universe view.
   The corresponding details appear in the Contents panel and Component Detail panel on the right.
3. In the Component Detail panel, select the Information tab and open the Alarm Management menu.
   The following alarm management parameters affect alarm event updates:
   - **Generate Alarm Events**
     Enables the generation of alarm change events (which indicate that alarms are generated, updated, or cleared).
     Default: Enabled (Yes).

     WARNING
     When **Generate Alarm Events** is enabled, always select the **Store Event in Historical Database** option for the event in the Event Configuration window. Otherwise, event information does not appear in the Events tab of the Component Detail pane as that event is not logged in the Historical database. In addition, always enable **Generate Alarm Events** when the **Store Event in Historical Database** option is selected. Otherwise, the **Severity**, **Cleared On** and the **Cleared By** fields are not updated in the Events tab.
   - **Add Events to Alarms**
     Controls whether alarm change events are added to each alarm. If disabled, alarm change events are not displayed in the Events tab of the Component Detail panel for the alarm. When enabled, adds any event that affects the alarm, thus incrementing the Occurrence counts. For example, events with different event types that generate the same alarm, such as alarm management or alarm clearing events, are also added.
     Default: Disabled (No).

     NOTE
     For more information, see the Distributed SpectroSERVER Administration section.

Verify that Originating Event Data Is Saved

High traffic levels can prevent the Archive Manager from consistently providing the events that are associated with reported alarms. In such a case, you can still retrieve some basic information about the events that are associated with alarms. The SpectroSERVER stores this information by default.

NOTE
Only information about the first event that is associated with an alarm (the originating event) can be retrieved.

The Store_Originating_Event attribute (0x1296f) of the Alarm Management application model determines whether originating event information is available to the AlarmNotifier. Verify that the default setting, Yes (Enabled), is in force so that event information is available in failover situations.

Follow these steps:

1. Click the Locater tab in the Navigation panel of the OneClick Console.
2. Expand Application Models.
3. Double click By Name.
4. The Search box opens.
5. Type "AlarmMgmt" in the Model Name Contains field, and click OK.
   The Alarm Management model appears in the Results panel.

6. Select the AlarmMgmt model.
   The corresponding details appear in the Component Detail panel.
7. In the Component Detail panel, click the Attributes tab.
8. Type "Store" in the Search box to locate the Store_Originating_Event attribute.
9. Double-click it to verify the value in the right pane.

Alarm Acknowledgement

The AlarmAck command allows you to acknowledge alarms. This command can be used at any shell command prompt to acknowledge specific alarms, or it can be incorporated into a script. AlarmAck returns a value of 0 if the operation succeeds. Otherwise, it returns a non-zero value.

To acknowledge an alarm, run the AlarmAck command with the following syntax:

```
AlarmAck -a alarm -l landscape
```

- **-a *alarm***
  Defines the alarm ID.
- **-l *landscape***
  Defines the landscape handle for the landscape where the alarm was raised.

  NOTE
  Available only for distributed SpectroSERVER environments.

To acknowledge all alarms for a model, run the AlarmAck command with the following syntax:

```
AlarmAck -m modelhandle
```

- **-m *modelhandle***
  Specifies the model handle for the model with the alarm conditions.

User-Clearable Alarms

The AlarmClear command clears user-clearable alarms. To determine whether an alarm is user-clearable, check the value of the UserClearable parameter in alarm notifications. AlarmClear can be launched from any shell command prompt to clear specific alarms, or you can incorporate it into a script. AlarmClear returns a value of 0 if the operation succeeds. Otherwise, it returns a non-zero value.

You can run the AlarmClear command to clear alarms using the following syntax:

```
AlarmClear -a alarm -l landscape
```

- **-a *alarm***
  Defines the alarm ID.
- **-l *landscape***
  Defines the landscape handle of the landscape where the alarm was raised.

SANM-Enabled Script Parameters

The SetScript, UpdateScript, and ClearScript scripts have additional parameters when they run on a computer where SANM is installed.

The following list describes the SANM-enabled script parameters:

- **FlashGreen**

Displays in ClearScript notifications but not in SetScript or UpdateScript notifications.
When enabled, the cleared alarm exhibits the *flash green* condition: the flash green option for the model is enabled, and the GET_FLASH_GREEN parameter in the .alarmrc resource file is set to True. Even though SetScript and UpdateScript notifications do not display this field, the parameter is passed to these scripts, but it is invalid and has a default value of False.

- **Location**
  Identifies the location model that contains the network element whose alarm is set, updated, or cleared. The element must be modeled in the OneClick World topology view. You can find the location model that contains the model for the problematic network element in a colon-separated, hierarchical list of location models. For example, an alarm for a model that is contained in Room 222 on the first floor of the Boston building in the northeast region of the United States appears as follows:
  USA:Northeast:BostonBldg:FirstFloor:Room222.
- **AlarmAge**
  Specifies the length of time that SANM retains an alarm from an instance of AlarmNotifier that is associated with that policy. The AlarmAge is set in the filters in an SANM policy. If the alarm must pass multiple filters with different ages, SANM uses the shortest, non-zero alarm age interval.
- **NotificationData**
  Lists notification data entries (names of persons) that SANM passes to an instance of AlarmNotifier that is associated with that policy. The entries are specified in the filters in an SANM policy. AlarmNotifier scripts can be configured to initiate email notifications to those persons in the notification data entries.
- **ProbableCause**
  Is the probable cause text associated with the alarm.
- **EventMessage**
  Is the message about the events that are associated with the alarm. This field is blank if the DX NetOps Spectrum alarm has no associated events, or if the event does not include alarm information.

Email Notifications

If you use an AlarmNotifier script to send an email notification, set the value for the VARFORMAIL parameter in the script. This parameter specifies to whom the email message is sent.

If you are using SANM-enabled AlarmNotifier, use the NotificationData parameter to set the value for VARFORMAIL. If you use NotificationData as the value for VARFORMAIL, email is sent to the persons who are specified in the NotificationData parameter in the SANM policy that is associated with the instance of AlarmNotifier that invokes the script. For example, if the Notification Data entry is formatted as "John: Mary or Sue: Lynn, Jeff", email is sent to John, Mary, Lynn, and Jeff, but not to Sue, because AlarmNotifier interprets the colon as an AND operator and does not act on the OR operator.

Other possible values for the VARFORMAIL parameter are RepairPerson or both. The RepairPerson option is the only option that is available for AlarmNotifier when it is not running with SANM. Both options indicate that the email notification is sent to the designated RepairPerson and to the person who is specified by the NotificationData parameter.

NOTE
For more information about configuring an AlarmNotifier script to send an email notification, see the AlarmNotifier section.

Third-Party Applications

You can customize or replace the SetScript, ClearScript, or UpdateScript for integration with a third-party application. If you create your own script or executable, understand which arguments are passed from DX NetOps Spectrum to the receiving script or executable. The script or executable must receive all of the arguments that DX NetOps Spectrum passes to it in the correct order.

NOTE
Any DX NetOps Spectrum attribute of the model with the alarm can be passed to AlarmNotifier and can be used in a script. For more information, see the AlarmNotifier section.

The following table shows the argument number, name, and format for each argument that is passed to each script when the USE_NEW_INTERFACE .alarmrc parameter is set to TRUE:

Argument	Name	Format
1	Date	mm/dd/yy
2	Time	hh:mm:ss
3	Model Type	Text
4	Model Name	Text
5	Alarm ID	Integer
6	Severity	Text
7	Cause	Text
8	Repair Screen	Text
9	Server	Text
10	Landscape	Hexadecimal
11	Model Handle	Hexadecimal
12	Model Type Handle	Hexadecimal
13	IP Address	xxx.xxx.xxx.xxx
14	Security String	Text
15	Alarm State	Text
16	Acknowledged	Text
17	Clearable	Text
18	Flash_Green	Text
19	Location	Text
20	Age	Integer
21	Notifdata	Text

The following table shows the argument number, name, and format for each argument that is passed to each script when the USE_NEW_INTERFACE .alarmrc parameter is set to FALSE:

Argument	Name	Format
1	Date	mm/dd/yy
2	Time	hh:mm:ss
3	Model Type	Text
4	Model Name	Text
5	Alarm ID	Integer
6	Severity	Text
7	Cause	Text
8	Repair Screen	Text
9	Status	Text
10	Server	Text

11	Landscape	Hexadecimal
12	Model Handle	Hexadecimal
13	Model Type Handle	Hexadecimal
14	IP Address	xxx.xxx.xxx.xxx
15	Security String	Text
16	Alarm State	Text
17	Acknowledged	Text
18	Clearable	Text
19	Flash_Green	Text
20	PCause	Text
21	Location	Text
22	Age	Integer
23	Notifdata	Text
24	EventMsg	Text

If USE_NEW_INTERFACE is set to TRUE, the Status, PCause, and EventMsg arguments are sent as environmental variables. The argument order is therefore affected. If USE_NEW_INTERFACE is set to FALSE, use the following syntax in your script to read data from the PCause and the EventMsg argument into a variable as follows:

```
<variablename>=`echo "$2" | tr '\350' '\012' | tr '\351' '"'`
```

This syntax is required to avoid problems when the script parses the extra data from new lines or other special characters.

Note: For more information about the USE_NEW_INTERFACE .alarmrc parameter, see AlarmNotifier.

SANM-Enabled .alarmrc Parameters

The AlarmNotifier resource file, .alarmrc, has several additional parameters when you run AlarmNotifier on a computer that has SANM installed.

The following list describes the SANM-enabled parameters:

- **APPLICATION**
  Defines the application name that identifies this AlarmNotifier application. If you use multiple AlarmNotifier applications on your network, distinguish them with unique application names, such as AlarmNotifier1 or AlarmNotifier2. You can then use unique SANM alarm-notification policies with each application. If you use the n option when invoking AlarmNotifier, the APPLICATION parameter value is ignored.
  Default: AlarmNotifier
- **GET_LOCATIONS**
  Lets you specify whether to notify you of the location of the device with the alarm. If you are not interested in location information, set this parameter to False. A False setting overrides any location that is specified as a filter parameter in an alarm-notification policy, reducing network traffic.
- **GET_PROBABLE_CAUSES**
  Lets you specify whether you want to receive the Probable Cause text that is associated with each alarm. If you are not interested in Probable Cause information, set this parameter to False, improving AlarmNotifier performance.
  Default: True.
- **GET_EVENTS**
  Lets you specify whether to receive the Event message that is associated with an alarm. If you are not interested in event information, set this parameter to False. Excluding events reduces network traffic that AlarmNotifier generates and improves performance.

Default: True.

- **GET_FLASH_GREEN**
  Lets you specify whether to receive the Flash Green status for a model. ClearScript is the only script that displays the Flash Green status. When Flash Green is enabled for a model, the model continues to flash green after alarms are cleared. The flashing status signals that alarms have occurred even though they no longer exist. If the value of GET_FLASH_GREEN is set to False, the Flash Green status is always passed to the ClearScript as false. If set to True, the Flash Green status is correctly passed as either False or True.
  Default: True.
- **MSG_TIMESTAMP_FORMAT**
  Sets the format for the timestamp on all SANM messages. The maximum length of the output string is 127 characters. Any characters other than the conversion strings are output as text in the timestamp. The default setting is %X %x:. The colon (:) is appended to the end of the timestamp. For example, to output the date/time for the current locale and the time zone name, the string %x %X %Z is entered as the value. If left blank, no timestamp is output on the messages. If an incorrect string is entered, that string displays as text in the output.
- **POLICY_LANDSCAPE**
  Lets you specify the landscape that AlarmNotifier uses for all SANM policy definitions. This parameter works with the POLICY_LANDSCAPE setting in the SANM .sanmrc file.
- **SHOW_ALL_EVENTS**
  Lets you specify whether to receive the most recent event or all events that were generated for an alarm. If set to False, AlarmNotifier only forwards the most recent event. For example, assume that an alarm was created based on an event, and then someone updated the status of that alarm. When the alarm status changed, another event that was related to that alarm was generated. In such a situation, AlarmNotifier only receives the status of that second event. The purpose of this type of filtering is to eliminate events that have already been forwarded. Filtering is especially important if the size of the message is relevant, for example, if the event message is sent as a page.
  Default: False.
- **GET_EXISTING_ALARMS**
  Specifies whether to receive all existing alarms.
  Default: True
- **UPDATE_EXISTING_ALARMS**
  Specifies whether to update the existing alarms. This is different than GET_EXISTING_ALARMS because setting this option to true does not cause the Set Script to get called for existing alarms.
  Default: True.
- **ENABLE_CORRELATION**
  Lets you to enable the alarm correlation awareness feature for all alarms. The value of the SHOW_SYMPTOM_ALARMS parameter determines whether a symptom alarm associated with a cause alarm to display.
  Default: False.
- **SEND_EVENT_UPDATES**
  Lets you to specify whether you want an update action to be triggered when an event is appended to an alarm.
  Default: True.

Using SANM in a Distributed SpectroSERVER Environment

This section discusses how you can use SANM in a DSS environment.

Landscapes and Alarm Monitoring

A Distributed SpectroSERVER (DSS) environment lets you divide network management tasks among several SpectroSERVERs. When you create a network model with multiple SpectroSERVERs, it is possible for SANM to access information from more than one SpectroSERVER simultaneously.

A landscape is the DX NetOps Spectrum term for a network domain that a single SpectroSERVER manages. When SANM operates in a distributed environment, it monitors alarms from all landscapes. Even though different landscapes can model each other in a DSS environment, SANM-enabled applications do not receive duplicate alarm information.

Because SANM evaluates alarms across VNMs in a DSS environment, you may want to limit the type of alarm notifications that you receive. In a DSS environment, limit the number of alarm notifications by carefully defining the parameters, Landscape, Subnet IP Address, and Device Location in the alarm notification policy.

SANM Policy Management Across Multiple Landscapes

Choose between two options for configuring SANM in a distributed environment. You can create SANM policies on any landscape and let SANM read all policies from all landscapes. Or you can create all SANM policies on one landscape and only let SANM read policies from that landscape. In either case, you can associate alarm-processing applications from any landscape with the SANM policies.

How to Create SANM Policies in a Single Landscape

If you set up a distributed environment so that all policies for all landscapes are defined and managed from a single SpectroSERVER, you can install alarm-processing applications on any of the SpectroSERVERs in the distributed environment. If the values in the application resource file are appropriate, the application finds the server that contains the SANM policy definitions and associates it with the appropriate policy. This configuration reduces the initial traffic on the network to associate alarm processing applications and SANM policies, and it also facilitates ongoing SANM policy management.

> **NOTE**
> You cannot migrate or move an SANM policy from one landscape to another. If you want to institute this configuration and already have policies defined on various landscapes, you must recreate these policies on the new landscape from which you will manage SANM policies.

To configure all SANM policies in one landscape, take the following steps:

1. Change the POLICY_LANDSCAPE parameter in the .alarmrc file to the landscape handle of the SpectroSERVER where SANM is installed, and where policies are created and managed.
2. Change the POLICY_LANDSCAPE parameter in the alarm-processing application resource file (.alarmrc) to the landscape handle of the SpectroSERVER where SANM is installed. This parameter instructs the application where to look for defined policies.
3. Restart the SpectroSERVER where SANM is installed and restart the alarm-processing applications so that the changes to the resource file parameters are read.
4. Open SANM, All Policies on the Locater tab of OneClick, and click the search icon to launch the selected search 
   The only available policies are the policies that are created on this landscape. All alarm-processing applications whose POLICY_LANDSCAPE parameter is set to the landscape handle of this landscape are seen in the applications list.

For example, if you have three landscapes (Landscape1, Landscape2, and Landscape3) in your distributed environment, and you have set the value of the 'POLICY_LANDSCAPE' parameter value to 'Landscape2'.

POLICY_LANDSCAPE=<landscape2>

- All the alarm-processing applications point to 'Lancscape2'.
- All the policies are saved to Landscape2 only.
- In case, you decommission the Landscape1 from the environment, you do not lose the policies associated with Landscape1 because all these policies are saved to Landscape2.
- If you decommission the Landscape2 from the environment, all the policies are deleted because all the policies in this environment are saved to Landscape2.

How to Create SANM Policies on Multiple Landscapes

You can set up a distributed environment so that SANM policies can be defined and managed on any SpectroSERVER. Alarm-processing applications on any SpectroSERVER in the distributed environment have access to all of these policies.

To configure SANM policies in multiple landscapes, verify the following requirements:

- Make sure the alarm-processing applications are associated with their respective landscapes.
- Makes sure the POLICY_LANDSCAPE parameter in the different alarm-processing application resource files (.alarmrc) has associated value for different landscapes.

Then take the following steps:

1. Restart the SpectroSERVER where SANM is installed.
2. Restart the alarm-processing applications so that the changes to the resource file parameters are read.
3. Open OneClick. Verify that all policies that have been created within the distributed environment are available.
4. Verify that all alarm-processing applications in the distributed environment are available for association.

For example, if you have three landscapes (Landscape1, Landscape2, and Landscape3) in your distributed environment, and you have set the “POLICY_LANDSCAPE =” value different for each alarm-processing application.

POLICY_LANDSCAPE=<respective landscape>

- All the alarm-processing applications are associated with their respective landscapes.
- All the policies are saved to different landscapes depending on the 'POLICY_LANDSCAPE' parameter setting in the different alarm-processing application resource files.
- In case, you decommission a landscape from the environment, you will lose the policies associated with that landscape only because all these policies are saved to its respective landscape.

NOTE

If the POLICY_LANDSCAPE =” value is empty (no landscape is set) then all the policies are saved to MLS.

- If the AlarmNotifier applications are running and points to MLS only, then all the policies can be created on MLS only.
- If you decommission any of the SpectroServers except MLS, then policies will not be lost because all the policies are saved to MLS only.

Methods for Determining Monitored Landscapes

You can use the following methods to determine which landscapes are monitored by SANM:

- Use the DX NetOps Spectrum Command Line Interface (CLI) application to connect to the SpectroSERVER to which SANM is connected. Then enter **show landscapes** on the command line.
  The CLI application displays a list of all landscapes that are modeled in that server.

  NOTE
  For more information, see the Command Line Interface section.
- Open any one of the detailed trace files that you specified for SANM-enabled applications. A trace file indicates the connection status of each landscape in the landscape map for the SpectroSERVER to which SANM is connected. Trace files are stored by default in a trace directory in the home directory of an SANM-enabled application.

Command Line Interface

This section explains how you can use the command-line interface to perform DX NetOps Spectrum operations from the UNIX, DOS, and Bash command prompts.

Introduction to Command Line Interface (CLI)

This section discusses the following Concepts:

- Use of CLI to perform DX NetOps Spectrum operations from the command prompt.
- DX NetOps Spectrum CLI commands
- How CLI commands can be incorporated into shell scripts or menu systems to give you a more powerful and versatile method of accessing DX NetOps Spectrum data.
- Components of the DX NetOps Spectrum Command Line Interface.
- Environment variables for the CLI.
- How the DX NetOps Spectrum CLI works by using the CLI local server and the startup file.

Command Line Interface Overview

The DX NetOps Spectrum Command Line Interface (CLI) is a core DX NetOps Spectrum component and is installed with the core DX NetOps Spectrum product.

You can access DX NetOps Spectrum data and can execute DX NetOps Spectrum operations from the OneClick user interface. However, if you prefer to execute DX NetOps Spectrum operations from the command line, you can use the CLI. For those tasks that you cannot execute in OneClick, CLI is the only DX NetOps Spectrum resource available to you.

CLI is a powerful tool, but it does not provide the safeguards that OneClick does, especially related to modeling. CLI must be used by DX NetOps Spectrum administrators who understand the potentially harmful effects of haphazardly creating and destroying models and modifying model attributes on a network modeling scheme.

CLI is a flexible option. You can open a CLI session and issue commands from any of the command prompts that are available on your system, such as UNIX, DOS, and Bash.

CLI Commands

CLI commands are similar to UNIX commands, and they can be used with UNIX or DOS commands, especially grep (find), pipes, and redirect symbols. Some CLI commands, however, can conflict with UNIX commands of the same name. For example, the CLI update command can conflict with the UNIX update command.

To avoid conflicts, use **./update** from within the vnmsh directory. When using a script, use the full pathname for the CLI command, for example, <*$SPECROOT*> **/vnmsh/update**.

> **NOTE**
> The CLI update command always provides a response, either a confirmation that the update was successful or a message that the update failed. If you receive no response from CLI when using the update command, type "**which update**". The system likely responds with:

```
/etc/update
```

For more information on commands that are used in the DX NetOps Spectrum Database tools, refer to the following utility programs:

- db_remove
- dbtool
- HostUpdate
- MapUpdate
- reports
- SSdbload
- SSdbsave
- Database Model Conversion Tool (DBconv)

CLI in Shell Scripts

CLI commands can be incorporated into shell scripts or menu systems to give you a more powerful and versatile method of accessing DX NetOps Spectrum data.

Each CLI command sends output reporting the success or failure of the command to standard error. Normal output that is expected as the result of the success of a command, however, is sent to standard output. Each of the commands also generates a return code of zero on success and a non-zero error code on failure. Return codes enable shell scripts using the CLI commands to proceed according to the success or failure of each command.

CLI Components

CLI components are described in this section as follows:

- Executable commands
- Four environment variables
- The daemon that maintains communication with a SpectroSERVER
- The set of sample shell scripts that incorporate CLI commands

CLI Environment Variables

You can set the following four environment variables for CLI:

- **CLIMNAMEWIDTH**
  Displays a model name. By default, the create, seek, and show commands display a maximum of 16 characters for a model name. However, with the environment variable CLIMNAMEWIDTH, you can specify up to 1024 characters to display for model names. For example, using the C shell:
  ```
  setenv CLIMNAMEWIDTH 32
  ```
  You can set this variable in your .login file, in a script, or simply before you issue a command. You can set or change any number of times in a CLI session, depending on the length of the model names.
- **CLISESSID**
  Represents the ID for use in scripts. Set the CLISESSID variable to <$$>, which represents the process ID of the running shell script. This variable is necessary when using cron to run CLI scripts concurrently. For example, using the bash shell:
  ```
  CLISESSID=<$$>; export CLISESSID
  ```
  Also, setting the CLISESSID environment variable to a unique value for each CLI session is required if you run CLI on Windows using the bash shell instead of DOS. You can give a unique timestamp to each bash shell, for example:
  ```
  export CLISESSID='date +%s'
  ```
- **SPECROOT**
  Displays the alarm or event description. The SPECROOT environment variable is required for the show alarms or show events commands when the -x option is specified. This variable gets the description of the alarm or event from the SG-Support directory tree if it can be located so that the output from the commands is expanded.

On UNIX, you can specify the SPECROOT variable in your login shell and can set this variable to the DX NetOps Spectrum home directory. For example:

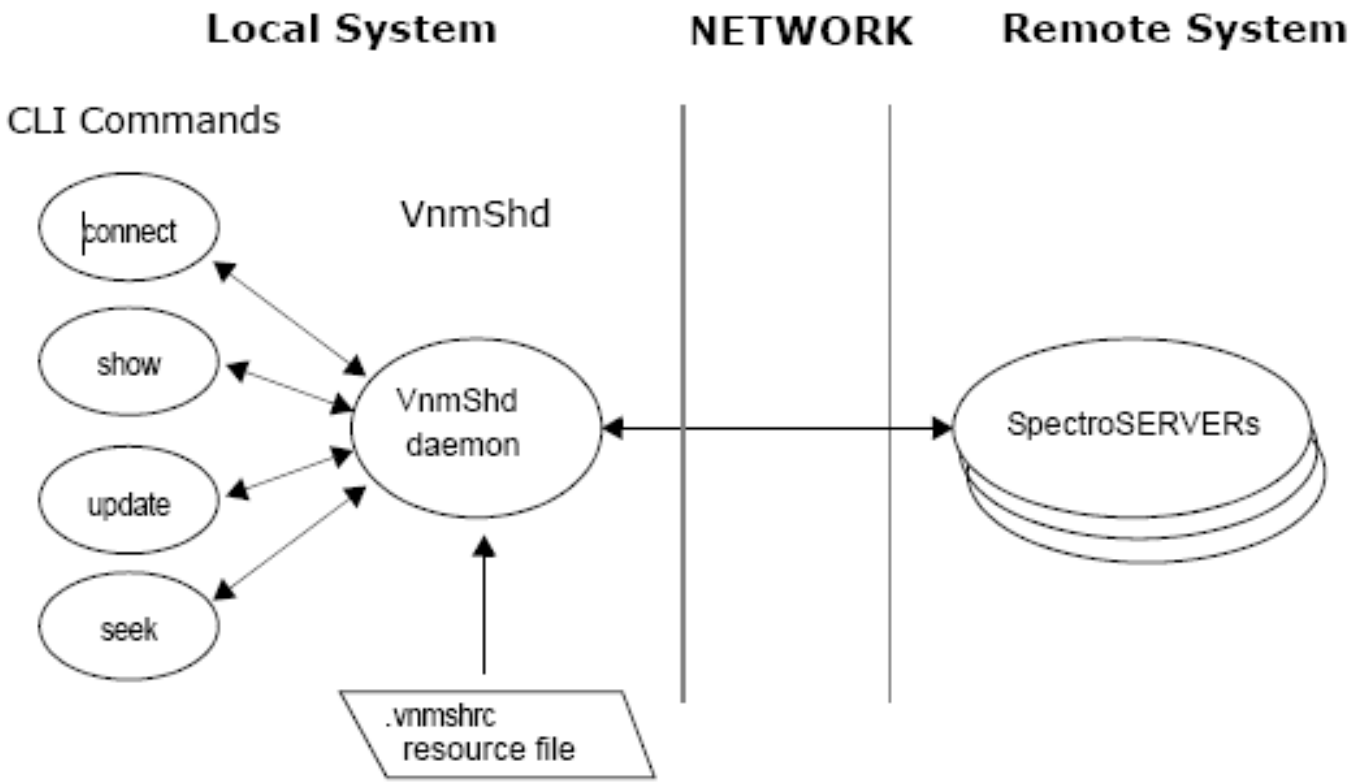
```
SPECROOT=/home/<sp>; export SPECROOT
```

On Windows, see your system documentation for details about setting environment variables.

- **CLIPATH**
  Displays the path of the <*$SPECROOT*>/vnmsh directory and the scripts require to use CLI commands.

CLI Architecture

The following image depicts the CLI architecture:



The CLI Local Server, which uses .vnmshrc at startup, performs the following major functions:

- Maintaining a constant network connection with SpectroSERVER. The CLI Local Server prevents disconnection when a command is executed each time. This server maintains a *single* connection to SpectroSERVER regardless of the number of CLI users that are connected to the daemon. The socket connects and disconnects are expensive as far as time and resource usage are concerned.
- Maintaining state information for each CLI user. The 'current' and setjump commands, for example, require the CLI Local Server to store state information. The current command stores a model handle and a landscape handle for use in future commands. The setjump command stores a text string to identify the current position of users in a DX NetOps Spectrum landscape.

The Startup File

The .vnmshrc file, the CLI Local Server startup file, is located in the <*$SPECROOT*>/vnmsh directory. This file contains several parameters that control how vnmsh communicates with the SpectroSERVER. These parameters are described in the following list:

- **vnm_hostname**
  Specifies the host name of the SpectroSERVER to connect to.
- **client_handshake_timeout**
  Specifies the number of milliseconds the client waits for server ID information, when setting up a connection.
  Default: 900
- **server_handshake_timeout**
  Specifies the number of milliseconds the server waits for client ID information, when setting up a connection.
  Default: 900
- **connect_time_limit**
  Specifies the maximum number of milliseconds to wait for a connection to the SpectroSERVER.
  Default: 1000
- **listen_backlog**
  Specifies the number of client requests to the SpectroSERVER held in queue while waiting for prior ones to complete.
  Default: 10
- **vnm_tcp_port**
  Specifies the TCP port that the vnmsh is using to communicate with the SpectroSERVER when the vnmsh is a SpectroSERVER client.
- **vsh_tcp_port**
  Specifies the TCP port where the vnmsh listens for TCP messages when the vnmsh is acting as a server to the client requests such as show, update.
- **debug_file**
  Specifies the file to which CLI writes error messages.
- **max_show_event_length**
  Specifies the maximum number of characters that are shown when the **show events -x** command is used to display an event message.
  Default: 512

The CLI Local Server

The first user to issue the connect command automatically starts the CLI Local Server (VnmShd daemon) on that workstation and establishes a connection to a SpectroSERVER. Only one CLI Local Server per workstation can be running, and that daemon makes only one connection to a SpectroSERVER.

After the CLI Local Server has been started on a workstation, all subsequent users who connect to CLI on that workstation use the same CLI Local Server.

Error Checking

DX NetOps Spectrum enforces certain rules when you perform tasks in OneClick. For example, rules control the allowable actions when you create or move device models in different views.

CLI does not enforce these rules and cannot perform any error checking. As a result, CLI lets users create models and place them wherever they want without performing error checking. You see an error if you attempt to use a CLI command in a manner that does not conform to its format.

Working with Command Line Interface

This section describes how to start CLI sessions on UNIX, DOS, and Bash prompts. This section also includes examples that demonstrate how to use CLI commands for common tasks in DX NetOps Spectrum. Also how to generate event reports and switch models using the CLI.

Start a CLI Session on UNIX

On a UNIX platform, you can start a CLI session from the shell prompt.

> **NOTE**
> You can use a script to pack up CLI so that it can be sent to another server. For more information, see the Distributed SpectroSERVER Administration section.

Follow these steps:

1. Start the SpectroSERVER to which you want to connect.
2. Navigate to the vnmsh directory in the DX NetOps Spectrum installation directory:
   ```
   $ cd <$SPECROOT>/vnmsh
   ```
3. Open the connection:
   ```
   $ connect
   ```
   You are connected to the CLI session.

Start a CLI Session on Windows using DOS Prompt

On the Windows platform, you can start a CLI session from the DOS prompt.

> **NOTE**
> You can use a script to pack up CLI so that it can be sent to another server. For more information, see the Distributed SpectroSERVER Administration section.

For all instances of UNIX (as opposed to CLI) commands in this section, substitute the equivalent DOS command when necessary. For example, use *find* instead of *grep*.

Follow these steps:

1. For DOS prompt, select Start, Programs, Command Prompt.
   The DOS prompt appears, ready to accept CLI commands.
2. Start the SpectroSERVER to which you want to connect.
3. Navigate to the vnmsh directory in the DX NetOps Spectrum installation directory:
   ```
   $ cd <$SPECROOT>/vnmsh
   ```
4. Open the connection:
   ```
   $ connect
   ```
   You are connected to the CLI session.

Start a CLI Session on Windows Using Bash Prompt

On the Windows platform, you can also start a CLI session from a bash shell prompt.

> **NOTE**
> You can use a script to pack up the CLI program so that it can be sent to another server. For more information, see the Distributed SpectroSERVER Administration section.

Follow these steps:

1. Click Start, Programs, and Command Prompt.
   The DOS prompt appears.
2. From the DOS prompt, type **bash**.
3. Click Start, Run, and type **bash -login**.
   You can start a CLI session from a bash shell prompt.
4. Start the SpectroSERVER to which you want to connect.

5. Navigate to the vnmsh directory in the DX NetOps Spectrum installation directory:
   ```
   $ cd <$SPECROOT>/vnmsh
   ```
6. Open the connection:
   ```
   $ connect
   ```
   You are connected to the CLI session.

Example Usage

The examples in this section demonstrate how to use CLI commands for common tasks in DX NetOps Spectrum.

Create a User Model

A User model gives a user access to DX NetOps Spectrum. Users are identified by login IDs.

> **NOTE**
> Before you start a CLI session, verify that the User Model is created and the SpectroSERVER to connect is started.

Follow these steps:

1. Connect to the SpectroSERVER.
   ```
   $ cd <$SPECROOT>/vnmsh
   $ ./connect
   ```
   You are connected to the SpectroSERVER.

   > **NOTE**
   > If you have trouble connecting, verify for error messages. For more information, see Error Messages.
2. Determine the model type handle for the model type you want to create using the show command. In this case, it is a model of type User. Enter this command:
   ```
   $ ./show types | grep User
   ```

   > **NOTE**
   > The “./” is important. Some UNIX systems use the show command for reading email. If the “.” is not the first path in the user's environment, then "./" are required.

   A list of model types that include the string 'User' appears with the User model type listed first.
   ```
   Handle     Name          Flags
   0x10004    User          V,I,D
   0x1040a    UserGroup     V,I,D
   0x1040f    DefUserGroup  V,I,N,U,R
   0xaa000d   GenSwUserPort V,I,D
   0xf000d    ForeUserAgen  V,I,D
   0xaf000c   ForeUserApp   V,I,D
   ```
3. List the attributes using the show command for the User model type and determine the attribute ID for the model name attribute. You need this attribute ID to create the model. Enter this command:
   ```
   $ ./show attributes mth=0x10004 | grep -i name
   ```
   A list of User model type attributes including the model name attribute appears.
   ```
   Id        Name                  Type          Flags
   0x10000   Modeltype_Name        Text String   R,S,M
   0x1006e   Model_Name            Text String   R,W,G,O,M,D
   0x10074   User_Full_Name        Text String   R,W,O,D
   0x1155f   gib_mtype_nameText    String        R,W,S,D
   0x11560   gib_mtype_name_menu   Text String   R,W,S,D
   0x11561   gib_model_name        Text String   R,W,D
   ```

```
0x11563   gib_model_name_menu   Text String   R,W,D
0x1197d   WatchNames            Tagged Octet  R,W,D
```

4. Create the model using the create command with model type handle, the attribute ID for the model name, and the value (the login ID name) for the user. In this example, the user login ID is j_doe. Enter this command:

   ```
   $ ./create model mth=0x10004 attr=0x1006e,val=j_doe
   ```

   A system message resembling the following command confirms that the model is created:

   ```
   created model handle = 0xbe0001b
   ```

   NOTE
   All handles and IDs used in these examples are fictitious. The model handle for the model that you created is different; model handles are created by the system.

Modify a Model Attribute

This section provides an example to change the value of a model attribute using CLI commands. In particular, this example demonstrates how to change the community string attribute value for the model (j_doe) created in a User Model. For more information, see Create a User Model.

Follow these steps:

1. Determine the j_doe model handle, and then set j_doe as the current model:
   a. $ ./show models | grep j_doe
      The following information about the j_doe model appears:

      ```
      0xbe0001b        j_doe(Active)        0x10004        User
      ```

   b. $ ./current mh=0xbe0001b
      The system confirms that j_doe is the current model:

      ```
      current model is 0xbe0001b
      current landscape is 0xbe00000
      ```

2. Determine the ID for the community string attribute.

   NOTE
   For the sake of brevity, this step shows a known portion (community string) of the attribute name as an argument to the grep command. If you do not know the name of the attribute, you can show and scan all attributes for the model to determine the correct attribute name and its attribute ID.

3. Enter this command:

   ```
   $ ./show attributes | grep -i community_string
   ```

   The attribute ID, the attribute name, and the community string value appear:

   ```
   0x1007a        User_Community_String        ADMIN,0
   ```

   DX NetOps Spectrum assigns a default value of ADMIN,0 to all user models when they are created. ADMIN,0 confers full administrative privileges in DX NetOps Spectrum to user models.

4. Change the administrative permission level from ADMIN,0 to example permission level ADMIN,5 (read-only) for the j_doe model using the update command. Enter this command:

   ```
   $ ./update attr=0x1007a,val=Subnet3,5
   ```

   An entry showing the change in the attribute value is returned:

   ```
   Id        Name                   Iid    Value
   0x1007a   User_Community_String         ADMIN,5
   ```

   The Iid attribute has no value here because it applies only to list attributes. For more information, see the *DX NetOps Spectrum* Administration section.

Create and Modify a Model in One Step

This section provides an example of how to create a model and replace a default attribute value with another value in a single command string. You can only execute a complex command of the type shown in this section if you know the values of the relevant model identifiers that are provided for the command before you attempt to execute.

The following example uses the parameter values introduced in Creating a User Model and Modifying a Model Attribute:

```
$ ./create model mth=0x10004 attr=0x1006e,val=j_doe attr=0x1007a,val=ADMIN,5
```

Sample CLI Script File - Create a New User

> **NOTE**
> You can execute shell scripts that incorporate CLI commands from the bash prompt in the Windows platform simply as you execute the command from the shell command prompt on UNIX.

This following example demonstrates how a script can be used to create a DX NetOps Spectrum user model.

```
#
#  Check to see if CLIPATH is set.  If it is not then we will have to create it.
#
#  Setup a variable to point to the /install_area/vnmsh directory so we can
#  find the commands we need.
#
if [ -z "$CLIPATH" ]
then
    CLIPATH=/usr/data/spectrum/7.0/vnmsh
    export CLIPATH
fi
#
#  Test to make sure the CLIPATH points to a valid directory
#
if [ ! -d $CLIPATH ]
then
       echo "ERROR: could not find $CLIPATH"
       echo "Please find the correct path to the vnmsh directory and set"
       echo "the CLIPATH environment variable to it."
       exit 0
fi
#
#  Now check to see how many command line arguments there are.  If there are
#  none, then echo a usage message.  If there is one, that is all we really
#  need to create a new user...  If there is a second argument then we can
#  set the Community_String at the same time.
#
#  This setup is only for creating a user on the local system or what the
#  .vnmshrc file points to for the vnm_hostname.  A third field could be
#  added that accepts the vnm_hostname to connect to.
#
#  Optionally, the getopts shell command can be used to parse "switches" to
#  the script:  -n for name, -c for community string and -v for vnm_hostname.
#
#  (NOTE:  getopts should be located in /usr/bin/getopts if the script is
#   done in bourne shell (sh).  k-shell has a built in getopts function)
#
```

```
if [ $# -eq 0 ]
then
       echo "Usage:  $0 username [Community_String]"
       exit 1
elif [ $# -eq 1 ]
then
       command="attr=0x1006e,val=$1"
       flag=0
elif [ $# -eq 2 ]
then
       command="attr=0x1006e,val=$1 attr=0x1007a,val=$2"
       flag=1
fi

#
#  Okay, we should be all set now to go ahead and create the new user.
#  The first thing we have to do is connect.
#
$CLIPATH/connect
#
#  Now let's check the exit status of the connection to see if we got in...
#
if [ $? -ne 0 ]
then
       echo "ERROR:  could not connect to <ss>.  $0 exiting"
       exit 0
fi
#
#  Okay if we made it this far then we have a connection.  Let's try the
#  create command.
#
$CLIPATH/create model mth=0x10004 $command
#
#  Now we check the exit status again and see if we actually created a model.
#
if [ $? -ne 0 ]
then
       echo "ERROR:  could not create a new user.  $0 exiting"
       exit 0

else
       echo -n "New user $1 created"
       if [ $flag -eq 1 ]
then
       echo " Community_String was set to $2"
fi
       echo "Successfully created new model... exiting."
fi
$CLIPATH/disconnect
exit 1
```

Event Report Generation

The CLI keeps a list of the 2000 most current events that occur on a landscape. However, if many events occur on a landscape, the most recent events are approximately one hour old.

You can set the SPECROOT environment variable when using the -x option with the show events command. The following command is an example of to run event reports using CLI:

```
$ ./show events | more
$ SPECROOT=/home/spectrum; export SPECROOT
$ ./show events -x > event_rpt
```

Model Switch

The jump and setjump commands are useful in scripts where you can move back and forth between different models. The setjump command lets you assign a text string to represent a model handle and its corresponding landscape handle. Then you can use the jump command with that text string to retrieve that information as the current model handle. For example:

- $ ./current mh=0xb6000f8
  ```
  current model is 0xb6000f8
  current landscape is 0xb600000
  ```
- $ ./setjump emme
  ```
  model 0xb6000f8 and landscape 0xb600000 stored under emme
  ```
- $ ./jump emme
  ```
  current model is 0xb6000f8
  current landscape is 0xb600000
  ```

Create a Troubleshooter Model

You can create and associate Troubleshooter models with User models using the CLI. Once created and associated, these troubleshooters can be assigned alarms and receive email notification that they must investigate and resolve the alarms.

The following procedure describes how to create a TroubleShooter model and associate it with a User model. The User model that is created in Create a User Model is used as an example.

Follow these steps:

1. Navigate to the <*$SPECROOT*>/vnmsh directory.
2. Connect to the SpectroSERVER by typing the following command at a command prompt (example from a bash shell with a $ prompt):
   ```
   $ ./connect
   ```
3. Determine the TroubleShooter model type. Enter this command:
   ```
   $ ./show types | grep -i trouble
   ```
   The TroubleShooter model type entry is returned.
   ```
   0x10372        TroubleShooter       V,I
   ```
4. Determine the TroubleShooter model type EmailAddress attribute ID. Enter this command:
   ```
   $ ./show attributes mth=0x10372 | grep -i email
   ```
   The EmailAddress entry appears:
   ```
   0x11d24        EmailAddress         TextString    R,W,D
   ```
5. Create a TroubleShooter model using the CLI create command:
   ```
   $ ./create model mth=0x10372
   ```

```
attr=0x1006e,val=j_doe_fixit
attr=0x11d24,val=j_doe@aprisma.com
```

A system message resembling the following command confirms that the model is created:

```
$ created model handle = 0xbe0001c
```

NOTE
All handles and IDs used in examples are fictitious. The model handle for the model you created are different. It is whatever your system creates for it.

6. Create the association between the j_doe User model (mh=0xbe0001b) and the j_doe_fixit TroubleShooter model (mh=0xbe0001c) using the CLI create command:

```
$ ./create association rel=Is_Assigned lmh=0xbe0001b rmh=0xbe0001c
```

A system message similar to the following command confirms that the association was created:

```
$ create association successful
```

Assign an Alarm to a Troubleshooter

This section describes how to list alarms and assign an alarm to a troubleshooter using CLI commands.

Follow these steps:

1. List alarms using the show command.
   This step shows how to find only those alarms with an alarm_severity of MAJOR.

```
$ ./show alarms | grep MAJOR
```

A list of MAJOR alarms appears. For example:

```
7509   09/27/2000   14:46:44   0xd80008   0xa6000df   duncan    9E133_36   MAJOR   No
7645   09/27/2000   14:47:16   0xd80008   0xa60025e   infinity  9H422_12   MAJOR   No
7518   09/27/2000   14:47:01   0xd80008   0xa6000eb   rugone    9E132_15   MAJOR   No
7979   09/27/2000   14:53:12   0xf40002   0xa600161   FDDI2     FddiMAC    MAJOR   No
8018   09/27/2000   14:53:13   0xf40002   0xa6003da   FDDI FNB  FddiMAC    MAJOR   No
7512   09/27/2000   14:46:47   0xd80008   0xa6000af   ruthere   9A426_02   MAJOR   No
```

1. Select an alarm to which you want to assign a troubleshooter. In this example, alarm ID 7512 for the 9A426-02 device is selected.
2. Select a troubleshooter to assign to the alarm. In this example, the j_doe_fixit TroubleShooter model that was created in Create a Troubleshooter Model is selected.

NOTE
Use the TroubleShooter model handle, 0xa600722, rather than the TroubleShooter model name, j_doe_fixit, to specify the troubleshooter in the update command in the next step.

3. Assign the alarm to the troubleshooter using the update command:

```
$./update alarm aid=7512 assign=0xa600722
```

A system message similar to the following example confirms that the troubleshooter was assigned to the alarm:

```
$ update: successful
```

The person who is represented by the j_doe_fixit model has now been assigned to the alarm. This person receives an email notification of the alarm assignment.

Create a Global Collection

You can create a global collection and can set the search criteria in a CLI session using GUID. A unique identifier (GUID) is a key attribute to create global collection. The GUID is required for global collection to function properly. You can obtain a GUID through an action to the VNM model.

NOTE
A global collection without a GUID in the CLI is invalid. When a global collection is created using OneClick, a GUID is automatically created. For more information, see the Modeling and Managing Your IT Infrastructure section.

Follow these steps:

1. Enter the following command:
   ```
   update action=(Action to get a unique identifier) 0x10474 mh= (VNM Model Handle)
   ```
   A GUID is created.

   NOTE
   The action to get a new GUID is 0x10474, which is the same as the global collection model type.
2. Enter the following command to create the global collection using GUID:
   ```
   create model mth=(Model Type for global collection) 0x10474 attr=(GUID) 0x12e56, val=(Previous value you
    received) 4a85b9af-0d52-1000-017f-0013727f8c0a
   ```
   The Global Collection is created and appears in the Navigation pane under global collections.

Example: Create a global collection with or without XML string

Enter the following command to create a global collection with or without XML string:

```
update action=(Action to get GUID)0x10474 mh=(Landscape)
Printed:
update action: successful
Response has 1 attributes:
 0) Attribute 0x0 text: EXAMPLE GUID(4a85b9af-0d52-1000-017f-0013727f8c0a)
create model mth=(Model Type for global collection)0x10474
attr=(GUID)0x12e56,val=(Previous value you received)4a85b9af-0d52-1000-017f-0013727f8c0a
attr=(dynamicCriteriaXML)0x12a6a,val=(XMLString)'<search-criteria><filtered models><equals-ignore-case><model-
name>sometext</model-name></equals-ignore-case></filtered-models></search-criteria>'
Printed:
created model handle = New model handle(0x78101069)
```

NOTE
You can specify the dynamicCriteriaXML (0x12a6a) attribute with the create command or you can update the model later.

Suppress Headers in CLI Output

To suppress the headers in CLI output, you can create a file that includes the functions provided in the following section and can refer this file at the top of each script.

The functions in the following procedure call CLI commands and strip the header information from the output of the commands.

Follow these steps:

1. Create a file named StripHeaders in your scripts directory.
2. Include the following functions in the StripHeaders file:
   ```
   tcreate() # only needed for the createalarm
       { # and create event commands
       $CLIPATH/create $@ | tail +2
       }
   tseek()
       {
   ```

```
        $CLIPATH/seek $@ | tail +2
    }
tshow()
    {
    $CLIPATH/show $@ | tail +2
    }
tupdate()
    {
    $CLIPATH/update $@ | tail +2
    }
```

3. Include the name StripHeaders at the top of your CLI script as follows:
   ```
   . StripHeaders
   ```
4. Call the tcreate(), tseek(), tshow(), and tupdate() functions instead of the corresponding CLI command whenever you want to strip the headers from CLI output.
   For example, the following line generates the output of the show models command without the CLI header information:
   ```
   tshow models
   ```

Command Descriptions

This section provides descriptions of CLI commands and output:

Command Descriptions Overview

You can make changes to the DX NetOps Spectrum knowledge base without the safeguards that are available in DX NetOps Spectrum using the CLI. A system crash or database corruption can result if you specify incorrect information. Therefore, proceed with caution when you use the create, destroy, or update commands.

> **NOTE**
> Use the CLI command parameters for creating and managing response time tests with CLI.

For more information, see the Service Performance Manager section.

ack alarm - Acknowledges Alarm

The ack alarm command acknowledges the alarm specified by alarm_id in the landscape that is specified by landscape_handle. If landscape_handle is not specified, the command acknowledges the alarm that is specified by alarm_id in the current landscape.

Acknowledging one alarm for a model means that you acknowledge only that alarm and no other alarm for that model.

The command has the following format:

```
ack alarm aid=<alarm_id> [lh=<landscape_handle>]
```

If ack alarm is entered with a valid alarm_id and a valid landscape_handle, the following message is displayed:

```
ack alarm: successful
```

Example: ack alarm

```
$ ack alarm aid=42 lh=0x400000
ack alarm: successful
```

Start, Re-start or Connect - Connects to SpectroSERVER

The start, restart or connect command connects the user of the DX NetOps Spectrum Command Line Interface to the SpectroSERVER running on host system, *hostname.* This command also sets the landscape that is specified by landscape_handle to be the current landscape. If the CLI Local Server is not already running, the connect command starts it.

The command has the following format:

```
connect [<hostname>] [lh=<landscape_handle>][vnmsocket=<vnmsocket>]
```

- **hostname**
  (Optional) If hostname is not specified, the command connects the user to the host specified in the CLI resource file .vnmshrc.

  NOTE
  DX NetOps Spectrum Command Line Interface does not support localhost or the 127.0.0.1 option. To connect to localhost, you can specify the actual hostname or do not specify any parameter.
- **landscape_handle**
  (Optional) If landscape_handle is not specified, the command sets the current landscape to the landscape of the host name specified.
- **vnmsocket**
  (Optional) If vnmsocket is not specified, the command connects to the SpectroSERVER using the socket specified in the .vnmshrc file. You can use vnmsocket to connect to another SpectroSERVER on a different port connection that is defined by vnmsocket.

On Unix, error messages that are reported by the CLI Local Server are displayed in the console window. On Windows, these errors are displayed in the user bash shell window.

Example: connect

```
#! /usr/bin/sh
# A sample script to get alarms of a specific
# severity and set the CLISESSID

if [$# !=1]
then
   echo "Usage: $0 <alarm severity>"
   exit 0
fi

CLISESSID=$$

$SPECROOT/vnmsh/connect
$SPECROOT/vnmsh/show alarms | grep -i $1
$SPECROOT/vnmsh/disconnect

exit 0
```

If the command is successful, the following message is displayed:

```
connect: successful hostname
current landscape is <landscape_handle>
```

Hostname is the user-entered SpectroSERVER host or the host that is specified in the .vnmshrc file. landscape_handle is the user-entered landscape or the landscape for the host.

Considerations when Using connect Command

The following are important considerations when using the connect command:

- The user on a terminal must use the connect command to initiate communications. The same user must use the disconnect command to terminate communication with the SpectroSERVER.
- Once the first user has entered the connect command, the CLI Local Server is connected to the SpectroSERVER.
- Other CLI users using the same CLI Local Server can connect only to those SpectroSERVERs that are in the landscape map of the initial SpectroSERVER. Once all users have disconnected, use the connect command to connect to SpectroSERVERs in a different landscape map.
- To successfully connect to the SpectroSERVER, the first user of the connect command must be defined as a user in the DX NetOps Spectrum database of the original SpectroSERVER.
- Windows users running CLI in the bash shell must also define CLISESSID.
- The terminal device for a particular user is determined using the ttyslot(3V) function.
- Cron scripts are not attached to a ttyslot. As a result, the ttyslot function returns 0 for all cron scripts. That is, two CLI scripts running as cron scripts at the same time appear as one CLI user to the CLI Local Server, which leads to unpredictable results. Therefore, you must insert a line at the top of the script to export the environment variable CLISESSID. Set CLISESSID to a unique numeric value. CLI can now distinguish between the different cron scripts. The following example defines a unique CLI session ID within a script:
  ```
  CLISESSID=$$; export CLISESSID
  ```
- This example sets the CLISESSID as the process ID of the shell running the script. CLI uses CLISESSID to identify a user when the ttyslot function returns zero. Set CLISESSID once for each CLI session. If a CLI script that is running as a cron script calls other CLI scripts, only the top-level script will set the CLISESSID environment variable. The other CLI scripts run under the same process ID unless you invoke a new shell (#!/bin/sh) at the top of the script. To invoke a new shell in the other scripts, export the CLISESSID and then connect and disconnect again.
- In some environments or configurations, even when the command is entered from a command line, the ttyslot function may return zero. In such a case, the connect command returns the following error:
  ```
  connect: variable CLISESSID not set
  ```
  In this situation, set CLISESSID either from the command line or from .cshrc or another startup file.
- The CLI uses the user name and terminal device to identify each CLI user. A user running multiple scripts from a terminal device at one time will appear to CLI as the same user. The CLI can give unpredictable results if a script is running in the background and another script is running in the foreground, or multiple scripts are running in the background.
  For example, Script A1 sets the current model to be Model A. Script B1, which is run by the same user from the same terminal device, sets the current model to be Model B. If Script A1 performs an update command on Model A, the update command is also performed on Model B of Script B1.
  Run only one CLI session from a particular terminal device at one time. To run multiple CLI sessions at once, run them from a separate terminal device, or run them using the at(1) or batch(1) commands with the CLISESSID environment variable set to a unique value for each.

create - Create Object

Use the create command to create an object.

> **NOTE**
> For information about how to create a model in a secure domain, run ./create to display a usage statement.

The command has the following format:

```
create  model ip=<IP Address | Low_IP-High_IP> [sec_dom=Secure_Domain_Address][comm=Community_Name]
 [to=Time_Out] [tc=Try_Count] [lh=landscape_handle] |
create  model mth=model_type_handle [attr=attribute_id,val=value ...] [lh=landscape_handle] |
```

```
create  association rel=relation lmh=left_model_handle rmh=right_model_handle
create  alarm [-nr] sev=alarm_severity cause=probable_cause_id [mh=model_handle] |
create  event type=event_type text=event_text [mh=model_handle|lh=landscape_handle]
```

create alarm

The command *create alarm* creates an alarm with severity alarm_severity and cause probable_cause_id for the model with model_handle. Valid alarm severity options are: CRITICAL, MAJOR, MINOR, OK, MAINTENANCE, SUPPRESSED, or INITIAL. By default, the new alarm replaces an existing alarm.

If create alarm is entered with a valid alarm_severity, a valid probable_cause_id, and a valid model_handle, the created entry in the alarm table is displayed. The create time is displayed in hh:mm:ss format.

Example: create

```
$ create alarm sev=CRITICAL cause=0x10308 mh=0x400134
ID     Date          Time        PCauseID    MHandle     MName    MTypeName     Severity    Ack
984    05/11/2000    12:33:27    0x10308     0x400134    12.84    Bdg_CSI_CN    CRITICAL    No
```

create association

The command *create association* creates an instance of the relation (an association) between the model with left_model_handle and the model with right_model_handle.

If create association is entered with a valid relation between a valid left_model_handle and right_model_handle, the following message is displayed:

```
create association: successful
```

Example: create association

```
$ create association rel=Collects lmh=0x400009 rmh=0x400134
create association: successful
```

create event

The create event command, creates an event with type event_type and text event_text for the model that is specified by model_handle. If a landscape_handle is specified, the event is created for the user model that created the event.

> **NOTE**
> In previous versions of the CLI, the event was created for the landscape model.

If model_handle or landscape_handle is not specified, the event is created for the user model that created the event. Or the event is created for the current model if one has been specified. Some events in DX NetOps Spectrum lack an associated model. For example, when an application connects to the SpectroSERVER, no model is associated with the event.

If create event is entered with a valid event_type, valid event_text, and a valid model_handle or landscape_handle (if present), the entry appears in the event table. The create time is displayed in hh:mm:ss format.

The event_type command (also named an event code in DX NetOps Spectrum) is a 4-byte hexadecimal number. The two most significant bytes specify the developer ID for the event (0001 for DX NetOps Spectrum-generated event codes), and the two least significant bytes are a unique event identifier. Not all event types include user-entered text. Examples of such event types are those that include the variable {S 0} in their event format files. For those event types that do not include user-entered text, the event_text parameter is ignored but must still be present on the command line.

For more information, see the Certifications section.

Example: create event

```
$ create event type=0x1061a text="fan down" mh=0x40013
Date          Time        Type       MHandle     MName    MTypeName
05/11/2000    12:39:42    0x1061a    0x400134    12.84    Bdg_CSI_CNB20
```

create model

You can specify create model with an IP address or with a model type handle. In either case, the system creates the model in the landscape that is specified by landscape_handle. If landscape_handle is not specified, the command creates the model in the current landscape.

NOTE
The model_name attribute is required only when creating a User model.

- If you specify create model with an IP address, the system finds the object at the specified ip_address and creates a model for it. The model has all of the properties of that object including any associated children. For example, if the object is a hub, the create model command creates a model of a hub with all of its ports.
- You can specify an IPv4 address or an IPv6 address. IPv6 ranges are not supported and this command does not support the setting of attribute IDs.
- To create several models at once, you can define a range of IP addresses with the create model command. Specify the Low_IP and High_IP parameters, separated by “-”. If the Community_Name is not specified, the newly created model is of type "Pingable". If the Community_Name is specified, the device is modeled to the appropriate model type. The Try_Count and Time_Out options are similar to options in the OneClick 'Create Model by IP' dialog.
- If you specify the create model command with a model type handle, the system creates a model of type model_type_handle. You can then set the value of one or more attributes for the created model.
- When you specify the create model command with a model type handle, you can also specify multiple attributes in that one command. Specify multiple 'attribute_id, value' pairs, separating each pair from adjacent pairs by a space.
- The attribute values that the user specifies when creating a model of a particular model type while using OneClick should be specified in the create model command. Otherwise, Inference Handler errors can occur within a SpectroSERVER when the model is created. For example, when creating a Hub_CSI_IRM3 model using OneClick, a window is displayed in which you can enter values for Model Name, Network Address, Community String. Specify values for these attributes when using the create model command to create a model of the same type using the CLI.
- If create model is specified with a valid model_type_handle and valid attribute_id, value pairs (if present), the created model handle is displayed.
- If create model is specified with a valid ip_address, the created model handle is displayed.

Example: create model

```
$ create model mth=0x102d attr=0x12d7f,val=132.177.12.84 attr=0x1006e,val=12.84lh=0x400000
created model handle = 0x400134
$ create model ip=206.61.231.1-206.61.231.5
Creating model for IP=206.61.231.1
created model handle =  0x9a00259
Creating model for IP=206.61.231.2
create model: DCM device unreachable
Creating model for IP=206.61.231.3
create model: DCM device unreachable
Creating model for IP=206.61.231.4
create model: DCM device unreachable
Creating model for IP=206.61.231.5
created model handle =  0x9a0025a
```

NOTE
By default, the create command displays a maximum of 16 characters for the model name. However, with the environment variable, CLIMNAMEWIDTH, you can specify a different number of characters (up to 1024) to be displayed for model names.

current - Sets Model or Landscape

The current command sets the model that is specified by model_handle to be the current model. Or this sommand sets the landscape that is specified by landscape_handle to be the current landscape. If the model_handle and the landscape_handle are not specified, current displays the current model handle and the current landscape handle.

When the user sets a current model, the CLI sets the current landscape to the landscape that contains the model. When a user sets the current landscape, the CLI sets the current model as undefined.

Separate current model and current landscape values are maintained for each session that is connected to the CLI Local Server.

The current command retains state information, the current model and the current landscape, for example, only for the session that named it.

This command has the following format:

```
current [mh=<model_handle>|lh=<landscape_handle>]
```

- If a valid model_handle is specified as input, the following message is displayed:
  ```
  current model is <model_handle>
  current landscape is <current_landscape_handle>
  ```
- If a valid landscape_handle is specified as input, the following message is displayed:
  ```
  current model is undefined
  current landscape is <landscape_handle>
  ```
- If model_handle and landscape_handle are not specified, the following message is displayed:
  ```
  current model is <current_model_handle>
  current landscape is <current_landscape_handle>
  ```
- If model_handle and landscape_handle are not specified and current model is not defined, the following message is displayed:
  ```
  current model is undefined
  current landscape is <current_landscape_handle>
  ```

Examples: current

```
$ current mh=0x400142
current model is 0x400142
current landscape is 0x400000
$ current lh=0x500000
current model is undefined
current landscape is 0x500000
$ current
current model is undefined
current landscape is 0x500000
```

NOTE
The current landscape always contains a value because it is set by the connect command.

destroy - Destroys Object

Use the destroy command to destroy an object. This command has the following format:

```
destroy model [-n] mh=model_handle |
destroy association [-n] rel=relation lmh=left_model_handle rmh=right_model_handle|
destroy alarm [-n] aid=alarm_id [lh=landscape_handle]
```

- **-n**
  If the -n (no prompt) option is specified with the destroy command, the system does not prompt for confirmation. This option is useful in CLI scripts.
  Unless the -n option is specified, one of the following messages is always displayed:
  ```
  destroy model: are you sure?
  destroy association: are you sure?
  destroy alarm: are you sure?
  ```
  Valid responses are y, yes, Y, Yes, n, no, N, and No.

destroy alarm

Destroys the alarm specified by alarm_id in the landscape that is specified by landscape_handle. Unless the -n option is specified, destroy alarm prompts you for confirmation before destroying the alarm. If the landscape_handle is not specified, the command destroys the alarm that is specified by alarm_id in the current landscape. Use the show alarms command to determine the alarm_ids for a model.

If the destroy alarm command is entered with a valid alarm_id and a valid landscape_handle, the following message is displayed:

```
destroy alarm: successful
```

Examples: destroy alarm

```
$ destroy alarm aid=300
destroy alarm: are you sure? y
destroy alarm: successful
```

destroy association

Destroys the association (instance of the relation) between the model with left_model_handle and the model with right_model_handle. Unless the -n option is specified, destroy association prompts you for confirmation before destroying the association.

If destroy association is entered with a valid relation between a valid left_model_handle and right_model_handle, the following message is displayed:

```
destroy association: successful
```

Example: destroy association

```
$ destroy association rel=Lost_and_Found lmh=0x400001 rmh=0x40h0142
destroy association: are you sure? y
destroy association: successful
```

destroy model

Destroys the model with the specified model_handle. Unless the n option is specified, destroy model prompts you for confirmation before destroying the model.

If destroy model is entered with a valid model_handle, the following message is displayed:

```
destroy model: successful
```

Example: destroy model

```
$ destroy model mh=0xa600715
Following model will be destroyed:
Model_Handle      ->     0xa600715
Model_Type_Handle ->     0x10004
Model_Name        ->     garciaparra
Model_Type_Name   ->     User
destroy model: are you sure? y
destroy model: successful
```

disconnect - Disconnects from SpectroSERVER

Use the disconnect command to disconnect the CLI user from the currently connected SpectroSERVER.

This command has the following format:

```
disconnect
```

If the command is successful, the following message is displayed, where host name is the name of the SpectroSERVER host to which the user was connected:

```
disconnect: successful from <hostname> or <IP address> - connected for xx hours, yy minutes
```

jump - Jumps to Saved Model or Landscape

The jump command jumps to the previously saved model and landscape. The jump command sets the current model and the current landscape to be the model and landscape that were saved under the label text_string by the setjump command. If text_string is not specified, a list of text_strings that were given in previous setjump commands is displayed.

The command has the following format:

```
jump [<text_string>]
```

- If jump is entered with a valid text_string that has been previously defined, the new current model and the current landscape are displayed:
  ```
  current model is <current_model_handle>
  current landscape is <current_landscape_handle>
  ```
- If jump is entered without a text_string, a list of the currently defined text_strings is displayed. For example:
  ```
  text_string1
  text_string2
  --
  ```
- If jump is entered and the new current model is undefined, the following message is displayed:
  ```
  current model is undefined
  current landscape is <current_landscape_handle>
  ```

Example: jump

```
$ jump tutorial
current model is 0x400142
current landscape is 0x400000
```

seek - Locates a Model

Use the seek command to locate a model. The seek command finds the model(s) in the landscape that is specified by landscape_handle that possess the specified value for the attribute that is specified by attribute_id. If landscape_handle is not specified, the command finds the model(s) in the current landscape that possess a value for the attribute with the specified attribute_id. You can also use a wildcard (*) with seek to find instances of models that contain a specified substring. If you enter a null value, you can find all models that have no name (for example, attr=0x1006e).

You cannot search for a one-character attribute value using the seek command. Attempting such a search returns an error.

The command has the following format:

```
seek [-i] [-s]  attr=attribute_id,val=value [lh=landscape_handle]
```

> **NOTE**
> The options can be used in any order, for example, -i -s, or -s -i.

- **-i**
  If the -i (ignore case sensitivity) option is specified with the seek command, then the model information that is specified with the val parameter is returned without regard to case.
- **-s**
  If the -s (substrings allowed) option is specified with the seek command, the model information that is specified with the val parameter is returned with substrings, if applicable.
  If seek is entered with a valid attribute_id and a valid value, all matching models are displayed in the following format:

  ```
  MHandle      MName   MTypeHnd         MTypeName
  modelhandle  name    modeltypehandle  name
  ```

  If no matching models are found, the following message is displayed:

  ```
  seek: no models found
  ```

  > **NOTE**
  > By default, the seek command displays a maximum of 16 characters for the model name. However, with the environment variable CLIMNAMEWIDTH, you can specify a different number of characters (up to 1024) to be displayed for model names.

Examples: seek

```
$ seek attr=0x1006e,val=<sp>
MHandle       MName      MTypeHnd   MTypeName
0xb100018     spectrum    0x1004     User
0xb10008d     spectrum    0x820000   ScmConfig
$ seek attr=0x1006e,val=<sp>
MHandle       MName      MTypeHnd   MTypeName
0xb100018     spectrum    0x820000   ScmConfig
$ seek attr=0x1006e,val=SPE
seek: no models found
$ seek attr=0x1006e,val=spe lh=0xb100000
seek: no models found
$ seek -i attr=0x1006e,val=<sp>
MHandle       MName      MTypeHnd   MTypeName
0xb10018      spectrum    0x10004    User
0xb1008c      spectrum    0x820000   ScmConfig
0xb1008d      spectrum    0x820000   ScmConfig
$ seek -i -s attr=0x1006e,val=<sp>
MHandle       MName      MTypeHnd   MTypeName
0xb10018      spectrum    0x10004    User
```

```
0xb10089      spectrum    0x820000   ScmConfig
0xb1008c      spectrum    0x820000   ScmConfig
0xb1008d      spectrum    0x820000   ScmConfig
$ seek -i -s attr=0x1006e,val=<sp> lh=0xb100000
MHandle       MName      MTypeHnd   MTypeName
0xb10018      spectrum    0x10004    User
0xb10089      spectrum    0x820000   ScmConfig
0xb1008c      spectrum    0x820000   ScmConfig
0xb1008d      spectrum    0x820000   ScmConfig
$ seek -s attr=0x1006e,val=<sp>
MHandle       MName      MTypeHnd   MTypeName
0xb10008c     spectrum    0x820000   ScmConfig
$ seek attr=0x110df,val=0.0.C.18
seek: no models found
$ seek -s attr=0x110df,val=0.0.C.18
MHandle       MName        MTypeHnd      MTypeName
0xb100070     frog10       0x210022      Rtr_CiscoIGS
0xb100072     frog10_1     0x220011      Gen_IF_Port
0xb10005b     cisco rtr    0x210022      Rtr_CiscoIGS
0xb100070     frog10_2     0x220011      Gen_IF_Port
0xb100070     cisco rtr_1  0x220011      Gen_IF_Port
0xb100070     cisco rtr_2  0x220011      Gen_IF_Port
$ seek attr=0x1006e,val=spe*
MHandle       MName           MTypeHnd    MTypeName
0xb10018      spectrum         0x10004     User
0xb10089      spectrum         0x820000    ScmConfig
0xb1008d      spectrum         0x820000    ScmConfig
$ seek attr=0x1006e,val=
MHandle       MName        MTypeHnd      MTypeName
0xd00258      0x102c8                    Physical_Addr
0xd002f8      0x102c8                    Physical_Addr
0xd00368      0x820000                   ScmConfig
0xd00259      0x102c8                    Physical_Addr

```

setjump - Saves Model and Landscape

The setjump command saves the current model handle and current landscape handle under the label text_string. The user can later use the jump command with text_string to set the current model handle and the current landscape handle back to the one stored under text_string. The user is prompted for verification if the same text_string is used in two setjump commands.

Separate setjump values are maintained for each session that is connected to the CLI Local Server. The setjump command retains information, that is, the session-assigned setjump text strings, only for the session that named it.

The command has the following format:

```
setjump [-n] <text_string>
```

- **-n**
  If the -n (no prompt) option is specified with the setjump command, then the system does not prompt if text_string has been used before.
- If setjump is entered with a new <text_string> and a current model exists, the following message is displayed:
  ```
  model <current_model_handle> and landscape
  <current_landscape_handle> stored under <text_string>
  ```
  where <current_model_handle> is the handle of the current model and <current_landscape_handle> is the handle of the current landscape.
- If setjump is entered with a new <text_string> and a current model does not exist, the following message is displayed:
  ```
  model undefined and landscape <current_landscape_handle>
  stored under <text_string>
  ```
- If setjump is entered with a text_string that has already been defined in a previous setjump command, the following message is displayed:
  ```
  setjump model: <text_string> already used. Overwrite?
  ```
  Valid responses are y, yes, Y, Yes, n, no, N, and No.

Example: setjump

```
$ current mh=0x400142
current model is 0x400142
current landscape is 0x400000
$ setjump -n tutorial
model 0x400142 and landscape 0x400000 stored under tutorial
```

show - Displays Object

To display objects, use the show command.

The command has the following format:

```
show models [mhr=low_model_handle-high_model_handle]
    [mth=model_type_handle][mname=model_name][lh=landscape_handle] |
devices [lh=landscape_handle]|
landscapes |
types [mthr=low_mth-high_mth] [mtname=mt_name]
         [flags=V|I|D|N|U|R] [lh=landscape_handle] |
relations [lh=landscape_handle] |
associations [mh=model_handle] |
parents [rel=relation] [mh=model_handle] |
```

```
children [rel=relation] [mh=model_handle] | attributes [-e]
         [attr=attribute_id[,iid=instance_id][,next]...|
         [attrr=low_attr-high_attr] [attrname=attr_name]]
         [mh=model_handle] |
attributes [-c] [-e]
         [attr=attribute_id[,iid=instance_id][,next]...|
         [attrr=low_attr-high_attr] [attrname=attr_name]]
         [mh=model_handle]|
attributes mth=model_type_handle [attrr=low_attr-high_attr]
         [attrname=attr_name]        [flags=E|R|W|S|T|G|O|M|D|P|L|V]
         [lh=landscape_handle] |
alarms [-a] [-x] [-t] [-s] [-d]
        [mh=model_handle|lh=landscape_handle] |
events [-x] [ -a | -n no_events ]
         [mh=model_handle|lh=landscape_handle] |
inheritance mth=model_type_handle [lh=landscape_handle] |
rules rel=relation [lh=landscape_handle] |
enumerations [attr=attribute_id] [mth=model_type_handle]
         [lh=landscape_handle] |
watch [mh=model_handle]
```

- **-a**
  If the -a (all) option is specified, show alarms do not perform any masking and displays all CRITICAL, MAJOR, MINOR, MAINTENANCE, SUPPRESSED, and INITIAL alarms.
- **-x**
  If the -x (expand) option is specified (and the variable $SPECROOT is set), the output of the show alarms command displays the text for the probable causes at the end of the output. The output of the show events command displays event formats. The number of characters displayed by the show events -x command is controlled by the .vnmshrc resource file parameter.
- **-d**
  If the -d option is specified, the output of the show alarms command displays the "Title" for every alarm listed. This option also displays all that the option -x displays.
- **max_show_event_length**
  If you are using a SpectroSERVER-only workstation to run CLI, the -x option does not provide the normal alarm cause or event format information because the CsPCause and CsEvFormat files do not exist in the SG-Support directory. Possible errors messages are:
  - No cause information available (associated with show alarms)
  - No event format information available (associated with show events)

  To remedy this problem, copy the SG-Support/CsPCause and SG-Support/CsEvFormat directories and files to the <*$SPECROOT*>/SG-Support directory on the SpectroSERVER workstation.
  Default: 512
- **-e**
  If the -e (enumerations) option is specified, the output of the show attributes command displays database enumeration strings.
- **-c**
  If the -c (Read Most Current) option is specified, the attribute Read Mode is set to Read Most Current. This mode uses the attribute value from the latest user interface poll, which is updated every 5 seconds. If this flag is not set, the Read Most Available mode is used. This mode uses the latest value stored in the database by the last DX NetOps Spectrum poll. Polling frequency is a user-defined interval.
- **-n**

If the -n (number of events) option is specified, the output of the show events command displays the specified number of events.

- **-t**
  If the -t (trouble ticket id) option is specified, the output of the show alarms command displays the trouble ticket id field.
- **-s**
  If the -s (impact severity) option is specified, the output of the show alarms command displays the impact severity field.

NOTE
For the show alarms and show events commands to work with the -x option, which displays probable cause messages for alarms and expanded event messages, OneClick must be installed on the local server, and the SPECROOT environment variable must be set to the path of the spectrum support root directory. For example, if the SG-Support files are in /usr/spectrum/SG-Support, set SPECROOT to /usr/spectrum.

show alarm

The show alarms command shows all alarms for the model that is specified by model_handle. Or it shows only the most severe alarm (if the alarm is CRITICAL, MAJOR, or MINOR) for each model in the landscape that is specified by landscape_handle. If landscape_handle is specified, show alarms masks any models that have INITIAL, SUPPRESSED, or MAINTENANCE alarms. As a result, only models with CRITICAL, MAJOR, or MINOR alarms are displayed. If neither model_handle nor landscape_handle is specified, show alarms also performs masking and shows only the most severe alarm (if the alarm is CRITICAL, MAJOR, or MINOR) for each model in the current landscape.

The Ack field indicates whether the alarm has been acknowledged. The possible values for this field are Yes and No. The Stale field indicates whether an alarm is stale. The possible values for this field are Yes and No. The Assignment and Status fields show the alarm troubleshooter information and the alarm status, respectively. The alarm creation time is displayed in hh:mm:ss format.

NOTE

To synchronize event and alarm support files with other OneClick servers, in a distributed environment, copy the folders containing the event format files and the probable cause files to the other SpectroSERVERs. $SPECROOT/custom/Events/CsEvFormat $SPECROOT/custom/Events/CsPCause Also copy the contents of these same directories to a custom directory on all of the SpectroSERVERs in your environment.

The show alarms command displays information in the following format:

```
Id  Date        Time      PCauseId  MHandle  MName  MTypeName  Severity  Ack  Stale  Assignment  Status
id  mm/dd/yyyy  hh:mm:ss  cause_id  handle   name   name       severity  ack  stale  assignment  status
```

If show alarms is used with the -x option, a table of cause codes and probable cause text messages is displayed after the last alarm. For example:

0x10402 DUPLICATE PHYSICAL ADDRESS0x10302 SpectroSERVER has lost contact with this device.

NOTE
The show command displays a maximum of 16 characters for the model name. However, with the environment variable CLIMNAMEWIDTH, you can specify a different number of characters (up to 1024) to be displayed for model names.

Example: show alarms

The show alarms command displays information in the following format:

```
$ show alarms lh=0x110000
ID   Date        Time      PCauseId   MHandle     MName     MTypeName  Severity    Ack  Stale   Assignment
 Status
928  05/11/2000  02:33:22  0x10c04    0x110000c   infinity  VNM        CRITICAL    No   No      McDonald
 Working on it
```

show association

The show associations command shows all instantiated relations (associations) that are defined for the model with model_handle. If model_handle is not specified, show associations shows all instantiated relations for the current model.

The show associations command displays information in the following format:

```
LMHandle   LMName   Relation   RMHandle   RMName
handle     name     relation   handle     name
```

Example: show associations

The show associations command displays information in the following format:

```
$ show associations mh=0x400141
LMHandle   LMName     Relation        RMHandle   RMName
0x400001   LostFound  Lost_and_Found  0x400141   12.77-bridge
```

show attributes

The show attributes command shows the attributes specified by attr=attribute_id for the model with model_handle. If no attribute_id is specified, show attributes lists all attributes and their values for the model with model_handle.

If model_handle is not specified, show attributes shows all applicable attributes for the current model. You can specify a range of attributes using attr=low_attr-high_attr. The instance ID for an attribute can be specified in instance_id when displaying a single attribute or a list of attributes for a particular model. The instance_id must be a sequence of positive integers separated by periods. Instance IDs can only be specified for list attributes. List attributes are attributes that have the list flag set.

The following rules apply to list attributes:

- To display all attribute values and instance IDs for a list attribute, do not enter an instance_id with the attribute_id. Enter an attribute_id only.
- To display the first attribute value and instance ID for a list attribute, enter the following command after the attribute_id:
  ```
  ,next
  ```
- To display a specific attribute value and instance ID for a list attribute, enter an instance_id with the attribute_id.
- To display the next attribute value and instance ID after a specific instance ID of a list attribute, enter the following command after the instance_id:
  ```
  ,next
  ```
- An instance ID cannot be specified when displaying all the attributes of a model, for the following reasons:
  - An instance ID only applies to list attributes (for example, board and port attributes of a hub)
  - The instance ID for certain attributes of a model may differ from the instance ID of other attributes within the same model.
- The show attributes command shows all attributes (by ID, name, type, and flags) for model_type_handle in the landscape specified by landscape_handle. If landscape_handle is not specified, this command shows all model types that are defined in the current landscape. The Flags field lists the abbreviations of each attribute flags (separated by commas) that is currently set. If a flag is not set, its abbreviation is not included in the list.
  The following list includes the attribute flags and their abbreviations:

- External = E
- Readable = R
- Writable = W
- Shared = S
- List = T
- Guaranteed = G
- Global = O
- Memory = M
- Database = D
- Polled = P
- Logged = L
- Preserve Value = V

NOTE
For a more detailed description of the attribute flags, see the Model Type Editor section.

The show attributes command displays information in the following format:

```
Id      Name      Iid      Value
id      name      iid      value
```

The show attributes mth command displays information in the following format:

```
Id      Name      Type      Flags
id      name      type      flags
```

Example: show attributes

```
$ show attributes mh=0xcd00011
Id          Name                        Iid      Value
0xd0000     Modeltype_Name                       User

```

show children

The show children command shows the children in relation to the model with model_handle. If relation is not specified, show children shows the children in all relations. If model_handle is not specified, the command shows the children for the current model.

The show children command displays information in the following format:

```
MHandle    MName    MTypeHn   MTypeName     Relation
handle        name     handle    name        relation
```

Example: show children

```
$ show children mh=0x400009
```

```
MHandle    Name    MTypeHnd   MTypeName      Relation
0x40000d   12.84   0x100d6    Bdg_CSI_CNB2   Collects
```

show devices

The show devices command shows a listing of all device models in the landscape that is specified by the landscape_handle.

The show devices command displays information in the following format:

```
MHandle   MName   MTypeHnd   MTypeName
Handle    Name    Handle     Name
```

Example: show devices

```
$ show devices lh=0x400000
MHandle     MName           MTypeHnd    MTypeName
0x1005c0    10.253.32.101   0x3d002     GnSNMPDev
0x100030    10.253.2.10     0x2c60021   RstonesSwRtr
```

show enumerations

The show enumerations command shows enumerated string value mapping for the corresponding enumerated value specified.

The show enumerations command displays information in the following format:

```
Id   String   Value
id   string   value
```

The show enumerations mth command displays information in the following format:

```
MHandle   String   Value
HandLE    string   value
```

Example: show enumerations

```
$ show enumerations attr=0x10004
ID        String        Value
0x10004   Lost          0
0x10004   Established   1
0x10004   INITIAL       2
$ show enumerations mth=0x10004
ID        String        Value
0x10004   Lost          0
0x10004   Established   1
0x10004   INITIAL       2
```

show events

The show events command shows the events for the model with model_handle or the events for all models in the landscape that is specified by landscape_handle. By default, the show events command shows the 2,000 most recent events for the model that is specified by model_handle or landscape_handle. If the -a option is specified, this command shows a maximum of 10,000 events for the model which is specified by model_handle or landscape_handle.

If the -n option is specified with an explicit no_events statement, the specified number of events is displayed for the model which is specified by model_handle or landscape_handle. If neither model_handle nor landscape_handle is specified,

this command shows events for all models in the current landscape. If the -x option is specified, the CLI displays text messages explaining the event types. The event time is displayed in hh:mm:ss format.

NOTE

To synchronize event and alarm support files with other OneClick servers, in a distributed environment, copy the folders containing the event format files and the probable cause files to the other SpectroSERVERs. $SPECROOT/custom/Events/CsEvFormat $SPECROOT/custom/Events/CsPCause Also copy the contents of these same directories to a custom directory on all of the SpectroSERVERs in your environment.

The show events command displays information in the following format:

```
Date          Time        Type     MHandlE    MName    MTypeName
mm/dd/yyyy    hh:mm:ss    type     handle     name     name
```

If show events is used with the -x option, the events displayed do not have a fixed format. The following is an example of typical output:

```
Thur 11 May, 2000 - 8:04:01 - Alarm number 10 generated for device AntLAN of type LAN_802_3.
Current condition is INITIAL(DEFAULT).
(event [00010701])
```

Example: show events

```
$ show events lh=0x400000
Date         Time       Type      MHandle    MName    MTypeName
04/25/1999   13:27:38   0x10302   0x4000f9   1.3      Host_IBM
04/25/1999   13:27:38   0x10202   0x400131   qa1sgi   Host_SGI
$ show events -n
Date         Time       Type      MHandle             MName             MTypeName
08/21/1999   11:30:02             0x100090xcd00067    els100-01.india   RMONApp

08/21/1999   11:15:52             0x100090xcd00067    els100-01.india   RMONApp
08/21/1999   11:10:27             0x100090xcd00067    els100-01.india   RMONApp
```

show inheritance

The show inheritance command shows the model type inheritance for the model type that is specified by model_type_handle in the landscape that is specified by landscape_handle. If the landscape_handle is not specified, the current landscape is used. The possible values for this field are Base or Derived.

The show inheritance command displays information in the following format:

```
MHandle   MName   Flags   Inheritance
handle    name    flags   inheritance
```

Example: show inheritance

```
$ show inheritance mth=0x1037b lh=0x400000
Handle    Name         Flags    Inheritance
0x10000   Root         V,D      Base
0x103ad   BanVinesFS   V,I,U    Derived
```

show landscapes

The show landscapes command shows all landscapes that are defined for each SpectroSERVER. The landscape map that is displayed is the map of the initial SpectroSERVER.

The show landscapes displays information in the following format:

```
SSName    Precedence    Port    Service    LHandle
ssname    precedence    port    service    handle
```

Example: show landscapes

```
$ show landscapes
SSName    Precedence    Port    Service   LHandle
devsgi    10            0xbeef  0x10101   0x28000000
devibm    10            0xbeef  0x10101   0x11f00000
```

show models

The show models command shows all models that are defined in the landscape, which is specified by landscape_handle. If landscape_handle is not specified, this command shows all models that are defined in the current landscape. A range of model handles can be specified by the following command:

```
mhr=low_model_handle-high_model_handle
```

Specific models can be searched for by specifying mname=model_name.

User models are identified by the show models command as either (Active) or (Not Active). If the user model status is (Not Active), the user cannot yet connect to the server. Once the user model status is (Active), the user can connect to the server.

The show models command displays information in the following format:

```
MHandle    MName    MTypeHnd    MTypeName
handle     name     handle      name
```

Example: show models

```
$ show models lh=0x400000
MHandle    MName    MTypeHnd    MTypeName
0x400004   World    0x10040     World
0x4000d9            0x10020     AUI
$ show models mname=
MHandle     MName        MTypeHnd        MTypeName
0xcd00016   0x1120002    AppDataServer
0xcd00022   0x1006b      SnmpPif
0xcd00030   0x1028f      IcmpPif
$ show models mhr=0xcd00000-0xcd000ff mth=0x230018 mname=india lh=0xcd00000
MHandle     MName                        MTypeHnd    MTypeName
0xcd000a3   hplaser.zeitnet.India.com    0x230018    TCP2_App
0xcd0002b   desire.zeitnet.India.com     0x230018    TCP2_App
```

show parents

The show parents command shows the parents in relation to the model with model_handle. If relation is not specified, it shows the parents in all relations. If model_handle is not specified, show parents shows the parents for the current model.

The show parents command displays information in the following format:

```
MHandle    MName    MTypeHnd    MTypeName    Relation
handle     name     handle      name         relation
```

Example: show parents

```
$ show parents mh=0x40000d
MHandle    MName              MTypeHnd    MTypeName    Relation
0x400009   auto-lan-30x1003c              LAN_802_3    Collects
```

show relations

The show relations command shows all relations that are currently defined in the landscape specified by landscape_handle. If landscape_handle is not specified, this command shows all relations that are defined in the current landscape.

The show relations command displays information in the following format:

```
Name             Type
relation_name    relation_type
```

Example: show relations

```
$ show relations
Name Type
Passes_Through MANY_TO_MANY
Lost_and_Found ONE_TO_MANY
Owns ONE_TO_MANY
Contains ONE_TO_MANY
```

show rules

The show rules command shows the rules for a relation. The relation is specified in the landscape that is specified by landscape_handle. If landscape_handle is not specified, the current landscape is used.

The show rules command displays information in the following format:

```
LMTHandle    LMTName    RMTHandle    RMTName
handle       name       handle       name
```

Example: show rules

```
$ show rules rel=Owns lh=0x400000
LMTHandle    LMTName    RMTHandle    RMTName
0x102da      Org_Owns   0x10043      Site
0x102da      Org_Owns   0x210023     Rtr_CiscoMGSshow
```

show types

The show types command shows all model types that are currently defined in the landscape that is specified by landscape_handle. If landscape_handle is not specified, this command shows all model types defined in the current landscape. The Flags field lists the abbreviations for each of the six attribute flags that are currently set. If a flag is not set, its abbreviation is not included in the list.

The following list includes the model type flags and their abbreviations:

- Visible = V
- Instantiable = I
- Derivable = D
- No Destroy = N
- Unique = U
- Required = R

The show types command [mth=low_mth-high_mth] shows all model types within the range between low_mth and high_mth.

NOTE
For more information about model type flags, see the Model Type Editor section.

The show types command displays information in the following format:

```
Handle    Name    Flags
handle    name    flags
```

Example: show types

```
$ show types lh=0x400000
Handle    Name          Flags
0x10000   Root          V,D
0x10080   Gen_Rptr_Prt  V,D
$ show types mthr=0x10002-0x10008
Handle    Name             Flags
0x10002   Network_Entity
0x10003   VNM              V,I,D,N,U,R
0x10004   User             V,I,D
0x10005   VIB
0x10007   DataRelay        V,D
$ show types mthr=0x210020-0x21002f mtname=Rtr_Cisco lh=0xcd00000
Handle      Name              Flags
0x210020    Rtr_CiscoAGS      V,I,D
0x210021    Rtr_CiscoCGS      V,I,D
0x210022    Rtr_CiscoIGS      V,I,D
0x210023    Rtr_CiscoMGS      V,I,D
0x210024    Rtr_CiscoMIM      V,I,D
0x21002b    Rtr_Cisco2500     V,I,D
0x21002c    Rtr_CiscoMIM3T    V,I,D
0x21002d    Rtr_Cisco3000     V,I,D
0x21002e    Rtr_Cisco4000     V,I,D
0x21002f    Rtr_Cisco7000     V,I,D
$ show types flags=VIDNUR lh=0xcd00000
Handle        Name              Flags
0x25e0000     MgmtInventory     V,I,D,N,U,R
0x10040       World             V,I,D,N,U,R
0x102cf       Top_Org           V,I,D,N,U,R

0x10091       Universe          V,I,D,N,U,R
```

show watch

The show watch command lists applicable watch data for a model that is specified by model_handle.

The show commands use the following defaults when landscape_handle and model_handle are not specified:

Command	Default
show alarms	current landscape

show associations	current model
show attributes	current model
show attributes mth	current landscape
show children	current model
show devices	current landscape
show enumerations	current landscape
show enumerations mth	current landscape
show events	current landscape
show inheritance	current landscape
show models	current landscape
show parents	current model
show relations	current landscape
show rules	current landscape
show types	current landscape
show watch	current model

NOTE
The ‘show alarms’ and ‘show events’ commands can work with the x option to display probable cause messages for alarms and expanded event messages.

Verify the following prerequisites:

- OneClick is installed on the local server.
- The environment variable SPECROOT is set to the path of the root directory (SG-Support).
  For example, if the SG-Support files are in/usr/spectrum/SG-Support, set SPECROOT to /usr/spectrum.

The show watch command displays information in the following format:

```
Watch_Id   Watch_Name   Watch_Type   Watch_Status
watch_id   watch_name   watch_type   watch_status
```

Example: show watch

```
$ show watch mh=0xc600015
Watch_Id     Watch_Name   Watch_Type   Watch_Status
0xffff0001   watch798     Calc         Active
```

stopShd - Terminates CLI Local Server

Use the stopShd command to terminate the CLI Local Server (VnmShd daemon). The stopShd command disconnects all DX NetOps Spectrum CLI users from the currently connected SpectroSERVER and terminates the CLI Local Server. This command prompts the user for confirmation before disconnecting users and shutting down the server. (You can also shut down the daemon by using the kill -2 command.)

The command has the following format:

```
stopShd [-n]
```

- **-n**
  Specifies 'no prompt'. Include this option with the stopShd command to disable confirmation prompts. Otherwise, the following message is always displayed:
  ```
  stopShd: n users are connected, are you sure?
  ```

The 'n' represents the number of connected users, including yourself.
Valid responses are y, yes, Y, Yes, n, no, N, No.
If the command is successful, the following message is displayed:

```
stopShd: successful
```

When stopShd terminates the CLI Local Server, the following message is displayed on the system console:

```
VnmShd: stopShd executed. Exiting...
```

Example: stopShd

```
$ stopShd
stopShd: 2 users are connected, are you sure? y
stopShd: successful
```

update - Updates Model and Model Attributes

Use the update command to update model and model type attributes.

The command has the following format:

```
update  [mh=modelhandle]
attr=attribute_id[,iid=instance_id],val=value
  [attr=attribute_id[,iid=instance_id],val=value...] |
  [mh=modelhandle]
  attr=attribute_id,iid=instance_id,remove
  [attr=attribute_id,iid=instance_id,remove...] |
  [-n] mth=model_type_handle |
attr=attribute_id,val=value [attr=attribute_id,val=value ... ]
  [lh=landscape_handle] |
alarm [-r] aid=alarm_id <assign=troubleshooter |
  status=status_text | ticket=troubleticketID |
  ack=(true|false)> [lh=landscape_handle] |
action=action_code [watch=watch_id] [mh=modelhandle]
```

- **-n**
  If the -n (no prompt) option is specified with the update command, then the system does not prompt for confirmation. This option is useful in CLI scripts.
- **-r**
  The -r (replace status text/replace trouble ticket ID) option can be specified with the update alarm command when using the status or the ticket arguments. When the -r option is used, the existing alarm status text or alarm trouble ticket ID is replaced with the text specified by the status argument or the ticket argument. When the -r option is not used, the new values are appended to the existing values.
- action_code
  - reconfig, 0x1000e, or 65550 to reconfigure a model
  - activate, 0x00480003, or 4718595 to activate a watch
  - deactivate, 0x00480004, or 4718596 to deactivate a watch
  - reconfigure_apps, 0x210008, or 2162696 to reconfigure application models on Cisco and Wellfleet devices
  - reload_event_disp, 0x000100a2, or 65698 to update the SpectroSERVER with changes to EventDisp and AlertMap files

    NOTE
    The watch = <*watch_id*> parameter is applicable only for the following actions: activate (or the hexadecimal equivalent 0x00480003) and deactivate (or the hexadecimal equivalent 0x00480004).

NOTE
The following points describe the features of update command:

- The update command updates the attribute specified by attribute_id value either for model with model_handle or for all models with the model type model_type_handle in the landscape specified by landscape_handle.
- Multiple attributes can be updated with one update command by specifying multiple attribute_id, value pairs, each pair that is separated from adjacent pairs by a space.
- The remove option removes instances that are specified from a list attribute.
- If landscape_handle is not specified when updating model type attributes, the current landscape is used. If model_handle is not specified, then the specified attribute of the current model is updated.
- When you are updating model type attributes, remember that only shared attributes can be updated. Shared attributes are attributes that have the shared flag set. Use the show attributes command to see if an attribute is shared.
- Security-sensitive attributes, such as User_Community_String and Model_Security_String, can be updated through CLI. However, the current user model cannot update its own User_Security_String or Security_String, but it can update those of other models.
- The update command also lets the user specify an instance ID when changing a single attribute value. When updating a list of attribute values, an instance ID can be specified for each attribute on the list. instance_id is the instance ID for the corresponding attribute. The instance_id must be a positive integer, or sequence of dot-separated positive integers.
- If an instance ID is not specified, the update command uses the first valid instance that it finds for the attribute. If no valid instances are found, an error message is displayed:
  ```
  update: no valid instance for list attribute <attr_id>
  ```
- The update alarm command updates the alarm specified by alarm_id with the value specified by the Troubleshooter (Troubleshooter model handle or Troubleshooter name), status_text, troubleticketID, or ack parameter. To clear the existing alarm values for Troubleshooter, Status text, or Trouble Ticket ID, you can set the appropriate parameter to have no value (status=, ticket=, or assign=). The landscape_handle parameter specifies the landscape in which the alarm will be found.
- The update action command performs an action specified by action_code on a device specified by model_handle. With action_code reconfig, any device of model type GnSNMPDev, or of any model type that inherits from GnSNMPDev, can be reconfigured. The activate or deactivate action_code update a watch status on a device of a specified model_handle. When the activate action object is sent, there may be a short delay between the time the watch status changes from INITIAL to ACTIVE, depending upon the intelligence that is built into the selected model. The watch_id of the watch slated to have its status updated can be obtained by using the show watch command. The reconfigure_apps action_code update application model types for Cisco and Wellfleet device models. The reload_event_disp action_code update the SpectroSERVER with changes made to EventDisp or AlertMap files.
- Use caution when using the update action command. As with any CLI command, you can corrupt the SpectroSERVER database if you use this command incorrectly. For example, inadvertently reconfiguring a critical router can cause unpredictable results on your network.
- If update is entered with a valid model_handle or valid model_type_handle, valid attribute_id(s), and valid values, the modified attributes and their values are displayed in the following format:
  ```
  Id Name Value
  Id Name Value
  ```
- If you do not use the -n option when updating models of a specified model type, the following confirmation message is displayed:
  ```
  update: all models of this type will be updated, are you sure?
  Valid responses are y, yes, Y, Yes, n, no, N, No.
  ```
- If the update alarm command is successful, the following message is displayed:
  ```
  update:successful
  ```
- If the update action command is successful, the following message is displayed:
  ```
  update action: successful
  ```

Examples: Update

- In the following example, the update command with an instance_id is used to disable port 7 on board 5 of the Hub represented by model handle 0x4001f6:

```
$ update mh=0x4001f6 attr=0x10ee0,iid=5.7,val=1
Id        Name              Iid       Value
0x10ee0   CsPortAdminState            1
```

- In the following example, the update command is used with the remove option to remove an IP address (iid) from the deviceIPAddressList (attr) for a particular model (mh).

```
$ update mh=0xc600018 attr=0x12a53,iid=10.253.8.65,remove
update: successful
```

- In the following example, the update command is used to update the attribute named AutoPlaceStartX on all models of the model type represented by model type handle 0x10059.

```
$ update mth=0x10059 attr=0x118f2,val=100 lh=0x400000
update: all models of this type will be updated, are you sure? y
Id    Name              Value
Id    AutoPlaceStartX   100
```

- In the following example, the update alarm command is used to update an alarm troubleshooter assignment.

```
$ update alarm aid=928 assign=0xa600722
update: successful
```

- In the following example, the update alarm command is used to update alarm status. The -r option is used to overwrite the existing status.

```
$ update alarm -r aid=928 status='Working on it'
update: successful
```

- In the following example, the update alarm command is used to update the alarm Trouble Ticket ID. The -r option is used to overwrite the existing value for Trouble Ticket ID.

```
$ update alarm -r aid=928 ticket='Ax1009'
update: successful
```

- In the following example, the update alarm command is used to clear the existing value for Trouble Ticket ID.

```
$ update alarm aid=928 ticket=
update: successful
```

- In the following example, the update alarm command is used to acknowledge the alarm.

```
$ update alarm aid=928 ack=TRUE
update: successful
```

- In the following example, the update command is used to restrict updating of the User_Community_String.

```
$ update mh=0x9a000ff attr=0x1007a,val=AA,11
update: successful
```

- In the following example, the update action command is used to reconfigure a Cisco router.

```
$ update action=reconfig mh=0xc600030
update action: successful
$ update action=activate watch=0xffff0001 mh=0xc600015
Watch_Id      MHandle      Watch_Status
0xffff0001    0xc600015    INITIAL
$ update action=0x480004 watch=0xffff0001 mh=0xc600015
Watch_Id      MHandle      Watch_Status
0xffff0001    0xc600015    INACTIVE
```

Sample Scripts

This section explains how to use the sample scripts that are included with CLI. The functionality and prerequisites for each script are explained in the section.

The sample scripts included with CLI demonstrate how CLI commands can be incorporated into UNIX shell scripts so that you can automate your CLI sessions. You can find some of these scripts, or some of the functions within them, useful for your own work.

CLI includes the following scripts, and a readme file that describes the scripts in the *<$SPECROOT>*/vnmsh/sample_scripts directory:

- active_ports
- app_if_security
- cli_script
- database_tally
- update_mtype
- octet_to_ascii.pl

Review the following prerequisites when you work with CLI scripts:

- Each script has an internal variable named CLIPATH. To use a script, set the CLIPATH variable to the pathname of the directory where CLI executables are located.
- The CLIPATH variable and the other environment variables that are pathnames can be *full* or *relative* pathnames depending on how the script is run. Use *full* pathnames for the CLIPATH and other environment variables when you run a sample script as a cron script. Otherwise, you can use *relative* pathnames for these variables.
- Except for update_mtype, you can run all the CLI scripts as cron scripts.

  NOTE
  Do not run update_mtype as a cron script because it prompts the user for input.
- When you run CLI scripts, specify the correct names for the vnm_hostname variable in the .vnmshrc file.

active_ports Script

Use the active_ports script to identify all ports for each board of an IRM2 hub and to identify the active ports on each board.

The active_ports script places a report for the hub with the name hub_name in a file with the name output_file. This report lists all the ports for each board. An asterisk (*) in the ON column of the report shows you which ports are active.

This script has the following format:

```
active_ports <hub_name> <output_file>]
```

app_if_security Script

Use the app_if_security script to update the Security_String attribute value in all the interface and application models in the DX NetOps Spectrum database. The app_if_security script does update by copying the attribute value from the parent model. The script does not update any models if the recipient model (child) already has a value for the Security_String attribute or if the parent does *not* have a Security_String attribute value. After updating a model's security string, administrators can use this script to update the security string of the model's children.

This script has the following format:

```
app_if_security
```

cli_script Script

Use cli_script to execute most of the CLI commands in batch mode when you provide a data file as input. The CLI sample data file, named datafile, contains switches that indicate the command to execute and also the necessary parameters to pass to the command. The script verifies that each command is executed successfully and also maintains a runtime log.

One advantage of this script is that you can create batch files using names instead of handles. For example, you can use a model type name, rather than the hexadecimal model type handle. While this makes the files easier to create and read, the real advantage comes when you want to perform subsequent actions on a model that you have created. Instead of assigning hexadecimal model handles to the model, you can refer to the model by name.

This script has the following format:

```
cli_script datafile
```

The cli_script uses two files, datafile and clean.awk, that are also located in the sample_scripts directory.

- **datafile**
  Contains the input for cli_script. It contains each CLI command currently implemented in cli_script. See the cli_script header information for instructions about the format and syntax of this file.
- **clean.awk**
  Contains the input used in execution. The .awk files are used for formatting what data appears to the console.

Consider the following points when working with cli_script:

- Remember to change the “dummy” Network_Address (255.255.255.255) in the sample datafile to a real address.
- If you move the cli_script to another directory, you must update the environment variable SPECROOT to the support root directory (SG-SUPPORT).
  For example, if the SG-SUPPORT files are in /usr/spectrum/SG-Support, set SPECROOT to /usr/spectrum.

database_tally Script

Use this script to determine how many models of each type are currently in the database. Administrators may find this script useful when evaluating system performance. The script displays a list of all the model types and the number of models of each model type in the database.

This script has the following format:

```
database_tally <vnm-name>
```

update_mtype Script

Use this script to update a specific attribute for all models of a model type. If the attribute is a shared attribute of the model type, the script does not update the model's attribute. One advantage of this script is that you can use the model and attribute names at the prompt rather than their hexadecimal ID handles.

Note: Set the CLIMNAMEWIDTH environment variable to 256. The high value prevents truncation of model names that can cause false matches when running the script.

This script has the following format:

```
update_mtype <model_name> \ <model_typename>[<attribute_name> | <attribute_id> <value>]
```

- **model_name | model_type_name**
  Specifies a model name, or part of a model name, for a model of the model type for which the attribute update is done. You can specify any model of the model type in the command.

The script then displays a listing of all model types that have models with names containing the model name argument that you entered. The script asks you to select a model type from the list.
If you use the model name instead of the model type name, the script updates all models whose names include the string entered on the command line or at the prompt. In this case, all models of a given model type are not updated as described above.

NOTE
We recommend using the model name or model type name at the prompt and not handle.

- **attribute_name | attribute_id**
  If you do not specify these arguments initially, the script prompts for attribute name or attribute id, when it runs. At this point, you must specify either the attribute name or part of the attribute name. The script then asks you to select from a list of attributes containing the text that you entered. You can run the entire script, therefore, without prior knowledge of the hexadecimal model type handles or attribute handles.

Error Messages

This section describes the most common error messages that the CLI throws in the response to an invalid or wrongly executed command. Each error message includes reason and action to be performed.

ack alarm <alarm_id> invalid alarm id

Reason:

The alarm ID that you entered is invalid.

Action:

Enter the ack alarm command again, using a valid alarm_id.

ack alarm <landscape_handle> invalid landscape handle

Reason:

The landscape handle that you entered for the alarm is invalid.

Action:

Enter the ack alarm command again, using a valid landscape_handle.

command failed to connect with VnmShd, please run connect first

Reason:

You attempted to run other commands before running the connect command.

Action:

Begin a CLI session with the connect command.

connect already connected to <hostname> since <date/time>

Reason:

The attempt to connect is unnecessary. You are already connected to a SpectroSERVER host.

Action:

None.

connect cannot open resource file <pathname>/.vnmshrc

Reason:

The connect command cannot find the CLI resource file .vnmshrc.

Action:

The .vnmshrc resource file must be in the same directory as the connect command itself.

connect can only connect to SpectroSERVERs in <hostname> landscape map - other user(s) already connected

Reason:

The connect command has already been used to connect to a particular SpectroSERVER. You can connect only to a SpectroSERVER that is in the landscape map of the original SpectroSERVER.

Action:

None

connect ERROR No such DX NetOps Spectrum user as <username>

Reason:

The first user of the connect command is not defined as a DX NetOps Spectrum user.

Action:

Reconnect to the SpectroSERVER as a DX NetOps Spectrum user.

connect <hostname> not responding or not permitting access

Reason:

The connect command cannot connect to SpectroSERVER because the hostname is incorrect, the SpectroSERVER is not running, or the user has no user model.

Action:

Verify that the hostname is correct, that SpectroSERVER is running, and that the user has a user model.

connect <landscape_handle> invalid landscape handle

Reason:

The landscape_handle specified by the user is not valid for the specified hostname, or the handle cannot be accessed by your VNM.

Action:

Verify that the landscape_handle is valid for the specified hostname, and verify that the handle can be accessed by your VNM.

connect incompatible SpectroSERVER <version>

Reason:

The user is attempting to connect to a SpectroSERVER host whose version is incompatible with the CLI version.

Action:

Update the version of CLI that you are using.

connect invalid <value> for CLISESSID

Reason:

The connect command is used within a cron script or the windowing system returns 0 for ttyslot and the environment variable CLISESSID is set to a non-numeric value.

Action:

Use the connect command outside of a cron script and set CLISESSID to a numeric value.

connect variable <CLISESSID> not set

Reason:

You have attempted to use the connect command within a cron script without first setting the CLISESSID environment variable.

Action:

When using connect within a cron script, set the environment variable CLISESSID.

create user not permitted to create alarm

Reason:

You are not permitted to create an alarm.

Action:

Verify your user permissions.

create user not permitted to create association

Reason:

You are not permitted to create an association.

Action:

Verify your user permissions.

create user not permitted to create event

Reason:

You are not permitted to create an event.

Action:

Verify your user permissions.

create user not permitted to create model

Reason:

You are not permitted to create a model.

Action:

Verify your user permissions.

create alarm <probable_cause_id> invalid alarm cause

Reason:

The create alarm command was entered with an invalid probable_cause_id.

Action:

Re-enter the create alarm command with a valid probable_cause_id.

create alarm <alarm_severity> invalid alarm severity

Reason:

The create alarm command was entered with an invalid alarm_severity.

Action:

Re-enter the create alarm command with a valid alarm_severity.

create alarm <model_handle> invalid model handle

Reason:

The create alarm command was entered with an invalid model_handle.

Action:

Re-enter the create alarm command with a valid model_handle.

create association <left_model_handle> invalid model handle

Reason:

The create association command was entered with an invalid left_model_handle.

Action:

Re-enter the create association command with a valid left_model_handle.

create association models belong to different landscapes

Reason:

The create association command was entered with a left_model_handle and a right_model_handle in different landscapes.

Action:

Use the same landscape for both handles.

create association rel=<relation> invalid relation

Reason:

The create association command was entered with an invalid relation.

Action:

Re-enter the create association command with a valid relation.

create association <right_model_handle> invalid model handle

Reason:

The create association command was entered with an invalid right_model_handle.

Action:

Re-enter the create association command with a valid right_model_handle.

create event <event_type> invalid event type

Reason:

The create event command was entered with an invalid event_type.

Action:

Re-enter the create event command with a valid event_type.

create event <landscape_handle> unknown landscape

Reason:

The create event command was entered with an invalid landscape_handle.

Action:

Re-enter the create event command with a valid landscape_handle.

create event <model_handle> invalid model handle

Reason:

The create event command was entered with an invalid model_handle.

Action:

Re-enter the create event command with a valid model_handle.

create model <attribute_id> invalid attribute id

Reason:

No model is created because the create model command was entered with an invalid attribute_id.

Action:

Re-enter the create model command with a valid attribute_id.

create model DCM device unreachable

Reason:

No model was created because the create model command was entered with an invalid ip_address. The DCM (Device Communication Manager) issues this error message.

Action:

Re-enter the create model command with a valid ip_address.

create model Device limit exceeded

Reason:

No model was created because the Branch Manager SpectroSERVER (50 device model limit) or the Site Manager SpectroSERVER (250 device model limit) contains the maximum number of device models it can contain.

Action:

Verify that the number of device models on the SpectroSERVER have not met the prescribed limits. If they have, you may need to delete some and then re-enter the create model command.

create model <landscape_handle> invalid landscape handle

Reason:

No model was created because the create model command was entered with an invalid landscape_handle.

Action:

Re-enter the create model command with a valid landscape_handle.

create model <model_type_handle> invalid model type handle

Reason:

No model is created because the create model command was entered with an invalid model_type_handle.

Action:

Re-enter the create model command with a valid model_type_handle.

create model <value> invalid value

Reason:

No model is created because the create model command was entered with an invalid value.

Action:

Re-enter the create model command with a valid value.

create model <value> No community name

Reason:

The community name provided in the create request was incorrect.

Action:

Re-enter the create command with a valid community name.

current <model_handle> invalid model handle current model is <current_model_handle>

Reason:

An invalid model_handle was specified so the current model and the current landscape are unchanged.

Action:

Re-enter a valid model_handle if you want to modify the current model and current landscape.

current <landscape_handle> invalid landscape handle current landscape is <current_landscape_handle>

Reason:

Since an invalid landscape_handle was specified, the current model and the current landscape are unchanged.

Action:

Re-enter a valid landscape_handle if you want to modify the current model and current landscape.

current <landscape_handle> not responding or not permitting access current model is <current_model_handle>

Reason:

A landscape_handle was specified and the OneClick for the landscape was down or the user did not have a user model on that landscape.

Action:

Verify that the OneClick for the landscape in question is running; verify that you have a user model on the landscape in question; and then re-enter the landscape_handle.

current <landscape_handle> not responding or not permitting access current landscape is <current_landscape_handle>

Reason:

A model_handle was specified and the SpectroSERVER for the landscape containing that model was down or the user did not have a user model on that landscape.

Action:

Verify that the SpectroSERVER for the landscape in question is running; verify that you have a user model on the landscape in question; and then re-enter the model_handle.

destroy user not permitted to destroy alarm

Reason:

You are not permitted to destroy an alarm.

Action:

Verify your user permissions.

destroy user not permitted to destroy association

Reason:

You are not permitted to destroy an association.

Action:

Verify your user permissions.

destroy user not permitted to destroy model

Reason:

You are not permitted to destroy a model.

Action:

Verify your user permissions.

destroy alarm aid=<alarm_id> invalid alarm id

Reason:

The destroy alarm command was entered with an invalid alarm_id.

Action:

Re-enter the destroy alarm command with a valid alarm_id.

destroy alarm <landscape_handle> invalid landscape handle

Reason:

The destroy alarm command was entered with an invalid landscape_handle.

Action:

Re-enter the destroy alarm command with a valid landscape_handle.

destroy association rel=<relation> invalid relation

Reason:

The destroy association command was entered with an invalid relation.

Action:

Re-enter the destroy association command with a valid relation.

destroy association <left_model_handle> invalid model handle

Reason:

The destroy association command was entered with an invalid left_model_handle.

Action:

Re-enter the destroy association command with a valid left_model_handle.

destroy association <right_model_handle> invalid model handle

Reason:

The destroy association command was entered with an invalid right_model_handle.

Action:

Re-enter the destroy association command with a valid right_model_handle.

destroy association association does not exist between given models

Reason:

An attempt was made to destroy an association between two models that do not exist.

Action:

Verify the existence of the two models belonging to the association you are attempting to destroy.

destroy association models belong to different landscapes

Reason:

The destroy association command was entered with a left_model_handle and a right_model_handle in different landscapes.

Action:

Re-enter the destroy association command using a left_model_handle and a right_model_handle from the same landscape.

destroy model <model_handle> invalid model handle

Reason:

The destroy model command was entered with an invalid model_handle.

Action:

Re-enter destroy model command with a valid model_handle.

disconnect failed

Reason:

The disconnect command failed.

Action:

Re-try the disconnect command.

disconnect failed to connect with VnmShd, please run connect first

Reason:

An attempt was made to run disconnect when the CLI Local Server was not running.

Action:

None. You are already disconnected.

disconnect not connected

Reason:

The disconnect command failed since the user was not connected to the SpectroSERVER.

Action:

None. You are already disconnected.

jump <text_string> text string not defined

jump:<text_string>: text string not defined

```
where text_string1, text_string2... are the currently defined text strings.
```

Reason:

The jump command was entered with an undefined text_string.

Action:

Re-enter the jump command using any of the defined text strings.

<pathname>/VnmShd not found

<pathname>/VnmShd: not found

```
connect: failed
where pathname represents the path to the directory in which CLI attempted to execute VnmShd.
```

Reason:

The connect command cannot find the CLI Local Server.

Action:

Make sure VnmShd and connect are in the same directory and then re-enter the connect command.

Please connect first

Reason:

After connect executed, you ran disconnect or stopShd and then attempted to run another command.

Action:

Reissue the connect command first.

seek <attribute_id> invalid attribute id

Reason:

The seek command was entered with an invalid attribute_id.

Action:

Re-enter the seek command with a valid attribute_id.

seek <error> attribute not keyed

Reason:

The seek command was entered with the attribute_id of an attribute that was not keyed.

Action:

Re-enter the seek command with an attribute_id of a keyed attribute.

seek <value> invalid value

Reason:

The seek command was entered with an invalid value.

Action:

Re-enter the seek command with a valid value.

show attributes <attribute_id> non list attribute

Reason:

The show attributes command was entered with an instance_id for a non-list attribute_id.

Action:

Re-enter the show attributes command with an instance_id for a list attribute_id.

show attributes <attribute_id> invalid attribute id

Reason:

The show attributes command was entered with an invalid attribute_id.

Action:

Re-enter the show attributes command with a valid attribute_id.

show attributes <instance_id> invalid instance id

Reason:

The show attributes command was entered with an invalid instance_id. An instance_id is invalid if it does not consist of a sequence of non-negative integers or if it does not exist for the specified attribute.

Action:

Re-enter the show attributes command with a valid instance_id.

show attributes <model_type_handle> invalid model type handle

Reason:

The show attributes command was entered with an invalid model_type_handle.

Action:

Re-enter the show attributes command with a valid model_type_handle.

show <landscape_handle> invalid landscape handle

Reason:

A show command that uses an optional landscape_handle was entered with an invalid landscape_handle.

Action:

Re-enter the show command with a valid landscape_handle.

show <model_handle> invalid model handle

Reason:

A show command that uses an optional model_handle was entered with an invalid model_handle.

Action:

Re-enter the show command with a valid model_handle.

show no current model defined

Reason:

A show associations command that uses an optional model_handle was entered but no model_handle was specified and no current model was defined.

Action:

Re-enter the show associations command, including both a model_handle and current model.

show alarms no cause information available

Reason:

The show alarms command was used with the -x option, and the DX NetOps Spectrum alarm files containing the probable cause text messages are not available.

Action:

For the show alarms command to work with the -x option, which displays probable cause messages for alarms and expanded event messages, OneClick must be installed on the local server, and the environment variable SPECROOT

must be set to the path of the Support root directory (SG-Support). For example, if the SG-Support files are in the following directory:

/usr/spectrum/SG-Support, set SPECROOT to /usr/spectrum.

show children <relation> invalid relation

Reason:

The show children command was entered with an invalid relation.

Action:

Re-enter the show children command with a valid relation.

show events no event format information available

Reason:

The show events command was entered with the -x option, and the DX NetOps Spectrum event files containing the event format text messages are not available.

Action:

For the show events command to work with the -x option, which displays probable cause messages for alarms and expanded event messages, OneClick must be installed on the local server, and the environment variable SPECROOT must be set to the path of the Support root directory (SG-Support). For example, if the SG-Support files are in the following directory:

/usr/spectrum/SG-Support, set SPECROOT to /usr/spectrum

show parents <relation> invalid relation

Reason:

The show parents command was entered with an invalid relation.

Action:

Re-enter the show parents command with a valid relation.

show rules <relation> invalid relation

Reason:

The show rules command was entered with an invalid relation.

Action:

Re-enter the show rules command with a valid relation.

show inheritance <model_type_handle> invalid model type handle

Reason:

The show inheritance command was entered with an invalid model_type_handle.

Action:

Re-enter the show inheritance command with a valid model_type_handle.

stopShd VnmShd not running

Reason:

An attempt was made to run stopShd when the CLI Local Server was not running.

Action:

Start the CLI Local Server.

stopShd failed

Reason:

The stopShd command failed.

Action:

Try connecting again, and then execute stopShd. If this does not work, kill the VnmShd process manually.

update <attribute_id> Attribute not writable

Reason:

No update occurred because an attempt was made to update model attributes that are non-writable.

Action:

Verify that the model attributes you want to update are writable and then re-enter the update command.

update <attribute_id> invalid attribute id

Reason:

No update occurred because the update command was entered with an invalid attribute_id.

Action:

Re-enter the update command with a valid attribute_id.

update <attribute_id> non shared attribute

Reason:

The update command was used for a model type and an attribute_id of a non-shared attribute was entered.

Action:

Re-enter the update command for the model type, this time using an attribute_id for a shared attribute.

update <instance_id> invalid instance id

Reason:

No update occurred because the update command was entered with an invalid instance_id.

Action:

Re-enter the update command with a valid instance_id.

update <landscape_handle> invalid landscape handle

Reason:

No update occurred because the update command was entered with an invalid landscape_handle.

Action:

Re-enter the update command with a valid landscape_handle.

update <model_handle> invalid model handle

Reason:

No update occurred since the update command was entered with an invalid model_handle.

Action:

Re-enter the update command with a valid model_handle.

update <model_type_handle> invalid model type handle

Reason:

No update occurred because the update command was entered with an invalid model_type_handle.

Action:

Re-enter the update command with a valid model_type_handle.

update <value> invalid value

Reason:

No update occurred because the update command was entered with an invalid value or values.

Action:

Re-enter the update command with valid values.

update <action_code> invalid action code

Reason:

No update occurred because the update command was entered with an invalid action_code.

Action:

Re-enter the update with a valid action_code.

VnmShd Error Failed to connect to SpectroSERVER

Reason:

The CLI Local Server failed to connect to the SpectroSERVER.

Action:

Verify that the SpectroSERVER is running.

VnmShd Error Lost connection with SpectroSERVER

Reason:

The CLI Local Server, detecting that the SpectroSERVER to which it was connected has terminated, terminates.

Action:

Restart the SpectroSERVER and then run the CLI Local Server.

UNIX to DOS Conversion

On the UNIX platform, CLI commands are typically used with UNIX commands in a terminal window. On the Windows platform, you can use CLI commands with DOS commands in a native DOS window. This appendix lists commonly used UNIX commands and their DOS equivalents.

NOTE
The appendix is intended to be a quick reference of UNIX and DOS commands rather than an exhaustive list. See your UNIX, DOS, or Windows documentation for more information about commands and their functions.

UNIX	DOS
#	rem
cat	type
cd	cd
chdir	chdir
clear	cls
cmp, diff	comp, fc
cp	copy
cp -r	xcopy
cpio, dump, tar, ufsdump	cpio, dump, tar, ufsdump
cpio, restore, tar, ufsrestore	restore
csh, sh	command
date	date, time
echo	echo
ed	edlin
exit	exit
exportfs, share	share
fdformat, format	format
format	fdisk
format->analyze	scandisk
fsck	chkdsk
goto (csh)	goto
grep	find
if	if
ln -s	subst
lp, lpr	print
ls	dir
ls -l	attrib
man	help
mkdir	md, mkdir
more	more
mv	move, ren, rename

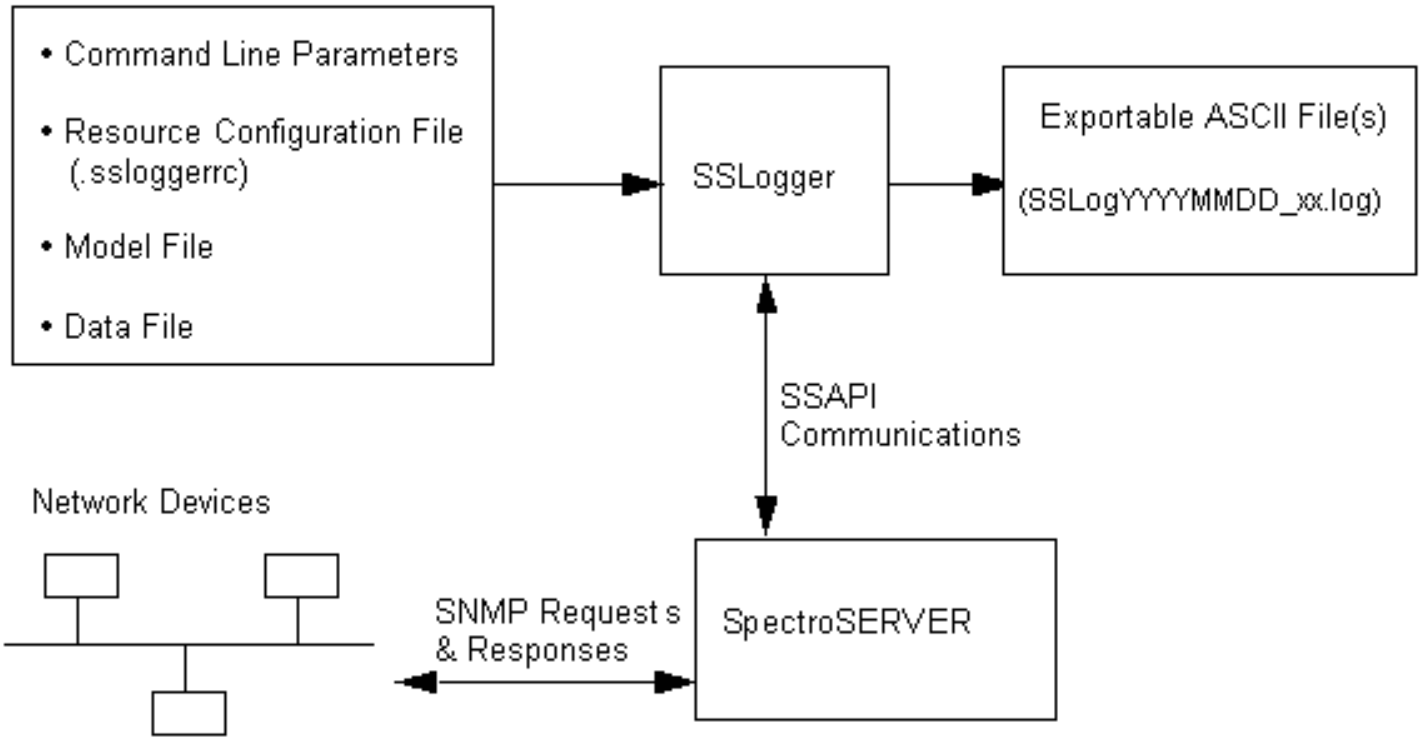
print (sh)	echo
rm	del, erase
rm -r	deltree
rmdir	rd, rmdir
set path= (csh), PATH= (sh)	path
set prompt= (csh), PS1= (sh)	prompt
set var= (csh), var= (sh)	set
shift	shift
showrev	ver
sort	sort
stty	mode
textedit, vi	edit
uncompress, unpack	expand

SSLogger

This section describes the SSLogger application and its benefits when compared with native DX NetOps Spectrum logging.

SSLogger is a DX NetOps Spectrum command-line application that works with SpectroSERVER to poll network devices and log the data to a simple ASCII file suitable for import into databases and reporting systems. As shown in the following diagram, you control SSLogger activity using command-line options and three input files (a configuration file, a model file, and a data file) which specify the target SpectroSERVER, the target devices and ports, the target attributes, the logging frequency per attribute, and the output file rotation frequency. SSLogger uses the SSAPI to communicate with SpectroSERVER, which obtains data from the target devices using SNMP requests. SSLogger then logs the specified data to an ASCII file, closing the current output file and creating a new one depending on your needs.

The following image illustrates the process that SSLogger uses to communicate with SpectroServer:



Benefits of SSLogger

SSLogger offers several advantages over DX NetOps Spectrum's native method of logging statistics:

- SSLogger lets you specify particular devices for which you want to log statistics. The DX NetOps Spectrum native method only allows you to specify the *types* of devices for which you want to log data, which means that you often are forced to poll and log more data than you want.
- SSLogger lets you set the polling and logging frequency for each attribute. The DX NetOps Spectrum native method only allows you to specify the frequency per model type.
- SSLogger writes data to a simple, readily exportable ASCII file. The v native method writes data to the Archive Manager's database, which requires additional steps to export the data.

Disabling DX NetOps Spectrum Native Logging

If you decide to log DX NetOps Spectrum statistics using SSLogger, you can turn off DX NetOps Spectrum native logging by setting the stat_logging_disabled flag to TRUE in DX NetOps Spectrum's /SS/.vnmrc file and then restarting SpectroSERVER. Setting this value to TRUE also turns off the polling of these logged attributes. It prevents DX NetOps Spectrum from using SNMP get actions to check attribute values and prevents DX NetOps Spectrum from writing the values to the Archive Manager database. This results in reduced device traffic as well as a reduced load on the Archive Manager database.

SSLogger Functionality When Contact Status is Lost

SSLogger functions differently when the contact status of a device (or group of devices) it is monitoring is lost. When SSLogger is scheduled to collect statistical data from a device and that device goes down, SSLogger will not write any data from the downed device to the .log file, effectively ignoring the device. SSLogger will not retry the downed device until the next scheduled poll cycle. SSLogger will continue to log data from devices that are up on the scheduled interval

with no interruption. Once DX NetOps Spectrum regains contact with the downed device, SSLogger will log its data on the configured scheduled interval.

SSLogger Input and Output

This section describes SSLogger input and output. It includes information about its command-line parameters as well as the content and syntax of the associated input files.

The SSLogger application uses the following four sources for input:

- Command-line parameters
- .ssloggerrc configuration file
- Model file
- Data file

Each of these input sources is described individually in this section.

Command-Line Parameters

You can use one or more of the following parameter flags with the SSLogger command. If you use these flags to specify a vnm, modelfile, or datafile that is different from the ones specified in your .ssloggerrc file, the values entered at the command line take precedence.

- **-help**
  Causes SSLogger to show a help message.
- **-vnm <*machine name*>**
  Specifies the target SpectroSERVER.
- **-modelfile <*model file name*>**
  Specifies the model file that SSLogger should use.
- **-datafile <*data file name*>**
  Specifies the data file that SSLogger should use.
- **-debug**
  Causes SSLogger to output debug information during operation.
- **-ctrace**
  Causes SSLogger to output SSLogger/SpectroSERVER communication information.
- **-strace**
  Causes SSLogger to output security information.

.ssloggerrc Configuration File

The SSLogger resource configuration file is named .ssloggerrc and contains the following keywords:

- **listen_port=**
  Specifies the port on which SSLogger communicates with the SpectroSERVER.
  Default: 0xd00f
- **vnm=**
  Specifies the target SpectroSERVER.
- **vnm_port=**
  Specifies the target SpectroSERVER communication port.
  Default: 0xbeef
- **modelfile=**
  Specifies the name of the model file that SSLogger should use.
- **datafile=**

Specifies the name of the data file that SSLogger should use.

- **max_threads=**
  Specifies the maximum number of worker threads that SSLogger should allocate for the work of logging attributes.
  Default: 30
- **thread_priority**
  Specifies the thread priority of each worker thread.
  Default: 80
- **debug_interval**
  Specifies how often (in seconds) SSLogger should output debug information if the -debug command line flag is used.
  Default: 600 seconds
- **max_oreq=**
  Specifies the maximum number of polling requests that SSLogger can have outstanding at one time. A zero (0) indicates that SSLogger can have an infinite number of outstanding requests. You can use this keyword to limit SSLogger's effect on SpectroSERVER performance.
  Default: 0

Model File

The model file specifies a list of devices that SSLogger will target. It can include devices of many different model types. Information is divided into four columns, as shown below.

```
#************************************************************
# modelfile
#
# This file specifies devices to monitor.
#************************************************************

0x40001a;   172.19.57.220;    0x1c80018;  2M46_04
0x40013c;   172.19.57.221;    0x1c80018;  2M46_04
0x40032c;   172.19.57.222;    0x1c80018;  2M46_04
0x4004ad;   172.19.57.223;    0x1c80018;  2M46_04
0x400063;   10.253.2.26;      0x2c60021;  RstoneSwRtr
0x400063;   10.253.2.27;      0x2c60021;  RstoneSwRtr
0x400063;   10.253.2.28;      0x2c60021;  RstoneSwRtr
0x400063;   10.253.2.29;      0x2c60021;  RstoneSwRtr
```

The entry for each device contains the model handle, model name, model type handle, and model type name. Semicolons are required. You can log statistics from a new device simply by adding a new line to the model file without changing the data file at all.

Data File

The data file tells SSLogger which attribute values to read. The file can include the keywords listed in this section.

group

The group keyword specifies a group of attributes. The name of the group is up to you. Information that defines each attribute in the group falls into the following five columns:

- The first column specifies the attribute name. You can use any name you want in this column, but it is recommended that you use the DX NetOps Spectrum attribute name as displayed in the CLI output in SSLogger Output.
- The second column specifies how often (in seconds) SSLogger should poll and log the attribute.
- The third column specifies the model type where the attribute is found. A value of 0x0 indicates the device model type.

NOTE
Under the example's port information group, there is a value of 0xd000a, which is the model type handle for port models.

- The fourth column is the DX NetOps Spectrum attribute ID.
- The fifth column specifies whether the attribute is a list/table attribute. The value.0 means the attribute is *not* a list/table attribute. Any other number or text means the attribute *is* a list/table attribute. You may want to put the OID in this field. The example below uses .1 to indicate a list/table attribute.

Example:

```
group: device_information
 sysUpTime            ; 10 ; 0x0 ; 0x10245 ; .0
 ipInReceives         ; 10 ; 0x0 ; 0x10098 ; .0
 ipOutRequests        ; 10 ; 0x0 ; 0x100a0 ; .0
 ifInOctets           ; 10 ; 0x0 ; 0x100cd ; .1
 ifOutOctets          ; 10 ; 0x0 ; 0x100d3 ; .1
group: port_information
 ifInOctets           ; 10 ; 0xd000a ; 0x10e41 ; .0
 ifOutOctets          ; 10 ; 0xd000a ; 0x10e42 ; .0
```

SSlogger_relation

When you want SSLogger to log attributes associated with a port that is associated with a device specified in your model file, you do not actually specify a port model handle. Instead, you specify the port's model type handle in the third column of an attribute line under a group keyword in the data file. You also specify how the port model is associated with the device model. This is done by using the SSlogger_relation keyword, one relation per keyword. If you do not specify any SSlogger_relation keywords, SSLogger will, by default, follow the two shown below. Otherwise, it will only follow the ones you specify.

```
SSlogger_relation: HASPART
SSlogger_relation: PossPrimApp
```

child_mtype_handles

The child_mtype_handles data file keyword affects *only* the display of the fourth column of the SSLogger output file. By default, only a device model handle appears in this column. By specifying the port model type handle under the child_mtype_handles keyword in the example data file below, you instruct SSLogger to display both the device model handle and the port model handle in the fourth column of the output file.

```
child_model_handles:
   0xd000a
```

mtype

The mtype keyword specifies a model type name and not a model name. This is how SSLogger interprets this keyword. For every device in the model file of this model type, poll and log the groups of attributes listed.

```
mtype: 2M46_04
   device_information
   port_information
```

Rotate_log_interval

The Rotate_log_interval keyword specifies how often (in hours or a fraction of an hour) SSLogger should close the current output file and open another one. If you do not specify this keyword, SSLogger will close the current output file and open a

new one at midnight every 24 hours. A value of 1 tells SSLogger to close the current output file at the top of the next hour and open a new output file. If the Rotate_log_interval value specified is .15, SSLogger will close the current output file and open a new output file every 15 minutes. If a value of 1.xx is entered, the value will be rounded to the nearest whole number. If you specify 2 and the current time is 2:25 p.m., SSLogger will close the current output file at 4:00 p.m., open a new file, close that file at 6:00 p.m., and so on.

on_rotate_execute

The on_rotate_execute keyword specifies a path to an executable to be run when the SSLogger log file is rotated. The path must be the full path to the executable. You must have read and executed privileges to run the executable.

```
on_rotate_execute: <full path to executable>
```

SSLogger Output

This section describes the content of the log file that is generated when you run SSLogger. SSLogger writes information to an ASCII file. The name of this output file is similar to the following: SSLog20010727_01.log.

> **NOTE**
> The filename contains the date. If you set the Rotate_log_interval keyword in the data file so that more than one SSLog file will be created in a single day, SSLogger increments the last two numbers in the output file name accordingly.

The output file is organized into the following seven columns, as shown below:

```
20010724; 10:17:26; 10:17:26; 0x40001a; -; 0x10245; 291399900
20010724; 10:17:26; 10:17:26; 0x40001a; 2; 0x100cd; 2041440626
20010724; 14:40:56; 14:40:56; 0x40001a:0x400040; -; 0x10e41; 1582426060
DATE ; START TIME ; END TIME ; MODEL HANDLE ; INTERFACE ; ATTRID ; VALUE
```

Each line in the file represents one reading of the attribute value:

- The first column indicates the date in YYYYMMDD format.
- The second column specifies the time just before SSLogger reads the attribute.
- The third column specifies the time just after SSLogger reads the attribute.
- The fourth column specifies the model handle of the model for which the attribute value is read. If you enter the port model type handle (0xd000a) under the child_mtype_handles keyword in the data file, this column will display both the device model handle and the port model handle.
- The fifth column displays a dash (-) if the attribute is *not* a list/table attribute. Otherwise, it displays the index number of a list/table attribute.
- The sixth column displays the attribute ID.
- The seventh column shows the attribute value itself.

Examples to Use SSLogger

This section provides detailed examples of how to use SSLogger in three different scenarios of increasing complexity. These examples will help you understand how to use SSLogger to log different types of DX NetOps Spectrum statistics. The examples are designed to let you follow along on your own system, creating your own input files and substituting your own and model ID values for the ones used in the examples. Sample output files are also provided. Although it is likely that most users will want to use SSLogger to log statistics associated with individual ports (interfaces) on network devices, the examples start with a simpler scenario and work their way up to the logging of ports. It is strongly suggested that you work through each of these three examples in succession before setting up your own production SSLogger scenario.

Set Up SSLogger

Before using the three examples, you should complete the setup procedure described here.

To set up SSLogger

1. Launch SpectroSERVER and OneClick.
2. Model a device (or choose one that you have already modeled) and write down the name of the device for future reference.
3. Create a text file called “modelfile” in the DX NetOps Spectrum SSLogger directory.
4. Type the following into the file and then save and close the file:

```
#*********************************************************************
# modelfile
#
# This file specifies devices to monitor.
#*********************************************************************
Create another text file called "datafile" in the SSLogger directory.
Type the following into the file and then save and close the file.
#*********************************************************************
# datafile
#
# This file specifies device information to monitor.
#*********************************************************************
```

   Open /SSLogger/.ssloggerrc with a text editor and modify it to reflect the name of your SpectroSERVER (vnm name) and the names of your model file and data file name. This file provides default parameters for running SSLogger. You can override the vnm, modelfile, and datafile settings by entering alternate values at the command line as needed.

```
listen_port=
vnm=<your SpectroSERVER name>
vnm_port=
modelfile=modelfile
datafile=datafile
max_threads=
thread_priority=
debug_interval=
max_oreq=
```

5. Start the Command Line Interface (CLI) from a terminal/Command Prompt window on your machine by navigating to the vnmsh directory and entering the following command:

```
./connect
```

   You are now ready to perform the steps involved in the following three examples.

Example 1 Logging Device Statistics

To complete the first example, you must modify your model and data files, run SSLogger, and analyze the output file.

Modify the Model File

The model file specifies the device models that you want SSLogger to target, or log statistics from. In this example, you will specify only one device model. However, you can list hundreds or thousands of devices in this file if desired.

To modify the model file

1. From the DX NetOps Spectrum vnmsh directory, enter the following CLI command:

```
./show models mname=<name of your model>
```

A list of all models whose name begins with the specified model name appears, identifying each model by model handle, model name, model type handle, and model type name. DX NetOps Spectrum often uses IP addresses to name models. The following sample output shows what the list might look like if the IP address 172.19.57.220 is used as the model name.
The entry with the model handle value 0x40001a represents the device, while the other models represent applications or ports of that device.

```
0x400059     172.19.57.220_IC   0x230012    ICMP_App
0x400056     172.19.57.220_Do   0x230052    CtDownLoadApp
0x400022     172.19.57.220_FD   0xd80004    FddiMAC
0x40004b     172.19.57.220_St   0x590006    RMONApp
0x40005b     172.19.57.220_IP   0x230016    IP2_App
0x400057     172.19.57.220_RS   0x230046    RFC1317App
0x40005d     172.19.57.220_DS   0xc40006    DS1App1406
0x40001a       172.19.57.220     0x1c80018   2M46_04
0x40001f     172.19.57.220_Tr   0xd0031     CT_Tp_Appl
0x40004a     172.19.57.220_21   0xd000a     CSIIfPort
```

2. Find your device in the resulting list, then add all four of the device information values to the model file you set up. For the device in this example, the model file would appear as follows:

```
#*************************************************************
# modelfile
#
# This file specifies devices to monitor.
#*************************************************************
0x40001a    172.19.57.220     0x1c80018   2M46_04
```

3. Separate the four device information values with semicolons, as shown below.

```
#*************************************************************
# modelfile
#
# This file specifies devices to monitor.
#*************************************************************

0x40001a;   172.19.57.220;    0x1c80018;  2M46_04
```

Modify the Data File

The data file specifies the attributes for which you want to log values. In this example you will use the following three attributes:

- ipInReceives
- ipOutRequests
- sysUpTime

To build the data file

1. From the vnmsh directory, enter the following CLI command using the model type handle for your device model from the third column in your model file:

```
./show attributes mth=<your model type handle> flags=E
```

All of the specified model type's attributes for which the external (E) flag is set are listed. For each attribute, the list shows the attribute ID, attribute name, attribute type, and attribute flag or flags.
The following sample output shows what the list might look like if the 172.19.57.220 device's model type handle of 0x1c80018 is used.

```
0x10098     ipInReceives         Counter      E,R
0x10099     ipInHdrErrors        Counter      E,R
```

```
0x1009a     ipInAddrErrors       Counter      E,R
0x1009b     ipForwDatagrams      Counter      E,R
0x1009c     ipInUnknownProtos    Counter      E,R
0x1009d     ipInDiscards         Counter      E,R
0x1009f     pInDelivers          Counter      E,R
0x100a0     ipOutRequests        Counter      E,R
0x100a1     ipOutDiscards        Counter      E,R
0x100a2     ipOutNoRoutes        Counter      E,R
0x101c1     icmpOutAddrMaskReps  Integer      E,R
0x10245     sysUpTime            Time Ticks   E,R,M,P
0x10b5a     sysContact           Text String  E,R,W,M
0x10b5b     sysName              Text String  E,R,W
```

2. In the output that you generate, find the three attributes targeted in this example (ipInReceives, ipOutRequests, and sysUpTime), and then add their names and IDs to your data file along with the model type name of your model so that it looks like the following example:

```
#*************************************************************
# datafile
#
# This file specifies device information to monitor.
#*************************************************************
group: device_information
 sysUpTime            ; 10 ; 0x0 ; 0x10245 ; .0
 ipInReceives         ; 10 ; 0x0 ; 0x10098 ; .0
 ipOutRequests        ; 10 ; 0x0 ; 0x100a0 ; .0
mtype: <model type name of your model>
 device_information
```

   In this data file example, group is an SSLogger data file keyword referring to a group of attributes. You can name a group anything you want. In this case, the device_information group includes the three target attributes, and there are five columns of information about them. The first column specifies the attribute name. You can use any name, but it is suggested that you use the DX NetOps Spectrum names as they appear in the output from Step 1. The second column tells SSLogger how often (in seconds) to poll and log the attribute value associated with the attribute. A polling interval of once every ten seconds would normally be too frequent, but it is used in this example to give you a large amount of output data in a short time. It is recommended that you set the polling interval to the same value as the Rotate_log_interval. The third column specifies the model type where the attribute is found. 0x0 indicates the *device* model type. In a later example, you will set this field to a *port* model type handle for certain attributes. The fourth column specifies the DX NetOps Spectrum attribute ID. The fifth column indicates whether the attribute is a list attribute; in this case the .0 means the attribute is *not* a list attribute.

Run SSLogger

To run SSLogger, enter the following command from the SSLOGGER directory:

```
./SSlogger
```

A message similar to the following appears:

```
sslogger version 3.0rev0 -- built on Jul 3 2001 at 09:33:13
SSlogger started at: Fri Jul 27 10:36:55 2001
```

Tail the SSLogger Output File

While SSLogger is running, you can look at the output file by using the “tail” command and specifying the name of the file, which contains the current date in YYYYMMDD format followed by a two-digit sequence number and a .log extension. For example, the first log file created by SSLogger on September 12, 2001 would be named SSLog20010912_01.log.

NOTE
See Rotate_log_interval for more information on how log files are sequenced and closed.

Assuming this is the currently active log file, you could view statistics being added to the end of the file by entering the following command from the SSLOGGER directory:

```
tail -f SSLog20010912_01.log
```

Replace the filename in the tail command above with the name of your own SSLogger output file, execute the command, and you will see a display similar to the following example.

```
1 20010718; 10:51:43; 10:51:43; 0x40001a; -; 0x10245; 239765127
2 20010718; 10:51:43; 10:51:43; 0x40001a; -; 0x10098; 1152773
3 20010718; 10:51:43; 10:51:43; 0x40001a; -; 0x100a0; 1142885
4 20010718; 10:51:53; 10:51:53; 0x40001a; -; 0x10245; 239766128
5 20010718; 10:51:53; 10:51:53; 0x40001a; -; 0x10098; 1152774
6 20010718; 10:51:53; 10:51:53; 0x40001a; -; 0x100a0; 1142886
7 ...
```

The output file contains seven columns of information:

- The first column shows the date.
- The second column shows the time just before SSLogger reads the attribute value.
- The third column shows the time just after SSLogger reads the attribute value.
- The fourth column shows the device model handle.
- The fifth column shows “-” if the attribute is *not* a list attribute. Otherwise, as seen in a later example, it shows the table index.
- The sixth column shows the attribute ID.
- The seventh column shows the attribute value.

NOTE
For more information about the output file contents, see SSLogger Output.

Example 2 Logging List Attribute Statistics

In Example 1, you logged single-value device attributes. Example 2 shows you how to log *list* attributes or tables of attribute data. As with the first example, this means modifying your data file, running SSLogger, and examining the resulting output file data.

Log List Attribute Statistics

In this example you will use the following two attributes:

- ifInOctets
- ifOutOctets

To log list attribute statistics

1. From the DX NetOps Spectrum vnmsh directory, enter the following CLI command using the model type handle for your device model from the third column in your model file:

   ```
   ./show attributes mth=<your model type handle> flags=ET
   ```

   Because you use the “E” and “T” flags, this command will list all of the specified model type's attributes for which the external (E) and table (T) flags are set. For each attribute, the list will show the attribute ID, attribute name, attribute type, and attribute flag or flags. The following sample output shows what the list might look like if the 172.19.57.220 device's model type handle of 0x1c80018 is used.

   ```
   0x100cd     ifInOctets            Counter           E,R,[]
   0x100ce     ifInUcastPkts         Counter           E,R,[]
   ```

```
0x100cf     ifInNUcastPkts         Counter           E,R,[]
0x100d0     ifInDiscards           Counter           E,R,[]
0x100d1     ifInErrors             Counter           E,R,[]
0x100d2     ifInUnknownProtos      Counter           E,R,[]
0x100d3     ifOutOctets            Counter           E,R,[]
0x100d4     ifOutUcastPkts         Counter           E,R,[]
```

2. In the output that you generate, find the two attributes targeted for this example (ifInOctets and ifOutOctets) and add their names and IDs to your data file so that it looks like the following example:

```
#*************************************************************
# datafile
#
# This file specifies device information to monitor.
#*************************************************************
group: device_information
 sysUpTime            ; 10 ; 0x0 ; 0x10245 ; .0
 ipInReceives         ; 10 ; 0x0 ; 0x10098 ; .0
 ipOutRequests        ; 10 ; 0x0 ; 0x100a0 ; .0
 ifInOctets           ; 10 ; 0x0 ; 0x100cd ; .1
 ifOutOctets          ; 10 ; 0x0 ; 0x100d3 ; .1
mtype: <model type name of your model>
 device_information
```

NOTE
The new lines have ".1" at the end which indicates that these attributes represent tables of information. Any value except ".0" indicates that the attribute is a table attribute. So you may want to put a complete OID in place of ".1" for documentation purposes.

3. Run SSLogger.
4. Tail the SSLogger output file. Again, you can look at the output file by using the "tail" command and specifying the name of the file, which should be the same as the name you used in the first example (see SSLogger Output for information on how and when new output files are opened). To do this, enter the following command from the SSLOGGER directory:

```
tail -f SSLog<current date in YYYYMMDD format>_01.log
```

This time your output should appear as follows:

```
20010724; 10:17:26; 10:17:26; 0x40001a; 1; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 1; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; -; 0x10245; 291399900
20010724; 10:17:26; 10:17:26; 0x40001a; -; 0x10098; 1307231
20010724; 10:17:26; 10:17:26; 0x40001a; -; 0x100a0; 1297366
20010724; 10:17:26; 10:17:26; 0x40001a; 2; 0x100cd; 2041440626
20010724; 10:17:26; 10:17:26; 0x40001a; 2; 0x100d3; 2308773051
20010724; 10:17:26; 10:17:26; 0x40001a; 3; 0x100cd; 2794679535
20010724; 10:17:26; 10:17:26; 0x40001a; 3; 0x100d3; 2497597136
20010724; 10:17:26; 10:17:26; 0x40001a; 4; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 4; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 5; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 5; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 6; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 6; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 7; 0x100cd; 183630755
20010724; 10:17:26; 10:17:26; 0x40001a; 7; 0x100d3; 176510228
20010724; 10:17:26; 10:17:26; 0x40001a; 14; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 14; 0x100d3; 0
```

```
20010724; 10:17:26; 10:17:26; 0x40001a; 15; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 15; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 16; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 16; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 17; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 17; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 18; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 18; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 19; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 19; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 20; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 20; 0x100d3; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 21; 0x100cd; 0
20010724; 10:17:26; 10:17:26; 0x40001a; 21; 0x100d3; 0
```

NOTE
The fifth column shows the table index on lines that represent table attribute data.

Example 3 Logging Port Statistics

This example shows how to log statistical information associated with a port. Once again, you will modify your data file, run SSLogger, and look at the output file. Note that you do *not* have to modify the model file, nor do you have to specify the model handles of the port models at all. Instead of stipulating port model handles, you will specify port model *type* handles and DX NetOps Spectrum relations. In this example you will also use the ifInOctets and ifOutOctets attributes.

Log Port Statistics

To log port statistics

1. From the vnmsh directory, enter the following CLI command using the model handle for your device model from the first column in your model file:

   ```
   ./show children rel=HASPART mh=<your model handle>
   ```

   This CLI command shows you the port models associated with your target device. You need to execute this command to determine the model type handles of the ports you want to target. In this case, all ports are the same model type. The sample output below shows what the list might look like using the 0x40001a model handle from the first example.

   ```
   MHandle     MName             MTypeHnd    MTypeName        Relation
   0x40003f    172.19.57.220_1   0xd000a     CSIIfPort        HASPART
   0x400040    172.19.57.220_2   0xd000a     CSIIfPort        HASPART
   0x400041    172.19.57.220_3   0xd000a     CSIIfPort        HASPART
   0x400042    172.19.57.220_5   0xd000a     CSIIfPort        HASPART
   ```

2. If your output shows several different kinds of ports, select one port model type and use its model type handle in the following command:

   ```
   ./show attributes mth=<your port model type handle> flags=E
   ```

   This returns a list of external attributes associated with the specified port model type as shown here:

   ```
   0x10e3f     ifAdminStatus             Integer       E,R,W,[]
   0x10e40     ifOperStatus              Integer       E,R
   0x10e41     ifInOctets                Counter       E,R
   0x10e42     ifOutOctets               Counter       E,R
   0x11315     ifInUcastPkts             Counter       E,R
   0x11317     ifInNUcastPkts            Counter       E,R
   0x11318     ifInDiscards              Counter       E,R
   0x11319     ifInErrors                Counter       E,R
   ```

```
0x1131a     ifInUnknownProtos         Counter       E,R
```

Your command output may or may not show the attributes ifInOctets and ifOutOctets. If not, you will have to choose a few of your own to use as you follow along with this example.

3. Add a new group called port_information to your data file, and then enter the attribute name, model type handle (not 0x0, which indicates device models), and attribute ID for each of your attributes. Finally, add the information for the SSlogger_relation and child_mtype_handles so that your data file looks like the example shown below.

```
#************************************************************
# datafile
#
# This is a sample data input file for sslogger.
#************************************************************
group: device_information
 sysUpTime            ; 10 ; 0x0 ; 0x10245 ; .0
 ipInReceives         ; 10 ; 0x0 ; 0x10098 ; .0
 ipOutRequests        ; 10 ; 0x0 ; 0x100a0 ; .0
 ifInOctets           ; 10 ; 0x0 ; 0x100cd ; .1
 ifOutOctets          ; 10 ; 0x0 ; 0x100d3 ; .1
group: port_information
 ifInOctets           ; 10 ; 0xd000a ; 0x10e41 ; .0
 ifOutOctets          ; 10 ; 0xd000a ; 0x10e42 ; .0
SSlogger_relation: HASPART
child_mtype_handles:
 0xd000a
mtype: <model type name of your model>
 device_information
 port_information
```

The SSlogger_relation keyword specifies which relations SSLogger should follow between any devices specified in your model file and any models of model types specified in the attribute lines of your data file. In this example, the value for this keyword is HASPART because that is the relation a DX NetOps Spectrum device model has to its port models.

NOTE
You can see a list of all DX NetOps Spectrum relations using the CLI “show relations” command.

The child_mtype_handles keyword affects ONLY the display of the fourth column of the SSLogger output file (see example in following section). By default, only a device model handle appears in this column. By specifying the port model type handle under the child_mtype_handles keyword, you instruct SSLogger to display *both* the device model handle and the port model handle in the fourth column of the output file.

4. Run SSLogger.
5. Once again, look at the output file by using the “tail” command and specifying the name of the SSLog file, which should be the same as the name you used in the previous examples (see SSLogger Output for information on how and when new output files are opened). To do this, enter the following command from the SSLOGGER directory:

```
tail -f SSLog<current date in YYYYMMDD format>_01.log
```

Your output should appear similar to the following sample:

```
20010718; 14:40:56; 14:40:56; 0x40001a; -; 0x10245; 241140428
20010718; 14:40:56; 14:40:56; 0x40001a; -; 0x10098; 1159008
20010718; 14:40:56; 14:40:56; 0x40001a; -; 0x100a0; 1149142
20010718; 14:40:56; 14:40:56; 0x40001a:0x400040; -; 0x10e41; 1582426060
20010718; 14:40:56; 14:40:56; 0x40001a:0x400040; -; 0x10e42; 1808004560
20010718; 14:40:56; 14:40:56; 0x40001a:0x400041; -; 0x10e41; 2251080181
20010718; 14:40:56; 14:40:56; 0x40001a:0x400041; -; 0x10e42; 1999870610
20010718; 14:40:56; 14:40:56; 0x40001a:0x400042; -; 0x10e41; 0
20010718; 14:40:56; 14:40:56; 0x40001a:0x400042; -; 0x10e42; 0
```

```
20010718; 14:40:56; 14:40:56; 0x40001a:0x40003f; -; 0x10e41; 0
20010718; 14:40:56; 14:40:56; 0x40001a:0x40003f; -; 0x10e42; 0
```

NOTE
Both the device and port model handles appear in the fourth column as described previously.

CA Business Intelligence (CABI)

CA Business Intelligence (JasperReports® Server) Documentation

Report Manager

DX NetOps Spectrum Reporting provides an analysis of the inventory, availability, changes, performance, and fault history of the network assets that are managed in DX NetOps Spectrum. You can share reports throughout the enterprise. DX NetOps Spectrum Reporting compiles the required data and presents it in a specified format.

The DX NetOps Spectrum Reporting data server extracts data from the DX NetOps Spectrum knowledge base and stores it in the reporting database. You can generate reports that provide information on various aspects of network assets that are relevant to an organization. DX NetOps Spectrum Reporting addresses the information requirements of not only the Information Technology (IT) group, but also of other groups in your organization.

DX NetOps Spectrum Reporting helps you make informed decisions on IT assets, and provides the following information:

- Assets that have the most issues.
- Events and Alarms that recur frequently.
- Number of routers or other gateway devices from a specific vendor that are deployed in the network.
- Devices that are the most and least frequently offline.
- Modified and deleted assets.

Report Customization

DX NetOps Spectrum Reporting lets you customize and specify the type of content to include in reports. You can specify how the data is organized and represented using text and graphics. Customization features include the following options:

- Detailed or summary versions of the asset information. Detailed information includes subviews for report items such as devices, ports, or vendors.
- Information that is organized by asset type, landscape, vendor, or global collections.
- Historical period -- asset information from an earlier day, week, month, year, a specific date range, or business day hours.
- Report layout -- title, subtitle, header and footer text, and sort order.
- Charts and graphs.
- Do-it-yourself Ad Hoc reports.
  For more information, see Generating Ad Hoc Reports.

Report Scheduling

DX NetOps Spectrum Reporting lets you set up, save, and schedule reports to run on a one-time or periodic basis. When you schedule a report, DX NetOps Spectrum Reporting automatically generates it at the time you specify and saves the report results. You can schedule reports for other users and also configure email reports to any number of recipients.

Reports On Demand

Running reports interactively, or on demand, provides the flexibility to generate the most recent and required information. The report on demand feature lets you perform the following actions:

- Experiment with various report types and configurations. Testing can be performed to select the reports that you want to schedule.
- Investigate acute problems or trends that occur in an IT infrastructure by generating reports over various intervals and settings.

Ad Hoc Reports

The DX NetOps Spectrum Ad Hoc Reporting feature enables you to define your own reports. DX NetOps Spectrum Ad Hoc Reporting lets you drag-and-drop data objects to construct reports that are specific to your environment. The data objects that are available in the Ad Hoc environment represent a significant subset of DX NetOps Spectrum attributes that support a wide range of custom reporting requirements.

DX NetOps Spectrum Ad Hoc Reporting lets you define all aspects of a report. You can select the data objects, parameters, and layout, using WEBI features.

For more information, see Generating Ad Hoc Reports.

Report Publishing

DX NetOps Spectrum Reporting lets you print and save reports in the following formats that accommodate the publishing, presentation, and recordkeeping requirements of your organization:

- Microsoft® Excel®
- Microsoft® Word®
- PDF
- RTF
- XML
- Crystal Reports® (RPT)
- Comma-separated values (CSV)

Report Types

To accommodate the diverse information requirements in your organization, you can generate various reports. DX NetOps Spectrum reports are grouped into report packs. Each report pack includes predefined reports that provide a specific type of information about your network assets.

Standard report packs include the following types of reports:

- **Alarm**
  Alarm reports generate historical information about alarm events for assets in the IT infrastructure. Alarm reports can assess the network health, identify alarm trends, find recurring or cyclical problems, and locate assets with past alarms.
- **Asset**
  Asset reports generate information about the inventory of assets in the IT infrastructure, including information about asset port availability and asset firmware versions. Asset reports can be used to determine how vendor products are distributed throughout the infrastructure. You can assess whether they are being used effectively and can identify opportunities for improvement.
- **Availability**

Availability reports provide historical information about uptime and downtime for assets in the IT infrastructure. A Projected-Availability report lets you determine the downtime that assets can sustain before they violate a threshold or SLA.
Note: Consult a DX NetOps Spectrum Reporting administrator for information about exemptions for planned outages or outages that occur on holidays.

- **Event**
  Event reports provide information about DX NetOps Spectrum events that are generated for DX NetOps Spectrum models. You can generate event reports for all models or for selected models. You can also generate reports that contain ranked lists of the most frequently occurring events during specific time periods. Event filtering options let you supply event codes to include or exclude from all event reports.

Upgrade reports include the following reports:

- **Legacy Reports**
  Legacy reports are scheduled reports that are migrated from previous DX NetOps Spectrum Reporting versions during an upgrade.

DX NetOps Spectrum Reporting also supports the following optional report packs:

- **Network Configuration Management (NCM)**
  Network Configuration Management (NCM) reports provide information about network configuration activities that NCM recorded. For more information, see the Network Configuration Manager section.

  NOTE

  NCM must be installed with OneClick to enable the NCM reports. There are no out of the box reports for NCM, a Jasper customer, can use the NCM domain to create their reports (ad hoc reports).

- **Response Time**
  Response Time reports provide information about response time test results and analysis that DX NetOps Spectrum Service Performance Manager compiled. The Response Time report pack includes trend and exception reports which help you troubleshoot response time issues before they become problems for end-users. Reports graphically depict past performance and trends in response times. Exception or Top N reports detail the areas where proactive action can be taken to avoid critical issues. For more information, see the Service Performance Manager section.

  NOTE
  DX NetOps Spectrum Service Performance Manager must be installed with OneClick to enable the Response Time reports.

- **Service and SLA**
  Service and SLA reports provide summary and historical information about service and Service Level Agreements (SLAs). The reports focus on service customer models that are created and managed with DX NetOps Spectrum Service Manager. Service and SLA reports enable you to track service assets, gauge service health, and analyze results to determine how to improve service performance.

  NOTE
  Service Manager must be installed with OneClick to enable the Service and SLA reports.

- **Virtual Private LAN Service (VPLS) Reports** (available if the DX NetOps Spectrum VPLS Manager application is installed with OneClick)
  DX NetOps Spectrum VPLS Manager is a DX NetOps Spectrum add-on management application for service providers who are deploying VPLS technology. By integrating DX NetOps Spectrum VPLS Manager with DX NetOps Spectrum Reporting, you can view reports for monitoring the health of your VPLS environment. For more information, see the VPLS Manager Solution section.

CA Business Intelligence - JasperReports Server

Refer to the CA Business Intelligence JasperReports® Server Documentation

Using Reports

This section describes the procedure to use, generate and schedule Reports.

Use BI Launch Pad to Generate Reports

You can access BI Launch Pad from the OneClick home page to generate and manage reports.

Consult your OneClick administrator for the following information:

- Supported Web browsers.
- CABI login credentials to access BI Launch Pad.

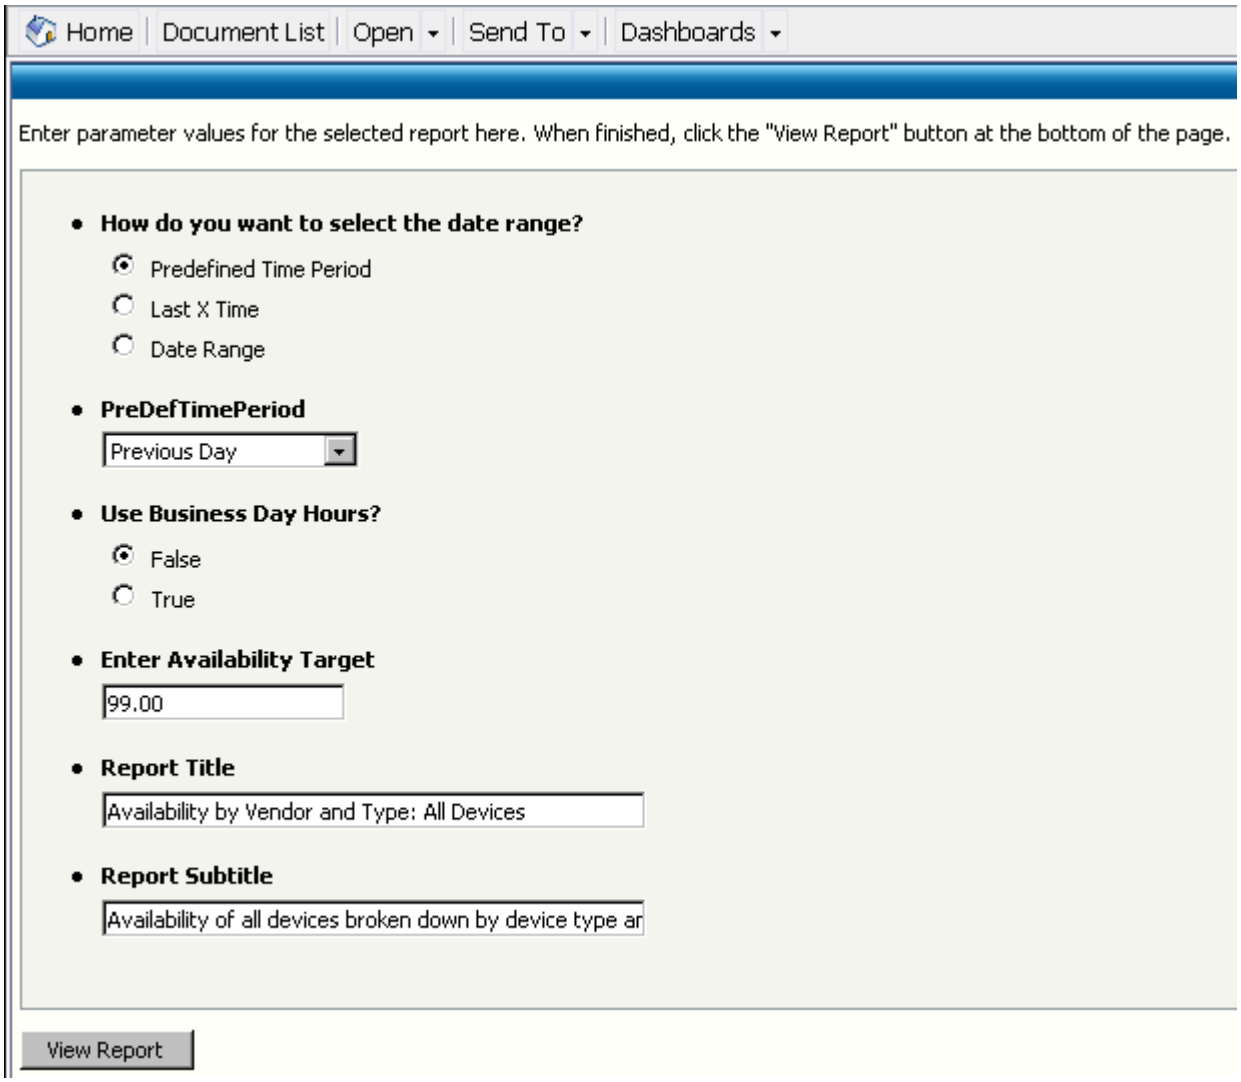
Follow these steps:

1. Log in to OneClick.
2. Click the BI Launch Pad tab in the OneClick Console.
   The BI Launch Pad window opens.

   NOTE
   You can also open BI Launch Pad directly from a Web browser to access DX NetOps Spectrum reports. The typical URL format is as follows:

   ```
   http://<hostname>/BILaunchPadApp
   ```
3. Click the Document List folder.
   The Document List folder lets you view all BI Launch Pad reports, including DX NetOps Spectrum reports.
4. Select the Public Folders, and then CA Reports.

   NOTE
   You can set the CA Reports folder as the BI Launch Pad start page through the Preferences section. For more information, see the CA Business Intelligence Implementation section.
5. Select DX NetOps Spectrum Reports.
   You can access report packs to which you have been granted rights. Consult your administrator for assistance if you cannot access a report pack.
6. Specify the parameter values for the selected report.
   The following image shows the parameter settings for an 'Availability by Vendor and Type: All Devices' report.



7. Click View Report.
   The report displays.
8. To Export/Save a report, click the Export icon and select the report type to save.
   The report is saved.

Understanding Report Parameters

When you generate a DX NetOps Spectrum report, a Parameter dialog lets you specify parameters applicable to the report.

All reports include a report title and subtitle that you can customize. Date range parameters let you generate reports that provide historical information on the availability of assets and their associated changes and problems.

Reports also include parameters for specifying graphical or tabular representations of information.

Usernames and Passwords

OneClick users are automatically added to CABI. The default CABI password is the username. Change the default password at your initial login.

If a default CABI password is set, contact the Spectrum Report Manager administrator to reset the password. For more information, see the Install Report Manager section.

The administrator can add users directly to CABI using the Central Management Console (CMC). CMC is a web-based tool that offers a single interface to perform administrative tasks, including user, content, and server management. CMC lets you publish, organize, and set security levels for your BusinessObjects Enterprise content. For more information, see the CA Business Intelligence Integration section.

Generate a Report in a Secure Environment

In DX NetOps Spectrum Spectrum Report Manager, model-based security is introduced to ensure that you can only report on models to which you have access. DX NetOps Spectrum Reporting honors the model-based security implementation that you have established in OneClick.

For DX NetOps Spectrum Reporting users that exist as OneClick users, user access resolution includes the following components:

- User security communities
- Landscape membership
- DX NetOps Spectrum Reporting View Data permission with a model landscape
- Security String to determine the model accessibility

The following picture illustrates the new access resolution process:

NOTE
For DX NetOps Spectrum Reporting users who lack corresponding OneClick accounts, unlimited reporting access to all models is initially provided.

If you have access to a model during the resolution process, you can effectively report on the model. If a model is inaccessible, any information pertaining to that model is absent from the reports (such as details associated with the model or model values in aggregations).

For more information, see the Install Report Manager section.

Displaying Graphical Elements in Reports

DX NetOps Spectrum Reporting lets you use graphical elements in many reports to represent various types of information on network assets. For example, frequency, proportion, and trends. You can use the graphical elements to generate reports that you plan to include in briefings and presentations for diverse (for example, technical and non-technical) audiences.

The following graphical elements are displayed in DX NetOps Spectrum reports.

Bar Graphs:

DX NetOps Spectrum Reports use bar graphs to display report results that indicate the volume and the relative frequency with which something occurred on an asset (such as, alarms) or a comparative ranking of various assets (such as, availability).

A bar graph from an alarm report illustrates the number of alarms that occurred for a particular group of assets over a particular time period. The graph indicates the number and proportion of alarms for each asset in the group.

Pie Charts:

DX NetOps Spectrum Reports use pie charts to display the percentage breakdown of report results in terms of proportion.

For example, a pie chart displays the following assets:

- An equivalent proportion of switch-routers and switches.
- A greater proportion of routers.
- A small proportion of non-specific pingable devices in the network segment.

Line Charts:

DX NetOps Spectrum Reports use line charts in Response Time reports to graph continuous data over time. Line charts indicate fluctuations in latency measured in milliseconds over a specific time period.

Color Indicators:

DX NetOps Spectrum Reports use the condition color indicators for alarm severity and alarm entries in Alarm reports. A color scheme specific to DX NetOps Spectrum is used to indicate threshold compliance levels in Availability reports.

Schedule a Report

You can schedule a report from the Schedule window. To run scheduled reports correctly, select options on the Parameters page.

Follow these steps:

1. Log in to OneClick.
2. Click the BI Launch Pad tab in the OneClick Console.
   The BI Launch Pad window opens.
3. Select Documents List, Folders, Public Folders, CA Reports, and DX NetOps Spectrum.
   A list of DX NetOps Spectrum reports display.
4. Select a report.
5. Right-click and select Schedule.
   The Schedule window appears.
6. Click Prompts.
   The Prompts page displays.
   The Prompts page is dynamic and provides various fields depending on the report values required. The Prompts page also displays when you run a report on demand.
7. Specify the values in the Prompts page.

8. Click the Schedule button.
   The report is scheduled.

View Scheduled Reports

After you schedule a report, you can verify the schedule by checking scheduled instances of that report.

The history report can be set to show all instances, instances that you own, and instances that are completed. In addition, you can filter instances by time.

If multiple scheduled reports are created from the same on-demand report, all instances for the scheduled reports are listed. You can organize the instance list by sorting on the Title column.

Follow these steps:

1. Navigate to the BI Launch Pad window.
2. Select Document List, Public Folders, CA Reports, and DX NetOps Spectrum.
   A list of DX NetOps Spectrum reports display.
3. Select the report.
4. Right-click and select History.
   The History window shows a history of scheduled instances for that report.

Print a Report

You can print any report from the report view, from a duplicate report view, and from a report subview. During the printing setup process, DX NetOps Spectrum Reporting saves a report to a PDF file. You can print or you can save the pdf file.

NOTE
You must have Adobe Acrobat Reader installed to print a report.

Follow these steps:

1. Navigate to the BI Launch Pad window.
2. Select Document List, Public Folders, CA Reports, and then DX NetOps Spectrum.
   A list of DX NetOps Spectrum reports display.
3. Select the report to print.
4. Click Print this Report (Do *not* use your browser print icon).
   The Print to PDF window opens.
5. Select All Pages to print the entire report, or specify the page range in the From and To fields.
6. Click Export.
   The File Download dialog opens.
7. Perform one of the following steps:
   - Print the report now:
     a. Click Open With in the File Download dialog. The report opens as a PDF file in Adobe Acrobat Reader.
     b. Use the Adobe Acrobat Reader print options to print the report. (You can also save the report to your computer from the Adobe window).
   - Save the report, and print it later:
     a. Click Save File in the File Download dialog to open the Save As window.
     b. Enter a filename (in place of the default filename, ReportViewer) and save it as an Adobe Acrobat document.

   The report is printed.

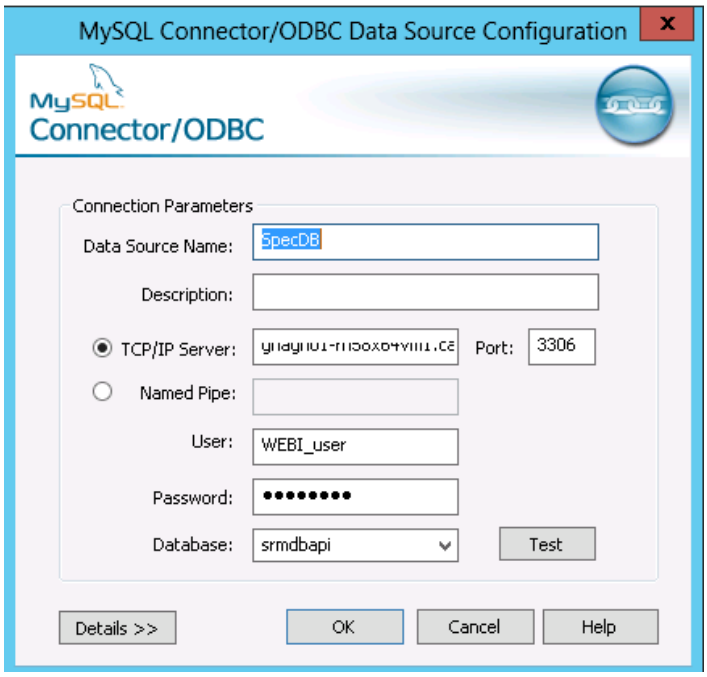
Generating Ad Hoc Reports

Starting from the 10.0 release, Ad Hoc reports use ODBC for accessing reporting database. You must create a data source name (DSN) on the CABI host, which connects to a SRM Host in OneClick.

The following section describe the procedures to configure DSN in Windows and Linux operating systems.

For Windows:

1. Go to Windows Administrative tools
2. Open ODBC Data Sources (64-bit) and add a System DSN with name “SpecDB” as shown below:



3. Similarly, create another DSN in ODBC Data Sources (32-bit) as well.
   If you do not see the MySQL ODBC driver, please download the connectors from https://dev.mysql.com/downloads/connector/odbc/5.1.html
4. Restart CABI Servers.

For Linux:

I. Installing UNIX ODBC Driver

1. Copy unixODBC-2.3.2.tar.gz package
   Download lin:http://www.unixodbc.org/unixODBC-2.3.2.tar.gz
2. Unzip and untar unixODBC-2.3.2.tar.gz
3. From unixODBC-2.3.2, run the following command to install ODBC manager:
   'yum install unixODBC unixODBC-devel'

II. Installing Mysql ODBC Driver

1. Download MySQL ODBC Driver mysql-connector-odbc-5.1.13-linux-el6-x86-64bit.tar
   Refer site link: https://dev.mysql.com/downloads/connector/odbc/5.1.html
2. Untar mysql-connector-odbc-5.1.13-linux-el6-x86-64bit.tar
3. Copy the lib and bin folder content to /usr/local/lib64 and /usr/local/bin respectively

III. Setting up ODBC configuration Execute the following steps as a CABI Install user

1. Create an environment variable with ODBCINI

ODBCINI=<CABI install directory>/sap_bobj/enterprise_xi40/odbc.ini

2. Add or update the LD_LIBRARY_PATH environment variable in
   <CABI install directory>/sap_bobj/setup/env.sh
   export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/local/lib64:/usr/lib64

   NOTE

   The path added above must be to the location of the libodbc.so and libodbcinst.so files which are installed with the UNIX ODBC manager.
3. Create or update the odbc.ini file in the above location to ensure it contains the DSN entry for MySQL ODBC DSN.

   NOTE

   Before updating, you must take backup of odbc.ini.

   [ODBC Data Sources]
   SpecDB=Spectrum DSN for WEBI reports
   [SpecDB]
   Description=Spectrum DB for Adhoc Reporting
   Driver=/usr/local/lib64/libmyodbc5.so
   SERVER=<*SRM OneClick Server name*> PORT=3306
   USER=WEBI_user
   PASSWORD=0n3cl1Ck
   Database=srmdbapi
   OPTION=3

4. Create Symbolic link in <CABI install directory>/sap_bobj/enterprise_xi40/dataAccess/connectionServer/drivers/lib64 folder
   ln -s /usr/lib64/libodbc.so ./libodbc.so.1
   ln -s /usr/lib64/libodbcinst.so ./libodbcinst.so.1
5. Modify the ODBC driver to 64 bit in mysql.sbo file under folder <CABI install directory>/sap_bobj/enterprise_xi40/dataAccess/connectionServer/odbc
   Change unix64 parameter under database tag as mentioned below:
   <Library Platform="Unix64">dbd_ux32odbc3</Library>
   to
   <Library Platform="Unix64">dbd_uxodbc3</Library>
6. Restart all servers from SIA/ using stopservers and startservers command.

Generate Ad Hoc Reports

This section describes the procedure to generate Ad Hoc Reports.

DX NetOps Spectrum Ad Hoc Reporting is a feature which provides flexibility to define your own reports. You can generate the following Ad Hoc reports using Ad Hoc Reporting:

- Simple Ad Hoc Reports
- Complex Ad Hoc Reports

The DX NetOps Spectrum Ad Hoc Reporting feature provides the following capabilities that enable you to define your own reports:

- Custom selection of data objects
- Custom selection of chart options
- Custom layout of report components

To enable custom reporting, DX NetOps Spectrum Reporting relies on the use of an internally designed BusinessObjects metadata layer referred to as a *universe*. A universe is a data abstraction mechanism that is provided by BusinessObjects

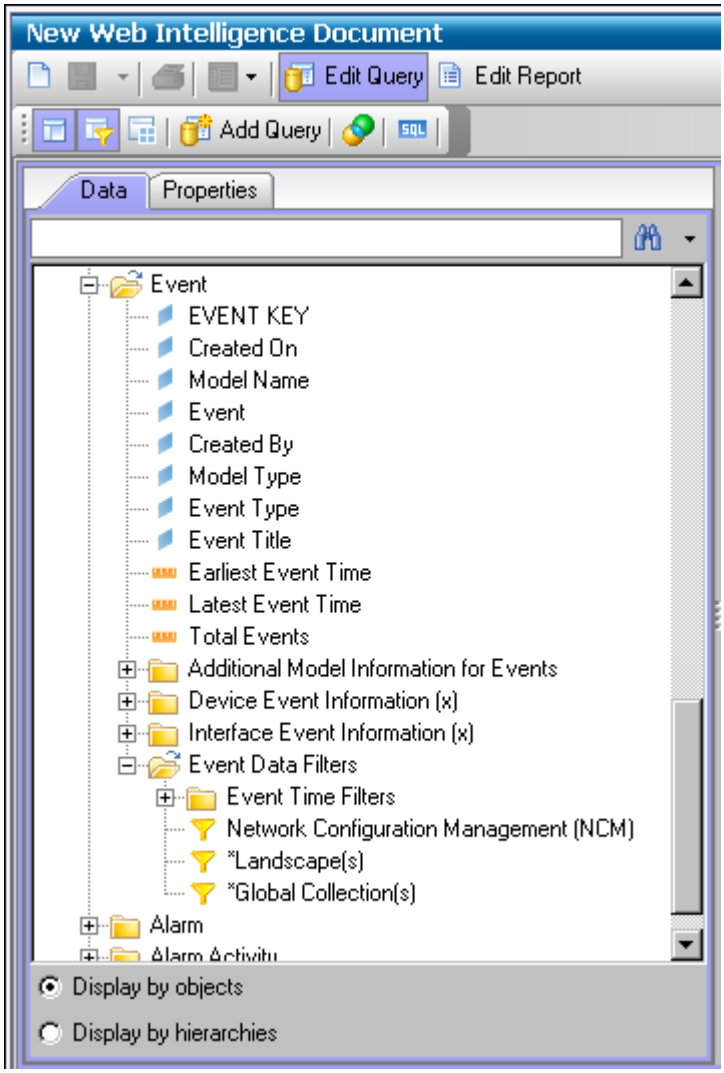
to allow data retrieval from a database without a deep understanding of the underlying data structures. A DX NetOps Spectrum-specific universe provided by CA is deployed to the BusinessObjects Enterprise software to support your Ad Hoc reporting needs.

Ad Hoc Reporting Folder Structure

Within each major folder (Asset, Event, Alarm, Alarm Activity, Availability/Outage), the primary or core objects/fields are presented. Subfolders provide supporting objects.

> **WARNING**
> Consider each major content folder as a self-contained source for report development. Do not mix the objects from one major content area (for example, Alarm) with another (Asset) when you design the report. Mixing objects from disparate content areas can lead to long-running queries against the database.

The following picture illustrates the folder structure of Ad Hoc Reporting.



Fields in capital letters designate the key or object that uniquely identifies the logical reporting entity that is associated with the major containing folder. For example, the inclusion of the EVENT KEY object in an event report query ensures that unique events are returned in the report result set.

The description of the icons is as follows:

- 
  Indicates dimension objects.
-
  Indicates measurement objects.
- 
  Indicates a condition or filter. The ready-made conditions assist you in efficient report development.
- * 
  Indicates a condition or filter. When a report is executed, a dialog appears for further information.
- (x)
  Indicates the objects contained within this folder. Do not mix with objects in a different folder that also has an (x) designation.
  For example, including objects from both the 'Device Event Information (x)' and 'Interface Event Information (x)' folders leads to no results. A model cannot be both a device and an interface simultaneously.

Generate a Simple Ad Hoc Report

You can generate a simple Ad Hoc Alarm Report using Web Intelligence. You can access Web Intelligence from BI Launch Pad.

Review the following considerations before using DX NetOps Spectrum Ad Hoc Reporting:

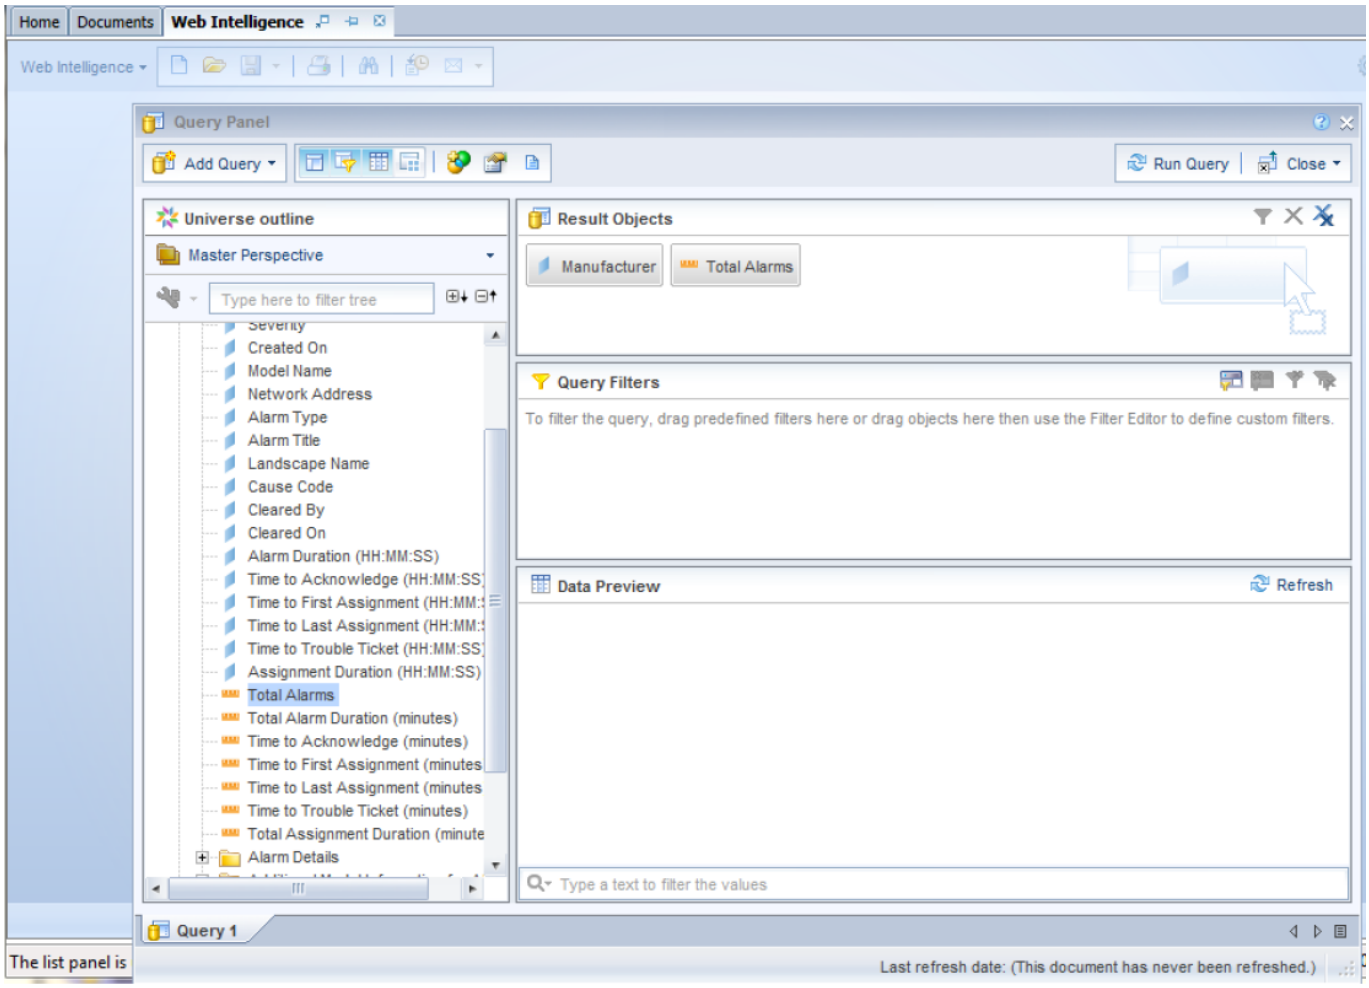
- Use time filters whenever possible to produce efficient running reports.
- Consider the amount of data your report is running against. For example, if you are generating a million events a day, running a year to date report on events likely negatively affect your performance. Specify the shortest time frame possible that produces the data that you require.

Follow these steps:

1. On the OneClick administration page, click BI Launch Pad.
2. Log in to the BI Launch pad.

   NOTE
   The process of initiating a new Web Intelligence session can take a few minutes while a Java applet loads.
3. On the top of the page, click Applications, Web Intelligence.
4. Click the icon in the Web Intelligence toolbar to open the Create a Document window ().
5. Select Universe from the data source list, click OK.
6. Select the 'Spectrum Ad Hoc - MySQL - EN' Universe type to launch a new DX NetOps Spectrum Ad Hoc Reporting Web Intelligence session.
   The Query Panel window appears. The Data panel structure parallels the DX NetOps Spectrum Reporting structure and displays the following nodes:
   - Asset
   - Event
   - Alarm
   - Alarm Activity
   - Availability/Outage
7. Click the + sign to expand folders and view data objects and filters that are related to the folder content.
8. Expand the Alarm folder to view objects.

Drag-and-drop fields from the Data panel to the Results Objects panel.
For example, from the Alarm panel, drag and drop the Manufacturer and Total Alarms objects into the Result Objects panel. The Manufacturer object is located within the 'Device Alarm Information' subfolder.
The following picture illustrates the process to drag and drop the Manufacturer and Total Alarm objects into the Result Objects panel:



9. Drag-and-drop Filter options.
   - Expand the 'Alarm Data Filters' subfolder to view only alarms that have occurred during the current calendar year.
   - Expand the 'Alarm Time Filters' subfolder. Then drag-and-drop the 'Year to Date (YTD)' filter into the 'Query Filters' panel.
10. Select Run Query to execute the query with the objects specified.
    A Report View perspective which contains the default report (simple, and un-formatted report) results display.
    The following picture shows the number of alarms that occurred during the calendar year by Device Manufacture.

Manufacturer	Total Alarms
Alcatel	1
Cisco	145
Enterasys	3
F5 Networks	2
HP	1
Microsoft	2
net-snmp	79
Network Appliance	1
Panthera Networks	3
Reserved/SNMP	5

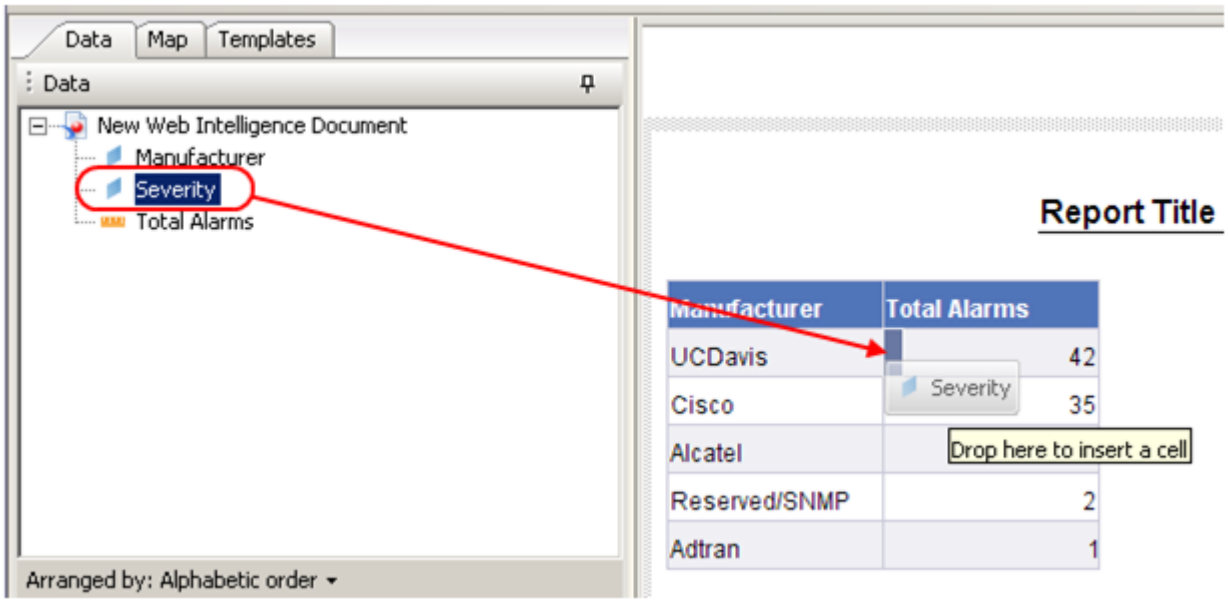
11. (Optional) Use the available formatting options to format the report (such as Title, Templates).
12. To save the document to the My Favorites folder, click Save As. (Optional) You can save the report to your local desktop or can publish the report to the CABI enterprise.
    A Simple Ad Hoc Report is generated.

Generate a Complex Ad Hoc Report with Advanced Formatting

You can generate a Complex Ad Hoc report by modifying a Simple Ad Hoc Report. You can further format your reports to make them more useful.

Follow these steps:

1. Access a Simple Ad Hoc report that you have generated.
   The baseline report captures the number of alarms that have occurred this year, sorted by the device manufacturer.
2. To sort the data, select the column header to sort, and then click Sort.
3. Select Edit Query.
   For example, you can perform the following steps to format your reports:
   a. Drag the Severity object located in the Alarm folder to the Result Objects panel.
   b. Select Run Query.
   c. Run the modified query.
      The Report View perspective displays.
      Report is updated to include the new Severity field that is added to the report query.
4. Drag-and-drop the Severity object into the report table.
   The updated report table now contains three columns.



5. To convert the existing table into a crosstab table, where Severity is on the Y-axis and Manufacturer is on the X-axis, drag the Manufacturer column heading above the table.

   NOTE
   Do not release the column heading until a tooltip appears indicating that a crosstab is created.

   The two-dimensional array enables you to see the total number of alarm counts breakdown by severity within each manufacturer. In addition, the crosstab is helpful for comparing alarm counts across device manufacturers.
6. To add subtotals to the table, perform the following steps:
   a. Highlight all the alarm count cells in the table (do not select the row/column headers).
   b. Click Sigma.
   c. Select Sum.
      The crosstab contains subtotals by manufacturer and severity.
7. To create a graphical representation of this data, such as a bar chart, perform the following steps:
   a. To copy the existing crosstab, select the entire crosstab, right-click, and select Copy.
   b. Move the cursor directly underneath the existing crosstab, right-click, and select Paste.
      You can now see a second identical crosstab below the first crosstab.
   c. To convert the bottom crosstab to a horizontal bar chart, select the entire crosstab, right-click, and select Turn To.
      The Turn To window appears. The Turn To window contains multiple tabs, each tab corresponds to the different types of charts available.
   d. Click the Bar tab, select the Horizontal Stacked chart option, and click OK.
      An unformatted horizontal stacked bar chart appears directly underneath the crosstab.
8. Perform the following steps to add legend and data values to improve the format of your report.
   a. To add a legend, select the entire chart, and click the Data tab.
   b. Expand the Appearance section in the Properties box.
   c. Click the Legend checkbox.
   d. To add data values, select the entire chart in the Appearance section and the Values subsection.
   e. Click the Show data checkbox.
      The report displays with both legend and data values.
9. To change the chart to reflect the standard DX NetOps Spectrum Reporting coloring conventions for alarm severity (Red=Critical, Orange=Major, Yellow=Minor), perform the following tasks:
   a. Within the Appearance and subsequent Data section, select the Palette option.

b. From the Select Palette dialog, select Edit Palette.
c. Select colors (Red, Orange, and Yellow).
d. Click OK to change the color palette.
e. Click OK to apply the modified palette to the chart.

10. Update the report title by double-clicking the default title box and entering a new title.
    A Complex Ad Hoc report is generated with advanced formatting.
11. Click Drill to drill down on data within the report to view individual alarms.
    Continue to select fields in the table report or bars in the graphic report until you have the data that you require.

Use WEBI Sample Reports

DX NetOps Spectrum Reporting includes WEBI Sample Reports, which are based on Crystal Reports. The WEBI sample reports also showcase some of the WEBI features:

- Graphing
- Aggregate Data Functions
- Varied Report Layouts
- Crosstabs and Pivot Tables.

Access WEBI Sample Reports

You can access and run WEBI Sample reports from BI Launch Pad. Using the WEBI sample reports as templates, you can create your own WEBI-based reports and select relevant DX NetOps Spectrum data.

Follow these steps:

1. From the BI Launch Pad window, select Document List, Public Folders, CA Reports, and then DX NetOps Spectrum.
2. Select Sample WEBI Documents.
   The available Sample WEBI documents/reports appear.
3. Double-click a report.
   The report displays.
4. Select report parameter values, where required.
5. Click Run Query.
   The report displays.

Copying and Editing WEBI Sample Reports

The WEBI Sample Reports can be used as a base for copying and editing to create your own WEBI reports.

Important! We recommended *not* editing the WEBI Sample Reports directly. Copy the report to another folder, and edit the report.

Follow these steps:

1. Create a folder outside the CA Reports folder hierarchy, and under the Public Folders level to contain your customized WEBI reports.

   NOTE
   Create folders outside the CA Reports folder hierarchy, and under the Public Folders level is important as product upgrades may overwrite contents inside the CA Reports folder. For more information, see the CA Business Intelligence Integration section.
2. Access the WEBI Sample Reports.
3. Select the report that you want to copy, right-click, and select Organize Copy.

4. Select the report folder that you created, right-click, and select Organize Paste.
   The report appears in the right-hand side panel.
5. Highlight the report that you copied, right-click, and select Modify.
   The Ad Hoc Reporting panel appears.
   a. To edit the report display, click Edit Report.
   b. To edit the query, click Edit Query.
   The Ad Hoc Reporting Panel provides multiple features. For more information, see Generating Ad Hoc Reports .

User Resolving Java Error in Report Manager Sample (WEBI) Reports

Symptom:

A Java error appears in the Spectrum Report Manager Sample (WEBI) reports. When I open sample report, I see the following error message:

```
Java has discovered application components that could indicate a security concern -- Block potentially unsafe
 components from being run? (recommended). (Yes/No)
```

If I select Yes, the report results do not display. If I select No, the report results are displayed.

Solution:

The issue occurs when running your browser on a Windows system with versions higher than Java 6 update 17. To resolve this issue, perform the following steps:

1. Open Java from the Control Panel.
2. Select the Advanced Tab
3. Expand the Security option.
4. Expand the Mixed Code option.
5. Select 'Enable - hide warning and run with protections'.
   The report runs successfully on Windows.

Report Manager DB Schema

Introduction

Spectrum Report Manager uses a MySQL database named "reporting" to store data. Another database "srmdbapi" provides views that are based on the reporting DB to query for data. This section provides an overview of all the database tables and views in 'reporting' and 'srmdbapi' databases so that the users can run their own queries and can use reporting tools of their own.

At startup, Spectrum Report Manager retrieves the data from the primary Archive Manager for each SpectroSERVER through OneClick and stores the data in the SRM databases.

Connecting to the database

Users can connect to the SRM database(which is on the OneClick server machine) using a ‘terminal window’ or a dos prompt (windows -> start -> Run -> cmd).

Use the below instructions to connect to the MySQL SRM DB instance running on the OneClick host

1. change to your $SPECROOT/mysql/bin directory
2. do a “mysql -uroot –proot” to connect to the mysql DB system
3. do a “use reporting;” (don't forget the ; at the end!)
4. Then user can run any of the select statements to fetch and see the data (don't forget the ; at the end of the statement)
5. Once done, run “quit” to disconnect.

Users are also encouraged to use utilities like ‘MySQL Workbench’ to connect to the SRM database and run the required queries.

If user wants to connect to the SRM database remotely from another box through utilities then they have to run a grant command so that access to MySQL DB is allowed from that host.

1. Go in to the $SPECROOT/mysql/bin directory Eg: /usr/Spectrum/mysql/bin
2. Login to mysql with the command “mysql -uroot –proot”
3. Once we logged in, use the command “grant all privileges on *.* to 'root'@'<ip address of the machine from where we are accessing the DB>' identified by 'root';”
4. Example:- grant all privileges on *.* to 'root'@'10.132.15.160' identified by 'root'; (now user can access the reporting DB from MySQL workbench running on host 10.132.15.160)

Once the access is granted then users can connect to the database and can run queries using the workbench.

'reporting' Database

This section contains information about 'reporting' database Tables and Views.

Click here to see how to write sample queries using reporting DB tables.

srmdbapi Database

'reporting' Database

DX NetOps Spectrum Report Manager (SRM) uses a MySQL database named '**reporting**' to store data. This database contains all the tables that are required to store the data that is used by SRM application to generate reports.

At startup, the DX NetOps Spectrum Report Manager retrieves the data from the primary Archive Manager for each SpectroSERVER through OneClick and stores the data in the SRM databases.

Following is the list of tables and views in the '**reporting**' database.

The relations shown in the following diagrams merely indicate table relations. They do not indicate 1:1 or 1: many relations.

Interpret the column icons as indicated below:

- Represents a Primary Key

- Simple NOT NULL column

- Simple column which can be NULL

Tables

alarm_user

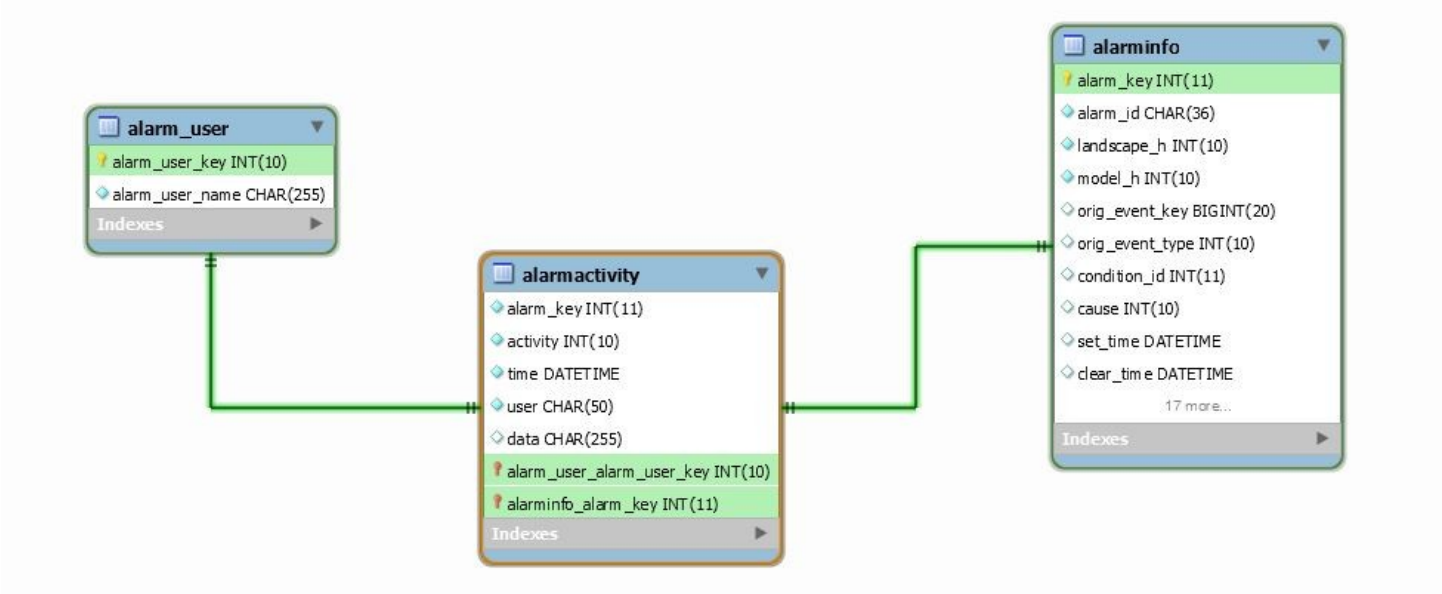
Description

This table lists the users who can manage the alarms in DX NetOps Spectrum.

Columns

Field	Type	Null	Key	Default	Extra	Comment
alarm_user_name	char(255)	NO	UNI			Name of the DX NetOps Spectrum user, who can manage the alarms.
alarm_user_key	int(10) unsigned	NO	PRI		auto_increment	Unique key for each user, who manages the alarm in DX NetOps Spectrum

Relations



alarmactivity

Description

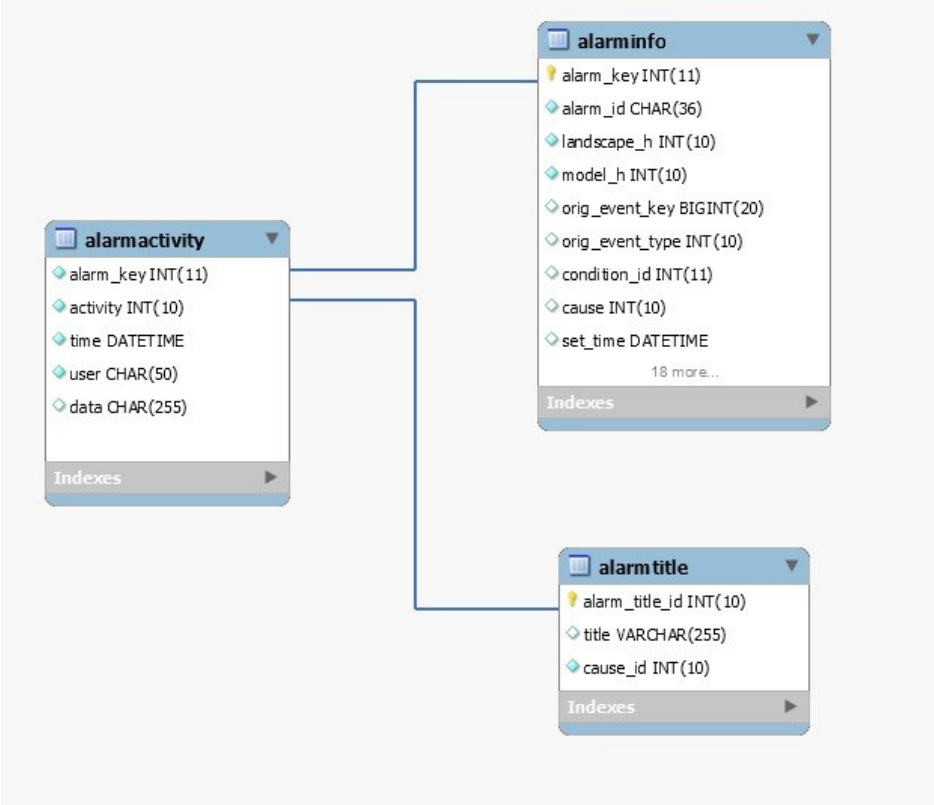
The alarmactivity table stores all the alarm activity that is monitored by SRM. The activity field denotes the type of alarm event generated. This field can be one of the following:

- Set alarm event
- Acknowledge alarm event
- Assign troubleshooter alarm event
- Clear alarm event
- User cleared alarm event
- Assign trouble ticket alarm event

Columns

Field	Type	Null	Key	Default	Comment
user	char(50)	NO	MUL		Name of the user, handling the alarm
time	datetime	NO	MUL	0000-00-00 00:00:00	Time of the activity performed in the alarm.
data	char(255)	YES			
alarm_key	int(11) unsigned	NO	MUL		Key value for specific type of Alarms.
activity	int(10) unsigned	NO	MUL		Activity that is performed by the user on the specific alarm.

Relations



alarmcondition

Description

This table represents the alarm criticality and condition.

Columns

Field	Type	Null	Key	Default	Comment
criticality	tinyint(2)	NO	UNI		Criticality of the alarm like Minor, Major, Critical
condition_name	varchar(11)	NO			Condition name of the alarm, which is mapped to the criticality.
condition_id	int(10) unsigned	NO	PRI		Unique ID for the alarm condition.

Relations

alarminfo

Description

This table contains all the alarm information including the assignee and trouble ticket IDs.

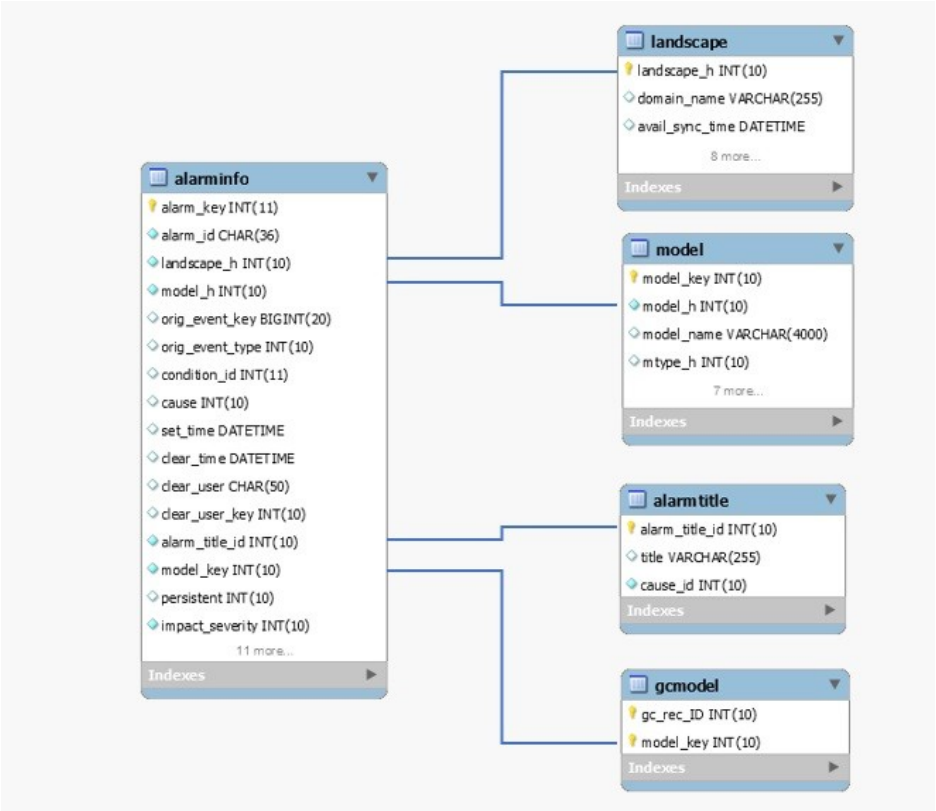
The alarminfo table stores relevant information for an alarm. There is one entry per unique alarm id, as opposed to the alarmactivity table which can have multiple entries for a single Alarm ID. An entry in this table is created when a “set alarm event” is received by SRM. The table is updated through the life of the alarm as each of the other alarm events are received by SRM.

Columns

Field	Type	Null	Key	Default	Comment
set_troubleticket_user_key	int(10) unsigned	YES	MUL		Trouble ticket user key for the specific alarm.
set_troubleticket_time	datetime	YES			Time of the trouble ticket assigned.
set_troubleticket_id	char(255)	YES			Trouble ticket ID of the alarm.
set_time	datetime	YES	MUL		Originated time of the alarm.
persistent	int(10) unsigned	YES	MUL	2	
orig_event_type	int(10) unsigned	YES			Originating event type for the alarm.
orig_event_key	bigint(20) unsigned	YES			Originating event key for the Alarm.
model_key	int(10) unsigned	NO	MUL	0	Unique model key for each alarm.
model_h	int(10) unsigned	NO	MUL		Model handle of the device, which has the alarm on it.
last_assigning_user_key	int(10) unsigned	YES	MUL		
last_assigned_user_key	int(10) unsigned	YES	MUL		
last_assigned_time	datetime	YES			

landscape_h	int(10) unsigned	NO			Landscape handle of the server, where the alarm present.
impact_severity	int(10) unsigned	NO		0	Severity of the alarm.
first_assigning_user_key	int(10) unsigned	YES	MUL		
first_assigned_user_key	int(10) unsigned	YES	MUL		
first_assigned_time	datetime	YES			First assigned time of the alarm to specific user.
condition_id	int(11)	YES			Condition of the alarm, which is mapped to the criticality.
clear_user_key	int(10) unsigned	YES	MUL		
clear_user	char(50)	YES			User who acknowledge the alarm.
clear_time	datetime	YES			When the alarm is cleared from DX NetOps Spectrum.
cause	int(10) unsigned	YES	MUL		Cause/Event ID of the specific alarm.
alarm_title_id	int(10) unsigned	NO	MUL	1	Unique ID for alarm title.
alarm_key	int(11) unsigned	NO	PRI		Unique ID for each alarm present in DX NetOps Spectrum
alarm_id	char(36)	NO	UNI		Alarm ID for specific type of alarms.
ack_user_key	int(10) unsigned	YES	MUL		Specific key for the user who acknowledges the alarm.
ack_time	datetime	YES			When the user acknowledge the alarm.

Relations



alarmtitle

Description

This table represents the title information of DX NetOps Spectrum alarms.

Columns

Field	Type	Null	Key	Default	Extra	Comment
title	varchar(255)	YES				Title of the Alarm.
cause_id	int(10) unsigned	NO	MUL			Cause or Event ID of specific type of alarm in DX NetOps Spectrum
alarm_title_id	int(10) unsigned	NO	PRI		auto_increment	Unique ID for each alarm present in DX NetOps Spectrum.

Relations

backups

Description

This table contains list of database backups.

bo_only_user

Description

This table includes the Business object user information.

boxi_user_sync

Description

This table includes the Business object user sync information.

bucketactivitylog

Description

This table includes the event information from the landscape to process in SRM database.

ca_reportstrings

Description

This table represents the information of localized string for the identifier.

configchangelog

Description

This table contains the information about NCM configuration file and logs.

Columns

Field	Type	Null	Key	Default	Extra	Comment
last_modified	bigint(20)	NO				Last_Modified time of the configuration file.
id	int(10) unsigned	NO	PRI		auto_increment	Unique ID of Configuration file.
filename	varchar(255)	NO				Name of the Configuration file.
content	blob	NO				Content of the configuration file

contentpkg

Description

This table represents the installation content package information.

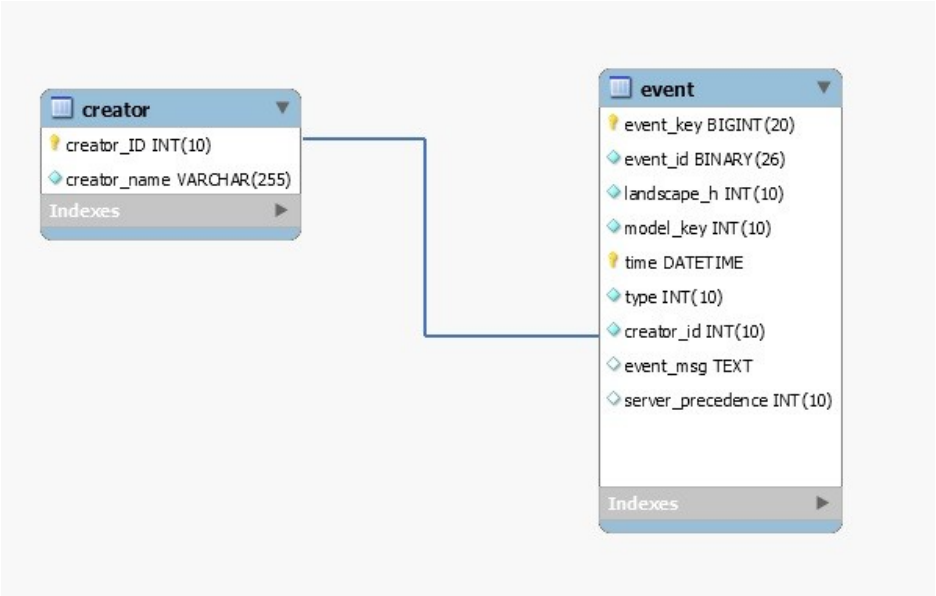
The contentpkg table associates content packages with Crystal Enterprise folder IDs. This table is not meant to be reported against, but instead is actually used by the Report Manager to help identify installation and security issues. A content package might only be installed once and this table helps identify if that is the case.

creator

Description

This table includes the model creator information.

Relations



data_retention_policy_changelog

Description

This table includes the information about the data retention policy.

devicemodel

Description

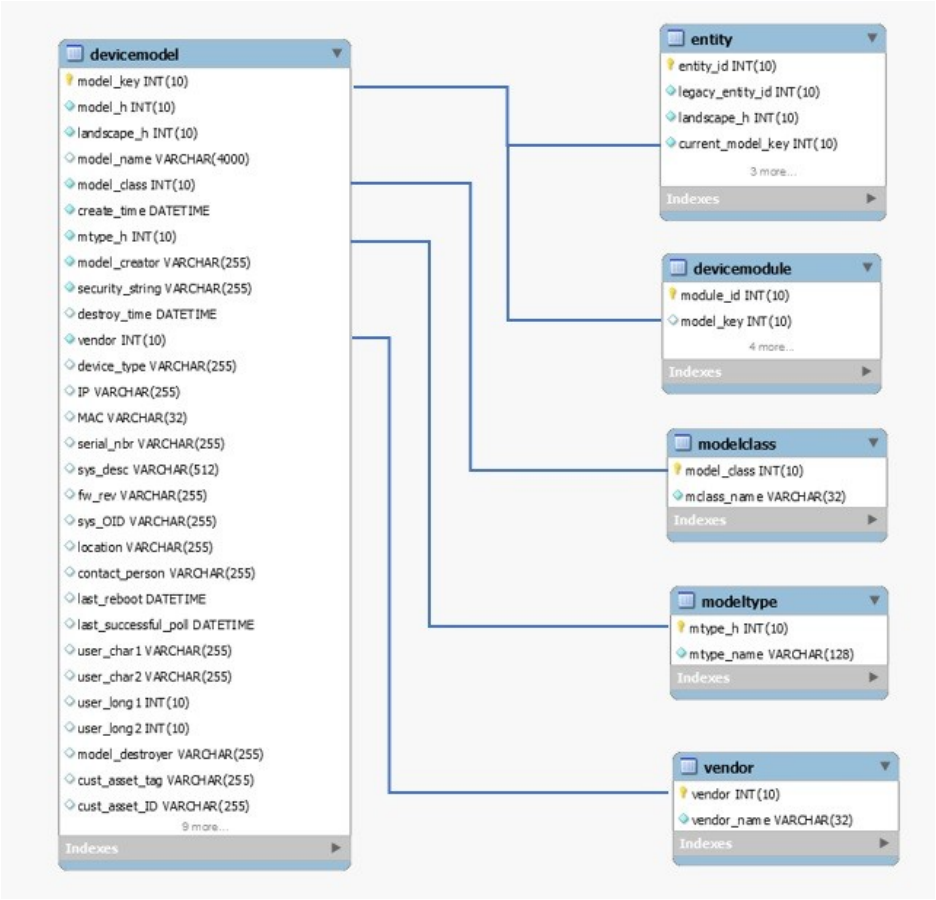
This table represents the complete device model information.

The devicemodel table is filled in initially as the Report Manager extracts model information from the respective SpectroSERVERs. New records are added by the Report Manager as it responds to model creation events for device models.

Certain attributes of this table can change and as such the Report Manager needs a way to keep up with these changes. To keep up with these changes, the Report Manager periodically requests current values for these attributes. These requests are made to the appropriate models through the OneClick architecture. Initially this period for updating device data is set to once every 24 hours.

The user-defined fields are to be left blank, but provide the administrator an opportunity to extend the Report Manager database to include data that is applicable to their assets.

Relations



devicemodel_uda

Description

The devicemodel_uda table contains user-defined polling attribute information.

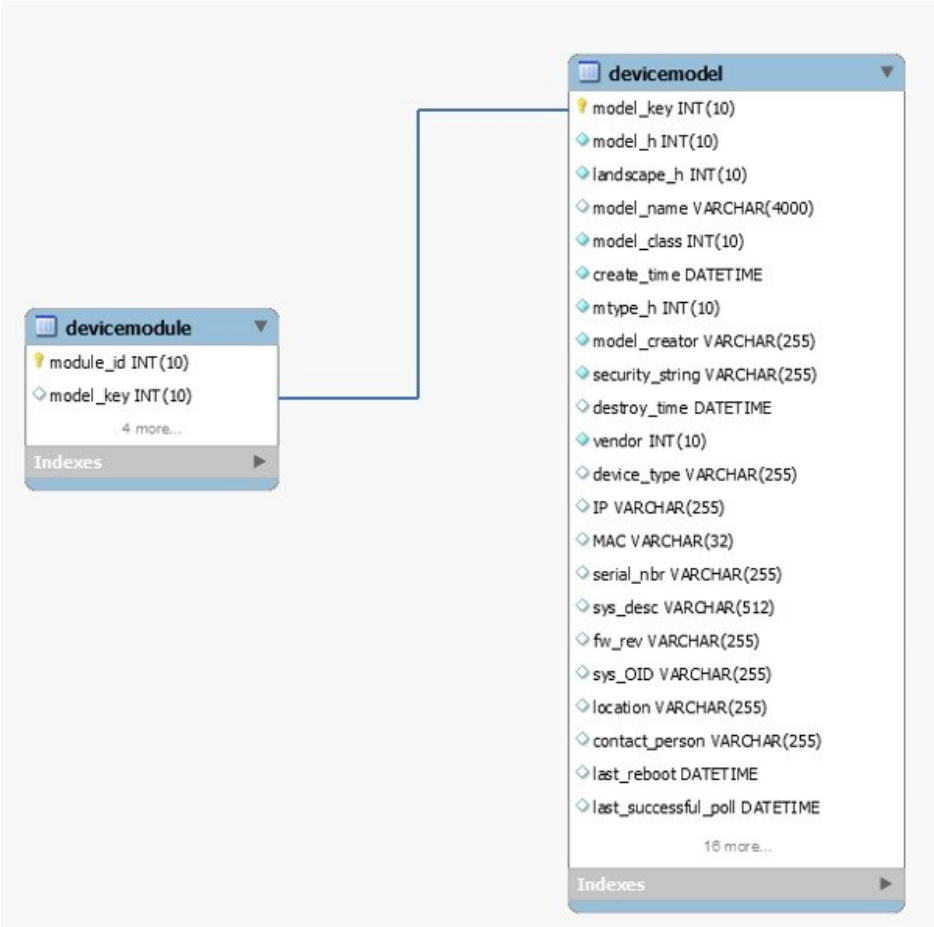
devicemodule

Description

This table includes the chassis information like module name, serial number etc.

This table captures the relationship between Chassis device models and the board modules contained within. This table is dynamically kept up to date.

Relations



Columns (till 10.2.1 release)

Field	Type	Null	Key	Default	Extra
module_id	int(10) unsigned	NO	PRI	NULL	auto_increment
model_key	int(10) unsigned	YES	MUL	NULL	
module_index	int(10)	YES		NULL	
module_name	varchar(255)	YES		NULL	
serial_nbr	varchar(255)	YES		NULL	
software_rev	varchar(255)	YES		NULL	

Columns
(from 10.2.2 release)

Field	Type	Null	Key	Default	Extra
module_id	int(10) unsigned	NO	PRI	NULL	auto_increment
model_key	int(10) unsigned	YES	MUL	NULL	
physical_index	int(10)	YES		NULL	
physical_modelname	varchar(255)	YES		NULL	
physical_name	varchar(255)	YES		NULL	

physical_class	int(10)	YES		NULL	
physical_contained_in	int(10)	YES		NULL	
serial_nbr	varchar(255)	YES		NULL	
software_rev	varchar(255)	YES		NULL	

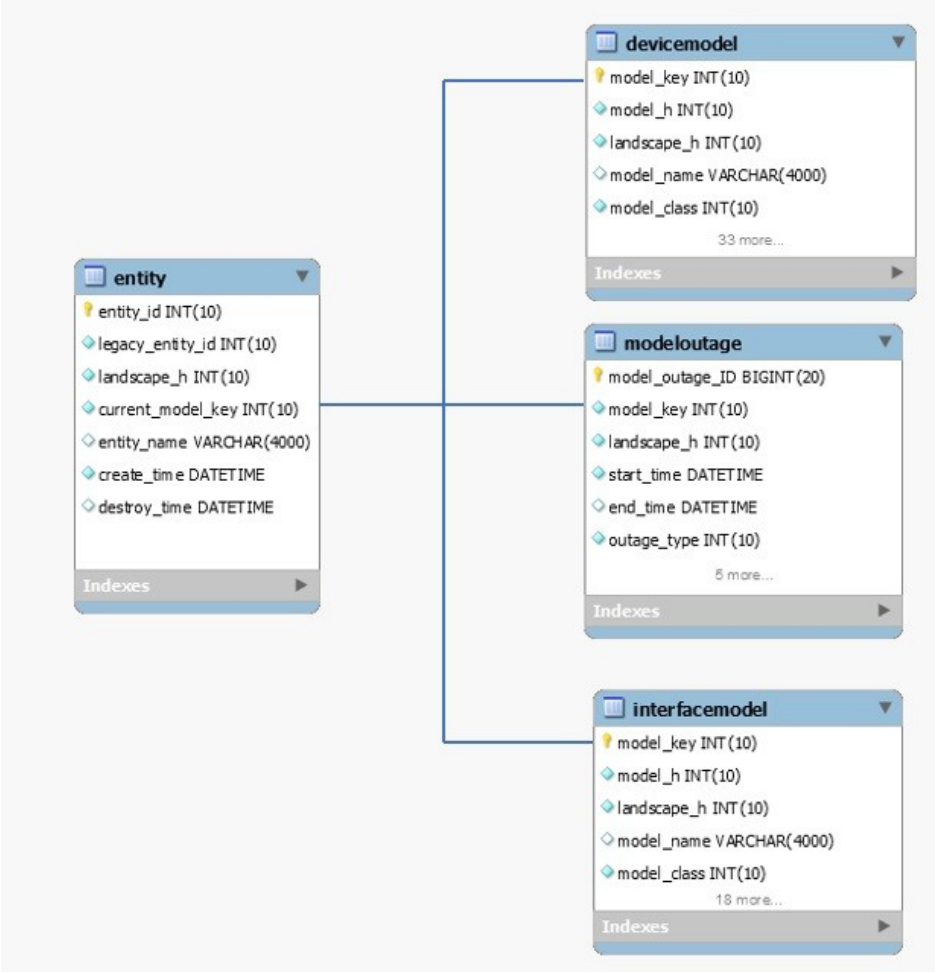
entity

Description

This table maintains distinct devices/interfaces across ALL landscapes.

The entity table is used to identify all entities uniquely that can be reported on. As new unique entities are added to the database, new entity records are created. Entity table record creation is closely tied to devicemodel and interfacemodel table record creation. The current_model, create_time, and destroy_time columns always correspond to the most recently created model.

Relations



entitygroup

Description

This table is about taking the device assets and grouping them into predefined groups that are based on Vendor, Model Class, Landscape.

The EntityGroup table is initially filled in during the startup of the Report Manager application. Queries are made to the individual SpectroSERVERs to learn of the existing model collections (which are actually models themselves).

The EntityGroup table is then kept up to date by having the Report Manager watch for the creation (and destruction) events of the collection models. When a new event occurs indicating the creation of one of these collection models, the name for that collection model is immediately obtained. A search of the EntityGroup table for a record with that name is performed. If no such record exists, one is immediately added. If a record does exist, no further processing is necessary.

entitygroupentity

Description

The EntityGroupEntity table is initially filled in during the startup of the Report Manager application. As EntityGroups are added to the system, queries are made back to each of the servers to determine the membership of those groups. In determining membership, the SpectroSERVER identifies a set of models. Each model can then be referenced in either the devicemodel or interfacemodel table. From there, an entity ID can be obtained and an appropriate entry can be made into this table.

The EntityGroupEntity table can then be kept up to date by monitoring the relationship changes associated with those collection models.

entitygrouptype

Description

The EntityGroupType table is filled in at the time of table creation. EntityGroupTypes are pre-defined before any EntityGroups have been defined. Table records include:

entity_group_type	eg_type_name
101	Vendor group
102	Model Class group
103	Landscape group
1000	User-Defined group
1001	User-Defined group

entitymodel

Description

The entitymodel is used to identify all model handles that an entity has had. This table gets filled in as part of the Entity table updating. When a record gets added to either the devicemodel or interfacemodel table, a process is kicked off to identify if this “new” model is either an existing/known entity, or a new (previously unknown/un-modeled) entity.

A new record gets added to the entitymodel table every time a “new” model record gets added to either the devicemodel or devicemodel table. When a record is added to the entitymodel table, the record is recorded with a timestamp. This timestamp enables the Report Manager to identify the most current model that represents an entity.

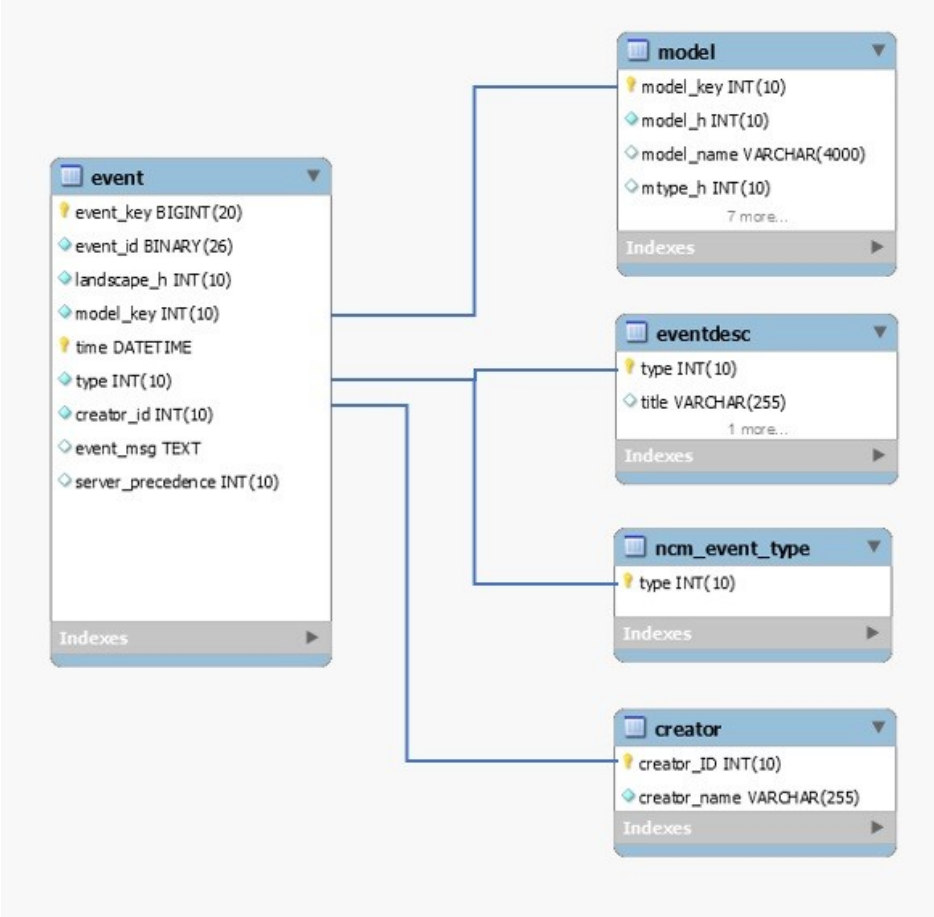
Columns

event

Description

This table described the complete event information like event ID, message, time etc.

Relations



eventactivitylog

Description

Contains number of events processed in each polling cycle for every landscape.

Columns

Field	Type	Null	Key	Default	Extra	Comment
log_id	int(10) unsigned	NO	PRI		auto_increment	Unique log id for each event processing polling cycle
landscape_h	int(10) unsigned	NO	MUL			landscape handle of SS

poll_start_time	datetime	NO				The time when polling cycle started
poll_end_time	datetime	YES				The time when polling cycle end
nbr_of_events	int(10) unsigned	YES				number of events processed in the current polling cycle

eventdesc

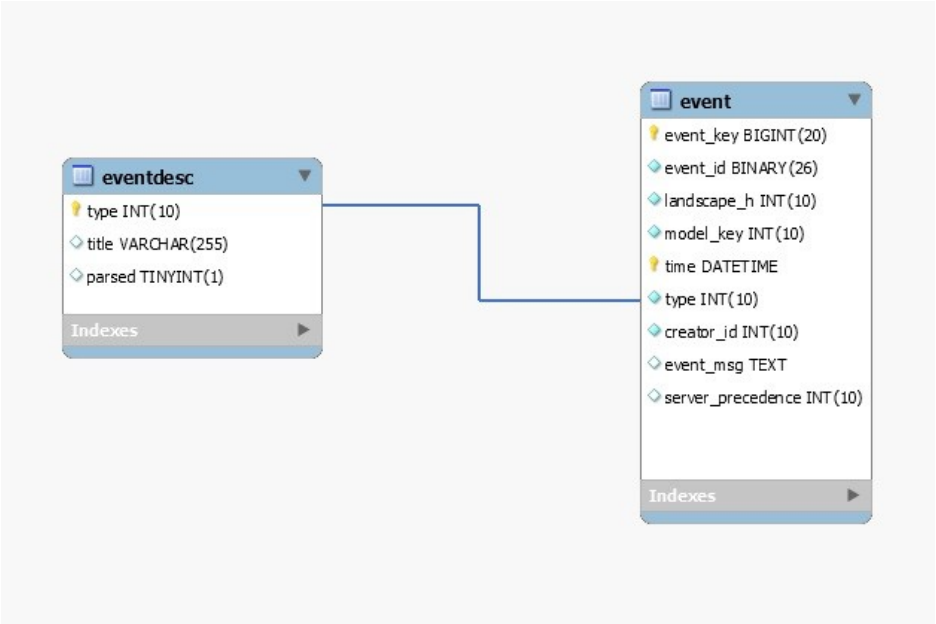
Description

Contains static list of events.

Columns

Field	Type	Null	Key	Default	Comment
type	int(10) unsigned	NO	PRI	0	Event Type
title	varchar(255)	YES			Event title
parsed	tinyint(1)	YES		0	

Relations



folderhierarchy

Description

Contains folder hierarchy present in OneClick explorer view.

Columns

folderidmap

Description

This table maps the SRM entitygroupid of the folder to the CsUniqueID that identifies the folder in One Click and DX NetOps Spectrum. This table is used for custom collection hierarchies.

Columns

Field	Type	Null	Key	Default	Comment
cs_unique_id	char(36)	NO	PRI		
folder_id	int(10) unsigned	NO	MUL		

gcmodel

Description

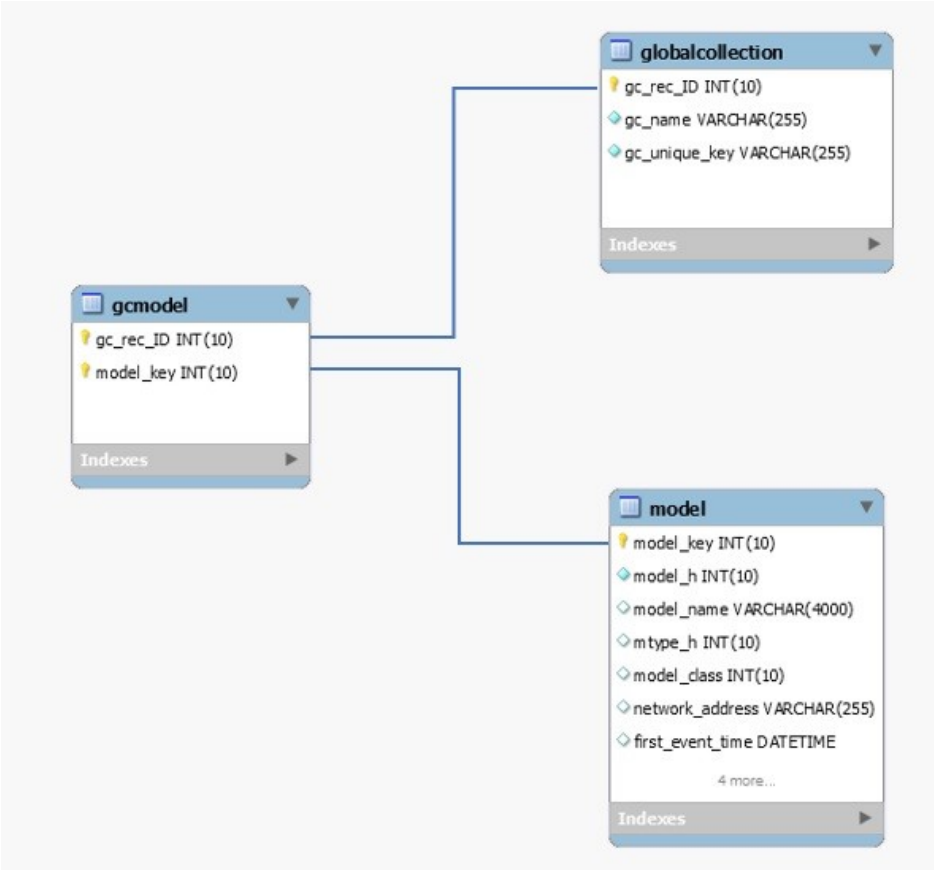
Contains mapping between global collections and models present in it.

Please note that this table does not include a flag like 'destroyed' or 'startdate/enddate' for the relation between the model and the global collection. It only represents the current assignment.

Columns

Field	Type	Null	Key	Default	Comment
gc_rec_ID	int(10) unsigned	NO	PRI		global collection record ID
model_key	int(10) unsigned	NO	PRI		model key of the model present in the global collection

Relations



globalcollection

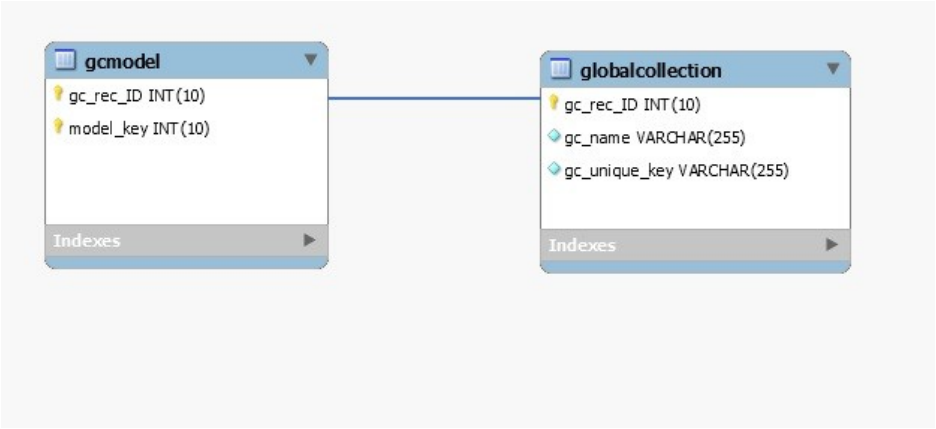
Description

Contains list of global collections.

Columns

Field	Type	Null	Key	Default	Extra	Comment
gc_rec_ID	int(10) unsigned	NO	PRI		auto_increment	unique record ID for each global collection
gc_name	varchar(255)	NO				Name of global collection
gc_unique_key	varchar(255)	NO	UNI			unique key for each global collection

Relations



groupentitygroups

Description

This table stores mapping of group_id to entity _group_id .

Since entity groups of type 'folder' can be made up of multiple entity groups (of type folder, collection or both), this table allows you to find all the entity groups that make up the specified entity group.

> **NOTE**
> When finding all entities of a specified entity group, use this table, not the entitygroup table.

Columns

Field	Type	Null	Key	Default	Comment
group_id	int(10) unsigned	NO	PRI		
entity_group_id	int(10) unsigned	NO	PRI		

handleractivitylog

Description

Containing the log of bucket processing done by all handlers for each landscape.

Columns

Field	Type	Null	Key	Default	Extra	Comment
log_id	int(10) unsigned	NO	PRI		auto_increment	Unique log id for each processing done by the handler
landscape_h	int(10) unsigned	NO	MUL			Landsacpe handle
staging_table	varchar(255)	NO	MUL			Name of the bucket which is getting processed
process_start_time	datetime	NO				Processing start time

process_end_time	datetime	YES				Processing end time
last_event_seq	int(10) unsigned	YES				
event_log_id	int(10) unsigned	NO	MUL			

handlerrollback

Description

This table stores model outage rollback data.

Columns

Field	Type	Null	Key	Default	Comment
landscape_h	int(10) unsigned	NO	PRI		
model_outage_update_ongoing	int(10) unsigned	NO		0	
last_model_outage_id	bigint(20) unsigned	YES			
last_model_outage_event_key	bigint(20) unsigned	YES			
dev_outage_update_ongoing	int(10) unsigned	NO		0	
last_dev_outage_id	int(10) unsigned	YES			
last_dev_event_time	datetime	YES			
int_outage_update_ongoing	int(10) unsigned	NO		0	
last_int_outage_id	int(10) unsigned	YES			
last_int_event_time	datetime	YES			

installedreports

Description

This table contains the file names of the reports that are loaded into the database by SRM. The report ID of the report that is stored in the database with its parent folder ID are also listed. This table is consulted when add or updating reports within SRM.

Columns

Field	Type	Null	Key	Default	Comment
report_ID	int(10) unsigned	NO	PRI		
parent_folder_ID	int(10) unsigned	NO			
file_name	varchar(255)	NO			

interfacemodel

Description

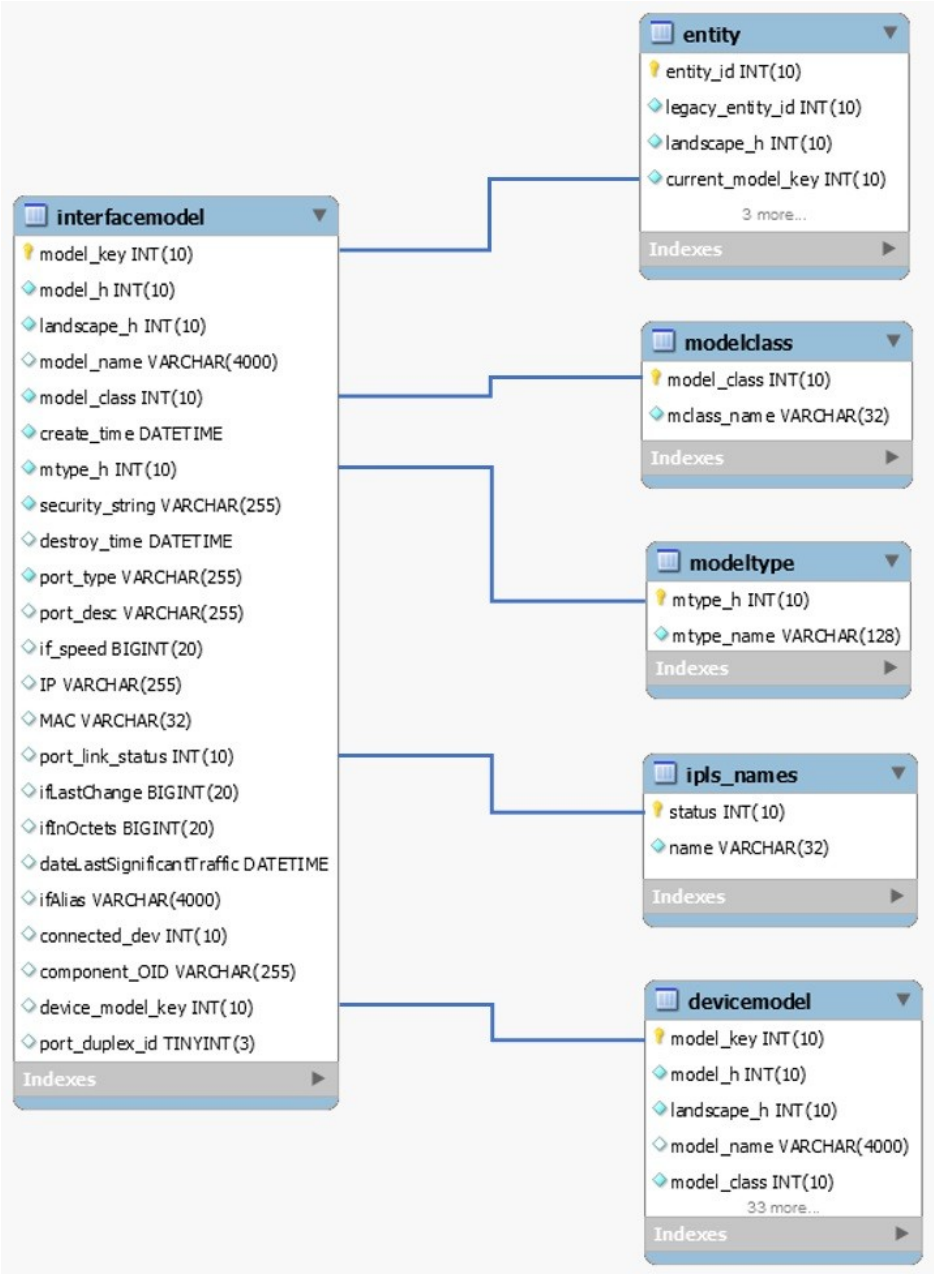
Contains interface information for all device models.

The interfacemodel table is filled in initially as the Report Manager extracts model information from the respective SpectroSERVERs. New records are added by the Report Manager as it responds to model creation events for interface models. The models that are reported on within the interfacemodel table are initially limited to those models that represent physical interfaces. Logical interfaces are not recognized or reported on with this first phase.

Columns

Field	Type	Null	Key	Default	Comment
model_key	int(10) unsigned	NO	PRI	0	model key of the interface
model_h	int(10) unsigned	NO	MUL		model handle of interface
landscape_h	int(10) unsigned	NO	MUL		Landscape handle of SS where the model is present
model_name	varchar(4000)	YES	MUL		Model name of the interface
model_class	int(10) unsigned	NO	MUL		model class of the interface
create_time	datetime	NO			Interface model creation time
mtype_h	int(10) unsigned	NO	MUL		Model Type Handle of the interface
security_string	varchar(255)	NO			security string of interface
destroy_time	datetime	YES			Destroy time of the interface model
port_type	varchar(255)	NO	MUL		Interface / port type
port_desc	varchar(255)	YES			Interface or port description
if_speed	bigint(20) unsigned	YES			Speed of the interface
IP	varchar(255)	YES			IP address of the interface
MAC	varchar(32)	YES			MAC address of the interface
port_link_status	int(10) unsigned	YES	MUL		Port or Interface link status
ifLastChange	bigint(20) unsigned	YES			value of ifLastChange mib attribute
ifInOctets	bigint(20) unsigned	YES			Value of ifInOctets mib attribute
dateLastSignificantTraffic	datetime	YES			The time when the last traffic is seen on the interface or port
ifAlias	varchar(4000)	YES			Contains the value of ifAlias mib attribute
connected_dev	int(10) unsigned	YES			Contains the interface to which this is connected
component_OID	varchar(255)	YES			
device_model_key	int(10) unsigned	YES	MUL		Model key of the device
port_duplex_id	tinyint(3) unsigned	YES			

Relations



ipls_names

Description

This table contains the different values for the port_link_status on an interface model found in the interfacemodel table. This table is filled when it is created with the following values:

Status	Name
0	Good
1	Bad
2	Unknown

3	Disabled
4	Unreachable
5	Init
6	L inked Port Bad
7	Linked Device Bad
8	Dormant
9	Port In Maintenance
10	Bad Suppressed
11	WA Link Bad
12	LL In Maintenance
13	Always Down

Columns

Field	Type	Null	Key	Default	Comment
status	int(10) unsigned	NO	PRI		Status number
name	varchar(32)	NO			Status name

Relations

landscape

Description

Contains the last poll /sync times for each landscape

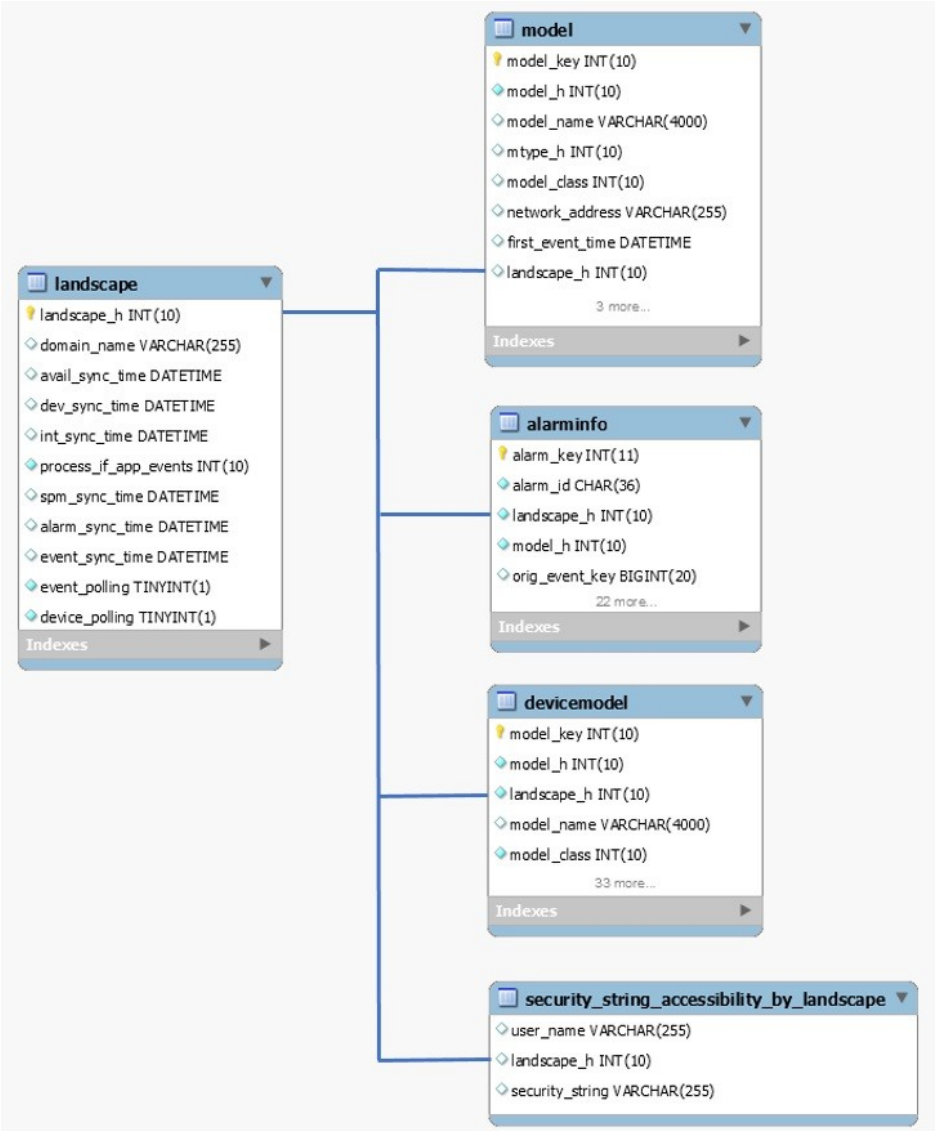
The landscape table lists those landscapes that report manager has seen. The dev_sync_time is the time the last known device event was recorded for the given landscape. The int_sync_time time is the time the last known interface event was recorded.

Columns

Field	Type	Null	Key	Default	Comment
landscape_h	int(10) unsigned	NO	PRI		Landscape handle which is polled by report manager
domain_name	varchar(255)	YES			Domain name of the landscape
avail_sync_time	datetime	YES			The last sync time for availability
dev_sync_time	datetime	YES			The last sync time for device availability
int_sync_time	datetime	YES			The last sync time for interface information

process_if_app_events	int(10)	NO		0	Indicates if it is ok to process application lost /react events for the interfaces
spm_sync_time	datetime	YES			The last sync time for SPM information
alarm_sync_time	datetime	YES			The last sync time for alarms information
event_sync_time	datetime	YES			The last sync time for events information
event_polling	tinyint(1)	NO		1	contains 1 if the event polling is enabled for this landscape else 0
device_polling	tinyint(1)	NO		1	Contains 1 if Asset polling is enabled else 0

Relations



managementoutage

Description

This table stores the management outages for the monitored landscapes.

Columns

Field	Type	Null	Key	Default	Extra	Comment
outage_ID	int(10) unsigned	NO	PRI		auto_increment	
landscape_h	int(10) unsigned	NO	MUL			
start_time	datetime	NO				
end_time	datetime	YES				
outage_type	int(10) unsigned	NO	MUL			

managementoutagetype

Description

This table lists the different types of management outages. This table is filled at table creation time with the following values:

- Expected
- Unexpected
- History

Columns

Field	Type	Null	Key	Default	Comment
outage_type	int(10) unsigned	NO	PRI		
outage_desc	varchar(32)	NO			

model

Description

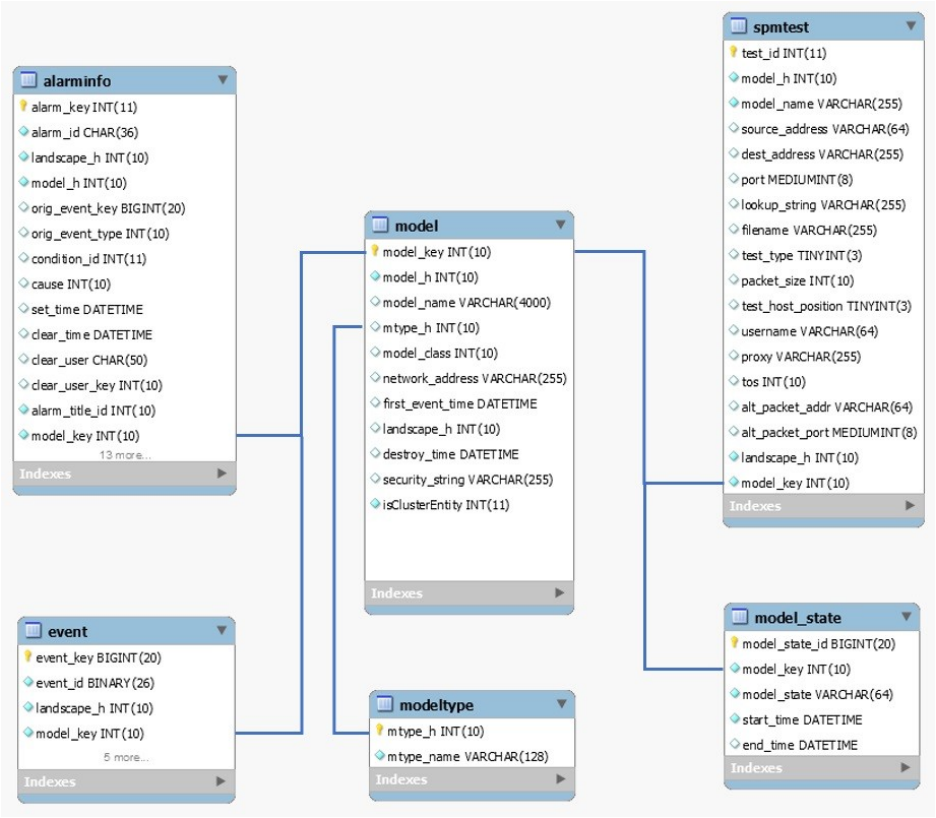
Contains information of all the DX NetOps Spectrum models. This table stores general model information.

Columns

Field	Type	Null	Key	Default	Extra	Comment
model_key	int(10) unsigned	NO	PRI		auto_increment	Unique Model Key for model
model_h	int(10) unsigned	NO	MUL	0		Model Handle of the model
model_name	varchar(4000)	YES	MUL			Name of the Model
mtype_h	int(10) unsigned	YES	MUL			Model Type Handle of the model
model_class	int(10) unsigned	YES	MUL			model class of the model

network_address	varchar(255)	YES				IP or Network address of the model
first_event_time	datetime	YES		2000-01-01 00:00:00		The time when first event got generated on the model
landscape_h	int(10) unsigned	YES	MUL			Landscape handle of SS where the model is present
destroy_time	datetime	YES	MUL			The time when model is destroyed
security_string	varchar(255)	YES	MUL	*UNKNOWN*		security string of the model
isClusterEntity	int(11)	NO		0		Flag that indicated if the model is cluster or not

Relations



model_state

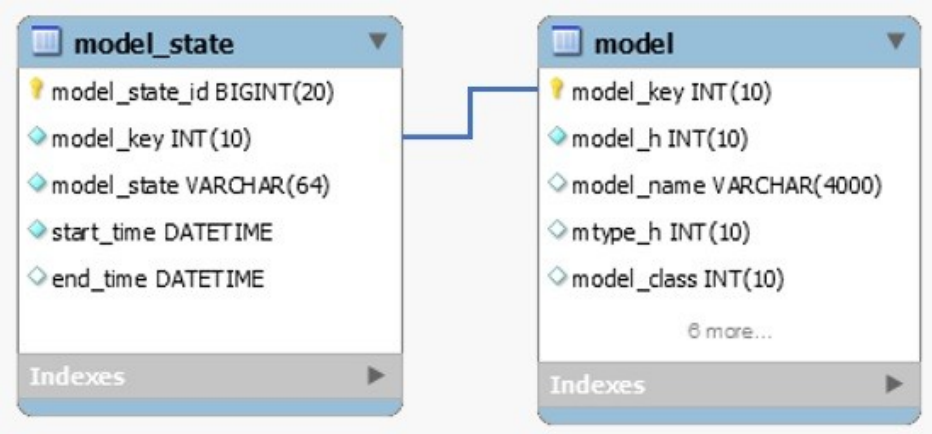
Description

Contains information about model state.

Columns

Field	Type	Null	Key	Default	Extra	Comment
model_state_id	bigint(20) unsigned	NO	PRI		auto_increment	Unique ID for each model state
model_key	int(10) unsigned	NO	MUL			Model key of the model
model_state	varchar(64)	NO	MUL			Model state
start_time	datetime	NO				The time when the model is in this state
end_time	datetime	YES				The time when the model is no longer in this state

Relations



modelclass

Description

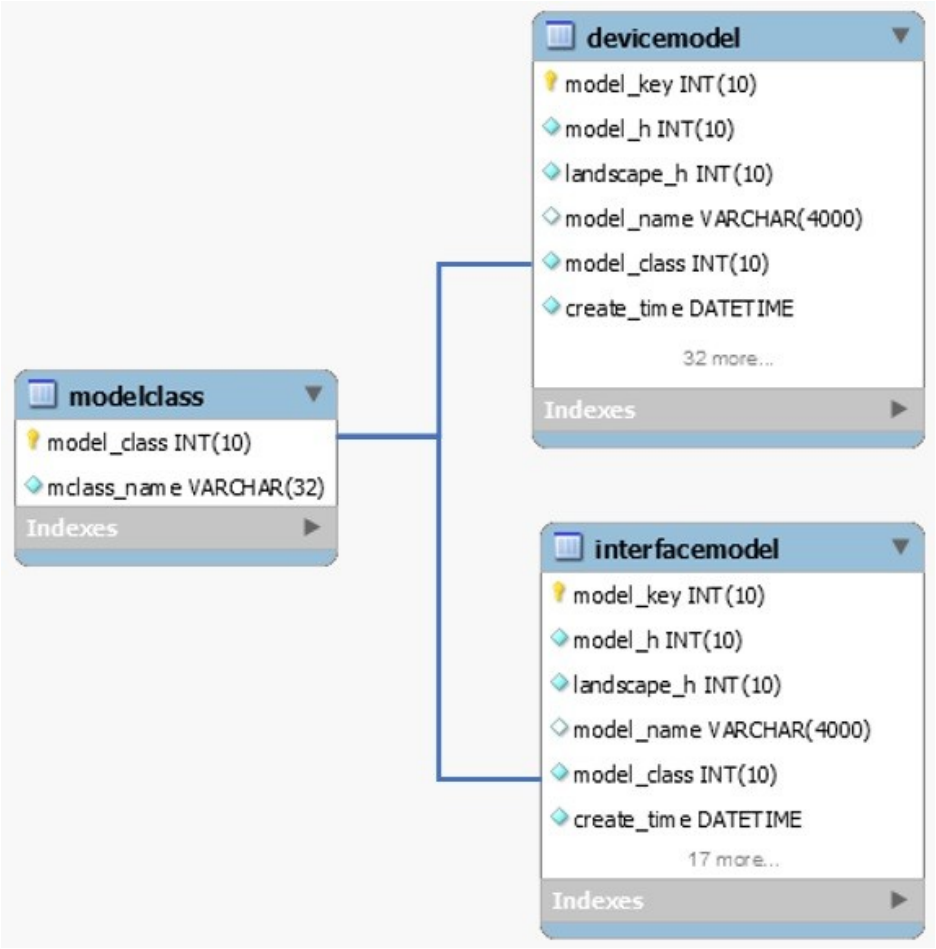
Contains static list containing list of all model class names.

The modelclass table is filled in at the time of table creation.

Columns

Field	Type	Null	Key	Default	Extra	Comment
model_class	int(10) unsigned	NO	PRI			unique number for model class
mclass_name	varchar(32)	NO	MUL			Name of the model class

Relations



modeloutage

Description

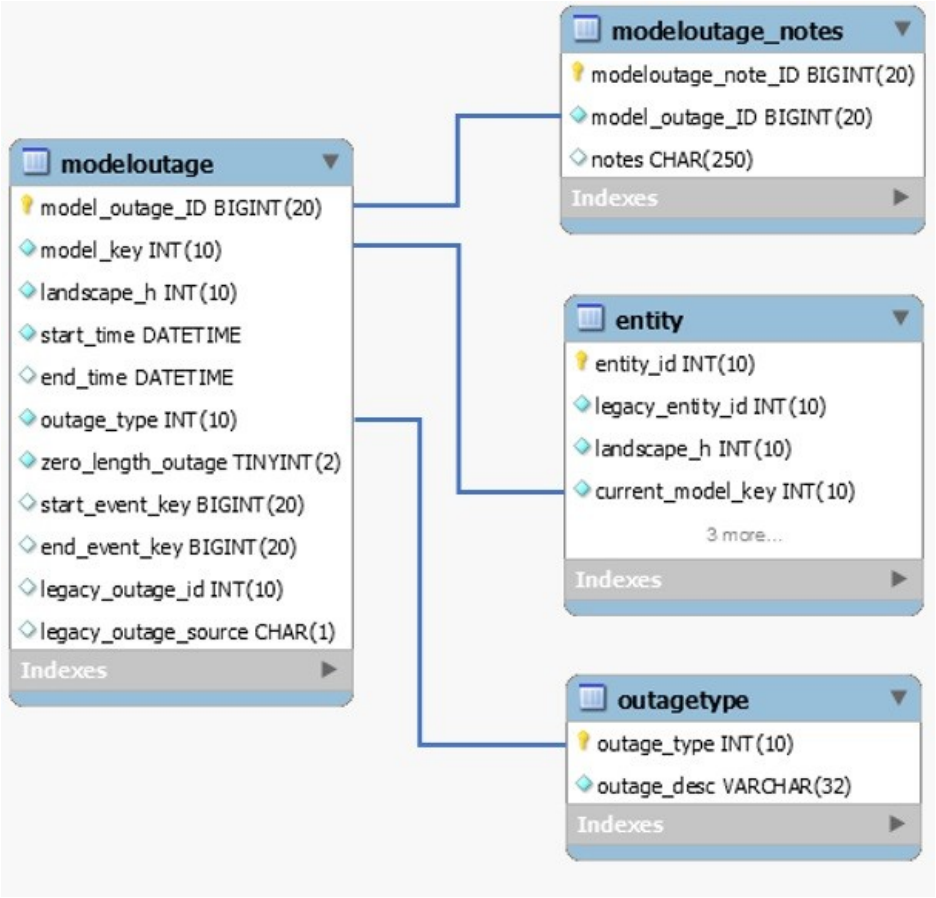
Contains all the outages for the model.

Columns

Field	Type	Null	Key	Default	Extra	Comment
model_outage_ID	bigint(20) unsigned	NO	PRI		auto_increment	Unique ID for each outage of the model
model_key	int(10) unsigned	NO	MUL			Model Key of the model
landscape_h	int(10) unsigned	NO	MUL			landscape handle of SS where the model is present
start_time	datetime	NO	MUL			The time when the outage started for the model
end_time	datetime	YES	MUL			The time when the outage got end for the model
outage_type	int(10) unsigned	NO	MUL			Type of outage on the model
zero_length_outage	tinyint(2)	NO	MUL	0		
start_event_key	bigint(20) unsigned	YES	MUL			

end_event_key	bigint(20) unsigned	YES	MUL			
legacy_outage_id	int(10) unsigned	YES				
legacy_outage_source	char(1)	YES				

Relations



modeloutage_notes

Description

Contains notes for each outage for the model.

Columns

Field	Type	Null	Key	Default	Extra	Comment
modeloutage_note_ID	bigint(20) unsigned	NO	PRI		auto_increment	unique ID for each model outage note
model_outage_ID	bigint(20) unsigned	NO	MUL			Outage ID corresponding to the outage ID in model table
notes	char(250)	YES				model outage notes

Relations

modeltype

Description

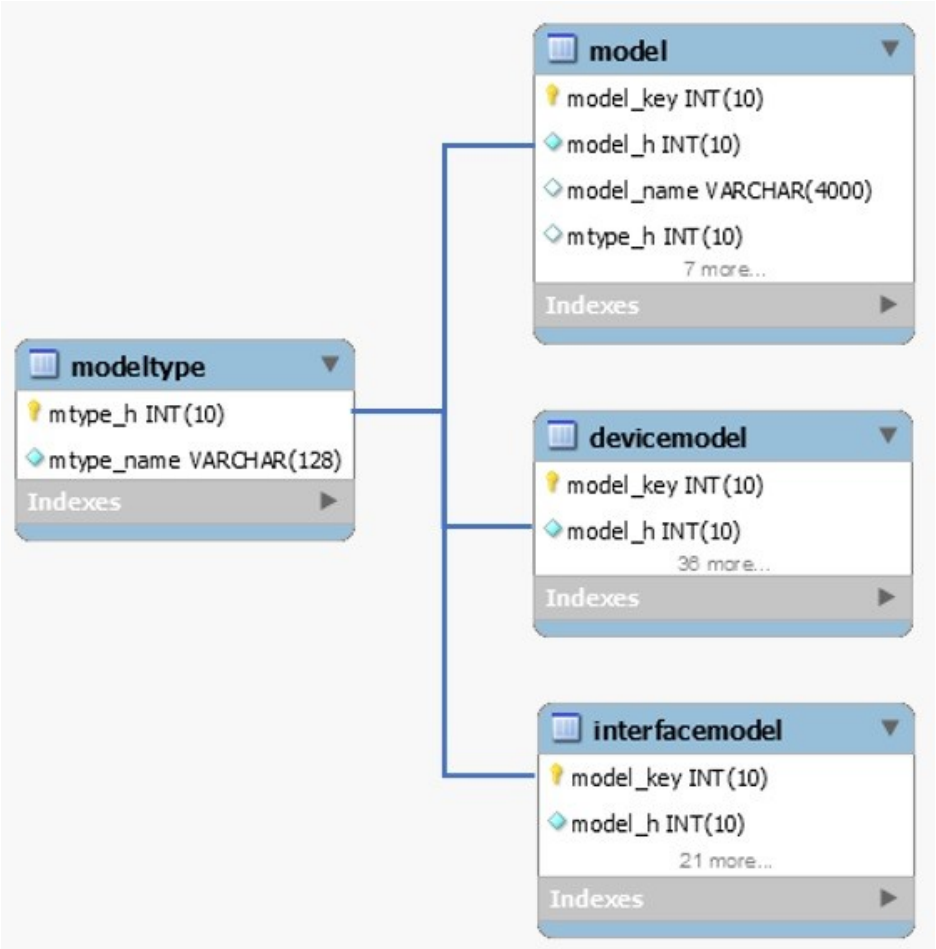
Contains Static list of all model type handles and their names.

The modeltype table is filled in as the Report Manager is starting up. The Report Manager contacts one of the SpectroSERVERs and sends a query requesting the handle and name for all device model types. Once this query is returned, the modeltype table is updated.

Columns

Field	Type	Null	Key	Default	Comment
mtype_h	int(10) unsigned	NO	PRI		Model type handle
mtype_name	varchar(128)	NO			Model Type Name

Relations



ncm_config

Description

Columns

Field	Type	Null	Key	Default	Extra	Comment
config_id	int(10) unsigned	NO	PRI		auto_increment	
config_text_id	int(10) unsigned	NO	MUL			
device_model_key	int(10) unsigned	NO				
change_time	datetime	YES				
trap_from	varchar(255)	NO				
trap_user	varchar(255)	NO				
trap_on	varchar(128)	YES				
lines_changed	int(11)	YES				
rel_lines_changed	int(11)	YES				
violated_policies	varchar(3000)	YES				

compliant_policies	varchar(3000)	YES				
spec_user_name	varchar(255)	YES				
comm_mode	varchar(128)	YES				
landscape	varchar(128)	YES				

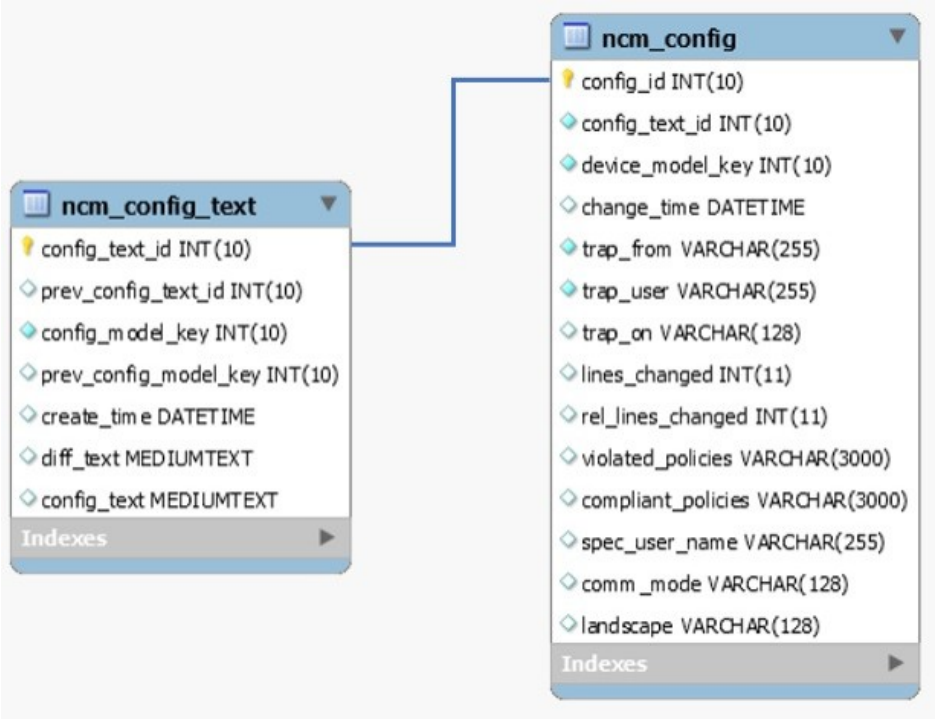
ncm_config_text

Description

Columns

Field	Type	Null	Key	Default	Extra	Comment
config_text_id	int(10) unsigned	NO	PRI		auto_increment	
prev_config_text_id	int(10) unsigned	YES	MUL			
config_model_key	int(10) unsigned	NO	MUL			
prev_config_model_key	int(10) unsigned	YES				
create_time	datetime	YES				
diff_text	mediumtext	YES				
config_text	mediumtext	YES				

Relations



ncm_event_type

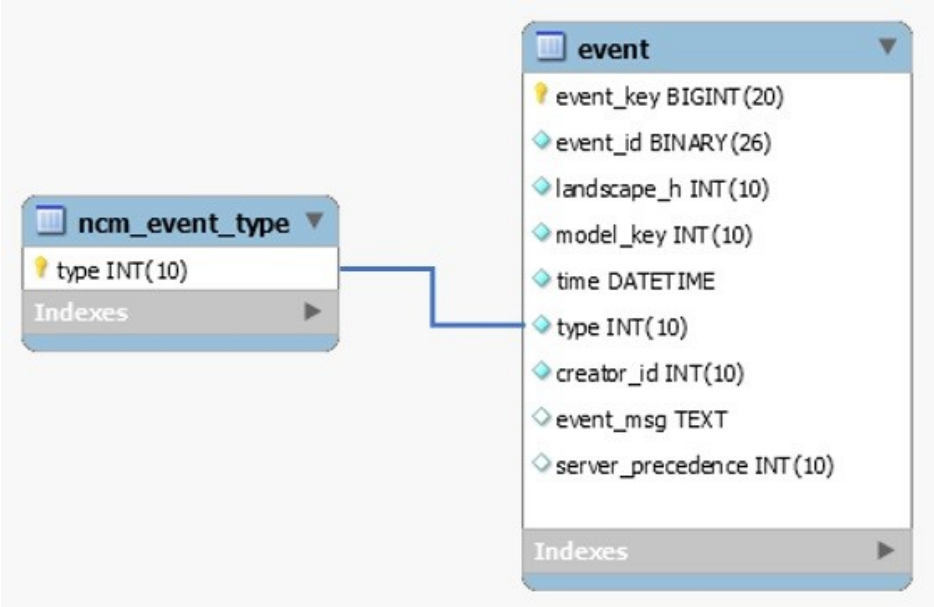
Description

Contains static list of all NCM event types

Columns

Field	Type	Null	Key	Default	Extra	Comment
type	int(10) unsigned	NO	PRI			NCM Event type

Relations



oc_user

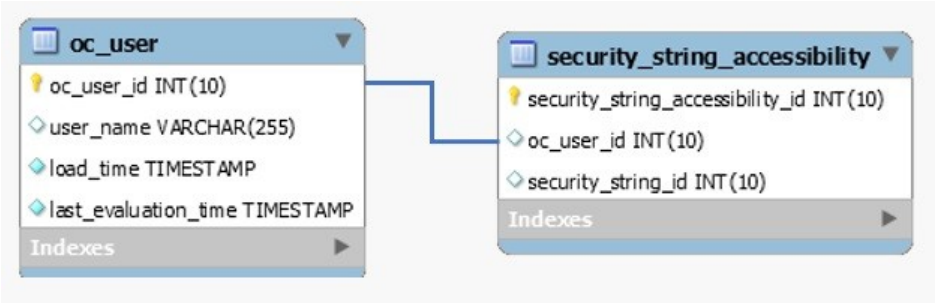
Description

This table contains list of oneclick users

Columns

Field	Type	Null	Key	Default	Extra	Comment
oc_user_id	int(10) unsigned	NO	PRI		auto_increment	
user_name	varchar(255)	YES	UNI			
load_time	timestamp	NO		CURRENT_TIMESTAMP		
last_evaluation_time	timestamp	NO		0000-00-00 00:00:00		

Relations



outagetype

Description

This table contains list outage types and descriptions

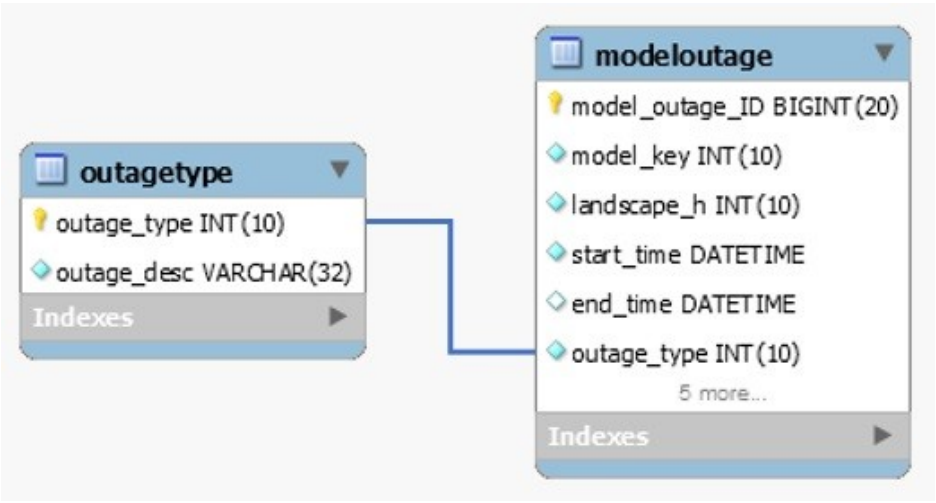
This table is filled in at the time of table creation. Outage types are pre-defined before any outages occur. Table records include:

outage_type	outage_desc
0	Initial
1	Unplanned
2	Planned
3	Exempt

Columns

Field	Type	Null	Key	Default	Extra	Comment
outage_type	int(10) unsigned	NO	PRI			
outage_desc	varchar(32)	NO				

Relations



pcause

Description

This table provides a mapping of cause codes to their titles. It is populated as each new cause is encountered by the alarm handler.

Columns

Field	Type	Null	Key	Default	Extra	Comment
cause_id	int(10) unsigned	NO	PRI			
title	varchar(100)	YES				

performance

Description

This table contains MySQL configuration settings for SRM DB, mostly static data

Columns

Field	Type	Null	Key	Default	Extra	Comment
id	int(10) unsigned	NO	PRI		auto_increment	
runcode	char(255)	YES				
runtime	datetime	YES

portduplex

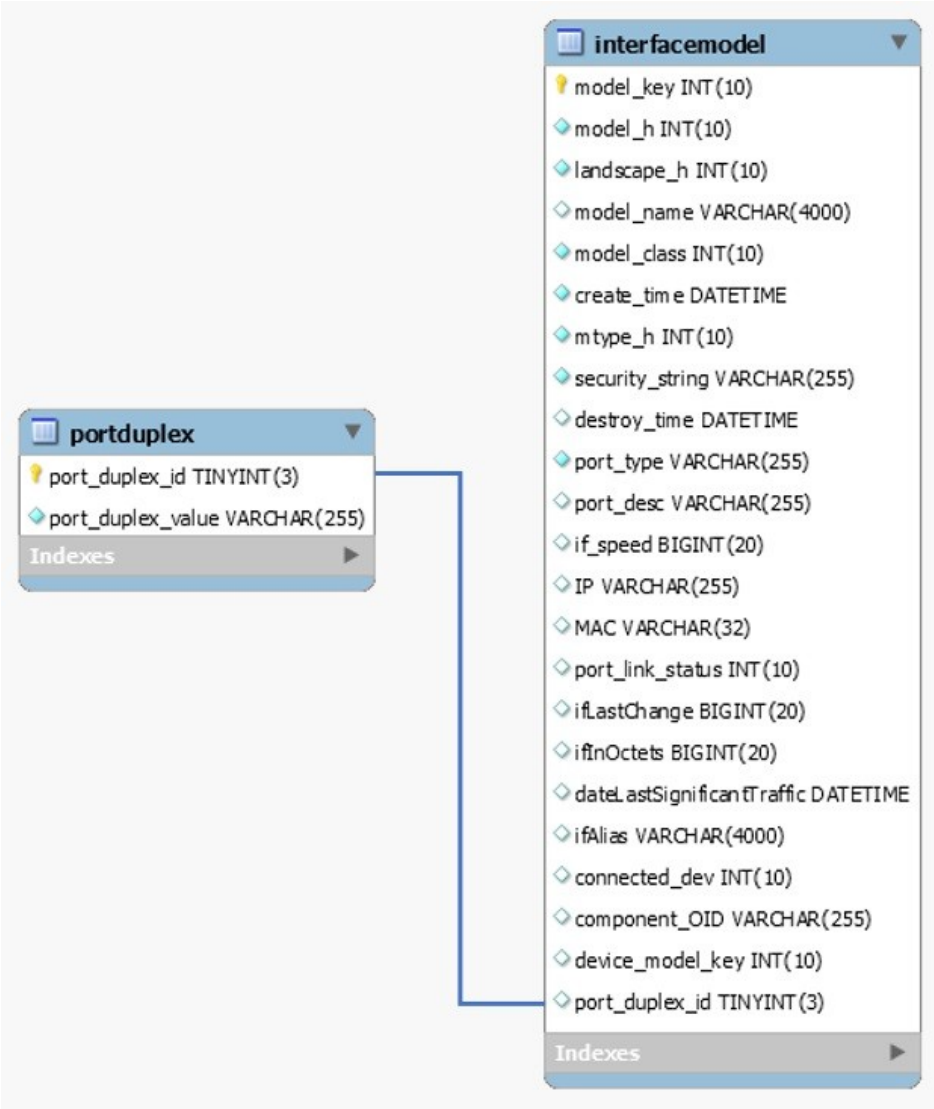
Description

This table contains port duplex IDs and corresponding values

Columns

Field	Type	Null	Key	Default	Extra	Comment
port_duplex_id	tinyint(3) unsigned	NO	PRI			
port_duplex_value	varchar(255)	NO				

Relations



registry

Description

This table provides a storage area for SRM to maintain different properties and attributes of the SRM application. The table stores generic mappings using key/value pairs. Registry entries can have one of the following types:

type id	type name
0	Boolean
1	String
2	Hidden
3	List
4	List Entry

Columns

Field	Type	Null	Key	Default	Extra	Comment
reg_user	varchar(255)	NO	PRI			
OneClickServerEntry	varchar(255)	NO				
SRMPollPeriod	tinyint(4)	NO				
SRMPollStartTime	tinyint(4)	NO				
SRMPollEndTime	tinyint(4)	NO

schemaversion

Description

This table stores data related to SRM schema versioning, change log etc. for one-time changes. Table 'schemaversion_recurring' table stores recurring changes.

Internal table, do not edit

Columns

Field	Type	Null	Key	Default	Extra	Comment
change_id	int(10) unsigned	NO	PRI		auto_increment	
session_id	int(10) unsigned	YES				
name	varchar(255)	NO	UNI			
category	varchar(255)	NO				
schema_comments	varchar(255)	NO				
major	tinyint(4)	NO				
minor	tinyint(4)	NO				
service_pack	tinyint(4)	NO				
start_time	datetime	YES				
end_time	datetime	YES				
duration_secs	int(11)	YES				
state	enum('A','N','F')	YES		A		
state_details	text	YES				

schemaversion_recurring

Description

This table stores data related to SRM schema versioning, change log etc. of recurring changes.

Internal table, do not edit

Columns

Field	Type	Null	Key	Default	Extra	Comment
change_id	int(10) unsigned	NO	PRI		auto_increment	

session_id	int(10) unsigned	YES				
name	varchar(255)	NO	MUL			
category	varchar(255)	NO				
schema_comments	varchar(255)	NO				
major	tinyint(4)	NO				
minor	tinyint(4)	NO				
service_pack	tinyint(4)	NO				
start_time	datetime	YES				
end_time	datetime	YES				
duration_secs	int(11)	YES				
State	enum('A','N','F')	YES		A		
state_details	text	YES				

schemaversion_session

Description

Table stores data related to SRM schema versioning session information. Internal table

Columns

Field	Type	Null	Key	Default	Extra	Comment
session_id	int(10) unsigned	NO	PRI		auto_increment	
session_name	varchar(255)	NO				
start_time	datetime	NO				
end_time	datetime	YES				
duration_secs	int(11)	YES				
state	enum('A','F')	YES				

security_string

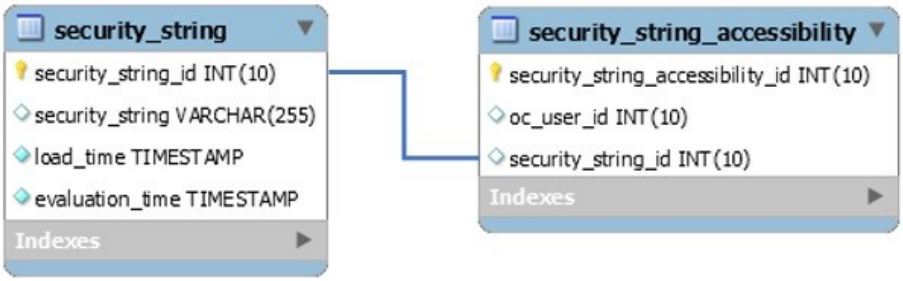
Description

This table stores list of unique security string IDs and security strings for models in reporting DB.

Columns

Field	Type	Null	Key	Default	Extra	Comment
security_string_id	int(10) unsigned	NO	PRI		auto_increment	
security_string	varchar(255)	YES	UNI			
load_time	timestamp	NO		CURRENT_TIMESTAMP		
evaluation_time	timestamp	NO		0000-00-00 00:00:00		

Relations



security_string_accessibility

Description

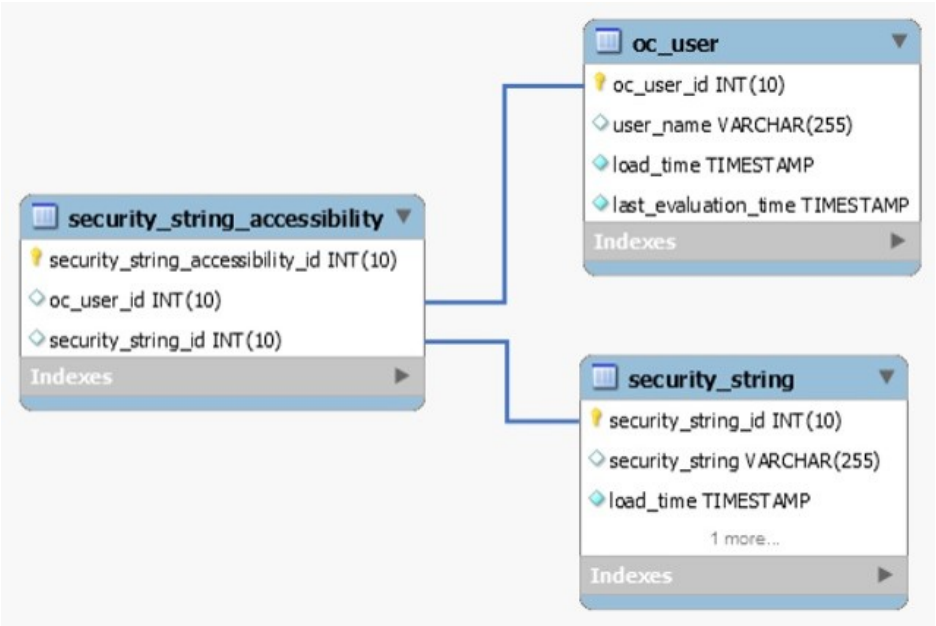
This table stores security string accessibility information. Maps Oneclick user ID to security string ID.

Internal table, do not edit

Columns

Field	Type	Null	Key	Default	Extra	Comment
security_string_accessibility_id	int(10) unsigned	NO	PRI		auto_increment	
oc_user_id	int(10) unsigned	YES	MUL			
security_string_id	int(10) unsigned	YES				

Relations



sm_attributes

Description

Service Manager attributes table - static data

Columns

Column name	Type	Null	Key	Default	Comment
attrID	int(10) unsigned	NO	PRI		Attribute ID of service manager model class
attrName	varchar(255)	NO			Attribute name of service manager model class

Relations

sm_customermhs

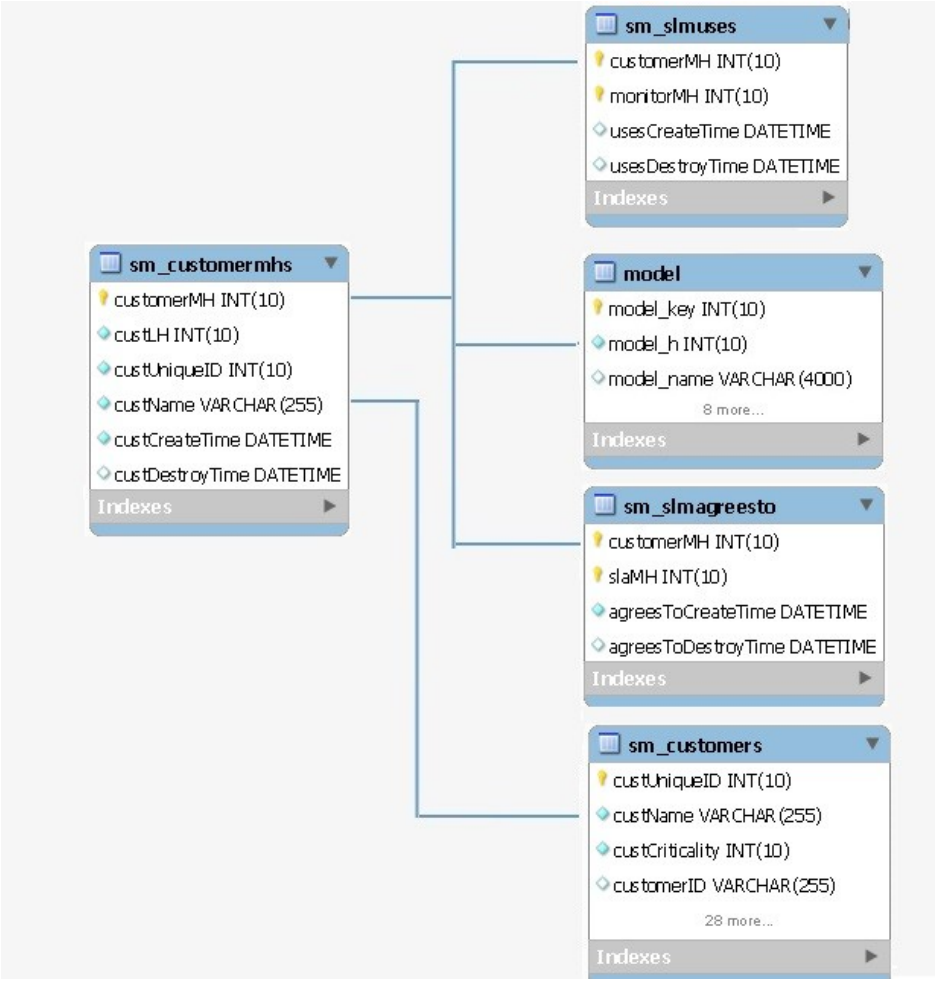
Description

This table stores service manager - customer model handles

Columns

Field	Type	Null	Key	Default	Comment
customerMH	int(10) unsigned	NO	PRI		Customer model handle
custLH	int(10) unsigned	NO			
custUniqueID	int(10) unsigned	NO	MUL		UniqueID of the customer
custName	varchar(255)	NO			customer name
custCreateTime	datetime	NO			customer create time
custDestroyTime	datetime	YES			customer destroy time

Relations



sm_customers

Description

This table stores Service manager – customer details

Columns

Field	Type	Null	Key	Default	Extra	Comment
custUniqueID	int(10) unsigned	NO	PRI		auto_increment	Customer unique ID
custName	varchar(255)	NO	UNI			Customer Name
custCriticality	int(10) unsigned	NO				Customer criticality

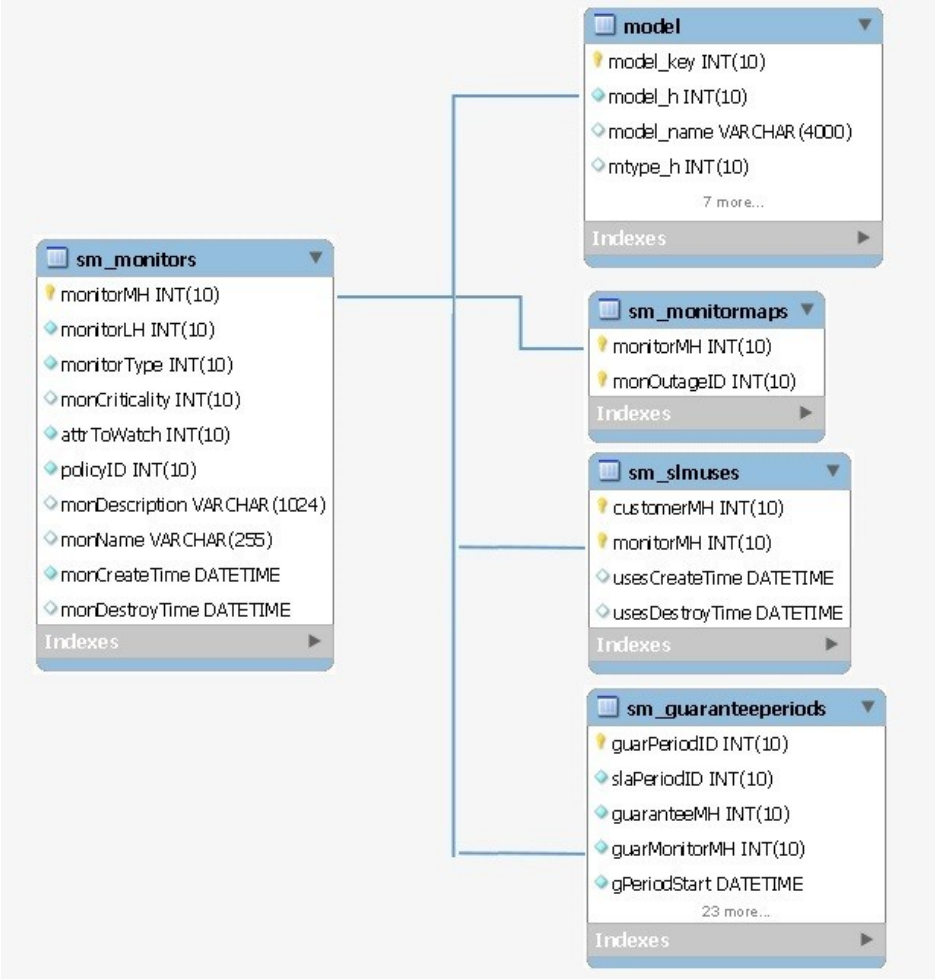
attrToWatch	int(10) unsigned	NO			Attribute to watch
policyID	int(10) unsigned	NO			Policy ID
monDescription	varchar(1024)	YES			Description of the monitor
monName	varchar(255)	YES			Name of the monitor
monCreateTime	datetime	NO			Monitor creation time
monDestroyTime	datetime	YES			Monitor destroy time

Relations



sm_periods

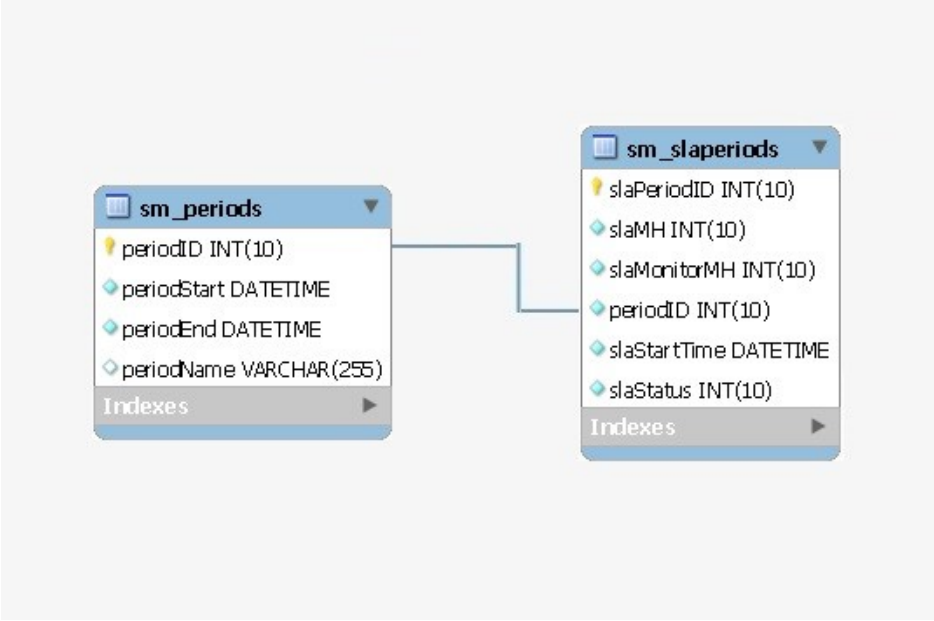
Description

Service Manager Gurantee period Information.

Columns

Field	Type	Null	Key	Default	Extra	Comment
periodID	int(10) unsigned	NO	PRI		auto_increment	Unique ID for each Guarantee period.
periodStart	datetime	NO				Guarantee Start period.
periodEnd	datetime	NO				Guarantee End period.
periodName	varchar(255)	YES				Guarantee period Name.

Relations



sm_policies

Description

Contains information about Service Manager policies.

Column

Field	Type	Null	Key	Default	Comment
policyName	varchar(255)	NO			Name of the Policy
policyID	int(11)	NO	PRI		Unique Policy ID for each service.
policyDescription	text	NO			Description of the Policy

Relations

sm_resourcecauses

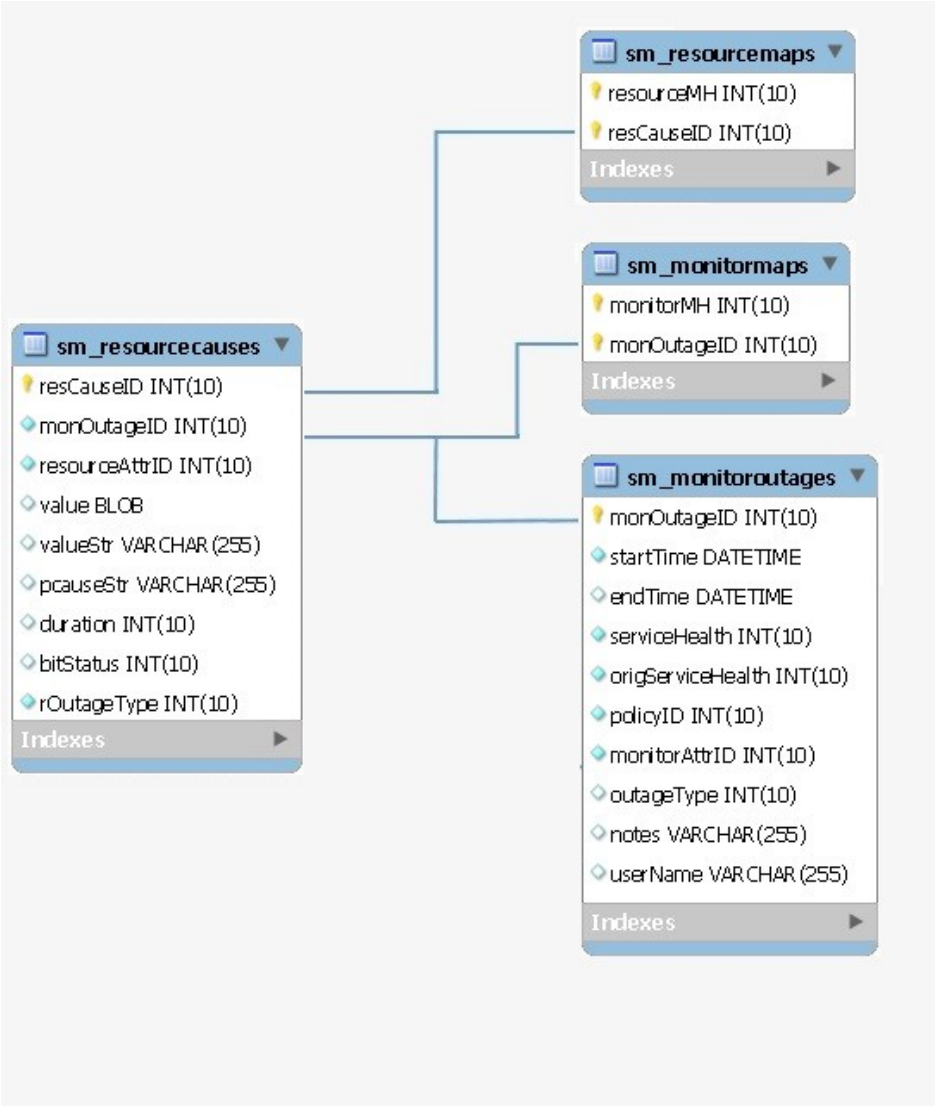
Description

The name of the table used to store the resource outages that make up each monitor outage. Each resource outage contains the model handle of the resource model that the outage was on, and the value that caused the monitor outage.

Column

Field	Type	Null	Key	Default	Extra	Comment
valueStr	varchar(255)	YES				Alarm status of the Resource.
value	blob	YES				Value that caused the monitor outage
rOutageType	int(10) unsigned	NO				Type of the Outage happened to the Resource.
resourceAttrID	int(10) unsigned	NO				Attribute ID of the Resource Monitor
resCauseID	int(10) unsigned	NO	PRI		auto_increment	Unique Cause ID of the Resource.
pcauseStr	varchar(255)	YES				Alarm Title of the Resource.
monOutageID	int(10) unsigned	NO	MUL			Unique Outage ID of the Resource Monitor
duration	int(10) unsigned	YES				Duration of the Event.
bitStatus	int(10) unsigned	YES				bitStatus

Relations



sm_resourcemaps

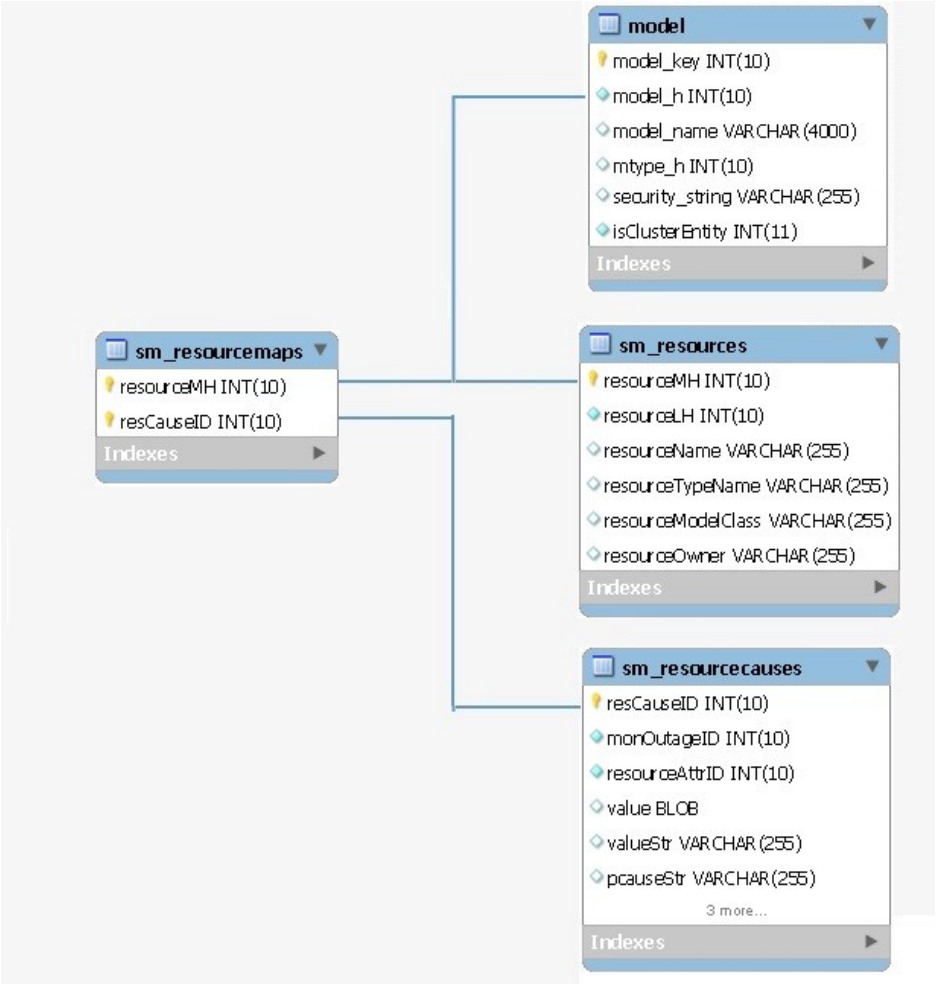
Description

The name of the table used to store the mapping between a resource cause and the model that caused it.

Column

Field	Type	Null	Key	Default	Comment
resourceMH	int(10) unsigned	NO	PRI		Unique Model_Handle of the Resource.
resCauseID	int(10) unsigned	NO	PRI		Unique Cause ID of the Resource.

Relations



sm_resources

Description

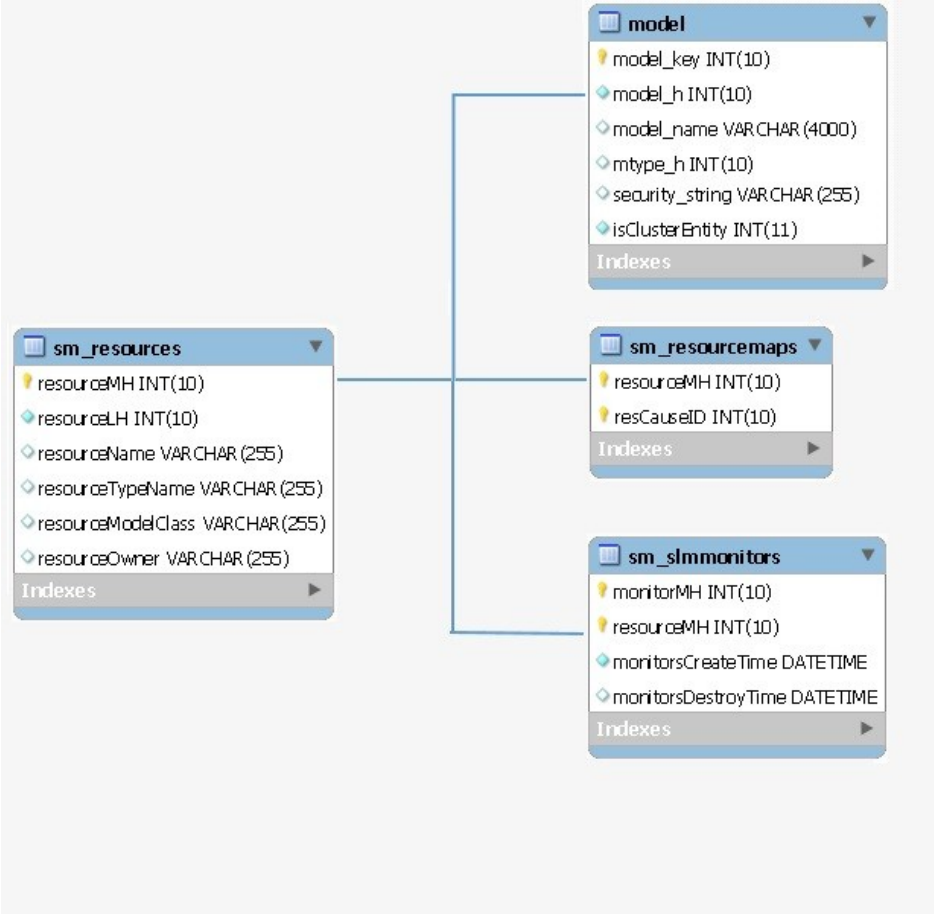
The name of the table that contains all the resources used by a service or attribute monitor.

Column

Field	Type	Null	Key	Default	Comment
resourceTypeName	varchar(255)	YES			Model_Type of the Resource.
resourceOwner	varchar(255)	YES			Owner of the resource
resourceName	varchar(255)	YES			Name of the Resource.
resourceModelClass	varchar(255)	YES			Model_Class of the Resource.
resourceMH	int(10) unsigned	NO	PRI		Unique Model_Handle of the Resource.

resourceLH	int(10) unsigned	NO			Landscape Handle of the Resource.

Relations



sm_schemaversion

Description

The name of the table that contains the current schema version of the SLM DB.

Column

Field	Type	Null	Key	Default	Comment
versionID	varchar(255)	NO	PRI		Unique version ID of the Schema.
comments	varchar(255)	NO			Brief description on the installed version.

Relations

sm_servicehealth

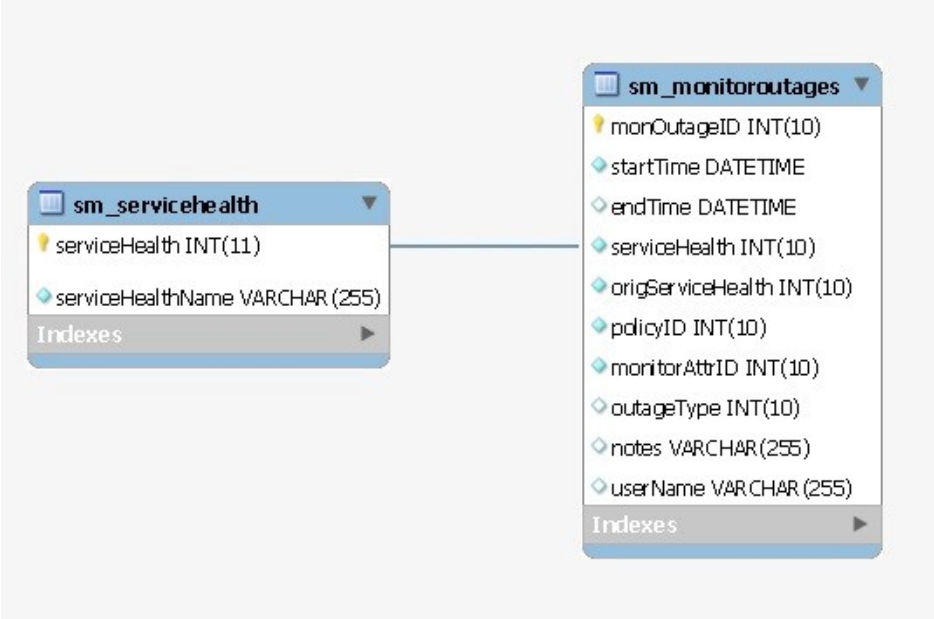
Description

The name of the table used to store attribute type data.

Column

Field	Type	Null	Key	Default	Extra	Comment
serviceHealthName	varchar(255)	NO				Name of the Service.
serviceHealth	int(11)	NO	PRI			Health of the Service.

Relations



sm_slaperiods

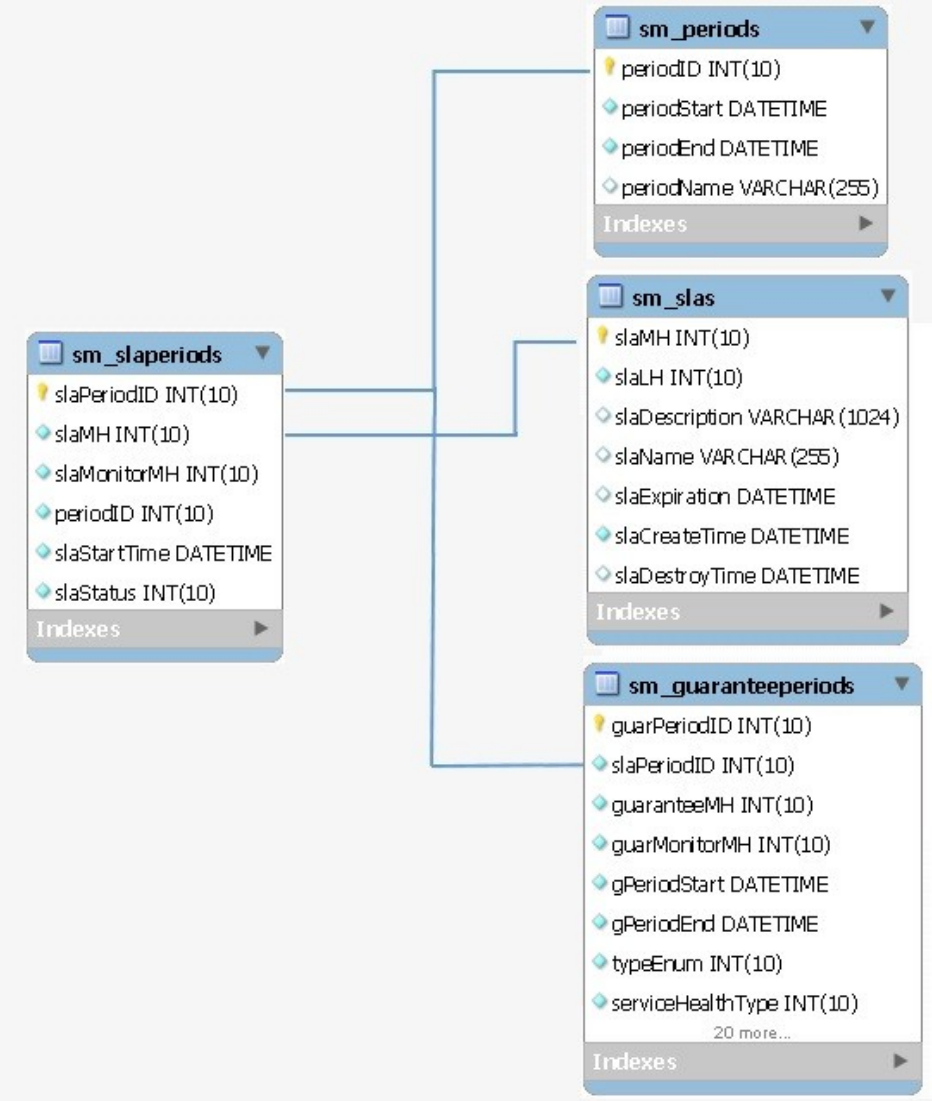
Description

Contains Information of Service Level Agreement.

Columns

Field	Type	Null	Key	Default	Extra	Comment
slaPeriodID	int(10) unsigned	NO	PRI		auto_increment	Unique Period ID for each SLA.
slaMH	int(10) unsigned	NO	MUL			Model_Handle of SLA.
slaMonitorMH	int(10) unsigned	NO				Model_Handle of slaMonitor.
periodID	int(10) unsigned	NO				Period ID of each SLA.
slaStartTime	datetime	NO				Start time of SLA.
slaStatus	int(10) unsigned	NO				Status of SLA

Relations



sm_slas

Description

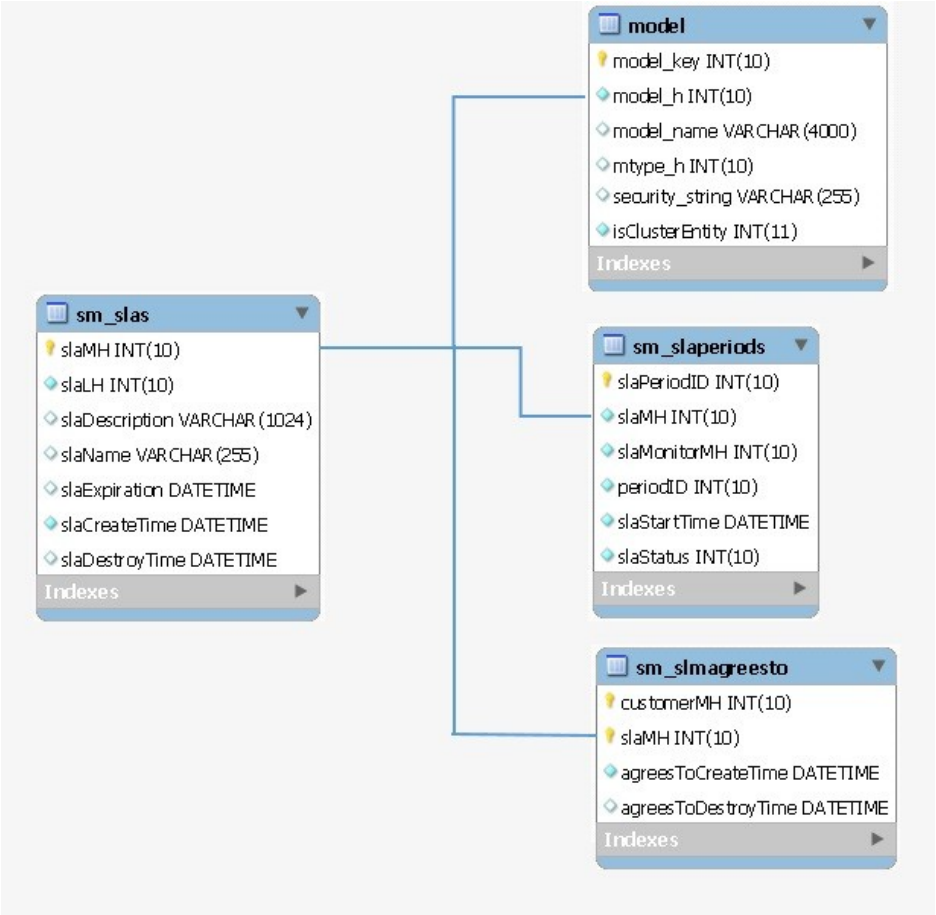
Contains information of all SLA models.

Columns

Column Name	Type	Null	Key	Default	Comment
slaMH	int(10) unsigned	NO	PRI		Model handle of SLA
slaLH	int(10) unsigned	NO			Landscape Handle of SpectroServer where the SLA is present
slaDescription	varchar(1024)	YES			Description of SLA
slaName	varchar(255)	YES			Name of the SLA

slaExpiration	datetime	YES			SLA expiration time
slaCreateTime	datetime	NO			Time when SLA is created
slaDestroyTime	datetime	YES			Time when SLA is destroyed

Relations



sm_slmagreesto

Description

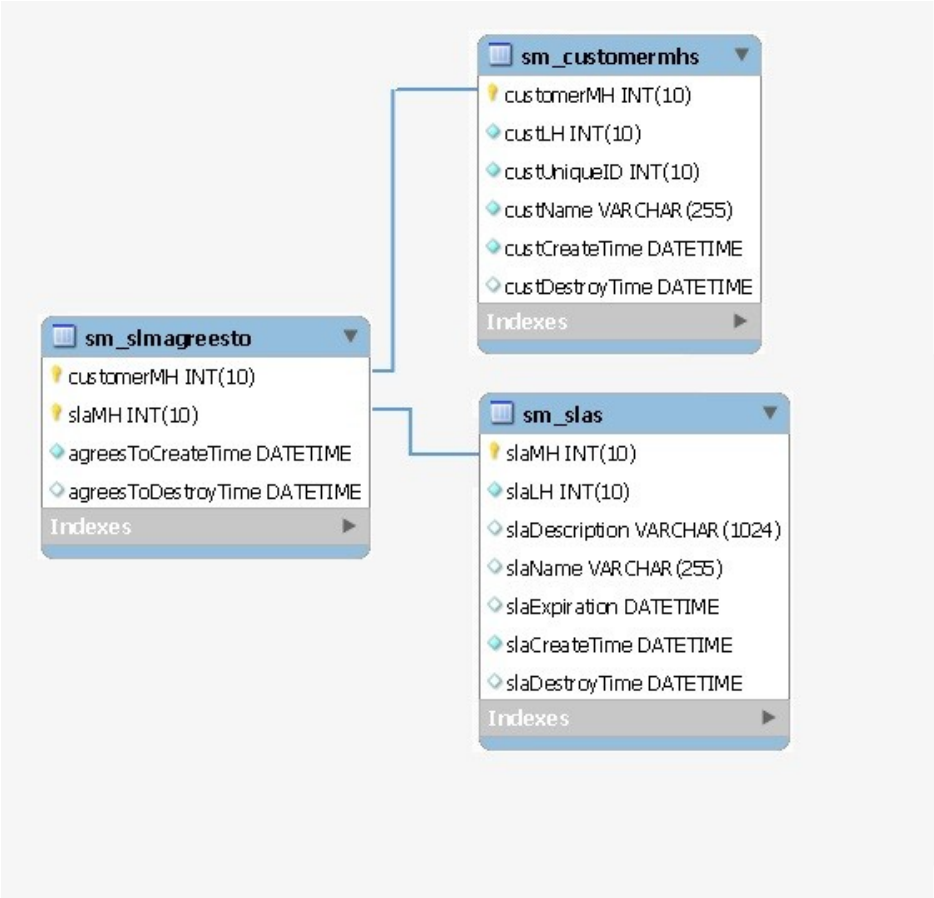
Contains associations between customers and their SLAs.

Columns

Field	Type	Null	Key	Default	Comment
customerMH	int(10) unsigned	NO	PRI		Model handle of customer in decimal
slaMH	int(10) unsigned	NO	PRI		model handle of SLA in decimal

agreesToCreateTime	datetime	NO			The time when customer is associated with SLA
agreesToDestroyTime	datetime	YES			The time when association between customer and SLA is removed

Relations



sm_slmlandscapes

Description

Contains last event retrieved time for each landscape.

Columns

Field	Type	Null	Key	Default	Comment
landscapeHandle	int(10) unsigned	NO	PRI		Landscape handle of SpectroServer
domainName	varchar(255)	NO			Domain Name of SpectroServer

servSyncTime	datetime	YES			Time the last event retrieved from the landscape

Relations

sm_slmmonitors

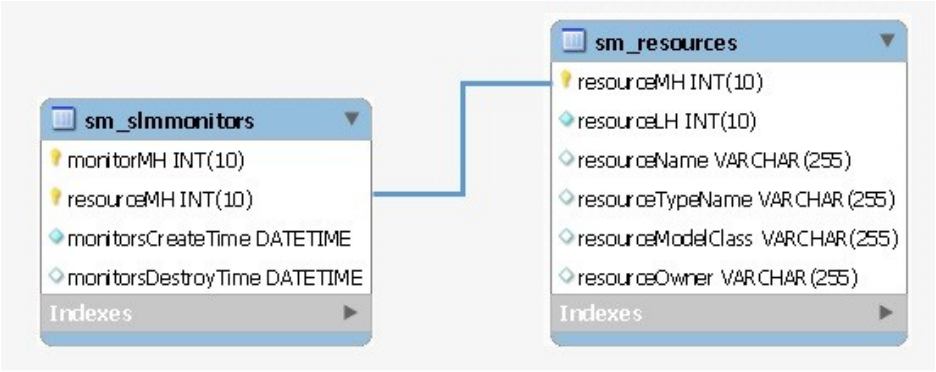
Description

Contains the association between services, resource monitors, and resources.

Columns

Field	Type	Null	Key	Default	Comment
monitorMH	int(10) unsigned	NO	PRI		contains Model handles of services and resource monitors
resourceMH	int(10) unsigned	NO	PRI		Contains model handles of resource monitors and resources (devices)
monitorsCreateTime	datetime	NO			Creation time of monitors (resource monitor or resources/ devices)
monitorsDestroyTime	datetime	YES			Destory time of monitors (resource monitor or resources/ devices)

Relations



sm_slmowns

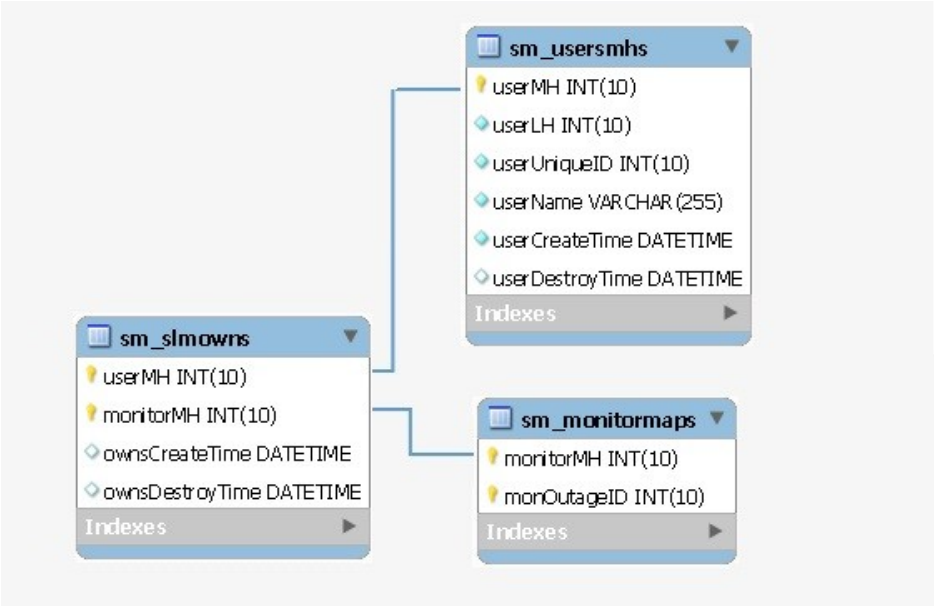
Description

Contains information about the services used by user (owner).

Columns

Field	Type	Null	Key	Default	Comment
userMH	int(10) unsigned	NO	PRI		User model handle
monitorMH	int(10) unsigned	NO	PRI		Model handle of the service that user (owner) uses
ownsCreateTime	datetime	YES			user (owner) creation time
ownsDestroyTime	datetime	YES			user (owner) destroy time

Relations



sm_slmuses

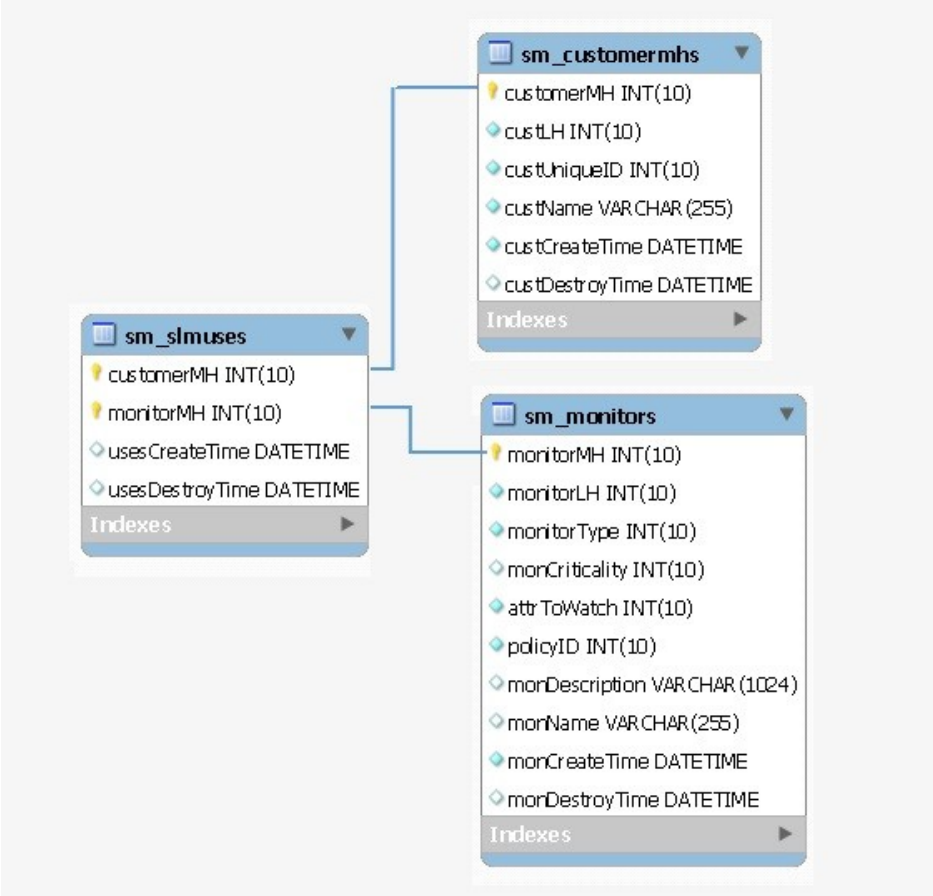
Description

Contains the information about the services used by customer.

Columns

Field	Type	Null	Key	Default	Comment
customerMH	int(10) unsigned	NO	PRI		Customer Model Handle
monitorMH	int(10) unsigned	NO	PRI		Model handle of the service that the customer use
usesCreateTime	datetime	YES			customer creation time
usesDestroyTime	datetime	YES			customer destroy time

Relations



sm_users

Description

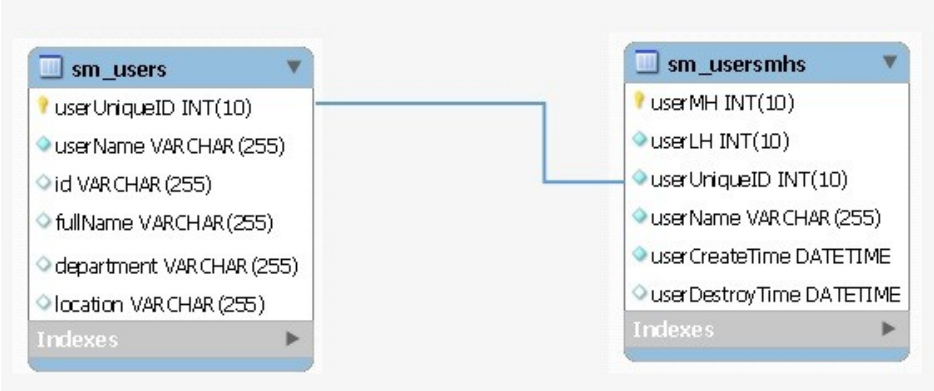
Contains contact information of users.

Columns

Field	Type	Null	Key	Default	Extra	Comment
userUniqueID	int(10) unsigned	NO	PRI		auto_increment	Auto incremented unique user IDs
userName	varchar(255)	NO	UNI			Name of the User
id	varchar(255)	YES				User ID
fullName	varchar(255)	YES				full name of the user
phone	varchar(255)	YES				Phone number of the user
email	varchar(255)	YES				email id of the user
street	varchar(255)	YES				street name of the user

city	varchar(255)	YES				city of the user
state	varchar(255)	YES				state of the user
country	varchar(255)	YES				country of the user
organization	varchar(255)	YES				organization of the user
site	varchar(255)	YES				site of the user loacated
department	varchar(255)	YES				Department of the user
location	varchar(255)	YES				Location of the user

Relations



sm_usersmhs

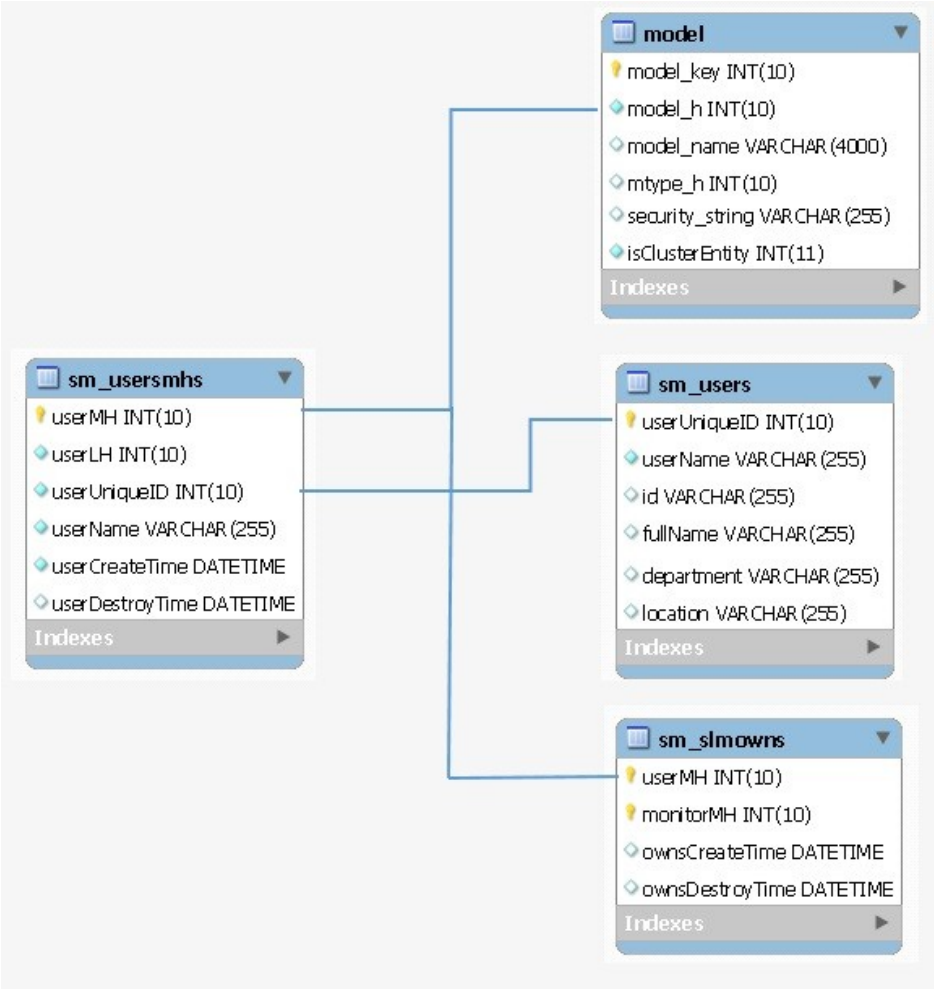
Description

Contain information about service owners or service users.

Columns

Field	Type	Null	Key	Default	Comment
userMH	int(10) unsigned	NO	PRI		service owner model handle
userLH	int(10) unsigned	NO			Landscape handles of the SS where the user is present
userUniqueID	int(10) unsigned	NO	MUL		Auto incremented unique user ids
userName	varchar(255)	NO			Name of service user / owner
userCreateTime	datetime	NO			The time when user created
userDestroyTime	datetime	YES			The time when user Destroyed

Relations



spmbasictestresults

Description

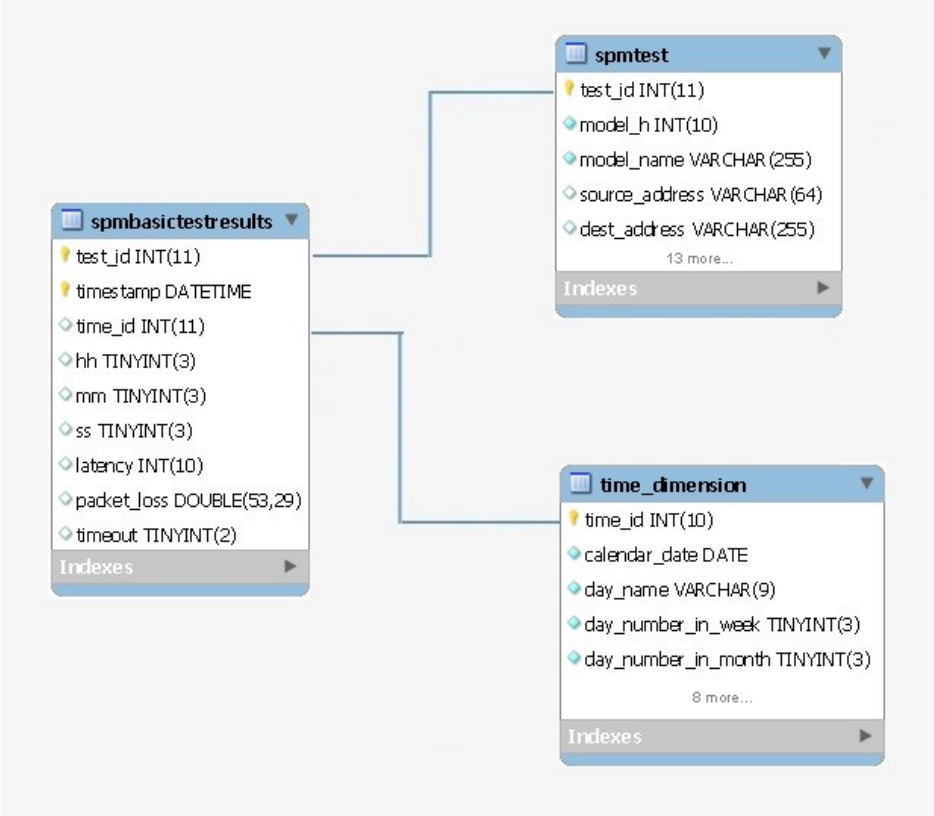
This table stores Service Performance Manager(SPM) basic test results data

Columns

Field	Type	Null	Key	Default	Comment
test_id	int(11) unsigned	NO	PRI	0	Test ID that uniquely identifies a SPM test
timestamp	datetime	NO	PRI	0000-00-00 00:00:00	Timestamp corresponds with time at which result occurred.
time_id	int(11) unsigned	YES	MUL		Time ID from time_dimension table
hh	tinyint(3) unsigned	YES			Hours field of "timestamp" field.

mm	tinyint(3) unsigned	YES			Minutes field of "timestamp" field.
ss	tinyint(3) unsigned	YES			Seconds field of "timestamp" field.
latency	int(10) unsigned	YES			latency for the test
packet_loss	double(53,29)	YES			pocket loss during test
timeout	tinyint(2)	YES			1=timeout occurred, 0=no timeout occurred

Relations



spmhttpfulltestresults

Description

This table stores Service Performance Manager(SPM) http full test results data

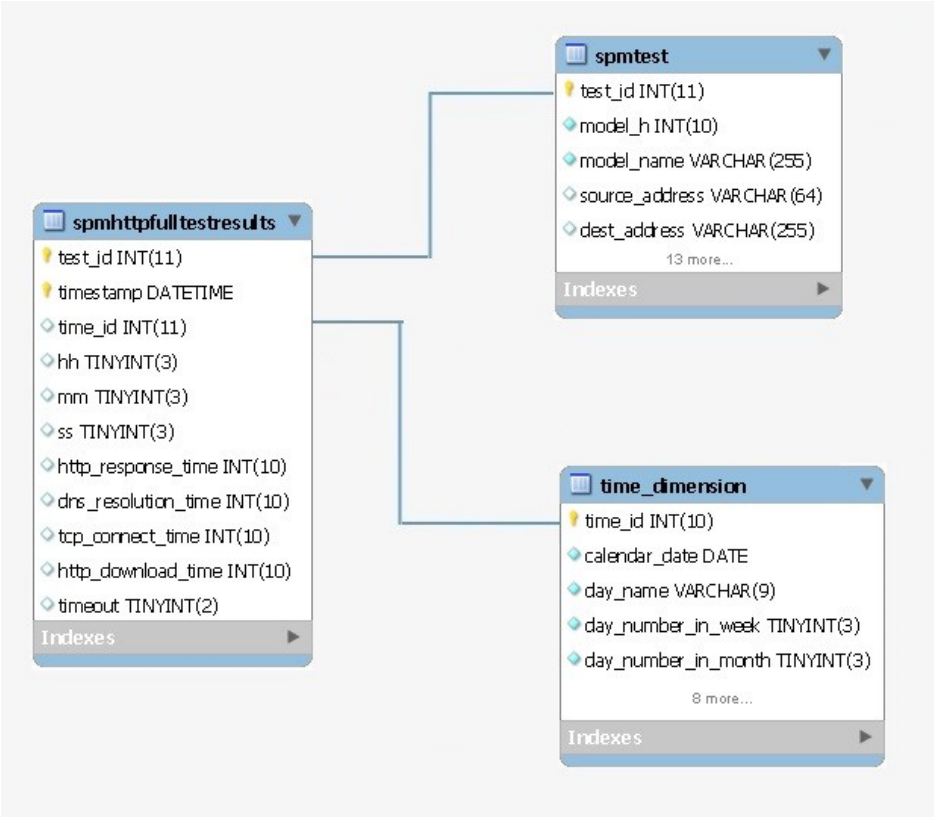
(HTTP tests measure the round-trip time to get a web page.)

Columns

Field	Type	Null	Key	Default	Comment
test_id	int(11) unsigned	NO	PRI	0	Test ID that uniquely identifies a SPM test

timestamp	datetime	NO	PRI	0000-00-00 00:00:00	Timestamp corresponds with time at which result occurred.
time_id	int(11) unsigned	YES	MUL		Time ID from time_dimension table
hh	tinyint(3) unsigned	YES			Hours field of "timestamp" field.
mm	tinyint(3) unsigned	YES			Minutes field of "timestamp" field.
ss	tinyint(3) unsigned	YES			Seconds field of "timestamp" field.
http_response_time	int(10) unsigned	YES			http test response time
dns_resolution_time	int(10) unsigned	YES			time took for dns resolution for this test
tcp_connect_time	int(10) unsigned	YES			tcp connect time
http_download_time	int(10) unsigned	YES			http download time
timeout	tinyint(2)	YES			1=timeout occurred, 0=no timeout occurred

Relations



spmjittertestresults

Description

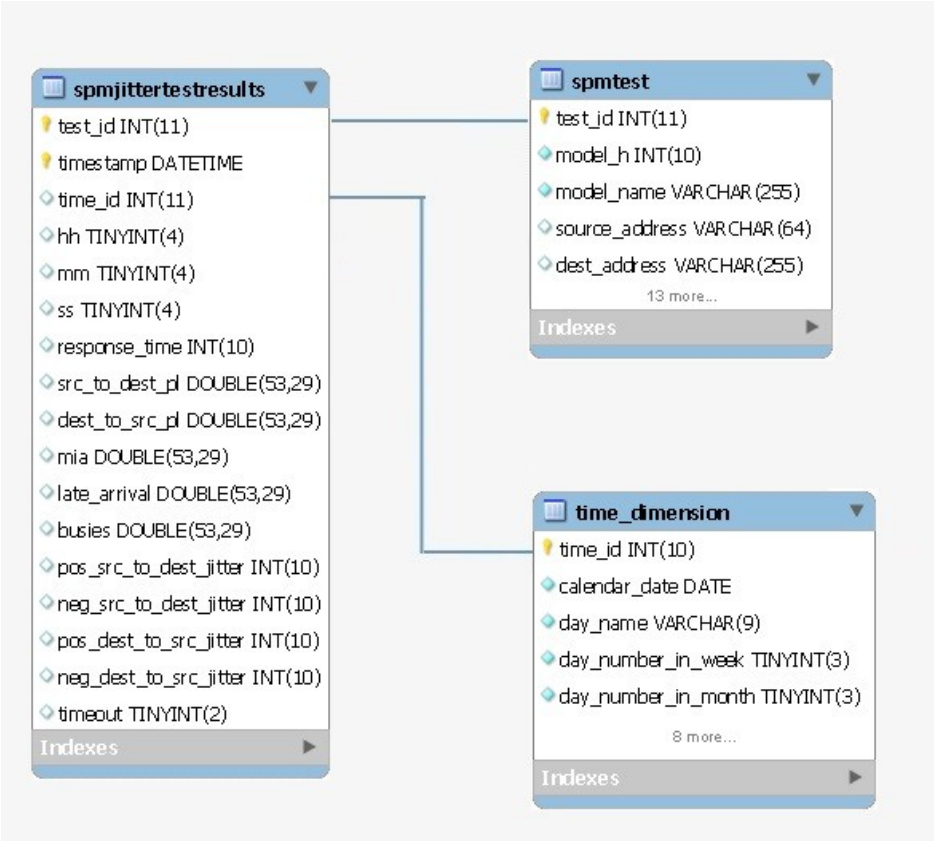
This table stores Service Performance Manager(SPM) jitter test results data

(Jitter tests measure both latency and loss between a test host and a voice-enabled endpoint.)

Columns

Field	Type	Null	Key	Default	Comment
test_id	int(11) unsigned	NO	PRI	0	Test ID that uniquely identifies a SPM test
timestamp	datetime	NO	PRI	0000-00-00 00:00:00	Timestamp corresponds with time at which result occurred.
time_id	int(11) unsigned	YES	MUL		Time ID from time_dimension table
hh	tinyint(4) unsigned	YES			Hours field of "timestamp" field.
mm	tinyint(4) unsigned	YES			Minutes field of "timestamp" field.
ss	tinyint(4) unsigned	YES			Seconds field of "timestamp" field.
response_time	int(10) unsigned	YES			response time for this jitter test
src_to_dest_pl	double(53,29)	YES			Source to Destination Packet Loss
dest_to_src_pl	double(53,29)	YES			Destination to Source Packet Loss
mia	double(53,29)	YES			Missing in Action – Packet Loss with Unknown Direction
late_arrival	double(53,29)	YES			Late Arrival
busies	double(53,29)	YES			Busies
pos_src_to_dest_jitter	int(10) unsigned	YES			Positive source to destination jitter
neg_src_to_dest_jitter	int(10) unsigned	YES			Negative source to destination jitter
pos_dest_to_src_jitter	int(10) unsigned	YES			Positive destination to source jitter
neg_dest_to_src_jitter	int(10) unsigned	YES			Negative destination to source jitter
timeout	tinyint(2)	YES			1=timeout occurred, 0=no timeout occurred

Relations



spmtest

Description

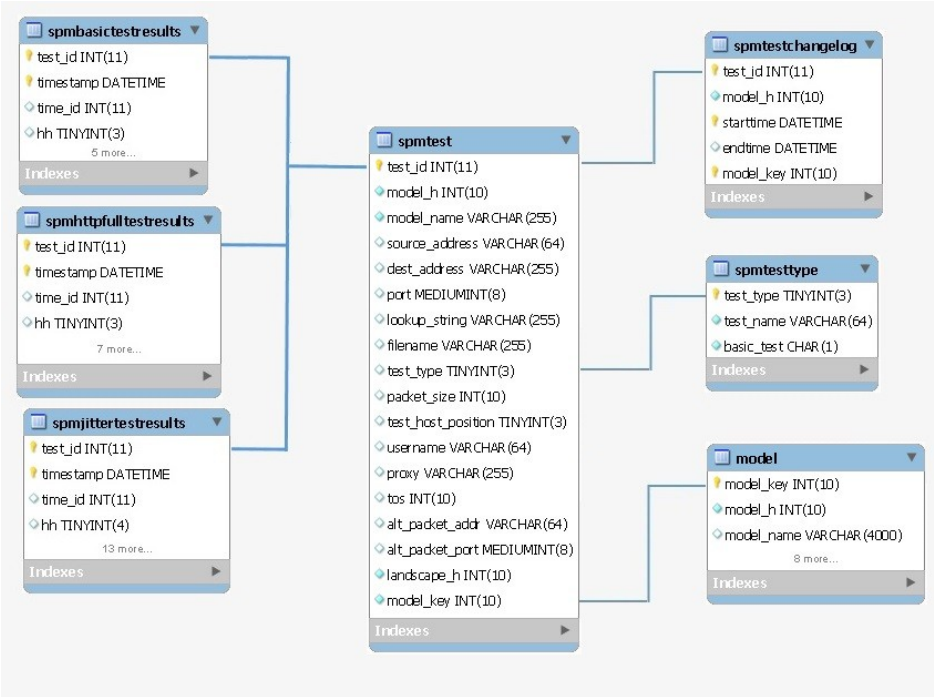
This table stores Service Performance Manager(SPM) test data

Columns

Field	Type	Null	Key	Default	Extra	Comment
test_id	int(11) unsigned	NO	PRI		auto_increment	Test ID that uniquely identifies a SPM test
model_h	int(10) unsigned	NO	MUL	0		Model Handle of the SPM Test Model (decimal form)
model_name	varchar(255)	NO				Model Name of the SPM Test model
source_address	varchar(64)	YES				Source address
dest_address	varchar(255)	YES				Destination address
port	mediumint(8) unsigned	YES				port
lookup_string	varchar(255)	YES				Lookup String

filename	varchar(255)	YES				Filename
test_type	tinyint(3) unsigned	YES	MUL			Type of test
packet_size	int(10)	YES				Packet Size
test_host_position	tinyint(3) unsigned	YES				Test Host Position
username	varchar(64)	YES				user name
proxy	varchar(255)	YES				proxy
tos	int(10) unsigned	YES				Type of service
alt_packet_addr	varchar(64)	YES				Alternate Packet Address
alt_packet_port	mediumint(8) unsigned	YES				Alternate Packet Port
landscape_h	int(10) unsigned	NO		0		Landscape Handle (hexadecimal form)
model_key	int(10) unsigned	NO	MUL	0		Internal Key that uniquely identifies the SPM Test Model

Relations



spmtestchangelog

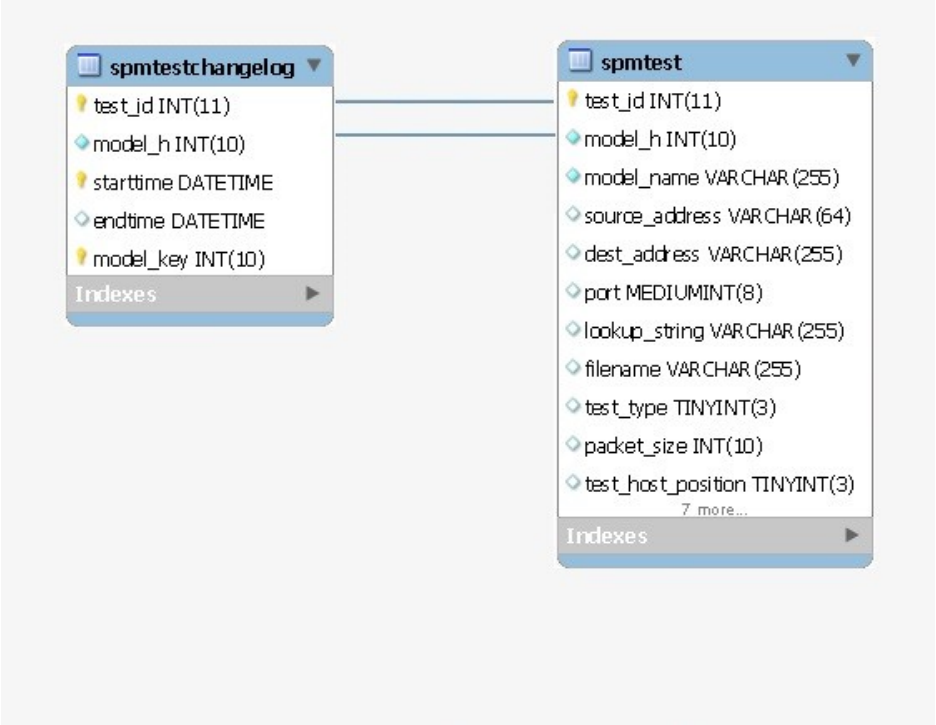
Description

This table stores Service Performance Manager(SPM) test change log data

Columns

Field	Type	Null	Key	Default	Comment
test_id	int(11) unsigned	NO	PRI	0	Test ID that uniquely identifies a SPM test
model_h	int(10) unsigned	NO	MUL	0	Model Handle of the SPM Test Model (decimal form)
starttime	datetime	NO	PRI	0000-00-00 00:00:00	Test start time
endtime	datetime	YES			Test end time
model_key	int(10) unsigned	NO	PRI	0	Internal Key that uniquely identifies the SPM Test Model

Relations



spmtesttype

Description

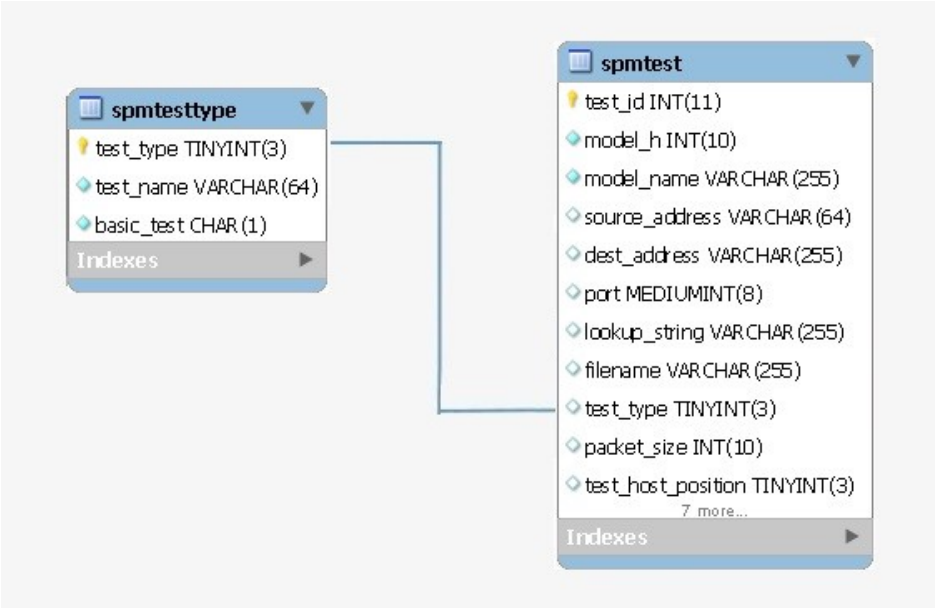
This table stores Service Performance Manager(SPM) test type data like test name and test type etc.

Columns

Field	Type	Null	Key	Default	Comment
test_type	tinyint(3) unsigned	NO	PRI	0	Type of SPM test
test_name	varchar(64)	NO			Name of the SPM test

basic_test	char(1)	NO		Y	Whether this test is basic test or not (Y/N)

Relations



time_dimension

Description

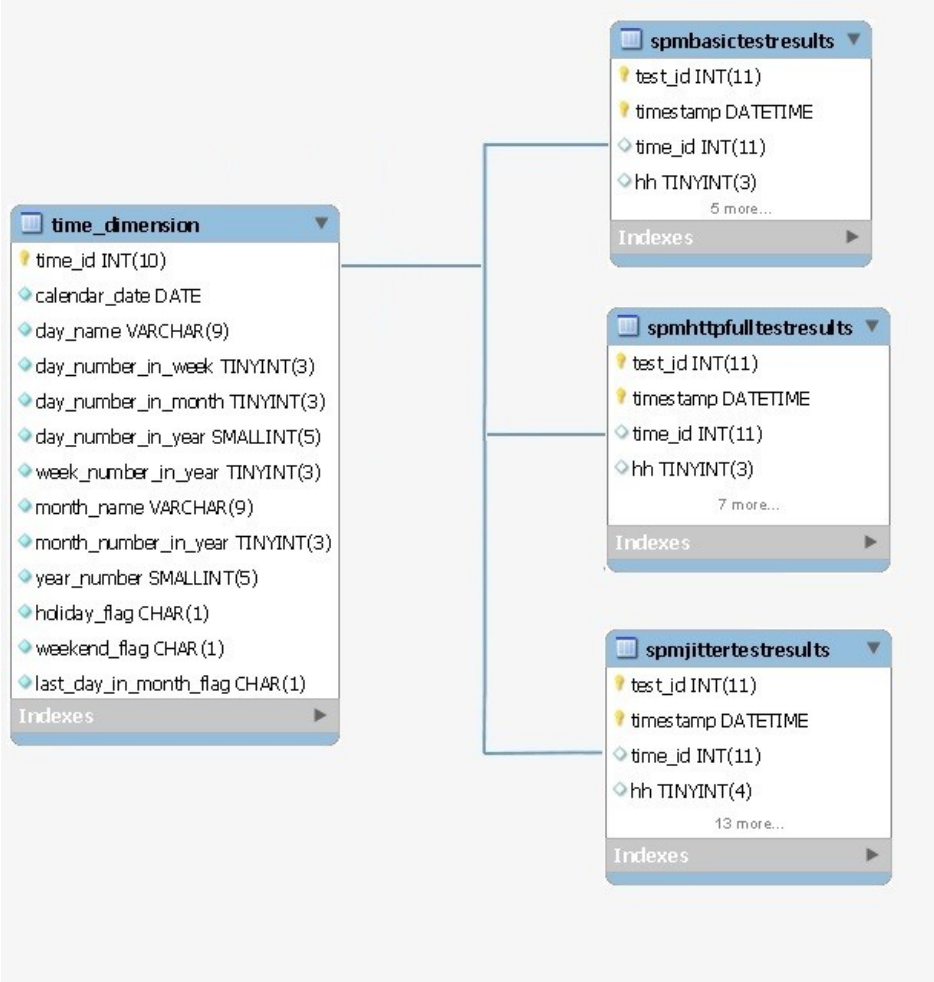
This table stores time dimension data for SPM test result tables

Columns

Field	Type	Null	Key	Default	Extra	Comment
time_id	int(10) unsigned	NO	PRI		auto_increment	Internal ID that uniquely identifies a time in the calendar
calendar_date	date	NO	UNI			Calendar date
day_name	varchar(9)	NO				Day Name (for example, Wednesday)
day_number_in_week	tinyint(3) unsigned	NO				Day Number in Week (Sunday=1, Saturday=7)
day_number_in_month	tinyint(3) unsigned	NO				Day Number in Month
day_number_in_year	smallint(5) unsigned	NO				Day Number in Year
week_number_in_year	tinyint(3) unsigned	NO				Week Number in Year
month_name	varchar(9)	NO				Month Name (for example, January)
month_number_in_year	tinyint(3) unsigned	NO				Month Number in Year (January = 1, December = 12)

year_number	smallint(5) unsigned	NO				Year Number
holiday_flag	char(1)	NO		N		Holiday flag (Y if holiday, N otherwise)
weekend_flag	char(1)	NO		N		Weekend Flag (Y, if Saturday or Sunday)
last_day_in_month_flag	char(1)	NO		N		Last Day in Month Flag (Y, if last day of month)

Relations



translated_string

Description

This table stores string translation data with basic language and target language information

Columns

Field	Type	Null	Key	Default	Extra	Comment
translated_string_id	bigint(20) unsigned	NO	PRI		auto_increment	Translated string ID
base_language	char(5)	YES				Base language of the string
base_language_string	char(255)	YES	MUL			Actual string in the base language
target_language	char(5)	YES				Target language of the string
target_language_string	char(255)	YES				Actual string in the target language

Relations

vendor

Description

This table stores device model vendor data

Columns

Field	Type	Null	Key	Default	Comment
vendor	int(10) unsigned	NO	PRI		Device model vendor ID
vendor_name	varchar(32)	NO			Device model vendor name

Relations

wirelessaps

Description

The table wirelessaps list the following details for event(s) raised on Wireless Controller / Access Points.

Field	Type	Null	Key	Default	Extra	Comment
ap_id	bigint(20) unsigned	NO	PRI	NULL	auto_increment	Unique Identifier
event_key	bigint(20) unsigned	NO		NULL		Event key for the Alarm.
timestamp	datetime	NO		NULL		Timestamp corresponds with time at which event occurred.
controller_mh	int(10) unsigned	NO	MUL	NULL		Model Handle of the WLC Controller.
ap_mh	int(10) unsigned	NO	MUL	NULL		Model Handle of the Access Point.
ap_grpName	varchar(255)	NO	MUL	NULL		Access Point Group Name.
clients_connected	int(10) unsigned	YES		0		Number of Clients connected to Access Point.

data_sent	bigint(20) unsigned	YES		0		The number of bytes sent on the Access Point.
data_received	bigint(20) unsigned	YES		0		The number of bytes received on the Access Point.

wkpeventfilemap

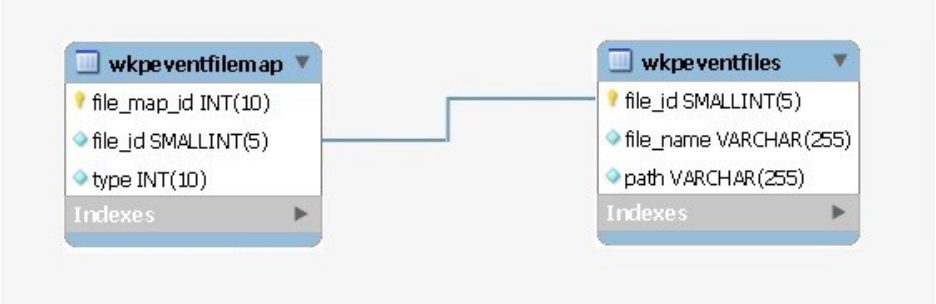
Description

The table wkpeventfilemap maps the event types found in the XML file and maps them to the file from which they were read.

Columns

Field	Type	Null	Key	Default	Extra	Comment
file_map_id	int(10) unsigned	NO	PRI		auto_increment	Event file map ID
file_id	smallint(5) unsigned	NO	MUL			Event file ID
type	int(10) unsigned	NO				Event file type

Relations



wkpeventfiles

Description

This table lists all the event filter XML files that were read from custom directory in OneClick.

Event filters are uniquely named sets of any number of predefined event codes. When users configure an event report, they can elect to specify in the Select the Event Types to include or exclude a field whether to include or exclude data in the report from events in a particular event filter.

An event filter is defined by an XML file that specifies the event codes. Users can create new event filter files, and they can copy and modify the event filter files included with Report Manager. This file resides in custom directory of OneClick.

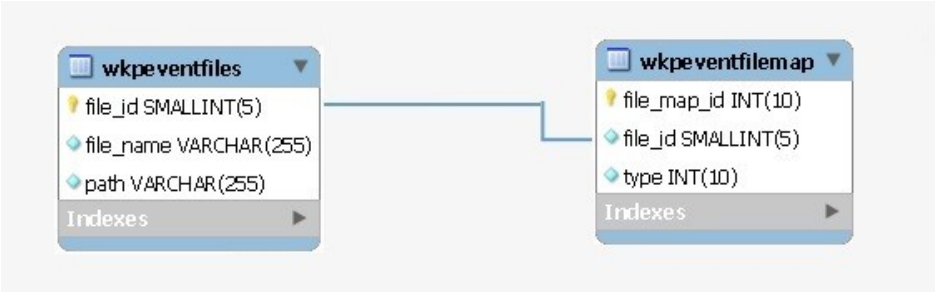
Report manager reads the event filter XML files from custom directory of OneClick. Once read, the data from each XML file is added to two tables: wkpeventfiles and wkpeventfilemap.

Table wkpeventfiles lists all the XML files that were read from the custom directory.

Columns

Field	Type	Null	Key	Default	Extra	Comment
file_id	smallint(5) unsigned	NO	PRI		auto_increment	Event file ID
file_name	varchar(255)	NO				Event file name
path	varchar(255)	NO				Event file path

Relations



z_entity

This is a legacy table, not used in reports

z_entitymodel

This is a legacy table, not used in reports

z_interfaceoutage

This is a legacy table, not used in reports

z_outage

This is a legacy table, not used in reports

Views

v_active_user_model

Description

View for a list of all active oneClick users: All Landscapes

Remarks

View: All Landscapes

v_alarm_activity

Description

List of all alarm activities that are done by oneclick users. Contains information related to assigned user, assigned time, trouble ticket ID etc.

Remarks

View: All Landscapes

v_bi_alarm_activity_by_user

Description

View Definition for report Top N Assets with Most Alarms

Remarks

View: All Landscapes

v_bi_topnalarmtypesmain

Description

View Definition for the report Top N Most Common Alarm Types

Remarks

View: All Landscapes

v_bi_topnassetswithmostalarmsmain

Description

View Definition for the report Alarm Activity by User

Remarks

View: All Landscapes

v_ncm_config_diff

Description

View definition to list NCM configuration changes. Will have data related to configID, change time, number of lines that are changed etc.

Remarks

View: All Landscapes

v_security_string_accessibility_by_landscape

Description

View definition to list the security string access data for users of all landscapes

Remarks

View: All Landscapes

v_user_report_security

Description

View definition as a union of all OC users and BO users

Remarks

View: All Landscapes

srmdbapi Database

The DX NetOps Spectrum Report Manager Database API (SRMDBAPI) provides a fully documented set of read-only database objects to support custom data analysis requirements of DX NetOps Spectrum user. Specifically, the SRMDBAPI consists of a set of database views that are contained within a dedicated multidimensional schema in the MySQL instance that is used by Report Manager.

These views contain the following basic content areas:

- Asset
- Alarm
- Outage/Availability
- Event
- SPM
- NCM

The SRMDBAPI allows users to access mission critical Spectrum Report Manager data. Users can point their Business Intelligence (BI) tools to valuable DX NetOps Spectrum data. Some of the possible use cases are as follows:

- Query this critical data using the BI tool in which customers have already invested.
- Extract the Spectrum Report Manager data and place it within another data repository.
- Incorporate Spectrum Report Manager data into a separate CMDB or financial database.

Click here to see how to write sample queries using srmdbapi views.

List of views in 'srmdbapi' database.

v_dim_alarm_condition

Description

This view enumerates the various alarm conditions (for example, Minor, Major) and associated criticality values.

Columns

Field	Key	Type	Length	Description
condition_id	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
condition_name		varchar	11	Condition Name
criticality	UNQ	tinyint	2	Criticality (1=Maintenance, 2=Minor, 3=Major, 4=Critical)

v_dim_alarm_title

Description

This view enumerates the various alarm titles and associated probable causes that have occurred in the reporting database.

Columns

Field	Key	Type	Length	Description
alarm_title_id	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
alarm_title		varchar	255	Alarm Title
pcause_id_hex		varchar	24	Probable Cause Code (hexadecimal form)
pcause_id_dec		int(unsigned)	10	Probable Cause Code (decimal form)
pcause_title		varchar	100	Probable Cause Title

v_dim_alarm_user

Description

This view enumerates the various usernames that are associated with alarm activity captured in the reporting database.

Columns

Field	Key	Type	Length	Description
alarm_user_key	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
alarm_user_name	UNQ	char	255	Username

v_dim_device_model

Description

This view enumerates all devices (active and destroyed) that are captured historically in the reporting database.

Columns

Field	Key	Type	Length	Description
model_key	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
model_h_dec		int(unsigned)	10	Model handle (decimal form)
model_h_hex		varchar	24	Model handle (hexadecimal form)

landscape_h_dec	FK	int(unsigned)	10	Landscape handle (decimal form); join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Landscape handle (hexadecimal form)
model_name		varchar	4000	Device Name
create_time		datetime		Creation Time
model_creator		varchar	255	Model Creator
security_string		varchar	255	Security String
destroy_time		datetime		Destroy Time
device_type		varchar	255	Device Type
ip		varchar	255	Network Address
mac		varchar	32	MAC Address
serial_nbr		varchar	255	Serial Number
sys_desc		varchar	255	System Descriptor
fw_rev		varchar	255	Firmware Version
sys_oid		varchar	255	System Object ID
location		varchar	255	Location
contact_person		varchar	255	Contact Person
last_reboot		datetime		Last reboot time
last_reboot_text		varchar	19	Last reboot time (text form)
last_successful_poll		datetime		Last successful poll time
model_destroyer		varchar	255	Model Destroyer
cust_asset_tag		varchar	255	Asset Tag
cust_asset_id		varchar	255	Asset ID
cust_asset_owner		varchar	255	Asset Owner
cust_asset_organization		varchar	255	Asset Organization
cust_asset_office		varchar	255	Asset Office
cust_asset_contract number		varchar	255	Asset Contract Number
cust_asset_contract startdate		varchar	255	Asset Contract Start Date
cust_asset_contract enddate		varchar	255	Asset Contract End Date
cust_asset_description		varchar	255	Asset Description
sdm_host_address		varchar	255	SDM Host Address
mclass_name		varchar	32	Model Class Name

mtype_h_dec		int(unsigned)	10	Model Type Handle (decimal form)
mtype_h_hex		varchar	24	Model Type Handle (hexadecimal form)
mtype_name		varchar	128	Model Type
vendor_name		varchar	32	Vendor Name
topology_model_name_string		varchar	4000	Topology Model Name String; this field can be used to support container-based reporting capabilities.
varchar_1_attrid_hex		varchar	24	Custom Attribute ID (Varchar1)
varchar_2_attrid_hex		varchar	24	Custom Attribute ID (Varchar2)
varchar_3_attrid_hex		varchar	24	Custom Attribute ID (Varchar3)
varchar_4_attrid_hex		varchar	24	Custom Attribute ID (Varchar4)
integer_1_attrid_hex		varchar	24	Custom Attribute ID (Integer1)
integer_2_attrid_hex		varchar	24	Custom Attribute ID (Integer2)
integer_3_attrid_hex		varchar	24	Custom Attribute ID (Integer3)
integer_4_attrid_hex		varchar	24	Custom Attribute ID (Integer4)
datetime_1_attrid_hex		varchar	24	Custom Attribute ID (Datetime1)
datetime_2_attrid_hex		varchar	24	Custom Attribute ID (Datetime2)
varchar_1_label		varchar	255	Custom Attribute Label (Varchar1)
varchar_2_label		varchar	255	Custom Attribute Label (Varchar2)
varchar_3_label		varchar	255	Custom Attribute Label (Varchar3)
varchar_4_label		varchar	255	Custom Attribute Label (Varchar4)
integer_1_label		varchar	255	Custom Attribute Label (Integer1)
integer_2_label		varchar	255	Custom Attribute Label (Integer2)
integer_3_label		varchar	255	Custom Attribute Label (Integer3)
integer_4_label		varchar	255	Custom Attribute Label (Integer4)
datetime_1_label		varchar	255	Custom Attribute Label (Datetime1)

datetime_2_label		varchar	255	Custom Attribute Label (Datetime2)
varchar_1_value		varchar	4000	Custom Attribute Value (Varchar1)
varchar_2_value		varchar	4000	Custom Attribute Value (Varchar2)
varchar_3_value		varchar	4000	Custom Attribute Value (Varchar3)
varchar_4_value		varchar	4000	Custom Attribute Value (Varchar4)
integer_1_value		bigint	20	Custom Attribute Value (Integer1)
integer_2_value		bigint	20	Custom Attribute Value (Integer2)
integer_3_value		bigint	20	Custom Attribute Value (Integer3)
integer_4_value		bigint	20	Custom Attribute Value (Integer4)
datetime_1_value		datetime		Custom Attribute Value (Datetime1)
datetime_2_value		datetime		Custom Attribute Value (Datetime2)

v_dim_device_module

Description

This view enumerates more information at the slot level for chassis-based devices.

Columns

Field	Key	Type	Length	Description
module_id	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
model_key	FK	int(unsigned)	10	Model Key that is associated with the parent device recorded in v_dim_device_model view; use this field to join to v_dim_device_model for additional device information.
module_index		int	10	Module Index (Slot)
module_name		varchar	255	Module Name (Description)
serial_nbr		varchar	255	Serial Number
software_rev		varchar	255	Software Version

v_dim_event

Description

This view enumerates all the Event Types encountered while processing events for reporting purposes.

Columns

Field	Key	Type	Length	Description
type_dec	PK	int(unsigned)	10	Event Type (decimal form); this field also uniquely identifies a record in this view.
type_hex		varchar	24	Event Type (hexadecimal form)
title		varchar	255	Event Title

v_dim_event_creator

Description

This view enumerates all the event creators that are encountered while processing events for reporting purposes.

Columns

Field	Key	Type	Length	Description
creator_id	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
creator_name		varchar	255	Creator Name

v_dim_global_collection_member

Description

This view enumerates all global collection members in the reporting database. You have a separate record for every global collection/model pairing.

Columns

Field	Key	Type	Length	Description
gc_rec_ID	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
gc_name		varchar	255	Global Collection Name

model_key	FK	int(unsigned)	10	Foreign key that uniquely identifies a member model. This field can be used to join to v_dim_model, v_dim_device_model, or v_dim_interface_model for additional member model information.

v_dim_interface_model

Description

This view enumerates all interfaces that are captured in the reporting database.

Columns

Field	Key	Type	Length	Description
model_key	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
model_h_dec		int(unsigned)	10	Model handle (decimal form)
model_h_hex		varchar	24	Model handle (hexadecimal form)
landscape_h_dec	FK	int(unsigned)	10	Landscape handle (decimal form) associated with this model; this field can be used to join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Landscape handle (hexadecimal form)
model_name		varchar	4000	Interface Name
create_time		datetime		Creation Time
security_string		varchar	255	Security String
destroy_time		datetime		Destroy Time
port_type		varchar	255	Port Type
port_desc		varchar	255	Port Description (raw value)
port_desc_text		longtext		Port Description (transformed value)
if_speed		Bigint (unsigned)	20	If Speed (Bytes/Sec)
ip		varchar	255	Network Address
mac		varchar	32	MAC Address

port_link_status		int(unsigned)	10	Port Link Status (raw value)
port_link_status_text		varchar	32	Port Link Status (transformed value)
iflastchange		bigint (unsigned)	20	Last Change
ifinoctets		bigint (unsigned)	20	If In Octets
Datelastsignificant traffic		datetime		Date Last Significant Traffic
hours_idle		bigint	21	Hours Idle
days_idle		bigint	21	Days Idle
ifalias		varchar	4000	If Alias
component_oid		varchar	255	Component OID
device_model_key	FK	int(unsigned)	10	Foreign Key that uniquely identifies the parent device for this interface. Use this field to join to v_dim_device_model.model_key for additional parent device information.
device_model_name		varchar	4000	Parent Device Name
port_status		varchar	32	Port Status
mclass_name		varchar	32	Model Class
mtype_h_dec		int(unsigned)	10	Model Type Handle (decimal form)
mtype_h_hex		varchar	24	Model Type Handle (hexadecimal form)
mtype_name		varchar	128	Model Type
connected_model_h_dec	FK	int(unsigned)	10	Model Handle of Connected Device (decimal form); The value is NULL if no device is connected. Use this field to join to v_dim_device_model.model_h for additional connected device information.
connected_model_h_hex		varchar	24	Model Handle of Connected Device (hexadecimal form); This is NULL if no device is connected.
is_connected		int	1	1 indicates that there is a connected device, 0 indicates no connected device.
duplex_status		varchar	255	Duplex Status

v_dim_landscape

Description

This view enumerates all the landscapes that have been encountered during processing reporting data.

Columns

Field	Key	Type	Length	Description
landscape_h_dec	PK	int(unsigned)	10	Landscape handle (decimal form)
landscape_h_hex		varchar	24	Landscape handle (hexadecimal form)
landscape_name		varchar	255	Landscape(Domain) Name

v_dim_model

Description

This view enumerates all the models that are encountered while processing reporting data.

Columns

Field	Key	Type	Length	Description
model_key	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
model_h_dec		int(unsigned)	10	Model handle (decimal form)
model_h_hex		varchar	24	Model handle (hexadecimal form)
model_name		varchar	4000	Model Name
network_address		varchar	255	Network Address
landscape_h_dec	FK	int(unsigned)	10	Landscape Handle (decimal form); join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Landscape Handle (hexadecimal form)
mclass_name		varchar	32	Model Class
mtype_h_dec		int(unsigned)	10	Model Type Handle (decimal form)
mtype_h_hex		varchar	24	Model Type Handle (hexadecimal form)
mtype_name		varchar	128	Model Type Name
security_string		varchar	255	Security String

destroy_time		datetime		Destroy Time (if applicable)

v_dim_ncm_event

Description

This view enumerates all event codes that are associated with Network Configuration Management (NCM).

Columns

Field	Key	Type	Length	Description
type_dec	PK	int(unsigned)	10	Event Type (decimal form); this field also uniquely identifies a record in this view.
type_hex		varchar	22	Event Type (hexadecimal form)
title		varchar	255	Event Title

v_dim_secure_device_model

v_dim_secure_device_model_nofx

v_dim_secure_interface_model

v_dim_secure_interface_model_nofx

v_dim_secure_model

v_dim_secure_model_nofx

v_dim_spm_test

Description

This view enumerates all the SPM Tests that are created while processing.

Columns

Field	Key	Type	Length	Description
test_id	PK	int(unsigned)	11	Internal ID/Key that uniquely identifies a record in this view
test_name		varchar	64	SPM Test Name
model_key	FK	int(unsigned)	10	Internal Key that uniquely identifies the SPM Test Model in v_dim_model.

model_h_dec		int(unsigned)	10	Model Handle of the SPM Test Model (decimal form)
model_h_hex		varchar	24	Model Handle of the SPM Test Model (hexadecimal form)
model_name		varchar	255	Model Name of the SPM Test model
source_address		varchar	64	Source Address
dest_address		varchar	255	Destination Address
port		mediumint (unsigned)	8	Port
lookup_string		varchar	255	Lookup String
filename		varchar	255	Filename
packet_size		int	10	Packet Size
test_host_position		tinyint (unsigned)	3	Test Host Position
username		varchar	64	Username
proxy		varchar	255	Proxy
tos		int(unsigned)	10	Type of Service
alt_packet_addr		varchar	64	Alternate Packet Address
alt_packet_port		mediumint (unsigned)	8	Alternate Packet Port
landscape_h_dec	FK	int(unsigned)	10	Landscape Handle (decimal form); join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Landscape Handle (hexadecimal form)
effective_start		datetime		Effective start time of the test
effective_end		datetime		Effective end time of the test (if applicable)

v_dim_time

Description

This view enumerates a separate record for every day in the calendar.

Columns

Field	Key	Type	Length	Description
time_id	PK	int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
calendar_date	UNQ	date		Calendar Date

day_name		varchar	9	Day Name (for example, Wednesday)
day_number_in_week		tinyint (unsigned)	3	Day Number in Week (Sunday=1, Saturday=7)
day_number_in_month		tinyint (unsigned)	3	Day Number in Month
day_number_in_year		smallint (unsigned)	5	Day Number in Year
week_number_in_year		tinyint (unsigned)	3	Week Number in Year
month_name		varchar	9	Month Name (for example, January)
month_number_in_year		tinyint (unsigned)	3	Month Number in Year (January = 1, December = 12)
year_number		smallint (unsigned)	5	Year Number
weekend_flag		char	1	Weekend Flag (Y, if Saturday or Sunday)
last_day_in_month_flag		char	1	Last Day in Month Flag (Y, if last day of month)

v_fact_alarm_activity

Description

This view enumerates alarm activities (for example, sets, clears, acknowledgements) that are processed in reporting database.

Columns

Field	Key	Type	Length	Description
alarm_key		int(unsigned)	10	Internal ID/Key that uniquely identifies a record in this view
activity		int(unsigned)	10	Internal Code that is used to identify various activities (1=Set, 2=Ack, 3=Assigned By, 33=Assigned To, 4 or 5=Clear, 6=Ticketed)
activity_title		varchar	17	Activity Title (for example, Set, Acknowledged, and so on)
time		datetime		Time at which activity occurred
username_text		varchar	50	Username that is associated with activity
set_count		int	1	Set Count

ack_count		int	1	Acknowledgment Count
assign_by_count		int	1	Assign By Count
assign_to_count		int	1	Assign To Count
clear_count		int	1	Clear Count
ticketed_count		int	1	Ticketed Count
data		char	255	Additional details

v_fact_alarm_info

Description

This view enumerates a separate record for every alarm that is processed in reporting database.

Columns

Field	Key	Type	Length	Description
alarm_key	PK	int(unsigned)	11	Internal ID/Key that uniquely identifies a record in this view
landscape_h_dec	FK	int(unsigned)	10	Landscape Handle (Decimal Form); join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Landscape Handle (Hexadecimal Form)
orig_event_key	FK	bigint (unsigned)	20	Originating Event Key; join to v_fact_event.event_key to capture additional event details.
condition_id	FK	int	11	Condition ID; join to v_dim_alarm_condition for additional condition information.
cause_id		int(unsigned)	10	Cause ID
set_time		datetime		Set Time
clear_time		datetime		Clear Time (if applicable)
duration_seconds		bigint	21	Duration in Seconds
duration_label		varchar	24	Duration Label (HH:MM:SS)
clear_user_key	FK	int(unsigned)	10	Uniquely identifies user who cleared this alarm; join to v_dim_alarm_user.alarm_user_key for more information.
alarm_title_id	FK	int(unsigned)	10	Uniquely identifies an alarm title; join to v_dim_alarm_title for more information.
model_key	FK	int(unsigned)	10	Uniquely identifies the model that is associated with this alarm; join to v_dim_model for more information.
ack_time		datetime		Acknowledgment Time
time_to_ack_seconds		bigint	21	Time to Acknowledge (Seconds)
time_to_ack_duration_label		varchar	23	Time to Acknowledge (HH:MM:SS)

ack_user_key	FK	int(unsigned)	10	Uniquely identifies the acknowledging user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
first_assigned_time		datetime		Time at which alarm was first assigned.
time_to_first_assign_seconds		bigint	21	Difference in time between set time and time to first assignment (Seconds)
time_to_first_assign_ duration_label		varchar	23	Difference in time between set time and time to first assignment (HH:MM:SS)
first_assigned_user_key	FK	int(unsigned)	10	Uniquely identifies the first assigned user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
first_assigning_user_ key	FK	int(unsigned)	10	Uniquely identifies the first assigning user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
last_assigned_time		datetime		Time at which alarm was last assigned.
time_to_last_assign_seconds		bigint	21	Difference in time between set time and time to last assignment (Seconds).
time_to_last_assign_ duration_label		varchar	23	Difference in time between set time and time to last assignment (HH:MM:SS).
last_assigned_user_key	FK	int(unsigned)	10	Uniquely identifies the last assigned user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
last_assigning_user_key	FK	int(unsigned)	10	Uniquely identifies the last assigning user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
set_troubleticket_time		datetime		Trouble ticket Time
time_to_trouble_ticket_seconds		bigint	21	Difference in time between set time and trouble ticket time (Seconds).
time_to_trouble_ticket_ duration_label		varchar	23	Difference in time between set time and trouble ticket time (HH:MM:SS).

set_troubleticket_user_key	FK	int(unsigned)	10	Uniquely identifies the trouble ticket user in v_dim_alarm_user; join to v_dim_alarm_user.alarm_user_key for more information.
set_troubleticket_id		char	255	Trouble Ticket ID
assignment_duration_seconds		bigint	21	Difference in time between lastassigned time and clear time (Seconds)
assignment_duration_label		varchar	24	Difference in time between last assigned time and clear time (HH:MM:SS)

v_fact_event

Description

This view enumerates every event record that is processed in the reporting database.

Columns

Field	Key	Type	Length	Description
event_key	PK	bigint (unsigned)	20	Internal ID/Key that uniquely identifies a record in this view
landscape_h_dec	FK	int(unsigned)	10	Uniquely identifies a landscape that is associated with the model on which this event occurred (decimal form); join to v_dim_landscape for additional landscape information.
landscape_h_hex		varchar	24	Uniquely identifies a landscape that is associated with the model on which this event occurred (hexadecimal form).
model_key	FK	int(unsigned)	10	Uniquely identifies the model that is associated with this event; join to v_dim_model for more information.
time		datetime		Time at which event occurred.
type_dec	FK	int(unsigned)	10	Event Type (decimal form); join to v_dim_event for more information.

type_hex		varchar	24	Event Type (hexadecimal form)
creator_id	FK	int(unsigned)	10	Uniquely identifies the creator for this event; join to v_dim_creator for more information.
event_msg		text		Fully constituted event message that is associated with this event.

v_fact_model_outage

Description

This view enumerates all outages that are processed in reporting database.

Columns

Field	Key	Type	Length	Description
model_outage_id	PK	bigint (unsigned)	20	Internal ID/Key that uniquely identifies a record in this view
model_key	FK	int(unsigned)	10	Uniquely identifies the model that is associated with this outage; join to v_dim_model for more information.
landscape_h_dec	FK	int(unsigned)	10	Uniquely identifies a landscape that is associated with the model on which this event occurred (decimal form).
landscape_h_hex		varchar	24	Uniquely identifies a landscape that is associated with the model on which this event occurred (hexadecimal form).
start_time		datetime		Start Time of Outage
end_time		datetime		End Time of Outage (if applicable)
duration_seconds		bigint	21	Outage Duration (seconds)
duration_label		varchar	24	Outage Duration (HH:MM:SS)

start_event_key	FK	bigint (unsigned)	20	Uniquely identifies the event that started this outage; join to v_fact_event on event_key for more information.
end_event_key	FK	bigint (unsigned)	20	Uniquely identifies the event that ended this outage; join to v_fact_event on event_key for more information.
notes		char	250	Outage Notes
outage_type		int(unsigned)	10	Outage Type (0=Initial, 1=Unplanned, 2=Planned, 3=Exempt)
outage_desc		varchar	NO	Outage Description

v_fact_spm_basic_test_results

Description

This view enumerates test results for the following Service Performance Manager (SPM) test types: ICMP Ping, UDP, Path Echo, TCP, DNS Lookup, POP3, DHCP, FTP, SMTP, and HTTP (total time only).

Columns

Field	Key	Type	Length	Description
test_id	PK	int(unsigned)	11	Combination of Test ID and Timestamp uniquely identifies a record in this view. Timestamp corresponds with time at which result occurred.
timestamp	PK	datetime	11	Combination of Test ID and Timestamp uniquely identifies a record in this view. Timestamp corresponds with time at which result occurred.
time_id	FK	int(unsigned)	11	Uniquely identifies a day in v_dim_time; join to v_dim_time for more information.
hh		tinyint (unsigned)	3	Hours field of "timestamp" field.
mm		tinyint (unsigned)	3	Minutes field of "timestamp" field.

ss		tinyint (unsigned)	3	Seconds field of "timestamp" field.
latency		int(unsigned)	10	Latency in milliseconds
packet_loss		double	53,29	Packet Loss
timeout		tinyint	2	1=timeout occurred, 0=no timeout occurred

v_fact_spm_http_full_test_results

Description

This view enumerates historical results that are associated with Service Performance Manager (SPM) HTTP tests.

Columns

Field	Key	Type	Length	Description
test_id	PK	int(unsigned)	11	Combination of Test ID and Timestamp uniquely identifies a record in this view. Timestamp corresponds with time at which result occurred.
timestamp	PK	datetime	11	Combination of Test ID and Timestamp uniquely identifies a record in this view. Timestamp corresponds with time at which result occurred.
time_id	FK	int(unsigned)	11	Uniquely identifies a day in v_dim_time; join to v_dim_time for more information.
hh		tinyint (unsigned)	3	Hours field of "timestamp" field.
mm		tinyint (unsigned)	3	Minutes field of "timestamp" field.
ss		tinyint (unsigned)	3	Seconds field of "timestamp" field.
http_response_time		int(unsigned)	10	Overall HTTP response time
dns_resolution_time		int(unsigned)	10	Portion of HTTP response time for DNS resolution
tcp_connect_time		int(unsigned)	10	Portion of HTTP response time for TCP connection

http_download_time		int(unsigned)	10	Portion of HTTP response time for HTTP Download
timeout		tinyint(2)	2	1=timeout occurred, 0=no timeout occurred

v_fact_spm_jitter_test_results

Description

This view enumerates historical results that are associated with Service Performance Manager (SPM) Jitter tests.

Columns

Field	Key	Type	Length	Description
test_id	PK	int(unsigned)	11	Combination of Test ID and
timestamp		datetime		Timestamp uniquely identifies a record in this view. Timestamp corresponds with time at which result occurred.
time_id	FK	int(unsigned)	11	Uniquely identifies a day in v_dim_time; join to v_dim_time for more information.
hh		tinyint (unsigned)	4	Hours field of "timestamp" field.
mm		tinyint (unsigned)	4	Minutes field of "timestamp" field.
ss		tinyint (unsigned)	4	Seconds field of "timestamp" field.
response_time		int(unsigned)	10	Latency
src_to_dest_pl		double	53,29	Source to Destination Packet Loss
dest_to_src_pl		double	53,29	Destination to Source Packet Loss
mia		double	53,29	Missing in Action – Packet Loss with Unknown Direction
late_arrival		double	53,29	Late Arrival
busies		double	53,29	Busies
pos_src_to_dest_jitter		int(unsigned)	10	Positive Source to Destination Jitter
neg_src_to_dest_jitter		int(unsigned)	10	Negative Source to Destination Jitter
pos_dest_to_src_jitter		int(unsigned)	10	Positive Destination to Source Jitter

neg_dest_to_src_jitter		int(unsigned)	10	Negative Destination to Source Jitter
timeout		tinyint	2	1=timeout occurred, 0=no timeout occurred

Sample reporting DB queries

The following sample SQL queries are presented to both demonstrate the potential of the 'reporting DB' in DX NetOps Spectrum and serve as a training aid. These queries merely represent a subset of what is possible from a functional perspective.

Log in to MySQL Server

You can log in to the MySQL server using the 'root' user before executing the following sample queries:

On Linux:

```
$SPECROOT/mysql/bin/mysql --defaults-file=../my-spectrum.cnf -uroot -proot reporting
```

On Windows:

```
$SPECROOT/mysql/bin -uroot -proot reporting
```

NOTE
Timestamps used in the below queries are just to fetch the detail belongs to that specific duration. Change the timestamps according to your requirements.

Get the alarm information for a specified time period

You can perform a query to obtain an alarm for a specified time. The result set contains alarm time, alarm name, alarm title, and the alarm message.

```
SELECT `landscape`.`domain_name`,
       `alarminfo`.`alarm_key`,
       `alarminfo`.`landscape_h`,
       `alarminfo`.`condition_id`,
       `alarminfo`.`set_time`
  FROM ((`reporting`.`alarminfo` `alarminfo`
         INNER JOIN `reporting`.`landscape` `landscape`
            ON `alarminfo`.`landscape_h` = `landscape`.`landscape_h`)
        INNER JOIN `reporting`.`model` `model`
           ON `alarminfo`.`model_key` = `model`.`model_key`)
WHERE (`alarminfo`.`set_time` >={ts '2015-01-01 00:00:00'} AND `alarminfo`.`set_time`<{ts '2015-11-16
 14:30:53'})
```

List all the Events for a specified time period

You can perform a query to obtain the list of all events that occurred on a specified time.

```
SELECT `event`.`time`,
       `model`.`model_name`,
```

```
       `model`.`network_address`,
       `creator`.`creator_name`,
       `event`.`type`,
       `event`.`event_key`,
       `event`.`event_msg`
  FROM ((`reporting`.`event` `event`
         INNER JOIN `reporting`.`model` `model`
            ON `event`.`model_key` = `model`.`model_key`)
        INNER JOIN `reporting`.`creator` `creator`
           ON `event`.`creator_id` = `creator`.`creator_ID`)
WHERE (`event`.`time` >={ts '2015-11-19 00:00:00'} AND `event`.`time`<{ts '2015-11-20 00:00:01'})
ORDER BY `event`.`time` DESC
```

Get the alarm activity grouped by a user for a specified time period

You can perform a query to obtain the details of an alarm activity that is grouped by a user for a specified time.

```
SELECT `alarmactivity`.`user`,
       `alarmactivity`.`activity`,
       `alarmactivity`.`time`
  FROM `reporting`.`alarmactivity` `alarmactivity`
WHERE (`alarmactivity`.`time` >={ts '2015-11-18 19:03:40'} AND `alarmactivity`.`time`<{ts '2015-11-19
 19:03:47'}) AND `alarmactivity`.`activity`<>1
```

Get the list of all active device models

You can perform a query to obtain the list of all active device models.

```
SELECT `devicemodel`.`model_name`,
       `devicemodel`.`IP`,
       `modelclass`.`mclass_name`,
       `devicemodel`.`device_type`,
       `devicemodel`.`fw_rev`,
       `devicemodel`.`last_reboot`,
       `devicemodel`.`destroy_time`,
       `devicemodel`.`model_h`,
       `vendor`.`vendor_name`,
       `entity`.`entity_name`,
       `entity`.`entity_id`,
       `devicemodel`.`model_key`
  FROM (((`reporting`.`entity` `entity`
          INNER JOIN `reporting`.`devicemodel` `devicemodel`
             ON `entity`.`current_model_key` = `devicemodel`.`model_key`)
         INNER JOIN `reporting`.`modelclass` `modelclass`
            ON `devicemodel`.`model_class` = `modelclass`.`model_class`)
        INNER JOIN `reporting`.`vendor` `vendor`
           ON `devicemodel`.`vendor` = `vendor`.`vendor`)
WHERE `devicemodel`.`destroy_time` IS NULL
```

Get SLA Summary by SLA name:

You can perform a query to obtain SLA summary by SLA name.

```
SELECT `sm_slaperiods`.`slaStartTime`,
       `sm_slas`.`slaDestroyTime`,
```

```
       `sm_periods`.`periodEnd`,
       `sm_customermhs`.`customerMH`,
       `sm_customermhs`.`custName`,
       `sm_slaperiods`.`slaStatus`,
       `sm_slaperiods`.`slaPeriodID`,
       `sm_slas`.`slaMH`,
       `sm_slas`.`slaName`,
       `sm_slmagreesto`.`customerMH`,
       `sm_slmagreesto`.`agreesToDestroyTime`
  FROM (((((`reporting`.`sm_slas` `sm_slas`
            INNER JOIN `reporting`.`sm_slmagreesto` `sm_slmagreesto`
               ON `sm_slas`.`slaMH` = `sm_slmagreesto`.`slaMH`)
           INNER JOIN `reporting`.`sm_slaperiods` `sm_slaperiods`
              ON `sm_slas`.`slaMH` = `sm_slaperiods`.`slaMH`)
          INNER JOIN `reporting`.`model` `model`
             ON `sm_slas`.`slaMH` = `model`.`model_h`)
         INNER JOIN `reporting`.`sm_periods` `sm_periods`
            ON `sm_slaperiods`.`periodID` = `sm_periods`.`periodID`)
        INNER JOIN `reporting`.`sm_customermhs` `sm_customermhs`
           ON `sm_slmagreesto`.`customerMH` = `sm_customermhs`.`customerMH`)
WHERE     `sm_slas`.`slaDestroyTime` IS NULL
       AND `sm_slaperiods`.`slaStatus` <= 3
       AND `sm_slas`.`slaMH` = 1
       AND `sm_slas`.`slaMH` <> 1
ORDER BY `sm_slaperiods`.`slaStatus` DESC,
         `sm_slaperiods`.`slaPeriodID`,
         `sm_slaperiods`.`slaStartTime` DESC
```

Get VPLS Site health history for a specified time period

You can perform a query to obtain the history of a VPLS Site for a specified time period.

```
SELECT `model`.`model_key`,
       `model_state`.`model_state`,
       `model`.`model_name`,
       `model_state`.`end_time`,
       `model_state`.`start_time`
  FROM (`reporting`.`model` `model`
        INNER JOIN `reporting`.`model_state` `model_state`
           ON `model`.`model_key` = `model_state`.`model_key`)
WHERE ((`model_state`.`start_time` <{ts '2015-11-23 15:53:31'} AND `model_state`.`end_time` IS
 NULL ) OR (`model_state`.`start_time`<{ts '2015-11-23 15:53:31'} AND `model_state`.`end_time`>={ts
 '2015-11-23 08:53:30'})) AND (`model_state`.`model_state`='Down' OR `model_state`.`model_state`='Good' OR
 `model_state`.`model_state`='Maintenance') AND `model`.`model_key`=1
```

Get SLA inventory by SLA name

You can perform a query to obtain SLA inventory by SLA name.

```
SELECT `sm_slas`.`slaName`,
       `sm_guaranteeperiods`.`guarName`,
       `sm_slas`.`slaMH`,
       `sm_guaranteeperiods`.`gPeriodEnd`,
       `sm_guaranteeperiods`.`gPeriodStart`,
       `sm_guaranteeperiods`.`criticalThresholdPercent`,
```

```
        `sm_guaranteeperiods`.`criticalThreshold`,
        `sm_guaranteeperiods`.`typeEnum`,
        `sm_guaranteeperiods`.`motThreshold`,
        `sm_guaranteeperiods`.`mttrThreshold`,
        `sm_guaranteeperiods`.`mtbfThreshold`,
        `sm_slas`.`slaDescription`,
        `sm_guaranteeperiods`.`guarDescription`,
        `sm_guaranteeperiods`.`guarPeriodID`,
        `sm_slas`.`slaDestroyTime`
   FROM (((`reporting`.`sm_slas` `sm_slas`
           INNER JOIN `reporting`.`sm_slaperiods` `sm_slaperiods`
              ON `sm_slas`.`slaMH` = `sm_slaperiods`.`slaMH`)
          INNER JOIN `reporting`.`model` `model`
             ON `sm_slas`.`slaMH` = `model`.`model_h`)
         INNER JOIN `reporting`.`sm_guaranteeperiods` `sm_guaranteeperiods`
            ON `sm_slaperiods`.`slaPeriodID` =
                  `sm_guaranteeperiods`.`slaPeriodID`)
 WHERE     `sm_slas`.`slaDestroyTime` IS NULL
        AND `sm_slas`.`slaMH` = 1
        AND `sm_slas`.`slaMH` <> 1
 ORDER BY `sm_slas`.`slaMH`
```

Service Manager

DX NetOps Spectrum Service Manager is a tool that provides the capability to monitor and manage IT infrastructure that is based on the business services that it provides. Rather than managing a collection of network devices, servers, and applications; you can organize and manage these elements based on how they provide or support specific services. DX NetOps Spectrum service models offer visibility on how the infrastructure elements affect the availability of the business services. This visibility aids in prioritizing infrastructure faults that are based on their impact on business services, and highlighting weaknesses in the environment.

The Service Manager application includes a comprehensive set of tools for creating, managing, and monitoring business services, Service Level Agreements (SLAs), and service customer models in DX NetOps Spectrum. Leveraging DX NetOps Spectrum fault-management capabilities, Service Manager provides real-time and historical insight into the status of your service management components. It also provides a suite of reports for all service management components which can be generated with the DX NetOps Spectrum Report Manager application.

You can manage and monitor Service Manager components in the following interfaces:

- The OneClick Console provides administrative personnel complete access to Service Manager configuration editors and service management models.
- The Service Dashboard provides service providers and customers access to status views of service management models and service outage management tools.
- The Service Level Manager portlet, which can be incorporated into the Unicenter Management Portal (UMP), provides summary status information about services, SLAs, and customers to Unicenter users with secure access to Service Manager models.

Service Manager lets you extend your infrastructure management capabilities beyond the per-device and per-application level. It provides you with the tools to build mechanisms that let IT-service providers and customers validate service availability and performance.

Services

A DX NetOps Spectrum service is a model that represents some logical business service. For example, a router model represents the status of a physical device similarly, a service model represents the status of the business service.

A service model contains a set of resources and a policy indicating the behavior of resources. Service resources are other DX NetOps Spectrum models that collectively provide or support the availability of a business service. A service is only available when its resources are available. In turn, the service model monitors the availability of its resources to determine its health or availability. By applying the collective resource availability to its service policy, the service model can depict the real-time health of the business service it represents.

A service model differs from other types of models in DX NetOps Spectrum. To confirm this information, perform the following actions:

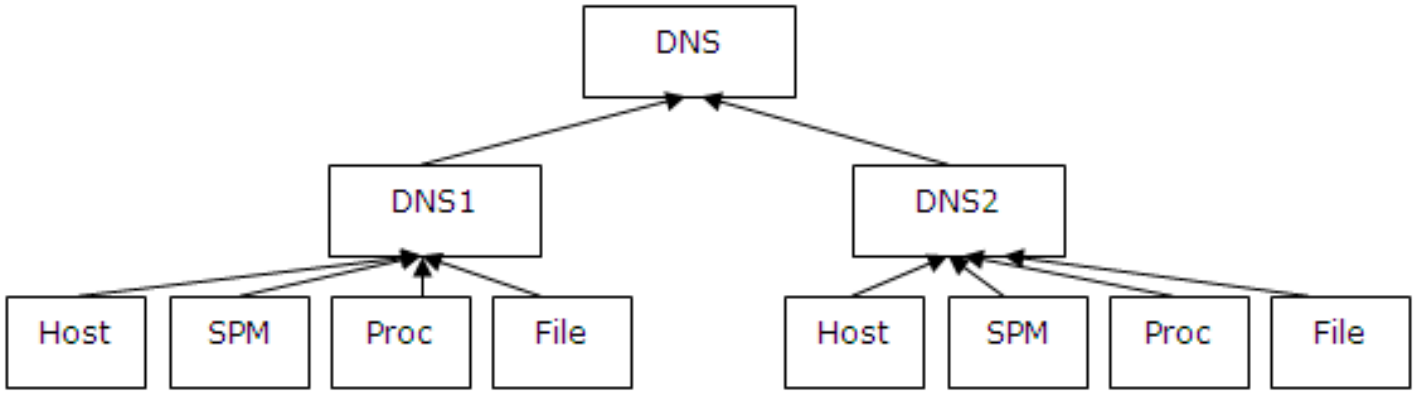
- Consider some of the patterns that are common in IT management. For example, redundant devices, hot swap back ups, load balanced servers, clustered or pooled resources.
- Verify how these patterns are used to support specific business services. One of the oldest and most common business services is DNS. The critical nature of DNS lets you deploy multiple DNS servers. DNS improves performance and also mitigates the risk of DNS failure.
- Represent the real-time status of the DNS service in an environment with two servers that are dedicated to DNS. Monitor the servers themselves as host models in DX NetOps Spectrum. The host model lets you understand the situation if contact is lost to the server and provides information about a number of other potential system faults. You can create SPM tests to validate that each server is responsive. You can also monitor critical processes or file systems on the servers.

Availability of DNS

DNS is available when both servers are functioning. If one of the servers is down, DNS is still available. However, DNS is not available when both the servers are down. The host models, SPM tests, monitored processes, and file systems are all individual models, any of which can fail and produce an alarm. You can view alarms to determine the availability of DNS which can become complex and error-prone with this small set of models.

You can manage this complexity using DX NetOps Spectrum Service Manager. Using service models, you can organize the host models, SPM tests, processes, and file systems to represent the DNS service and express the availability of that service.

The following diagram illustrates the process to implement DNS in DX NetOps Spectrum Service Manager.



Service Policy

In addition to the resources that constitute a service, each service specifies a policy that infers service viability (its service health) based on the collective status of its resources. The role of the service policy is to create an accurate representation of the service health that is based on the health of the resources that comprise the service. The objective is to ensure that the health indicated by the service model in DX NetOps Spectrum reflects the performance of service. Selecting or creating the appropriate service policy is essential to ensure that service health is accurately represented in DX NetOps Spectrum.

A policy specifies a single attribute to monitor for the collective set of service resources. The policy is comprised of two basic components, the Attribute Map and the Rule Set. The Attribute Map associates resource attribute values to service health values. The Rule Set defines the health of the service by giving a set of resource health values.

A service can also include one or more resource monitors instead of a single policy. Each resource monitor can use its own policy extending the monitoring capability of the service.

A number of policies are shipped with DX NetOps Spectrum Service Manager which represent common resource monitoring patterns. If applicable, you can use these policies to familiarize yourself with the creation of custom policies. The use of custom policies can be necessary to verify the accuracy of health that is represented by the service model.

Customers

A DX NetOps Spectrum Customer model or Customer represents any person or an organization that uses services or is a party to a Service Level Agreement (SLA). DX NetOps Spectrum Service Manager lets you associate customers with the services and SLAs to monitor the service management components on a per-customer basis.

SLAs

A DX NetOps Spectrum SLA model, or *SLA*, comprises one or more service *guarantees* that specify the service obligations stipulated in an SLA contract for a particular time period (for example, week, month). Service Manager lets you specify the following two types of guarantees:

- Availability
- Response time.

Both types of guarantees record service outage time and compare it against a user-specified threshold for a period. Availability guarantees also support supplemental thresholds (Mean Time to Repair, Mean Time Between Failure, and Maximum Outage Time).

Create SLAs from scratch or from SLA templates and associate multiple SLAs with a single service and multiple customers with an SLA.

Service Health Values

A *service health* value indicates the viability of a service, whether it is operating at an acceptable or less than acceptable level or is inoperable. Service Health also indicates whether a service is in maintenance mode or in an initial state, if the service has no resources.

The following table lists and describes service health values and corresponding DX NetOps Spectrum alarm states.

Service Health	Description	Icon Color
Up	The service is operating normally.	Green

Down	The service is unavailable. The service is experiencing a critical outage.	Red
Degraded	The service is available but operating at a limited capacity. The service is experiencing a major outage.	Orange
Slightly Degraded	The service is available but operating at a slightly diminished capacity. The service is experiencing a minor outage.	Yellow
Maintenance	The service has been put into maintenance mode and is not actively monitoring resources. The service is experiencing a maintenance outage.	Brown
Loss Of Management	The SpectroSERVER has been shut down. The service is experiencing a loss of management outage.	Gray
Defunct	The service has a configuration error. The service stays in the nonfunctional state until the error has been corrected.	Blue
Initial	The service has no resources associated with it. The service stays in an initial state until resources have been associated with the service.	Blue

Service Management Features

DX NetOps Spectrum Service Manager includes the following features:

- Views that let you monitor the health of services in real time and relate the services to customers affected by IT infrastructure faults.
- Service health records that provide the basis for reports that you can generate on a scheduled or on an on-demand basis using Report Manager.
- SLA violation alarms that notify you when an agreement has been violated or is in danger of being violated.
- Root cause analysis of any service degradation (in terms of infrastructure alarms).
- The capability to designate maintenance periods for services.
- The capability to exempt any service outage from impacting an SLA.
- Extensions to Modeling Gateway that let you create service management components and schedule service maintenance through an XML feed.
- A web page that is added to UMP for viewing service management-related information.

OneClick Licenses and Service Manager Privileges

To access Service Manager from the OneClick Console, OneClick administrator privileges or operator license is required. To access the Service Dashboard, Service Manager license is required. For more information, see the OneClick Administration section.

The following table compares license types and the default roles and privileges that are associated with them:

OneClick License	Default Role	Default Privileges
Operator	OperatorRW	Ability to update service descriptions and view service information and the Service Management hierarchy in the OneClick Console.
Administrator	AdministratorRW	Ability to create and edit services, customers, and SLAs with Service Editor, and create and edit policies, attribute maps, and rule sets with Service Policy Editor.
Service Manager	ServiceManagerRW	Access Service Dashboard.

Service Manager Installation Considerations

WARNING
Service Manager must be installed on both the SpectroSERVER and OneClick servers.

Review the following Service Manager installation considerations:

- The modeling catalog and all modeling intelligence exist within SpectroSERVER.
- The historical database and event handling code exist on the OneClick web server which is installed with OneClick.
- All the client UI components and dashboard are installed with OneClick.
- If you have a separate OneClick installation for Report Manager, install Service Manager on that server to populate the Service and SLA reporting tables.

Plan Service Management Implementation

To benefit fully from the Service Manager capabilities, plan your service management implementation. You can contemplate the following questions and considerations:

- What business services do you want to monitor?
- What particular resources -- processes, software applications, and IT devices -- support those services?
- How can conditions and faults that affect services be detected? Which resource attribute(s) can be monitored to determine the health of a service?
- Who can be notified if a service fails?
- What are the service performance obligations, and how can they be quantified?
- What is the criticality of a given service relative to other services?
- Consider implementing a Service Manager solution as an iterative process. In the initial phase, concentrate on obvious resources and obvious faults. Answer the question: the service does not work, if _____ is down. This information can give you a good foundation for enhancing the service later.
- Identify common sub services or foundation services. If all the multiple services rely on a common set of resources group (resources in their own service), then you can make that service a resource of higher-level services that depend on it.
- Create empty services if you know that a service exists, but you are not familiar with the resources that comprise it. These services left initial are important. These services represent areas of infrastructure that are not familiar, and need to be explicitly monitored.
- Build your services such that they can be easily enhanced. Rather than services which directly monitor resource models such as devices and applications, build services using resource monitors. It is easy to enhance these services in the future by adding new resource monitors without having to change the overall structure of the service.

Service Manager Utilities

You can work with the following utilities to create and manage the Service Manager components:

- **Service Editor**
  Lets you create and manage services, SLAs, SLA guarantees, SLA templates, SLA guarantee templates, customers, and customer groups.
- **Service Policy Editor**
  Lets you create and manage service monitoring policies and the constitute components, attribute maps, and rule sets.
- **Condition Correlation Editor**
  Lets you build correlation domains to monitor resources for specific resource events or combinations of events. These correlation domains can then be used as service resources, extending the monitoring capability of the service from attribute monitoring to event monitoring.

Open the Service Editor

The Service Editor is the primary administrative tool for configuring service models, SLAs, and Customers. The Service Editor displays service models in a flat list or in a hierarchy view. From the Service Editor, you can create new service models or can edit existing service models.

Follow these steps:

1. Select the OneClick Console or the Service Dashboard.
2. Click Tools, Utilities, Service Editor, from the main menu.

   NOTE
   The Service Editor is not available if you do not have access privileges or the OneClick installation does not include the Service Manager product.

   The Service Editor opens.

Open the Service Policy Editor

The Service Policy Editor lists service monitoring policies and policy specifications and includes commands for creating and managing policies. It lets you create and manage policies and their constituent components, attribute maps, and rule sets.

Follow these steps:

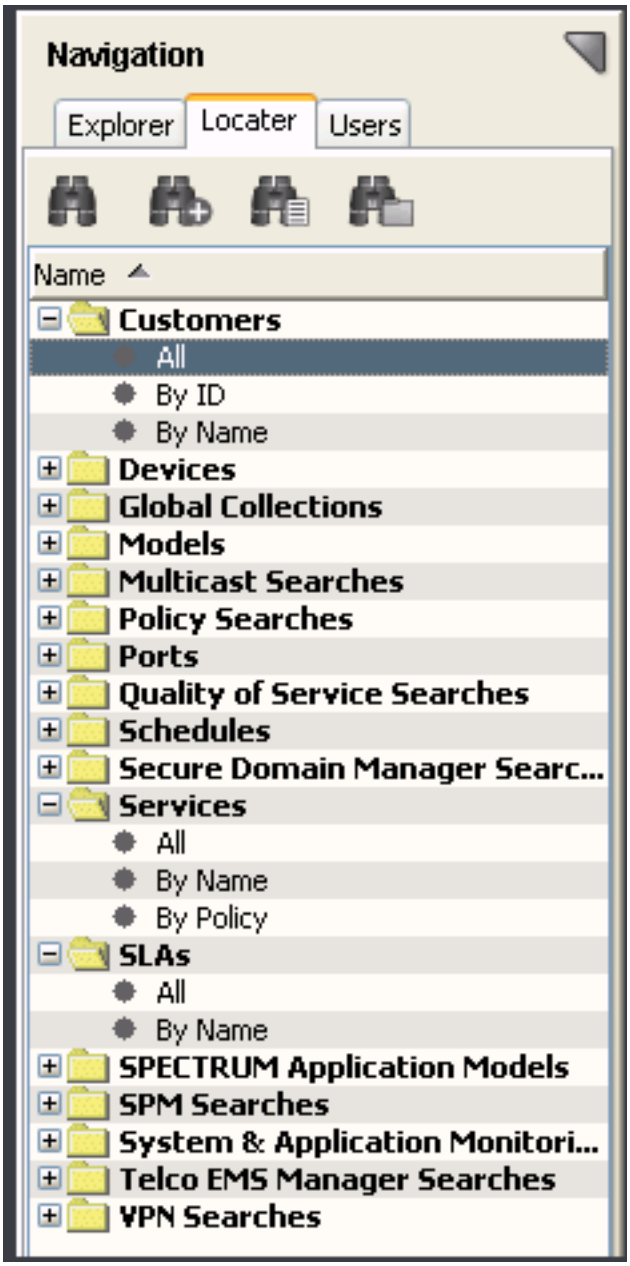
1. Select the OneClick Console or the Service Dashboard.
2. From the main menu, click Tools, Utilities, and Service Policy Editor.

   NOTE
   The Service Policy Editor is not available if you do not have access privileges or the OneClick installation does not include the Service Manager product.

   The Service Policy Editor appears.

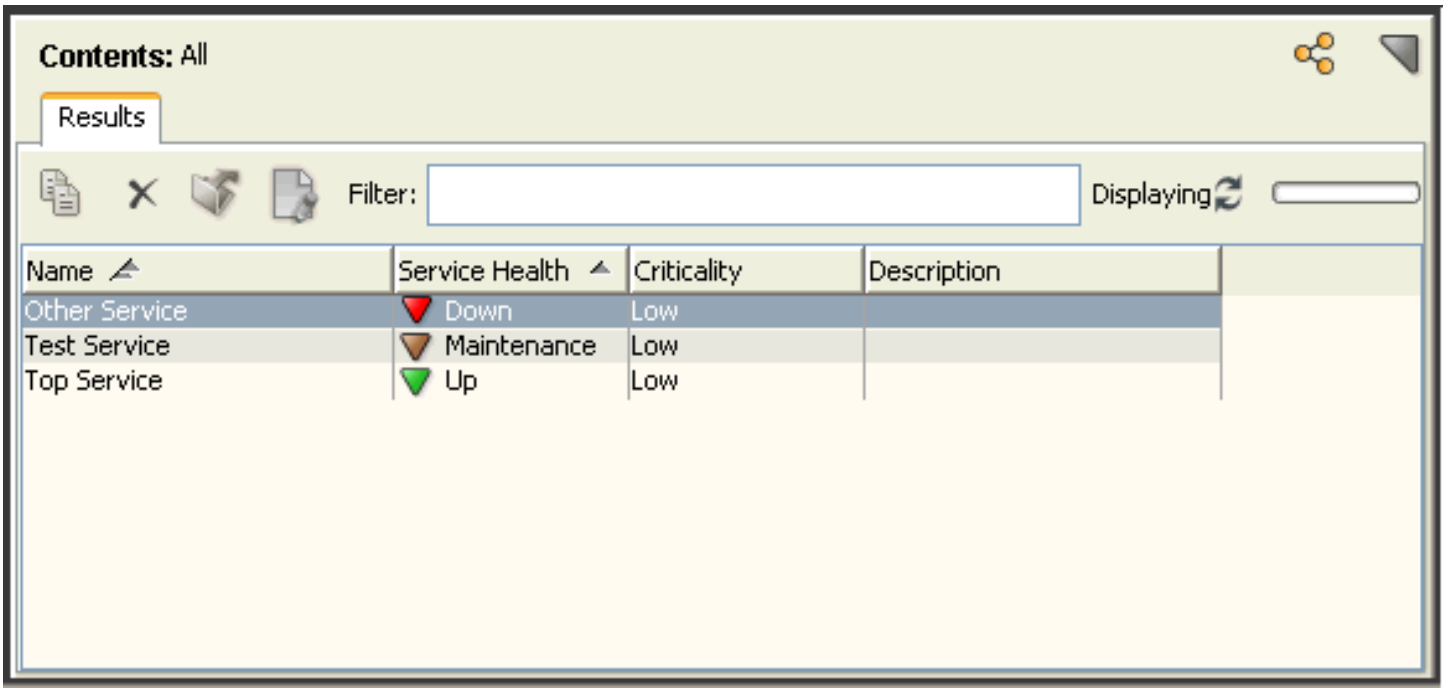
Locating Service Manager Components

You can locate and display services, service customers, and SLAs in the Locater tab of OneClick Console Navigation panel. Search can be initiated from Customers, Services, and SLAs folders, as shown in the following image:

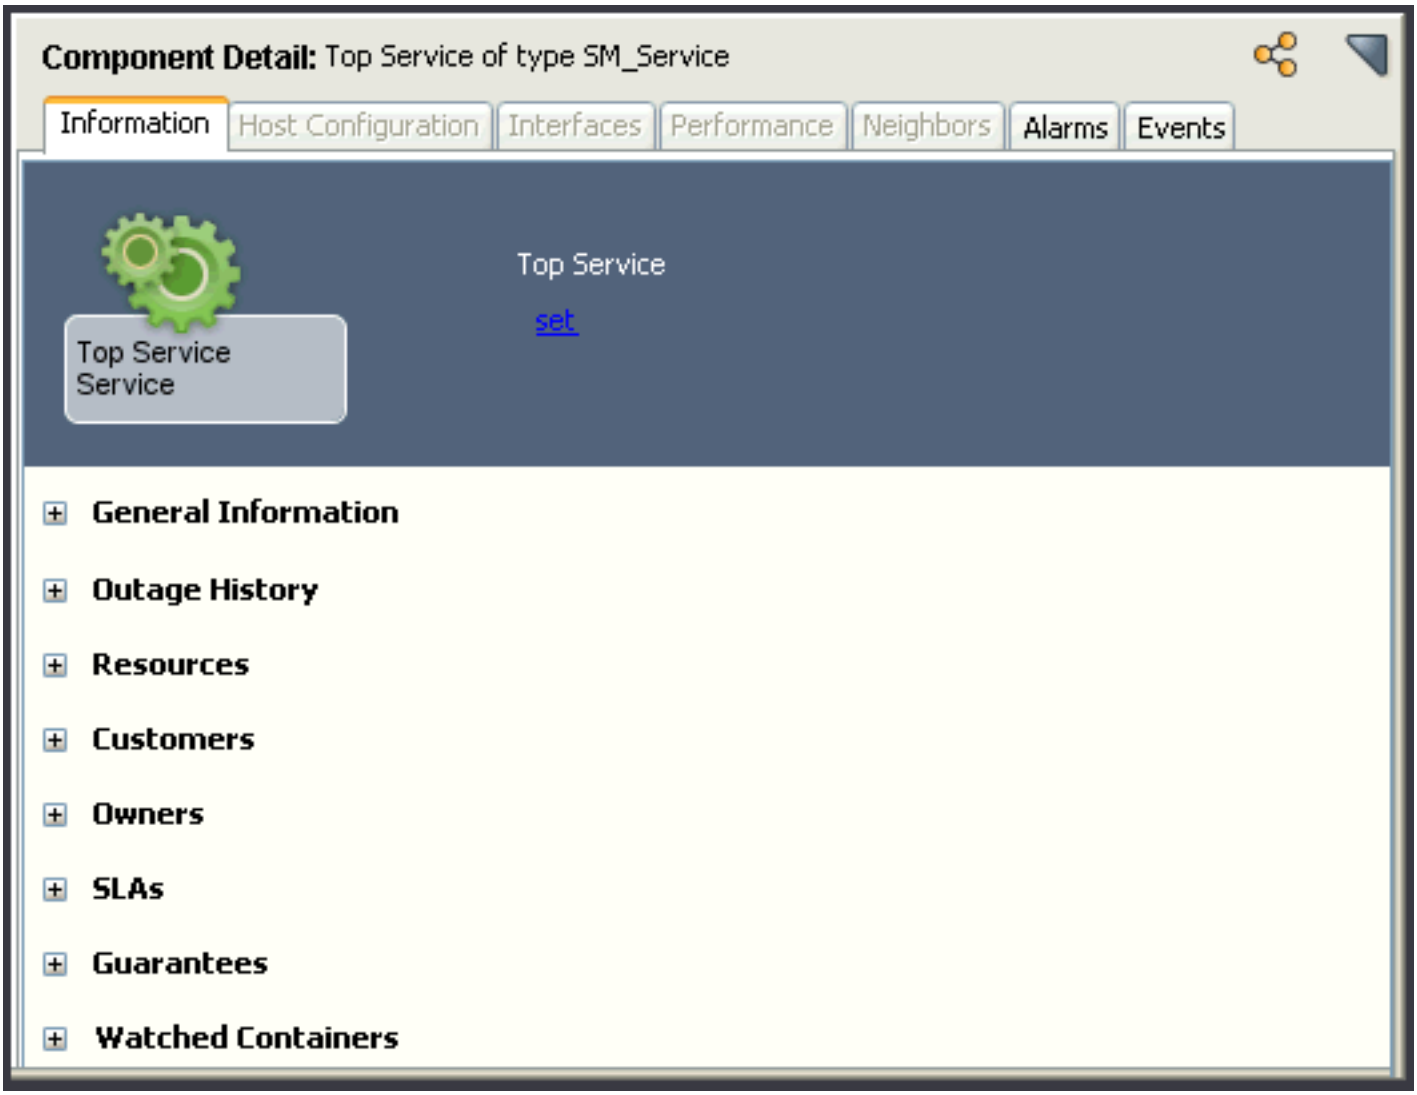


You can track the Service Manager components in a distributed SpectroSERVER environment. For more information, see the Using OneClick section.

The following image displays the search results that appear in the Contents panel of OneClick Console:



The following image displays the details about all aspects of the selected entry in the Component Details panel:



Roll-Up Indications for Service Manager Models

The Service Management tree consists of a set of four models. The root model is the Service Management model, which contains three top-level manager models, such as Service Manager, Customer Manager, and SLA Manager models. These top-level managers organize all of the user created service management components. All service models can be organized under the Service Manager model which is displayed in OneClick with the name Services. Similarly all SLA models and customer models appear under SLAs and Customers.

The Condition of each of these manager models is equivalent to the worst status of all contained models. For example, if the worst service within the landscape has a service health of Degraded, the Service Manager model on that landscape has a Condition of Major. If the worst SLA within the landscape has a SLA status of Violated, the SLA Manager has a Condition of Critical. You can view the Condition of a manager model by the icon color. No alarms are associated to the Condition of the manager models.

Within the Service Dashboard, all landscapes are merged into a single tree in the Explorer panel. Within the service dashboard, a set of folders represent the collective set of manager models from each landscape. Regardless of how many landscapes occur within a DSS the Service Dashboard displays only one folder for each category of manager model.

These folders have the same names as the set of models within the SpectroSERVER: Services, Customers SLAs. The icon for each folder displays the status of the worst top-level model within the DSS. If the worst Service Manager status within the DSS is Minor, the Service Folder in the Service Dashboard displays a yellow icon. Similarly, if a Customer Manager within the DSS has a Condition of critical, the Customers folder in the Service Dashboard displays a red icon.

Service Manager Component Views Outside of the OneClick Console

You can view the Service Manager components outside of the OneClick Console from the following interfaces:

Service Dashboard

The Service Dashboard is a service management only view. It provides visibility to the real-time status for all Services, Customers, and SLAs. The Service Dashboard provides OneClick like console with an Explorer tree, component detail view, and topology view. In addition, the Service Dashboard provides some historical service management views including service outage history, and SLA/Guarantee trending. The dashboard is designed for anyone who is interested in monitoring Service Manager components, and enforces DX NetOps Spectrum model security.

Unicenter Management Portal

CA Unicenter users can view summary information about Service Manager components by adding content from the Service Manager portlet. The Service Manager portlet displays flat lists of service models, customer models, and SLAs models. The Service Manager portlet also provides context launching to the OneClick Console or Service Dashboard.

Service Management Solution Design Guidelines

The key to a successful service management deployment is accuracy in service modeling. The goal when designing services can be to create the most accurate representation possible. Given that objective, often you do not understand how each service functions, and all of the resources on which the service relies. One of the most challenging aspects of building a service management environment is collecting all of the information that is required to model each service. For this task, you require a significant amount of collaboration to create accurate services.

It is rare that a single individual has all the information that is required to build a large service management environment. In most businesses, different teams specialize in different areas of the business each focused purely on their own domain. Ironically it is this typical business structure that creates the need for a service management solution. The more difficult it is to build the service management environment, the greater the need for doing so.

The following section outlines some guidelines for planning and building a service management solution. It takes time to plan and to model a large and complex service management environment. Investing the time to collect information and develop a plan for building the service management solution helps to confirm your success. Part of your plan can include incremental goal, identifying a timeline and milestones for the project. A representation of services for each organization can be included, perhaps a demonstration of how specific infrastructure faults are now processed and prioritized based on service impact. Establishing these milestones lets you realize value throughout the process, and motivates you to expand your solution continually.

One final note on planning is to recognize that you are building a service management solution that must continue to evolve. Your plan may identify a time and point of completion, but that does not mean you will never again have to create or edit a service model. Business infrastructure is continually changing, and you may find that services change too. Your goal is to build a service management solution that is flexible and easy to maintain. On performing this task, you can confirm that your solution can accommodate the dynamic nature of your business.

Service Model Identification and Creation Guidelines

Determining where to start creating your service management environment is the most daunting task. Various techniques such as top down, bottom up, most critical first are available. Regardless of which technique you select, follow the available guidelines.

The first step is to define a phased approach. Develop a multi-phase plan, before you create any service models. The goal of this plan to two folds. A multi-phase plan helps you manage the complexity of creating a large environment and confirms that you receive incremental value throughout the deployment process. It is important that you are able to recognize value from each service that you create and so from each phase of your deployment.

Each environment is different, but the following three-phase deployment plans can work for you, or can be adapted to fit your environment.

Phase I Build a Service Hierarchy Reflecting Your Business Environment

Phase I focuses on building all of the major services, and establishing the service hierarchy which reflects your business environment. This phase produces all of the high-level business-related services, and many of the lower layer services on which they rely. Phase I implementation does not provide a comprehensive solution that encompasses all possible service faults. But creates a hierarchy which shows the services, each organization relies upon and the impact those services have on the overall business.

Throughout this process, identify services with which you are not familiar and for which you cannot determine resources. You can create an empty service. Defining empty services can shed light on areas of the business or infrastructure which are not familiar.

Generally you can start identifying high-level services by listing different organizations within your business environment. If your business is a service provider, this may include different customers and core service components that are shared by those customers. If you are working in an enterprise environment often, you can simply list the different departments within the business. These departments can frequently be considered high-level services. You can also identify dependencies within these high-level services.

Once you have determined the high-level business-specific services, think about what services they rely on. This next tier of services is commonly associated to specific job functions within an organization. These services may be related to specific applications, specific data, and specific security access. Identify various specialized and shared services.

Once you have identified the services upon which various organizations rely, consider the requirements for providing those services. At this level, identify servers for applications or databases. Depending of the nature of these services, recognize specialized service hierarchies and application interdependencies.

You have now defined a broad set of services which are critical to various job functions. This lets you look for shared component services that these job function services require. Regardless of the variety of applications or access areas, you can find many common services that provide the foundation for the specialize services. At this level, you see common networking or domain management services like DNS and DHCP.

Finally, determine the shared network resources upon which all higher-level services rely. Locate core areas of networks that manage traffic and control access. These core services ultimately impact virtually all other services which you have identified.

You have probably collected enough information to start creating service models. For this initial phase of service creation focus on the most obvious resources and obvious faults. The goal of this phase is not to create comprehensive services, but to establish the broad service hierarchy which depicts how the business functions.

It is easy to fall into the trap of trying to define a perfect service that covers all possible resource faults. The problem is that you quickly get mired by complexity, and require assistance from domain experts who understand the intricacies of each service. This process consumes much time, and can stall the process of building the overall service hierarchy.

You can revisit each service in subsequent phases and can refine the resource monitoring capacity to handle the more complex fault scenarios.

As a guideline for determining resources for the first phase, complete the following statement: "The service won't work if _____ is down". The answers to this question are the resources that you can monitor for the first phase. Take care not to dwell on all of the potential resources. Create the service with the obvious resources and move on. Most of your services for phase I have other services as their resources. You can determine that one service relies on another service. Although you do not understand how the other service works, you can create the empty service and move on.

Phase I is complete when you have built a service hierarchy which reflects your business environment. Consult with others and validate your overall design. The hierarchy that you have created serves as the baseline for subsequent phases.

Phase II Add Significant Resource Monitoring Capacity

The goal of phase II is to increase the accuracy of your service models. You can expect the following two things on increasing accuracy:

1. Adding resource monitoring capacity to encompass more potential faults, and eliminating resource monitoring configuration which may produce false service outages.
2. Enhancing your resource monitoring capacity such that you can identify various levels of service degradation instead of simply showing that a service is Up or Down.

Typically in phase II you can revisit the lower layer services which you created in phase I and any empty services that are identified in phase I.

For phase II, you can expand many of the lower layer services by adding new resource monitoring capacity. Refine the resource statement to include the following subtle faults:

- The service won't work if _____ is not available
- The service won't work if _____ is not responding
- The service won't work if _____ is not running
- The service won't work if _____ is not found
- The service won't work if _____ is slow
- The service won't work if _____ is at maximum capacity

Consider the following statements to identify resource faults which degrade service health:

- The service will be slow if _____ is down
- The service may not work if _____ is not available
- The service cannot perform these functions if _____is not accessible
- The service will not be able to handle all requests if _____ is at maximum capacity

In phase II, you can start adding monitoring capability for system resources, performance statistics, and response times. You can refine the existing service resources by identifying more discrete resources, such as the specific interfaces that a service relies instead of devices.

In addition to monitoring, the Condition or status of resource models you can add new resource monitors to evaluate the value of other attributes which express the performance of a model.

Throughout phase II, identify many new service models which encompass subtle, but critical pieces of functionality upon which other services rely.

Look for dependencies between services particularly where an application server relies on another application. Look for areas where network configuration is critical to data processing for security access or quality of service.

Once again take care not to go too deeply into the intricacies of each service. Limit your phase II enhancements to the type of refinements common to many services. For example, regardless of the application, system resources affect availability. Additionally, poor response time between various parts of network impacts many higher-level services.

In particular, do not yet expand resource monitoring to include application-specific detail. This type of monitoring can be addressed in Phase III.

Phase II is complete, when you have added significant resource monitoring capacity. Except for specific application faults, your solution should now be able to process a much wider set of enterprise faults. Similarly, your solution should also be able to report various levels of service degradation.

Phase III Ongoing Refinement

Phase III can be considered the ongoing phase. Regardless of how complete the solution seems to be, there is most likely some potential to refine it further. During phase III, you can extend your resource monitoring capacity to the most complex resource faults. It is difficult to define an end point for phase III, but one guideline is to consider the resolution process. If the resolution process is the same regardless of the fault your monitoring capacity is granular enough. It is tempting to add new resource monitors continually for specific types of faults, but this task is only useful if the course of action differs for each fault.

Depending on your level of expertise, it is the phase where you are most likely to require the collaboration of other domain experts for specific services.

When dealing with application-based services, collect information about the application-specific resources that can be monitored. For example, specific processes, files systems, and log files. Add new services and resource monitors for these various aspects of the application. You can also add monitoring for specific connection ports, and where possible specific transactions.

As part of phase III, add monitoring capacity for configuration changes. It includes monitoring of network configuration policies, and server configuration utilities. Look for configuration changes that can degrade or otherwise impact services.

Whenever possible include monitoring of user access and security mechanism for different applications or networks.

Look for scenarios where a service is impacted even if no specific fault occurs on the service resources. Also look for instances where a service is impacted differently depending upon a combination of resource faults.

You can again refine the following service resource statements to look for additional types of faults:

- The service won't work if the _____ process is not running.
- The service won't work if _____ is restricting access.
- The service won't work if the _____ queue is full.
- The service wont' work if the _____ is archiving.
- The service won't work if _____ doesn't authenticate the user.

Each time that a new resource monitoring capacity to a service you are expanding the set of resource faults the service covers, increases the accuracy of the service.

It is difficult to define when phase III is complete. New resource faults are discovered which were not previously identified. Ideally your design can accommodate these new faults. Each time a new fault is discovered, adapt your resource monitoring such that the next time the fault occurs you can correctly understand its service impact.

Basic Service Definition

Once you have determined what services to model, you can identify several key properties of each service and can characterize the behavior of the service under certain circumstances. To complete this process, perform the following tasks:

Define the Role of the Service

Primarily, identify the role of the service model. The service role encompasses the capability and purpose of the service.

The capability identifies what the service is monitoring. Each service model must represent a capability that can be monitored. This capability can be a tangible process, such as an email service. Alternately, the monitored capability can be more abstract or can represent human resources service. Regardless of the service role, you can state that the service measures the health of some capability.

Once you have identified the capability that is being monitored, define the purpose for monitoring that capability. The purpose is a statement of value that you expect to get from monitoring the capability. For example, many services are intended to provide real-time fault analysis. You can create a service to know the health of the email system. Or a service that shows the impact of resource faults within your infrastructure. Other services are designed to monitor responsibility or compliance. For example, a service that monitors server availability to confirm that it is in compliance with some specified guarantee. In addition, some service models are used to represent organizational dependencies, such as regional offices, depending on resources from a centralized location.

Determining the role of the service helps you select service resources. You can specify service criticality and can define service relationships with customers and SLAs.

Identify Service Resources

Once the service role is defined, you can identify service resources. Service resources provide the capability that the service is monitoring.

For example, consider a service with the role of monitoring the real-time availability of a web-based application. Most likely the application is hosted by one or more servers. These servers can be considered as service resources.

It is important to understand that identifying service resources is an iterative process. It is recommended first to identify the most obvious resources that provide the services capability. In the previous example, the servers hosting the web application are the most obvious resources.

Later, determine the process to monitor the services resources. In many cases, determining the process to monitor one resource reveals other previously unidentified resources. You can manage the service modeling process and can implement your solution in phases. The first phase encompasses the most obvious resources, and higher-level faults. Subsequent phases add additional or more discrete monitoring capability.

Select Resource Models

Once you have identified a service most obvious resources, determine what DX NetOps Spectrum models best represent those resources.

Using the example of a service with the role of monitoring, the real-time availability of a web-based application; you can start with device models that represent the servers. These are likely to be Host models of some sort in DX NetOps Spectrum, or can simply be Pingable models.

Specify the Service Policy

Having located the set of DX NetOps Spectrum models that represent the service resources, determine the best way to monitor these models. This is the process of specifying the service policy that the service applies to its monitored resources.

The first part of specifying the service policy is identifying the model attribute that can be monitored to determine the status of the resource.

Selecting the attribute to monitor has a lot to do with the type of resource that is being monitored. If the model is a Pingable, monitoring its Contact Status attribute can be reliable. If the resource model is a Port model, monitoring its Port Status can be a good choice. Perhaps the resources of the service are other services. In that case, you can monitor the Service Health of the resources models.

For the first phase of service creation, stick to the obvious resources and obvious resource faults. You can identify several attributes that can be used to express the status of a resource model. For the first phase, select the attribute that provides the broadest representation. You can refine the service later by adding more attribute monitoring, or narrowing the specific faults that are associated to an attribute.

Most of the models in DX NetOps Spectrum have the Condition attribute. This attribute is commonly associated to alarms on the model. For example, if a model has a major or orange alarm, the value of its Condition attribute is Major. Condition is often the simplest attribute to use for monitoring a resource. If you cannot identify another attribute that expresses a model's status Condition is probably a good starting point.

> **NOTE**
> It is often easiest when creating services to start by monitoring the Condition of the service resource models. Although this can be a good starting point, the value of Condition is often influenced by many different types of outages some of which may not be appropriate for the service.

Consider resource failure affects on service health

The next part of specifying the service policy is to consider how each individual resource impacts the service. More specifically, consider how the failure of each resource affects the health of the service.

The health of a service model can be expressed by four values, such as Up, Down, Degraded, and Slightly Degraded. Consider each resource that has been identified, and the health of the service should indicate, if that resource fails.

A fault matrix table can be a useful tool to document how various resource failures can impact the health of a service. The fault matrix is a table with columns for each resource, and a column for service health. Here is an example of a simple fault matrix for a pair of servers that support a web-based application. The columns Server 1 and Server 2 contain potential status for each server, the Service Health column contains the logical service health given the status of each Server.

Server 1	Server 2	Service Health
Up	Up	Up
Down	Up	Slightly Degraded
Up	Down	Slightly Degraded
Down	Down	Down

After reviewing the table, you can describe the behavior of the service with the following statements:

- If either Server 1 or Server 2 are Down the Service Health is Slightly Degraded
- If both Server 1 and Server 2 are Down the Service Health is Down

Stated in a resource independent manner, the following two expressions can be identified:

- When any 1 resource is Down the service is Slightly Degraded
- When all resources are Down the service is Down

In terms of a DX NetOps Spectrum service policy, these two expressions can be considered rules, and collectively they make up a rule set. The combination of an attribute and a rule set is the service policy.

By first identifying which resource model attribute represents its status, and next identifying a set of rules which describes how each resource impacts service health you have now specified the service policy.

DX NetOps Spectrum service manager provides a number of policies out-of-the-box, but you can create your own policies whenever an out-of-the-box policy does not match the resource behavior that you have identified.

You have determined the basic structure of the service, and can model it in DX NetOps Spectrum. You can consider this model to be a first-phase model. Chances are throughout this process you identified some areas where the monitoring capacity of the service is not adequate. As mentioned before service modeling is an iterative process, each phase expands, or refines the monitoring capacity of the service to make it more accurate.

The next section refining the service definition covers some of the common issues you will find when first defining a service, and provides some techniques for how to improve your service models.

Refining the Service Definition

Regardless of the role that is defined for a service model, your goal can be to create a service such that the health of the service model accurately depicts the logical status of the service. You can eliminate scenarios where the service is logically down, but the service model indicates that it is up. Similarly, a service model cannot indicate that its health is impacted if logically the service is functioning normal. The following section introduces some techniques for refining your service models. These techniques are best applied in phases. Do not make too many enhancements at once. Define a strategy to improve your services, and implement that strategy. Break down the service revision process into multiple phases that can be managed and validated.

You can find various reasons for inaccuracy of service models monitoring capacity. This section covers a few of these reasons and discuss ways to improve your service models.

The following reasons are potential scenarios that can affect the accuracy of a service model:

Missing Resource Models

The most common issue when building service models is failure to identify all of a service resource. The principle reason for this is that most of the time we identify the resources that are providing the service directly to an end user, and not the capabilities that those resources rely on.

Continuing with the example of a web-based application, often when focusing on user faces applications, we start with the servers which host the application. This is a great starting point, but you may find that you have missed servers that support the application. Consider how the web application relies on a database to provide content. The following table displays the changes of our fault matrix:

Database	Server 1	Server 2	Service Health
Up	Up	Up	Up
Down	Up	Up	Down
Down	Down	Up	Down
Down	Up	Down	Down
Down	Down	Down	Down
Up	Down	Up	Slightly Degraded
Up	Up	Down	Slightly Degraded
Up	Down	Down	Down

The table is a bit more complicated, but you can see that with the addition of the Database, the previously identified rule set no longer works. You can see that regardless of the status of Server 1 and Server 2, if the Database is Down, the service is Down.

This type of pattern is common, and you have identified that the service relies on more than the web servers it requires extra resource which behaves differently than the web servers. To support this new set of resources, use a new model type named Resource Monitor.

The job of a resource monitor is to manage diverse sets of resources which do not follow a behavior pattern that can easily be captured in a single policy. A resource monitor is similar to a service in that it applies a policy to a set of resource values to determine its own health. It can be useful to think of resource monitors as a type of sub-service. A resource monitor by itself does not represent a logical service, but rather a critical aspect of that service.

In this example, you can see how resource monitors can be used. The following behavior is captured for the web servers and their relationship to the health of the service.

Server 1	Server 2	Service Health
Up	Up	Up
Down	Up	Slightly Degraded
Up	Down	Slightly Degraded
Down	Down	Down

If we specifically consider how the database impacts the service that a simple matrix can be created.

Database	Service Health
Up	Up
Down	Down

Capture each of these patterns into its own resource monitor.

The Database RM monitors the database resource with the following rule:

- When all resources are down the service is down

The Webserver RM monitors the web servers with this rule set:

- When any 1 resource is Down the service is Slightly Degraded
- When all resources are Down the service is Down

The service monitors the two resource monitors, and the service health reflects the status of the worst resource monitor. The following table show the fault matrix for the service:

Database RM	Webserver RM	Service Health
Up	Up	Up
Down	Up	Down
Down	Slightly Degraded	Down
Down	Down	Down
Up	Down	Down
Up	Slightly Degraded	Slightly Degraded

From this matrix you can see the following rule set for the service:

- When any 1 resource is Down the service is Down
- When any 1 resource is Slightly Degraded the service is Slightly Degraded

By expanding the service from monitoring the condition of two host models to instead monitoring the health of two resource monitors we have improved the accuracy of the service model. You can notice that the database resource is never referred to as a host model or a database server. Because the database is likely to be a service itself.

This scenario of missing resources is common that you can consider it when creating service models. Even if the database server was not identified as a service resource in the initial phase the service could still have been created to monitor a single resource monitor for the web servers. In later phases, as additional resources are identified, it is easy to add new resource monitors to the service itself.

Resource Models Which Are Not Discrete Enough

Missing service resources is certainly one common cause of inaccurate service model. Another cause for inaccuracy in the services model is resource models that are not discrete enough. Usually, DX NetOps Spectrum monitors devices at a fairly high level, and reports their condition that is based on fairly basic criteria. For example, a host model that responds to SNMP traffic and has normal CPU and memory utilization can be considered Up or Normal.

Going back to the web application service example, consider if the simple host monitoring is adequate to determine if the web application is working. Imagine, if on webserver 1, a critical file system has become full, and on webserver to the actual webserver process was not running. In this case, the web application service is not available to users, but the given basic host monitoring the service model indicates a health of Up.

In addition to the host being contactable, various other aspects can be monitored to determine if the web application is running. To determine the application status, you can use the following common components:

- Monitoring critical processes
- Monitoring critical file systems
- monitoring application connectivity and response time

Looking at each web server, you can define a fault matrix using the following example:

Host	Process	File System	App Connection	Service Health
Up	Up	Up	Up	Up
Down	Down	Down	Down	Down
Up	Down	Up	Down	Down
Up	Up	Down	Up	Down
Up	Up	Up	Down	Down

In the preceding abbreviate matrix, you can notice that for the webserver to be considered up, consider more than simply a host model. A webserver process, a critical file system, and the web application can also be responsive to connections and requests.

You can notice that rather than simply a host model each webserver is actually a service in and of itself. From the preceding example, you can envision a service with three resource monitors.

The Host RM, simply monitors the Condition of the host model. The Proc and FS RM monitors the Condition of a process model, and a file system model. The App Conn RM monitors the status of a series of response time tests that send requests to the server.

At first, given that the Host RM and the Proc and FS RM are both monitoring the Condition attribute, you can combine them into a single resource monitor. You can separate the resource models into two resource monitors as they represent different classes of models. In the next section, you can notice, isolating the host model within its own resource monitor that gives you the ability to exclude host-related alarms (that do not impact the service).

The Host RM and Proc and FS RM models have simple fault matrix tables.

For the Host RM model:

Host	Service Health
Up	Up
Down	Down

For the Proc and FS RM Model:

Process	File System	Service Health
Up	Up	Up
Down	Up	Down
Up	Down	Down
Down	Down	Down

The App Conn RM is based on response time monitoring. It is at your discretion to use the multi-level threshold capability of DX NetOps Spectrum service performance manager to create more health values. For simplicity, look at a Timeout, Critical Threshold, and Major Threshold configuration. The following matrix looks like a condensed set of response time test values:

Response Time	Service Health
Normal	Up
Timeout	Down
Critical Threshold	Down
Major Threshold	Degraded

Consider the following fault matrix for a single webserver:

Host RM	Proc and FS RM	App Conn RM	Service Health
Up	Up	Up	Up
Down	Down	Down	Down
Up	Down	Down	Down
Up	Up	Down	Down
Up	Up	Degraded	Degraded

You can determine that all resource monitors must be Up for the webserver to be considered Up. Remember, this is the fault behavior for a single web server.

In the review, we earlier expanded the web application service to include two resource monitors: Database RM, and Webserver RM. At the time, the webserver RM was monitoring the Condition of two host models. From the preceding matrix, you can identify that rather than two host models, the webservers can be represented as two service models each with three resource monitors. The previous configuration still applies, but now the webserver RM monitors the service health attribute of two services models, instead of the Condition of two hosts. You can see that despite vastly improving the accuracy of the web application service the structure of the service remains intact. The fault matrix that is determined early is still accurate:

Database RM	Webserver RM	Service Health
Up	Up	Up
Down	Up	Down

Down	Slightly Degraded	Down
Down	Down	Down
Up	Down	Down
Up	Slightly Degraded	Slightly Degraded

What has been improved is the definition of Up for the webserver RM.

Resource Faults that Should Not Impact the Service

Missing resources and resources that are not discrete enough can often lead to a service indicating a health of Up when it should not. Sometimes a service model may indicate a health of Down or Degraded when logically it is not. This can best be described as a non-service impacting resource fault.

Two common situations are available that produce this type of problem, both of which are different.

The first situation is when a resource model status is influenced by associated child models. This situation can happen, if you select a model that is logically a service resource but has a status that can be affected by other models (that are not service resources). For example, when you specify a network device as a resource for a particular service, rather than the interfaces that actually support the service. Another example, when dealing with host models or servers to specify that the host itself alarms for a failed process or file system instead of the monitored process or file system model. If the process or file system is not logically a part of the particular service, the service may indicate an affected health when it should not. Such situations are easy to resolve by selecting the most appropriate model as the service resource, for example, a specific interface, or monitored process.

The second situation occurs exclusively when a service monitors the Condition of its resource models. The Condition of a resource model holds the value of the most severe alarm on the model. DX NetOps Spectrum generates thousands of different types of alarms. Some of these alarms are indicative of service impacting faults, but many are not. By default, DX NetOps Spectrum monitors devices for various reasons, but principally to ensure that are functioning correctly from a network infrastructure perspective. You can see various alarms which faults have to do with network management, but these alarms may have no logical impact on the capability that is being monitored by the service. Similarly, a given model can be a resource of multiple services, such that a particular alarm can be significant for some services and not others. This occurs frequently when the purpose of the service is to monitor compliance that is based on some specific responsibility.

Service Manager alarm type exemption functionality is designed to support resource alarms which should not impact service health. When you discover that certain resource faults should not impact a service, you can specify an alarm type exemption configuration. This configuration can be specified for an individual service or resource monitor, or if the behavior is common it can be specified in a service policy.

By applying alarm type exemptions, you can again improve the accuracy of your service models by eliminating false service outages.

Service impact of non-alarm producing Events

Sometimes, you can encounter a situation where a resource model experiences an event that does not produce an alarm on the resource. However, it logically affects the capability being monitored by the service. When deployed with a primary focus on network infrastructure management, often many events that are produced by or passed to DX NetOps Spectrum which do not produce alarms. Because the events are too common or insignificant. That said there are circumstances where these events are ignored and can be considered for a specific service. In some situations, it can be appropriate for you to map the event to a new alarm, which affects the Condition of a resource model. As the alarm configuration takes effect for all models of a given type, it may not be a good practice if the event is significant only for a few models.

When the situation arises that an event is service impacting, but does not produce an alarm, you can consider creating a Correlation Domain to represent the service resource. Much like a service determines its own health by monitoring attributes of its resources, a correlation domain can determine its own condition by monitoring events occurring on its resources.

To support non-alarm producing events, create a Correlation Condition for the event. You can perform this task by specifying the event code for the logical set, and then the corresponding event code for the logical clear.

Revisit the Database service that discussed early in this section, for example, the Database service is comprised of two host models. At some time during the day, each database server can initiate an automatic data archival process. Consider that DX NetOps Spectrum was integrated with a database management tool which can produce an event on the DX NetOps Spectrum host model when the archival process begins and another event when the archival process is complete. Since this behavior is normal for the server, there is no alarm. However, during the archival process, the server may not respond as quickly to requests.

In general, the data archival process does not impact the database service as a whole. However, if both database servers were archiving data simultaneously, the service becomes Slightly Degraded. If one of the database servers is down, and the other is archiving data, the service becomes Degraded.

You can create a Correlation Condition and a pair of Correlation Rules to capture this behavior.

The Correlation Condition consists of a set event code and clear event code which correspond to the start and completion of the archival process.

Two new Correlation rules can be created which specify an Implied Cause of either Service Impact Slightly Degraded or Service Impact Degraded. Service Manager adds these out-of-the-box Conditions with a Service Impact Down Condition. Consider the following correlation rules:

- DB Archiving Exists AND Device Contact Lost Exists Implied Cause Service Impact Degraded
- DB Archiving Count = 2 Implied Cause Service Impact Slightly Degraded

Both rules specify the Correlation Domain as the root cause target. The new rules can be combined into a new Correlation Policy that is named Data Archival Policy. You can create a Correlation Domain using the Data Archival Policy, and can specify both database servers as resources.

Finally, to extend the Database service, a new resource monitor, Data Archival RM can be created to monitor the Condition of the correlation domain.

By using this approach, you are able to show the service impact of non-alarm producing events.

Patterns of Resource Faults Which Impact Services

You can encounter resource monitoring scenarios where the relationship of particular service resources is too complex to capture simply by monitoring the Condition attribute of the models. More specifically, the Condition of the model can have a greater or lesser significance depending on some additional resource monitoring criteria.

Consider the following scenario. An account management team working in a remote office uses a local database server to access customer information. If the local system is down, the account management team can access the information that they require by connecting to a server at the company head quarters. The service representing the customer account system behaves in the following manner:

- If the local server is down, and the head quarters server is up, the customer account service can be Slightly Degraded
- If the local server is up and the head quarters server is down, the customer account service can be Up.
- If the local server is down and the head quarters server is down, the customer account service can be Down
- If the local server is down and the head quarters server is in maintenance, the customer account service can be Down
- If the local server is in maintenance and the head quarters server is in maintenance, the customer account service can be Down

As you can see, the service impacting scenarios are fairly complex. Even though there are two servers providing the service, the servers are not treated equally.

For handling a resource monitoring scenario, such as Correlation Domain can be used that manages the complexities of monitoring the individual resources.

A service utilizing two resource monitors can be used to implement this example. First, you can isolate the local server into its own resource monitor, which uses a simple fault matrix. The Local Server RM uses a policy to support this pattern.

Local Server	Service Health
Up	Up
Down	Slightly Degraded

The second resource monitor that is Local and Remote Domain RM also has a simple fault matrix:

Local & Remote Domain	Service Health
Up	Up
Down	Down

The Local and Remote Domain RM, monitors a Correlation Domain which contains the host model for the local server and the host model for the head quarters server.

Verify the following status table of the Condition of the Correlation Domain:

Local Server	Remote Server	Domain Condition
Normal	Normal	Normal
Contact Lost	Normal	Normal
Normal	Contact Lost	Normal
Contact Lost	Contact Lost	Critical
Contact Lost	Maintenance	Critical
Maintenance	Maintenance	Critical
Maintenance	Contact Lost	Critical

The domain uses a policy with the following rules, all utilizing the domain for the root cause target.

- Device Contact Lost Count = 2 Implied Cause Service Impact Down
- DeviceInMaintenance Count = 2 Implied Cause Service Impact Down
- Device Contact Lost Exists AND DeviceInMaintenance Exists AND Device Contact Lost Model Does Not Equal DeviceInMaintenance Model Implied Cause Service Impact Down

The Customer Account Service monitors the service health of the two resource monitors in the following way:

Local Server RM	Local and Remote Domain	Server Health
Up	Up	Up
Slightly Degraded	Up	Slightly Degraded
Slightly Degraded	Down	Down
Up	Down	Down

The Customer Account Service bases its health on the worst status of the two resource monitors which is the common high sensitivity pattern.

Using this approach, you can create accurate resource monitoring capacity for your services even when the scenarios have complex requirements.

Service Attributes and Relationships

When creating a service, specify the number of attributes and associate the service to its resources and other service management models. This section explains the attributes that can be configured and the potential relationships that you can create for each service model.

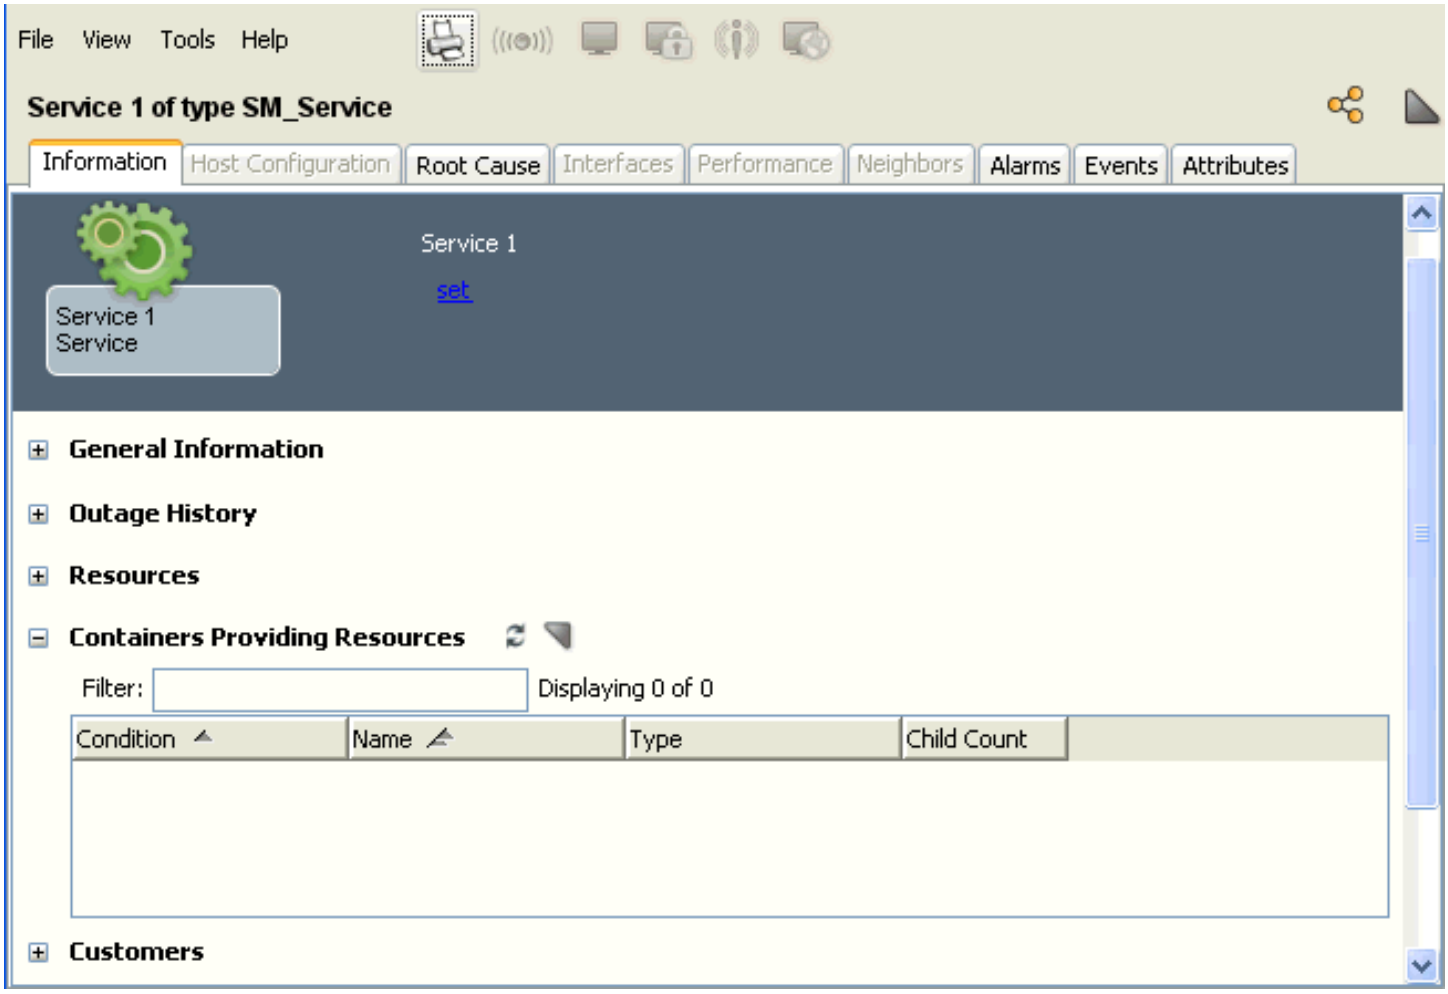
- **Name and Description**
  The service name and description identify the service model. You can define multiple services with the same name, provided they have unique descriptions.
  You do not have rules for defining service names. However, you are recommended to use some naming scheme or convention that lets you identify a service model, if you encounter it outside of the service management hierarchy. Some naming schemes include multiple parts that let you categorize the service geographically or organizationally. Other naming schemes associate the service to a particular customer or function.
  It is a useful practice to state the service role in the service description. The service role is determined in the planning phase, and states the capability and purpose of the service model.
- **Criticality**
  Service criticality is an enumerated value ranging from a Low value of 10 to a High value of 30. All or a portion of a service's criticality can be added to the Impact value of any resource alarms affecting the service.
  If a service is down, the entire value is factored into the calculation. If a service is degraded as a result of the resource alarm, one half of the service criticality value is factored into the impact calculation for the alarm. If a service is slightly degraded, one-fifth of the value is factored into the calculation.
  Verify the following Criticality values:
  - Low (default) = 10
  - Medium Low = 15
  - Medium = 20
  - Medium High = 25
  - High = 30

  For example, a Degraded High criticality service has an impact of (50percent) * 30 = 15, and a Down Low criticality service has an impact of (100percent) * 10 = 10. The alarm that caused the Degraded High criticality service has a comparatively greater impact than the alarm the caused the Down Low criticality service. If alarms are sorted and prioritized by impact value, the alarms impacting the most critical services are given the highest priority.
- **Landscape**
  The landscape field specifies the landscape where the service model resides. The landscape option appears only when multiple SpectroSERVERs are deployed in a distributed environment.
  To optimize performance, the service can be created on the landscape where all or most of its resources reside. If the service has resources spanning multiple landscapes review Service Models in a DSS environment.
- **Security String**
  The security string secures access to the service model in DX NetOps Spectrum. For more information, see the OneClick Administration section.

  NOTE
  Security in the service dashboard differs from the OneClick Console. If a user does not have access to a service model, all icons and list entries for that service are absent from the service dashboard. This dashboard differs from the OneClick console where icons are exposed, but no model data is available.
- **Maintenance Mode**
  Service models support maintenance mode as do many other models in DX NetOps Spectrum. When a service is "in maintenance", it is not actively monitoring any of it resources.

You can create a service in maintenance to avoid the generation of any service outages while you are still building your service hierarchy and identifying resources. In this capacity maintenance, the model is used to show that the service is under construction.
Service models also support scheduled maintenance. Schedule maintenance defines preconfigured periods of time where the service stops actively monitoring its resources. Commonly service level agreements specify periods of time which are reserved for service maintenance.

- **Generate Service Alarms**
  Each service can be configured to generate alarms that correspond to changes in service health.
  Disabling the generation of alarms for the service means that an alarm cannot be generated, the service health is still modified based on policy evaluation. All icons within the OneClick Console and Service Dashboard shows the appropriate color for service health regardless of whether an alarm is generated. Regardless of the generate service alarms setting, all or a portion of the service's criticality are added to any resource alarms impacting the health of the service. The service is shown in the service impact table of such resource alarms, even if no alarm is generated for the service model itself. Any guarantee models associated with the service tracks outage time regardless of whether an alarm is generated for the outage.
  There are several reasons to disable the generation of service alarms. The first is to reduce the number of alarms that are produced in DX NetOps Spectrum. If you are sure that all resource alarms indicate the service impact, then the service alarm can be unnecessary.
  Another reason to disable service alarms is when the alarm is redundant. Often multiple services are created which monitor many of the same resources, but with a different role. For example, you can create a service model that focuses on the real-time status of a service and can have it generate alarms. Other services models monitor specific aspects or resources of the service model for SLA purposes and can be configured such that they do not produce an alarm.
- **Containers**
  The containers setting specifies how a service monitors its resources, if the specified resource is a type of container model. This setting applies only to those resources which are containers and is not used for non-container resources. You can add different types of containers to a service. Depending on the type of container, you can configure the service to monitor the container model itself or the contents of the container. When set to Monitor Contents (default), the service applies the policy to the models within the container. When using Monitor Container, the service applies the policy to the container itself.
  When Monitor Contents is specified the service monitors the containment relations of the container model, and updates its resources as models are added or removed from the container.
  Consider, for example, the effect of physically removing a router and replacing it with a new router during a network upgrade. If the original router model was placed in a container model that is monitored by Service Manager, it automatically removes from the service. If you place the new router in the same container, it automatically monitors as part of the service.
  Many environments tend to be dynamic (the service resources can periodically change). Consider the addition of new infrastructure components that increase capacity and mitigate the risk of failure. As these resources are added services, you can take them into account. Structured containers and services can adapt easily to these types of changes.
  You can view a list of containers in a service under Containers Providing Resources in the OneClick Console or Service Dashboard Information view. Verify the following image:



The Containers Providing Resources subview indicates the container condition, name, type, and child count (the number of resources in the container).

The Containers setting applies to all resources which are derived from the Container model type. If you want different behavior for different containers within the same service, consider the use of multiple resource monitors, which each has its own container monitoring setting.

- **Service Policy**
  During the planning phase, you identified the resource attribute to monitor and the rule set by which to determine service health. You can select an existing policy that matches this behavior or can create a new one.
  The policy should reflect the behavior of the resources that the service monitors. You can select the policy first by which resource attribute can be monitored, and next by which policy best reflects the behavior of the resources collectively. For example, if the service monitors a pair of redundant servers, a redundancy type policy would be appropriate. If you find no single policy accurately reflects the behavior of the resource, you can create multiple resource monitors to organize resources that are based on their specific monitoring requirements.
  Service Manager provides a set of standard policies that represent common service monitoring requirements. It also lets you create custom policies to meet your particular requirements.

If the service uses resource monitors, or have other services as its resources only Service Health based policies can be used.

Create a Service

Have an understanding of service and the resources that provide the service, before creating a service. Consider how the resources can be monitored and the relative impact of resource outages on the availability of the service. Identifying the resources and how they impact the service makes policy and resource selection easy.

Services that you create appear under the Service tab in Service Editor, in Service Dashboard, and in OneClick Console under Service Management in the Navigation panel.

Follow these steps:

1. Open the Service Editor.
2. Click Tools, Utilities, Service Editor from the main menu.
3. Click the Services tab.
   At the bottom of the Services table you can see the following options/tabs:
   - List - Creates a service as a child of the top-level services model
   - Hierarchy - Creates a service as a child of the service which is selected when the Create button is clicked

   If you are going to create a service as a child or resource of another service the parent service must use a Service Health based policy.
4. Click Create.
   The Create Service dialog appears. The Create Service dialog lets you specify service properties, the IT resources that support the service, and the service policy or resource monitors that define which resource attributes are monitored.
5. Specify the following service properties, some are required for service creation other are optional. Most required fields have default values, but always consider if these values are appropriate.
   - **Name (Required)**
     Multiple services can have the same name provided they have unique descriptions. Consider using a naming scheme or convention that allows for quick identification of the service model.
   - **Description (Optional)**
     Describes the service. You can enter unique descriptions for services that have the same name to facilitate finding each service using a list filtering utility. The service description appears within Service Availability and Service Health Reports.
   - **Criticality (Required)**
     Specifies the criticality value that is factored into the impact calculation for a service resource model in an alarm state (the root cause alarm).
   - **Landscape (Required)**
     Specifies the landscape where the service model can be created. The landscape field appears only when you are working in a DSS environment.
   - **Security String (Optional)**Specifies the security string for the service model.
   - **In Maintenance (Optional)**
     Selecting this option puts the service model into maintenance mode.
   - **Generate Service Alarms (Required)**
     Specifies whether DX NetOps Spectrum generates alarms for the service model which correspond to changes in service health.
   - **Containers (Required)**
     Specify how the service should monitor resources which are containers.
6. Specify the service policy and click the Set button to select or create a service policy.
   For services that define resource monitors or monitor of have other services as their resource only Service Health based policies can be used.
   Note: When you specify Service Policy, the Service Editor automatically selects the most appropriate table to display the resources of the service.

Note: The service policy dictates which attribute of the resources can be monitored. Make sure the service resources that you specify support the attribute that you select. If a resource is specified which does not support the attribute, DX NetOps Spectrum generates a yellow (minor) alarm for the Service Management model.

7. If the service uses resource monitors, click the gear icon to create each resource monitor.
   For each resource monitor, specify a name and policy. You can also specify the Container behavior, and an alarm type exemption.
8. Configure alarm type exemptions.
   This feature is only available for services that are using a Condition-based Policy.
9. Select containers and resources for a service by clicking the binoculars icon to launch the resource locater; search for resources and add them to the service.
   If you have created resource monitors first select the resource monitor, and then launch the resource locater.
   When specifying resources which are container mode, the Containers configuration that is specified in step 5 applies.
   For more information about working with searches, see the OneClick Administration section.
   If you are creating the service on the main location server, select resources from any landscape. If the service is created on a landscape which is not the MLS, you are restricted to select resources only from the local landscape, and the MLS. Notify your organization DX NetOps Spectrum administrator if the search does not find the resources that you expect to find.
10. Select the resources (models) you want to include from the returned search list and click Add Selected to Monitored Resources. Close the Locate Resources dialog when you have all the resources.
11. Click the Create button to create a service model.
    The service now appears in the table view of the service editor.

Resource Monitors

Resources in Maintenance Mode

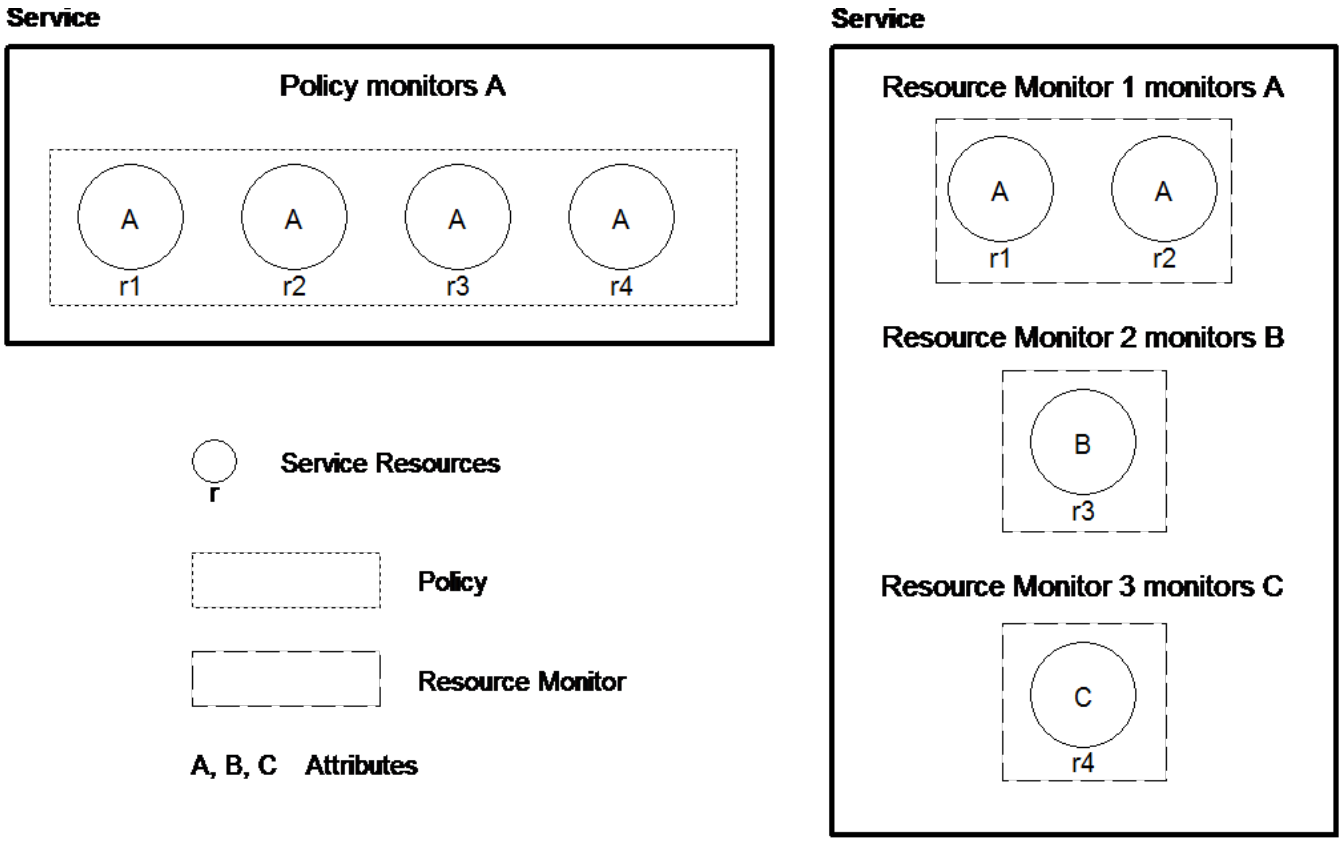
When a service resource is put into maintenance mode, Service Manager stops monitoring the resource during the maintenance mode period. For certain types of resources (port models, monitored process models, and monitored file system models, for example), Service Manager respects the maintenance status of the parent device model.

When the parent model for the following resource types is put into maintenance mode, the service stops monitoring the resource:

- interface models
- monitored process models
- monitored disk (file system) models

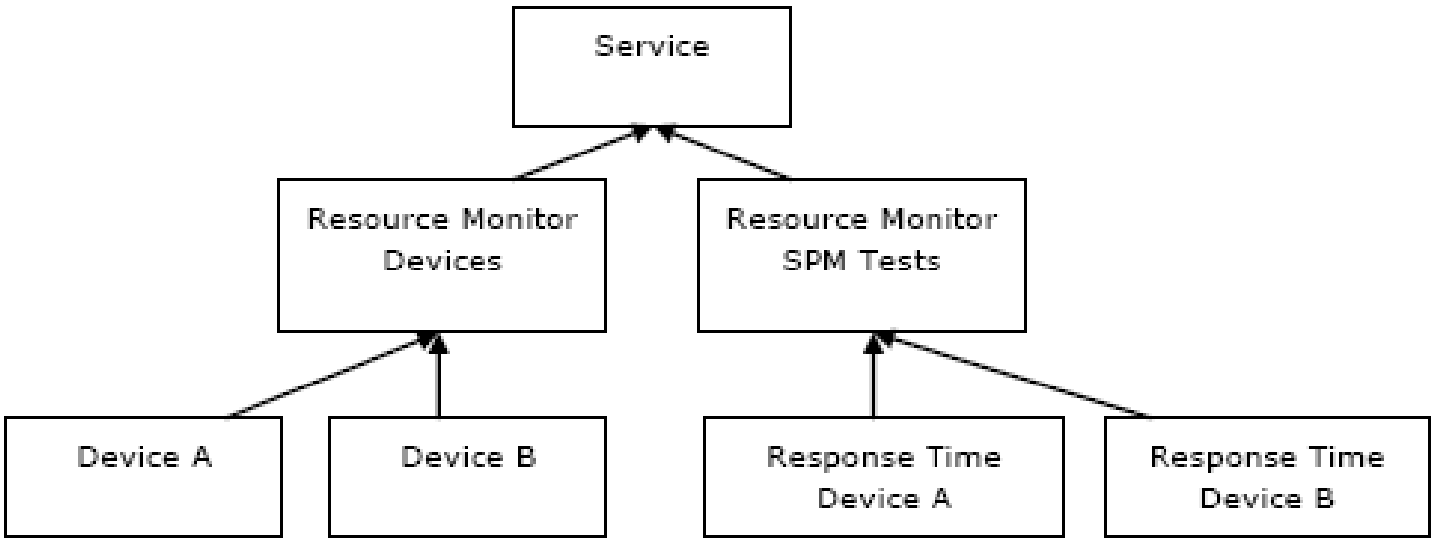
A resource monitor is a DX NetOps Spectrum model. A policy, which is not a model, specifies a *single* watched attribute common to *all* resources monitored by a service, a resource monitor monitors an *attribute* common to *one or more* service resources to determine its own service health status, the same way a service determines its health status. Using resource monitors lets you implement a finer mode of monitoring service health than is provided by a single policy.

The following diagram illustrates the difference between the two by showing how each could be implemented for the same service:



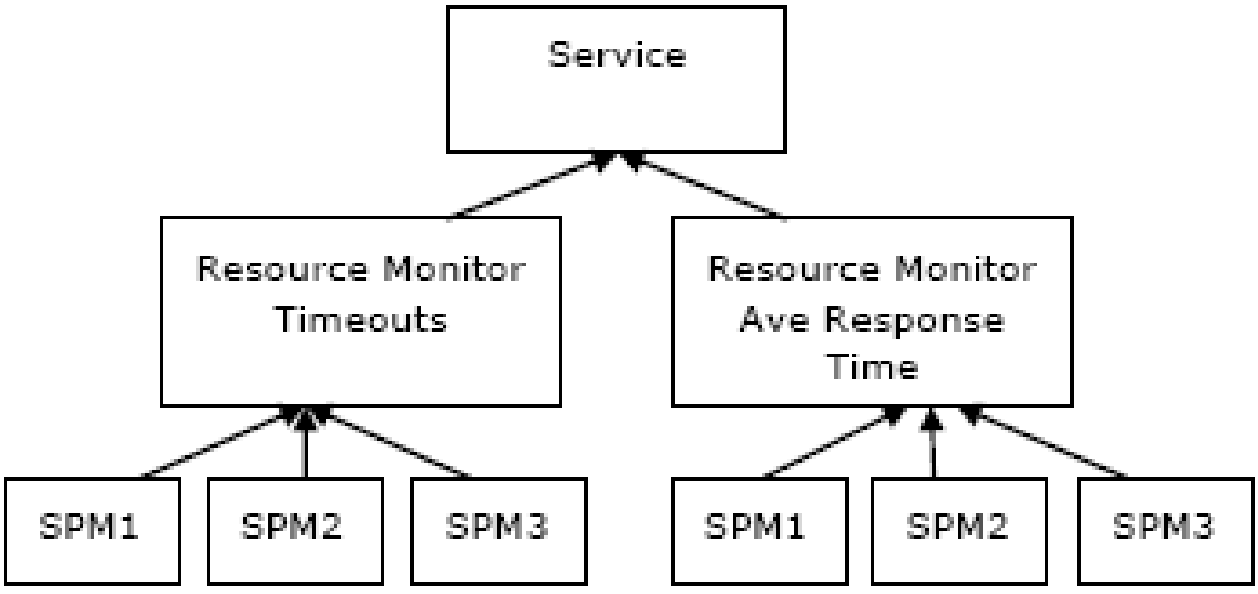
A resource monitor is a resource of a service, and you can apply multiple resource monitors to monitor a service. A service monitors the service health attribute of each resource monitor to determine its own health.

A simple scenario of when resource monitors can be used is when the resources of a service are of mixed types. For example, when monitoring a pair of device models, and a pair of response time test models. Different policies are used to monitor device models, and SPM test models, resource monitors could be created to organize the device models, and the SPM test models in the following way:



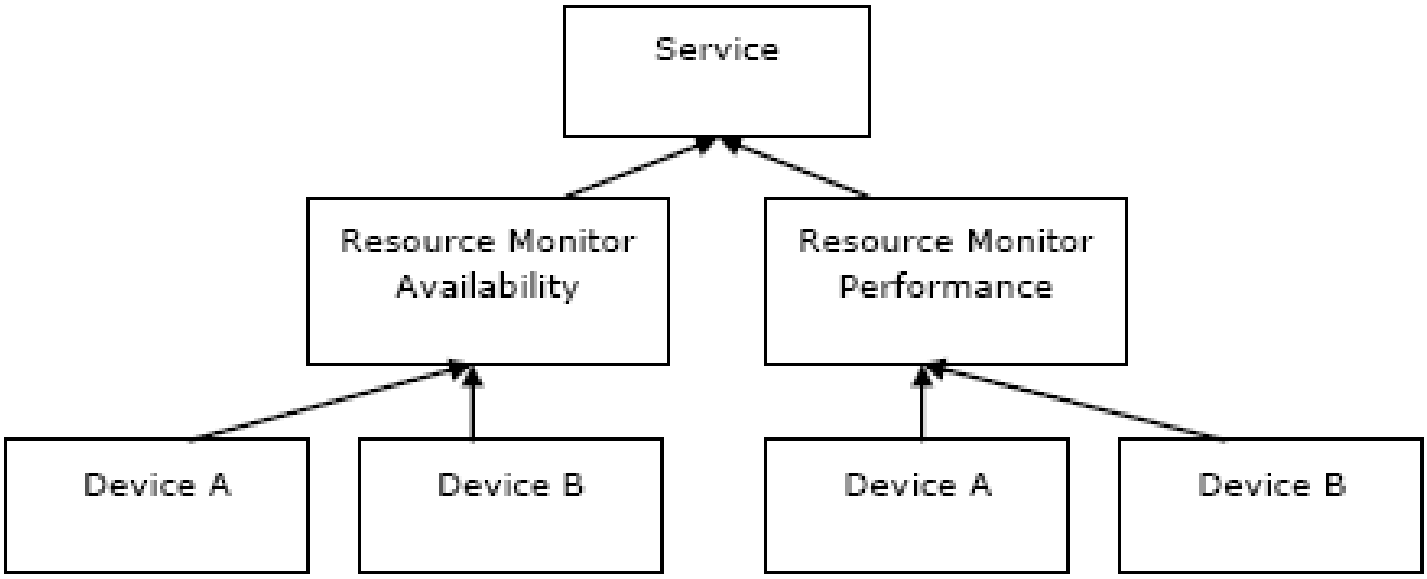
The Service model would use a policy such as Service Health High Sensitivity, the Resource Monitor for Devices uses the policy Condition Redundancy, and the Resource Monitor for Response Time tests uses Response Time Redundancy.

In other cases, you can monitor multiple attributes of the same resources. In other words, apply multiple policies to the same resources. For example, you may be interested in monitoring a set of SPM Tests with a response time policy such that the service is impacted when too many response time tests are timing out. You also want to monitor the average response time of the same response time tests such that the service is impacted when the average response time exceeds some specific threshold. Again resource monitors can be used to create this type of service.



In this scenario, the service uses the Service Health High Sensitivity policy. The Resource Monitor for timeouts could use a custom policy focusing specifically on the Latest Error Status value of Timeout for the SPM Tests. The Resource Monitor for average response time uses another custom policy that compares the average Latest Result for the SPM tests to a particular set of threshold values.

In yet another scenario, multiple resource monitors can monitor the Condition of common resources, but can use different policies to organize resource outages by fault type. For example, resource monitors could be used to categorize availability impacting faults and performance impacting faults:



In this configuration, the Service uses a service health policy, the availability resource monitor uses a customer policy with an Alarm Type exemption configuration designed to isolate resource faults that are designated as availability impacting. The performance resource monitor would in turn use of custom policy which isolates resource faults that are designated as performance impacting.

Create a Resource Monitor

You can monitor multiple attributes on a single resource with different resource monitors.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab and click Create.
   The Create Service dialog appears.
3. Click 
   The Create Resource Monitor dialog appears.
4. Perform the following steps:
   a. Enter a name for the resource monitor and, optionally, a security string.
   b. Select whether the resource monitor monitors the resources in a container or the container itself.
   c. Select a policy.
   d. (Optional) Specify which alarms you want to affect or not affect the health of the resource monitor.
   e. Click OK.
   The resource monitor appears in the Containers in Resources to Monitor list in the Create Service dialog.
5. Add the resources with the attribute you want to monitor (the attribute that is specified by the resource monitor policy) with the resource monitor:

a. Select the resource monitor.
b. Click the Locate resources and containers icon.
c. Select the containers and resources for the resource monitor.
d. Click Add Selected to the Monitored Resources.

The resources appear under the resource monitor icon in the Containers and Resources to the Monitor panel.

Specify the Alarm Types That Affect or Do Not Affect Service Health

Content

You can specify resource alarm types to affect or not affect service health when you create a service or resource monitor with a policy that specifies the Condition attribute. You can perform this task from the Exemptions Panel by selecting the appropriate alarm impact options.

Note: This functionality replaces the manual setting of the Exempt_Cause_List attribute which was documented for previous releases.

Consider the following information before you specify resource alarm types:

- Individual services or resource monitors can specify a list of alarm types to be excluded from or included in the service health calculation.
- Service alarm type exemptions can be used to establish a specific behavior for individual services. For example, only this service is affected by this alarm type, or this particular service should not be affected by this alarm type.
- Service alarm type exemptions take precedence over any configuration that is defined at the policy.

> **NOTE**
> When you specify alarm type exemptions for a service, Service Manager ignores any exemption specification that is defined for the policy that is used by the service.

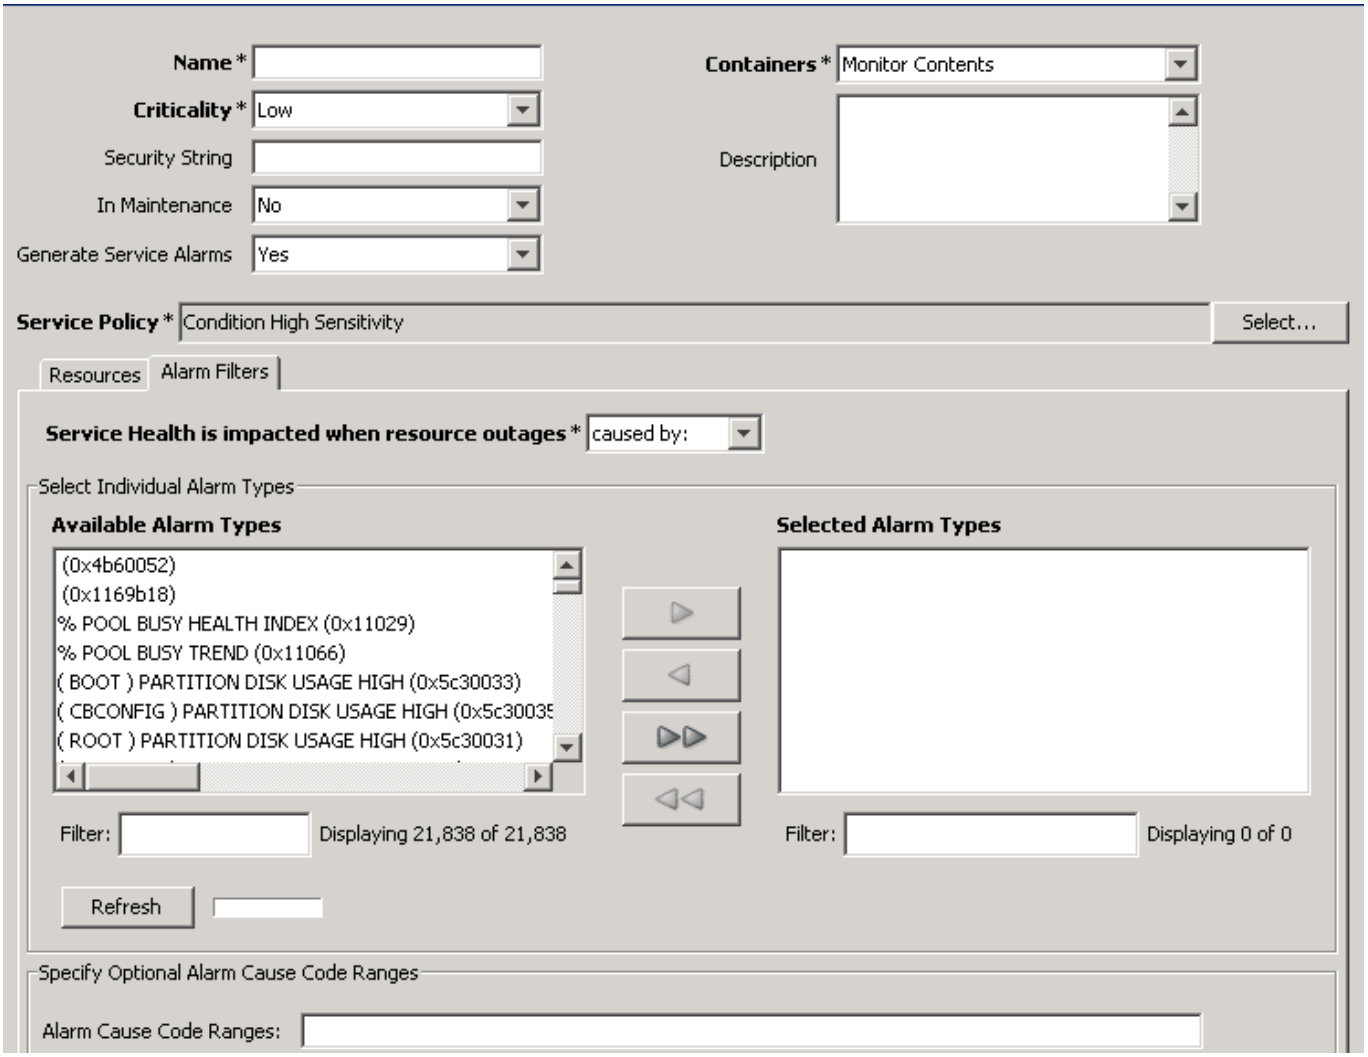
Follow these steps:

1. Perform one of the following tasks:
   – Create a service.
   – Create a resource monitor.
2. Click the Exemptions tab and select one of the following alarm impact options from the Service Health Impacted Only When Resource Outages * drop-down list:
   – **Caused By**
   Only these selected alarm types impact the service health.
   – **Not Caused By**
   Exclude these alarms from impacting the service.
   – **Disabled (default)**
   Do not use service level alarm type exemptions. If the policy defines exemptions, you can use it.
3. Move the available alarm types that you want to affect or not affect a service to the Selected Alarm Types box, or specify a range of alarm cause codes.
   The alarm types are specified.

Alarm Filters

In DX NetOps Spectrum, the health of a service can be impacted based on the alarms that are generated on the resources on which the service is monitored. If a filter is applied to any specific alarm, that particular alarm participates in affecting the health of the service. The alarm is also considered while calculating the health of a service.

The following image shows the Alarms Filter tab and the available options:



If the alarm filters tab is disabled, the alarm functionality does not work, irrespective of alarm types that are selected to impact the health of the service. By default, the alarm filters tab is disabled.

- Service Health is impacted when resource outages*
  - **caused by**
    Impacts the health of the service if the generated alarm on Service Monitored Resources (SMR) is of the selected alarm type.
  - **not caused by**
    Impacts the health of the service if the generated alarm on SMR is not of the selected alarm type.
- **Alarm Cause Code Ranges**
  Impacts the health of the service if the generated alarm on SMR falls in the specified alarm cause code range.
- **Specify Alarm Title Keywords**
  Impacts the health of the service if the generated alarm title on SMR matches with the specified alarm title. For example, CHASIS.

  NOTE
  You can define the same functionality (Alarm Title Keyword, Alarm Types) on Alarm Filter at the service policy level.

Add a Resource to a Service

You can create a service and can add resources to the service, or can add resources to an existing service or resource monitor using the OneClick Console as an alternative to using the Service Editor.

Follow these steps:

1. Select the resource (model) you want to add to an existing service or a service you plan to create.
2. Right-click the model and click Add To, Service.
   The Add to Service/Resource Monitor dialog appears. This dialog lists available services.

   NOTE
   To display resource monitors for a service, select the service.
3. Create a service to which you can add the resource or can add the resource to an existing service or resource monitor:
   – To create a service, click Create.
   The Create Service dialog appears. It lists the selected resource as a resource of the service. Specify service properties as described in Create a Service.
   – To add the selected resource to an existing service or a resource monitor, select the service or resource monitor to which you want to add the resource and click OK.
   The resource is added to the service or resource monitor.

Delete a Resource from a Service

You can remove a resource from a service using the OneClick Console as an alternative to using the Service Editor.

Follow these steps:

1. Select the resource (model) that you want to remove from an existing service.
2. Right-click the model and click Remove From, Service.
3. Click OK.
   The resource is removed from the service.

Edit a Service

You can change all service properties anytime after you create a service.

Consider the following information before you edit a service:

- If you change a service name, all historical data in reports for the service that is generated with DX NetOps Spectrum Report Manager is listed under the new name.
- If you delete a service that is monitored by an SLA, the SLA guarantee goes to the Initial (Blue) state.
- If a service has a resource monitor monitored by an SLA and you delete the resource monitor, the SLA guarantee watching it goes to the initial (Blue) state.

  WARNING
  Editing services can be performed by authorized personnel who are aware of the potential ramifications of these actions, particularly as they relate to services monitored by SLAs.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab, select the service that you want to edit from the list, and then click Edit.
   The Edit Service dialog appears.
   Edit the settings, as described in Create a Service, and click OK.
   The service is edited.

Delete a Service

Before you delete a service, verify that it is not associated with an SLA you intend to implement that is scheduled to be activated.

WARNING
Deleting services can be performed by authorized personnel who are aware of the potential ramifications of these actions, particularly as they relate to services monitored by SLAs.

Follow these steps:

1. Open the Service Editor dialog.
2. Click the Services tab, select the service that you want to remove from DX NetOps Spectrum, and then click Delete.
3. Respond to the confirmation message that appears to complete the deletion.
   The service is deleted.

Cut a Service

DX NetOps Spectrum Service Manager lets you cut a resource monitor as part of editing a service.

Create a service and add a resource monitor. The policy and resources do not matter. Save and edit the service.

NOTE
With the resource monitor selected, the cut icon is disabled.

Follow these steps:

1. Open the Service Editor dialog.
2. Click the Services tab, select the service that you want to cut from the resource monitor, and then click Cut.
   The service is cut.

Service Maintenance Schedule Management

When you schedule maintenance for a service, DX NetOps Spectrum puts the service in maintenance mode (brown state) for the duration that is specified by the schedule. A service in maintenance mode is a planned outage. If the service is monitored by an SLA, the frequency and duration of the scheduled planned outages are typically defined by the SLA contract between a service provider and a service customer. Planned service outages are not accumulated as down or degraded time by SLA guarantees.

You can manage service maintenance schedules in the following ways:

- Create and save multiple one-time and recurring schedules.
- Add schedules to the list of schedules to be implemented on an as-desired basis.
- Remove schedules from the list of schedules to be implemented.

Create a Maintenance Schedule

When you create a schedule, Service Manager saves it to DX NetOps Spectrum. The schedule is added by default to the list of schedules that can be implemented for the service. If you do not want the schedule to be implemented, you can remove it from the list and can add it to the list at another time. You have two ways to create or specify a maintenance schedule for a service. You can specify scheduled maintenance from the Component Detail view of a service model much like other DX NetOps Spectrum models, or you can configure scheduled maintenance from the service editor.

Follow these steps:

1. Open the Service Editor.

2. Click the Services tab, select the service for which you want to manage maintenance schedules, and then click the Scheduled Maintenance tab.
3. Click Create.
   The Create Schedule dialog appears.
4. Configure the new schedule and click OK.
   Service Manager adds the schedule to the Current Schedules list.

Add a Maintenance Schedule to the Current Schedules List

If you want to implement a maintenance schedule for a service, include it in the Current Schedules list for the service.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab, select the service for which you want to manage maintenance schedules, and then click the Scheduled Maintenance tab.
3. Select the schedule to add from the Available Schedules list and move it to the Current Schedules list.
   The maintenance schedule is added to the Current Schedules list.

Remove a Maintenance Schedule from the Current Schedules List

If you do not want to implement a maintenance schedule, you can remove it from the Current Schedules list.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab, select the service for which you want to manage maintenance schedules, and then click the Scheduled Maintenance tab.
3. Select the schedule that you want to remove from the Current Schedules list, and then move it to the Available Schedules list.
   The maintenance schedule is removed from the Current Schedules list.

Associate an Owner with a Service

Service Manager lets you designate one or more users as owners of a service. A service owner serves as the contact person for the service. Service owner information and also be available from Service Availability and Service Health reports.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab, select the service to associate with an owner, click the Owners tab, and then click Select Service Owners.
   The Select Owners dialog appears.
3. Move the owner to associate with the service from the Available Owners list to the Service Owners list and click OK.
   The owner is associated with a service.

Associate a Customer with a Service

Service Manager lets you associate one or more customer models with a service to help you track and manage services and customers. You can generate service reports with DX NetOps Spectrum Report Manager based on service customer associations. When a service is associated with one or more customer models, the Criticality of each customer can be

factored into the alarm impact for any service impacting outage. This assures that resource outages which impact highly critical customers can have a greater impact value.

Follow these steps:

1. Open the Service Editor.
2. Click the Services tab, select the service that you want to associate with a customer, click the Customers tab, and then click Select Service Customers.
3. The Select Customers dialog appears.
4. Move the customer that you want to associate with the service from the Available Customers list to the Customers that use this Service list and click OK.
   The customer is associated with a service.

Service Models in a DSS Environment

When creating service models in a distributed SpectroSERVER (DSS) environment there are some important factors to consider. Service models can be associated with resource models from other landscapes. The supported behaviors are as follows:

- A service model that is created on the MLS can monitor resources from the MLS or any second tier landscape.
- A service model that is created on a second tier landscape can monitor resources models on its own landscape or the MLS, but not other second tier landscapes.

The following behaviors apply to services which use global collections to define their resources:

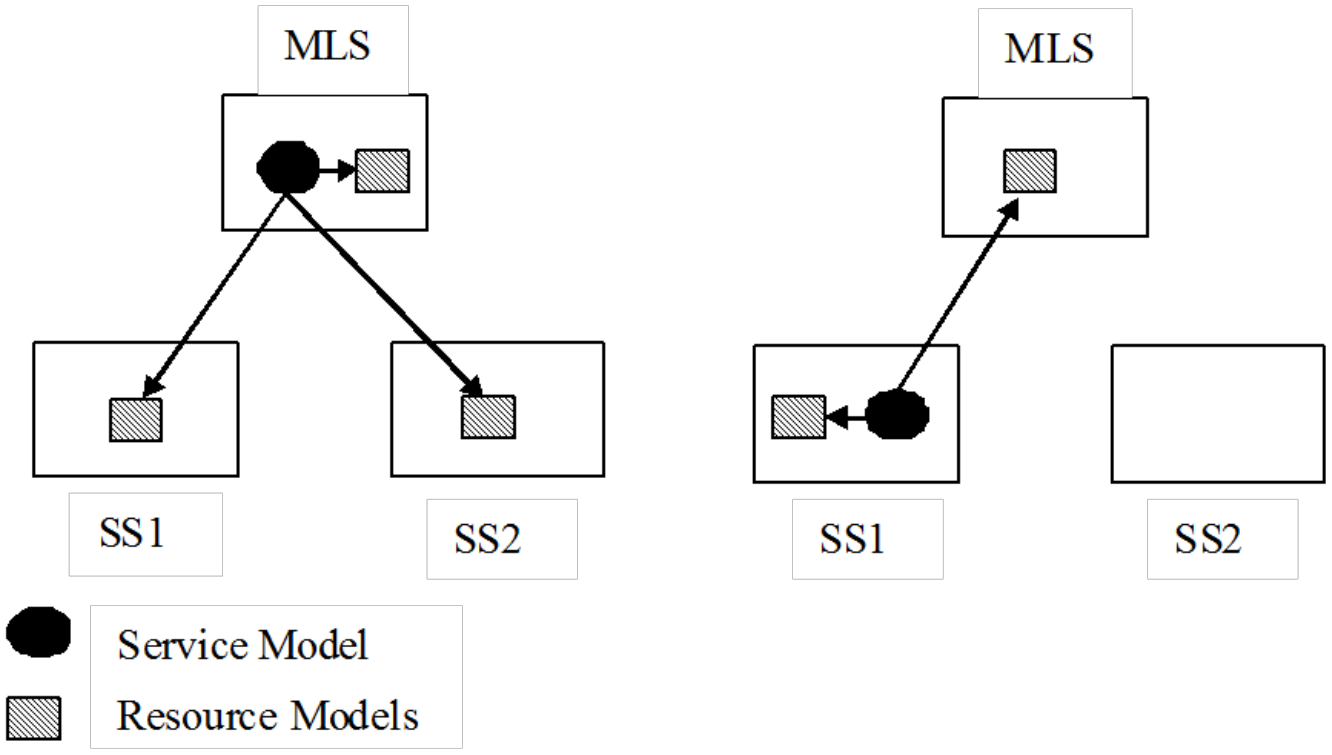
- A service model that is created on the MLS using a global collection can monitor all resources that are contained by the global collection.
- A service model that is created on a second tier landscape using a global collection can monitor only those resources in the collection which reside on its own landscape or the MLS.

In 9.2, the performance-heavy cross landscape watches are replaced with asynchronous action notifications, relieving some of the burdens from the SpectroSERVERs. In addition, a relay mechanism allowing the MLS to forward second tier notifications from one landscape to another allows second tier services to monitor resources from other second tier landscapes.

This lets you construct services with less concern over performance impact. In addition, it lets you create services on landscapes where the service should logically reside without concern over what landscape required remote resources reside upon. This does not eliminate the need for an efficiently designed service hierarchy, but it provides flexibility which makes it easier to design the service hierarchy. All resources from all landscapes are visible, regardless of where the service mode is being created.

Example: Supported Service to Remote Resource Configurations

The following image depicts the supported service to remote resource configurations:



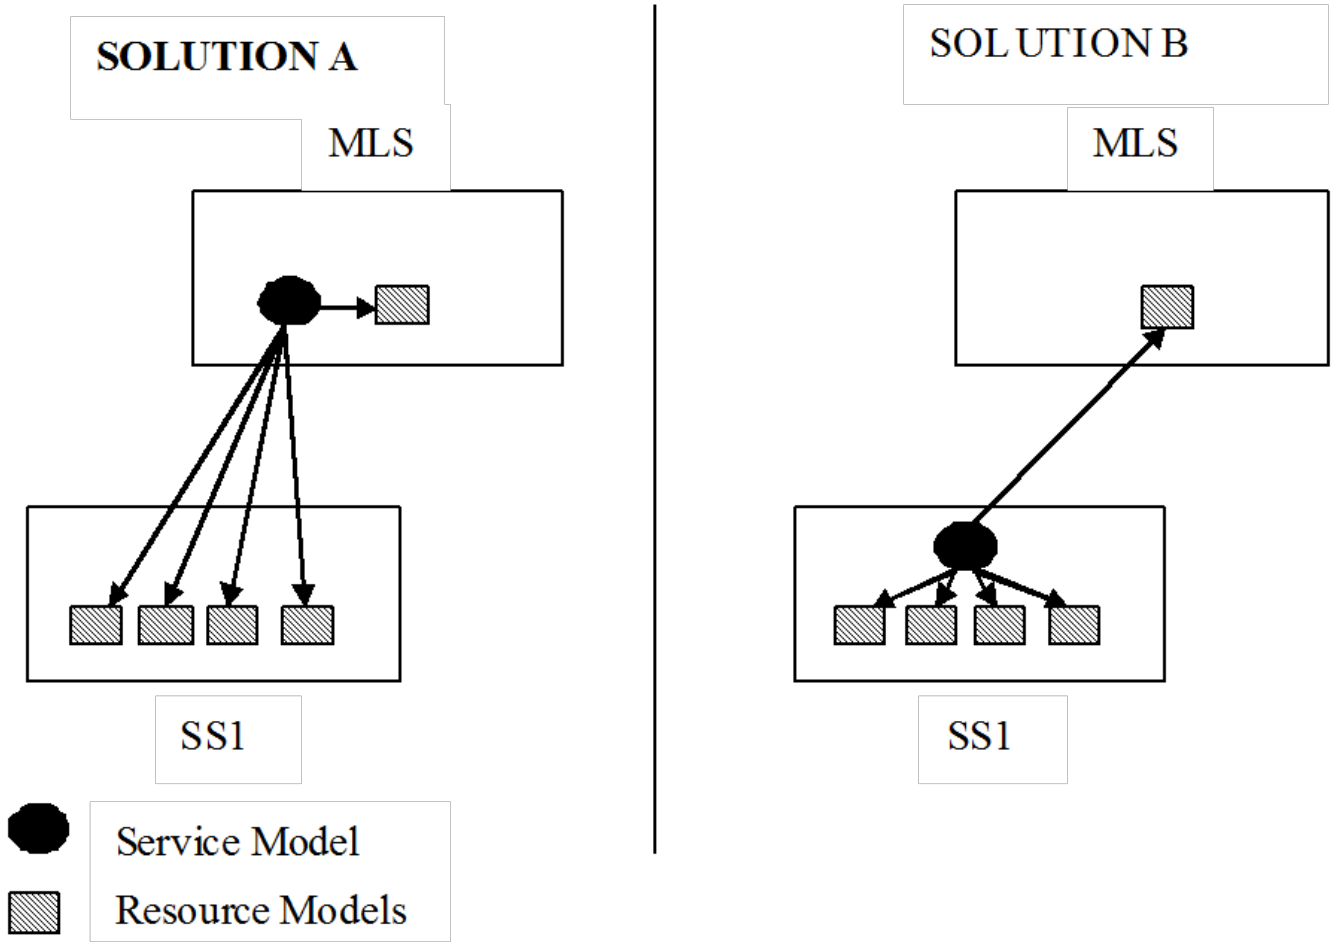
In addition to understanding which configurations are supported it is also important to consider the efficiency of the service model, and resource distribution impact. Monitoring a resource that resides in the same landscape is more efficient than monitoring a resource that resides in another landscape. When creating service models, strive to minimize the number of service resources that reside on remote landscapes. Consider the following example. Service XYZ has five resources, 1 of these resource models resides on the MLS while the other 4 reside on SpectroSERVER 1 (SS1). The following image depicts two potential designs for service XYZ:

Service Model Example: Resource Distribution Impact

Because of the reduced number of resources residing on a remote landscape, Solution B is a more efficient design. If the service can reside on either landscape, select the landscape where most resources exist. You can summarize this statement by saying ‘build the service closest to the bulk of its resources’.

There are some circumstances where the service has resources on multiple second tier landscapes and must reside on the MLS. In these scenarios, more efficient service design can be created by consolidating the remote resources into a sub-service which is monitored by the parent service on the MLS.

The following image depicts two solutions which can be created when the service must reside on the MLS:

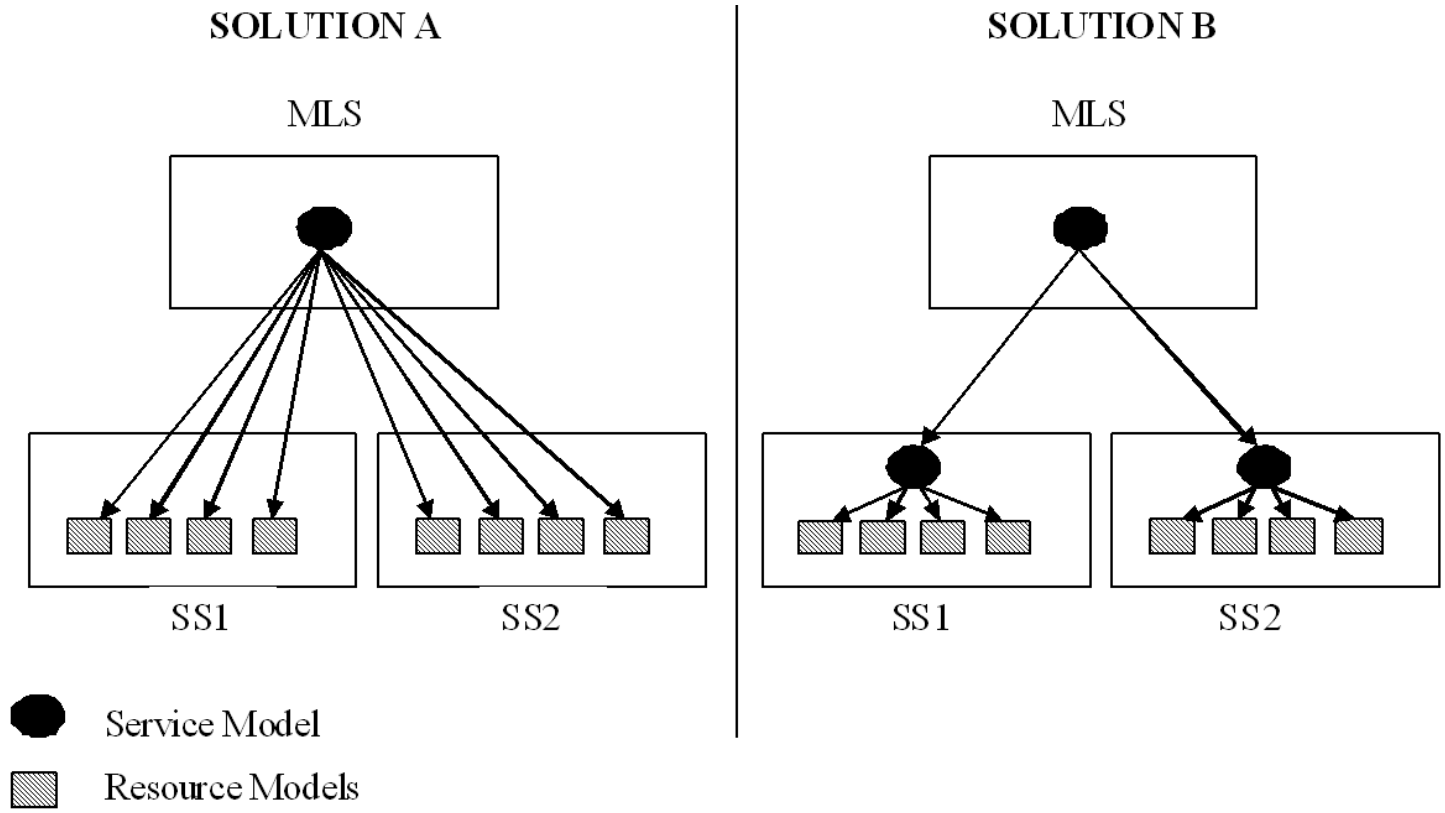


Service Model Example: Service Resides on the MLS

Solution B represents a more efficient design by minimizing the number of resources that are monitored remotely. In Solution B, the service models that are created on SS1 and SS2 become resources of the service that is created on the MLS. When creating service hierarchies, such as the one depicted in Solution B, it is important to verify the policies that are used for each service, reflects the behavior of the resources from each landscape.

When creating services that use global collection consider the number of remote resources that result from the use of the global collection. When any type of container is used to specify service resources by default, the service monitors the contents of the container. A global collection can contain models from multiple landscapes.

The following image illustrates the use of a global collection that can potentially create an inefficient service design.



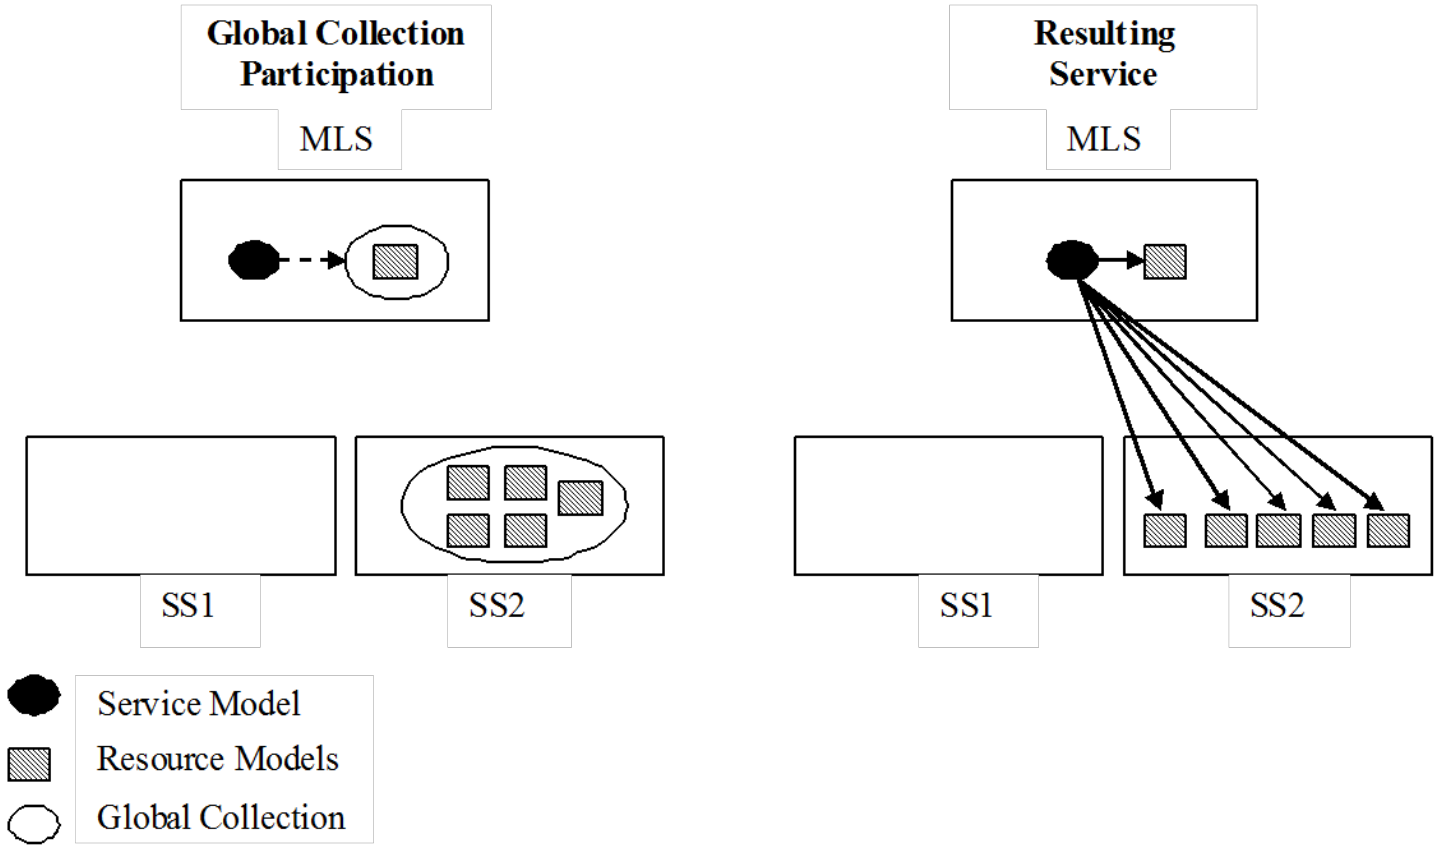
Again Solution B, represents a more efficient design by minimizing the number of resources that are monitored remotely. In Solution B, the service models that are created on SS1 and SS2 become resources of the service that is created on the MLS. When creating service hierarchies, such as the one depicted in Solution B, it is important to verify the policies that are used for each service, correctly reflects the behavior of the resources from each landscape.

When creating services that use Global Collection consider the number of remote resources that result from the use of the Global Collection. When any type of container is used to specify service resources by default, the service monitors the contents of the container. A Global Collection can contain models from multiple landscapes. Consider the following images, and how the use of a Global Collection could potentially create an inefficient service design.

Example: Global Collection

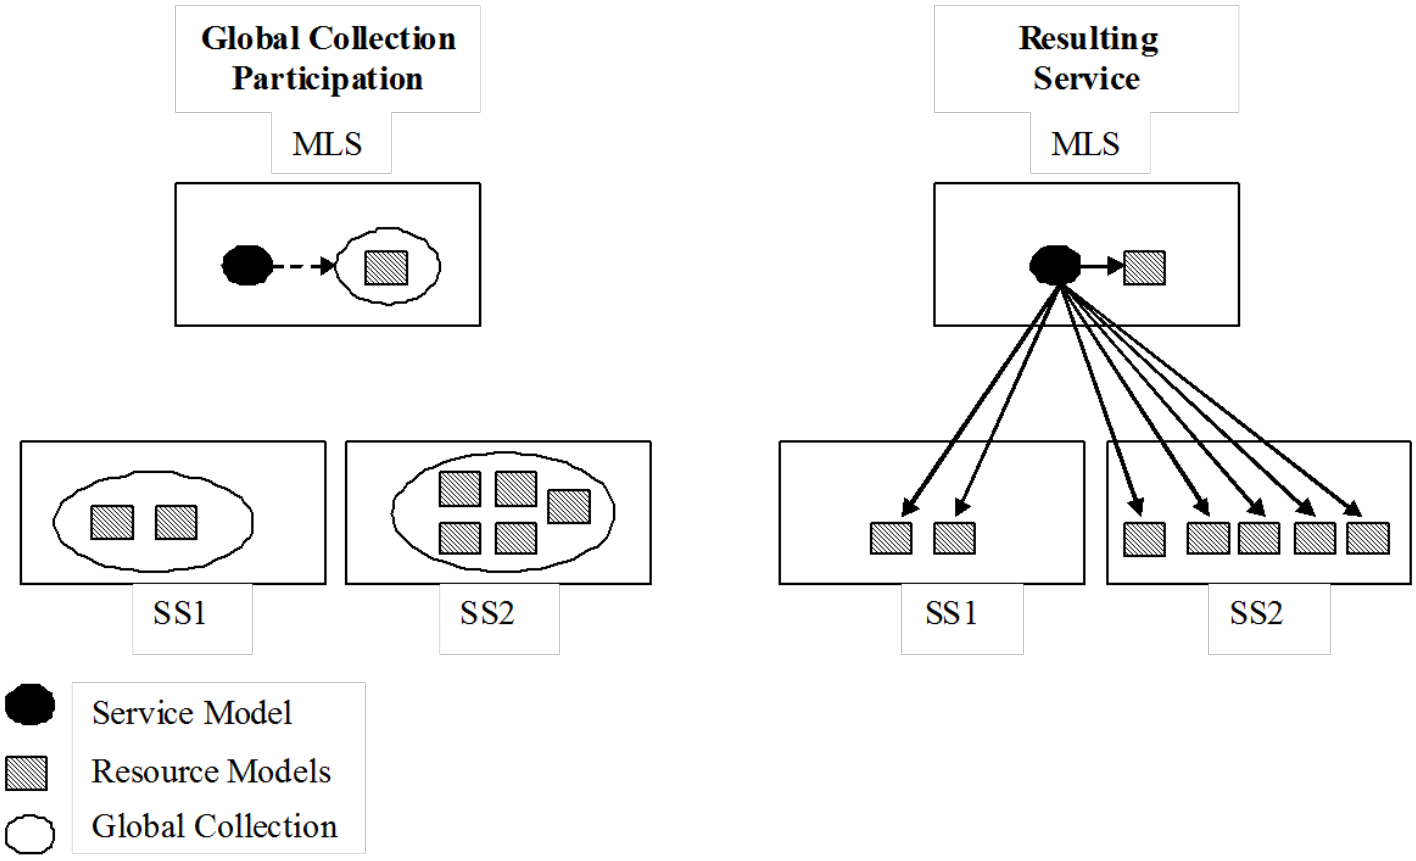
In the following scenario, if the service is created on the MLS it would be monitoring five remote resources. If the service was created on SS2, it only has to maintain one remote resource.

However, improving efficiency of this scenario cannot be as simple as moving the service to SS2. The service is using a global collection to specify its resources to support a set of potentially dynamic resources. Consider if two more models are created on SS1 which participate in the global collection.



Global Collection Example: Add Two Additional Models

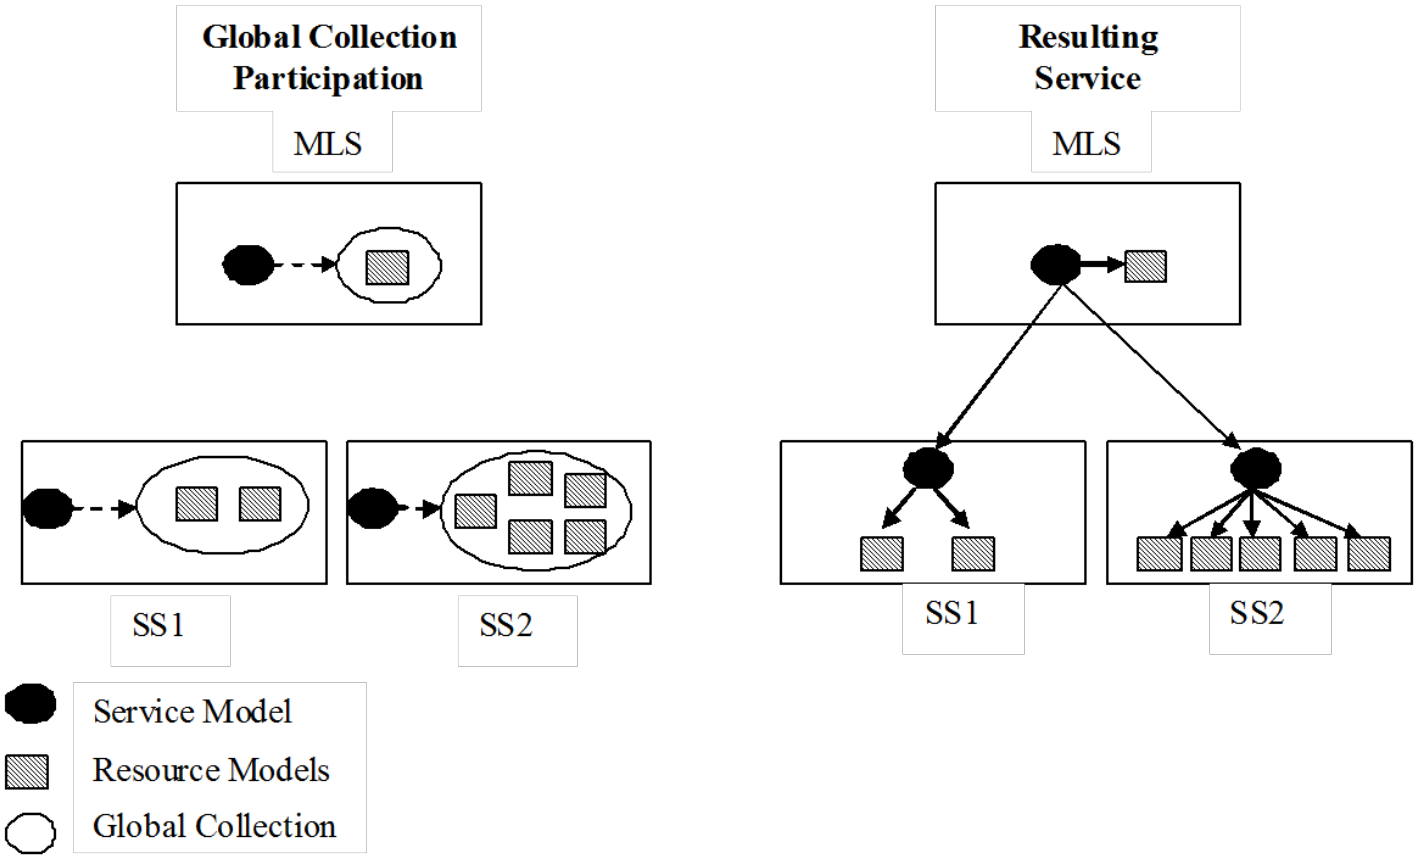
If the global collection contained resources from all landscapes, the service has to reside on the MLS. An alternative to consider is the use of multiple services that monitor the local copy of the global collection, residing on the same landscape. Although logically a global collection is a single model, it is implemented as a set of duplicate models with a model residing on each landscape for which the global collection is specified.



Example: Multiple Services Monitoring the Local Copy of the Global Collection

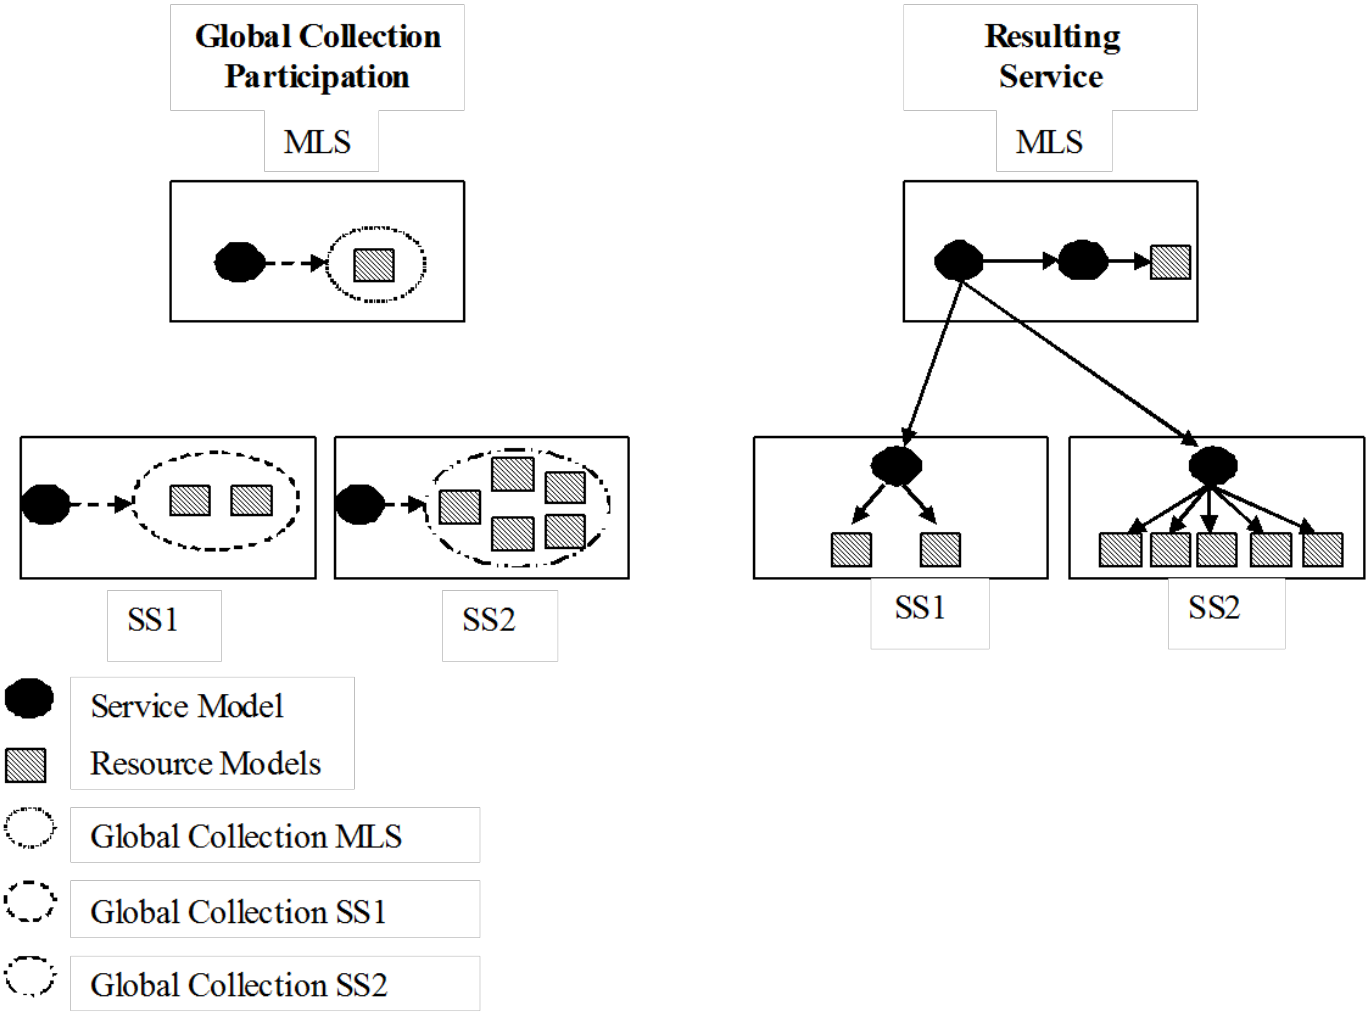
Although this approach does produce a more efficient service, it can be complex to maintain and may require the use of DX NetOps Spectrum Command Line Interface (CLI) to implement.

An alternate technique would be to create multiple global collections which are bound to a single landscape. Services can then be created on each landscape, with a parent service to monitor them.



Example: Multiple Global Collections Bound to a Single Landscape

This design allows for the benefits of a dynamic collection, but also provides an efficient service design. It may not be ideal to maintain multiple Global Collections in this way so you must weigh the costs and benefits of this solution.



Policies

A service policy reflects the behavior of a set of resources that logically impacts a service. The policy specifies which resource attribute is monitored and how those attributes are interpreted to determine the health of a service. A number of common policies are available out-of-the-box, and users can create their own policies to more accurately monitor service resources.

A policy includes the following basic components:

- **Attribute map**
  The attribute map serves two purposes. First, it specifies which resource attribute is monitored. Second, it maps resource attribute values to a set of resource health values. The mapping is done based on the logical severity of the attribute value. For example, if the attribute map represents the Port Status attribute, a disabled port can be logically considered as a down resource. If the attribute map represents the status of a response time test, a minor threshold violation and a slightly degraded resource can be considered.

This mapping allows policy rule sets to handle various resource types in a common way by having only to consider the resource health values of down, degraded, and slightly degraded.

- **Rule set**
  A rule set consists of a number of statements evaluating the cumulative mapped resource health values of a set of service resources against some criteria. Each rule within the set specifies the criteria and the resulting service health value if the criteria are met. For example, a rule can look something like: When all resources are down the service is down. This means that given the mapping of the monitored attribute if all resources have a resource health of down the resulting health of a service using this policy can be down.
  As mentioned, the rule set consists of multiple statements or rules. The rules are evaluated from the top down, and the first rule which is satisfied determines the health of any service using that policy. If none of the rules in the rule set are satisfied, the service health can be up.

  WARNING
  Editing and deleting policies and attribute maps and rule sets can be performed by authorized personnel who are aware of the potential ramifications of these actions, particularly policies for services that are watched by Service Level Agreements (SLAs).

Policy Types

Before you create a custom policy, have a clear understanding of what you want to monitor (the watched attribute and its status values) and the method that is used for the monitoring. Two distinct types of service monitor policies are available, such as:

- Status policies use an attribute map to compare the status of monitored attributes that are indicated by the rule sets. These policies use the *All*, *Any*, or *Percentage* rule sets.
- Statistical policies use Aggregate rules and compare the value of the monitored attribute to the computed value set by each rule. A statistical policy requires an attribute map to specify which attribute can be monitored, but the mapped values are ignored in favor of the attributes pure values. The attributes values can be summarized in several ways, such as average, minimum, maximum. The summarized values are then compared against numeric thresholds that are specified in the rule-set.

For example, a status policy can monitor the operational status of an interface, where a statistical policy can monitor the error rate of an interface.

Create a Policy

You can create policies using any combination of standard and user-defined attribute maps and rule sets. When you create a policy, it becomes available to other Service Manager users. You can also create a policy by saving a uniquely named version of an existing policy.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Policies tab and click Create.
   The Create Policy dialog appears. Service Manager autofills the Author field with your DX NetOps Spectrum user name.
3. Enter a unique name for the policy in the Policy field.
4. Select an attribute map.
   Properties for the map you select appear. If the attribute maps available do not meet your requirements, you can create an attribute map or can edit an existing user-created attribute map.
5. Select a rule set.

Rules for the rule set you select appear. The rule set specifies the status (or health) of a service is based on the mapped health values of the service resources. A rule set consists of conditional statements that assert what the health of the service is based on the collective set of resource health values.
If the available rule sets do not meet your requirements, you can create a rule set or can edit an existing user.

6. (Optional, and only applicable if you chose a Condition attribute map).
   Specify alarm type exemptions for the policy. This option consists of a set of alarm types and how they are applied either inclusively (caused by) or exclusively (not caused by).
   You can specify alarm type exemptions at the policy level, if the policy is used by multiple services. If the alarm type exemption configuration is only relevant for a single service, it can be better to define if for the service itself rather than at the policy level.
   Consider the following points before you allow or disallow alarm type lists in policies:
   - Alarm type exemptions that are configured at the policy are enforced only for services using the policy which do not define their own alarm type exemptions. If a service using the policy is later edited and has alarm type exemptions that are configured for it, the policies configuration can be ignored from that point forward.
   - Any changes that you make to the alarm type exemption configuration for a policy affect all services that use the policy.

   Follow these steps to specify alarm type exceptions for a policy:
   a. In the policy create/edit dialog Click Set. (If the set button is disabled, it is likely that the specified attribute map is not for the Condition attribute, only Condition-based policies can specify alarm type exemptions).
      The Configure Inclusive or Exclusive Alarm Types dialog appears.
   b. Specify Caused By or Not Caused By.
   c. Select the appropriate alarm types and click OK.
   d. The Create Policy dialog shows the alarm type inclusion or exclusion list that you specified.
7. Click Create.
   The policy appears in the Policy list in the Service Policy Editor dialog.

Add Alarm Types to a Custom Condition Policy

You can add resource impacting alarm to the list of alarm types that are specified in any user created policy which uses a Condition attribute. This option is available when selecting an Alarm in the Alarm tab of the OneClick Contents Panel.

Follow these steps:

1. Select one or more alarm types to include in the policies from any OneClick alarm view.
2. Right-click and click Add Alarm Type to Service Policies.
   The Specify Alarm Types for Service Policies dialog appears. This dialog lists selected alarm types and all custom (user-created) Condition policies.

   NOTE
   You can include the Alarm Behavior column by right-clicking any table column heading. This indicates how the policy interprets the alarm exemption Caused By or Not Caused By.
3. Select the policies to which you want to add the alarm types and click OK.
   The alarm types are included in the alarm type list for each selected policy. If you selected a policy without an alarm type configuration, Service Manager defaults to a setting of Not Caused By for the policy.

Create a Policy from a Copy

You can create a policy by copying an existing policy and saving it with the settings you require under a different name.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Policies tab, select the policy from which you want to create a policy, and click Copy.

The Create Policy: <*Policy Name*> dialog appears. It includes the settings for the policy you are going to use as the basis for your new policy.

3. Enter a unique name for the new policy in the Policy field.
4. Edit policy properties, as described in Create a Policy, and click Create.
   The new policy appears in the Policy list in the Service Policy Editor dialog.

Edit a Policy

You can modify all user-created policies. Service Manager implements modified policy settings immediately after you save them.

Follow these steps:

1. Open the Service Editor.
2. Click the Policies tab, select the policy that you want to edit, and then click Edit.
   The Edit Policy: <*Policy Name*> dialog appears.

   NOTE
   Policy edits are applied to all services or resource monitors which are currently using the policy. Depending on the nature of the edit, it results in a change to the service health of one or more services.
3. Edit the settings, as described in Create a Policy, and click OK.
   The policy is edited.

The following limitations apply to the service policy editing:

- You can edit or delete user-created policies, attribute maps, or rule sets. However, Service Manager prevents you from deleting any policy (or any attribute map or rule set that are part of it) that is used by a service or resource monitor.
- You cannot edit or delete CA-authored Service Manager policies.
- You can copy any policy and can save it under a unique name and can edit it or can delete.
- You cannot edit or delete CA-authored attribute maps and rule sets.
  You can copy any attribute map or rule set and can save it under a unique name.

Delete a Policy

You can delete any user-created policy that is not currently in use. If the policy used by a service deletion fails, an error dialog indicating the failure is displayed.

NOTE
When you delete a policy**,** do not delete its attribute map and rule set.

Follow these steps:

1. Open the Service Editor dialog.
2. Click the Policies tab and then select the policy that you want to delete.
3. Click Delete.
   The policy is removed from the Policy list.

Attribute Maps

Attribute maps associate natural resource attribute values to equivalent resource health values, and let you specify a root cause reason string for each mapped value. Any attribute which has whole number values can be mapped. Multiple attribute maps can exist for the same attribute, and can have different value mappings or simply different root cause reason strings. Each attribute map has its own name which describes its purpose.

The attribute map serves two purposes when added to a service policy. First it specifies which resource attributes monitored. It provides a mapping of how the resource attribute values indicate the health of the resource. When the specified attribute changes for a resource model, the service evaluates the value to determine its relative resource health and apply that health value with all of the other resources health values to the rule set.

If the out-of-the-box attribute maps are not sufficient, you can create a custom attribute map. All user-created attribute maps can be edited and deleted by any Service Manager user.

Consider the following information about attribute maps:

- An attribute map must have a unique name.
- You cannot edit or delete CA-authored attribute maps.
- Any attribute can have multiple mappings.
- Service resource(s) must support the attribute that is specified in the attribute map. DX NetOps Spectrum generates a minor (yellow) alarm on the Service Management model, if a service uses a policy that specifies a watched attribute that is not supported by the service resources.
- You must know what values an attribute returns and what they indicate about the state of the resource(s) on which they are monitored to map those values to service health values.
- At a minimum, an attribute map must include one mapped value, and must define a default root cause reason.
- You can map multiple attribute values to the same service health value. For example, port statue values of disabled, down, and unreachable are all mapped to a resource health of down.
- If the attribute you select returns enumerated values, each value must be mapped to up, down, degraded, or slightly degraded before you can save the new mapping.
- Service Manager attribute maps now support range values in addition to single value mapping.

For example, an attribute map value can appear in this form single value 100, range value 100-200. Using the following information, you can configure attribute maps:

1-99 = Slightly Degraded

- 100-199 = Degraded
- 200-300 = Down

Also supported is greater than and less than operators, so a set of mapped values may look like the following equations:

- <100 = Down
- 100-200 = Degraded
- 300-400 = Degraded
- >400 = Down

Create an Attribute Map

You can create a custom attribute map using Service Policy Editor.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Attribute Maps tab and click Create.
   The Create Attribute Map appears.
3. Specify the following properties:
   - **Attribute Map**
     Identifies the attribute map. Provide a unique name.
   - **Default Root Cause Reason**
     Identifies the underlying reason for the service health state. Later, when you map particular attribute values to service health values, you can overwrite the default reason for each mapping.
4. Click Attribute.

The Attribute Selector dialog appears.

5. Select an attribute of the allowed type (counter, integer, date, time ticks, and gauge), and then click OK.
   The Create Attribute Map dialog appears.
6. Click Add.
   The Add Value to Service Health Mapping dialog appears.
7. Enter the following values:
   - **Attribute Value**
     Specifies the attribute value that you want to map to a service health value.
   - **Service Health**
     Specifies the service health value that you want to map to the attribute value.
   - **Root Cause Reason**
     Describes the root cause that you want to provide for this particular mapping. The root cause reason is displayed in the root cause tab of the OneClick Component detail panel, and the Outage Details in a service outage history table.
     You can create new attribute maps specifically to provide better root cause reasons. For example, the standard Condition attribute map defines generic root cause reasons.
     It is useful to create multiple purpose-specific attribute maps for the Condition attribute. For example, you can define a Condition attribute map specific for services monitoring cable modems and can define root cause reasons like: “Modem disconnect, and Data transfer fault.” These attribute maps are more descriptive strings, which are used in place of standard Condition strings of “A critical problem was detected on the resource, and A major problem was detected on the resource.”
8. Click OK.
   The Mapped Values panel lists the new attribute value and service health mapping.
9. Click Create to save the new attribute map.
   The new attribute map appears in all attribute map lists in Service Manager, and it can be used in all user-created policies.

Create an Attribute Map from a Copy

You can create an attribute map by copying an existing map and saving it with the settings you require under a different name.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Attribute Maps tab, select the map that you want to copy, and click Copy.
   The Create Attribute Map dialog appears. It includes the settings for the map you want to copy.
3. Specify a unique name, modify settings as required (using the set command where applicable), and click Create.
   The new attribute map appears in all attribute map lists in Service Manager, and it can be used in all user-created policies.

Edit an Attribute Map

You can edit any user-defined attribute map regardless of whether it is included in a policy that is in use. If edits to the attribute map are saved, all services or resource monitors using related policies reevaluate their health that is based on the edit and can result in a change in service health for the models.

Consider the following information before editing an attribute map:

- You can change the attribute map name, the service health designation for an attribute value, the default root cause reason, and the root cause reason for each service health mapping.
- You cannot change the attribute that is originally specified.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Attribute Maps tab, select the attribute map that you want to edit, and then click Edit.
   The Edit Attribute Map: <*Attribute Map Name*> dialog appears.
3. Modify settings as required (using the set command where applicable), and click OK.
   The attribute map is edited.

Delete an Attribute Map

You can delete any user-created attribute map that is not part of a policy currently in use.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Attribute Maps tab, select the map that you want to delete, and click Delete.
   The attribute map is removed from the attribute maps list.

Rule Sets

A rule set consists of a set of rules. Each rule is a conditional statement that is comprised of a comparator and a resulting health value. A rule is considered satisfied if the cumulative resource health matches its criteria. For example, when all resources are Down the service is Down. If all resources within the service have a resource health of down, the rule can be satisfied, and the policy can be evaluated to a resulting health of down.

Rules are evaluated from top-down, the first rule within the ruleset which is satisfied dictates the health of any service or resource monitor using the policy. It is important to consider rule evaluation when creating a rule set, and verify that rules of lesser significance do not hide rules of greater significance. For example, consider a rule set with the following logic:

Rule 1 = When any 1 resource is Down the service is Degraded.

Rule 2 = When all resources are Down the service is Down.

A rule set like Rule 1 and Rule 2 can never return anything other than Degraded, because even if all resources are down, Rule 1 is still satisfied as one resource is down.

Service Manager supports four different categories of rules which can be used to form a rule set. All, Any, and Percent Rules use the mapped values that are provided by the attribute map. Aggregate rules use the resource attributes natural values.

Verify the following rule types:

- **All**
  When all the monitored service resources or all resources that are watched by a resource monitor have the service health value (down, degraded, or slightly degraded), the service or resource monitor is (down, degraded, or slightly degraded).
- **Any**
  When a particular number of monitored service resources or a particular number of resources that are watched by a resource monitor have the service health value (down, degraded, or slightly degraded), the service or resource monitor is (down, degraded, or slightly degraded).
- **Percent**
  When the percentage of monitored service resources or the percentage of resources that are watched by a resource monitor have the value (down, degraded, or slightly degraded), the service or resource monitor is (down, degraded, or slightly degraded).
- **Aggregate**

When the (Sum, Minimum, Maximum, and Average) for all monitored service resources or the (Sum, Minimum, Maximum, and Average) of resources that are watched by a resource monitor is (less than, greater than, or equal to) the Integer or attribute value you designate, the service or resource monitor is (down, degraded, or slightly degraded).

A status policy rule set can consist of any combination of All, Any, and Percentage rules. Because mapped values are ignored, a statistical rule set can use only Aggregate rules.

Consider the following information about rule sets:

- You can create any number of uniquely named rule sets.
- Uniquely named rule sets can include identical rules.
- You can create new versions of existing rule sets.
- You cannot edit or delete CA-authored rule sets.
- The order in which you list a rule in rules set is important. The first rule that is satisfied dictates the service health value returned.

Create a Rule Set

You can create an original custom rule set or another version of an existing rule set in the Service Policy Editor if the CA-authored rule sets do not meet your requirements for a policy. All user-created rule sets can be modified and deleted by any Service Manager user.

Follow these steps:

1. Open the Service Policy Editor.
2. Click the Rule Sets tab and click Create.
   The Create Rule Set dialog appears.
3. Enter a name for the new rule set in the Rule Set field.
   The Author field auto-fills with the current Service Manager user name.
4. Click Add to create a rule for the ruleset.
   The Create Rule dialog appears.
5. Configure rule parameters, including the type and the conditions for the type, and click OK.
   The rule appears in the Create Rule Set dialog.
6. Rearrange rules as necessary using the Up Arrow and Down Arrow buttons, and click Create.
   The rule set is created.

Create a RuleSet from a Copy

You can create a rule set by copying an existing ruleset and saving it with the settings you require under a different name.

Follow these steps:

1. Open the Service Editor.
2. Click the Rule Sets tab, select the ruleset you want to copy, and click Copy.
   The Create Rule Set dialog appears. This dialog includes the settings for the ruleset you are going to use as the basis for your new ruleset.
3. Specify a unique name and edit rules and modify rules as required, and then click Create.
   The rule set appears in all ruleset lists in Service Manager, and it can be used in all user-created policies.

Edit a Rule Set

You can edit any user-defined ruleset regardless of whether it is included in a policy that is in use. If edits to the ruleset are saved, all services or resource monitors using related policies reevaluate their health that is based on the edit, which results in a change in service health for the models.

Follow these steps:

1. Open the Service Editor.
2. Click the Rule Sets tab, select the ruleset you want to edit, and then click Edit.
   The Edit Rule Set: <*Rule Set Name*> dialog appears.
3. Modify the name of the rule set in the Rule Set field.
4. (Optional) Use the arrow keys to rearrange rules.
5. Edit a rule by selecting the rule and clicking Edit.
   The Edit Rule dialog appears.
6. Change rule settings as needed and click OK.
   The Edit Rule dialog appears.
7. Click OK.
   Your edits are saved.

Delete a Rule Set

You can delete a rule set that is not part of a policy currently in use by a service or resource monitor.

Follow these steps:

1. Open the Service Editor.
2. Click the Rule Sets tab view, select the ruleset you want to delete, and click Delete.
   The rule set is removed from the rule sets list.

Creating and Managing Customers

This section describes the procedure to Create and Manage customers.

Customers and Customer Groups

Customers are DX NetOps Spectrum models that represent a person or organization that is associated with services or SLAs. The use of customer models enables you to track and monitor each customer service and SLAs.

A customer model status attribute reflects the status of the customer's services. The customer status can be equivalent to the worst service health value for all of the customer services. For example, assume that a customer is associated with services A, B, and C. If service A is up, service B is degraded, and service C is down, the customer status attribute has a value of severe to reflect a service down. If service C is restored to up and B remains degraded, the customer status attribute indicates a significant impact to reflect a service degraded. Customer icons within OneClick and the Service Dashboard indicate the value of the customer status attribute. No alarms are associated to changes in customer status. The visual indication is only the icon color.

Each customer model also has a criticality attribute with values ranging from low to high. Similar to the criticality of a service model, all or a portion of the customer model's criticality is added to the impact of any resource alarms that are affecting the customer's services. This confirms that alarms impacting highly critical customers have a high impact value.

Customer models can be added to customer groups. The customer group model provides a way to organize similar customers. The condition of a customer group can be equivalent to the worst status of all customers within the group. No alarms are associated to condition changes for the customer group model, the only visual indication is icon color.

Customers and customer groups you create appear under the Customers tab in the Service Editor, in Service Dashboard, and in OneClick under Service Management in the Navigation panel.

Create a Customer

A customer identifies a person or an organization that is associated with a service, an SLA, or both. In addition to the Criticality and Security String parameters included for all DX NetOps Spectrum models, it includes customer identity and contact information and other fields in which you can enter additional information.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab.
   A list of customers that are created in Service Manager appears.
3. Click Create Customer.
   The Create Customer dialog appears.
4. Complete the required fields (denoted by asterisks).
5. (Optional) Specify the customer group (using the Customer Group tab) to which you want to add the customer and click Create.
   The customer is created.

Customer Criticality and a Service's Outage Alarm Priority

A customer criticality is factored into the impact calculation of any alarms that cause a service outage for one of the customer services. For example, Customer A has a Medium criticality value of 15 and Customer B has a Low criticality value of 5 and both Customer A and B are associated with services that have high criticality values and are down.

The root cause alarm for the outage on Customer A service has an increased impact of + 30 for the service and + 15 for the customer. The root cause alarm for Customer B service has an increased impact of +10 for the service and +5 for the customer.

Because Customer A has a higher criticality value, the alarms that affect Customer A service have a higher impact. Although both example alarms affect high criticality services, the root-cause alarm that affects Customer A service has a higher impact value. If the alarm view in OneClick is ordered by alarm impact, the alarm affecting Customer A can appear higher in the alarm table.

Create a Customer Group

Service Manager lets you organize customers in groups in any way that meets your requirements for tracking and managing customers.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab and click Create Group.
   The Create Customer Group dialog appears.
3. Enter a Customer Group Name, the landscape where you want to create the group, and, optionally, a security string.
4. Under Group Location, select the group in which you want the new customer group saved.

   NOTE
   By default, Service Manager saves all customers and customer groups under the customer manager model on the landscapes where the customer model or customer group model exists.
5. Click Create.
   The customer group is created.

Edit Customer Settings

You can edit customer settings as required.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab, select the customer that you want to edit, and then click Edit.
   The Edit Customer dialog appears.
3. Modify the settings:
   – Under the Contact Information tab, you can edit all contact information except the landscape where the customer was created.
   – Under the Customer Group tab, you can move the customer to a new location.

   Click OK.
   The customer settings are edited.

Edit a Customer Group

You can edit customer group settings as required.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab, select the customer group that you want to edit, and click Edit.
   The Edit Customer Group dialog appears.
3. Modify the settings.

   NOTE
   You can modify the group name and security string. You cannot modify the landscape where the group was created.
4. Click OK.
   The customer group is edited.

Move a Customer or a Customer Group

As your customer list grows, you can reorganize your customers and customer groups by moving them from their current locations to new locations. When you move a customer group, you also move its customers with it.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab, select the customer or customer group you want to move.
3. Drag and drop the customer or customer group to the new location.
   The customer or customer group is moved.

Delete a Customer or a Customer Group

You can delete customers and customer groups you no longer use. When you delete a customer group, you can select to delete or retain its customers.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab, select the customer or customer group you want to delete, and then click Delete.

   NOTE
   If you are deleting a customer group, you are prompted to retain the group customers or delete them with the group.
3. Respond to the confirmation message that appears to complete the deletion.
   The customer or customer group is deleted.

Associate a Service or an SLA with a Customer

Service Manager lets you associate customers with services and SLAs. Verify the following benefits:

- You can track services and SLAs associated with customers in Service Dashboard, Service Editor, and OneClick
- You can generate service and SLA reports about specific customers with DX NetOps Spectrum Report Manager.

Follow these steps:

1. Open the Service Editor.
2. Click the Customers tab, select the customer that you want to associate with a service or SLA.
3. Click the Services or SLAs tab and click Select Customer Services or Select Customer SLAs.
   The Select Services or Select SLAs dialog appears.
4. Move the services or SLAs you want to associate with the customer from the Available Services or Available SLAs list to the Customer Services or Customer SLAs list (Do the opposite to remove services or SLAs).
5. Click Ok,
   The service or SLA is associated with the customer.

   NOTE
   Only the real-time health of services impact the status of associated customers. The customer status attribute indicates the real-time status of a customer in terms of any impacted services. Changes to the SLA status of SLA models associated to a customer does not alter the customer models status as the SLA status does not indicate a real-time value.

Creating and Managing Service Level Agreements

About Service Level Agreements

DX NetOps Spectrum represents a service level agreement or operational level agreement with an SLA model. A Service Manager SLA model or SLA, incorporates measurable provisions which are defined by the service or operational level agreement. These provisions are implemented as service models within DX NetOps Spectrum which are in turn monitored by the SLA model. The SLA monitors the real-time health of each associated service, and records outage time when the service is down. The recorded time is compared against a number of thresholds to determine the status of the SLA for a given period. SLA models can be created as individual SLAs or from preconfigured SLA Templates.

Guarantees

Each SLA specifies one of the more guarantees. A guarantee is a DX NetOps Spectrum model that represents and monitors a provision of the SLA. Each guarantee is associated with a service or resource monitor. The guarantees record service outage time and compares the amount of recorded time to a threshold specified by the user. A guarantee is considered violated if the amount of accumulated service downtime exceeds the threshold that is specified by the users. If the guarantee has not recorded any outage time, or the recorded outage time is less than the threshold, the guarantee is considered the complaint. The status of an SLA equals to the status of its worst guarantee. In other words, if any SLA's guarantee is violated, the SLA is violated. The status of an SLA is always expressed in terms of a period. Once an SLA is violated, it remains violated during the current period, unless outages contributing to the violation are edited in such a way that recorded outage time is removed from the guarantee.

Many SLAs include some form of an availability guarantee. For example, an SLA can stipulate that the service is guaranteed to be available 99.9 percent of each month. These statements define both the availability threshold and the period for which the threshold applies.

SLAs commonly include performance or response time provisions. For example, an SLA can state that service response time is 100 ms or better 99.9 percent during the hours of 8 AM to 5 PM each weekday.

Service Manager provides both Availability and Response Time guarantees. Functionally availability and response time guarantees are similar in the way that outage time is recorded. The Availability guarantees offer three additional thresholds for mean time to repair, such as maximum outage time and mean time between failures. The distinction of availability that is compared to response time is used for organizational convenience rather than functional purposes, as an availability guarantee can be configured to perform identically to a response time guarantee.

An SLA can include as many guarantees (either availability or response time) as required, to monitor all measurable provisions in a service level agreement. The SLA is considered complaint when all of it guarantees are compliant, or violated if any of its guarantees are violated. Guarantees and SLAs can also have a status of warned or at risk if a guarantee has record service outage time such that a violation is likely to occur. When the status of the SLA changes to a warned or violated state, an alarm is generated on the SLA model. This alarm remains on the model until the SLA period ends, or a user-initiated outage edit causes the recorded time to fall below the threshold.

Guarantee thresholds can be configured in one of two ways. The first and most common is by the percentage of availability. When configuring percentage-based thresholds a user specifies is the desired availability for the guaranteed service. Users can also configure guarantee thresholds by the number of seconds of outage time not to be exceeded for the period. Configuring a threshold that is based on a set number of seconds can eliminate some of the variability found with percentage-based thresholds for monthly periods.

Regardless of how the threshold is configured, the guarantee determines its status that is based on the amount of recorded outage time compared to the amount of allowable outage time for the period. Consider an SLA that stipulates that a service must be available 99.5 percent of the time for the SLA period. The SLA must include a guarantee that specifies the availability threshold (99.5 percent). Stated another way, the service cannot be down more than 0.5 percent of the total time for the SLA period, in this case, a calendar month. For a thirty-day month, out of 720 available hours, the service cannot be down more than 3.6 hours.

In addition, the SLA stipulates that no individual service outage can exceed 15 minutes, and the average time to repair an outage cannot exceed 10 minutes. These statements indicate that one addition to the overall threshold of 99.5 percent, the guarantee can also specify the threshold for MOT (maximum outage time), and MTTR (mean time to repair). If any of the guarantees thresholds are violated the guarantee, and likewise the SLA is considered violated for the period.

Period

A *SLA period* is the interval for which the guarantees can compute their status. The most common SLA periods are monthly. The guarantees that are specified for the SLA records time and calculates status on a monthly basis, with a specific start and end time. For example, if the SLA period is monthly, the first period begins at midnight on the first of the month, and end at midnight on the first day of the following month. The next SLA period begins immediately after the current SLA period ends.

In addition to the overall SLA period, some service level agreements can define specific hours that a guarantee is relevant for. For example, the SLA may state availability of 99.9 percent from 8 AM to 5 PM, Monday through Friday. These time frames within the period are named *business hours*.

Business hours can also be described as the times when the guarantee is active. A guarantee does not record outage time for service outages occurring outside of its business hours. Percentage-based guarantee thresholds are also calculated specifically to include only the time for which the guarantee is active. Therefore, if a guarantee defines a percentage-based threshold then the business hours has far less allowable outage time than a guarantee that specifies the same threshold, but no business hours.

SLA Considerations

SLA status must be accurate based on the stipulations of the guarantee in the SLA. In most cases, you can notice that not all service outages can impact SLA. One of the most common problems that users can encounter when using SLA models is guarantees recording outage time for issues that are not guaranteed by the SLA. The reason for this is that services designed for accurate real-time monitoring generally do not lend themselves well to SLAs.

When designing a service to encompass all possible fault scenarios, you can build a vast set of resource monitoring capabilities. SLAs on the other hand tend to be focused on specific types of service outages. For example, consider a critical application service. For real-time monitoring, you may want to understand the availability of the physical servers, the critical processes, system resources, network connections, application, and network response time. For accurate real-time management, the service must consider a wide range of potential resource faults.

In support of the application service, the server team has an SLA that stipulates the physical servers, available 99.9 percent of the time during regular business hours. The server team is responsible for the physical servers, but not for the applications running on them, or the network which provides access to them. So, the availability guarantee for the server teams, SLA should only record time if there is a failure of the server. SLA should not record time if there is a failure of the application or a network failure that prevents access to the server.

Therefore, the design of a service that is designed for real-time monitoring is likely to be different from a service that is designed to isolated specific resource faults for an SLA. Let us look at a couple of aspects of the previous scenario, and consider how service design can be different.

First, consider how the availability of the physical servers is monitored in CA Spectrum. If contact is lost to the server, then the server can be considered not available. In terms of SLA; however, it is not enough to say that contact is lost, the SLA must consider the distinction between a server outage and a network outage preventing access to the server. In CA Spectrum, the availability guarantee must only record outage time if the server is red, and must not record outage time if the server is gray. If the application service is designed for real-time monitoring, it is unlikely that its designers included resource monitoring components to distinguish between these two types of outages.

Next, consider how server faults must be distinguished from application or process failures. The server team is not responsible for the processing running on the server itself. To begin any monitored processes outages probably should be isolated to the process model and not the server. Other system resource-related failures may or may not be the responsibility of the server team, for example, high CPU is likely the result of the applications on the server, failures of local file systems on the other hand could be the responsibility of the server team. Again it is unlikely the original designers of a service for real-time monitoring would have considered making these distinctions in their service design.

You can use the two techniques to verify that SLAs accurately monitor the services they guarantee.

The first option is to simply create a parallel set of services that specifically monitor the components that are guaranteed by the SLA. These services are built in addition to services designed for real-time monitoring. They can monitor a smaller set of resources, possibly use different service policies, and do not generate alarms. SLA-specific services can also define periods of maintenance which makes them inactive outside of the SLA specified business hours. This is probably the easiest technique, but it does not always scale well. Consider the example of the server team SLA, imagine that the application team and the network also have SLAs. For one logical application service, you can easily produce four service hierarchies to support, one for real-time monitoring, one server-specific, one application-specific, and one network specific. The implementation and maintenance of these services can be daunting.

The second option, an alternate technique, is to verify that all services are built with a modular design. It is valuable to remember that the use of resource monitors makes it easier to extend the monitoring capability of service. This is true not only when adding new resources, but also when adding support for SLAs. Resource monitors are used to isolating specific faults such that guarantees can be associated with the specific resource monitor. If well-designed, the same service can be used for multiple SLAs, and still used for real-time monitoring.

Create an SLA

When you create an SLA, name it, specify the period that it is in effect, and the guarantee thresholds for the services or resource monitors that are monitored by the SLA. After you create an SLA, associate it with an SLA customer. You can also modify an SLA as necessary when service delivery requirements change.

Consider the following points before creating an SLA:

- An SLA can have multiple guarantees.
- You can associate a single service to an SLA, but guarantees can be created for that service, or any of it sub services or resource monitors.
- You may need to create new service components to isolate the specific set of faults for which the guarantee is responsible.
- SLA models reside on the same landscape as the service the SLA is associated to.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab and click Create.
   The Create SLA dialog appears.
3. Specify the following SLA properties:
   - **SLA Name**
     Identifies the SLA model. OneClick lists SLA names under the Service Management - SLAs category in the Explorer view for each landscape where you have created SLAs. You can use duplicate names for SLAs. However, to facilitate filtering when searching through a lengthy list of identically named SLAs, provide different descriptions for each SLA.
   - **Control**
     Specifies whether the SLA is activated during the current SLA period (Active), the default setting, or the next period (Inactive Until Next Period).

     NOTE
     If you activate an SLA during an SLA period, Service Manager does not prorate allowable outage time. The service that is associated with the SLA is allowed the amount of down or degraded time that is specified for the entire period. For example, if an SLA allows five hours of outage for a 30-day month and activate an SLA on 15th of the month, the service that is associated with the SLA can be unavailable for up to five hours over the course of remaining 15 days. In terms of an availability obligation, this situation allows for twice as much service outage than a service customer would expect over the remaining 15-day period. In this case, you can modify the availability threshold for the SLA guarantees to an amount of time for the partial period proportional to the entire period. For example, in the previous example, you could change the availability threshold to two and half hours for the partial 15-day period.
   - **Description**
     (Optional) Describes the SLA. You can enter unique descriptions for SLA that have the same name to facilitate finding each SLA using a list filtering capabilities.
   - **Security String (Optional)**
     Identifies the security string for the SLA model. The security string secures access to the SLA model in DX NetOps Spectrum. For more information, see the OneClick Administration section.
   - **Notes**
     (Optional) Includes any information about the SLA you want to enter not covered in the Description field.
   - **Expiration Date**
     Specifies the date a recurring SLA period expires. Check the box, and enter the date in the field that appears. If the date falls within an SLA period, the SLA stays in effect to the end of the period.
   - **Period**
     Specifies the interval during which the SLA is in effect. Select the period from the drop-down list, or click Create to create an SLA period.

4. Configure one or more guarantees for the SLA.
5. Associate a service to the SLA by moving it from the Available Services list to the SLA Services list.
6. Click Create.
   The SLA is created.

Create an SLA from an SLA Template

An SLA template is an SLA configuration that you create and save as a template and from which you can create multiple SLAs. When you create an SLA from an SLA template the SLA inherits the template settings. You can tailor SLA settings that are inherited from a template except for the following items:

- Guarantees -- The guarantees in an SLA template can only be modified in the SLA template workspace, and any changes to the guarantees extend to only those SLAs created from the template that have been kept in sync with the template.
- Period -- The period in an SLA template can only be modified in the SLA template workspace, and any changes to it extend to only to those SLAs created from the template that have been kept in sync with the SLA template.

Consider the following information before you create an SLA from an SLA template:

- When you create an SLA from an SLA template, you can select whether to keep the SLA in sync with (or associated with) the SLA template. If you select to keep the SLA in sync with the template, all changes to the template guarantees and SLA period extend to the SLA. If you select not to keep the SLA in sync with the template, changes to the template guarantees and the SLA period do not extend to the SLA created from the template.
- The settings for any SLA created from an SLA template that has been deleted convert to local settings.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab and then click Create From Template.
   The Select SLA Template dialog appears.
3. Select the SLA template that you want to use to create the SLA and click OK.
   The Create SLA From Template dialog appears.
4. Configure the settings that can be edited as required.
5. Select or clear the option to keep the SLA in sync with the template. You can also clear the option anytime after you have created the SLA from the template.
6. Click Create.
   The SLA is created from an SLA template.

Guarantee Types

You can specify one of the following guarantees for a service or a resource monitor:

- **Availability**
  You can specify an availability threshold that is expressed as a percentage of the period for which the service is available or the amount of time in seconds that the service must not exceed for the period. This guarantee interprets the time that a service or a resource monitor service health value is down as outage time. You can also specify these supplemental thresholds when you specify an availability guarantee:
  - **Mean Time Between Failure (MTBF)**
    (total time between failures) / (total number of failures - 1)
    If the interval between failure falls below this value, the status of the guarantee changes to At Risk and DX NetOps Spectrum generates a Major (Orange) alarm for the SLA. Any time the interval between failures exceeds this value, DX NetOps Spectrum clears the At Risk alarm. If the guarantee is At Risk at the end of the period, DX NetOps Spectrum generates a Critical (Red) alarm for the SLA.
  - **Mean Time to Repair (MTTR)**

(total outage time) / (total number of outages)
If the average outage duration exceeds this value, the status of the guarantee changes to At Risk and DX NetOps Spectrum generates a Major (Orange) alarm for the SLA. Any time the average duration falls below this value, DX NetOps Spectrum clears the “At Risk” alarm. If the guarantee is At Risk at the end of the period, DX NetOps Spectrum generates a Critical (Red) alarm for the SLA.

- **Maximum Outage Time (MOT)**
  If the service or resource monitor has an outage that exceeds this value, The SLA is violated, and DX NetOps Spectrum generates a Critical alarm for the SLA.

- **Response Time**
  Lets you define a threshold for monitoring a service or resource monitor that determines its service health from the results of response time (or performance) tests. This guarantee interprets the time that a service or a resource monitor service health value is degraded as outage.

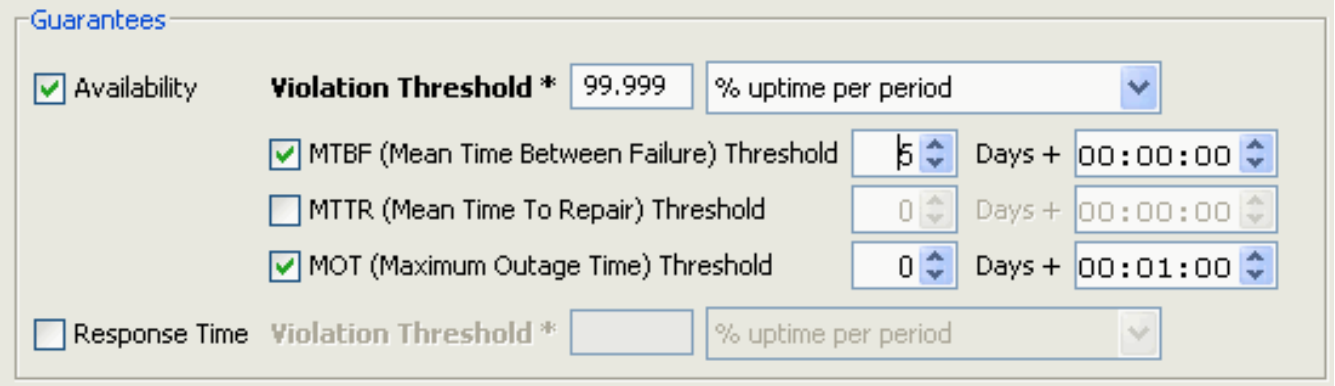
Create a Guarantee for a Top-Level Service

You can create a guarantee for a top-level service, which lets you create a guarantee for an entire service but not to any sub-services and resource monitors.

Follow these steps:

1. Select a threshold type: Availability or Response Time:
   - Specify a Violation Threshold value for % uptime per period or seconds of outage time per period for the threshold(s). The default uptime percentage is 99.9.
   - If you specify an availability threshold, specify values for any or all of the MTBF, MTTR, and MOT thresholds.

   Service Manager provides a name for the guarantee using this format: *Threshold type - SLA name*. For example: Availability - Web Service SLA. The following is an example availability guarantee that includes an uptime threshold and MTBF, MTTR, and MOT supplemental thresholds:



Guarantee is created for a top-level service.

Create a Guarantee for a Service, Sub-Service, or Resource Monitor

You can create a guarantee for a service, a sub-service, or a resource monitor.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab, select the SLA for which you want to create the guarantee, click the Guarantees tab, and then click the Create button.
   The Create Guarantee dialog appears.

3. Specify the following guarantee properties:
   - **Guarantee Name**
     Identifies the guarantee model.
   - **Control**
     Specifies whether the guarantee is Enabled or Disabled during the current SLA period. When you disable a guarantee, it does not accumulate outage time during the SLA period. Generally a guarantee is created in the disabled state if SLA and the services it guarantees are still be defined. However, there may be scenarios where due to alterations of a specific service it makes sense to periodically disable one of more guarantees.
   - **Guarantee Type**
     Specifies the type of guarantee: Availability or Response Time.
   - **Outage Type**
     Specifies whether the guarantee accumulates Down or Degraded time. response time guarantees accumulate only degraded time, while availability guarantees can be configured to accumulate either down time or degraded time.
   - **Accumulation Method**
     Service Manager provides two accumulation methods: Straight time and Per Resource.
     Straight time means that the guarantee records outage time that corresponds exactly to service outage time. One minute of service outage time produces one minute of outage time for the guarantee. Straight time is almost always the appropriate configuration for a guarantee. Under rare circumstances per resource configurations are used to record time that is based on the resources contributing to the service outage.
     Per resource guarantee is only used for a specific type of SLA which actually guarantees specific availability of individual service resources as opposed to the service as a whole. The result is the guarantee can record outage time in excess of the actual service outage time. Once again per resource guarantees are specialized and uncommon.
   - **Violation Threshold *n*% uptime per period or seconds of outage time per period**
     Specifies a service availability threshold that if during the current SLA period results in a critical alarm on the SLA model. The default uptime percentage is 99.9.
   - **(Optional) Generate warning alarm after accumulating *n*% of allowed outage time**
     The warning percentage is a percentage of the violation threshold in terms of allowable outage time. When a guarantee becomes warned a major alarm is generated on the SLA. This option lets you take action before the SLA becomes violated.
4. Select the Service or Resource Monitor tab, and then select a service or resource monitor by moving it from the Available Services and Groups box to the Service or Group being Measured box.
5. (Optional) Specify "business hours" intervals during which you want the guarantee in effect.

   NOTE
   By default a guarantee is always active, that means it records outage time 24x7.
6. Click Create.
   The guarantee is created.

Specify Business Hours for a Guarantee

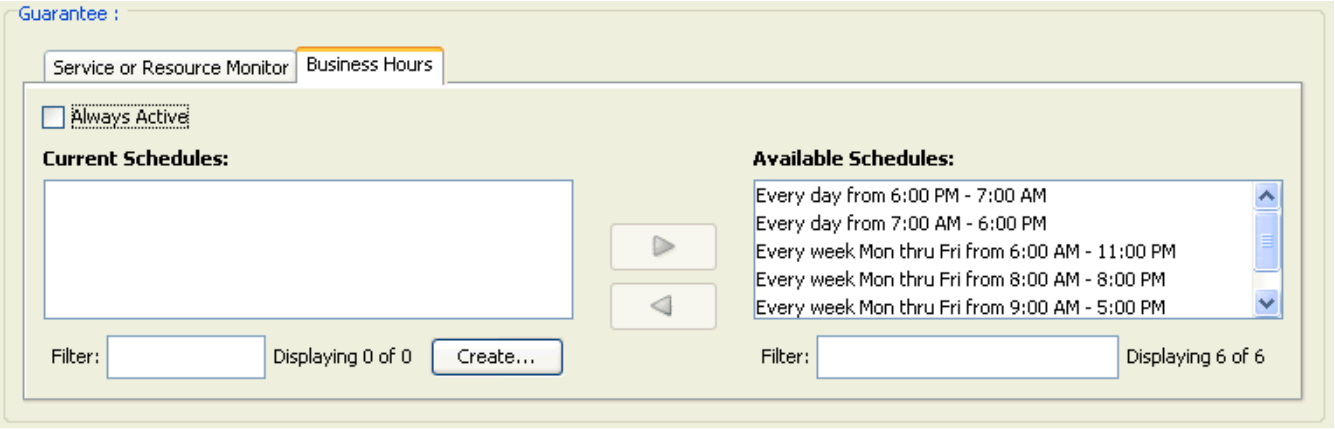
If you are creating a guarantee for an SLA that measures service availability or performance for a particular portion of a day, or “business hours,” you can identify those hours in the guarantee. This means that the guarantee accumulates service outage time only during the business hours, and the SLA availability threshold applies only to the business hours.

You can also specify multiple intervals for a guarantee, as long as they do not overlap. For example, if you want a guarantee to watch a service or resource monitor from 7 AM to 5 PM on Monday, Wednesday, and Friday, 6 AM to 6 PM on Tuesday and Thursday, and continuously throughout the weekend. You can specify these three schedules in the guarantee.

For guarantees which specify a percentage of availability, it is important to understand that the availability calculation is made against the time the guarantee is active. This means that a guarantee defining business hours can have less available outage time than one with the same availability threshold that does not define business hours.

Follow these steps:

1. Open the Service Editor dialog.
2. Click the SLAs tab, select the SLA that contains the guarantee you want to modify, and click the Guarantees tab.
3. Select the guarantee that you want to specify business hours for and click Edit.
4. Click the Business Hours tab, and clear Always Active, as shown in the following figure:



NOTE
If you want the guarantee in effect continuously throughout the SLA period, click the Business Hours tab and select Always Active (default).

5. Select and move one or more intervals from the Available Schedules list to the Current Schedules list.
6. (Optional) If you require a custom interval, take the following steps:
   a. Click Create.
   b. Configure the interval and click OK.
      The custom interval is added to the Available Schedules list.
   c. Select and move the custom interval from the Available Schedules list to the Current Schedules list.
7. Click OK.
   Business hours are specified for the guarantee.

Edit a Guarantee

You can edit a guarantee anytime after you create it; however changes to thresholds or business hours are not recommended.

Consider the following points before editing a guarantee:

- Modified thresholds take effect during the current period, this may not be desirable.
- A guarantee begins a new down or degraded time tally when you change the service or resource monitor with which it is associated during the current period.
- A guarantee modifies its outage time tally during a period if an outage has occurred and ended during the period and the outage has had its status modified (to exempt for example) during the period.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab, select an SLA from the list of SLAs, click the Guarantees tab (in the lower panel) and click Edit.
   The Edit Guarantee dialog appears.
3. Edit the settings, as described in Create a Guarantee for a Service, Sub-Service, or Resource Monitor and click OK.
   The guarantee is edited.

Delete a Guarantee

You can delete a guarantee for an SLA as your requirements for the SLA change.

WARNING
Delete with caution. Deleting the only guarantee for an SLA renders it inoperative.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab, and then select the SLA from which you want to delete a guarantee.
3. Click the Guarantees tab, select the guarantee that you want to delete, and then click Delete (in the lower panel).
4. Respond to the confirmation message that appears to complete the deletion.
   The guarantee is deleted.

Create an SLA Period

Service Manager provides two default SLA periods that commence at the following times for the time zone where the SpectroSERVER is located:

- On the first of every month at 12:00 AM
- On the 15th of every month at 12:00 AM

You can specify one of these periods when you create or edit an SLA, or you can create and specify a custom period that meets your particular service contract requirements. Service Manager saves the periods that you create so you can use them for other SLAs.

Follow these steps:

1. Click the Create button next to the Period field in the Create SLA dialog or the Edit SLA dialog.
   The Create Period dialog appears.
2. Specify a period, and optionally a description, and then click OK. Repeat as necessary to create and save more periods.
   The SLA period is created.

Edit an SLA

Periodically it is necessary to alter the configuration of a SLA model. Service Manager allows certain edits, but you can take care in the types of changes that are made. If the required change involves alteration of guarantee thresholds, business hours or the SLA period it is recommended that you do not make these edits to an active SLA. The period and guarantee thresholds are the essence of the SLA. If the guarantees stipulations are changed, it implies that a new SLA is available.

Therefore it is important that the real-time status of an SLA, and its historical reported status are based on complete periods with consistent thresholds. Consider how confusing data may look if an SLA recorded that same amount of outage time across two periods, but is compliant for one period and violated for the next due to a threshold change.

It is recommended to set an expiration date of the SLA to correspond with the end of the current period, instead editing a standing SLA. Later create a SLA with the new threshold settings, and set its control value to Inactive Until Next Period. This confirms that the current SLA completes the period with its existing configuration and the new SLA takes over seamlessly at the beginning of the next period.

If you change the service that is associated with the SLA, you can see the following output:

- Service Manager resets the start time of the SLA.
- All of the SLA guarantees go to the Initial (Blue) state, which means that you must associate a new service or resource monitor to each guarantee.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA tab, select the SLA you want to edit from the list, and then click Edit.
   The list field, Template Name, indicates whether the SLA was created from an SLA template. If it was, the field lists the source SLA template name.
   The Edit SLA dialog appears. If you select an SLA created from an SLA template, the dialog includes the Keep in sync with the template selection box. You can clear the sync option if you want to disassociate the SLA from its source SLA template and edit all SLA fields. Otherwise, you can edit only those settings that are not managed in the source SLA template.
3. Edit the settings, as described in Create an SLA and click OK.
   The SLA is edited.

Delete an SLA

You can delete an SLA anytime after you create it. However, you would typically not delete an SLA that is actively monitoring a service.

> **WARNING**
> Be cautious when deleting SLAs because you may inadvertently delete an SLA that is actively monitoring a service.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab, select the SLA you want to remove from DX NetOps Spectrum, and then click Delete.
3. Respond to the confirmation message that appears to complete the deletion.
   The SLA is deleted.

Associate a Customer with an SLA

Service Manager lets you associate one or more customers with an SLA to help you track and manage SLAs and customers. The status of the customer model is not impacted by the status of the SLAs associated to it. You can generate SLA reports with DX NetOps Spectrum Report Manager based on SLA-customer associations.

Follow these steps:

1. Open the Service Editor.
2. Click the SLAs tab, select the SLA you want to associate with a customer, click the Customers tab, and then click Select SLA Customers.
   The Select Customers dialog appears.
3. Move the customer that you want to associate with the SLA from the Available Customers list to the Customers that use this SLA list and click OK.
   The customer is associated with an SLA.

SLA Templates

An SLA template includes configuration settings that are inherited by the SLAs that you can create from the template. It lets you create multiple SLAs with similar settings for different customers and services without having to configure each SLA individually. The use of SLA templates is common in traditional service provider environment that offers similar SLAs to multiple customers. The SLA template also allows you to make changes or additions to all associated SLAs by editing the template itself. Although this can be a convenient feature, be cautious when making edits guarantee thresholds or business hours setting.

The following SLA template settings cannot be edited in an SLA that has been created from a template while the SLA in sync with the template:

- Period
- Guarantees

All other inherited settings can be modified in the SLA. All settings can be modified, however, if an SLA is disassociated (in sync option deselected) from its parent template.

The guarantees that you create for SLA templates are referred to as guarantee templates. You create and manage guarantee templates in the SLA Template workspace the same way you do with guarantees in the SLA workspace.

Create an SLA Template

You can create as many SLA templates as you require, but the templates must have unique names.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA Templates tab and click Create.
   The Create SLA Template dialog appears.
3. Specify settings for the SLA template.

   NOTE
   SLA Templates are often created with a control of Inactive. It lets you instantiate the actual SLAs in the inactive state, and activate them when appropriate.
4. (Optional) Configure basic guarantee settings for the template. You can specify more detailed guarantee settings or a new guarantee for the template (such as guarantee template) after you create the template.
5. Click Create.
   The SLA template is created.

Edit an SLA Template

You can edit an SLA template anytime before or after it is in effect.

Consider the following information before editing an SLA template:

- Changes to the period and guarantees in a template extend to all SLAs created from it that are in sync with the template. This may not be desirable.
- When you delete a template, the associations between the SLAs created from it that are in sync with the template are severed. This means you can edit all period and guarantee settings in the SLAs that were once managed exclusively in the former template.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA Templates tab, select the template that you want to edit from the list, and click Edit.
   The Edit SLA Template dialog appears.
3. Edit the settings, as described in Create an SLA, and click OK.
   The SLA template is edited.

Delete an SLA Template

You can delete an SLA template anytime after you create it. When you delete an SLA template, all SLAs created from the template that are kept in sync with it become fully editable.

Follow these steps:

1. Open the Service Editor.

2. Click the SLA Templates tab, select the template from the list you want to remove from DX NetOps Spectrum, and click Delete.
3. Respond to the confirmation message that appears to complete the deletion.
   The SLA template is deleted.

Guarantee Templates

You can create guarantee templates for SLA templates. You can edit guarantee template settings, and those changes extend to all SLAs created from the SLA template that includes the guarantee template.

You can modify guarantee templates only from the SLA Templates workspace. You cannot access guarantee templates from the Guarantees tab in the SLA workspace.

You cannot specify watched services or Resources Monitors for guarantee templates. You can associate the guarantee to services and resource monitors you specify when you create an SLA from an SLA template that includes the guarantee template.

NOTE
Be cautious when editing guarantee templates for the reasons that are outlined in the Edit an SLA section.

Create a Guarantee Template

Guarantee templates can be created in the Create SLA Template dialog or in the Create Guarantee Template dialog. This section describes the latter method.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA Templates tab, select the SLA template for which you want to create the guarantee template, click the Guarantee Template tab, and then click Create.
   The Create Guarantee Template dialog appears.
3. Configure settings, and then click Create.
   The guarantee template appears under the Guarantee Template tab for the SLA template and is inherited by all SLAs created from the template.

Edit a Guarantee Template

You can edit a guarantee template any time after you create it. Because they are changed within the context of an SLA template and all SLAs created from it that are in sync with the template are also changed. Be cautious when editing guarantee templates for the reasons that are outlined in the Edit an SLA section.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA Templates tab and select the SLA Template that includes the guarantee template you want to edit from the list of templates.
3. Click the Guarantee Templates tab to display guarantee templates for the selected SLA template.
4. Select the guarantee template that you want to edit from the list, and then click Edit (in the lower panel).
   The Edit Guarantee Template dialog appears.
5. Edit the settings as necessary as described in Edit a Guarantee, and click OK. For more information, see Create a Guarantee for a Service, Sub-Service, or Resource Monitor.

Delete a Guarantee Template

You can delete a guarantee template as your requirements change.

WARNING
Delete with caution. Deleting the only guarantee template for an SLA template renders the SLAs created from and in sync with the template inoperative.

Follow these steps:

1. Open the Service Editor.
2. Click the SLA Templates tab and select the SLA template from the list of templates from which you want to delete a guarantee template.
3. Click the Guarantee Templates tab, select the guarantee template that you want to delete, and then click Delete (in the lower panel).
4. Respond to the confirmation message that appears to complete the deletion.
   The guarantee template is deleted.

Creating Service Management Components with Modeling Gateway

You can create service management component models using the DX NetOps Spectrum Modeling Gateway Toolkit to define service component model configurations in XML input files and import the files into DX NetOps Spectrum. Defining service management models with the Modeling Gateway Toolkit and importing them into DX NetOps Spectrum instead of creating them with Service Editor is advantageous in the following ways:

- Modeling Gateway lets you define new models in bulk. Once you have created a particular service management model, you can use the XML input file for the model as a template for creating other models of that type.
- You can edit service management models that are imported through Modeling Gateway either by using the Service Editor or by simply editing and re-importing the original XML file.
- There can be an opportunity to automate the creation of service management models by producing an xml file for import that is based on an external data source. You can verify the Modeling Gateway capabilities and prerequisites. For more information, see the Modeling Gateway Toolkit section.

About the XML Framework

The hierarchy models (SM_Service_Mgt, SM_ServiceMgr, SM_SLA_Mgr, CustomerManager) must be arranged and named in the XML input file according to the following example.

The following example illustrates the basic framework of the XML input file. Each service management component is added within the appropriate section of the file. Service models can be created within the SM_ServiceMgr block, or within other services. Customer models and Customer Group models are created within the CustomerManager block. Finally the SLA models are created within the SLA_Mgr block.

```
<?xml version="1.0" standalone="no"?>
<!DOCTYPE Import SYSTEM ".import.dtd">

<Import>

<SM_Service_Mgt
      name="Service Management"
      containment_relation="SlmHasServiceComponent">

    <SM_ServiceMgr
        name="Services"
```

```
        containment_relation="SlmContains">

    </SM_ServiceMgr>

    <SM_SLA_Mgr
        name="SLAs"
        containment_relation="SlmContainsSLAs">

    </SM_SLA_Mgr>

    <CustomerManager
        name="Customers"
        containment_relation="Groups_Customers">

    </CustomerManager>

</SM_Service_Mgt>

</Import>
```

The following image displays the hierarchy that is represented in the OneClick Console.

WARNING
Although the name and containment_relation attribute values in the framework tags must be adhered to in the XML file you import, the individual service, resource monitor, customer, SLA, and guarantee models you import must have unique names. This differs from the OneClick client. Because modeling gateway uses name for uniqueness. Services with the same name are interpreted as the same model.

Service Models

Service models must be defined within the SM_ServiceMgr tag in the XML file that you import. For each landscape where Service Manager is installed, there is only one SM_ServiceMgr model with the model name, Services.

Each service model in a given landscape must be either SlmContains by the ServiceManager or SlmMonitors by another service model.

To use Modeling Gateway effectively, understand the mapping between policies and policy IDs. For example, if a service monitors other services or resource monitors, it can be configured with a service health policy (IDs 6-9). Also, you can determine a policy ID for a user-created policy by setting up the Policies table in the Service Policy Editor to display IDs.

Policies and Watched Attributes

When using Modeling Gateway to model services, the value for the MonitorPolicy_ID can be set to the id number associated with the policy the service uses. Service policy ids can be seen in the service policy editor by adding the Service Policy ID column to the service policies table. Out-of-the-box policies start at 1, user created policies start at 1000.

In addition to viewing policy ID in the service policy editor, you can see the policy id that is displayed at the following link.

http://<server>/spectrum/slm/ policyrep.jsp

Remember that when specifying the Monitor Policy_ID, verify that the AttrToWatch matches the attribute for the policy that you have selected.

NOTE
If your XML file creates a mismatch between a monitor policy ID and watched attribute (for example, watching Contact Status using policy ID 2), Service Manager puts the service in a defunct condition, which is reported as an outage and can be viewed in Service Dashboard. When a service becomes default an alarm is generated on the Service Management model. This alarm is major for services which are associated to an SLA, and minor for services which are not.

Example: Services That Monitor Resources Directly

The following XML document configures a service named “Test Service.” It monitors the contact status of two Cisco routers and generates a critical alarm if contact to either router is lost:

```
<!-- Each SpectroSERVER will have only one -->
<!-- SM_ServiceMgr model, named “Services”. -->

<SM_ServiceMgr
    name="Services"
    containment_relation="SlmContains">

    <SM_Service
        containment_relation="SlmMonitors"
        name="Test Service"
        AttrToWatch="Contact_Status"
        MonitorPolicy_ID="11"
        Criticality="10"
        Generate_Service_Alarms="true">
        <Device ip_dnsname="10.253.9.7" />
        <Device ip_dnsname="10.253.9.8" />
    </SM_Service>

</SM_ServiceMgr>
```

This relation associates a service with resources.

Enter either a SPECTRUM-provided Policy ID (1-21) or ID (1000, 1001, ...) for a policy created in Service Editor.

Enter device (resource) IP address or DNS name.

- The Services model contains (has an SlmContains relationship with) Test Service. This can make the Test service a direct child of the service manager. The Test service appears under the Services icon in the OneClick navigation panel.
- Test Service monitors (has an SlmMonitors relationship with) the 10.253.9.7 and 10.253.9.8 devices and watches their Contact_Status attributes using the Contact Status High Sensitivity policy.
- The value of Generate_Service_Alarms is true, indicating that when the service health value is down, degraded, or slightly degraded, DX NetOps Spectrum generates an alarm for the service.

Example: Services That Monitor Resources in Resource Monitors

The following XML document defines a service, XYZ Service, that monitors two other services (Core Routers and DNS) directly. In addition, the XYZ service defines three resource monitors by specifying SM_AttrMonitor elements. The first resource monitor XYZ Condition monitors the contents of the XYZ Network container. The second resource monitor XYZ Response Time monitors an SPM test call XYZ_RTM_1. Finally, the service also defines a resource monitor, XYZ Port Status which monitors an interface model.

```
<SM_Service
        containment_relation="SlmMonitors"
        name="XYZ Service"
        Criticality="25"
        AttrToWatch="Service_Health"
        MonitorPolicy_ID="8"
        Generate_Service_Alarms="true">

        <SM_AttrMonitor
            containment_relation="SlmWatchesContainer"
            name="XYZ Condition"
            AttrToWatch="Condition"
            MonitorPolicy_ID="2">

            <Topology_Container model_type="Network" name="XYZ                    Network Servers" />
        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="XYZ Response Time"
            AttrToWatch="LatestErrorStatus"
            MonitorPolicy_ID="18">

            <RTM_Test name="XYZ_RTM_1" />
        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="XYZ Port Status"
            AttrToWatch="Port_Status"
            MonitorPolicy_ID="15">

            <Port ip_dnsname="10.253.50.5"
            identifier_name="ifIndex"
            identifier_value="45" />
        </SM_AttrMonitor>

        <SM_Service name="Core Routers"/>
        <SM_Service name="DNS"/>

    </SM_Service>
```

Example: Using XML to Define a Service Template

If you encounter a scenario where many services share a common pattern or structure. You can define that structure in xml, and can use it as a common template. For example, you can build services to monitor a set of applications which are

all different, but have common service modeling components. You can define the structure and import as many service models as you need from it. Some of the data can be added for import, or you can create empty services and resource monitors. You can add resources to them using the OneClick client.

The following syntax shows an example of the xml for a small service hierarchy that define a set of reusable service and resource definitions. The TMPL text represents wildcard test that can be changed to a more meaningful name for each set of services to be imported.

For this example, you can see a service which includes monitoring capability for some application servers, and associated database servers. As well as some additional some response time and performance monitoring. This example is not intended to match any specific requirements, but serves as an example to create an xml template for a set of services with common requirements.

```
<SM_Service
    containment_relation="SlmMonitors"
    name="TMPL Application Service"
    Criticality="10"
    AttrToWatch="Service_Health"
    MonitorPolicy_ID="7"
    Generate_Service_Alarms="true">

    <SM_Service
        containment_relation="SlmMonitors"
        name="TMPL Application Servers"
        Criticality="10"
        AttrToWatch="Service Health"
        MonitorPolicy_ID="9"
        Generate_Service_Alarms="true">

        <SM_Service
            containment_relation="SlmMonitors"
            name="TMPL Application Server 1"
            Criticality="10"
            AttrToWatch="Service Health"
            MonitorPolicy_ID="7"
            Generate_Service_Alarms="true">

            <SM_AttrMonitor
                containment_relation="SlmMonitors"
                name="TMPL App Host 1"
                AttrToWatch="Condition"
                MonitorPolicy_ID="3"
                Cause_List_Control="2"
                      Special_Cause_List="0x1106f-0x11232">

                // Excludes all eHealth alerts

            </SM_AttrMonitor>

            <SM_AttrMonitor
                containment_relation="SlmMonitors"
                name="TMPL App Server 1 Critical Processes"
                AttrToWatch="Condition"
                MonitorPolicy_ID="3">
```

```
        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL App Server 1 System Resources"
            AttrToWatch="Condition"
            MonitorPolicy_ID="3">

        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL App Server 1 Connection"
            AttrToWatch="Response Time"
            MonitorPolicy_ID="19">

        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL App Server 1 Performance"
            AttrToWatch="Condition"
            MonitorPolicy_ID="3"
            Cause_List_Control="1"
                  Special_Cause_List="0x1120a,0x11219">

            // Includes 2 specific eHealth alerts only
        </SM_AttrMonitor>

    </SM_Service>

</SM_Service>

<SM_Service
    containment_relation="SlmMonitors"
    name="TMPL Database Servers"
    Criticality="10"
    AttrToWatch="Service Health"
    MonitorPolicy_ID="6"
    Generate_Service_Alarms="true">

    <SM_Service
        containment_relation="SlmMonitors"
        name="TMPL Database Server 1"
        Criticality="10"
        AttrToWatch="Service Health"
        MonitorPolicy_ID="7"
        Generate_Service_Alarms="true">

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL DB Host 1"
```

```
            AttrToWatch="Condition"
            MonitorPolicy_ID="3"
            Cause_List_Control="2"
                  Special_Cause_List="0x1106f-0x11232">

            // Excludes all eHealth alerts

        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL DB Server 1 Critical Processes"
            AttrToWatch="Condition"
            MonitorPolicy_ID="3">

        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL DB Server 1 System Resources"
            AttrToWatch="Condition"
            MonitorPolicy_ID="3">

        </SM_AttrMonitor>

        <SM_AttrMonitor
            containment_relation="SlmMonitors"
            name="TMPL DB Server 1 Connection"
            AttrToWatch="Response Time"
            MonitorPolicy_ID="19">

        </SM_AttrMonitor>

    </SM_Service>

</SM_Service>

</SM_Service
    containment_relation="SlmMonitors"
    name="TMPL Application Performance & Response Time"
    Criticality="10"
    AttrToWatch="Service Health"
    MonitorPolicy_ID="7"
    Generate_Service_Alarms="true">

    <SM_Service
        containment_relation="SlmMonitors"
        name="TMPL Application Response Time"
        Criticality="10"
        AttrToWatch="Response Time"
        MonitorPolicy_ID="20"
        Generate_Service_Alarms="true">
```

```
        <SM_Service>

        <SM_Service
            containment_relation="SlmMonitors"
            name="TMPL Application Performance
            Criticality="10"
            AttrToWatch="Condition"
            MonitorPolicy_ID="4"
            Cause_List_Control="1"
                  Special_Cause_List="0x1106f-0x11232">

                // Includes eHealth alerts only

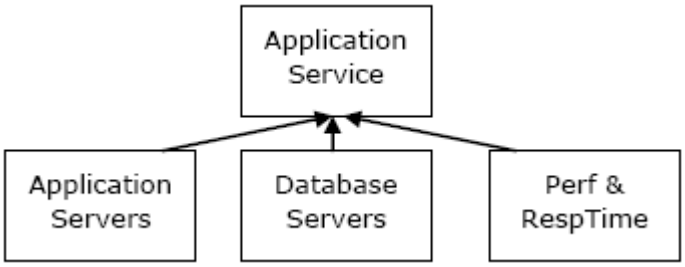
            Generate_Service_Alarms="true">

        <SM_Service>

    </SM_Service>

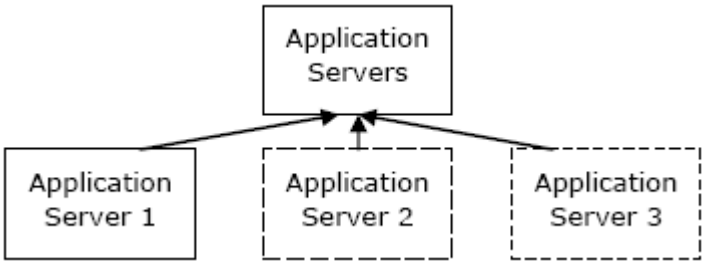
</SM_Service>
```

Now let us review each component in the xml to understand its purpose and how it fits within the service hierarchy that is defined by the xml. At the top of the hierarchy we have the application Service which has three direct child services:



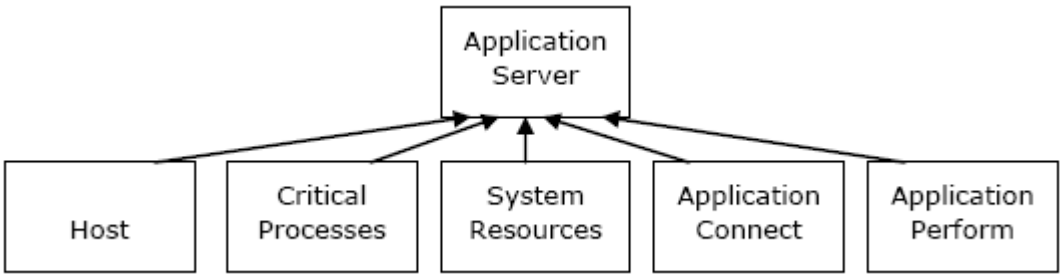
The Application Service monitors each of its child service with a high sensitivity policy. Therefore, the Application Service can have a service health equal to that of its worst direct resource.

The Application Servers service is designed to monitor child services which represent individual servers. Each server is represented by a service model with five resource monitors. The xml example contains only Application Server 1, but you could add this section for as many servers as necessary.

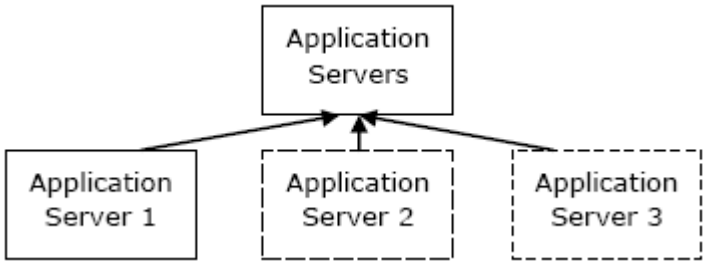


The Application Servers service could monitor the health of individual child services with a redundancy, percentage of low sensitivity policy.

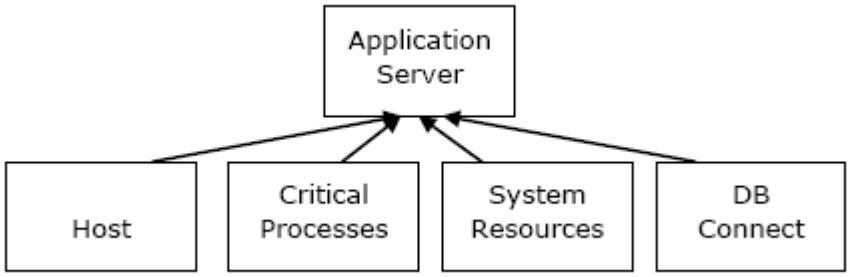
Each Application Server service; however, would monitor its resource monitors with a high sensitivity policy. The resource monitors focus on the host itself, critical processes, system resources, application connection, and application performance. You can notice that the Host resource monitor excludes CA eHealth notifications which are performance-based. The Application Performance resource monitor is only impacted by CA eHealth notifications. Both resource monitors would likely have the same host model as a resource, but are affected by different types of resource outages. This allows you to determine if the service outage is related to availability or performance.



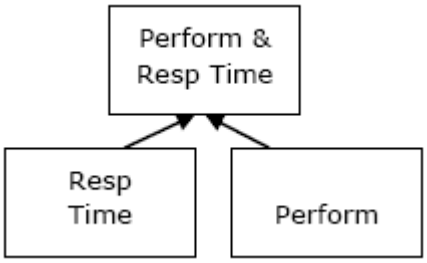
The Database Servers service has a similar structure to Application Servers. Multiple individual servers can be supported.



Each individual server supports four resource monitors. These detect faults on the host model, critical database processes, system resources, and database connections. Once again, you can see that the Host resource monitor excludes CA eHealth notifications.



Finally the service also includes a component for monitoring performance and response time. Application Response Time sub service would focus on monitoring SPM tests in DX NetOps Spectrum. You can use default response time policies, or perhaps develop a custom policy for average response time. The Performance sub service would detect resource faults that are based on CA eHealth performance notifications that are sent to DX NetOps Spectrum. The performance service would likely use a set of host models as its resources where CA eHealth notifications are mapped to resource alarms.



This example is not designed to fit a specific scenario, but provide you with an example of how modeling gateway can be used to model common patterns in your environment.

If you are able to identify all of the resources, they can be added to the service and resource monitor elements in the xml file. Even if you are not sure of all service resources, services and resource monitors can still be imported and empty of resources. The empty services and resource monitors appear with blue icons in DX NetOps Spectrum prompting you to the need to fill in the resources.

Example: Define a Service Maintenance Schedule

In addition to defining the structure of a service and its resources you can also specify a maintenance schedule for service. The following XML segment defines a maintenance schedule for a service named "ABC Service", using an existing schedule model.

```
<SM_Service
     containment_relation="MaintenenceScheduledBy"
     name="ABC Service">

          <Schedule name="Every day from 6 PM - 7 AM"
                    SCHED_Recurrence="2"
                    SCHED_Duration="46800"
                    SCHED_Start_Hour="18"
                    SCHED_Start_DoM="0"
                    SCHED_DayBitMask="0"
                    SCHED_Start_Day="0"
                    SCHED_Description=""
                    SCHED_Start_Year="0"
                    SCHED_Start_DoW="0"
                    SCHED_Start_MoY="0"
                    SCHED_Start_Minute="0"
                    SCHED_Start_Month="0"
                    SCHED_Daily_Repeat_Limit="2"
                    SCHED_Recurrence_Multiplier="1"/>

</SM_Service>
```

Example: Define an Alarm Exemption List for a Service or Resource Monitor

You can specify an alarm type exclusion list for a service using modeling gateway. This setting applies to the service model, and can be used in lieu of any setting that is made at the policy level. This xml configuration is equivalent to specifying the alarm type exemption in the Exemptions tab of the Service Editor. If the configuration you want to specify for this service is defined within a policy, specify the policy ID.

The following XML segment specifies the three alarms (0xabcd0001, 0xabcd0001, 0xabcd0002) that are the only alarm types to affect (Cause_List_Control="1") the service:

```
<SM_Service
          containment_relation="SlmMonitors"
          name="Access Routers"
          Criticality="30"
          AttrToWatch="Condition"
          Cause_List_Control="1"
          Special_Cause_List="0xabcd0001,0xabcd0001,0xabcd0002"
          MonitorPolicy_ID="2"
          Generate_Service_Alarms="true">

          <Device ip_dnsname="10.253.9.16" />
          <Device ip_dnsname="10.253.9.17" />
          <Device ip_dnsname="192.168.152.5" />
          <Device ip_dnsname="172.19.17.174" />
      </SM_Service>
```

The following XML document specifies a range of alarms (0xeeee0000-0xeeee002b) that can be excluded from impacting the health of the service (Cause_List_Control="2") the resource monitor:

```
      <SM_AttrMonitor
          containment_relation="SlmMonitors"
          name="Access Routers"
          Criticality="30"
          AttrToWatch="Condition"
          Cause_List_Control="2"
          Special_Cause_List="0xeeee0000-0xeeee002b"
          MonitorPolicy_ID="2">

          <Device ip_dnsname="10.253.9.16" />
          <Device ip_dnsname="10.253.9.17" />
          <Device ip_dnsname="192.168.152.5" />
          <Device ip_dnsname="172.19.17.174" />
      </SM_AttrMonitor>
```

Example: Associate an SLA to a Service

Service models can be associated to SLA models using modeling gateway. This association does not create any specific guarantee models, or associate the service to any existing guarantee model. Associations for guarantees must be done explicitly and can be covered later in this document.

The following sample XML shows how to associate an SLA to a service:

```
<SM_SLA
        containment_relation="SlmGuarantees"
        name="Acme Service Level Agreement">

        <SM_Service name="Acme"/>
</SM_SLA>
```

Example: Create a Guarantee for an SLA

Guarantee models are created within an SLA element, and can be associated to a service or resource monitor model. The following XML shows how to create a guarantee for an SLA call Acme Service Level Agreement. You can call the guarantee as Engineering Guarantee and record outage time when the Engineering service is Down.

```
<SM_SLA
     containment_relation="SlmHasGuarantee"
     name="Acme Service Level Agreement">

     <SM_Guarantee
        containment_relation="SlmIsMeasuredBy"
        name="Engineering Guarantee"
        GuaranteeControl="1"
        GuaranteeType="0"
        ServiceHealthType="1"
        WarningThresholdPercent="80.5"
        ViolationThresholdPercent="99.5"
        GuaranteeNotes="Tracks Down Time For Engineering Service"
        GuaranteeDescription="Availability Guarantee for Acme Engineering"
        MOT_Threshold="300"
        MTBF_Threshold="300"
        MTTR_Threshold="300">

        <SM_Service name="Engineering"/>

     </SM_Guarantee>
</SM_SLA>
```

Guarantee business hours can be specified using xml, by defining the schedule. The following example shows how a schedule named Business Hours can be associated to the Engineering Guarantee model.

```
        <SM_Guarantee
            containment_relation="SlmSchedulesGuarantee"
            name="Engineering Guarantee"
            GuaranteeType="0">

            <Schedule
                name="Business Hours"
                SCHED_Recurrence="2"
                SCHED_Daily_Repeat_Limit="0"
                SCHED_Duration="25200"
                SCHED_Recurrence_Multiplier="1"
                SCHED_Start_DoM="0"
                SCHED_Start_DoW="0"
                SCHED_Start_Hour="8"
                SCHED_Start_Minute="0"
                SCHED_Start_Month="0"
                SCHED_Start_Day="0"
                SCHED_DayBitMask="0"
                SCHED_Start_Year="0"
                SCHED_Start_MoY="0"
                SCHED_Description="Standard Business Hours 8AM Start"/>
        </SM_Guarantee>
```

Example: Define an SLA

The SLA Manager is the top-level model for all SLAs. Each SpectroSERVER has one SLA Manager model.

In addition to creating the SLA and its guarantees, the SLA period can be defined using modeling gateway. The following XML example shows how to define an SLA period, by specifying the period schedule.

```
<SM_SLA_Mgr
    name="SLAs"
    containment_relation="SlmContainsSLAs"
    >
<SM_SLA
        containment_relation="SlaPeriod"
        name="Acme Service Level Agreement"
        SLA_Control="1"
        SLA_ExpirationDate="1514696400"
        SLA_Notes="Manages SLA for Acme Services"
        SLA_Description="Acme Management Technologies Internal Service Level Agreement">

         <Schedule
            name="Daily SLA Schedule"
            SCHED_Recurrence="2"
            SCHED_Duration="0"
            SCHED_Start_Hour="0"
            SCHED_Start_DoM="0"
            SCHED_DayBitMask="0"
            SCHED_Start_Day="0"
            SCHED_Description=""
            SCHED_Start_Year="0"
            SCHED_Start_DoW="0"
            SCHED_Start_MoY="0"
            SCHED_Start_Minute="0"
            SCHED_Start_Month="0"
            SCHED_Daily_Repeat_Limit="0"
         SCHED_Recurrence_Mutiplier="1"/>

</SM_SLA>

</SM_SLA_Mgr>
```

Example: Define a Customer and a Customer Group

Customer models must be defined within the CustomerManager tag in the XML file. Each SpectroSERVER has one Customer Manager model, and it must be named as Customers.

The following example XML document defines a customer that is named Product Development within a customer group named XYZ Group:

```
<CustomerManager
        name="Customers"
        containment_relation="Groups_Customers">

        <SM_CustomerGroup
                name="XYZ Group"        <-- Specify Customer Group name here.
                containment_relation="Groups_Customers">

                <!-- This code defines a Customer and associates -->
                <!-- it with a Service. A Customer contains -->
                <!-- primary and secondary contact information, -->
                <!-- and a criticality that can effect the -->
                <!-- severity of a Service outage for Service -->
                <!-- models used by the Customer. -->

                <SM_Customer
                        containment_relation="SlmUses"
                        name="Product Development"      <-- Specify Customer name here.
                        CustomerField4="Pease International TradePort"
                        CustomerField5="123 Big Dr."
                        CustomerField6="Portsmouth, NH 03801"
                        CustomerField7="USA"
                        CustomerID="11DU-156"
                        Criticality="10"
                        Contact_Name="Fred Flintstone"
                        Contact_Title="Product Development Manager"
                        Email_Address="fred@proddev.com"
                        Phone_Number="123-456-7890"
                        Mobile_Phone_Number="123-456-1111"
                        Secondary_Contact_Name="Barney Rubble"
                        Secondary_Contact_Title="Product Development Manager"
                        Secondary_Phone_Number="123-456-9999"
                        Secondary_Mobile_Phone_Number="123-456-8888"
                        Secondary_Email_Address="barney@proddev.com">

                        <SM_Service name="Development"/>    <-- Specify service name here.

                </SM_Customer>

                <!-- This code associates a Customer with an SLA. -->
                <SM_Customer
                        containment_relation="SlmAgreesTo"
                        name="Product Development">

                        <SM_SLA name="XYZ Service Level Agreement"/>

                </SM_Customer>
```

Example: Import XML Input Files

You can use Modeling Gateway to import your Service Manager configuration files. Use the Modeling Gateway to test the XML document in Example: Services That Monitor Resources Directly.

Follow these steps:

1. Create a file containing the example XML document and save it to the <*$SPECROOT*>/SS-Tools directory with the file name, slm_test1.xml.
2. To run the modelinggateway tool for importing a single file, use the following syntax.

   Windows

   ```
   modelinggateway.bat -vnm vnm_name -i import_file [-o outputfile] [-debug debugfile]
   ```

   Linux

   ```
   modelinggateway -vnm vnm_name -i import_file [-o outputfile] [-debug debugfile]
   ```

   – **-vnm *vnm_name***
   Specifies the SpectroSERVER host name.

   – **- i *import_file***
   Specifies the XML file name which contains the necessary input information (that is compiled with .modelinggateway.dtd.)

   NOTE

   If you are importing from multiple files, specify the files names that are enclosed in comma-separated {} brackets. For example, refer to the syntax sample for importing multiple files.

   – **-o *outputfile***
   (Optional) Logs the error information to the file named in the *outputfile* parameter.

   NOTE

   If you don't specify the debug/output file names, the error information is logged to a file named *import_file*.log;where, *Import_file* is the name of the XML file.In case of multiple imports, the debug/output files are appended and you can see consolidated logs.

   – **-debug *debugfile***
   (Optional) Indicates that you would like to create a debugging output file during the import process. When using the -debug option, you can provide your own debug file name for output. If you do not supply a value for *debugfile*, the debug file name defaults to the *import_file* name suffixed with ".debug."

   NOTE
   The -debug option requires disk space on the machine where Modeling Gateway is run. For example, a large debugging output file can result when the number of models in the *import_file* is large or when the device models have large interface densities.

   ### Import Multiple Files

   The modelinggateway tool now supports import from multiple XML files. You can now specify any number of import files.

   To run the modelinggateway tool for importing multiple files, use the following syntax:

   ```
   modelinggateway -vnm vnm_name [-user SS user][-i{importfile1,importfile2...}]|[ -cmdb]-e exportfile][-o
    outputfile] [-debug debugfile]
   ```

3. If no errors are reported, device and container models are created. The output can be similar to the following output:

   ```
   Import session started Fri, December 29, 2006, at 02:53:32 EST
   Start parsing file slm_test1.xml
   ```

```
Start importing file slm_test1.xml
Container models created: 1
Identifying ports...
Import session finished Fri, December 29, 2006, at 02:53:38 EST
```

Service Attributes (SM_Service)

When creating service management models with Modeling Gateway, the XML code must provide values for the service attributes (sm_service) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	SlmMonitors SlmWatchesContainer MaintenenceScheduledBy
name	The model name of the service.	Text string, up to 256 characters
Criticality	The impact severity of the alarm relative to other current alarms. A higher Criticality value contributes to a higher impact severity value for alarms in OneClick.	10 = Low 15 = Medium Low 20 = Medium 25 = Medium High 30 = High
AttrToWatch	The attribute monitored on the service resource models. The AttrToWatch value should be consistent with the MonitorPolicy_ID. For example, if you specify AttrToWatch="Condition", you should specify a MonitorPolicy_ID for a Condition Policy (1-5).	Condition RM_Condition(service health) Contact_Status Port_Status LatestErrorStatus (Response Time)
MonitorPolicy_ID	The ID of a specific monitor policy as defined on the GlobalConfig model type. The ID should be consistent with the AttrToWatch value.	1 - 21 (DX NetOps Spectrum default) 1000 - *n* (User-defined)
Generate_Service_Alarms	Determines whether the SM_Service model generates alarms upon a change in service health.	True or False
Special_Cause_List	The alarm cause codes to include in an alarm type exemption list for a service.	Text string in the form of comma separated alarm causes or ranges separated with a hyphen (-)
Cause_List_Control	The integer that defines which alarm types affect or do not affect a service.	0=Unused (Ignore Cause) 1=Inclusive (Caused By) 2=Exclusive (Not Caused By)

Monitor Resource Monitor Attributes (SM_AttrMonitor)

When creating service management models with Modeling Gateway, the XML code must provide values for the monitor resource monitor attributes (SM_AttrMonitor) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	SlmMonitors SlmWatchesContainer
name	The model name of the resource monitor.	Text string, up to 256 characters
AttrToWatch	The attribute monitored by the resource monitor. The AttrToWatch value should be consistent with the MonitorPolicy_ID. For example, if you specify AttrToWatch="Condition", you should specify a MonitorPolicy_ID for a Condition Policy (1-5). **Note:** See Policy ID Mappings for more information.	Condition RM_Condition (service health) Contact_Status Port_Status LatestErrorStatus (Response Time)
MonitorPolicy_ID	The ID of a specific monitor policy as defined on the GlobalConfig model type. It should be consistent with AttrToWatch value. **Note:** See Policy ID Mappings for more information.	1 - 21 (DX NetOps Spectrum default) 1000 - *n* (User-defined)
Special_Cause_List	The alarm cause codes to include in an alarm type exemption list for a resource monitor.	Text string in the form of comma separated alarm causes or ranges separated with a hyphen (-)
Cause_List_Control	The integer that defines which alarm types affect or do not affect a resource monitor.	0=Unused (Ignore Cause) 1=Inclusive (Caused By) 2=Exclusive (Not Caused By)

Customer Group Attributes (SM_CustomerGroup)

When creating service management models with Modeling Gateway, the XML code must provide values for the customer group attributes (SM_CustomerGroup) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	Groups_Customers
name	The model name of the customer group.	Text string, up to 256 characters

Customer Attributes (SM_Customer)

When creating service management models with Modeling Gateway, the XML code must provide values for the customer attributes (SM_Customer) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	SlmUses
name	The model name of the customer.	Text string, up to 256 characters
CustomerField4	Address Line 1	Text string, up to 256 characters
CustomerField5	Address Line 2	Text string, up to 256 characters
CustomerField6	City, State, Postal Code	Text string, up to 256 characters
CustomerField7	Country	Text string, up to 256 characters
CustomerID	Any identification number.	Alpha-numeric string
Criticality	The impact severity of the alarm relative to other current alarms. A higher Criticality value contributes to a higher impact severity value for alarms in OneClick.	10 = Low 15 = Medium Low 20 = Medium 25 = Medium High 30 = High
Contact_Name	The person associated with the customer model.	Text string, up to 256 characters
Contact_Title	The contact person title.	Text string, up to 256 characters
Email_Address	The contact person email address.	Text string, up to 256 characters
Phone_Number	The contact person phone number.	Text string, up to 256 characters
Mobile_Phone_Number	The contact person mobile phone number.	Text string, up to 256 characters
Secondary_Contact_Name	The alternate contact person name.	Text string, up to 256 characters
Secondary_Contact_Title	The alternate contact person title.	Text string, up to 256 characters
Secondary_Phone_Number	The alternate contact person phone number.	Text string, up to 256 characters
Secondary_Mobile_Phone_Number	The alternate contact person mobile phone number.	Text string, up to 256 characters
Secondary_Email_Address	The alternate contact person email address.	Text string, up to 256 characters

SLA Attributes (SM_SLA)

When creating service management models with Modeling Gateway, the XML code must provide values for the SLA attributes (SM_SLA) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	SlaPeriod SlmHasGuarantee SlmGuarantees
name	The model name of the SLA.	Text string, up to 256 characters

SLA_Control	Specifies whether the SLA is active during the current SLA period or becomes active at the onset of the next period.	0 (inactive until next period) or 1 (active)
SLA_ExpirationDate	The UNIX timestamp, measured as the number of seconds from January 1, 1970.	For example, the value 1514696400 - Dec 31, 2017
SLA_Notes	Any text notes about the SLA.	Text string, up to 256 characters
SLA_Description	Any text description of the SLA.	Text string, up to 256 characters

Guarantee Attributes (SM_Guarantee)

When creating service management models with Modeling Gateway, the XML code must provide values for the guarantee attributes (SM_Guarantee) listed in the following table.

Attribute	Description	Possible Values
containment_relation	The set of supported relations from which associations can be created.	SlmIsMeasuredBy
name	The model name of the guarantee.	Text string, up to 256 characters
GuaranteeControl	Specifies whether the guarantee is active or inactive during the current period.	0 (inactive) or 1 (active)
GuaranteeType	Specifies whether the guarantee monitors service availability or performance (response time).	0 (availability) or 1 (performance)
ServiceHealthType	The type of service health time that is accumulated by the guarantee. An availability guarantee can accumulate both down and degraded time. A performance guarantee accumulates only degraded time.	1 (Down) or 2 (Degraded)
WarningThreshold	The number of seconds of outage time allowed per period before a warning alarm is issued.	0 - *n*
WarningThresholdPercent	The percentage of outage time allowed before a warning alarm is issued.	0 - 100%
ViolationThreshold	The number of seconds of outage time allowed per period before a violation occurs.	0 - *n*
ViolationThresholdPercent	The percentage of uptime per period below which a violation occurs.	0 - 100%
GuaranteeNotes	Any text notes about the guarantee.	Text string, up to 256 characters
GuaranteeDescription	A text description of the guarantee.	Text string, up to 256 characters
MOT_Threshold	Maximum outage time in seconds	0 - *n*
MTBF_Threshold	Mean time between faults in seconds	0 - *n*
MTTR_Threshold	Mean time to repair in seconds	0 - *n*

Schedule Attributes (Schedule)

When creating service management models with Modeling Gateway, the XML code must provide values for the schedule attributes (Schedule) listed in the following table.

Attribute	Description	Possible Values
name	The model name of the schedule. **Note:** DX NetOps Spectrum renames the schedule name that you provide.	Text string, up to 256 characters
SCHED_Recurrence	Specifies when the schedule is implemented.	1 = Always (24 x 7) 2 = Daily 3 = Weekly 4 = Monthly 5 = Yearly
SCHED_Start_Hour	The hour the schedule starts.	0 - 23
SCHED_Start_Minute	The minute the schedule starts.	0 - 59
SCHED_Start_DoW	The day of the week the schedule starts	0 - 6
SCHED_Start_DoM	The day of the month the schedule starts.	1 - 31
SCHED_Start_Month	The month of the year the schedule starts.	0 (Jan.) - 11 (Dec.)
SCHED_Start_Year	The year the schedule starts. Entering 0 starts the schedule in the current year.	0
SCHED_Start_MoY	The month of the year the schedule starts. Entering 0 starts the schedule in the current month.	0
SCHED_Description	The description of the schedule.	Text string, up to 256 characters
SCHED_Duration	The duration the schedule is in effect in seconds.	0 - *n*
SCHED_Recurrence_Multiplier	The number of times the schedule is implemented.	1 - *n*
SCHED_Daily_Repeat_Limit	The number of consecutive days to repeat a daily schedule at the start of each recurrence period. Applicable to Weekly, Monthly, or Yearly recurrence only.	0 - *n*

Monitoring Service Management Components with the Service Dashboard

The Service Dashboard is Service Manager dedicated operational and administrative console. The Service Dashboard includes many of the same operational features as the OneClick Console, but focuses purely on service management components. The service dashboard offers an at-a-glance view to the real-time status of services, SLAs, and customers. Using Service Dashboard, you can also view history outage information, outage trends and summarized service availability.

The Service Dashboard

The Service Dashboard provides a service-centric view of your service management environment. Unlike the OneClick Console, which enforces user security at the data level, the Service Dashboard shows only the service, SLA, and customer models to which you have security access. If you do not have access to a specific model, you can still see explorer and topology icons in the OneClick Console. Within the service dashboard, if you do not have access to a model, that model is absent from all dashboard views. In some circumstances, you can allow the DX NetOps Spectrum Administrator to provide the service dashboard to specific DX NetOps Spectrum users to view only the appropriate service and SLA components.

Using the Service Dashboard, you can navigate to your service management environment through the dashboard explorer and topology panels. Component detail information for services, SLA, and customer models is equivalent to that available in OneClick with the addition of some new panels which display outage history and SLA/Guarantee trend information.

Unique to the Service Dashboard is the service topology view. The semi-customizable topology icons indicate service health. The topology icons are expandable and provide navigation to lower layer services. You can edit and annotate the topology view for those service hierarchies you create.

Open the Service Dashboard

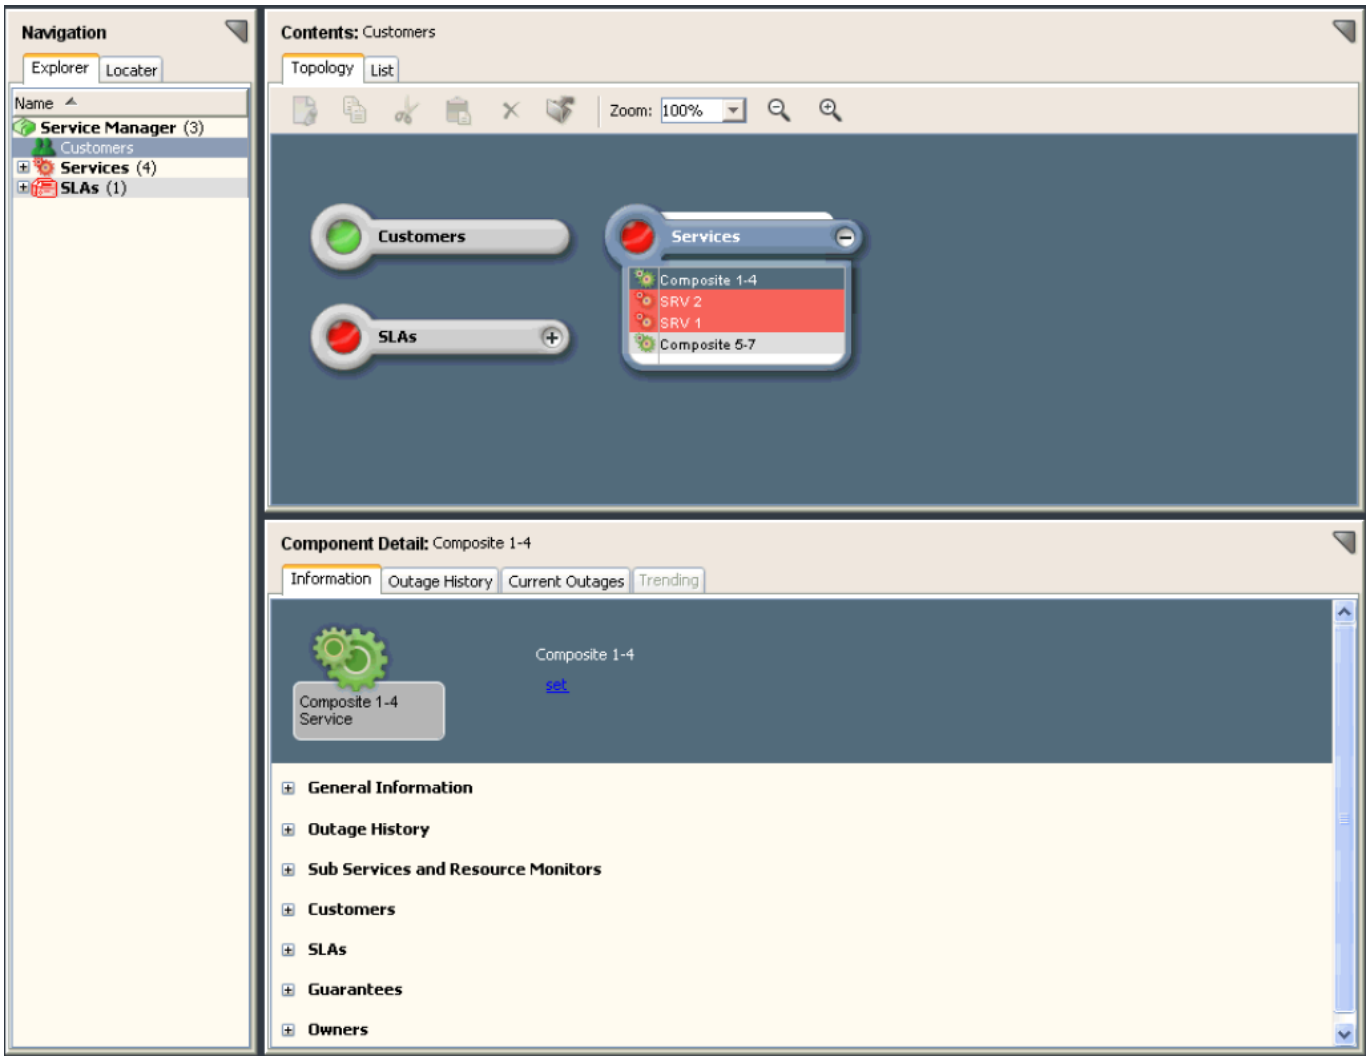
You can use various methods to open the Service Dashboard.

NOTE
You must have Service Manager license privileges to access the Service Dashboard.

Follow these steps:

1. Take *one* of the following steps:
   - Click the Service Dashboard link on the OneClick home page.
   - Click Tools, Utilities, Service Dashboard, from the main menu.
   - Right-click Service Manager in the Navigation panel and select Utilities, Service Dashboard in the OneClick Console.

   The following image shows the areas of the Service Dashboard you work with to monitor service components.



The Service Dashboard interface includes three main information panels that you work with to monitor your organizations services management components:

- **Navigation Panel**
  Displays components in a hierarchical folder structure. It provides the following options:
  - **Explorer tab**
    Lets you select the component that you want to view in the Contents panel and the Component Details panel. It groups components by services, SLAs, and customers. The explorer tab in the service dashboard condenses all landscapes into a single tree. You can notice that services which reside on different landscapes are all organized into the same services folder. This tab allows you to view your service management implementation without consideration of how many SpectroSERVER are deployed.
  - **Locater tab**
    Lets you search for the services, SLAs, or customers you want to view in the Contents panel. For example, can specify a particular component name or you can specify all components from a service management component category.
- **Contents Panel or Topology Panel**
  Displays summary information about the status of components you specify in the Navigation panel. You can select Topology and List views of service management components that are selected in the Navigation panel. The panel

topology view provides basic editing tools that you can use to arrange component icons, create basic shapes in the view, and annotate the view.
Note: Only the topology of user created hierarchies can be edited. Specifically the topology of the top tier folder that is named Services cannot be edited. This folder is comprised of multiple landscapes, and is shared among users. Given the variability in user access it would not be practical to allow topology editing to the top tier services topology.

- **Component Detail Panel**
  Displays detailed information about components that are selected in the Navigation or Contents panels. Tables and sub-view available in the Component Detail panel contains service configuration information and real-time and historical outage information.

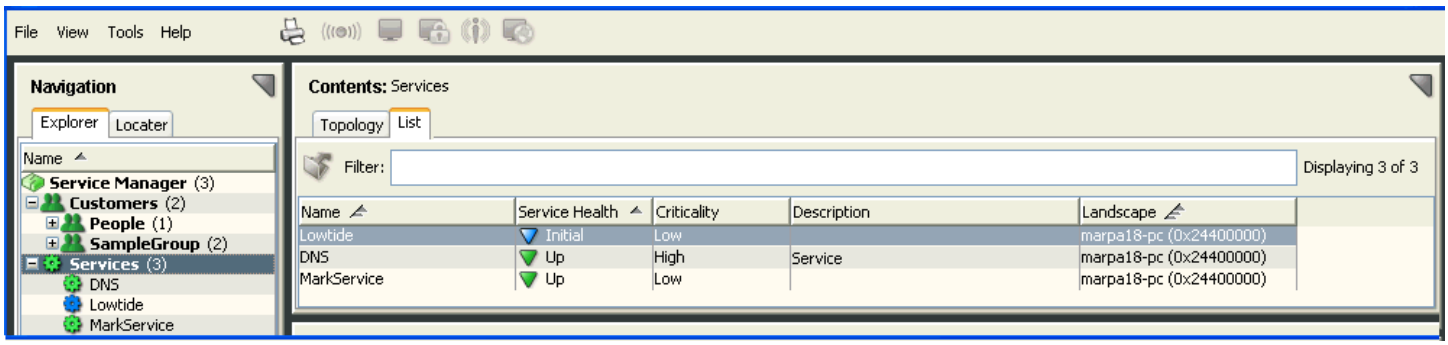
Topology and List Views in the Contents Panel

The Contents Panel contains a Topology and List view. The topology view provides expandable icons which indicate the real-time status of each service management component. The List view provides a table of service component models and specific attribute data. When a model is selected in the navigation panel, both the List and Topology views show the selected models children. If the selected model has no logical children, the List and Topology views show the selected model as contained by its parent.

NOTE
The List view is the default view for component results that are found through the Locater tab. You can specify a List view for components that are selected from the Explorer tab.

The Component Details panel displays comprehensive information about the component that is selected in the Contents panel.

To display a List view of a service management component group that is selected in the Explorer tab, click the List tab in the Contents panel, as shown in the following image:



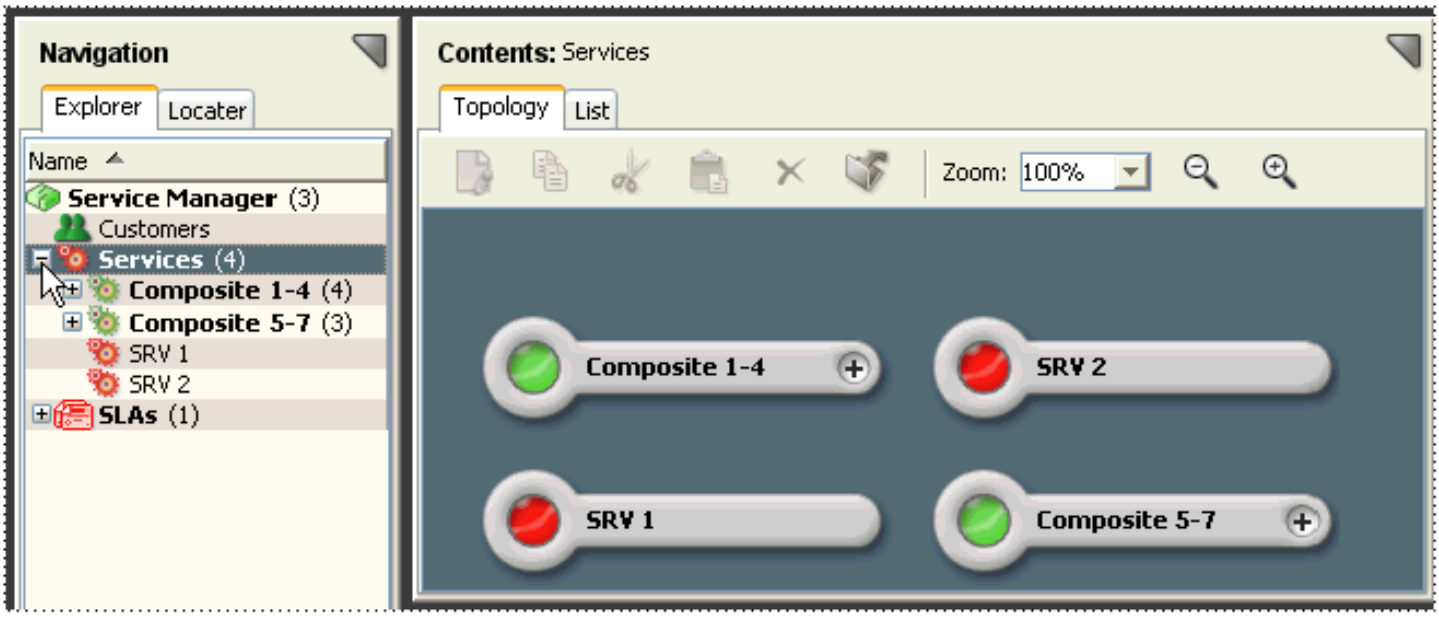
Explorer Folders and Topology Icons

The service dashboard does not display the service hierarchy about the landscapes where the models reside. Within the service hierarchy, you can see only the parent/child relationships of their service models. Within the OneClick Console, a service can appear as a top tier service directly under the service manager model on its landscape. If the service is a child of a service on another landscape, it can be seen in the dashboard only as a child, and not as both a child and top tier service. This behavior has changed from earlier releases of Service Manager in which the service would have appeared both directly under the Services folder and a child of the other service.

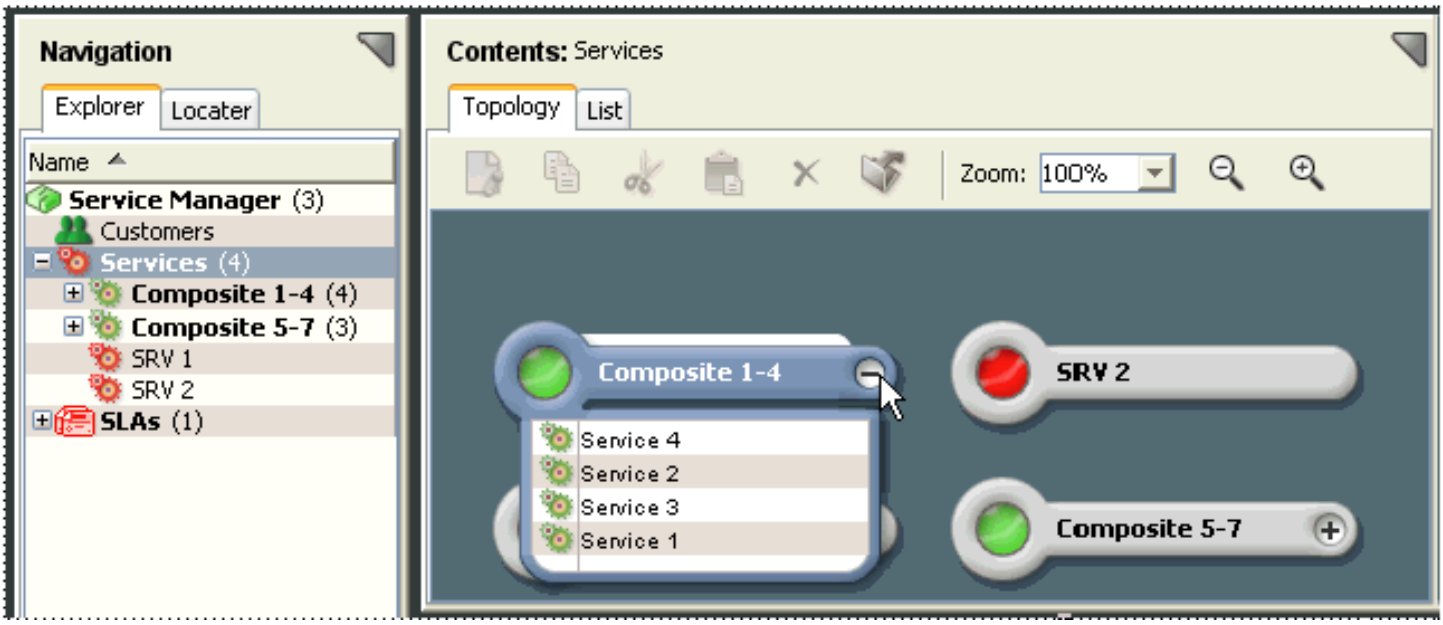
If a service management component displayed in the Explorer tab of the Navigation panel has a (+) next to it, this behavior indicates that the model or folder has one of more children. If you select a model, the List or Topology view displays the child models.

Icons within the topology view can also have (+) displayed in the icon itself. This behavior indicates that the model has children, click the plus sign (+) to expand and show a table of the associated child models.

For example, click the plus sign (+) next to a folder in the Navigation panel or on an icon in the Contents panel, or double-click a folder or icon:



For example, click the plus sign (+) on an icon in the Contents panel and then click a component from the drop-down list:



Status Indicators

The top-level service management component icons -- Services, SLAs, and Customers -- indicate the most severely affected corresponding top-level category for each landscape. If the Services icon is red, it indicates that the service manager model (Services) in at least one landscape has a Condition of critical.

The following table describes service component icon colors, and the associated state attribute values:

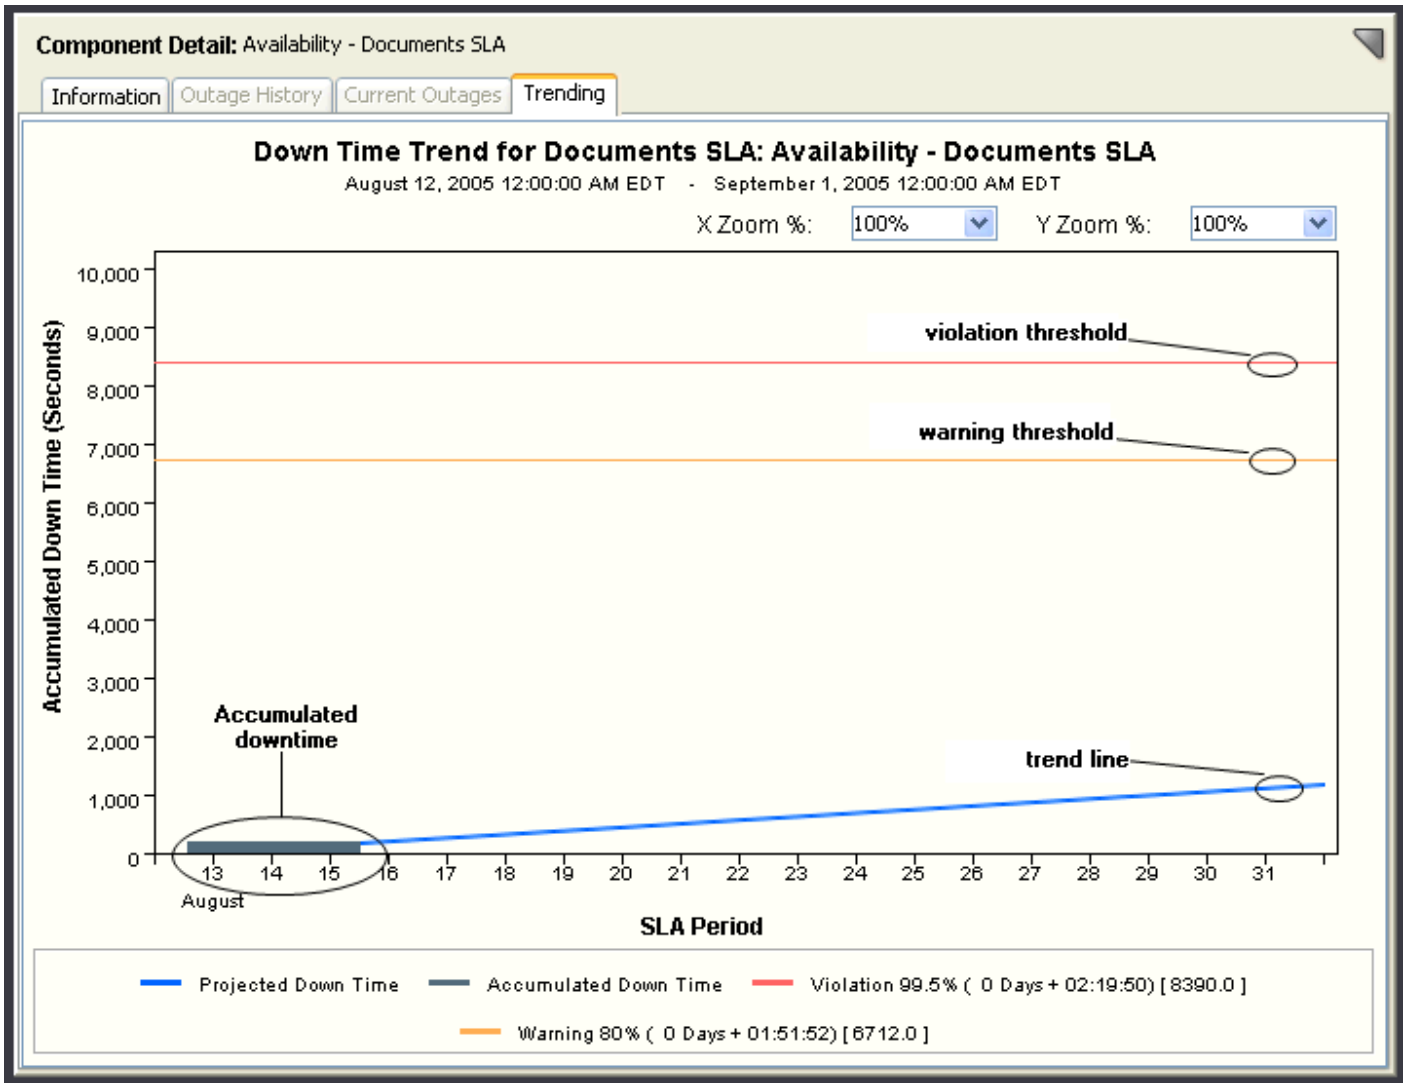
Color	Service	SLA	Customer
Green	Normal	Unaffected	Not Impacted
Yellow	Slightly Degraded	Compliant	Slightly Impacted
Orange	Degraded	Warned (at risk)	Significantly Impacted
Red	Down	Violated	Severely Impacted

Access Information about a Service Management Component

When you select a service management component from the Navigation panel or the Contents panel, the Service Dashboard Component Detail panel displays detailed information about it.

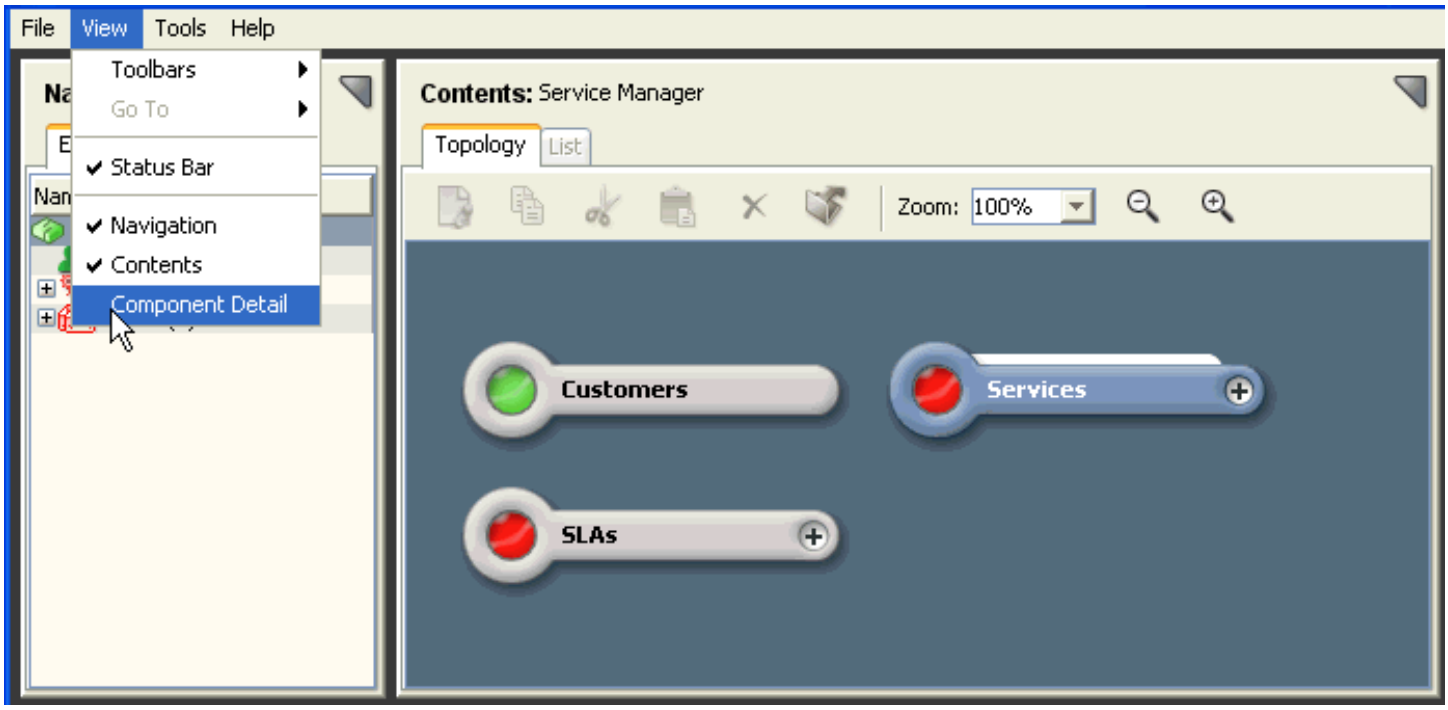
Follow these steps:

1. Open the Service Dashboard.
2. To access information in the Component Detail Panel, navigate to a model from either the Navigation or Contents views.
3. When the model is selected the Component Detail panel contains the following tabs:
   - **Information tab**
     Displays detailed information about any service management component (customers, services, SLAs, guarantees). Contains a number of sub-view each with detailed configuration information or historical data.
   - **Outage History tab**
     Displays the outage history for the last 31 days for the selected service.
   - **Current Outages tab (service and customer models only)**
     Displays information for any current service outage, including the cause of the current outage, assignment, trouble ticket ID, and status note of root cause alarm.
   - **Trending tab (SLAs and guarantee models only)**
     Displays accumulated outage time for a guarantee and a trend line to indicate the probability for the guarantee to become warned or violated within the current SLA period.
     The following shows an example of a trend chart:



Service Dashboard Interface Management

To show and hide Service Dashboard panels and the Status bar, select the interface component to display from the View menu, or clear the interface component to hide. The following image shows that the Component Detail panel has been deselected and is not included in the Dashboard interface:



To dock and undock Dashboard panels, which include the Navigation, Content, and Component Detail panels and Component Detail information panels, click the Dock/Undock icon. The following image shows and example of Docking/ Undocking icon locations (circled). An undocked panel includes many of the same interface controls and options available from the main Service Dashboard.

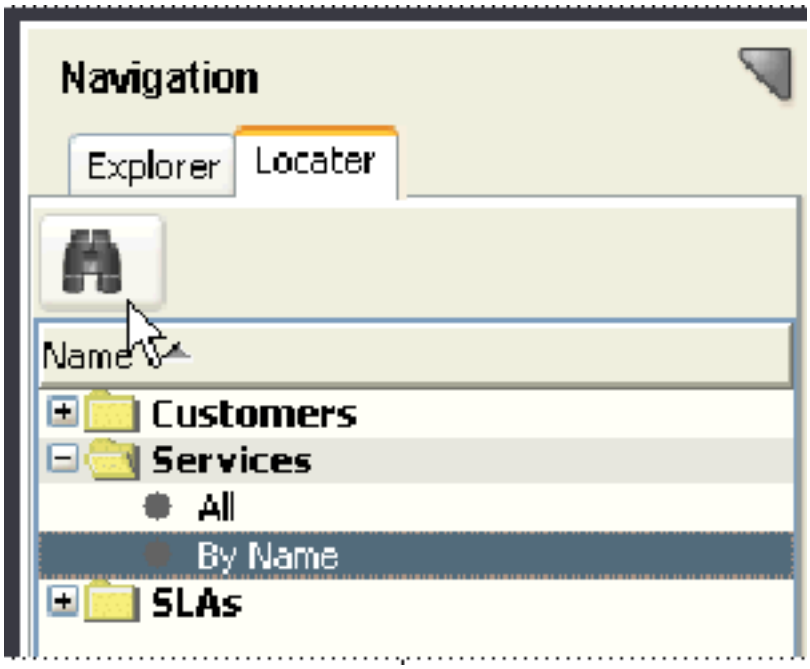
Locate Service Management Components

You can use the Dashboard Locater tab to display those service management components you specify, in the Contents panel and Component Detail panel.

Follow these steps:

1. Open the Service Dashboard.
2. Click the Locater tab in the Navigation panel.
3. Expand the customers, services, or SLAs folder from which you want to locate a component.
4. Specify whether to locate all components or a particular component from the selected component category:
   - Select All and to locate all components, click 

     
     The Select landscape to search dialog appears.
     Specify the landscape that you want to search and click OK.
   - Select By Name and to locate a specific component, click  .



The Search dialog appears.
Enter the component name in the Model Name field and click OK.

NOTE
To specify which landscapes to search, click the Landscapes button to open the Select Landscapes to Search dialog.

Results are displayed in the Contents panel.

Print Dashboard Views

Service Dashboard lets you print content from the Explorer and Locater tabs. You can also print the content from the Topology and List tabs. The Results view in the Contents panel and the Information view of the Component Details panel can be printed.

Follow these steps:

1. Click File, Print.
   The Print dialog appears.
2. Select the content that you want to print, and click OK.

Export Dashboard Views

Service Dashboard lets you save content from the Contents panel in multiple formats, using the export function.

You can export to a PNG (portable network graphics) format from the Explorer tab Topology view.

You can export to CSV (comma-separated values - spreadsheet compatible), text, and HTML formats from the Explorer tab List view and the Locater tab Results view.

Follow these steps:

1. Click 
   The Save As dialog appears.
2. Select an available format and click Save.

The dashboard view is exported.

Use the Service Dashboard Editing Tools

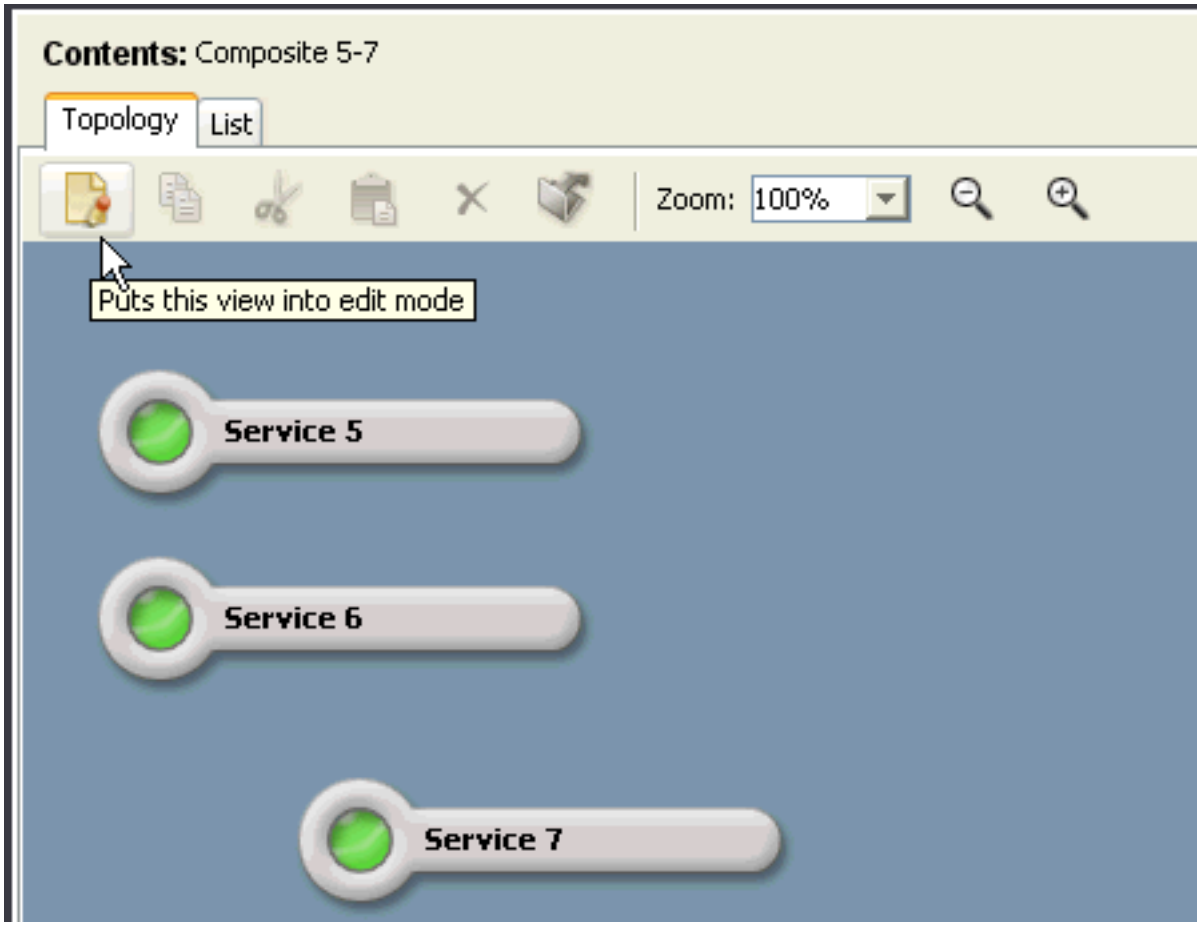
The Service Dashboard editing tools let you customize the topology views for Service, SLAs, and Customer Groups. Only the topology views of user created models can be edited. You cannot edit the topology views of the top tier service management folders.

You can perform the following tasks:

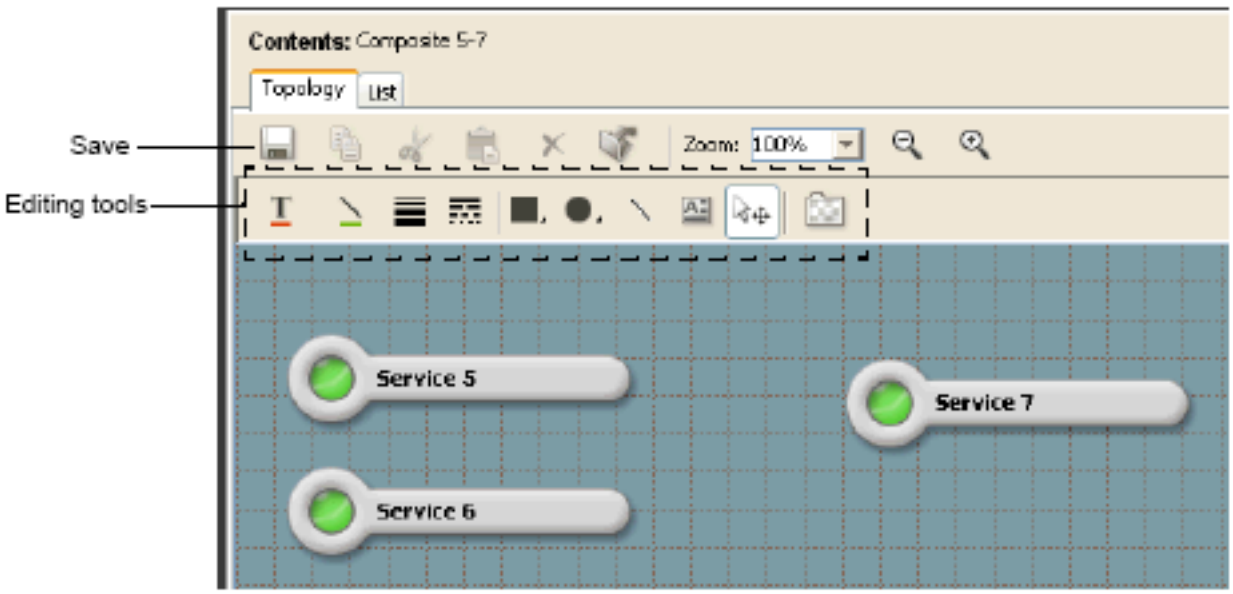
- Arrange component icons.
- Create basic shapes (rectangles, ovals) and lines.
- Enter annotations.
- Modify annotation text color, font, style, and size.
- Modify the topology view background color, grid dimensions (which you can use to align and resize shapes and lines), and size.

Follow these steps:

1. Click the Edit Mode icon in the Content panel Topology view, as shown in the following image:



The Topology view changes to editing mode and the editing toolbar appears. You can invoke a description of an editing tool by holding the cursor over the icon for the tool. The editing tools are a subset of tools available for editing the OneClick topology, and function in the same mapped.
Icon placement can be done either in tiled format or in custom format by selecting and dragging icons.



2. Edit the view as required and click Save.

Service Outage Management

Service dashboard provides various options for viewing current or historical service outages. From the current outage tab you can the view the following outage details:

- The health or severity of the outage
- The start time of the outage
- The resource or resources that are contributing the outage
- Any trouble shooter assignment or notation added to the outage

You can view and edit service outages from the Outage History tab panel or the Outage History sub-view of the Information tab panel.

The following information is available from the outage history table:

- Start time, end time, and duration of all outages.

  NOTE
  With Service Manager r9.2, the outage limitation of 31 days has been removed. You can now specify the date range of all outages.
- The resource or resources that caused each outage
- The name of the person that is assigned to troubleshoot the current service outage
- The status of an outage (unplanned, planned, or exempt)

The Outage History tab panel also offers a pie chart depicting service health or historical availability for the past 31 days.

The service outage editor is available from either the Outage History tab panel of the outage history sub-view. The outage editor allows user to add outage note or change the status of an outage by marking it as exempt or planned.

View Current Outages

Service Dashboard lets you view information about a service that is in an outage state.

Follow these steps:

1. Open the Service Dashboard dialog.
2. Select the service with the outage that you want to review.
3. Click the Current Outage tab in the Component Detail panel.
   The Component Detail panel displays information about the current outage, including the resource or resources that are contributing to the outage.

View Outage History

Service Dashboard lets you view information about all past and current outages for a service over the last 31 days.

Follow these steps:

1. Open the Service Dashboard.
2. Select a service that you want to review.
3. Click the Outage History tab in the Component Detail panel.
   The Component Detail panel displays information about the service outage history, including a chart with a summary of outage information and an itemized list of recent outages.
   The panel also displays Outage Details pertaining to the resources which contributed to the outage.

Service Outages

A service outage can have one of three potential status values: Unplanned, Planned, or Exempt. Usually the status of a service outage influences only how the historical record for that outage can be interpreted.

Most service outages have the status of Unplanned unless they are edited by the user. Unplanned outage time counts against the historical availability of a service model. It can be recorded if an SLA has associated one of more guarantees to the service.

You can use the service outage editor to change the status of an Unplanned outage to either Planned or Exempt. A status of planned indicates that the outage was expected to happen, and can be considered a maintenance outage. A status of Exempt indicates that the outage was not expected, but the cause or nature of the outage is such that the outage time should not be counted against the historical availability of the service. Outages which have a status of planned or exempt does not contribute time to SLAs.

Editing an outage does not change the real-time status of a service. If a service is Down and the user marks the outage as exempt the service remains down, as that is the true health of the service. Even though the real-time health of the service is unchanged and if a guarantee records time for the outage, you can remove the time from the guarantee that can change the status of an SLA.

Edit a Past or Ongoing Outage Status

You can edit the status of an ongoing or historical outage.

Consider the following information before editing a past or ongoing outage status:

- If an ongoing outage is edited, the outage status persists during the outage regardless of changes to the resources that contribute to the outage. Therefore, if the outage is marked as exempt, it remains exempt even if the resources contributing to the outage change. The current outage status can be seen in the Information tab for any service model.
- Outage time that is exempted or marked as planned is subtracted from the outage time tallied by a guarantee. This means that the status of an SLA that includes the guarantee changes accordingly. For example, an SLA with a status

of violated resulting from a service outage that exceeded an availability guarantee threshold is restored to compliant when the outage is exempted.

Follow these steps:

1. View the Outage History tab or open the Outage History sub-view of the Information tab.
2. Expand the Recent Outages subview in the Component Detail panel and select the outage that you want to edit from the Recent Outages list.

   NOTE
   Outages with health values of Down, Degraded or Slightly Degraded can be edited. You can also notice periods of Maintenance time, Initial time, and Loss of Management time in the outage table.
3. Click Outage Editor.
   The Edit Service Outage dialog appears.
4. Select an outage type for the service outage from the Set Outage Type of the drop-down list. The following options are available:
   - **Unplanned**
     Outages count against service availability.
   - **Planned**
     Outages do not count against service availability.
   - **Exempt**
     Outages are the unplanned outages that you have determined and must not count against service availability.
5. (Optional) Enter comments in the Notes/Reason field for the outage you changed. You can also enter comments for any outage regardless of whether you changed its status.
6. Click Save.
   The login name of the user who edited the outage is recorded and is displayed in the outage history table and in reports.
   The outage status is edited.

   NOTE
   You can also edit outages with the Affected Services Editor in Report Manager. For more information, see the Install Report Manager section.

Monitoring Service Management Components with Unicenter Management Portal

This section describes the procedure to Monitor Service Management Components with Unicenter Management Portal.

About the Service Level Manager Portlet

The Service Level Manager portlet provides summary status information about services, SLAs, and customers to Unicenter users with security access to Service Manager models. The portlet can be incorporated into the Unicenter Management Portal (UMP).

The portlet displays information about services, SLAs, and customers in a customizable tabular format. The portlet also provides context-sensitive links to the OneClick Console and Service Dashboard where you can view more detailed information about the services, SLAs, and customers.

Publish the Service Level Manager Portlet in UMP

Before viewing and accessing resources that are provided by the Service Level Manager portlet, first publish the portlet in UMP. For more information, see *UMP Documentation*.

Follow these steps:

1. Click the Knowledge tab and select Publish File.
2. Enter the URL for the Service Level Manager portlet in the Content box.

For example: http://abcde-sun/spectrum/slm

3. Enter a title for the Service Level Manager portlet and click OK.
   The Library tab displays the portlet title.
4. Click the portlet title to open the portlet.
   You are prompted to log in with a DX NetOps Spectrum user name and password. After you log in, the portlet appears.
5. Click the Work Place tab and select the workplace where you want to add the portlet.
6. Select Add Content, select the Service Level Manager portlet name, add it to the desired column, and click OK.
   The portlet is published in UMP.

View Service Information

You can use the Service Level Manager portlet to view service information.

Follow these steps:

1. Click the Services tab.
   The table displays status information about service models, as shown in the following image:

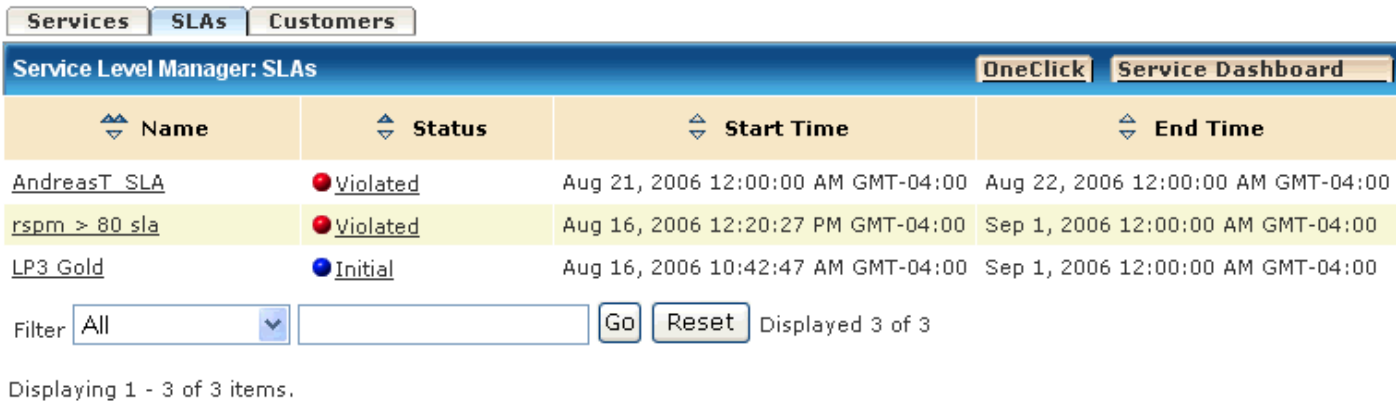
2. To view context-sensitive views of a service in OneClick and Service Dashboard, perform one of the following actions:
   - Click a service Name to view a detailed information view of the service in OneClick Console.
   - Click the Service Health indicator for a service to view information about the service in Service Dashboard.

View SLA Information

You can use the Service Level Manager portlet to view SLA information.

Follow these steps:

1. Click the SLAs tab.
   The table displays status information about SLA models, as shown in the following image:



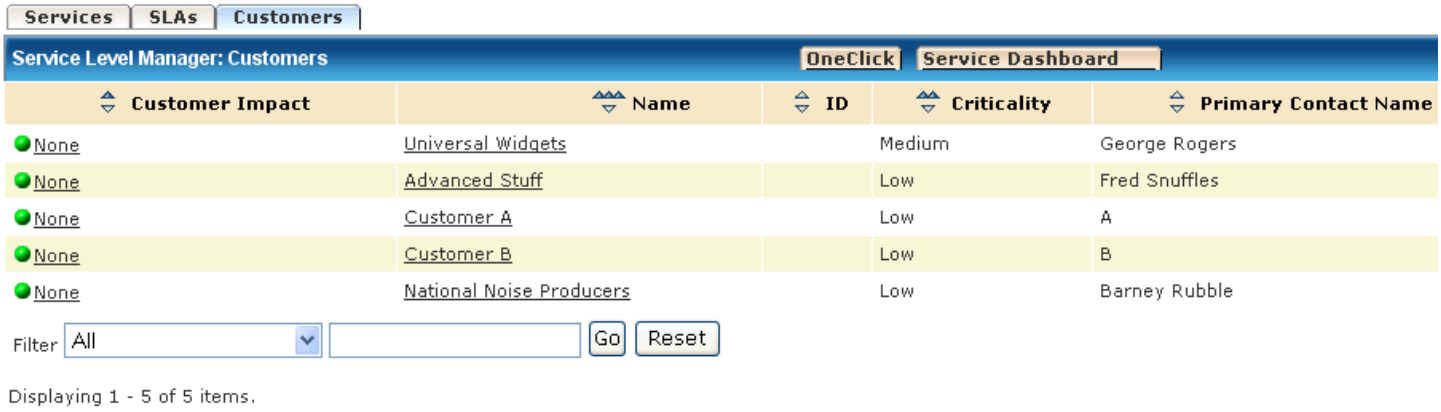
2. To view context-sensitive views of an SLA in OneClick Console and Service Dashboard, perform one of the following actions:
   – Click an SLA Name to view a detailed information view of the SLA in OneClick Console.
   – Click the Status indicator for an SLA to view information about the SLA in Service Dashboard.

View Customer Information

You can use the Service Level Manager portlet to view customer information.

Follow these steps:

1. Click the Customers tab.
   The table displays status information about customer models, as shown in the following image:



1. To view context-sensitive views of a customer in OneClick and Service Dashboard, perform one of the following actions:
   – Click a customer Name to view a detailed information view of the customer in OneClick Console.
   – Click the Customer Impact indicator for a customer SLA to view information about the customer in Service Dashboard.

Open the OneClick Console and the Service Dashboard

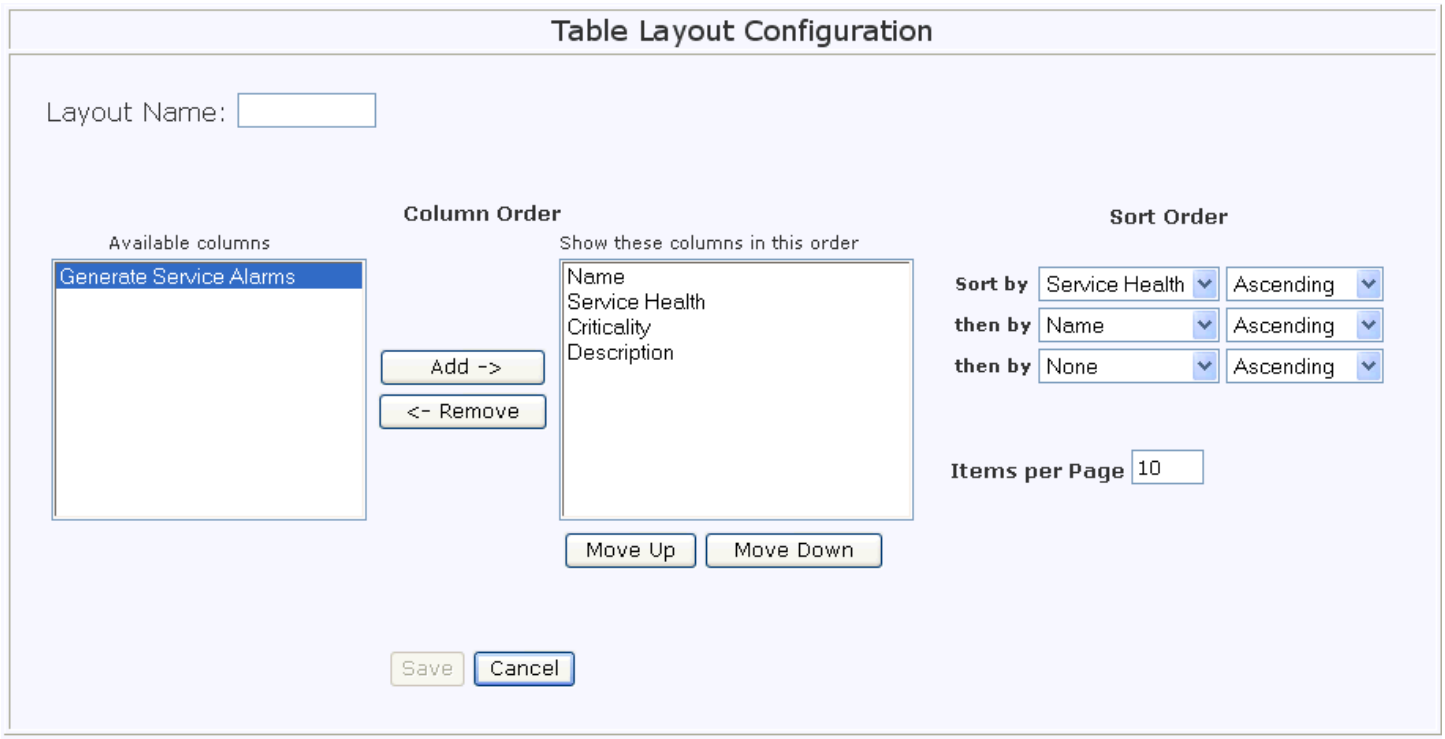
You can open the OneClick Console and the Service Dashboard from any component view in the Service Level Manager portlet. Perform one of the following actions:

- Click the OneClick button.
- Click the Service Dashboard button.

Apply and Manage Layouts

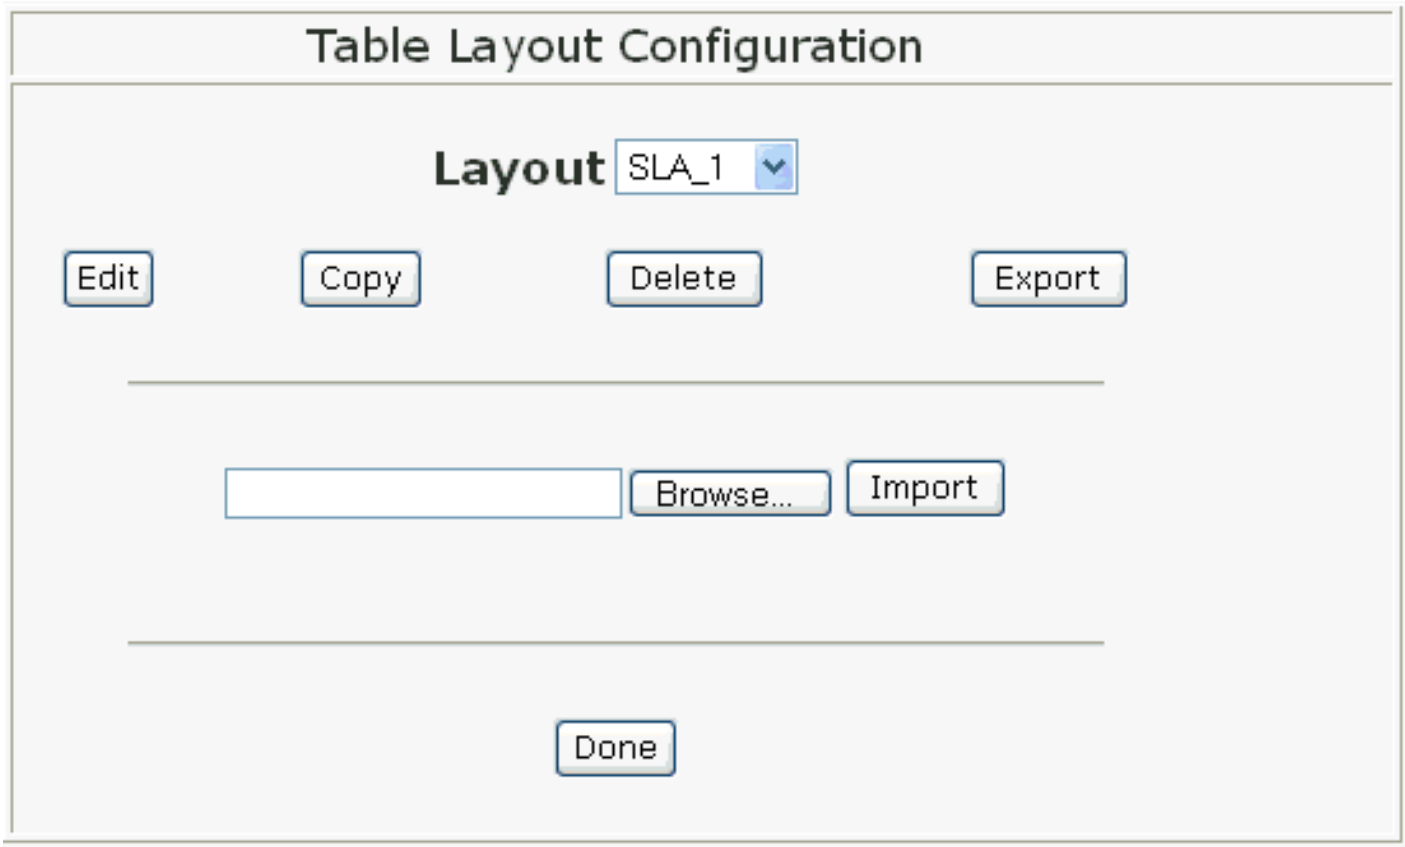
The Service Level Manager portlet lets you customize the type of information to include in the services, SLAs, and customers views. It lets you customize how you want to organize the information. You can also save multiple customized layouts for each view, edit all user-created layouts, export and import layout files, and remove layouts from the Service Level Management portlet.

The following image shows an example default layout for a service:



Perform the following actions to apply and manage layouts:

- To apply a layout to a component view, select it from the Configuration drop-down list. The table displays the columns and sort order that is specified for the layout.
- To create a layout for a component view, apply the default layout to the view, click Configure to open the Table Layout Configuration window, specify settings, and click Save.
- To manage a layout, apply the layout that you want to edit, copy, or delete to the current component view and click Configure.
  The Table Layout Configuration windows appears with available layout management options, as shown in the following image:



Select the following actions that you want to perform:

- Click Edit if you want to modify the layout.
- Click Copy if you want to create another version of the layout.
- Click Delete if you want to remove the layout from Service Level Management. You can export a layout to your hard drive before you delete it in case you want to re-use the layout in the future by importing it back into Service Level Management.
- Click Export if you want to save a copy of the layout to your hard drive (as a .prx file).
- Click Browse to locate a layout file on your hard drive and then click Import to add a layout to the list of available layouts.

Service Manager Policy Descriptions

Policy ID Mappings

The following table lists associations between watched attributes and monitor Policy IDs (1-21) for standard monitoring policies that are shipped with Service Manager.

NOTE
User-defined policies begin with ID value 1000 (and are incremented by 1, 1001, 1002, and so on).

To view user-defined Policy IDs, access the following link: http://<server>:CA_Portal/spectrum/slm/policyrep.jsp.

Watched Attribute (AttrToWatch)	Monitor Policy ID (MonitorPolicy_ID)	Policy
Condition_Value	1	Condition Value Sum Greater Than Or Equal

Condition	2	Condition Redundancy
Condition	3	Condition High Sensitivity (Default Policy)
Condition	4	Condition Low Sensitivity
Condition	5	Condition Percentage
RM_Condition	6	Service Health Redundancy
RM_Condition	7	Service Health High Sensitivity
RM_Condition	8	Service Health Low Sensitivity
RM_Condition	9	Service Health Percentage
Contact_Status	10	Contact Status Redundancy
Contact_Status	11	Contact Status High Sensitivity
Contact_Status	12	Contact Status Low Sensitivity
Contact_Status	13	Contact Status Percentage
Port_Status	14	Port Status Redundancy
Port_Status	15	Port Status High Sensitivity
Port_Status	16	Port Status Low Sensitivity
Port_Status	17	Port Status Percentage
LatestErrorStatus	18	Response Time Redundancy
LatestErrorStatus	19	Response Time High Sensitivity
LatestErrorStatus	20	Response Time Low Sensitivity
LatestErrorStatus	21	Response Time Percentage

Condition Value Sum Greater Than Or Equal

Watched attribute: Condition_Value

Default reason: The condition value has violated the allowable threshold.

This policy is different from the other standard Service Manager policies. Other policies include an attribute map, which defines the attributes that are monitored. This policy monitors the aggregate value of the Condition_Value (0x1000b)attribute for all resources that are associated with a service.

Rule Set

- When the sum of the Condition_Value attribute for all monitored resources is equal to or greater than the value of Red_Threshold (0x10012), the service is down.
- When the sum of the Condition_Value attribute for all monitored resources is equal to or greater than the value of Orange_Threshold (0x10011), the service is degraded.
- When the sum of the Condition_Value attribute for all monitored resources is equal to or greater than the value of Yellow_Threshold (0x10010), the service is slightly degraded.

You can adjust the values for Red_Threshold, Orange_Threshold, and Yellow_Threshold on the service model, or can adjust Value_When_Red (0x1000e), Value_When_Orange (0x1000d), or Value_When_Yellow (0x1000c) on the service component resource models to obtain the desired behavior.

Port Status Policies

Watched attribute: Port_Status

Default Reason: Bad Port Status

Value Mapping

- Service Health = Down if the watched attribute value is down, disabled, or unreachable
- Service Health = Up if the watched attribute value is up

Port Status High Sensitivity

- When any 1 resource is Down then the service is Down.

Port Status Low Sensitivity

- When all resources are Down then the service is Down.
- When all resource(s) are Down then the service is Degraded.

Port Status Redundancy

- When all resources are Down then the service is Down.
- When any 1 resource(s) is Down then the service is Slightly Degraded.

Port Status Percentage

- When 75 percent of the resources are Down then the service is Down.
- When 50 percent of the resources are Down then the service is Degraded.
- When 25 percent of the resources are Down then the service is Slightly Degraded.

Port Status - Automatically Configured

PollPortStatus has been automatically configured for interface models which are added or removed from services or resource monitors. Verify the following scenarios for Port Status:

- If an interface model has a PollPortStatus of False (No), when the model is added to a service or resource monitor PollPortStatus can be set to True (Yes). (OneClick View Attributes which imply false are displayed as ‘No’ and true are displayed as ‘Yes’.)
- If an interface model has a PollPortStatus of True, when the model is added to a service or resource monitor, no changes are made. When the model is removed from the service or resource monitor the PollPortSTatus is left as true.
- There is a caveat to the functionality described earlier. In scenarios where the PollPortStatus is automatically updated from false to true, that information is only preserved for the lifecycle of the running SpectroSERVER. The PollPortSTatus would not be restored to False when the interface is removed from the service, if the SpectroSERVER shutsdown between the time the interface was added and removed.

Condition Policies

Watched attribute: Condition_Value

Default reason: Bad Condition

Value Mapping

- Service Health = Down if the watched attribute value is Critical or Suppressed
- Service Health = Degraded if the watched attribute value is Major
- Service Health = Slightly Degraded if the watched attribute value is Minor
- Service Health = Up if the watched attribute value is Normal

Condition High Sensitivity (Default Policy)

- When any 1 resource(s) are Down then the service is Down.
- When any 1 resource(s) are Degraded then the service is Degraded.
- When any 1 resource(s) are Slightly Degraded then the service is Slightly Degraded.

Condition Low Sensitivity

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When all resources are Slightly Degraded then the service is Slightly Degraded.
- When any 1 resource(s) are Down then the service is Degraded.
- When any 1 resource(s) are Degraded then the service is Slightly Degraded.

Condition Redundancy

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When all resources are Slightly Degraded then the service is Slightly Degraded.
- When any 1 resource(s) are Down then the service is Slightly Degraded.

Condition Percentage

- When 75 percent of the resources are Down then the service is Down.
- When 50 percent of the resources are Down then the service is Degraded.
- When 25 percent of the resources are Down then the service is Slightly Degraded.

Response Time Policies

Watched attribute: LatestErrorStatus

Default reason: Bad Response Time

Value Mapping

- Service Health = Down if the watched attribute value is Timeout or Threshold_Critical
- Service Health = Degraded if the watched attribute value is Threshold_Major
- Service Health = Slightly Degraded if the watched attribute value is Threshold_Minor
- Service Health = Up if the watched attribute value is OK

Response Time High Sensitivity

- When any 1 resource(s) are Down then the service is Down.
- When any 1 resource(s) are Degraded then the service is Degraded.

Response Time Low Sensitivity

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When any 1 resource(s) are Down then the service is Degraded.
- When any 1 resource(s) are Degraded then the service is Slightly Degraded.

Response Time Redundancy

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When any 1 resource(s) are Down then the service is Slightly Degraded.

Response Time Percentage

- When 75 percent of the resources are Down then the service is Down.
- When 50 percent of the resources are Down then the service is Degraded.
- When 25 percent of the resources are Down then the service is Slightly Degraded.

Service Health Policies

Watched attribute: RM_Condition

Default reason: Bad Service Health

Value Mapping

- Service Health = Down if the watched attribute value is Down
- Service Health = Degraded if the watched attribute value is Degraded
- Service Health = Slightly Degraded if the watched attribute value is Slightly Degraded
- Service Health = Up if the watched attribute value is Up

Service Health High Sensitivity

- When any 1 resource(s) are Down then the service is Down.
- When any 1 resource(s) are Degraded then the service is Degraded.
- When any 1 resource(s) are Slightly Degraded then the service is Slightly Degraded.

> **NOTE**
> This is the default Policy for a SM_Service model that monitors resource monitor models/monitor groups/ SM_AttrMonitor models.

Service Health Low Sensitivity

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When all resources are Slightly Degraded then the service is Slightly Degraded.
- When any 1 resource(s) are Down then the service is Degraded.
- When any 1 resource(s) are Degraded then the service is Slightly Degraded.

Service Health Redundancy

- When all resources are Down then the service is Down.
- When all resources are Degraded then the service is Degraded.
- When all resources are Slightly Degraded then the service is Slightly Degraded.
- When any 1 resource(s) are Down then the service is Slightly Degraded.

Service Health Percentage

- When 75 percent of the resources are Down then the service is Down.
- When 50 percent of the resources are Down then the service is Degraded.
- When 25 percent of the resources are Down then the service is Slightly Degraded.

Contact Status Policies

Watched attribute: Contact_Status

Default reason: Bad Contact Status

Value Mapping

- Service Health = Down if the watched attribute value is Lost
- Service Health = Up if the watched attribute value is Established

Contact Status High Sensitivity

- When any 1 resource(s) are Down then the service is Down.

Contact Status Low Sensitivity

- When all resources are Down then the service is Down.
- When any 1 resource(s) are Down then the service is Degraded.

Contact Status Redundancy

- When all resources are Down then the service is Down.
- When any 1 resource(s) are Down then the service is Slightly Degraded.

Contact Status Percentage

- When 75 percent of the resources are Down then the service is Down.
- When 50 percent of the resources are Down then the service is Degraded.
- When 25 percent of the resources are Down then the service is Slightly Degraded.

Resource Monitor Implementation

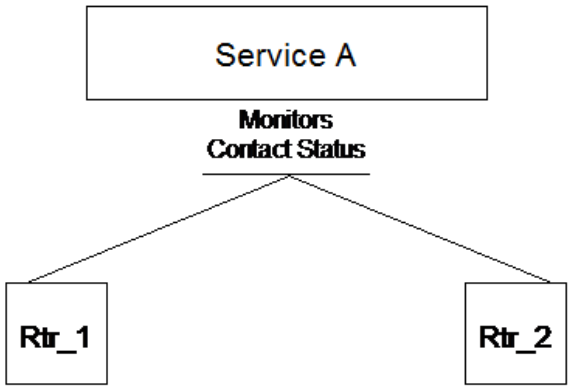
Policy Implementation Monitor Routers

Service A monitors two routers: Rtr_1 and Rtr_2. Service A functions if Rtr_1 or Rtr_2 is up, but it cannot function if both routers are down. Service A uses the Contact Status Low Sensitivity policy to monitor the service.

This policy rule set stipulates the following information:

- If all resources are down, service is down.
- If any 1 resource(s) are down, service is degraded.

Service with Policy



Service A seems to adequately monitor Rtr_1 and Rtr_2, but, on second glance, not enough to determine Service A actual viability. What about the case where Service A is not only dependent on the routers but also on particular router ports? The Contact Status Policy only monitors whether the routers are up or down.

The contact status of the routers could be established, simultaneously the ports on which Service A depends could be unavailable. Because of the limited scope of monitoring provided by its policy, Service A appears viable when actually it is not. Service A requires the more precise method of monitoring its resources that resource monitors provide.

Resource Monitor Implementation Monitor Routers and Their Ports

Scrutiny of the policy implementation reveals that it does not monitor the status of router ports that support Service A. The ports must be monitored with contact status of the routers. In addition, ports 4 and 5 on each router must be available for Service A to function optimally and that at least two of the four ports must be available for Service A to function adequately.

The following two resource monitors can be created as resources of Service A:

- Router Contact Resource Monitor -- Monitors the contact status of Rtr_1 and Rtr_2 (same as the policy implementation).
- Port Status Resource Monitor -- Monitors the port status of ports 4 and 5 on each router. Because at least two of four ports must be available. This resource monitor uses a Port Status Percentage Policy that reports down when 75 percent of the ports are unavailable and degraded when 50 percent of the ports are unavailable.

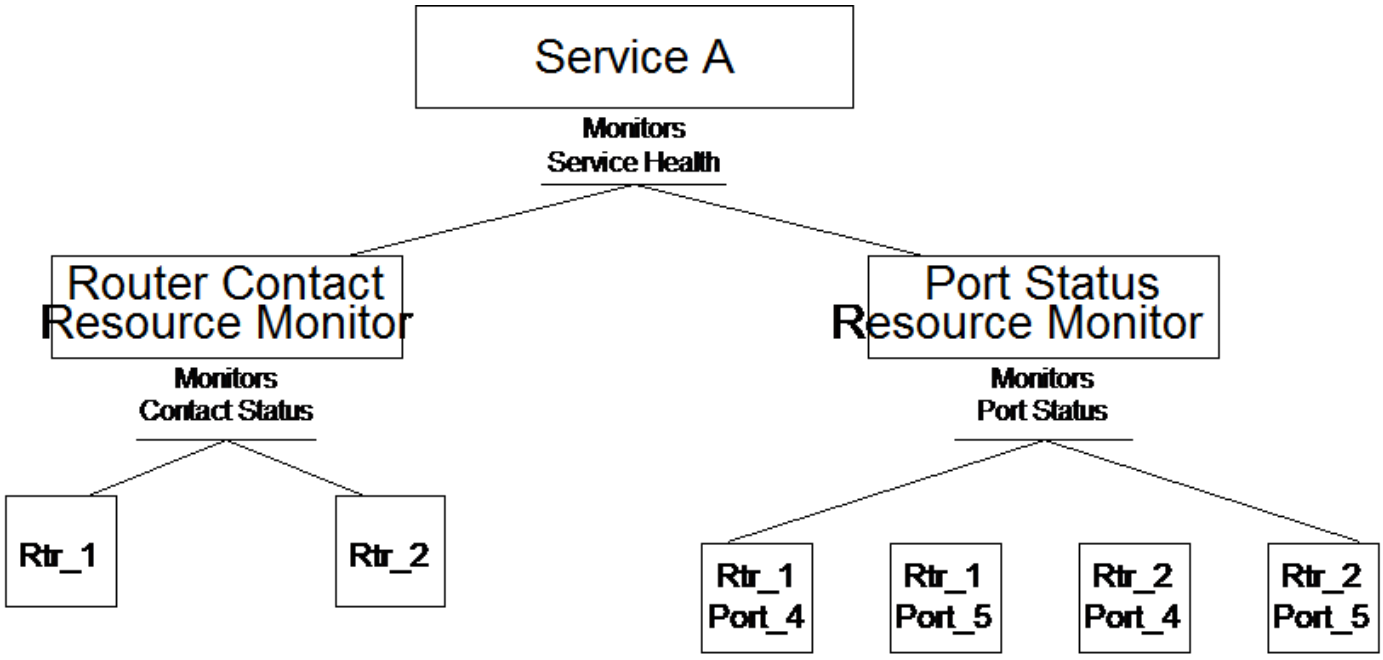
The result is that Router Contact Resource Monitor and Port Status Resource Monitor become resources of Service A. Rtr_1 and Rtr_2 become resources of the Router Contact Resource Monitor. Ports 4 and 5 on each router become resources of the Port Status Resource Monitor.

Service A monitors the service health attribute of Router Contact Resource Monitor and Port Status Resource Monitor with the Service Health High Sensitivity Policy. This policy rule set stipulates the following information:

- When any 1 resource(s) are Down then the service is Down.
- When any 1 resource(s) are Degraded then the service is Degraded.
- When any 1 resource(s) are Slightly Degraded then the service is Slightly Degraded.

So, if either one of the resource monitors is Down, Service A is down.

Resource Monitors Monitor Routers and Ports



Refined Resource Monitor Implementation Monitor Routers, Ports, and Response Time Tests

Further scrutiny of service A reveals that database server responsiveness and FTP transfer time are critical to its functionality. Assume that two RTM_Test models in DX NetOps Spectrum define critical, major, and minor thresholds for

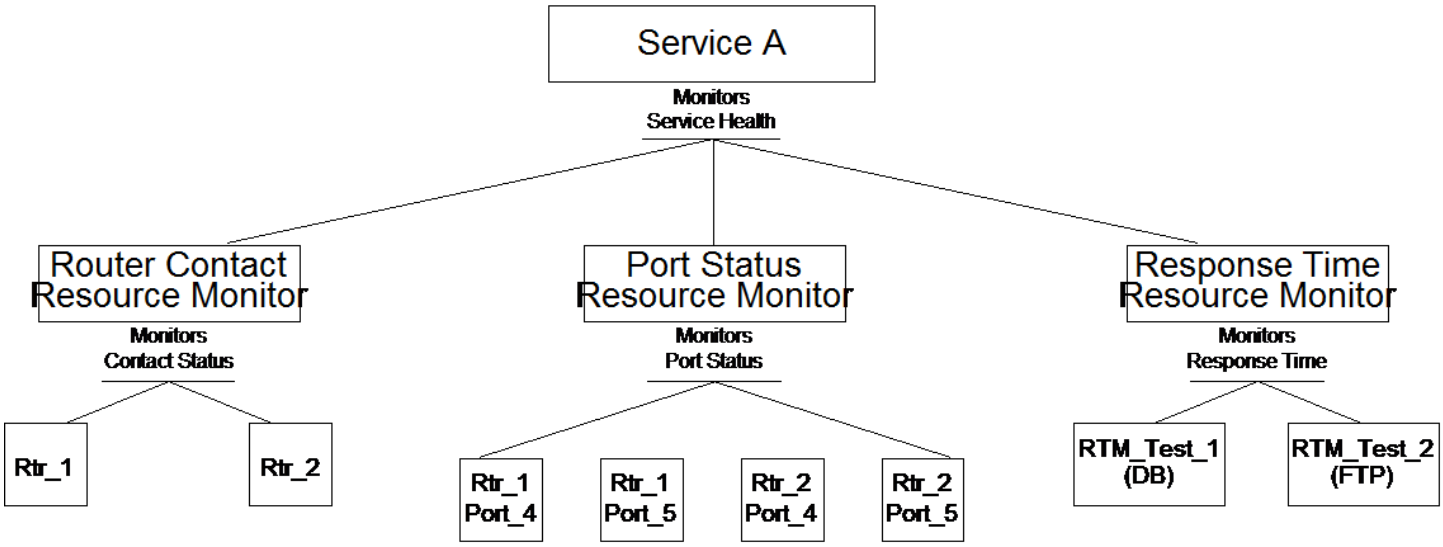
response time to the database server and the FTP server. These tests can be resources of another resource monitor (the Response Time resource monitor), which becomes another resource of Service A.

Response Time Resource Monitor monitors the response time tests with the Response Time High Sensitivity Policy. This Policy rule set stipulates the following information:

- When any 1 resource(s) are down then the service is down.
- When any 1 resource(s) are degraded then the service is degraded.

Therefore, if this resource monitor reports down (either test indicates unacceptable response time latency) then Service A is down as stipulated by the Service Health High Sensitivity Policy which monitors all Service A Resource Monitors.

Resource Monitors Monitor Routers, Ports, and Response Time



RollMaintenanceToResourceMonitor Attribute

When you use a Resource Monitor for multiple Services that are in active and Maintenance Mode states, the following attribute allows you manage the resource monitor behavior for services in maintenance mode.

Attribute	Description	Possible Values
RollMaintenanceToResourceMonitor	Allows you to manage the Resource Monitor status for Services in Maintenance Mode.	YES (default) NO

Example:

When the RollMaintenanceToResourceMonitor attribute value is set to ‘YES’ (default value)

If you add a resource monitor from an active service to a service that is in maintenance mode, the resource monitor turns into maintenance mode in all the services where it is being used.

When the RollMaintenanceToResourceMonitor attribute value is set to ‘NO’

If you add a resource monitor from an active service to a service that is in maintenance mode, the resource monitor does not turn into maintenance mode in all the services. The resource monitor continue to be in its state in other active services.

Administration and Maintenance

Customize a Service Editor Information Table

You can specify the information tables for services, customers, SLAs, and SLA templates in the Service Editor dialog. Specify the information types (columns) to include, the sort order (by status, by name, or by date for example), and the font and text size. You can revert to default settings. For more information about customizing interface settings, see the Using OneClick section.

Follow these steps:

1. Open the Service Editor.
2. Select the tab for which you want to customize an information table and right-click any column heading.
   The Table Preferences dialog appears.

   NOTE

   In the Table Preferences dialog, the column name 'Current MOT' is now renamed as 'Peak Outage Time'. The 'Peak Outage Time' indicates the maximum outage time a service has undergone.
3. Configure the table properties and click OK.
   The information table is customized.

Customize a Service Policy Editor Information Table

You can specify the information tables for policies, attribute maps, and rule sets in the Service Policy Editor dialog. Specify the information types (columns) to include, the sort order (by status, by name, or by date, for example), and the font and text size. You can also revert to default settings. For more information about customizing interface settings, see the Using OneClick section. .

Follow these steps:

1. Open the Service Editor.
2. Select the tab for which you want to customize an information table and right-click any column heading.
   The Table Preferences window appears.

   NOTE

   In the Table Preferences dialog, the column name 'Current MOT' is now renamed as 'Peak Outage Time'. The 'Peak Outage Time' indicates the maximum outage time a service has undergone.
3. Configure the table properties and click OK.
   The information table is customized.

Remove Service Manager Historical Data from All Landscapes

You can remove Service Manager historical data from all landscapes.

NOTE
Once you remove historical data from the database, you can no longer generate reports about them.

To remove Service Manager historical data from all landscapes, run the following script:

- Windows:
  ```
  <$SPECROOT>\bin\SMIntializeDB.bat
  ```
- UNIX/Linux:
  ```
  <$SPECROOT>/bin/SMIntializeDB
  ```

Remove Service Manager Historical Data from a Single Landscape

You can remove Service Manager historical data from a single landscape.

> **NOTE**
> Once you remove historical data from the database, you can no longer generate reports about them.

To remove Service Manager historical data from a single landscape, run the following script:

- Windows:
  ```
  <$SPECROOT>\bin\SMInitializeLandscape.bat <lh>
  ```
  - **lh**
    Indicates landscape handle.
- UNIX/Linux:
  ```
  <$SPECROOT>/bin/SMInitializeLandscape <lh>
  ```
  - **lh**
    Indicates landscape handle.

Remove Destroyed Service Manager Models from All Landscapes

You can remove destroyed Service Manager models from all landscapes.

Note: Once you remove destroyed Service Manager models from the database, you can no longer generate reports about them.

To remove destroyed Service Manager models (services, SLAs, and so on) and historical data for those models from all landscapes, run the following script:

- Windows:
  ```
  <$SPECROOT>\bin\SMRemoveDestroyedModels.bat
  ```
- UNIX/Linux:
  ```
  <$SPECROOT>/bin/SMRemoveDestroyedModels
  ```

Custom Resources Table

If a service using a policy with a custom attribute map is created, customize the Resources table to display the data you want to view about the monitored attribute that is specified in the custom attribute map. The Resources table appears in the following locations:

- Resources link under the OneClick Information tab
- List tab in OneClick Contents panel
- Service Dashboard List tab
- Resources tab in Service Editor

For more information about customizing OneClick interface elements, see the OneClick Customization section.

The following table lists Resources table configuration files for attributes that are monitored by standard Service Manager attribute maps:

Attribute	Attribute ID	File
Contact Status	0x10004	table-resources-0x10044-config.xml
Condition	0x1000a	table-resources-0x1000a-config.xml
ConditionValue	0x1000b	table-resources-0x1000b-config.xml
Port Status	0x10f1b	table-resources-0x10f1b-config.xml
Service Health	0x12a40	table-resources-0x12a40-config.xml

Response Time	0x456008c	table-resources-0x456008c-config.xml

These default files are located in the following directory:

```
<$SPECROOT>/tomcat/webapps/<sp>/WEB-INF/slm/config
```

Suppose, for example, you have a service that monitors “load in” data on a set of port resources. In this case, you can create a custom Resources table to display NRM_PortLoadIn (0x12aad) attribute data for a set of ports that are monitored by the service instead of the default Condition attribute data. The NRM_PortLoadIn (0x12aad) attribute example is used in the sections that describe how to configure the custom file.

Create the Custom Table File

You can create the custom file from scratch and can save it to the custom file directory, or you can save a modified version of the default table-resources-config.xml file from the following directory to the custom file directory:

```
<$SPECROOT>/tomcat/webapps/spectrum/WEB-INF/slm/config
```

Follow these steps:

1. Create the following custom file directory:
   ```
   <$SPECROOT>/custom/slm/config
   ```
2. Save all custom Resources table configuration files for Service Manager to this directory.
3. Create the custom file using the following naming convention:
   ```
   table-resources-<attribute ID>-config.xml
   ```
   For the load in attribute example:
   ```
   table-resources-0x12aad-config.xml
   ```

Example: Resources Table Configuration File

The following script shows an abbreviated example of the table-resources-0x12aad-config.xml configuration file. OneClick loads the table that is specified by this file to display the “load in” data column with other types of data for the port resources that are monitored by the service.

Elements pertaining to the “load in” example are highlighted in bold.

```
<?xml version="1.0" encoding="utf-8"?>

<table id="table-resources-0x12aad-config"
       xmlns="http://www.aprisma.com"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="http://www.aprisma.com
                           ../../common/schema/table-config.xsd">

  <orientation>horizontal</orientation>

  <swing-table-template>
    <show-vertical-lines>true</show-vertical-lines>
    <show-horizontal-lines>false</show-horizontal-lines>
  </swing-table-template>

  <swing-header-row-template>
    <static-color idref="row-header-color-config"/>
  </swing-header-row-template>
```

```
  <swing-row-template>
    <enumerated-color idref="alternatingrow-color-config"/>
  </swing-row-template>

  <column-list>
    <column>
      <name>Load In</name>
      <content>
        <attribute>0x12aad</attribute>
       </content>
      <default-width>125</default-width>
    </column>

    <column idref="column-normalizedstatus-config">
      <default-width>125</default-width>
    </column>

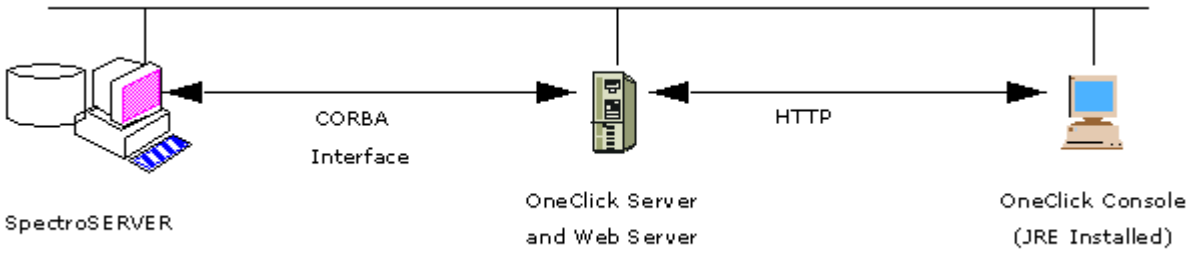
    <column idref="column-modelname-config">
      <default-width>125</default-width>
    </column>
</column-list>

  <default-sort>
    <sort-column-list>
      <sort-column>
        <name>
          com.aprisma.spectrum.app.topo.client.interfaces.render.NormalizedStatusColumn
        </name>
        <direction>ascending</direction>
      </sort-column>
      <sort-column>
        <name>
          com.aprisma.spectrum.app.util.render.ModelNameColumn
        </name>
        <direction>ascending</direction>
      </sort-column>
    </sort-column-list>
  </default-sort>
</table>
```

Using OneClick

OneClick delivers DX NetOps Spectrum information to network operators and troubleshooters using an intuitive graphical user interface. OneClick provides customized access to information and tools for users who monitor or troubleshoot specific portions of a network that DX NetOps Spectrum manages.

The OneClick architecture uses the Java Network Launch Protocol (JNLP) and the Java Web Start application to let remote systems and users access the OneClick server. JNLP is a standard for application delivery that does not require traditional installers or the launching of executable code. After installation, the OneClick Console communicates with the web server on the OneClick server using port 80 by default for Windows, or port 8080 for UNIX. The web server communicates as a single client of the SpectroSERVER using the CORBA interface, as illustrated by the following diagram:



The following DX NetOps Spectrum and OneClick content provides information that is related to installing, customizing, and maintaining OneClick:

- Fresh Install provides detailed instructions for installing the OneClick server and client.
- OneClick Administration provides information about how to configure and administer the OneClick environment, applications, and users.
- OneClick Customization provides information about customizing the OneClick interface by modifying XML files and other techniques.
- Modeling and Managing Your IT Infrastructure describes how to configure OneClick to discover and model the elements on the network.

How to Set Up the OneClick Client

The following process describes how to set up and start using the OneClick client.

> **NOTE**
> For more information about each of these steps, see Fresh Install .

Follow these steps:

1. Verify that your workstation meets the minimum OneClick client requirements before installing or running the OneClick client.
2. Install JRE. The OneClick Console and OneClick add-on applications require Java Runtime Environment (JRE). The JRE includes the Java Web Start client, which is required to run Java Network Launching Protocol (JNLP) applications like OneClick.
   You can install JRE 1.8.0_112 for 10.2/JRE 1.8.0_121 for 10.2.1 from OneClick home web page. To install JRE, click the "**Install JRE**" option on OneClick home page and follow the steps thereafter.
   After you install the JRE, you can start OneClick.
3. Associate .jnlp files with Java Web Start.
4. Launch the OneClick Console.

View the Client Details Web Page

The OneClick Client Details page lets you view the clients that you have opened. You can also log out of clients from this page. From 10.4.1, the Client Details table shows the client type in the WebApp column. In case the client is a WebApp, the Host Name and the Host Address columns show the **respective client** details. Previously, these columns displayed the **localhost** details, when the client was a WebApp.

NOTE
In case WebApp is launched on the same machine where OneClick is installed, and you launch the WebApp using **localhost** as the hostname, the client details page shows the hostname and host address as "0:0:0:0:0:0:0:1".

NOTE
This web page is not automatically updated with the latest client information. To verify that you have the latest information, reload the page in your browser.

How to View the Client Details Page

Follow these steps:

1. Navigate to http://<*webserver*>/spectrum/index.jsp in a web browser.
   The OneClick home page opens.
2. Click the Client Details link.
   The Client Details web page opens, displaying a Client(s) Logged On table.

How to Log off Clients Using the Client Details page

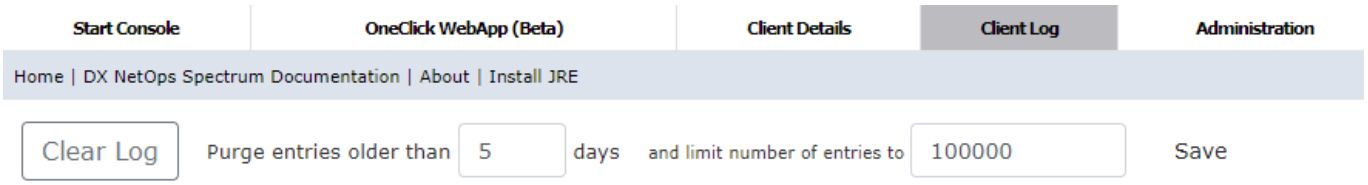
Follow these steps:

1. In the Client(s) Logged On table, select the checkboxes next to your user name for the clients that you want to log out.
2. Click Log off Clients.
   A confirmation dialog opens.
3. Click OK.
   The clients are logged out.

NOTE
Administrators accessing the Client Details page can view all currently logged in users. For more information, see OneClick Administration.

View Client Log

The OneClick Client Log page lets you view log history of the logged in and logged out users of the OneClick client. The details include login date, time, and host details. Using the Client Log page you can view logs, clear logs, purge entries, and limit the number of entries to display.



Follow these steps:

1. Navigate to http://<*webserver*>/spectrum/index.jsp in a Web browser.
   The OneClick home page opens.
2. Click the Client Log link.
   The Client Log web page opens, displaying log of the logged in users.
3. Click the 'Clear Log' button to clear the entire log details.
4. Enter the number of days in the 'Purge entries older than days' field to delete the entries, which are older that the given days.

NOTE

Starting from 10.2.2 release, the Purge functionality of the log entries is enhanced to purge by size as well as by time. The purge timer gets triggered with Tomcat startup and runs every hour and purges the client log data based on the configuration provided (i.e, number of days and number of entries).

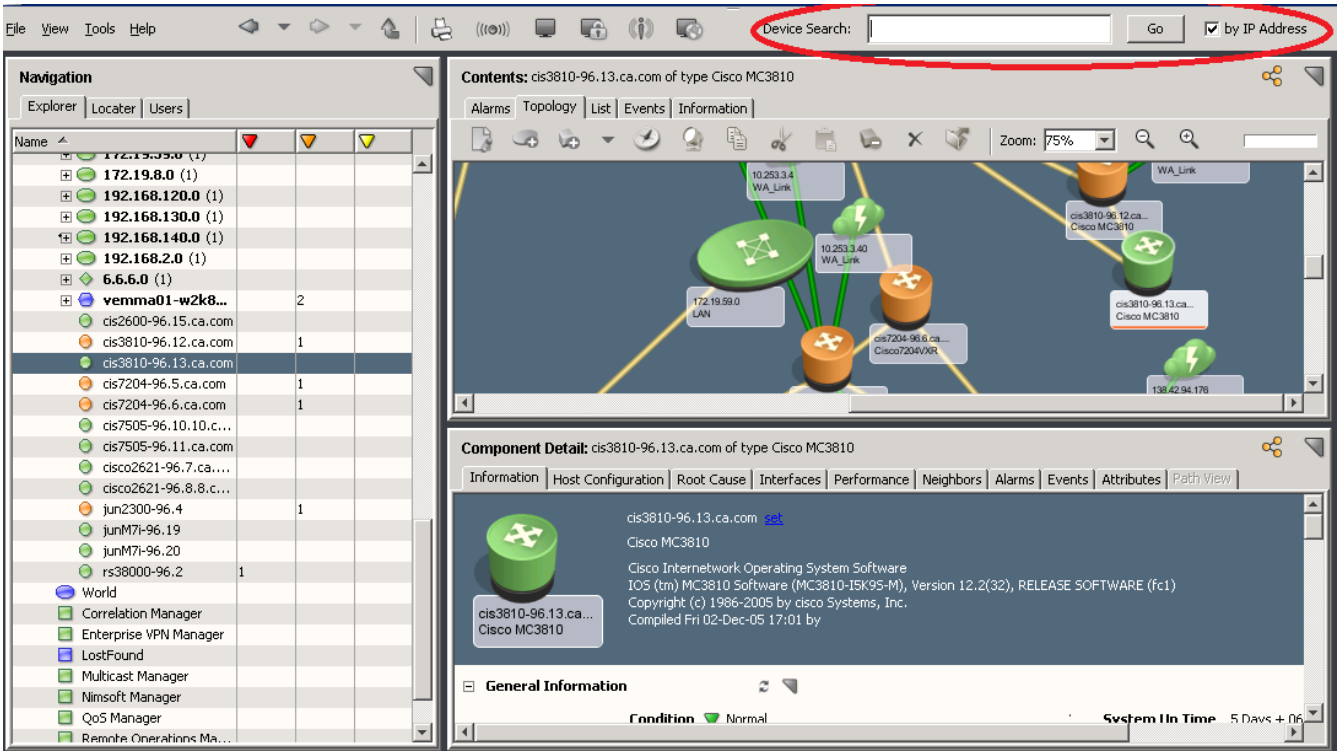
5. Enter the number of entries in the 'Limit number of entries to' field to display only the given entries. (applies from 10.2.2)
6. Click the Save button to save the configuration.

NOTE

Information! When multiple users access the Client Log file, If the client log is huge then you may encounter Out of Memory issue for OneClick Web server. To resolve this issue, you need to change the purge interval accordingly so that the entries older than the given number are purged automatically and the log will have less entries. You can also limit the number of entries to display so that only those many entries are fetched in the log.

OneClick Console User Interface

The OneClick Console user interface comprises three panels that display information about your network assets: the Navigation panel, the Contents panel, and the Component Detail panel. The following image shows an example of the OneClick Console user interface:



The information that is displayed in each panel depends on the item that is selected in the Navigation panel. Each panel displays a different context. The titles of the Content and Component Detail panels describe the context. Tabs in the Contents and Component Detail panels provide detailed lists of devices, alarms, events, and other information about specific items.

You can customize the display by docking, cloning, or removing panels.

NOTE
The OneClick Console supports multiple add-on applications, such as VPN Manager, Service Performance Manager, Multicast Manager, and Service Manager. For more information, see the user documentation that is provided with those applications.

Navigation Panel

You can use the Navigation panel to access information about your network assets. The Navigation panel includes the following features:

- Alarm views
- Topology views
- Device lists
- Event views
- Detailed device information
- Containers
- Landscapes
- OneClick applications
- Searches

The Navigation panel is on the left side of the default OneClick user interface. Two tabs are available to OneClick operators: the Explorer tab and the Locater tab.

Explorer Tab

The Explorer tab in the Navigation panel displays a hierarchical view of landscapes, containers, OneClick applications, and device models. In this view, container and device icons indicate the model class and status of each container and device model. The OneClick administrator at your organization created the views in the Explorer tab by modeling devices to represent your network infrastructure.

NOTE
OneClick filters containers and devices from the Explorer view if they are child objects of a container to which you lack view permissions.

The Explorer tab shows a high-level view of alarms that are active for devices in each container and application. You can modify the default alarm view in the Explorer tab. For more information, see Customize Columns.

Use the Explorer tab to select a container. You can then view information, alarms, events, lists, and topologies for that selection in the Contents panel. You can also select the OneClick application in the Name column to view information, alarms, events, lists, and topologies for that selection. You can also expand and collapse containers and applications in the Explorer tab as necessary.

NOTE
Items in the Explorer tab are sorted numerically.

Locater Tab

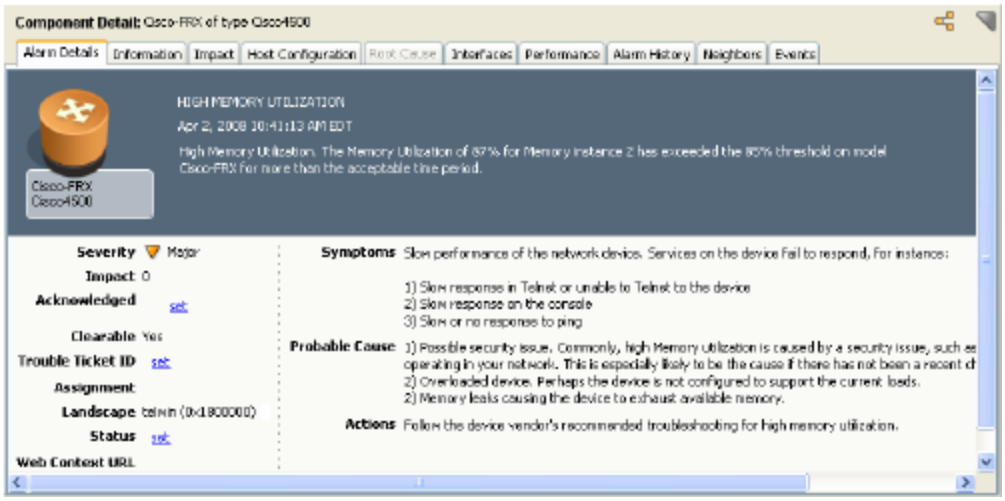
The Locater tab provides search functionality for locating network assets (device and application models) and viewing details about them. Search results appear in the Results tab of the Contents panel. Detailed information about network assets selected in the results list appears in the Component Detail panel.

Contents Panel

The Contents panel is located in the upper right of the OneClick interface. The information in the Contents panel depends on the context that is set from the Navigation panel. If the Locater tab in the Navigation panel is the active tab, the Results tab appears in the Contents panel. The Results tab shows the results of the last search performed in the current user session. If the Explorer tab is the active tab in the Navigation panel, the Contents panel displays the Alarms, Topology, List, Events, and Information tabs for the selected device, container, or application. By default, the Alarms tab is the active tab in the Contents panel.

Component Detail Panel

The Component Detail panel displays more detailed information for the item that is selected in the Contents panel. The following image shows an example of the Component Detail panel.



OneClick Tabs

OneClick categorizes information by tabs that appear in both the Contents and Component Detail panels. The tabs that you see depend on the context, which depends on the current selection in the Navigation panel. The following list describes these OneClick tabs in detail.

- **Alarms tab**
  Appears in either the Contents or Component Detail panel depending on context.
- **Alarm Details tab**
  Appears in the Component Detail panel and shows detailed information about the alarm that is selected in the Alarms tab.
- **Topology tab**
  Displays network topology models that are created manually or by Discovery.
- **List tab**
  Displays all models of the container that is selected in the Explorer tab.
- **Events tab**
  Displays events for the container, model, or application that is selected in either the Explorer tab or the Contents panel. The display includes all alarms and events for the selected model.
- **Information tab**
  Displays details about the container, device, or application that is selected.
- **Host Configuration**

Capture, view, upload, and export device configuration files.

NOTE
For more information, see the Network Configuration Manager section.

- **Impact tab**
  Displays the impact and symptoms for a selected alarm.

  NOTE
  The state of devices in the Impact tab does not always reflect the current device state.
- **Root Cause tab**
  Displays the root cause for a device that is down. The root cause can be helpful when a device has multiple alarms. You can view the date and time of occurrence of each alarm in the "Date/Time" column. You can also view the Condition, Name of the model, Alarm Title, and more information in other columns.
- **Interfaces tab**
  Displays interface information for the selected alarm or device.
- **Performance tab**
  Displays performance information for the selected device, including CPU & Memory Utilization.
- **Alarm History tab**
  Displays the historical information for the selected alarm including associated events, status, when created, and cleared. For general device alarm history, use the Events tab.
- **Neighbors tab**
  Displays the model that is selected from either the Explorer tab or the Contents panel and any models that are directly connected to it.

Alarms Tab

The Alarms tab displays any alarms that exist for the device, container, or application that is selected in the Navigation panel Explorer tab. Your OneClick administrator would have preconfigured the view of the alarms to show only a subset of alarms available.

Select an alarm in the Alarms tab to display detailed information for that alarm in the Component Detail panel. The toolbar that is displayed at the top of the Alarms tab lets you quickly process alarms in OneClick.

Alarm Severity Colors

Color	Severity	Description
Blue	Initial	Contact with device is not established.
Gray	Suppressed	Device cannot be reached due to a known error condition that exists on another device.
Brown	Maintenance	Device is offline for maintenance purposes.
Red	Critical	A loss of service has occurred; immediate action is required.
Orange	Major	A loss of service has occurred or is impending; action is required within a short period of time.
Yellow	Minor	A situation has occurred that does not require immediate action. This severity is also used for alarms created to convey information only, such as "Duplicate IP."

Green	Normal	Contact has been made with the device. Device is operating normally. No alarms are associated with this device.

Alarms List Columns

The columns in the table categorize the information for each alarm that is displayed in the Alarms tab. The default alarm information categories include Severity, Date/Time, Name, Network Address, Type, Acknowledged, Alarm Type, and Landscape. Other categories are present if OneClick add-on applications are installed. And the OneClick administrator can create custom alarm categories.

You can select the columns to display in the Alarms list. As with all table columns in OneClick, you can sort on the content for each column by clicking the column heading. Click a column header to toggle the sort order.

Filter the Alarms List

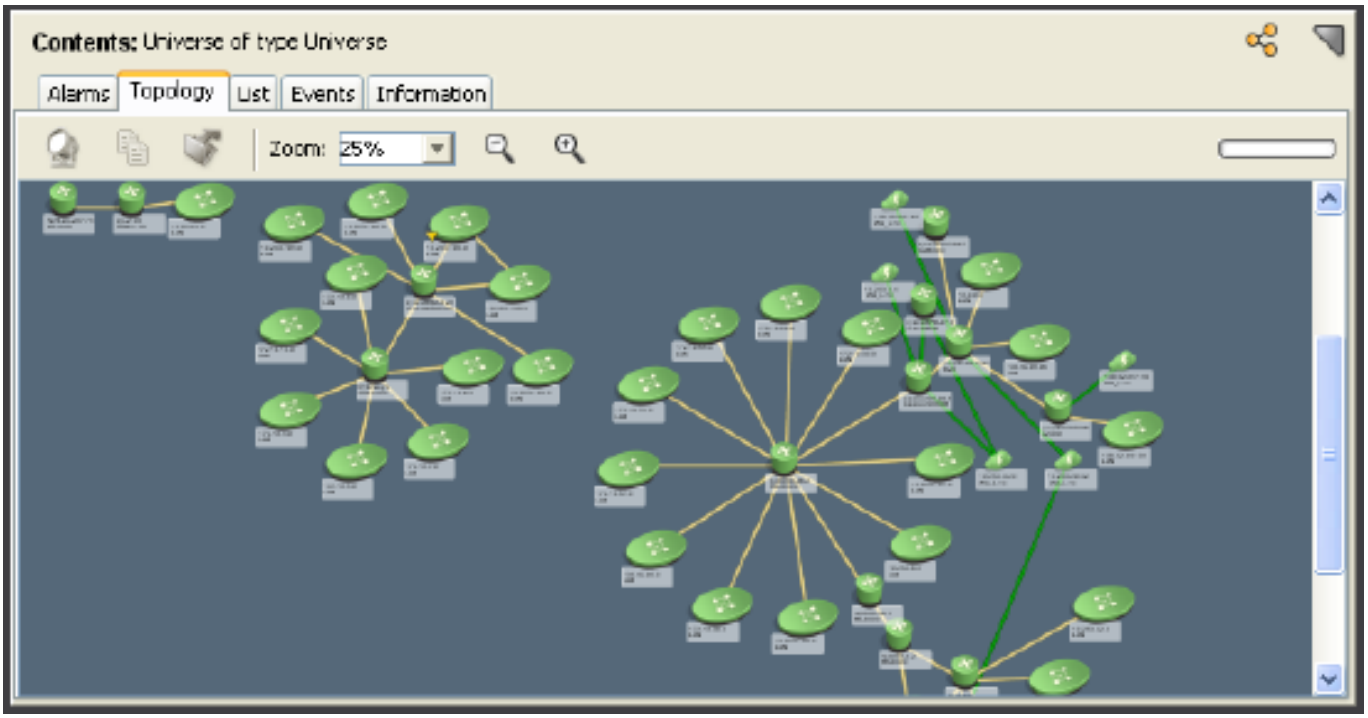
You can filter the alarms list as follows:

- Select Show or Hide from the Filter drop-down list and enter text in the Filter text box. As you type, the Alarms list displays or hides only those alarms with attributes that match the current text in the Filter field.
  This behavior depends on your Filter drop-down list selection. For example, view only critical alarms by selecting Show from the Filter drop-down list and typing **crit** in the text box.
- You can also create alarm filters to save and reuse.

Topology Tab

The Topology tab appears in the Contents panel and shows network topology diagrams for selected containers and collections. Expand the view of a container or collection in the Explorer tab, and then select a specific device in that container. The Topology view shows that device in the Contents panel. Double-click an icon in a topology view to change the context of the Navigation panel to display that device, container, or application. The Topology tab is not available if either My Spectrum or a landscape is selected in the Explorer tab.

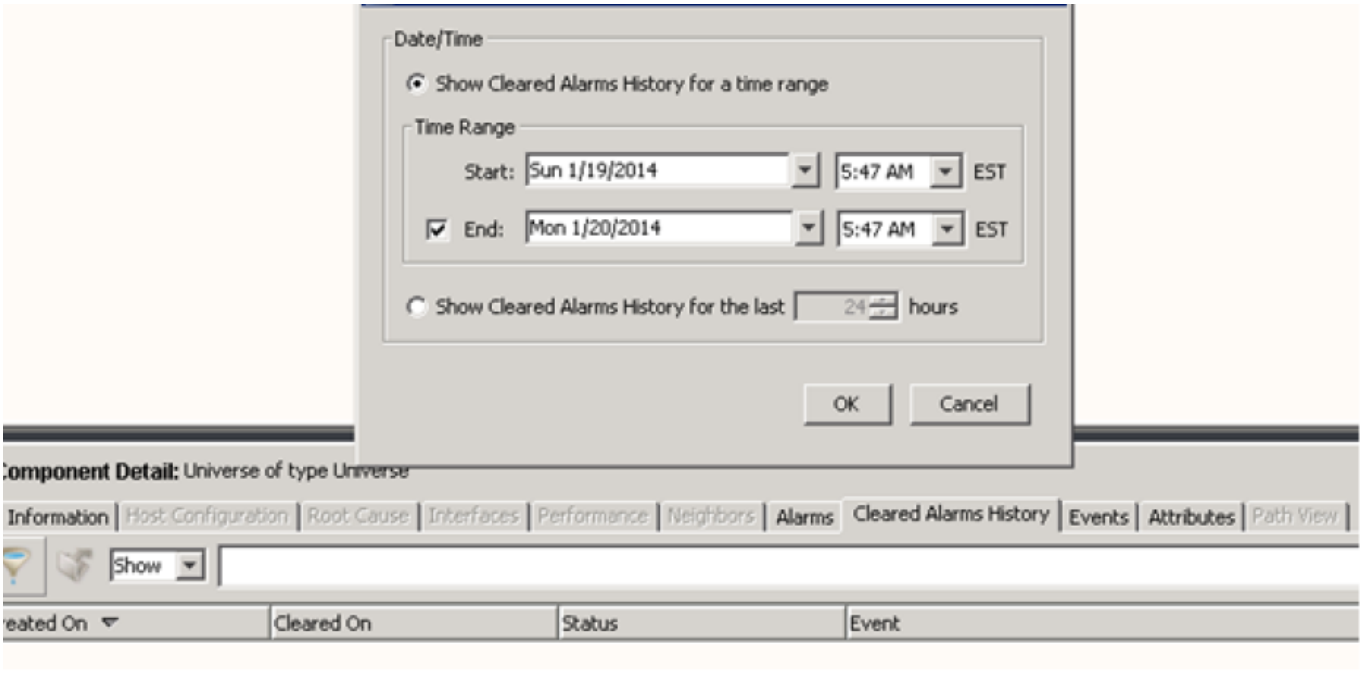
The following image shows an example of the Topology tab view:



Cleared Alarms History Tab

You can view the Cleared Alarms History tab from the Component Detail panel. The Cleared Alarms History tab displays historical information about the cleared alarms for the selected model. Historical information includes associated events and the status of created and cleared alarms. By default, cleared alarm history is displayed for the last 24 hours. You can use the Time Range option to view the cleared alarms history of a specific period.

The following image shows the Cleared Alarms History tab view:



List Tab

The List tab displays all models of the container that is selected in the Explorer tab.

If a device is selected in the Explorer tab, all models are displayed for the container of that device. This view is updated when models are added or removed or when attributes are updated. Double-click an entry in the List tab to select that model in the Explorer tab. This tab is not available when My Spectrum or any landscapes are selected in the Explorer tab.

Results Tab

The Results tab displays the results of searches performed in the Locater tab in the Navigation panel.

Events Tab

The Events tab appears in either the Contents or Component Detail panel. The Events tab displays all events for the item that is selected in either the Explorer tab or the Contents panel. If you select My Spectrum, the Events tab appears only in the Component Detail panel.

Information Tab

The Information tab appears in either the Contents or Component Detail panel, depending on the context set. The Information tab displays detailed device configuration information, VLAN and VPN configuration settings, and more. The Information tab is not available when My Spectrum or any landscapes are selected in the Explorer tab.

OneClick Toolbars

Toolbars are available in several OneClick panels and tabs. OneClick toolbars use graphical buttons and icons to provide quick access to features and functionality.

Hide Toolbars

By default, all available toolbars are shown in the OneClick Console. You can hide the toolbars that you do not use.

Follow these steps:

1. Select View, Toolbars.
   A submenu lists the available toolbars. Toolbars that are visible are checked.
2. Click a checked toolbar to hide it.
   The menu closes and the toolbar is removed from the applicable view.

Main Toolbar

The Main toolbar, which appears at the top of the OneClick Console, contains buttons for completing tasks common to many OneClick applications. The following table describes the buttons of the Main toolbar:

Button	Description
	**Navigation:** Moves you among views that you have recently accessed. Arrows select views from a list.
	**Go Up:** Moves you up to the next level in the hierarchy. A tooltip indicates the next level.
	**Ping:** Sends an ICMP Ping to the selected devices from the SpectroSERVER modeling the device.
	**TraceRoute:** Performs the traceroute operation on SpectroSERVER- and SDC-moldeled devices. Traceroute is a tool that helps you diagnose the network. It displays the route. It also helps in measuring the transit delays of packets that take place across the Internet Protocol network. For directly connected devices, this option performs the traceroute operation through SpectroSERVER. For SpectroSERVER-modeled devices, the traceroute prints the TTL for each hop with respect to SpectroSERVER. For devices modeled through SDC, check the connection status and perform the traceroute operation. In this case, the traceroute operation is performed through SDC. Additionally, the traceroute prints the TTL for each hop with respect to SDC.
	**Telnet:** Establishes a communication session with the selected device using Telnet from the SpectroSERVER modeling the device.
	**Secure Shell:** Establishes an encrypted communication session with the selected device using Secure Shell (SSH), from the SpectroSERVER modeling the device.
	**Poll:** Initiates contact with the selected devices from the SpectroSERVER modeling the device.
	**Web Administration:** Opens a browser using the IP address of the selected device. Available only for models that have the WebAdminURL attribute.

NOTE
You can also access the functions of the Main toolbar from the File, View, and Tools menus or, from the right-click menu. This selection depends on the current view.

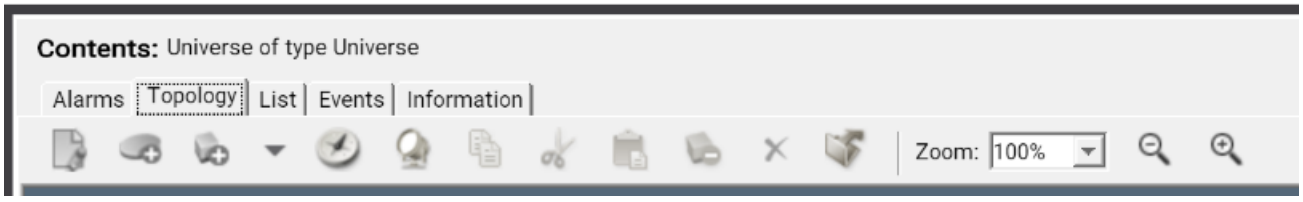
Alarms Toolbar

The Alarms toolbar contains buttons for quickly process alarms in OneClick. The following table describes the buttons and functionality that are available in the Alarms toolbar.

Button	Description
	**Information:** Opens a dialog containing details about the alarm currently selected in the table.
	**Clear selected alarms:** Clears the selected alarms. Cleared alarms are removed from the **Alarms** table.
	**Acknowledge selected alarms:** Acknowledges the selected alarms.
	**Unacknowledge selected alarms:** Unacknowledges the previously acknowledged, selected alarms.
	**Assign a troubleshooter:** Opens the Select Troubleshooter dialog from which you can assign a troubleshooter to the selected alarms.
	**Unassign the troubleshooter:** Removes a troubleshooter from the selected alarms.
	**Update alarm attributes on the selected alarm(s):** Opens the Update Alarm Attributes dialog from which you can update values for certain alarm attributes, such as a trouble ticket number or an acknowledgment.
	**Mail:** Opens the Mail Selected Alarms dialog, from which you can email alarms to a recipient. The mail is populated with alarm information. The mail content has URLs of OneClick console and WebApp (added in 10.4.2.1).
	**Unsnooze:** Unsnoozes all previously snoozed alarms.
	**Alarm Filter:** Create an alarm filter.
	**Export:** Specify a file format and location to export the Alarms list.
Filter	**Filter:** Supply text to filter the current **Alarms** list view. Select Show or Hide from the Filter drop-down list to specify whether to show or hide filter matches.

Topology Toolbar

The Topology toolbar appears in the Topology tab in the Contents panel. The following image shows an example of the Topology toolbar.



You can use the Topology toolbar to perform the following tasks:

- Spotlight router redundancy, configured VLANs, VPNs, and LSP Paths.

  NOTE
  LSP Path spotlighting is not available if you do not have MPLS Manager installed. VPN spotlighting is not available if you do not have VPN Manager installed.

- Copy selected items to the paste buffer so that you can paste them to another OneClick field or another application.
- Export the contents of the selected Topology view to a file.
- Adjust the Topology tab view for the current session only by zooming in or out.

  NOTE
  Users with administrative privileges also have access to editing tools in the Topology toolbar. For more information, see the Modeling and Managing Your IT Infrastructure .

Neighbors Toolbar

The Neighbors toolbar appears in the Neighbors tab in the Component Detail panel. The Neighbors toolbar functions like the Topology tab toolbar. However, it lacks a Spotlight button.

OneClick Status Bar

The Status bar is at the bottom of the OneClick Console and provides the following functionality:

- Displays information about the OneClick infrastructure. For example, you can see the connection status of the servers and services that let OneClick provide accurate, real-time network information.
- Lets you view messages from OneClick administrators.
- Identifies the username that is used to log in to the current OneClick session, and the name of the OneClick server to which the current client is connected.
- Lets you change your password using a "Change Password" link.

Using and Customizing OneClick

Change Your OneClick Password

You can change your OneClick password from the OneClick home page or the status bar in the OneClick Console.

Follow these steps:

1. Navigate to *one* of the following locations:
   – The bottom of the OneClick home page.
   – The status bar at the bottom of the OneClick Console.
2. Click the 'Change Password' link.
3. Enter your current password, your new password, and reenter your new password.
   Your password is changed.

Favorites Folder

The Favorites folder is something all OneClick users can populate and maintain for their own benefit, without administrator assistance.

In the Explorer tab of the Navigation panel, you can add any OneClick element below the landscape level to your Favorites folder by right-clicking the element and choosing Add To, Favorites. You can also add Global Collections to your favorites by right-clicking your Favorites folder and choosing Add Collections.

To remove an element from the Favorites folder, right-click the element within the Favorites folder and choose Remove.

> **WARNING**
> If you right-click an element and select Delete, the element is not only removed from the Favorites folder, but some models can also be deleted permanently from the system. For more information, see the Modeling and Managing Your IT Infrastructure .

You can create subfolders by right-clicking Favorites (or a subfolder within Favorites) and selecting New Folder. Use the right-click menu to cut, copy, paste, rename, and delete subfolders.

Set SPECTRUM_BROWSER Variable

By default, OneClick uses the Mozilla Firefox browser on Linux systems. For Windows systems, OneClick uses the default browser as defined on the system. You can override the default OneClick settings with the SPECTRUM_BROWSER environment variable.

Define SPECTRUM_BROWSER as part of your environment. Include the full path for the command that opens the browser of your choice. Use a placeholder to specify the URL in the SPECTRUM_BROWSER variable using {0} (<*full_path_browser*>/firefox.exe {0}).

When you click a link in OneClick, The URL link replaces the {0}.

The SPECTRUM_BROWSER variable overrides other platform or system browser selection variables.

Set OneClick Preferences

The Set Preferences dialog lets you customize your view of OneClick. You can set preferences in OneClick for a number of categories and add-on applications such as General settings, the Alarms tab, and the Explorer tab. The Set Preferences dialog provides access to these settings. When you select the top-level preferences group in the Set Preferences dialog, all available preferences and the tools to edit them appear.

Other preferences that are only available to administrators can be set for all users or for categories of users.

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the folder for the individual preference or preference group that you want to change in the Name column.
3. Set new values for the selected preference in the right panel as desired.

   > **NOTE**
   > If Make Changes Permanent is selected at the bottom of the dialog, any preferences that you set become your default settings. If you clear this option, your changes only apply to the current session.
4. Click Apply.
5. Click OK.
   The preferences are set, and the Set Preferences dialog closes.

Alarms Tab Preferences

Use the Alarms Tab in the Set Preferences dialog to specify settings for OneClick alarms. Alarm preferences and categories available for modification include the following attributes:

- **Acknowledge When Assign**
  Specifies whether to auto-acknowledge alarms when assignments are made.
- **Alarm Filter**
  Sets the filter that is used for all displayed alarms tables. Click Set Alarm Filter to access the Alarm Filter dialog.
- **Alarm Notification**
  Specifies settings for alarm popup alerts and sounds:
  - **New Alarm Popup Alert**
    Specifies whether you see a popup alert for new alarms. You can also specify the duration and transparency of the popup.
  - **New Alarm Sound**
    Enables or disables sound notifications for new alarms. Sound notification is a male, English-speaking voice announcing the number and severity of alarms when they are generated.
- **Alarms Table**
  Specifies settings for how the alarms table displays including column order, available columns, sorting, and font.
- **Default Alarm Snooze**
  Specifies the default alarm snooze time. The value has to be greater than zero and less than 24 hours.
- **Email Subject Templates**
  Specifies the available templates that can be included in the Subject heading of an email message.
- **Email Templates**
  Specifies the available templates that can be included in an email message.
- **Expert Clear**
  Suppresses confirmations for clearing selected alarms.
- **Show secondary when in maintenance**
  Specifies whether to show secondary alarms for a device that is in maintenance mode.
- **Trouble Ticket URL**
  Specifies a URL in which to enclose the trouble ticket ID. Set the URL for a trouble ticket management system at your organization. The ticket number for an alarm appears as a hyperlink that opens a Web browser to the trouble ticket system URL. The trouble ticket ID can be substituted for the URL at run time by specifying “{0}” in the URL string. The following example shows this substitution:
  ```
  http://acme/ticket?id={0}
  ```

Display Initial and Suppressed Alarms

> **WARNING**
> Displaying Initial and Suppressed alarms is not recommended in OneClick. These alarms can create a significant amount of network traffic.

If the Disable Initial Alarms and Disable Suppressed Alarms settings for the Virtual Network Machine (VNM) managing your network are disabled, you can view initial and suppressed alarm conditions. Only users with OneClick administrator privileges can change these settings. Go to the Disable Initial and Suppressed Alarms attributes in the Alarm Management submenu for the VNM.

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Alarms Tab folder, select Alarm Filter, and click Set Alarm Filter.
   The Alarm Filter dialog opens.
3. Click Add.
   The Enter Filter Name dialog opens.
4. Enter a name for the new alarm filter and click OK.
5. Click the Severity tab in the Alarm Filter dialog.

6. Select the Initial and Suppressed alarm categories and click to move them to the Show list.
   Click OK.
7. The Alarm Filter dialog closes.
8. Click OK.
   The Set Preferences dialog closes.
9. Right-click the Name column header in the Explorer tab.
   The Table Preferences dialog opens.
10. Select the Initial Alarm Count and Suppressed Alarm Count check boxes.
11. Click OK.
    Initial and Suppressed alarms are displayed in OneClick.

Events Tab Preferences

Select Events in the Set Preferences dialog to set preferences for the Events tab. The following preferences are available for customization:

- **Default Time Interval**
  Specifies the default time interval that is used to retrieve events for display in the Events tab. OneClick uses this value initially to display events for a model. You can change this value using the Event Filter dialog.
- **Email Subject Templates**
  Specifies the available templates that can be included in the Subject heading of an email message.
- **Email Templates**
  Specifies the available templates that can be included in an email message.
- Events Table
  - **Columns**
    Specifies the columns of information to display in the Events table.
  - **Font**
    Specifies the font family and type size used in the Events table.
  - **Sort**
    Specifies the default sorting methodology for the Events table.
- **Filtered Event Types**
  Specifies the types of events to exclude from the Events table.
- **Show events for subcomponents**
  Specifies whether to show events for the subcomponents of the selected model in the Events tab. For example, ports are subcomponents. OneClick uses this value to display events for a model. You can change this value in the Event Filter dialog.

Exclude Event Types

You can exclude event types from displaying in the Events table.

How to Add Filtered Event Types to the Excluded Event Types List

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Events Tab folder in the Name column and click Filtered Event Types.
3. Click Browse under the Excluded event types list.
   The Select Event Type dialog opens displaying all the available event types.

   NOTE
   If you know the event code for the event type to exclude, enter it in the Filter box beneath the list of excluded event types and click Add.

4. Select the desired event from the Select Event Type dialog and click OK.
   The Select Event Type dialog closes. The event code appears in the text box beneath the list of excluded event types.
5. Click Add.
   The event type is added to the Excluded event types list.
6. Click Apply in the Set Preferences dialog.
   The event types you selected are now excluded and are not displayed in the Events table.

How to Remove Filtered Event Types from the Excluded Event Types List

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Events Tab folder in the Name column and click Filtered Event Types.
3. Select the excluded event type that you want to remove from this list.
4. Click Remove.
5. Repeat for other event types that you want to include in the Events table.
   The event types that you selected are again displayed in the Events table.

Email Templates

OneClick contains email templates that you can use to email alarms or events. These email templates let you automatically include specific values from the related alarm or event in your email messages. You can modify existing email templates from either the Preferences dialog or the email message dialog itself.

The following types of email templates are available in OneClick:

- **Subject Templates**
  Specifies the fields to include in the subject line of the email messages that use this template.
- **Message Templates**
  Specifies the fields to include in the body of the email messages that use this template.

Create Email Templates

You can create new email templates by editing existing email templates.

> **NOTE**
> The following procedure describes how to create email templates for alarms. The same steps apply to setting up email templates for events. For more information, see Events Tab Preferences.

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Alarms Tab folder in the Name column. Take one of the following steps:
   – Click Email Templates
   – Click Email Subject Templates
3. Select a template from the Templates drop-down list.
4. Click Edit to modify the selected template.
   The Edit Template dialog opens.
5. Enter a name for this new template in the Save As field.
6. Select the information that you want to display in the new message template.
   Each option corresponds to a column in the alarm.
7. (Optional) Click Move Up or Move Down to change the order in which the information appears in the message.
8. Click OK when you have finished creating the template.

The new template appears in the Templates drop-down list.

Modify Email Templates

You can modify existing email templates.

> **NOTE**
> The following procedure describes how to modify email templates for alarms. However, the same steps apply to setting up email templates for events.

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Alarms Tab folder in the Name column, and take one of the following steps:
   – Click Email Templates.
   – Click Email Subject Templates
3. Select a template from the Templates drop-down list.
4. Click Edit to modify the selected template.
   The Edit Template dialog opens.
5. Select the information to display in the message template.
6. (Optional) Click Move Up or Move Down to change the order in which the information appears in the message.
7. Click OK when you have finished modifying the template.
   The modified template is now available in the Templates drop-down list.

General Preferences

This section describes the general preferences available in the Set Preferences dialog. Depending on your access rights, you may not have access to all of the following settings.

- **SNMP Community Strings List**
  Lets you edit the stored SNMP community strings list. Use this setting to add SNMP community strings to the list, remove stored SNMP community strings that were typed incorrectly, or clear the entire list.

  > **NOTE**
  > The OneClick administrator can lock this preference.
- **Default Field Font**
  Specifies the default font that is used for all field views in the Information panels.
- **Default Table Font**
  Specifies the default font used in all OneClick tables. This setting can be overridden for a specific table by using the Table Preferences dialog.
- **Email Address List**
  Specifies the email addresses available from the To/Cc fields in Mail dialogs. You can add and remove addresses as needed. Also, any email address that you type manually into a Mail dialog in OneClick is automatically saved to this list. You can also add names along with the email address using the following format: *<RecipientA Name>*:*<RecipientA Email Address>.*
- **Locale**
  Specifies the regional locale that is used to format dates, time, and numbers. This setting overrides the operating system setting. You can maintain the same locale setting independent of the system where you are logged on.

  > **NOTE**
  > Restart the OneClick client to apply this setting.
- **Look and Feel**
  Specifies the look and feel for the OneClick client. The default setting is the native look and feel for the system running the client, such as Windows. If you choose to override the system default, OneClick attempts to use the same look and

feel setting independent of the system you are logged on to. If the system does not support the specified look and feel, OneClick uses the system default.

NOTE
Restart the OneClick client to apply this setting.

- **New Message Sound**
  Specifies whether there is a sound indicator when you receive a new message from OneClick administrators.
- **Scrollbar Increment**
  Specifies the amount that each scrollbar adjusts to when you click the scrollbar arrow.
- **Time Format**
  Specifies the time format in OneClick as either 12-hour or 24-hour.
- **Time Zone**
  Specifies whether to use Coordinated Universal Time (UTC) to display dates and time in OneClick. By default, OneClick uses the local system time zone.
- **Tool Tip Delay**
  Specifies the amount of time, in seconds, that your cursor remains over a button, field, or other component in the OneClick interface before a tooltip displays.

Explorer Tab Preferences

The following Explorer preference options are available in the Set Preferences dialog in the Explorer Tab section.

- **Expansion Limit**
  Displays a warning when you expand an Explorer node whose number of elements exceeds the limit specified.
- **Explorer Table**
  Specifies the following preferences for the Explorer tab:
  - **Columns**
    Specifies the Alarm category columns that appear in the Explorer.

    NOTE
    For more information, see Display Initial and Suppressed Alarms.
  - **Fonts**
    Specifies the font and type size that are used to display text in the Explorer.
  - **Sort**
    Specifies the default sorting method for the Explorer.
- **Initial View**
  Specifies how the Explorer tab appears in the OneClick Console each time you start the application.

Expand and Collapse the Explorer View

You can collapse the hierarchy in the Explorer tab with one click.

Follow these steps:

1. Click the Explorer tab.
2. Select the node that you want to collapse, right-click, and select Collapse All.
   Everything beneath the selected node is collapsed to the level of the selected node.
3. (Optional) Select a node that you want to expand, right-click, and select Expand All.
   Everything beneath the selected node is fully expanded.

Locater Tab Preferences

This section describes the Locater tab preferences available in the Set Preferences dialog. Depending on your access rights, you may not have access to all the following settings.

- **Prompt for Landscapes**
  Specifies whether to prompt you for the landscape you want to search when executing a search from the Locater tab.
  Default: Yes
  – **Results Table**
  – **Columns**
    a. Specifies the columns of information to display in the table.
  – **Font**
    a. Specifies the font family and type size used in the table.
  – **Sort**
    a. Specifies the default sorting methodology for the table.

Topology Tab Preferences

This section describes the Topology tab preferences that are available in the Set Preferences dialog. Depending on your access rights, you may not have access to all the following settings.

- **Annotation Font**Specifies the default font settings for topology annotation text. You can modify font, style, size, and background and foreground colors.
- **Grid Properties**
  Affect the topology view in Edit mode. Only administrators can place OneClick topologies into Edit mode.
- **Initial Zoom**
  Affects the default view of the Topology tab. Select from the following options:
  – The system default zoom percentage. The OneClick administrator sets the value.
  – A custom zoom percentage.
  – Fitting the topology into a visible window with the zoom level at or above a minimum setting.
- **Model By Type**
  Specifies the model types that are available from the Model by Type dialog. Model types are available when you manually create models by model type in the Topology tab.

  NOTE
  For more information, see Modeling and Managing Your IT Infrastructure .
- **Performance**Specifies whether to enable anti-aliasing when rendering pipes.
  Default: Yes
- **Show Off Page Reference Models**
  Specifies whether off-page reference models are displayed in the Topology tab.
- **Show Pipe Label**
  Specifies whether to show pipe (connection) labels in the Topology tab.
  Default: No
- **Telnet/SSH Connection Type**
  Specifies the connection type for telnet and ssh.
  Default: Connect to the device through OneClick web server and SpectroServer
- **Telnet/SSH Terminal Type**
  Sets the terminal type for telnet and ssh.
  Default: vt100
- **VLAN Duplicates**
  Specifies whether to show VLAN duplicate IDs even if the same device appears more than once in a Global Collection.

  NOTE
  If you change any of the Topology preferences, and ‘Make Changes Permanent’ is selected, the changes are in effect each time you use OneClick.

Table Preferences

You can change the way columns appear in OneClick by right-clicking a column heading. In the Table Preferences dialog, you can select the columns that you want to display. The available choices vary depending on the OneClick application you are using.

You can resize a column by clicking and dragging a column header to the left or right. You can also resize a column to fit the longest text string. Double-click the column header boundary to the right of the column. Click a column heading to sort a list by the attribute values in a particular column.

You can also set table preferences in each of the Set Preferences dialog categories that support tables.

View Row Details

You can view more information about the rows in OneClick Console lists from the Row Details dialog. The Row Details dialog displays the value for each available field. Values for fields that are not currently displayed in the list are also included.

Follow these steps:

1. Right-click the desired row item and select Row Details.
   The Row Details dialog opens.
2. (Optional) Click another row in the same list.
   The Row Details dialog displays values for the newly selected row.
3. Click Close when you have finished reviewing row details for items in this list.

Filter OneClick Lists

You can filter the items that are displayed in OneClick lists using the Filter text box. A Filter text box appears in many OneClick panels and tabs. The filtering feature lets you enter text to filter the data that appears in columns and lists. As you type in the Filter text box, the list displays or hides only the items that contain the text you entered. You can include or exclude items by selecting Show or Hide from the Filter drop-down list.

Select Landscapes

A DX NetOps Spectrum landscape is the network view of a specific DX NetOps Spectrum server. In a distributed DX NetOps Spectrum environment, multiple DX NetOps Spectrum servers are used to manage the network. Each server has its own view of the network. Depending on how your DX NetOps Spectrum environment is configured, you may have access to more than one DX NetOps Spectrum server.

As such, the ‘Select Landscapes to Search’ dialog can appear when you perform certain actions. This dialog asks you to select those landscapes on which you want to perform the actions. This dialog lists the included landscapes on the left, and the excluded landscapes on the right. If you have only a single landscape, that single landscape appears in the list of included landscapes.

OneClick Panels

By default all three panels appear in the OneClick interface, however, you can modify your view of the panels as needed.

- **View menu:** Each panel is listed in the View menu. If the panel has a checkmark next to it, it is viewable. If the panel does not have a checkmark next to it, it is not currently viewable in the OneClick Console interface.
- **Docking and Cloning:** Each OneClick panel can be docked, undocked, or cloned using the following buttons:

- 
  Undock: Click to undock a OneClick Console panel.
- 
  Dock: Click to dock a previously undocked OneClick Console panel.
- 
  Clone: Click to clone a OneClick Console panel.

Dock and Undock Panels

Undocking a panel opens it in its own window, at the same time removing it from the main OneClick Console view. Undocking panels can help you to make better use of your screen space.

You can dock an undocked panel by clicking Dock or by using the View menu. To display panels that you have closed, click the View menu and select the panel to display.

Clone Panels

Click Clone in either the Contents panel or the Component Detail panel to open a separate window containing another instance of the panel. Clicking Clone in the Contents panel while the Component Detail panel is visible opens a new window containing instances of both panels.

Use cloning to view more than one area of your network. The display of information of a cloned window is not affected when you navigate away from the original source to view other network assets.

Copy Text from the Component Detail Panel

You can copy text from the Component Detail panel.

Follow these steps:

1. Select the text in the Component Detail panel you want to copy by taking *one* of the following steps:
   - Place the cursor over the beginning of the range of text you want to copy, press and hold the left mouse and drag the cursor across the range of text.
   - Double-click a word that you want to select, or triple-click to select an entire line of text.

   The text range is highlighted.
2. Take *one* of the following steps with the text range highlighted:
   - Right-click and select Copy.
   - Press Ctrl+C.
3. Paste the text into the writable field in OneClick or in another document or email program.

Insert URLs in OneClick

You can insert URLs into writable fields in the Component Detail panel.

Follow these steps:

1. Find the field in the Component Detail panel where you want to add a URL.
   For example, select the Notes field from the General Information submenu and click set.
2. Enter the text and the URL to include in the note. For example:
   Issue is described at http://internal.info.xyz.com
3. Click Save.

NOTE
Including spaces or commas in a URL can cause some browsers to have problems locating the web resource. To include spaces or commas in a URL that you are including in the Component Detail panel, use the hexadecimal equivalent and proper encoding:

- For a comma, use **%2C**
- For a space, use **%20**

NOTE
The OneClick administrator can provide more information about URL formatting.

Monitoring Your Network with OneClick

This section contains the following topics:

Global Collections

Global Collections help organize operator views of network devices that span containers or landscapes. OneClick administrators create Global Collections, and operators monitor Global Collections by selecting them in the Explorer tab, and then viewing the Alarms, Events, and List tabs in the Contents panel.

A Global Collection can be empty for the following reasons:

- Collections are not configured.
- Your user account does not have access to existing collections.
- Dynamic collections do not currently contain any models.

OneClick administrators maintain Global Collections and grant or restrict access to them.

NOTE

When the **Global Collections, List tab** contents search exceeds a pre-defined number of models, a relevant dialog box stating: **"There are <number> models to be displayed. This may take time. Would you like to proceed?"** appears. If you select **No**, the **List tab** and other tabs for that **Global Collection** will remain empty. To initiate the display of its contents, switch back and forth to any other container item (with **List Tab** enabled) in **Explorer Tab** like another **Global Collection**, **Cluster Manager**, **Policy Manager** etc. The pre-defined threshold is configurable by modifying **ModelIdCountThreshold** parameter value in **<SPECROOT>\tomcat \webapps\spectrum\WEB-INF\web.xml** on **OneClick Server** and restarting **OneClick Server**.

NOTE
For more information, see the Modeling and Managing Your IT Infrastructure .

Network Searches

Searching your network with DX NetOps Spectrum is a fundamental network management task. As an operator, you can run predefined searches using the Locater tab to identify specific models or groups of models on your network. You can choose from several categories of search criteria when performing a search. For example, not only can you search for network assets, but you can also search for configuration items, such as schedules. You can determine which schedules are in effect and can determine the models to which a schedule is applied.

Some predefined searches that are available from the Locater tab include the following objects:

- All Devices
- Devices, By IP Address
- All Application Models
- All SNMPv3 Devices
- All Schedules

If you are operating in a Distributed SpectroSERVER (DSS) environment, some searches require you to select the landscapes to include in your search using the landscape selection dialog.

NOTE
For more information, see the OneClick Administration.

Search Your Network

You can run predefined searches of your network from the Locater tab.

Follow these steps:

1. Click the Locater tab in the Navigation panel.
2. Find the search that you want to run in the Locater tab and do *one* of the following actions:
   - Double-click the search.
   - Select the search and click the search icon to launch the selected search 

   If no further information is required, the search runs and the results are displayed in the Results tab. If more information is required, the Search dialog opens.
3. Take *one* of the following steps:
   - Type the value you want to search for.
   - Select the value that you want to search for from the drop-down list:

   The value that you want to search for is now listed in the Search dialog.
4. (Optional) Select the Ignore Case checkbox for a search that is not case-sensitive.
5. (Optional) Click the List button to search for multiple values for a single attribute.
6. Click OK.
   The search runs. The results are displayed in the Results tab of the Contents panel.

NOTE

When the search results exceed a pre-defined number of models, a relevant dialog box stating: **"There are <number> models to be displayed. This may take time. Would you like to proceed?"** appears. This pre-defined threshold is configurable by modifying **ModelIdCountThreshold** parameter value in **<SPECROOT>\tomcat\webapps\spectrum\WEB-INF\web.xml** on **OneClick Server** and restart OneClick Server.

Search for Multiple Values for a Single Attribute

You can specify a list of values to search on using the List button in the Search dialog after executing a search.

> **NOTE**
> The List button is not available for regular expression searches or for 'negative' searches, such as Does Not Contain, Does Not Start With, Does Not End With, Not Equal To.

Follow these steps:

1. Run the desired search for which you want to enter a list of values.
   The Search dialog opens.
2. Click List.
   The List of Values dialog opens.
3. Do *one* of the following actions:
   – Type the values that you want to search for in the List of Values dialog.
   – Click Import, select the file that contains the values you want to search for, and click Open.

   > **NOTE**
   > The values that you enter are logically OR'ed together. For example, if you enter "router 1, router 2, router 3", the search returns "router 1 OR router 2 OR router 3."

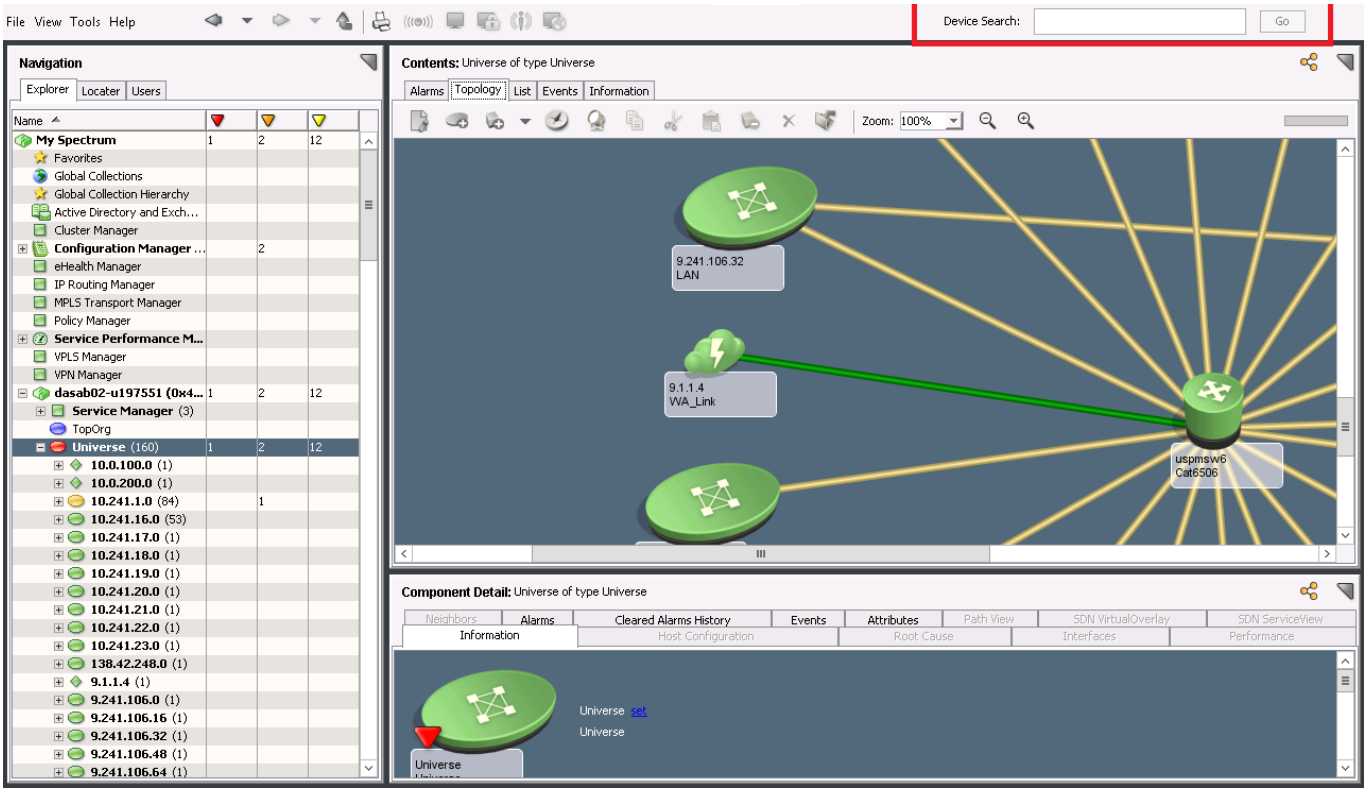
   The values that you are searching for are displayed in the List of Values dialog.
4. (Optional) Select the Ignore Case checkbox.
   The search is now case-insensitive.
5. Select one of the following characters from the Delimiter drop-down list, depending on which delimiter you are using to separate each value in the list:
   – <new line>
   – <space>
   – ,
   – ;
6. Click OK.
   The List of Values dialog closes.
7. Click OK
   The search runs and results are displayed in the Results tab in the Contents panel.

About OneClick Quick Device Search

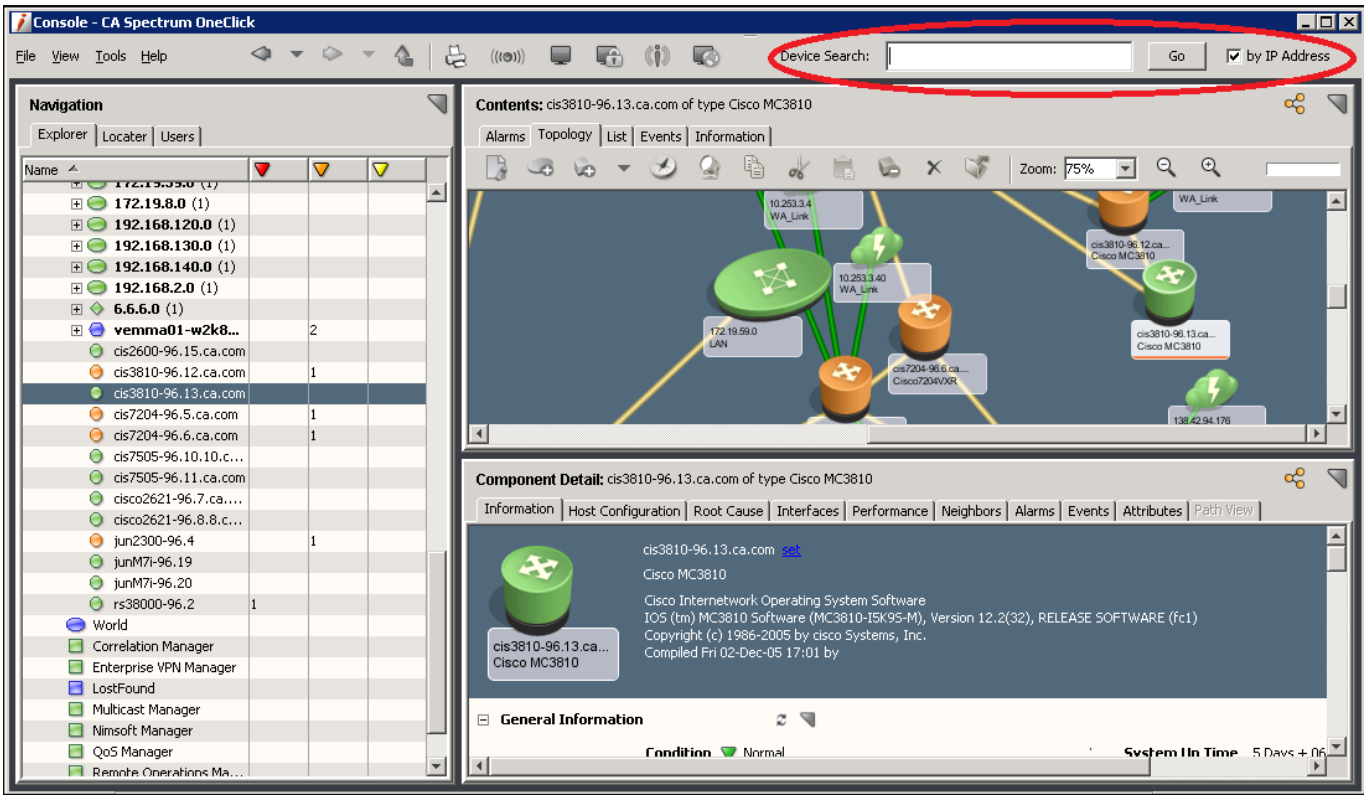
OneClick allows you to directly find a device model without going to the Locater Search. Enter the full IP address of the device in the device search bar of the OneClick console. You can also find a device by its redundant IP addresses, if that device has **Redundancy Preferred Addresses**. To find a device by its full name or a string, uncheck the "by IP Address" check box and enter the full name or a string.

From the 10.2.2 release, the Device Search functionality is enhanced to find a device by its full name, IP Address or a string.

The following image shows how the device search bar looks like (from 10.2.2 release):



The following image shows how the device search bar looks like (till 10.2.1 release):



Searching by a String

A search result that includes a list of all devices containing the matching string in their names is displayed. The search result includes device name, IP address, and the device landscape.
When you double-click the required device from the search result, the device is highlighted in the navigation panel.

Searching by Full Device Name or IP Address

The exact device is highlighted in the navigation panel. In a DSS environment when the device exists in multiple landscapes, you get the search result with the same information.

Select the device belonging to the required landscape.

In both cases, alarms and other information of the device are displayed in the Contents and Component Detail pane.

NOTE

Ensure to enter a valid IP address when you find by IP address. Only a valid IPv4 address enables the search.

Searching by a String, Full Device Name or IP Address (from 10.2.2 release)

From the 10.2.2 release, the Device Search functionality is enhanced to find a device by its full name, IP Address or a string. Enter the full name, IP Address or a string and click Go.

A search result that includes a list of all devices containing the matching string in their names is displayed. The search result includes device name, IP address, and the device landscape.
When you double-click the required device from the search result, the device is highlighted in the navigation panel.

In a DSS environment when the device exists in multiple landscapes, you get the search result with the same information. Select the device belonging to the required landscape.

In both cases, alarms and other information of the device are displayed in the Contents and Component Detail pane.

Manage Alarms

OneClick provides tools to identify and manage the alarms that are displayed in the Alarms tab. Some settings let administrators customize the alarms that are generated in OneClick. Other settings are available to let operators manage the alarms that they see in OneClick.

Alarm Filter Dialog

The Alarm Filter dialog lets you create alarm filters to determine how alarms appear in your OneClick Alarms tab. The dialog contains the following tabs:

- **Landscape**
  Defines the landscapes for which to display alarms.
- **Severity**
  Defines the alarm severities that are applied to this filter.
- **State**
  Specifies the states that you want to show. Options are as follows:
  - **Acknowledged State**
    Acknowledged, Not Acknowledged, Both.
  - **Clearable State**
    Clearable, Not Clearable, Both.
  - **Primary/Secondary State**
    Show Primary For Containers/All For Devices, Show Only Primary, Show All Alarms.

    NOTE
    Select Both under Acknowledged State or Clearable State to see both options for that state.
  - **Symptoms**
    Specifies whether to show alarms that are determined to be the cause of symptoms.
- **Network Address**
  Specifies a range of network addresses for which to show or hide alarms.
- **Assignment**
  Specifies which assigned troubleshooters can view alarms. Please note that all troubleshooters will show if you have access to the Alarm Filter.
- **Model Class**
  Specifies the model classes for which you do not want to display alarms.
- **Model Type**
  Specifies the model types for which you do not want to display alarms.
- **Alarm Type**
  Specifies the alarm types for which you do not want to display alarms.
- **Attribute**
  Attribute: Select an attribute of a device to filter.
  Comparison Type: Specifies how to compare the value of the attribute ID with the value in the Attribute Value field. Only the comparison types appropriate to the data type of the attribute are displayed.
  Ignore Case: Select the Ignore Case check box if you do not want the comparison to be case-sensitive. This selection is only enabled when it is appropriate for the data type of the attribute that you selected.
  Attribute Value: Enter or select the desired attribute value that you want to use in the comparison.
  The Show Advanced button in this tab lets you use complex attribute filtering.

The following buttons are available in the Alarm Filter dialog from every tab:

- **Clear Tabs**
  Clears all fields in all tabs, and clears any filters that are set in the tabs.
- **Clear All**
  Clears all fields in all tabs and in the Advanced filter section. If you click Clear All and click OK, all alarms appear because no filters are set.
- **Show Advanced**
  Opens the Advanced Filter panel.
- **Available Filters**
  Contains saved filters so that you can apply, edit, or delete them.
- **Add**
  Creates an alarm filter using the Enter Filter Name dialog. The new alarm filter displays in the Available Filters drop-down list.
- **Delete**
  Removes the selected filter from the Available Filters list.

Filter Alarms

You can determine how alarms appear in your OneClick view using alarm filters created in the Alarm Filters dialog.

To open the Alarm Filter dialog, do *one* of the following actions:

- In the Set Preferences dialog, select Alarm Filter from the Alarms Tab folder and click Set Alarm Filter.
- Click the Filter icon (in the Alarms toolbar) 

You can create alarm filters to customize which alarms OneClick displays in the Alarms tab. You can also create advanced alarm filters, as described in Advanced Alarm Filter.

Multiple Alarm Filters

You can create multiple alarm filters to screen for specific alarm conditions on specific devices, containers, or other models. You can use these filters to view different alarm conditions simultaneously in multiple Alarm views. Create multiple Alarm views by cloning the Component Detail or Contents panel, and displaying the Alarm tab in each panel. Select a different alarm filter that you have created to troubleshoot or watch for specific conditions in each Alarm view.

Create and Save Alarm Filters

You can create and save alarm filters so that you can retrieve and use them later.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Click the Filter icon (in the Alarms toolbar) 
   The Alarm Filter dialog opens.
3. Click Add.
   The Enter Filter Name dialog opens.
4. Enter the name of the filter you want to create and click OK.
5. Click the tab that you want to use to configure the filtering criteria. These tabs are described in Advanced Alarm Filter.
6. Click Apply.
   The filter settings are saved and the filter is applied to the Alarms tab view.
7. Click OK.

The alarm filter is now created and saved and the Alarm Filter dialog closes.

Use Advanced Alarm Filtering

The Advanced Filter provides more flexibility when compared to simple filtering because it lets you make multiple selections of the types of filters you want to apply. Simple filtering, on the other hand, simply groups all filter selections and applies them in a linear fashion, (for example Filter by Landscape *and* Secondary Alarms *and* Model Type). In simple filtering, all criteria must be met; in advanced filtering, any of the criteria you define can be met.

Advanced alarm filtering has two requirements:

- At least two sets of filter criteria.
- Alarms are filtered in an “either/or” fashion.

For example, with advanced filtering, you can display red (Critical) HubCat5000 model types or yellow (Minor) Pingable model types. In this case, neither red (Critical) Pingable model types nor yellow (Minor) HubCat5000 model types show up in the Alarms list. Simple alarm filtering does not make such a fine distinction. Instead, all Minor and Critical Pingables and all Minor and Critical HubCat5000 display with simple filtering.

This procedure continues the example and describes advanced filtering for critical HubCat5000 model types or minor pingable model types.

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Alarms Tab folder in the Name column and click Alarm Filter, Set Alarm Filter.
   The Alarm Filter dialog opens.
3. Click the Model Type tab and hide all model types except HubCat5000 models by doing the following actions:
   a. Click the double-right arrow button to move all model types from the Show list to the Hide list.
   b. Type **HubCat5000** in the Filter field on the right side of the dialog.

      NOTE
      Scroll down to see the Filter field.

   c. With the HubCat5000 model type selected, click the single-left arrow button.

   HubCat5000 is moved to the Show list.
4. Click the Severity tab and move Major and Minor alarms to the Hide list.
5. Click Show Advanced.
   The Alarm Filter dialog expands to display the Advanced Filter section.
6. Click Add in the Advanced Filter section.
   Your selections are placed into the Advanced Filter panel; the panel now displays the following filter:
   ```
   Severity (Hide Suppressed, Major, Minor, Initial, Maintenance) AND Model Type (Show HubCat5000)
   ```
7. Click Clear Tabs.
   The filters that you just set are cleared.

   NOTE
   The filter that you created still appears in the Advanced Filter panel, but now you are going to add to it.
8. Click the Model Type tab and move all model types to the Hide list except Pingable.
9. Click the Severity tab and move Major, Critical, Initial, and Suppressed alarms to the Hide list.
10. Click Add in the Advanced Filter panel to move your selections to the Advanced Filter panel.
    The panel now displays the following filter:
    ```
    Severity (Hide Suppressed, Major, Minor, Initial, Maintenance) AND Model Type (Show HubCat5000)
    OR Severity (Hide Critical, Suppressed, Major, and Initial) AND Model Type (Show Pingable)."
    ```
11. Click Add next to the Available Filters list.
    Your settings are saved and the Enter Filter Name dialog opens.

12. Enter a name for the filter you want to save.
13. Click OK.
    The Enter Filter Name dialog closes and the filter you saved appears in the Available Filters drop-down list.
14. Click OK.
    The Alarm Filter dialog closes.
15. Click OK.
    The Set Preferences dialog closes.

Refresh

Starting from the 10.2.3 release, a new option (Refresh) is available in the Alarms tab to refresh the alarm filters without logging out of the OneClick. When new alarm filters are created and applied to a user or group of users, the 'Refresh' button becomes active. You can click this button to update the Available Filters drop-down list with newly created and applied advanced filters.

System Cleared Alarms

System cleared alarms are alarms that are cleared automatically by the system without user acknowledgment. The result is a device that returns to a normal (green) condition. You can track these alarms as part of network monitoring.

Enable system cleared alarm tracking on a per-model basis. With tracking enabled, you can locate these system cleared alarms from the Locater tab by running the Devices > All Devices with System Cleared Alarms search. You can then acknowledge them as needed.

> **NOTE**
> This search only finds devices that had an alarm that was cleared by the system. An aged out alarm which is cleared displays the "System.Alarm_AgeOut" value in its corresponding "Cleared By" column under "Cleared Alarms History" tab. The corresponding cleared event also displays this value in its "Cleared By" column under Events tab.

Example: System Cleared Alarms

The following example describes two devices, each with tracking enabled.

Device A has one critical alarm. The system clears the critical alarm; the device returns to normal condition and is found by the Devices, All Devices with System Cleared Alarms search.

Device B has one critical alarm and one major alarm. The system clears the critical alarm, but not the major alarm. Because the condition is *not* normal, the search does not find the device.

Track System Cleared Alarms

You can track system cleared alarms as part of monitoring your network.

How to Enable System Cleared Alarm Tracking

Follow these steps:

1. Select the model for which you want to track system cleared alarms.
2. Right-click and select Track System Cleared Alarms.
   Any system cleared alarms that occur on this model are now tracked.

How to Locate System Cleared Alarms

Follow these steps:

1. Click the Locater tab in the Navigation panel.
2. Double-click the Devices, All Devices with System Cleared Alarms search.
   If additional input is not required, the search runs immediately; the search results appear in the Contents panel.

All system cleared alarms are displayed.

How to Acknowledge a System Cleared Alarm

Follow these steps:

1. Select the model with the system cleared alarm on it.
2. Right-click and select Acknowledge System Cleared Alarms.
   The alarm is acknowledged.
   The model no longer appears in the Devices, All Devices with System Cleared Alarms search.

How to Disable System Cleared Alarm Tracking

Follow these steps:

1. Select the model for which you want to disable system cleared alarm tracking.
2. Right-click and select Ignore System Cleared Alarms.
   Any system cleared alarms that occur on this model are no longer tracked.

Update Alarm Attributes

By default, DX NetOps Spectrum lets you update the following two alarm attributes from the Alarms tab:

- Alarm Status
- Trouble Ticket ID

Updating an attribute of an alarm lets you provide more information about the alarm to other users. For example, update the status of an alarm to let other operators know how the situation related to an alarm is being handled.

> **NOTE**
> You can also define your own custom alarm attributes as needed. For more information, see OneClick Customization .

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Select the alarm that you want to update.
3. Click the update alarm attributes
   icon 
   The Update Alarm Attributes dialog opens.
4. Select the attribute that you want to update from the Attribute drop-down list.
5. Type the new value for the attribute in the Attribute Value field.
6. Click OK.
   The Update Alarm Attributes dialog closes. The alarm attribute is updated.

Snooze Alarms

You can snooze alarms for any period shorter than 24 hours. The Snooze feature is helpful, for example, if some alarms are not as critical as others. Snooze an alarm to postpone action on a less critical issue so that you can focus on the more serious alarms.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Select the alarms that you want to snooze.
3. Right-click the selected alarms, select Snooze, and select *one* of the following options:

- Snooze Selected Alarms.
- Snooze Selected Alarms for All (You must have the Administrator privileges to use this option)
- Snooze Alarms From Corresponding Sources.

The Snooze Alarms dialog opens.

4. Take the following steps:
   a. Complete the fields to indicate how long the alarms remain snoozed.
   b. (Optional) Select the Save Current Time as Default check box.
   c. Click OK.

   The alarms that you selected are no longer visible in the Alarms tab and reappear when the snooze time has expired.

Snooze Alarms for All Users

If you have the Administrator privileges, you can snooze alarms for all users.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Select the alarms that you want to snooze for all users.
3. Right-click the selected alarms, select **Snooze**, then select **Snooze Selected Alarms for All Users**.
4. Take the following steps:
   a. Complete the fields to indicate how long the alarms remain snoozed.
   b. (Optional) Select the Save Current Time as Default check box.
   c. Click OK.

   The alarms that you selected are no longer visible in the Alarms tab for all users and reappear when the snooze time has expired.

Unsnooze Alarms

You do not have to wait for the default snooze time to expire before you can view snoozed alarms again. You can unsnooze these alarms whenever you are ready to focus your attention on them.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Click the Unsnooze icon (in the Alarms toolbar) 

   All previously snoozed alarms are visible again in the Alarms tab.

Unsnooze Alarms for All Users

If you have the Administrator privileges, you can unsnooze alarms for all users.

Follow these steps:

1. Click the Alarm tab in the Contents panel.
2. Select the alarms that you want to snooze for all users.
3. Right-click in the Alarms view, select **Snooze**, then select **Unsnooze Alarms for All Users**.

NOTE

The option 'Unsnooze Alarms for All Users' is enabled only when the option 'Snooze Selected Alarms for All Users' is applied to any alarm.

Alarm Troubleshooters

You can assign individuals, named troubleshooters, the responsibility of investigating alarms and solving problems. Troubleshooters are assigned to alarms using the Alarms toolbar. When you assign a troubleshooter to an alarm, they automatically receive an email about the alarm. You can edit the email before it is sent.

Create Troubleshooters

First create troubleshooters before you can assign an alarm to them.

Follow these steps:

1. Click Tools, Utilities, Troubleshooters.
   The Troubleshooters dialog opens.
2. Click Create.
   The Create Troubleshooter dialog opens.
3. In the Create Troubleshooter dialog, do the following:
   a. Enter the name of the troubleshooter and email address.
   b. Select the landscapes to which you are assigning the troubleshooter.
   c. Click OK.
4. To add the troubleshooter to a new landscape, do the following:
5. 1. Select the troubleshooter from the Troubleshooters list.
   2. Click Landscapes.
      Landscapes for Troubleshooter dialog opens.
   3. Select the new landscape from ‘Does not exist in’ list and move it to the ‘Exist in’ list.
   4. Click OK.
      The troubleshooter is added to the selected landscape.
6. Click Close.
   The troubleshooter is now created and you can now assign this troubleshooter to an alarm.

Assign and Unassign Troubleshooters

You can use the Alarms toolbar to assign and unassign troubleshooters to the alarms that are displayed in the Alarms list. Troubleshooters must already exist in OneClick to assign them.

> **NOTE**
> The administrator must configure email services on the OneClick server to enable the sending of notification email messages to the assigned troubleshooter. For more information, see the OneClick Administration .

How to Assign a Troubleshooter and Send a Notification Email

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Select the alarms to which to assign a troubleshooter.
3. Click the Assign Troubleshooter
   icon 
   The Select Troubleshooter dialog opens.
4. Select a troubleshooter from the list.
5. (Optional) Click Edit Mail to edit the message before sending it to the troubleshooter.
6. Click OK.
   The Select Troubleshooter dialog closes. An alarm notification email message is sent to the troubleshooter you selected.

How to Unassign a Troubleshooter

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Select the alarms from which to unassign a troubleshooter.
3. Click the Unassign Troubleshooter icon  .
4. Confirm that you want to unassign the troubleshooter from the alarm.
   OneClick sends an email message to the troubleshooter with information about the change.

View Troubleshooter Assignments

You can display the Assignment column in the Alarms list to see the names of troubleshooters that are assigned to each alarm.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
2. Right-click the column header in the Alarms list.
   The Table Preferences dialog opens.
3. Select Assignment in the Columns tab and click OK.
   The Assignment column now appears in the Alarms list, displaying the names of troubleshooters that are assigned to alarms.

Email Alarms

You can send email messages which contain alarm details to troubleshooters and nontroubleshooters as needed.

Follow these steps:

1. Click the Alarms tab in the Contents panel.
   The Alarms list opens.
2. Select the alarms that you want to send in an email.
3. Click the Email icon  .
   The Mail Selected Alarms dialog opens.
4. Do any of the following actions:
   - Type one or more new recipient email addresses in either the To field or the Cc field, separated by semi-colons. These new addresses are saved to the Email Address List in your General preferences.
   - Use an existing email address by doing the following action:
     a. Click To or Cc.
        The Select Email Address dialog opens.
     b. Select one or more email addresses from the list and click To or Cc.
        The email addresses are added to the To or Cc field in the Select Email Address dialog.
     c. Click OK.
        The Select Email Address dialog closes and the email addresses you selected appear in either the To field or the Cc field in the Mail Selected Alarms dialog.
5. Type a subject in the Subject field, or select a subject template from the drop-down list.
6. Select the message template to use from the Templates drop-down list, or edit the template.
7. Click Send.
   The message is sent.

Manage Events

View events for containers and modeled devices by selecting the container or device in the Explorer tab, and then clicking the Events tab in the Contents panel or the Component Detail panel. You can filter the Events tab using the Event Filter dialog.

Email Events

You can email events using the same steps that you use to email alarms. For details, see Email Alarms.

Event Filtering

You can filter the events displayed in the Events tab by entering text to filter on in the Filter text box. You can also create event filters to save and reuse.

Event Filter Dialog

The Event Filter dialog lets you set more conditions for filtering events. You can access this dialog from the Events tab by clicking

(Filter) in the toolbar, or by right-clicking an event in the Events list and selecting Filter from the menu.

You can filter your current view of the Events list as follows:

- Display Events for a Date and Time Range
- Display Events for a Range of Hours
- Display Events for Ports and Applications
- Exclude and Include Events in the Event Table by Type
- Advanced Event Filter

> **NOTE**
> When you change many of these settings in the Event Filter dialog, the change only applies to the current instance of the Events tab. Default values for the Date/Time and Show events for subcomponents options are applied each time that you select the Events tab for a model. These default values can be set using the Set Preferences dialog (View, Preferences). Default preference values for these and other options can be set globally for all users by the OneClick administrator using the Set Preferences dialog.

Display Events for a Date and Time Range

In the Date/Time section of the General tab in the Event Filter dialog, you can limit the events shown in the Events tab to a particular range by selecting the ‘Show events for a time range’ option. Enter a start date and time for the range. If you do not select an end date and time for the range, OneClick displays all the events starting for that date and time onward. Create an end date and time for the range by selecting the End check box, and entering a date and time.

When you select the ‘Show events for a time range’ option, the Events tab shows the time range for which events are currently being displayed just above the Events list.

Display Events for a Range of Hours

You can show only those events that fall within the range of specific hours.

Follow these steps:

1. Click the Events tab in the Contents panel.

2. Click

(Filter) in the Events tab toolbar.
The Event Filter dialog opens.
3. Select ‘Show events for the last <*X*> hours.’
4. Enter a number in the selection box to indicate how many hours of recent events you want to see in the Events list.
5. Click OK.
The Events list now displays only those events from the past number of hours you specified.

NOTE
When you select ‘Show events for the last <*X*> hours,’ the Events tab shows the time range for which events are currently being displayed just above the Events table.

Display Events for Ports and Applications

You can show events for device model subcomponents including port and application models by selecting the ‘Show events for subcomponents’ option. By default, this option is not selected.

Exclude and Include Events in the Event Table by Type

You can add and remove events that are in the Exclude Event Types List. Events listed in the Exclude Event Types list are not displayed in the Events table.

NOTE
The following procedures only impact the Events tab view in the context in which you perform the task. You cannot save event view settings to use later.

You can exclude event types directly from the Events table.

To exclude event types from being displayed in OneClick, right-click the event that you want to exclude in the Events table and select Exclude from the menu.

The event is removed from the Events table.

How to Exclude Event Types from Being Displayed in OneClick using the Event Filter Dialog

Follow these steps:

1. Click the Events tab in the Contents panel.
2. Click

(Filter) in the Events tab toolbar.
The Event Filter dialog opens.
3. Click the Event Type tab.
4. Do *one* of the following actions:
   – Enter the value for the event type directly in the text field.
   – Click Browse, select the desired event value from the list that appears, and click OK.

   The selected event value is entered in the text field.
5. Click Add.
The event is added to the ‘Excluded event types’ list.

How to Include Event Types in the Events Table

Follow these steps:

1. Click the Events tab in the Contents panel.
2. Click
   
   (Filter) in the Events tab toolbar.
   The Event Filter dialog opens.
3. Select the Event Type tab.
4. Select the event type that you want to display in the Events table from the ‘Excluded event types’ list.
5. Click Remove.
   The event type is removed from the ‘Excluded event types’ list and appear in the Events table when it is generated.

   NOTE
   OneClick administrators can also use the Set Preferences dialog to specify whether any event types are excluded from the Events table.

Create Advanced Event Filters

You can select or create an advanced event filter using the Advanced tab in the Event Filter dialog. The advanced filters that you create are stored and can be reused. To use an existing advanced filter, select one from the Available Filters drop-down list.

How to Create an Advanced Event Filter

Follow these steps:

1. Click the Events tab in the Contents panel.
2. Click
   
   (Filter) in the Events tab toolbar.
   The Event Filter dialog opens.
3. Click the Advanced tab.
4. Select the Attribute from the drop-down list.
5. Select the Comparison Type from the drop-down list.
6. Enter the Attribute Value in the text box.
7. If you selected either Event Type or Model Type Name as the Attribute and you do not know the attribute value, click Browse.
   Either the Select Event Type or Select Model Type dialog opens.
8. Select the desired Event Type or Model Type from the dialog, and click OK.
   The Attribute value appears in Attribute Value field.
9. Click Add.
   The Enter Filter Name dialog opens.
10. Enter a name for the filter, and click OK.
11. Take *one* of the following steps:
    – Click OK to apply the filter and close the Event Filter dialog.
    – Click Show Advanced to continue and create a complex filter by using And/Or relationships between multiple advanced filters.

How to Clear Advanced Event Filters

Follow these steps:

1. Click the Events tab in the Contents panel.

2. Click

(Filter) in the Events tab toolbar.
The Event Filter dialog opens.
3. Click the Advanced tab.
4. Click Clear.
5. Click OK.

How to Delete an Advanced Event Filter

Follow these steps:

1. Click the Events tab in the Contents panel.
2. Click

(Filter) in the Events tab toolbar.
The Event Filter dialog opens.
3. Click the Advanced tab.
4. Select the filter you want to delete from the Available Filters drop-down list.
5. Click

(Delete).
6. Click OK.

Interface Information

You can view information about the interfaces of a device model by selecting the model and selecting the Interfaces tab in the Component Detail panel. The Interfaces tab displays a list of the configured interfaces and subinterfaces for the selected device, along with the parameters defined in this section.

> **NOTE**
> The colors of icons in the Name, Condition, and Status fields have the same meaning as the colors that indicate device model status throughout OneClick.

Not all of the parameters that are listed here appear in the default Interfaces tab view. See Customize Columns for information about displaying hidden columns in tables.

- **Name**
  Specifies the name of the interface.
- **Condition**
  Specifies the contact status for the device, in addition to any alarm conditions in effect for the device model.
- **Status**
  Indicates whether the interface is operational or nonoperational. An interface may be nonoperational for various reasons including being administratively disabled. Some of the possible values include up, down, off, and dormant.
- **Type**
  Identifies the physical layer interface standard that the interface uses, such as Ethernet, SONET, and V.35.
- **Description**
  Describes whether the interface is physical or logical, and the interface ID, such as et.2.1
- **Device Connected**

Specifies the name and status (green for up or red for down) of the device that the current interface is connected to. The device name is a hyperlink that displays the Information tab for the connected device.

- **Port Connected**
  The name of the port on the device that the current port is connected to. The port name is a hyperlink that displays the Interfaces tab for the device that the current port is connected to.
- **QoS Policy**
  Specifies the QoS policy name that applies to this interface.
- **Index**
  Specifies the value of the index object in the standard RFC or proprietary MIB that uniquely identifies this interface within the device.
- **Board.Port**
  Identifies the board and port number on the device for the corresponding port. For example, if the port is port 4 on a module in the third slot device, the Board.Port value is 3.4.
- **MAC Address**
  Specifies the MAC address of the corresponding interface.
- **IP Address**
  Specifies the IP address of the corresponding interface.
- **Port Speed**
  Specifies the connection speed of the corresponding interface.
- **Duplex Status**
  Specifies the duplex state of the corresponding interface, either full, half, unknown, or N/A.
- **Trunk Membership**
  Identifies if an interface is a member of an 802.3ad trunk. Trunk Membership displays either the trunk ID that the interface is a member of, or a zero for no membership.
- **Network Link Type**
  Describes the type of network device the interface is connected to. Possible values are:
  - End Station Link
  - Internal Link
  - No Link
  - Router Link
  - Shared Access Link
  - Switch Link
  - Unknown Link
- **% Total Utilization**
  Utilization rate of the corresponding interface that is expressed as percentage of the total capacity of the interface. For interfaces that share bandwidth between inbound and outbound traffic (such as Ethernet interfaces in half duplex-mode) thresholds against % Total Utilization are helpful in monitoring the “load” on the interface.
- **% In Utilization**
  Utilization rate of the corresponding interface that is expressed as percentage of the total inbound capacity of the interface. For interfaces that provide dedicated bandwidth to inbound and outbound traffic separately (such as Ethernet interfaces in full-duplex mode) individual thresholds against % Inbound Utilization and % Outbound Utilization can be more helpful in monitoring the “load” on the interface. This type of threshold configuration proves useful when an interface is expected to experience predominantly outbound or inbound traffic (such as one on a web server or a load balancer).
- **% Out Utilization**
  Utilization rate of the corresponding interface that is expressed as percentage of the total outbound capacity of the interface.
- **IF Alias**
  Specifies the value of the MIB II object ifAlias for the corresponding interface.
- **IF Name**

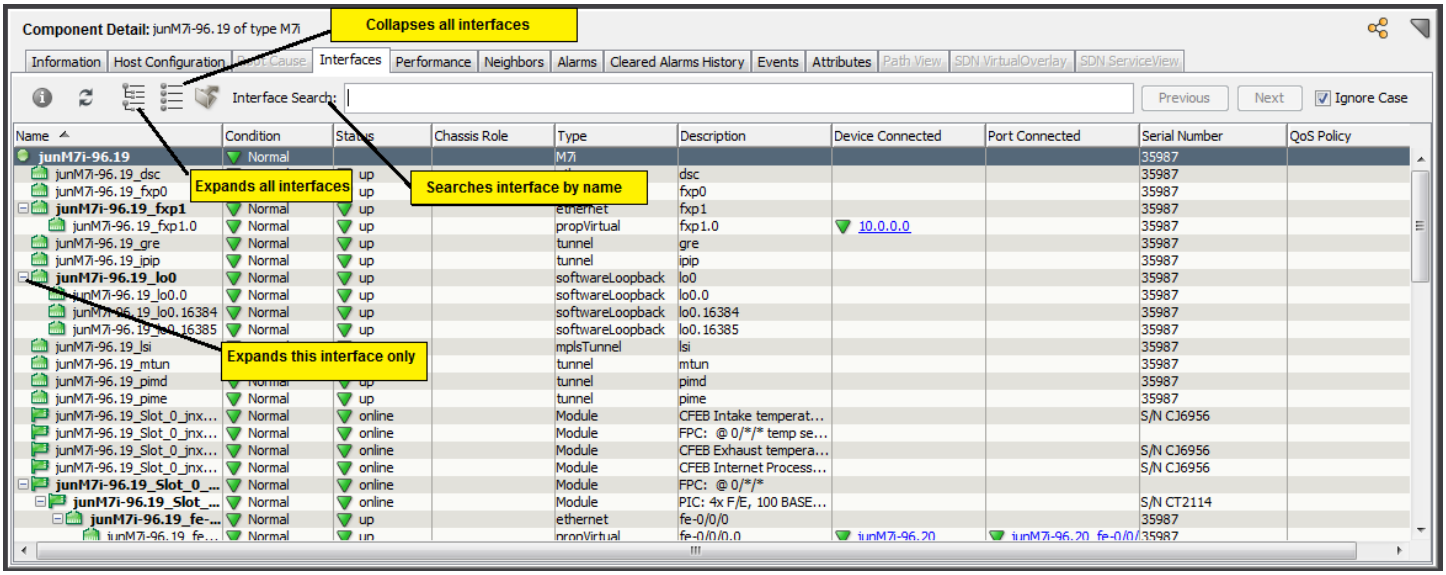
Specifies the value of the MIB II object ifName for the corresponding interface.

NOTE
For performance reasons, clicking (Refresh) in the Interfaces tab does not update external attributes (like ifAlias, for example). To update all values, instead select the specific rows in the list that you would like to update and click Refresh.

Subinterfaces

When a device supports virtual or subinterfaces, and subinterface modeling is enabled for the device model, DX NetOps Spectrum models the endpoints associated with multiplexed physical connections as subinterfaces. For example, Cisco IPSEC tunneling on a physical Ethernet interface, Permanent Virtual Circuits (PVCs) on a physical ATM interface, and Data Link Connection (DLC) circuits on a physical Frame Relay interface.

Some modeled interfaces also have subinterfaces available for viewing. The plus sign (+) next to modeled interfaces indicates that subinterfaces are available.



You can expand subinterfaces individually by clicking the plus sign (+) to expand the view of the interface. You can also click the Expands all interfaces icon

.

This icon expands the view of every subinterface belonging to this modeled interface.

Modeling of subinterfaces must be enabled on a model or device by a network administrator. For more information, see Modeling and Managing Your IT Infrastructure .

Interface Search

The Interface Search option allows you to search for an interface in the interface list by interface name.

The search can be a case-sensitive or case-insensitive search. The interface tree is automatically expanded when you click in the search box. You can use Previous or Next buttons to navigate the matching entries.

NOTE

The search time depends on the number of interfaces or subinterfaces. If the interfaces are more, then it may slow down the search.

Interface Component Detail Window

The interface Component Detail window provides access to tabs and subviews displaying information about the selected interface and its parent device. To display the interface Component Detail window, select the interface in the Interfaces tab and click the information icon  .

Interface Thresholds Subview

The Thresholds subview displays the current settings of pairs of parameters that are used to define interface alarm trigger and reset levels. Each parameter has the following threshold settings:

- A threshold level above which an alarm can be generated.
- A reset level that defines the value below which an existing threshold alarm condition is cleared.
- An allowed threshold violation duration which defines the duration, in seconds, that a threshold level can be violated before generating an alarm.

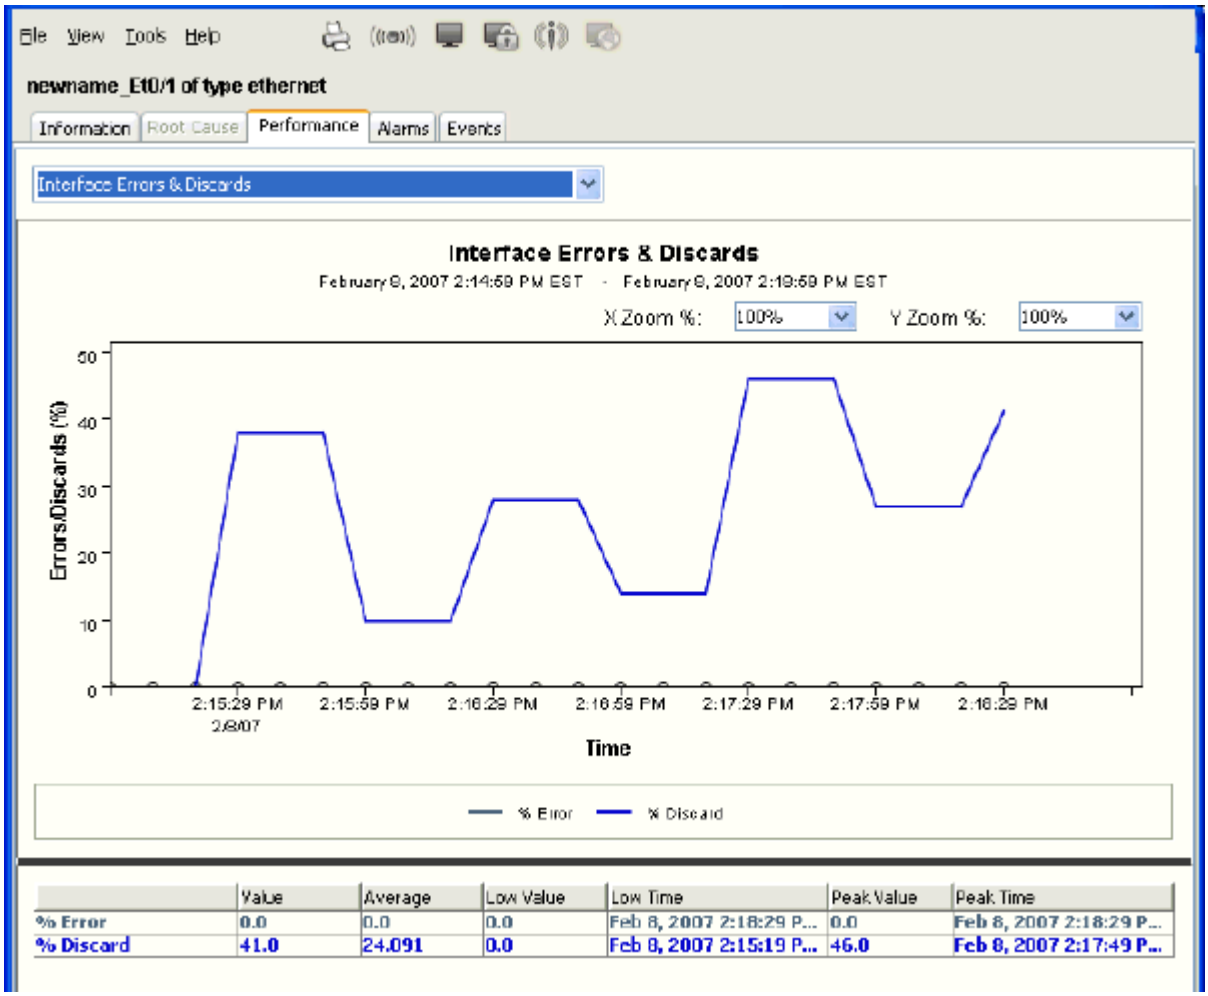
The following interface thresholds parameters appear in the Thresholds subview:

- % Total Utilization: Defines the level of port capacity used that triggers an alarm condition for a port.
- % Inbound Utilization: Defines the level of inbound port capacity used that triggers an alarm condition for a port.
- % Outbound Utilization: Defines the level of outbound port capacity used that triggers an alarm condition for a port.
- Total Packet Rate (packets/sec): Defines the number of packets per second that triggers an alarm condition for a port.
- % Errors: Defines the error rate on a port that triggers an alarm condition.
- % Discarded: Defines the percentage of discarded packets on a port that triggers an alarm condition.

> **NOTE**
> Network administrators can set the values for these parameters. For more information, see the Modeling and Managing Your IT Infrastructure .

Interface Performance View

The Performance view for the selected interface displays real-time graphs of interface utilization, throughput, and errors and discards. You can select from the performance views available using the drop-down list. You can set the zoom level for the X and Y scales for each graph, and each graph includes a legend explaining the data that appears in the graph. The following image shows an example of the interface Performance view:



Spotlighting Model Relationships

The spotlighting feature in OneClick lets you isolate and visualize the following model relationships within your network that are not readily visible from the Topology view:

- Router redundancy
- VPNs
- VLANs
- LSP Paths

The Topology view does not visually distinguish these model relationships, making it more difficult to picture them within the context of your network. With spotlighting, these model relationships are accentuated, showing you where they appear in the network topology.

For example, you can use the spotlighting feature to select an LSP Path to view in the Topology view. Viewing LSP Path information from this view can help you more easily understand which devices make up a Path in an MPLS environment. From this view, you can also see if any alarming devices are impacting a Path's performance.

> **NOTE**
> LSP Path spotlighting is not available if you do not have MPLS Manager installed. VPN spotlighting is not available if you do not have VPN Manager installed.

Spotlight Model Relationships in the Topology Tab

You can use the spotlighting feature in OneClick to see the VLANs, VPNs, LSP Paths, and router redundancy groups that are configured on your network. You can only spotlight these items if they have been enabled and configured on your network. For example, network administrators configure VLANs.

The following example describes how to spotlight VLANs, however, this procedure also applies to VPNs, LSP Paths, and router redundancy groups.

Follow these steps:

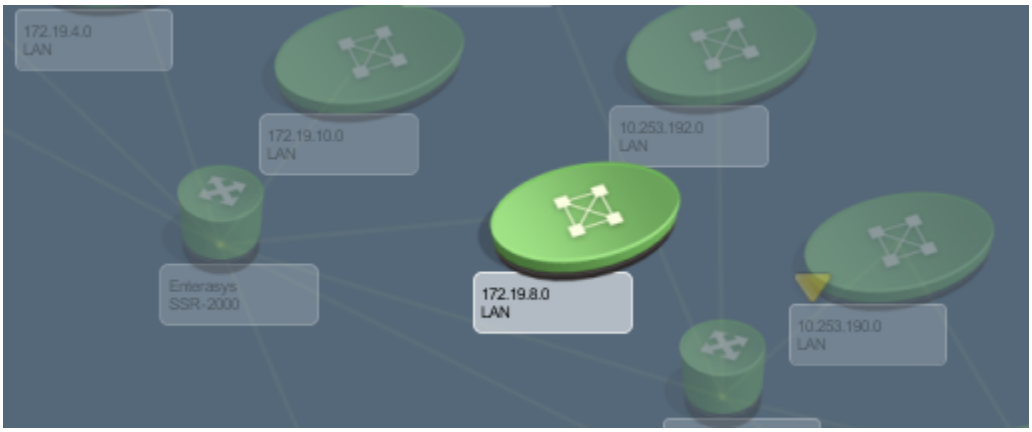
1. Select the desired Topology or container in the Navigation panel.
2. Click the Topology tab.
3. Click
   
   (Spotlight View), VLAN List in the Topology tab toolbar.
   The Topology tab view highlights the VLANs in the network and the VLAN List dialog opens, listing all the VLANs in the selected topology.
4. Select the VLAN that you want spotlight from the list and click the Information button.
   The VLAN List dialog expands to display OneClick tabs, which provide information about the selected VLAN.

> **NOTE**
>
> Starting from the 10.2.3 release, a new OneClick view is added in the Device Information tab to display (Port) interface name from JUNIPER_VLAN MIB. For Juniper EX Series Switch, VLAN information reads the data from JUNIPER-VLAN-MIB instead of dot1q bridge. The corresponding VLAN ID and VLAN Name mapping is displayed in the VLAN Spotlight View.

Highlight Modeled Devices

The Topology view for a Universe or other container can include many models, making it difficult to find a specific device or model. The OneClick highlighting feature can enable you to locate a model in the Topology view.

You can use the OneClick highlight mode to highlight modeled devices and containers in a topology view. In highlight mode, all devices except the highlighted device become translucent. The highlighted device stands out, as shown in the following image:



How to Find a Single Model using Highlight Mode

Follow these steps:

1. Select the container in the Explorer tab that you want to display in the Topology view.
2. Click the Topology tab in the Contents panel to view the topology.
3. Locate and select the model in the Explorer tab that you want to highlight.
4. Press the Shift key.
   The topology view and the device you selected appear.
5. (Optional) Navigate around the topology view using the horizontal and vertical scrollbars to locate the highlighted model if it does not appear in the viewable area of the topology.
6. Press the Shift key again to exit the highlight mode.
   You are returned to your original view of the Topology tab.

How to Find Multiple Models using Highlight Mode

Follow these steps:

1. Select the container in the Explorer tab that you want to display in the Topology view.
2. Click the Topology tab in the Contents panel to view the topology.
3. Press and hold the Shift key. The icons in the topology view become translucent.
4. Place the cursor over the model you want to highlight in the Explorer tab, without selecting it.
   The model is highlighted in the topology view.

   NOTE
   Use the scroll bars in the Topology tab to locate the highlighted device. The topology view does not adjust to show the highlighted device because it is not selected.
5. Move the cursor to the next model you want to highlight. As you move the cursor over any model in the Explorer tab, it becomes highlighted in the topology view.
   – If you place the cursor over a model that contains other models, such as a global collection, the devices in the global collection that are visible in the topology are highlighted.
   – If you place the cursor over a device that is part of a multicast group configured in OneClick, all of the devices in that multicast group that are visible in the topology are highlighted.
6. Release the Shift key to exit the highlight mode.
   You are returned to your original view of the Topology tab.

Connection Status Indicator

The OneClick Console provides visual indicators when the connection status to the SpectroSERVER changes. If the connection is lost, the borders around the OneClick Console turn red. If the connection has switched to a secondary SpectroSERVER, the borders turn yellow. The Information, Interfaces, and Performance tabs also display an orange border if the connection is lost to the selected device. A brown border indicates that the selected device model is in maintenance mode.

Check Connection Status

OneClick provides the status of connections to servers and services. The Connection Status dialog provides connection status and shows status logs for the servers and services used by the OneClick Console and OneClick add-on applications. The dialog provides the following information:

- Web services provided by the OneClick server
- Landscape service provided by the SpectroSERVER
- Events services provided by the SpectroSERVER

NOTE
The status of other services and server connections is available when you view the Connection Status dialog from other OneClick applications.

Follow this step:

- In the OneClick status bar, click the Connection <*status*> icon 
  The Connection Status dialog shows the status of web, landscape, and event services.

OneClick Messages

You can receive messages from OneClick administrators if your DX NetOps Spectrum environment is configured to support this option.

In the status bar, the Messages icon appears 

The Messages icon displays a + sign when you have unread messages. Retrieve your messages by clicking the Messages icon, which opens the Messages dialog. The Messages dialog lets you access messages that are sent to you by a OneClick administrator.

OneClick Schedules

You can schedule OneClick actions to occur at a given time with a recurrence if desired. Schedules include the following information:

- Start date
- Start and end times
- Total duration in hours
- Recurrence
- Description

When you apply a schedule to a modeled device, the event starts and ends at the specified start and end times in the time zone of the SpectroSERVER managing the device.

Access Schedules

You can locate existing schedules in OneClick by using the Schedules search function in the Locater tab. Once you have performed a search and one or more schedules appear in the Results list, you can access information about a schedule.

Schedule Information View

The schedule Information tab contains subviews which display schedule parameters. The schedule information that appears depends on the OneClick add-on applications that are installed as part of your DX NetOps Spectrum environment.

You can access the schedule Information view after running a search for schedules. Select a schedule from the Results list and select the Information tab in the Component Detail panel.

Schedule General Information Subview

The following parameters appear in the General Information subview in the Information tab for the selected schedule.

- **Creation Author**

Identifies the user who created the schedule. Schedules that ship with DX NetOps Spectrum show CA as the author.

- **Creation Time**
  Identifies when the schedule was created.
- **State**
  Identifies whether a schedule is active.

  NOTE
  A schedule with no duration, such as a schedule associated with Discovery Configurations, always appears as Inactive.
- **In Use**
  Identifies whether or not the schedule is applied to any devices, services, or other models.
- **Description**
  Optional text describing the schedule.

Items Scheduled for Maintenance Subview

The Items Scheduled for Maintenance subview displays all the devices that the schedule is applied to as a maintenance schedule. You can right-click any of the table headings to display a list of other columns available for viewing in this table.

Discoveries Planned with this Schedule Subview

The Discoveries Planned with this Schedule subview displays all the Discovery configurations to which this schedule is applied. See Modeling and Managing Your IT Infrastructure for more information about OneClick discovery and modeling configurations.

Create Schedules

You can create your own schedule by clicking **Schedule**, for example, in the **In Maintenance** field in the General Information subview.

Follow these steps:

1. Click **Schedule**.
   The Add/Remove Schedules dialog opens.
2. Click **Create**.
   The Create Schedule dialog opens.
3. Complete the fields as desired.
4. Click **OK**.
   The Create Schedule dialog closes and the schedule you created appears in the **Current Schedules** list.
5. Click **OK**.
   The Modifying Schedules dialog opens, indicating that the changes you made are being applied.

OneClick Schedules in a DSS Environment

In a Distributed SpectroSERVER (DSS) environment, there are likely to be SpectroSERVERs located in different time zones. Each SpectroSERVER interprets all schedules as local time. When you create schedules and apply them to devices that are managed in different landscapes, the scheduled item begins and end at the specified times local to each time zone. OneClick and DX NetOps Spectrum do not correlate schedules so that they start and end simultaneously across time zones. The following example illustrates how time zones and schedules work in a DSS environment.

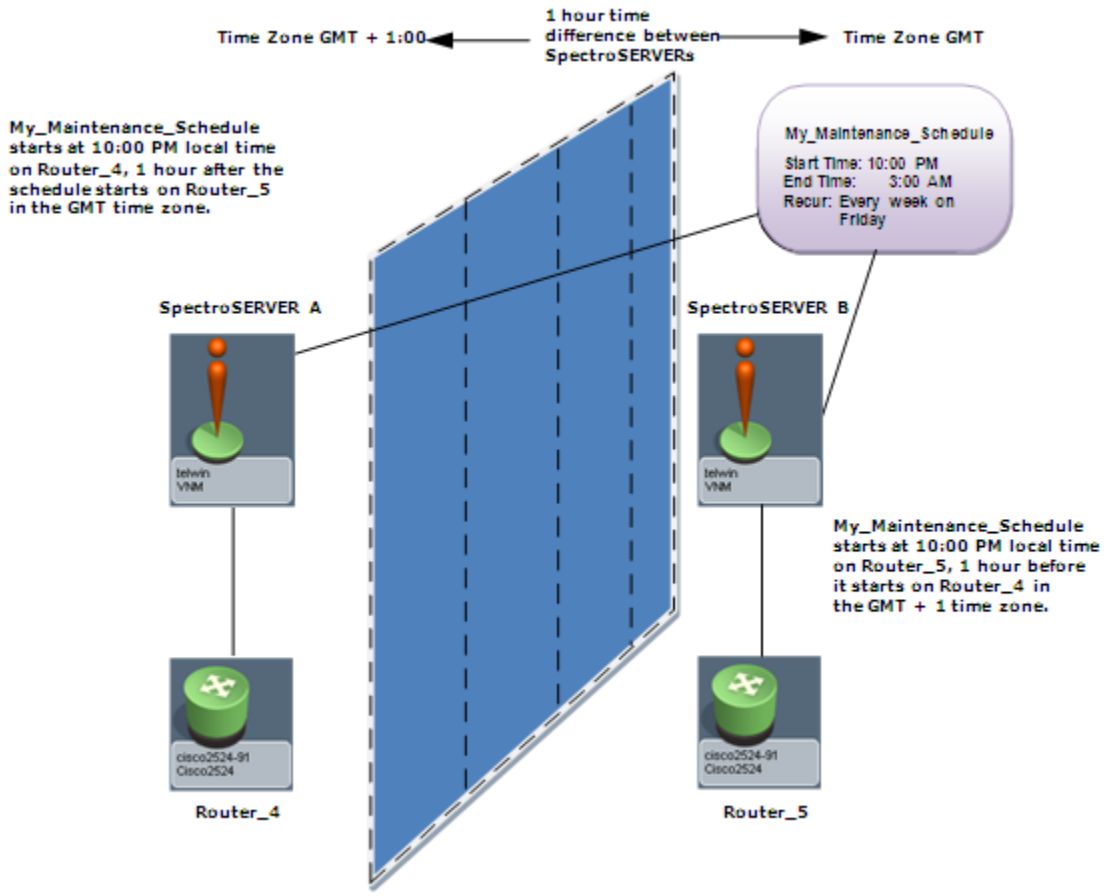
Apply a schedule to devices in different time zones

A schedule named My_Maintenance_Schedule specifies putting a device into maintenance mode starting at 10:00 PM and ending at 3:00 AM. My_Maintenance_Schedule is applied to Router_5 in the GMT time zone, and to Router_4 in the GMT+1 hour time zone.

Applying My_Maintenance_Schedule to these two devices results in the following situations:

- Router_5 enters maintenance mode at 10:00 PM GMT and exits maintenance mode at 3:00 AM GMT.
- Router_4 enters maintenance mode at 10:00 PM GMT+1 (11:00 PM GMT) and exits maintenance mode at 3:00 AM GMT+1 (4:00 AM GMT).

The following diagram illustrates this example:



Recurring Schedules

When creating a schedule, you can specify a recurrence. Consider the following things when you use recurring schedules:

- The Start Date controls when the schedule goes into effect. Consider the following points when specifying the Start Date:

  - The Start Date defaults to today's date. You can also specify today's date by using the Today button from the drop-down calendar. For recurring definitions, the default value of today's date is ignored unless you explicitly specify today's date by using the Today button.
  - If the Start Date field remains unchanged, the schedule goes into effect immediately; any scheduled action occurs on the next instance of a date and time that complies with the schedule.
  - If the Start Date field is modified in any way, regardless of if it is today's date or a future date, it must fall on a day that complies with the recurrence definition. For example, if the recurrence definition specifies that an action is performed every Saturday, the Start Date must be a Saturday.
- The recurrence definition for Daily, Weekly, and Monthly supports a year's time frame. For example, when specifying an action to occur every *x* weeks, you cannot exceed 51, which is one unit less than a year. To use anything greater, use Yearly.

  NOTE
  Although you can manually enter a value beyond a year's time frame, the recurrence definition defaults to the last valid value entered.
- If a schedule with no duration is set, as is the case for a schedule associated with Discovery Configurations, viewing it in a Locater search result list always shows its State as Inactive. Check the In Use column to determine whether it is associated with any tasks. To see its associated tasks, select the schedule and view its Information tab in the Component Detail panel.
- After a schedule is created, you cannot modify its definition. To change the time or duration for which a task is scheduled, a new schedule must be created and the associated task must be altered to use the new schedule.

Maintenance and Hibernation Mode for Devices

Maintenance and hibernation modes in OneClick let you suspend management traffic to a modeled device and its components. When a modeled device is in maintenance or hibernation mode, the SpectroSERVER continues to receive and process all SNMP traps for that device. However, it does not generate events or alarms for the device or its components.

Maintenance mode differs from hibernation mode by requiring you to disable the maintenance mode option before the device can resume normal management traffic. By contrast, hibernation mode automatically restarts normal management traffic as soon as the SpectroSERVER detects successful communication with the device after a set of successful polls.

Hibernation mode takes precedence over maintenance mode on a device model. However, if the device model has interface models in maintenance mode, those models remain in maintenance mode after the hibernation device model resumes normal management communication.

By default, placing a device model into maintenance or hibernation mode also places its interface models and application models into maintenance or hibernation mode. When a modeled device is in maintenance or hibernation mode, its topology icon displays a brown condition color. Brown alarms are shown for all device models in maintenance or hibernation mode, but they are not shown on the application and interface models that have inherited the mode from the device model.

Place Devices in Maintenance Mode

The device maintenance mode setting is in the General Information subview of the Information view. Find the Information view in the Contents panel or in the Component Detail panel.

Follow these steps:

1. Select the device in the Navigation panel, in a Topology view, or in a List view.
2. Click the Information tab.

3. Expand the General Information subview.
4. Click Set next to the In Maintenance setting and select Yes from the drop-down list.
   The device is now in maintenance mode, and its icon changes to brown.

Schedule Maintenance Mode

Schedule Maintenance Mode

You can schedule when a device enters maintenance mode by applying a maintenance schedule. You can apply an existing schedule or can create a maintenance mode schedule.

> **NOTE**
> See OneClick Schedules for information about how OneClick and DX NetOps Spectrum apply schedules across time zones in DSS environments.

Follow these steps:

1. Select the device for which you want to set up a maintenance mode schedule.
2. Click the Information tab.
3. Expand the General Information subview if necessary, locate 'In Maintenance', and click Schedule.
   The Add/Remove Schedules dialog opens. Any maintenance schedules applied to the device appear in the Current Schedules column.

   > **NOTE**
   > You can also open the Add/Remove Schedules dialog by clicking Tools, Utilities, Schedule Maintenance.
4. Do *one* of the following:
   - **To apply an existing schedule to the device**, select the schedule from the Available Schedules column, and click the left arrow button to move it to the Current Schedules column.

     > **NOTE**
     > A device can have more than one schedule that is applied to it.
   - **To remove an existing schedule from the device**, select the schedule from the Current Schedules column and click the right arrow button to move it to the Available Schedules column.
   - **To create a new schedule**, click Create; the Create Schedule dialog opens. Configure a schedule by selecting a Start Date, a Start Time, and either an End Time or Duration. Select the Recurrence factor.

     > **NOTE**
     > You can create a one-time maintenance mode window by leaving the Recurrence set to None. Enter a Description that adequately identifies the schedule you are creating.
5. Click OK.
   The new schedule appears in the Available Schedules column in the Add/Remove Schedules dialog.
6. Click OK.
   The maintenance mode scheduling changes are applied to the device.

Maintenance Mode Schedule Synchronization

From 10.2.3, the Maintenance Mode schedules on devices from DX NetOps Spectrum will be synchronized to CA UIM and from CA UIM to DX NetOps Spectrum, using the integration via spectrumgtw probe v8.65.

> **WARNING**
>
> Deploying and configuring the maintenance mode probe v8.53 is a prerequisite before configuring the spectrumgtw probe for Maintenance Mode Schedule synchronization. For more information refer Maintenance Mode probe Release Notes.

After you create a schedule on a device on either DX NetOps Spectrum and CA UIM), the schedules will get synchronized (bidirectional) after the next inventory sync that spectrumgtw performs.

The Maintenance Mode schedules will get synchronized from DX NetOps Spectrum to CA UIM only for the devices that are part of the Global Collection in DX NetOps Spectrum. However, for devices synced from CA UIM to DX NetOps Spectrum, maintenance schedules will be synchronized irrespective of whether the devices are placed in the Global Collection or not. The sync interval is 30 minutes. Any updates, creation or deletion of schedules are synchronized either if the spectrumgtw probe is restarted or after the sync interval.

NOTE

- DX NetOps Spectrum will synchronize or create CA UIM schedules, only if a minimum of one associated model exists in the UIM schedule.
- Maintenance schedules without any devices will not be synchronized.
- CA UIM does not support Yearly schedules, consequently yearly maintenance schedules existing in DX NetOps Spectrum will not be synchronized.
- If you manually place a device in maintenance in DX NetOps Spectrum, the device state is not synchronized to CA UIM. The synchronizations only applies to a device which enters maintenance mode by applying a schedule.

Synchronization for different time zones

If DX NetOps Spectrum is in Daylight Saving time zone and CA UIM is in non-Daylight Saving time zone or vice versa then the Maintenance Mode Schedule Synchronization is not supported.

The following table explains the supported/not-supported scenarios:

DX NetOps Spectrum (SpectroSERVER)	CA UIM	Support
Daylight Saving	Daylight Saving	Supported
Non-Daylight Saving	Non-Daylight Saving	Supported
Daylight Saving	Non-Daylight Saving	Not Supported
Non-Daylight Saving	Daylight Saving	Not Supported

Determine Whether Devices are Scheduled for Maintenance

You can determine if a device is scheduled for maintenance from the List tab or from the Information tab of a device.

How to Determine If a Specific Device is Scheduled for Maintenance

Follow these steps:

1. Select the device from either the List tab or the Topology tab.
2. Click the Information tab in the Component Detail panel.
3. View the In Maintenance section in the General Information subview.
   The Assigned Maintenance Schedules list displays the maintenance schedules that are assigned to this device.

How to Determine If Any Devices are Scheduled for Maintenance

Follow these steps:

1. Click the List tab.
2. Review the information in the Assigned Maintenance Schedules column.

NOTE
If you do not see the Assigned Maintenance Schedules column**,** add it to complete this procedure.The Assigned Maintenance Schedules column displays the maintenance schedule that is assigned to each device. If a device has more than one schedule that is assigned to it, a 'view' link is displayed.

3. (Optional) If a device has multiple schedules that are assigned to it, do the following actions:
   a. Click the 'view' link.
      The Assigned Maintenance Schedules dialog opens.
   b. Review the schedules that are assigned to this device.
   c. Click Close to close the Assigned Maintenance Schedules dialog.

Suppress Events and Alarms for Devices in Maintenance or Hibernation

When a model is in maintenance or hibernation mode, no events are processed for that model. That includes events that would typically clear an alarm on the model, and events that would create an alarm. For example: If a link_down event generated an alarm on a device model before the model being placed in maintenance mode and a link_up event occurred while the device model is in maintenance mode, the SpectroSERVER does not clear the alarm because the link_up event is not processed.

In this example, the SpectroSERVER would not resume normal management traffic to the maintenance modeled device until you manually disable the maintenance mode option for this device in the Component Detail panel.

If, in this example, the modeled device was placed in hibernation mode instead of maintenance mode, the SpectroSERVER would have to make a set of successful communication attempts to the device before it could resume normal management traffic with the device.

NOTE

The poll result of a device in maintenance, if pinged manually only has a 'successful' or a 'unsuccessful' message with no description. Generally users execute a poll before resetting the device to 'normal'. With the latest release of 10.3.1, this scenario is addressed with an enhancement that displays the actual status of a device in poll results to help users with descriptive result status (example that is shown in **Fig.1 and Fig.1.1**).

Fig.1 Example of a device which is in maintenance and is up with the descriptive polling result.

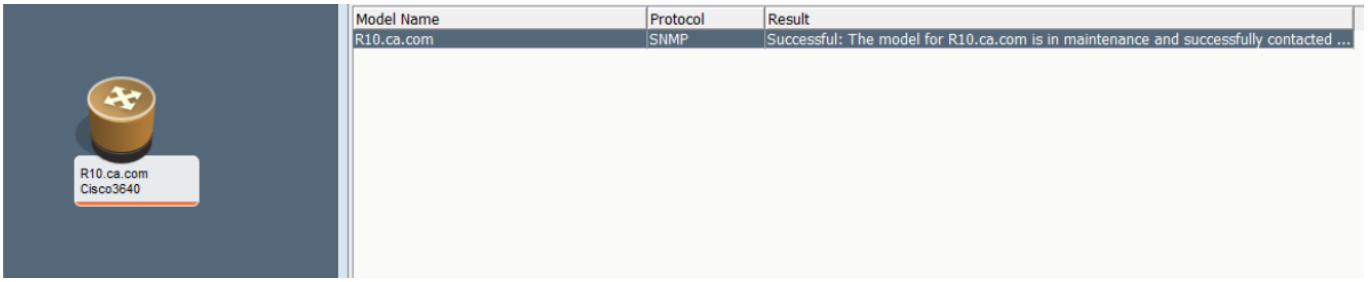


Fig 1.1 Example of a device which is in maintenance and is down with the descriptive polling result.

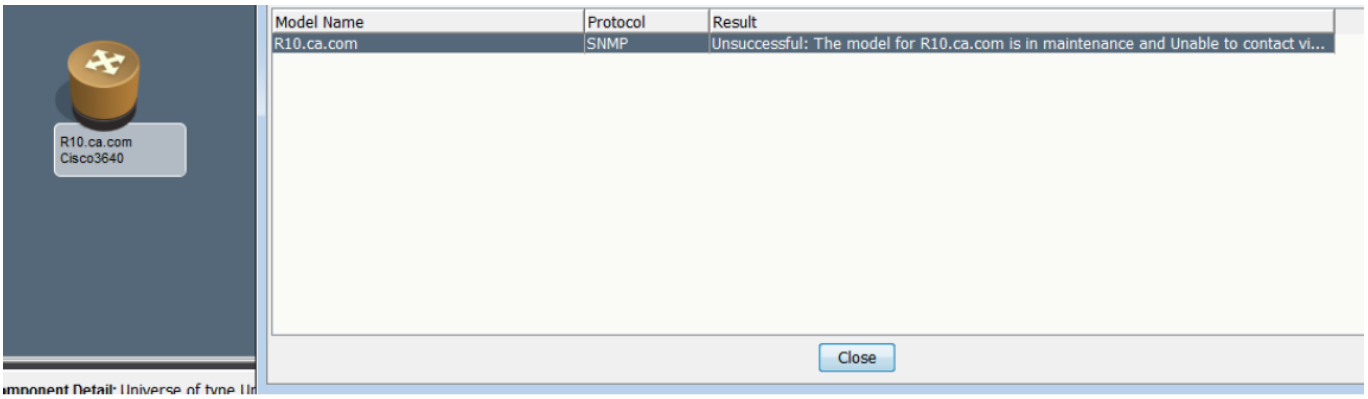


Secondary Alarms and Devices in Maintenance Mode

You can configure DX NetOps Spectrum to show or hide secondary alarms when a device is in maintenance mode. The ‘Show Secondary Alarms When Device is in Maintenance’ parameter in the Set Preferences dialog controls this behavior. If this parameter is enabled, secondary alarms are shown when a device is in maintenance mode.

NOTE
You cannot show or hide secondary alarms for devices in hibernation mode.

The 'Show Secondary Alarms' option is disabled by default. Secondary alarms are hidden when a device is in maintenance mode and are shown later when the device is taken out of maintenance mode.

NOTE

The ‘Show Secondary Alarms' setting only applies when the primary and secondary alarms are enabled in the Alarm Filter settings in the Set Preferences dialog.

Show Brown Alarms for Interfaces and Applications

You can display brown alarms for interfaces and applications that have inherited maintenance or hibernation mode from the device model by using the DX NetOps Spectrum Command Line Interface (CLI).

- To generate brown alarms on interface models that have inherited maintenance mode, set the device model attribute 0x00012a7a (rollMMAlarmToIF) to TRUE.
- To generate brown alarms on application models that have inherited maintenance mode, set the device model attribute 0x00012a7b (rollMMAlarmToApp) to TRUE.

NOTE
For more information, see Command Line Interface .

Place Devices in Hibernation Mode

In the Component Detail panel for a modeled device, the In Hibernation attribute indicates whether a device is in hibernation mode. When a device model is in hibernation mode, management traffic to the device and its components is suspended until a predefined number of communication attempts have succeeded. When the device can be contacted, the device model automatically resumes normal management communication.

Change the Number of Communication Attempts

The default number of successful communication attempts is 3 with the polling interval time (default 60 seconds) between each attempt. You can change the default number of successful communication attempts using the DX NetOps Spectrum

Command Line Interface (CLI) or the OneClick Attribute Editor. For more information about the DX NetOps Spectrum CLI, see Command Line Interface .

Either method requires changing the GlobalConfig mtype 0x00010470; the attribute HibernationCommSuccessTries 0x12acb is initially set to the default value of 3.

> **NOTE**
> You can also change this value using the Attribute Editor. For more information, see Modeling and Managing Your IT Infrastructure .

Hibernate After Maintenance

You can specify whether a device goes into hibernation mode when it comes out of scheduled maintenance. Maintenance Schedules include an option to automatically hibernate.

Follow these steps:

1. Select the device that you want to put into hibernation after maintenance.
2. Set up a maintenance mode schedule for the device as described in Schedule Maintenance Mode.
3. Click the Information tab in either the Contents or Component Detail panel and expand the General Information subview if necessary.
4. Locate the Hibernate After Maintenance setting, click set, and select Yes from the drop-down list.
   The device now automatically hibernates after a scheduled maintenance window closes. In hibernation, the device is polled 3 times and, if successful, the device comes out of maintenance.

Place Interface Models in Maintenance or Hibernation Mode

In the Component Detail panel of a device interface, enable the In Maintenance option to place the interface model into maintenance mode. This action suspends the management of the interface. However, DX NetOps Spectrum still performs regular management on the device and on its other interface.

> **NOTE**
> Unlike the maintenance mode, hibernation only applies to devices; you cannot place the interfaces alone into hibernation mode.

In the maintenance or hibernation mode, the following conditions apply to the interface model:

- Brown alarms are shown for interfaces in hibernation mode.
- Alarms are not created for the port.
- Events are logged for the port.
- No polling, logging, or other device communication is performed for the port model until the interface resumes normal management.
- Link Down traps that are sent are ignored, and no alarms are generated.
- If the Live Pipes option is enabled for a connection and one of its endpoints is in hibernation mode, the color of the pipe in the topology view turns brown. Status polling for that port is discontinued.

If a connection is modeled with a WA_Link model connection to two ports, and one of those ports is in hibernation mode (or maintenance mode), an alarm is created on the WA_Link and WA_Segment models. The WA_Link icon in the OneClick topology views turns brown. If Live Pipes are enabled on this link, the pipe remains green as long one port is up. If the second port is down or unreachable, the pipe condition color turns gray.

If DX NetOps Spectrum loses contact with a device model that is connected to a port in hibernation or maintenance mode, the ‘Device Has Stopped Responding to Polls’ alarm is suppressed for that device and for all adjacent devices. If device_contact_lost alarms are suppressed because of their position relative to a port in hibernation (or maintenance)

mode, the hibernation or maintenance mode alarm reflects these lost devices in its Impact and Severity attributes. View these lost devices in the **Impact** tab of the **Alarm Details** panel for that maintenance alarm.

Maintenance and Hibernation for WLC and AP interface models

In the maintenance or hibernation mode, the following conditions apply to the WLCs and AP interface models:

1. If WLC is in Maintenance/Hibernation mode, maintenance alarm is generated on WLC and all other alarms on WLC device are suppressed. The Access Points connected to the WLC are put into maintenance mode.
2. If AP and its Parent WLC are kept in Maintenance/ Hibernation then both will be in maintenance and all other alarms (except maintenance alarm) on both devices will be suppressed.

NOTE

- If AP goes into Maintenance/ Hibernation, only maintenance alarms are generated on the AP and all other alarms are suppressed.
- If AP is in maintenance and its parent WLC goes into maintenance at a later point, even then, all connected APs will go in maintenance. Once WLC is up, connected APs will be reverted to the previously managed state.

Place Wide Area Link Models in Maintenance or Hibernation Mode

A wide area link model represents a wide area connection between two router interfaces and includes:

- A WA_Link model that appears in the topology view.
- A WA_Segment model that exists within the WA_Link model and connects the two router interfaces together.

To place a wide area link into maintenance or hibernation mode, you have to modify settings for both the WA_Link and WA_Segment models.

In the Component Detail panels of both the WA_Link and the WA_Segment models, set the In Maintenance or In Hibernation setting to Yes to place the wide area link model into maintenance mode or hibernation mode. Management of the wide area link is suspended while regular management of the connected router interfaces continues.

When in maintenance or hibernation mode, both the WA_Link and WA_Segment models have a brown condition. The two connected router interfaces remain managed, and events and alarms are still generated on them.

NOTE
You can also put the router interfaces into maintenance mode, which allows full customizable control over how events and alarms are generated for wide area links. See Place Interface Models in Maintenance or Hibernation Mode.

To take a wide area link model out of maintenance or hibernation mode, modify settings for both the WA_Link and WA_Segment models accordingly.

Place ESX Host in Maintenance Mode or Hibernation

An *ESX host* is a physical computer that uses ESX Server virtualization software to run virtual machines. Hosts provide the CPU, memory, storage resources, and network connectivity for the virtual machines.This article describes how you can place an EXS host in maintenance and hibernation modes. Hibernation mode automatically restarts normal management traffic as soon as the SpectroSERVER detects successful communication with the device after a set of successful polls. Whereas, the Maintenance Mode requires you to disable the maintenance mode option before the device can resume normal management traffic.

To place an ESX Host in maintenance mode, enable the In Maintenance option in the Information tab of the Component Detail panel. This action suspends management of the ESX Host. However, DX NetOps Spectrum still performs regular management on the ESX Host and on its virtual machines.

In the maintenance mode, following conditions apply to the ESX Host:

WARNING

From 10.2.1, you can choose to place only the ESX Host server in maintenance mode, and not the VMs under the ESX Host. See Maintenance Mode Correlation for more information.

- By default, all the VMs under the ESX Host are automatically placed in maintenance mode. If the maintenance mode is turned off on the ESX Host, all the VMs are removed from maintenance mode.

  NOTE

  If a VM is already in maintenance mode before the ESX Host placed in maintenance mode; even after the ESX Host is out of maintenance mode, the state of VM remains maintenance mode only.
- Traps are not processed.
- Events are generated.
- Maintenance Alarms of VMs are correlated to ESX Host Maintenance Alarm.

Schedule Maintenance Mode for ESX Host

Schedule the maintenance mode of an ESX Host by applying a maintenance schedule or by creating schedule. You can apply multiple schedules to an ESX Host. For more information on applying schedule and creating a schedule see the Schedule Maintenance Mode section.

NOTE

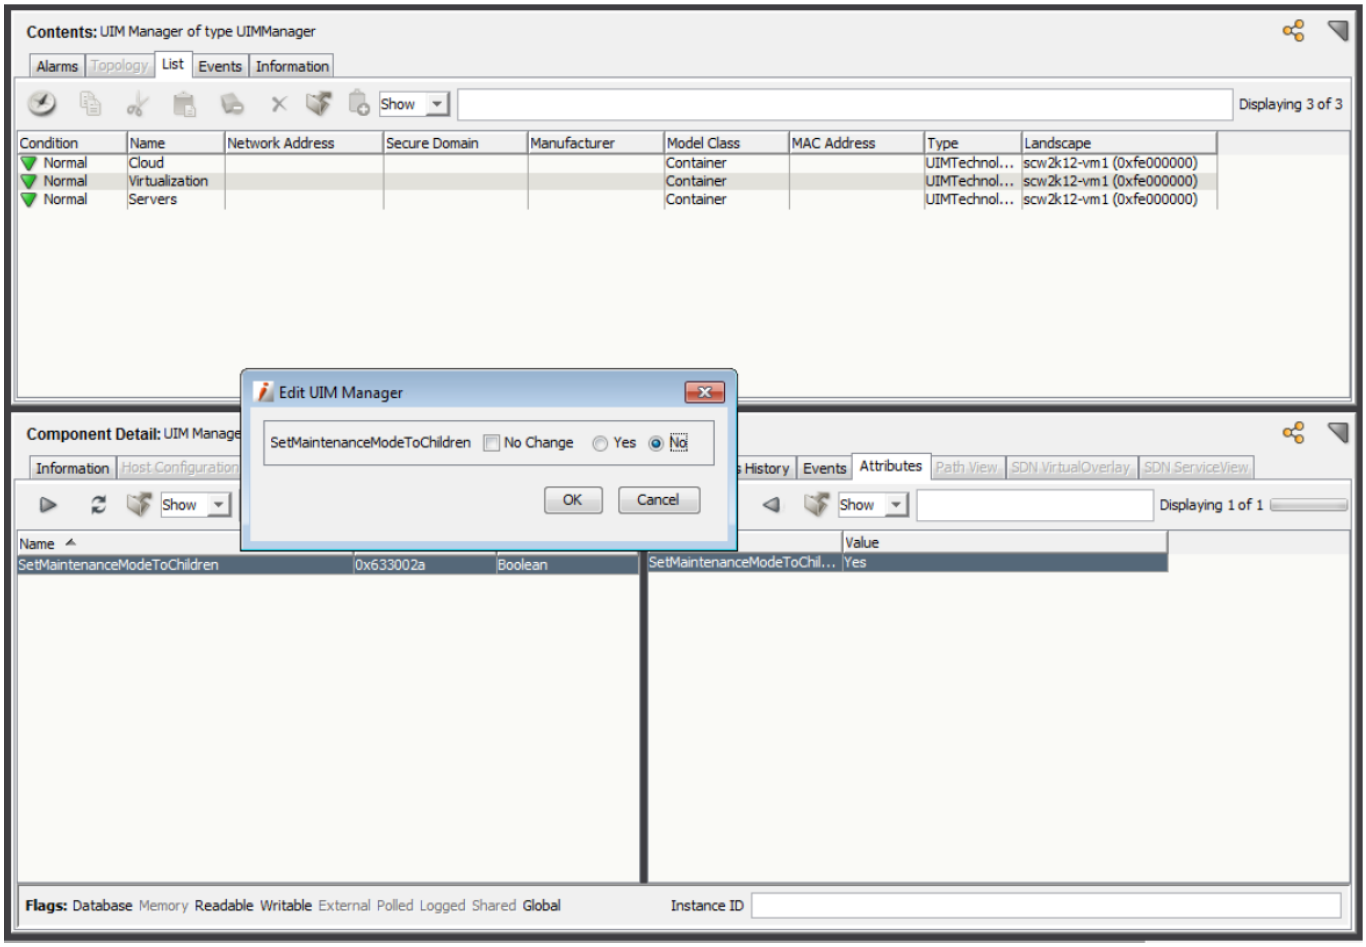
See OneClick Schedules for information about how OneClick and DX NetOps Spectrum apply schedules across time zones in Distributed SpectroSERVER environments.

Maintenance Mode Correlation

The default, Maintenance Mode Correlation behavior is such that, when an ESX Host is placed in maintenance mode, all the VMs under the ESX Host are automatically placed in maintenance mode. The maintenance alarms on VMs are correlated to the ESX Host maintenance alarm. From 10.2.1, you can modify the default behavior, (where you can edit an attribute "SetMaintenanceModeToChildren /0x633002a") enabling you to choose only the ESX Host Server to be placed in maintenance, while ensuring that the the maintenance mode correlation does not apply to the VMs under the ESX Host.

To enable maintenance mode only for the ESX Host and not for the VMs, follow these steps:

1. In the DX NetOps Spectrum OneClick console, Explorer Tab hierarchy, navigate to UIM Manager, select the List tab and then the Attributes tab in the Components Detail panel.
2. In the Component Details panel, Search bar, enter one of the following:
   - Attribute Name: **SetMaintenanceModeToChildren**
   - Attribute ID: **0x633002a**
     By default, the value of this attribute is set to Yes.



3. Double-Click the Attribute result on the right pane.
   The Edit UIM Manager dialog appears.
4. Clear the No Change check-box and select No in the dialog.
5. Click OK.
   The Attribute Edit Results dialog appears with a confirmation of the change in attribute value, along with landscape details.

   NOTE

   Click Undo on the Attribute Edits Results dialog to revert the Maintenance Mode correlation back to default.

Once you have successfully edited the attribute; the maintenance mode correlation no longer applies to the VMs under the ESX Host. Now, only the ESX Host server will be placed in maintenance while the VMs under the same, will no longer be placed under maintenance. The VMs will remain in active state and will be monitored as usual for alarms and events.

Place ESX Host in Hibernation Mode

To place an ESX Host in hibernation mode, enable the In Hibernation option in the Information tab of the Component Detail panel. This action suspends management of the ESX Host.

When the ESX Host is placed in Hibernation mode, all the VMs under the ESX Host are automatically placed in maintenance mode. The maintenance alarms on VMs are correlated to ESX Host hibernation alarm.

In the Hibernation mode, following conditions apply to the ESX Host:

- Brown alarms are shown for interfaces in hibernation mode.
- No polling, logging, or other device communication is performed until normal management is resumed.
- Hibernation Alarm is shown on ESX Host and Maintenance Alarm is shown on VM.
- Maintenance Alarms on all the VMs are correlated to single ESX Host Hibernation Alarm.

If an ESX Host is placed in Hibernation, which is already in maintenance, then Spectrum shows both Maintenance and Hibernation alarms on the ESX Host.

NOTE

The Hibernation Alarms of VMs under an ESX are not correlated to ESX Host Maintenance Mode or Hibernation Alarm.

Hibernate After Maintenance

To place an ESX Host in hibernation mode after scheduled maintenance, refer to the steps explained in the Hibernate After Maintenance section.

Migrating a VM from an ESX Host to Another ESX Host

The following section describes scenarios of VM migration from a source ESX to a destination ESX.

Scenario 1	Result
(A) • ESX1 (source) is in Maintenance Mode. • VM is in inherited Maintenance. (the 'inheritedMaintenance' attribute is 'YES') • ESX2 (destination) is in Maintenance Mode.	The migrated VM under ESX2 is in Inherited Maintenance Mode.
(B) • ESX1 (source) is in Maintenance Mode. • VM is in inherited Maintenance. (the 'inheritedMaintenance' attribute is 'YES') • ESX2 (destination) is NOT in Maintenance Mode.	The migrated VM under ESX2 (destination) is NOT in Inherited Maintenance Mode.

Scenario 2	Result
(A) • ESX1 (source) is NOT in Maintenance Mode. • VM is in Maintenance Mode. • ESX2 (destination) is in Maintenance Mode.	The migrated VM under ESX2 (destination) is in Maintenance Mode.
(B) • ESX1 (source) is in Maintenance Mode. • VM is in Maintenance Mode. • ESX2 (destination) is NOT in Maintenance Mode.	The migrated VM under ESX2 (destination) is in Maintenance Mode.

Scenario 3	Result
(A) • ESX1 (source) is in Maintenance Mode. • VM is in Maintenance Mode. (the 'inheritedMaintenance' attribute is 'NO') • ESX2 is in Maintenance Mode.	The migrated VM under ESX2 (destination) is in Maintenance Mode.

(B) • ESX1 (source) is in Maintenance Mode • VM is in Maintenance Mode (the 'inheritedMaintenance' attribute is 'NO') • ESX2 (destination) is NOT in Maintenance Mode	The migrated VM under ESX2 (destination) is in Maintenance Mode.

Exporting Data and Images from OneClick

You can export table data from OneClick to a file. Some OneClick views, such as the Topology view, the Neighbors Topology view, and the Link Information view, can be exported as images.

Export Table Data

You can export table data from OneClick to a file. Table data can be exported from the Alarms tab, the List tab, and other tabs.

Follow these steps:

1. Navigate to a table that contains the Export button
   
   (Export) in the toolbar.
2. Click
   
   (Export).
   The 'Export table data to file' dialog opens.
3. Complete the following information:
   – **Save in**
   Specifies the location to save the exported data file.
   – **Save as type**
   Specifies the file type that you want to use when saving the exported data.
   – **File name**
   Defines the name for the exported data file.
   – **Files of type**
   Specifies the type of file format to use. The following file formats are supported for export:
   • Comma separated values (CSV)
   • Tab-delimited text
   • HTML.
4. Select a location to save the file and click Save.
   The file is saved in the directory that you selected.

Copy and Paste Table Data

You can copy and paste OneClick table data to an external application. In the following procedure, the Alarms table is used as an example, but you can use this procedure in other OneClick tables too.

Follow these steps:

1. Select the alarms to export in the Alarms tab of the Contents panel.

   NOTE
   To select all alarms in the Alarms list, click any alarm and press Ctrl+A.

2. Copy the selected alarms as tab-delimited text (Ctrl+C).
3. Open a spreadsheet application or text editor.
4. Paste Ctrl+V to paste the tab-delimited text into a document.
   The data from the Alarms table appears in the spreadsheet application or text editor that you selected.

Fix Exported CSV Files Containing Board.Port Data

When you export a table that includes Board.Port data to CSV and open it in Microsoft® Excel, trailing zeros are truncated. For example, if the Board.Port value is 2.10, it appears as 2.1 in the spreadsheet. These trailing zeros are not truncated if you export to TXT or HTML format. However, you can take a few steps to fix an exported CSV file in which trailing zeros have been truncated.

Follow these steps:

1. Rename your CSV file from <*filename*>.csv to <*filename*>.txt.
2. Select File, Open in Microsoft Excel.
3. Select 'Text Files' from the Files of Type drop-down list.
4. Select your file and click Open.
   The Text Import Wizard dialog opens.
5. Select Delimited, and click Next.
6. Select Comma, and click Next.
7. Select the column that contains data with trailing zeros.
8. Select Text from the Column Data Format section.
9. Click Finish.
   Microsoft Excel opens the file. The trailing zeros are preserved.

Export Topology Views

Some OneClick views, such as the Topology view, the Neighbors Topology view, and the Link Information view, can be exported outside DX NetOps Spectrum.

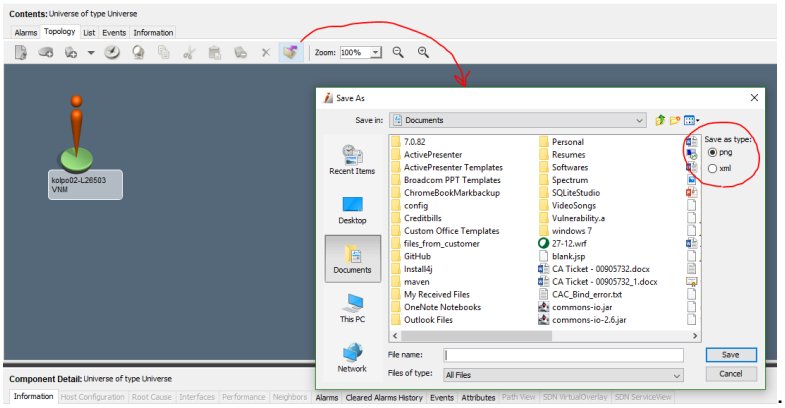
You can now export the topology in XML and PNG formats. You can import the topology to third-party imaging applications supported by mxGraph (for example, draw.io) and change the topology based on your requirements. You can then export the updated topology to any supported output formats of that third-party imaging application.

NOTE

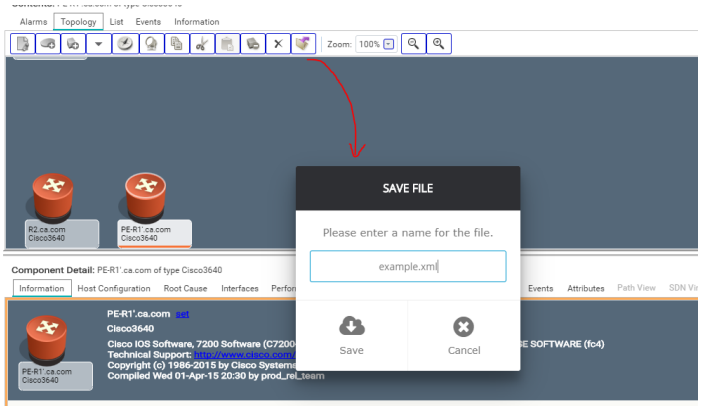
- The image is saved according to the current zoom level in the view.
- To get clearer and bigger images, zoom the topology before exporting it.
- Only the model name and device type are displayed along with the image.
- Overlapping images are not shown properly.

Follow these steps:

1. Navigate to the entity that has a topology image.
2. Select the desired topology or container in the Navigation panel.
3. Click the Topology tab.
4. Click (Export View to PNG or XML)  .
   The Save As dialog opens. By default, the topology is saved in PNG format.
5. Perform one of the following tasks:
   a. In Console: enter the desired file name and select **XML** as the file type from the **Save as type**.



b. In WebApp: enter the desired file name and the file extension as **.XML**.



6. Select a location to save the file and click **Save**.
   The topology is exported to the specified location.

You can now import the saved XML file to a third-party imaging application, re-arrange the topology, and export it to any supported file format.

> **WARNING**
> The default setting for image size to export is 640x480 pixels. You can create a large image when exporting the Topology view (4000x4000 pixels or larger). Excessive size can cause an out-of-memory error in OneClick. Reduce the size of the image that you are exporting by zooming out in the Topology view. Consult your OneClick administrator to increase your client memory settings.

Keyboard Shortcuts

The following keyboard shortcuts are available in the OneClick Console.

- **CTRL + P**
  Opens the Print dialog from which you can specify what you want to print and which printer you want to use.
- **CTRL + G**
  Sends an ICMP Ping to the selected devices, from the SpectroSERVER modeling the device.
- **CTRL + R**
  Opens the TraceRoute dialog that lets you perform the traceroute operation on SpectroSERVER- and SDC-moldeled devices. For directly connected devices, it performs the traceroute operation through SpectroSERVER. For devices modeled through SDC, check the connection status and perform the traceroute operation. In this case, the traceroute operation is performed through SDC.
- **CTRL+T**

Establishes a communication session with the selected device using Telnet, from the SpectroSERVER modeling the device.

- **CTRL+H**
  Establishes an encrypted communication session with the selected device using Secure Shell (SSH), from the SpectroSERVER modeling the device.
- **CTRL+L**
  Polls the selected devices from the SpectroSERVER modeling the device.
- **CTRL+W**
  Web administration. Launches a browser using the IP address of the selected device. Available only for models that have the WebAdminURL attribute.
- **ALT+LEFT ARROW**
  Goes back to a previous container or device.
- **ALT+RIGHT ARROW**
  Goes forward to a container or device after navigating back.
- **ALT+V, S**
  Shows or hides the Status bar.
- **ALT+V, N**
  Shows or hides the Navigation panel.
- **ALT+V, C**
  Shows or hides the Contents panel.
- **ALT+V, D**
  Shows or hides the Component Detail panel.
- **ALT+H**
  Opens the Help menu from which you can access DX NetOps Spectrum support, DX NetOps Spectrum training information, and DX NetOps Spectrum documentation.

Mobile Application

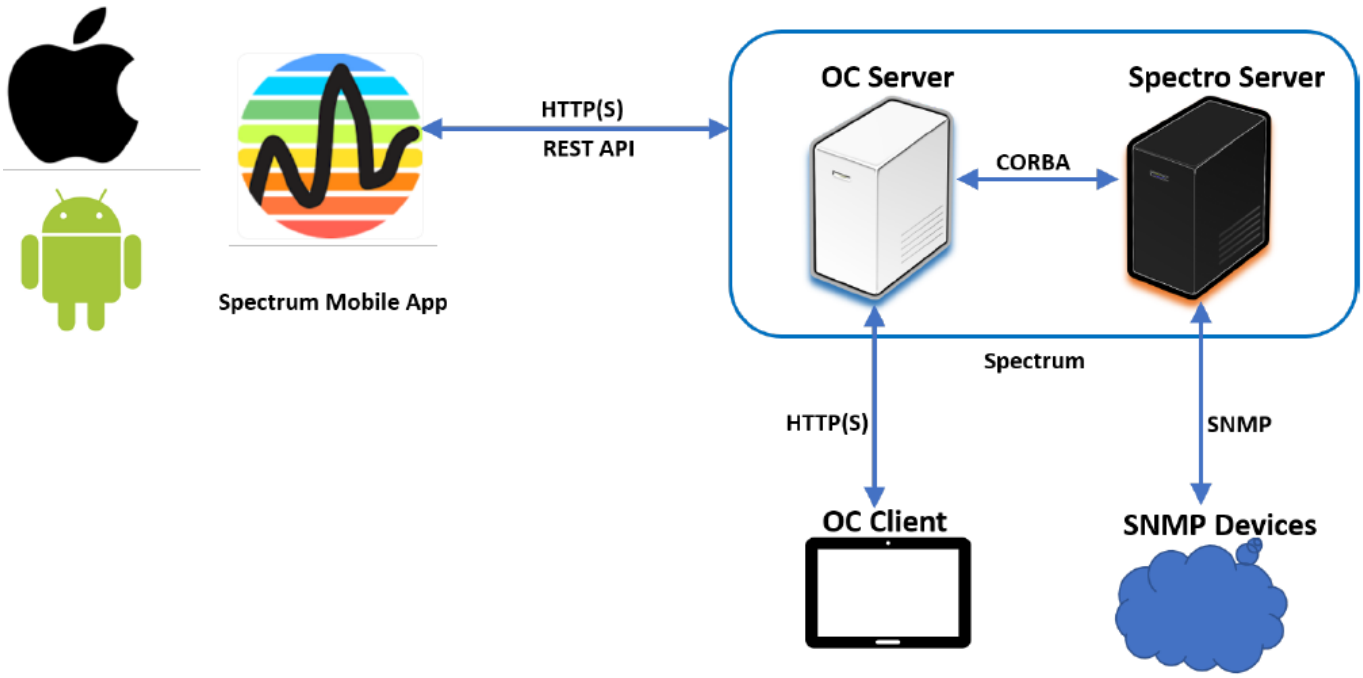
DX NetOps Spectrum Mobile lets you view the alarms through your mobile devices. This application is built on the Sencha framework and it supports both the iOS and Android platforms. The application displays detailed information of alarms such as landscape, description, date, and time. You can configure the application to poll the DX NetOps Spectrum webserver periodically and to obtain the recent alarms. The application lets you perform alarm actions such as view, search, filter, acknowledge, and assign troubleshooter. To connect the application to the OneClick server, you must specify the host name or IP address of the OneClick server host and the server port number.

The application lets you view the top alarms through your mobile devices. You can download the mobile application from App Store or Play Store.

- iOS version 8 or higher
- Android version 4.1 or higher

Architecture

This application runs on the Flutter framework. The application contacts the OneClick server using REST API to obtain the alarm-related information. The OneClick server collects the alarm information from the SpectroSERVER through CORBA.



The latest version of the application includes the following enhancements:

- Support for the alarms filtering capability.
- CPU/memory performance graph support for the SNMP devices.
- Ability to view events for the devices generated in the last four hours.
- Ability to change the device state to the maintenance mode.
- Ability to search the devices on the server.
- Support for the global collection alarm and device views.
- Support for the dark mode theme.
- Various bug fixes and performance improvements.

Using the Mobile Application

Using the mobile application, you can view an overview and details of the alarms and the associated devices and perform various actions, such as the following:

- View alarms by severity on the dashboards and also access the devices that are in a critical condition
- Search for alarms based on the severity, alarm title, device name, device IP address
- View alarms details for approximate 20000 alarms. The details include information, such as description, possible causes, symptoms, recommendations, and the devices that are impacted by the alarms.
- Acknowledge alarms
- Clear alarms and refresh the alarms list
- View device details of 10000 devices and the associated alarms
- Report the alarms or provide feedback
- Share the details on various social media platforms

This article contains the following topics:

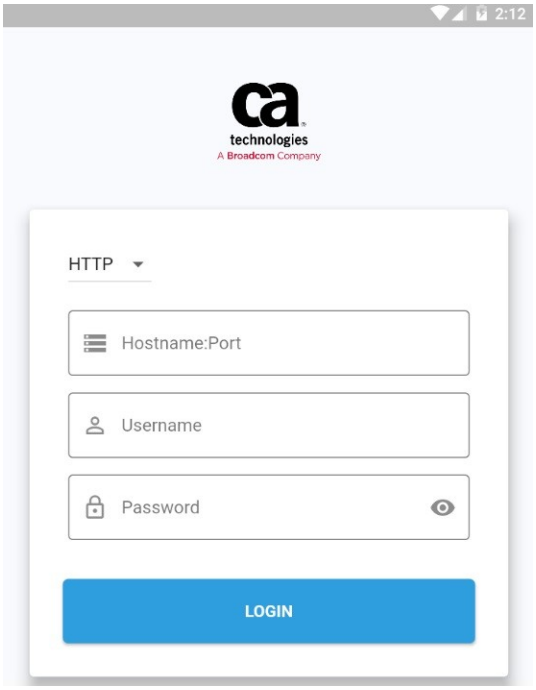
Prerequisite

Ensure that the following actions are completed before you access the mobile application.

- You have installed the mobile application
- You are connected to the enterprise network through the VPN or Wi-fi.
- The OneClick server runs on the enterprise network that you are connecting to from your mobile.

Accessing the Mobile Application

Open the mobile application from your mobile device, and connect it to a OneClick server host.



- Select the HTTPS option from the drop-down to connect to the OneClick server. By default, you connect using HTTP.
- **Hostname:Port**: specify the hostname or IP address and the port number to connect to the OneClick Server. Define the value in this format: *<hostname or IP address>:<port number>*
- The default port number for HTTP is 80 and for HTTPS is 443. The mobile application automatically adds these port numbers. However, if the OneClick server is configured with a different port number, you must specify the port number in the format provided.
- **Username**: define the username to connect to the OneClick server.
- **Password**: define the password to connect to the OneClick server.
- **Login**: click the button to log in to the mobile application.
- The mobile application saves the credentials, by default.

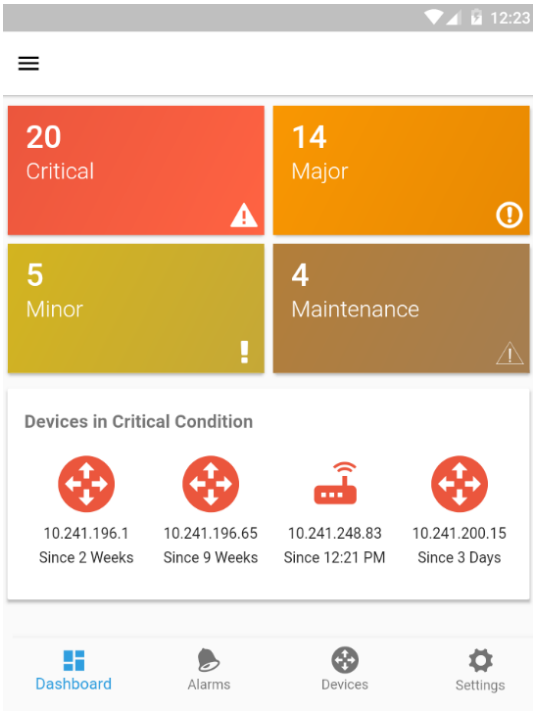
Options Available with the Application

After you log in to the mobile application, you can access the following screens and perform actions to manage the alarms from the DX NetOps Spectrum Database:

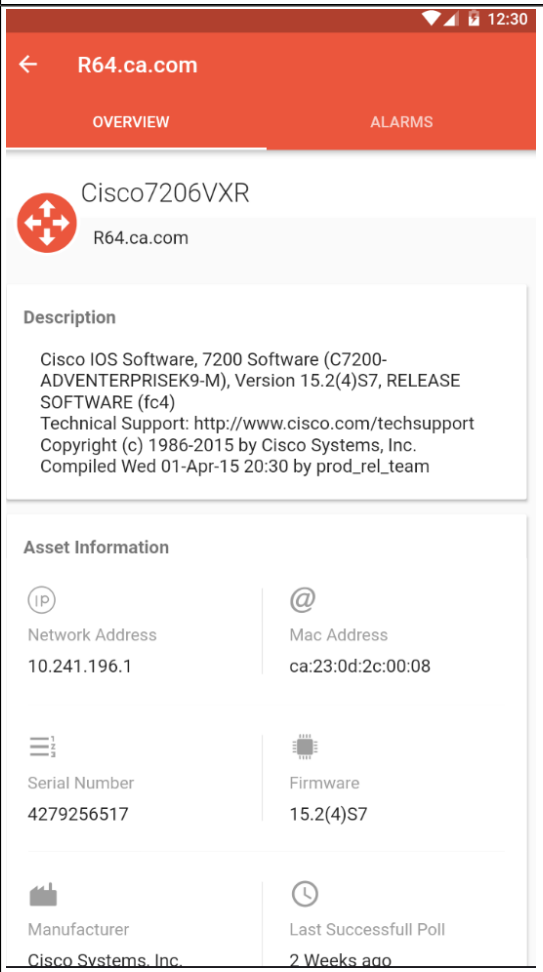
- Dashboard
- Alarms
- Alarm Details
- Device Details
- Settings

Dashboard Screen

The Dashboard is the default view when you log in to the mobile application. On this screen, you can view a summary of alarms based on the severity and any device and the type of device that is in a critical condition.

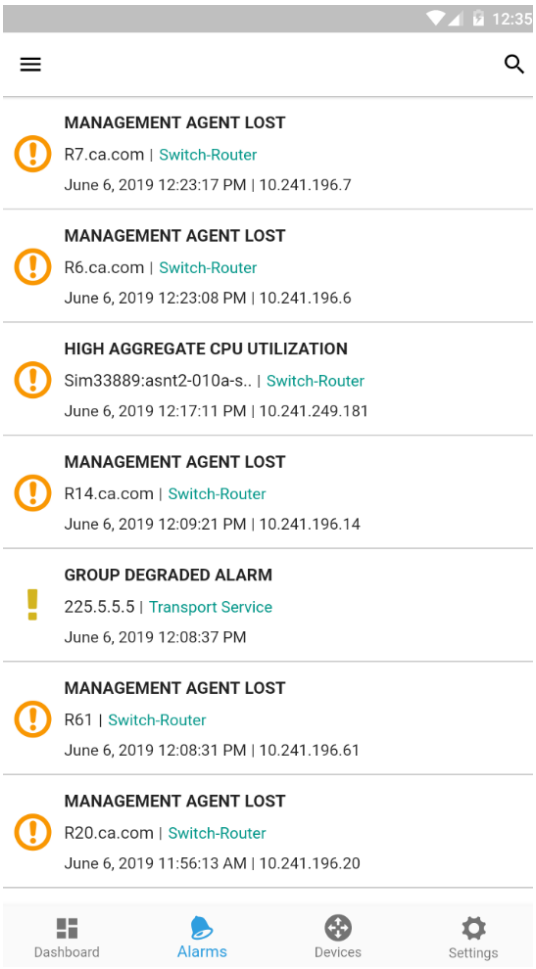


Actions Available on Dashboard Screen	Description
View Device Details	Click on any device on the Dashboard to view the overview of the device and any associated alarms.

Actions Available on Dashboard Screen	Description
	


Alarms Screen

Once connected to the specified OneClick server, the mobile application fetches the latest 20000 alarms (Critical, Major, and Minor) and displays on the Alarms screen. This list of 20000 alarms is grouped in the descending order of the date of occurrence of alarms. The alarms are polled automatically and refreshed.



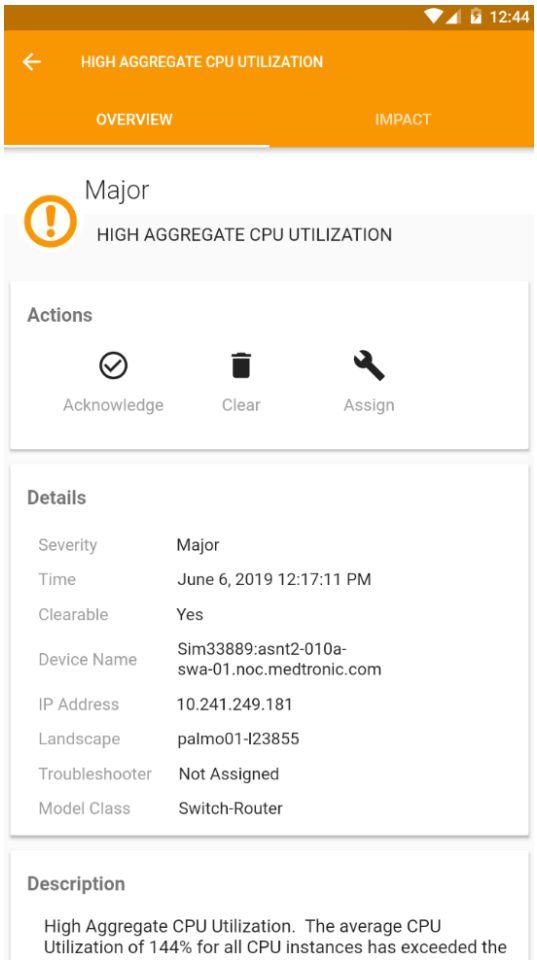
Actions Available on the Alarms Screen	Description
Search Alarms	The Alarms screen lets you search alarms by alarm title, device name, device IP address.
Filter Alarms	The Alarms screen lets you filter the latest alarms by severity. You can sort Critical, Major, and Minor alarms from the list of alarms. By default, all alarms are displayed irrespective of the severity. To view alarms of a severity type, click on the Critical, Major, or Minor option at the bottom of the screen.

Actions Available on the Alarms Screen	Description
Acknowledge Alarms	To acknowledge an alarm, select an alarm and slide to the right to view the acknowledge option.  When you click on the Acknowledge option, a message Alarm updated appears indicating that you have acknowledged the alarm.
Clear Alarms	To clear an alarm, select an alarm and slide left. You can clear alarms only in instances where the **Clear** option is available.  After you click on the Clear option, the alarm is cleared from the OneClick server and the DX NetOps Spectrum database. After you clear the alarm, the list of alarms is refreshed.

Alarm Details Screen

When you select an alarm from the list, the alarm detail screen displays the following details:

- **Overview** tab:
  - Severity: Critical, Major, Minor
  - Alarm details
  - Description of the alarm
  - Alarm symptoms
  - Possible causes of the alarm
  - Any recommended action
- **Impact** tab: In this tab, you can view the list of impacted alarms. The alarm details screen is as follows:

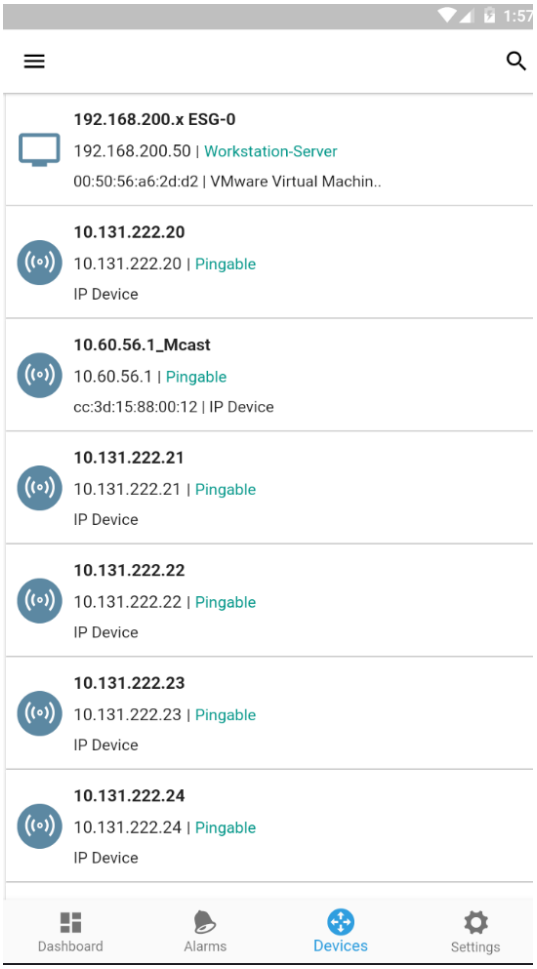


Actions Available on the Alarms Details Screen	Description
Acknowledge Alarms	When you select an alarm, you view the details of the alarms, which lets you acknowledge that alarm. Click the **Acknowledge** icon in the **Actions** section to acknowledge the alarm. To unacknowledge, double-click **Unacknowledge** in the **Actions** section
Clear Alarms	Click the Clear icon in the Actions section, to remove the alarm from the OneClick server and the DX NetOps Spectrum database. After you delete the alarm, the list of alarms is refreshed. This option is enabled only for alarms that can be cleared.

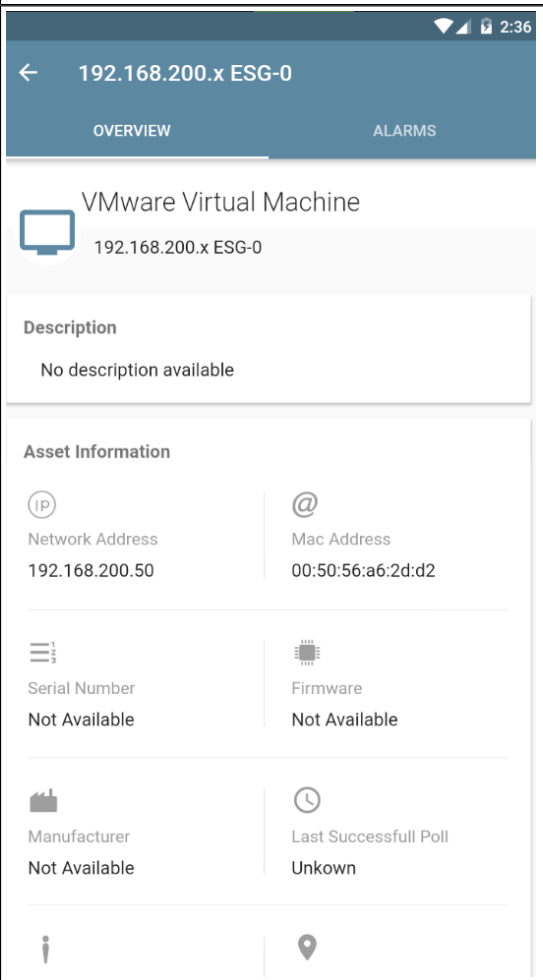
Actions Available on the Alarms Details Screen	Description
Assign Troubleshooter	When you select an alarm, you can view the alarm details, which lets you assign a troubleshooter for that alarm. Before you assign a troubleshooter, ensure that you have configured a list of troubleshooters in the OneClick server. When the assignment is complete, an email notification is sent to the troubleshooter about the assignment. Click the Choose drop-down, to view the list of names that you can assign the alarm to for troubleshooting.  After you select a name, click the Assign button. The alarm appears assigned to the name that you selected. You can unassign only the assigned alarms to a troubleshooter. To unassign, click the Assign icon and the name gets removed.

Device Details Screen

Click on the **Devices** option at the bottom of the screen to view the list of devices from the DX NetOps Spectrum database. The device details screen is as follows:

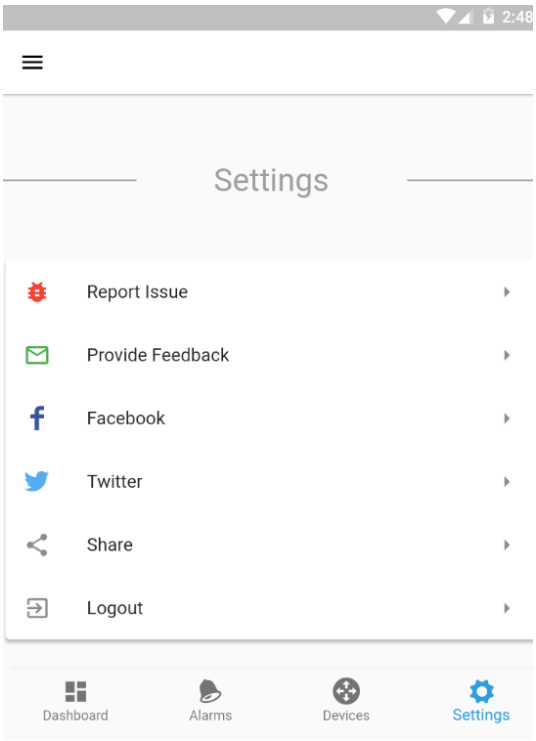


Actions Available on Device Details Screen	Description
View Device Details	To view the device details, click on any device from the list. The device details page displays an overview of the asset in the Overview tab, such as network address, Mac address, Serial Number, Firmware, Manufacturer, polling details, landscape, location. In the Alarms tab, you can view the list of alarms associated with the device.

Actions Available on Device Details Screen	Description
	


Settings Screen

Click the **Settings** option at the bottom of the screen to report an issue, provide feedback, share the details, or to logout from the mobile application. Logging out also logs you out from the OneClick server.



OneClick WebApp

About OneClick WebApp

From 10.4, instead of launching the WebApp separately, the WebApp is embedded in DX NetOps Spectrum. The OneClickWebApp launches in a separate tab with the same port details as DX NetOps Spectrum. The OneClickWebApp address is http://<OC-HostName>:<OC-Port>/spectrum/webapp. Manual configuration is not required in the console-menubar.jsp page. Logging out of the WebApp redirects you to the DX NetOps Spectrum administration page.

> **NOTE**
> If javaSript is not enabled in your web browser, WebApp does not work. To enable javaSript, see How to enable JavaScript in Windows.

OneClick WebApp Improvements in 10.4.2

The following improvements are done in the current release:

- Window Undocking is supported. Click the **UP arrow** (in the browser's title bar) as shown in the following image to toggle window docking:

- DX NetOps Spectrum OneClick WebApp is 508 compliant.
- The memory footprint of webtomcat is reduced by around 60%, hence the OneClick WebApp is that much lighter.
- Launch the **OneClick WebApp in-context** to open the alarm, explorer, and topology. For more information, see Launch OneClick Clients with Context.

OneClick WebApp Improvements in 10.4.2.2

This release includes the following OneClick WebApp-related enhancements:

OneClick WebApp Audio Alarm

An audio message announces the new alarm in WebApp. For more information, see Alarms Tab Preferences.

OneClick WebApp Security

The OneClick WebApp administrator can use the **Admin** console to view all the open WebApp sessions from multiple machines. When you try to launch an open session, you can see a warning message `Session is mirrored by OneClick WebApp Administrator.`

Memory Requirements for OneClick WebApp Web Server:

For every new session that opens in the client, OneClick WebApp takes around 300 MB to 500 MB of server memory, as it creates a Java process for each client.

NOTE

DX NetOps Spectrum now ensures that the OC WebApp port is updated to 9443 if it is available, or to any other available port.

NOTE

10.3.2 introduces the download and upload option as an improvement to the OneClick WebApp. These upload and download improvements are made where the client file system is made available.

The Service Desk ticket launch now opens in a separate browser.

Configure OneClick WebApp in Docker

This section describes the procedure to configure the OneClick WebApp in Docker. You need the X Windows System virtual framebuffer X server package (`xorg-x11-server-Xvfb)` to start the webswing.

Follow these steps:

1. While creating the container, create a port mapping like it is done for the OneClick port.
   For OneClick WebApp:

   ```
   docker run -e ROOT_PASSWORD=???.qaperf184 -e MAIN_LOCATION_SERVER=719de9a39c46 -e
    MAIN_LOCATION_SERVER_IP=172.17.0.2 -e TOMCAT_PORT=8080 -p 9090:8080 -p 9443:9443 -e MASTER_NODE=docker-
   rh74vm2 -it 1032ocimage
   ```

   Here 9443 is the port number that WebApp uses, once the OC container is created.
2. Perform one of the following tasks to install the package.
   a. If the package is **available**, follow these steps:
      a. Copy the `xorg-x11-server-Xvfb` file to the `<docker_host>/container` directory using the ‘docker copy <filename> <containerName:/path>’ command.
      b. Install the package.
   b. If the package is **not available**, follow these steps:
      a. In the docker container, go to the `/etc/yum.repo.d` directory.
      b. Move all the repo file in this directory except the `Vi test.repo` file to a temporary location.
      c. Open the `Vi test.repo` file.
      d. Insert the following code chunk:

      ```
      [test]
      name=test
      ```

```
baseurl=http://vault.centos.org/<version>/os/x86_64
gpgcheck=0
enabled=1
```

e. Save and close the file.

f. Run the following commands:

```
yum clean all
yum repolist
```

g. Install the package using the yum install `xorg-x11-server-Xvfb` command.

3. When package installation is completed, move the repo files that you put in a temporary location to the current directory.

Steps to Run OneClick WebApp on Windows

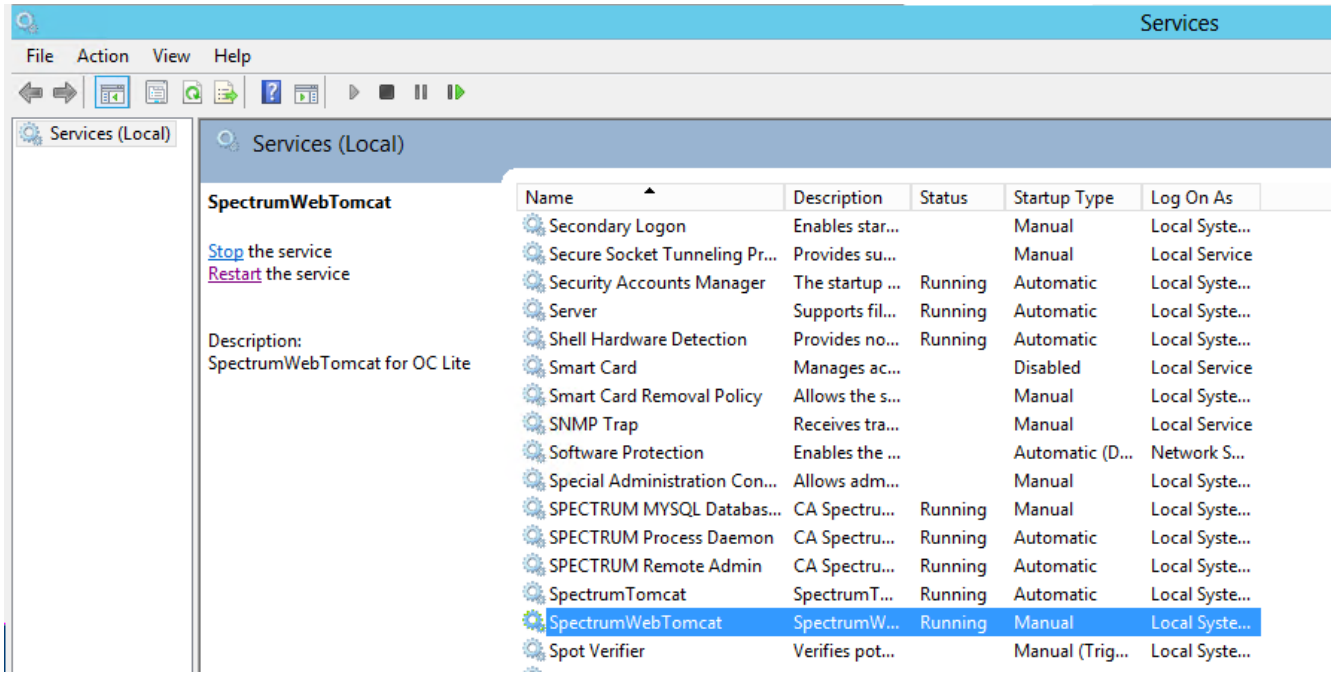
This section describes the steps to run OneClick WebApp on Windows.

NOTE
The OneClick WebApp application runs in a separate tomcat web server, also called as the OneClick WebApp web server. The OneClick WebApp web server runs on a service that is referred to as the SpectrumWebTomcat. By default, the SpectrumWebTomcat service is in a running state.

Following these steps:

1. To start the SpectrumWebTomcat service, launch **services.msc** from your windows machine. Find and select the SpectrumWebTomcat service option (which as mentioned, is in the stopped state) and start it. The OneClick WebApp web server takes a couple of minutes to start.

   NOTE
   The Webtomcat web server and the OneClick web server, run on separate ports. DX NetOps Spectrum ensures the assigning of the next available port number (by reading the OneClick webserver port number) to the Webtomcat webserver.



a. Launch the OneClick Admin page and select the OneClick WebApp option (as shown here) to launch the OneClick WebApp application. Directly launching the WebApp URL is not supported. You must launch it from the OneClick Admin page.

NOTE

To change the port number that has been assigned to the OneClick WebApp web server, navigate to the following location: **%SPECROOT%Webtomcat>conf>server.xml** file and look in the connector folder for the HTTP protocol. For example:

```
<Connector port="9443" protocol="HTTP/1.1" connectionTimeout="20000"
 redirectPort="8443" />
```

In the example that is given above, the port number that is assigned to the OneClick WebApp web server is 9443.

2. If the OneClick WebApp web server does not start, analyze, and fetch the webtomcat logs for troubleshooting, from the following log locations:

```
%SPECROOT%webtomcat/bin/webswing.log
%SPECROOT%webtomcat/logs/stdout.><date-stamp>.log
```

Steps to Run OneClick WebApp on Linux

This section describes the steps to run OneClick WebApp on Linux. Install the 'X virtual frame buffer' (Xvfb) for Linux machines.

Prerequisites

1. Download and Extract the installation package (xorg-x11-server-Xvfb-1.10.4-6.el6.x86_64.rpm) to a temporary directory.

```
wget http://vault.centos.org/<version>/os/x86_64/Packages/<package_name> tar <package_name>
```

2. Install the package using one of the following methods.

```
yum install <package_name>
    OR
yum localinstall <package_name>
```

3. Verify that the following Linux packages are available, else install them:
   These packages enable the graphical environment that is required to use the Swing framework.
   DX NetOps Spectrum Dependencies:
   - xorg-x11-server-Xvfb
   - libXdmcp
   - xorg-x11-server-common
   - libXfont2
   - libxkbfile
   - xorg-x11-xkb-utils

   OneClick WebApp Dependencies
   - libXext
   - libXi
   - libXtst
   - libXrender

   NOTE
   For more information see the Webswing documentation.

Following are the steps to run OneClick WebApp on Linux:

NOTE

The OneClick WebApp application runs in a separate tomcat web server, also called as the OneClick WebApp web server. The OneClick WebApp web server runs on a service referred to as the SpectrumWebTomcat.

1. (Optional) To start the OneClick WebApp web server, navigate to the **$SPECROOT>webtomcat>bin** directory and execute the following command:
   ```
   ./startWebTomcat.sh
   ```

   NOTE
   The OneClick WebApp web server and the OneClick web server, run on separate ports. 10.3.1 ensures the assigning of the next available port number (by reading the OneClick web server port number) to the OneClick WebApp webserver.
2. Launch the OneClick Admin page and select the OneClick WebApp option (as shown here) to launch the OneClick WebApp application. Directly launching the WebApp URL is not supported. You must launch it from the OneClick Admin page.

   NOTE
   To change the port number that has been assigned to the OneClick WebApp web server, navigate to the following location: **$SPECROOT>webtomcat>conf>server.xml** file and look in the connector folder for the HTTP protocol.
   For example:
   ```
   <Connector port="8081" protocol="HTTP/1.1" connectionTimeout="20000"
    redirectPort="8443" />
   ```
   In the above example, the port number that is assigned to the OneClick WebApp web server is 8081.
3. Troubleshoot any issue in starting the OneClick WebApp web server, analyze, and fetch the web tomcat logs from the following log locations:
   ```
   %SPECROOT%webtomcat>logs>Catalina.out
   %SPECROOT%webtomcat/bin/webswing.log
   ```
4. To stop the OneClick WebApp application, run the following command:
   ```
   ./stopWebTomcat.sh
   ```

SSL Support for OneClick WebApp

The SSL feature is enabled with OneClick and available with previous versions of DX NetOps Spectrum. Installation takes care of the client certificates and setting the SSL to true in the configuration. Selecting the link the OneClick administration page loads the DX NetOps Spectrum console without errors.

NOTE
If OneClick is SSL enabled before upgrading, the OneClick WebApp URL appears in **https**.

Enable SSL support

This section discusses the steps to enable SSL support or change the OneClick WebApp URL.

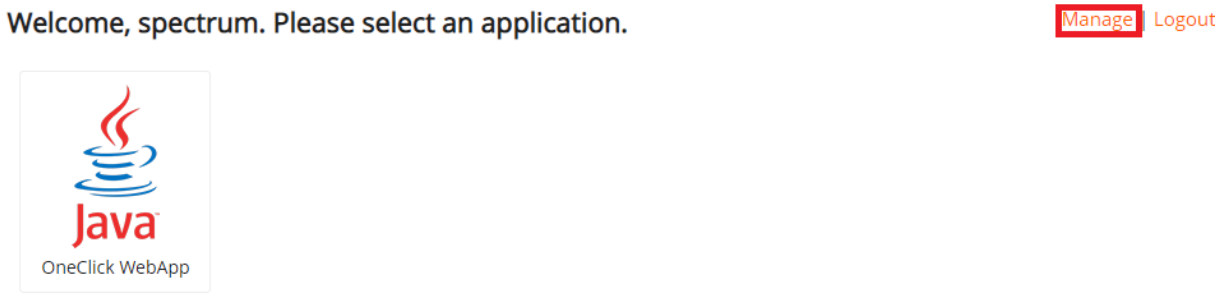
Follow these steps:

1. Navigate to the **tomcat >conf>server.xml** file and copy the connector https ports-related information and paste it in the **webtomcat>conf folder>server.xml file** under the **https connector** section.
2. Change the SSL connector **port entry** that you pasted in the **webtomcat/conf/server.xml** file, so that it does not conflict with the standard OneClick Tomcat SSL **port**.
3. Restart the web tomcat service.

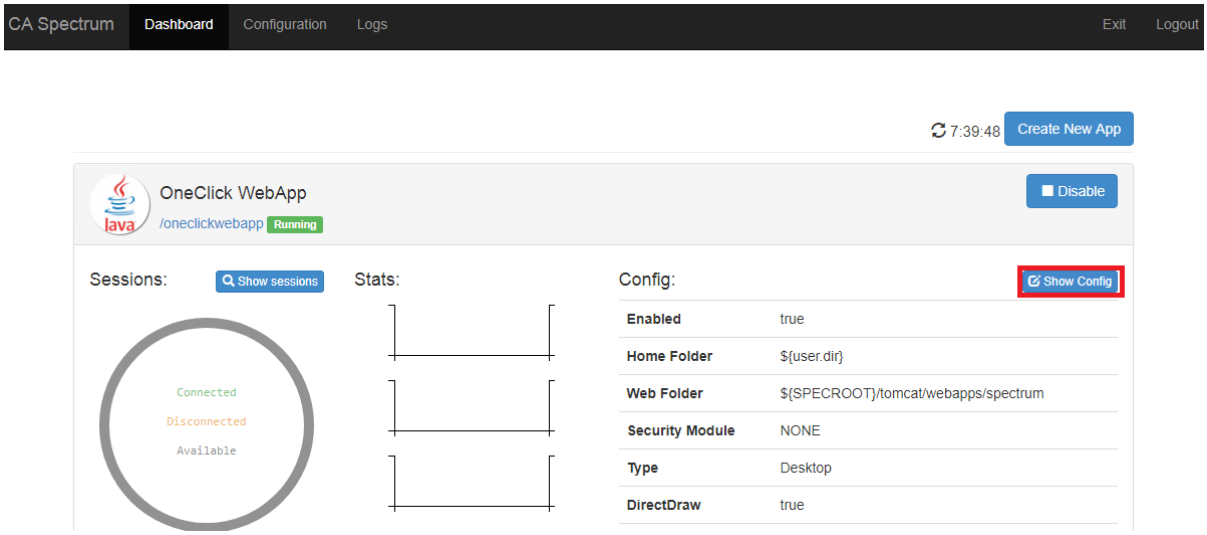
Post Upgrade Tasks

Follow these steps if you have enabled SSL in OneClick after upgrading to 10.3.x or if you have changed the OneClick ports after upgrading to 10.3.x:

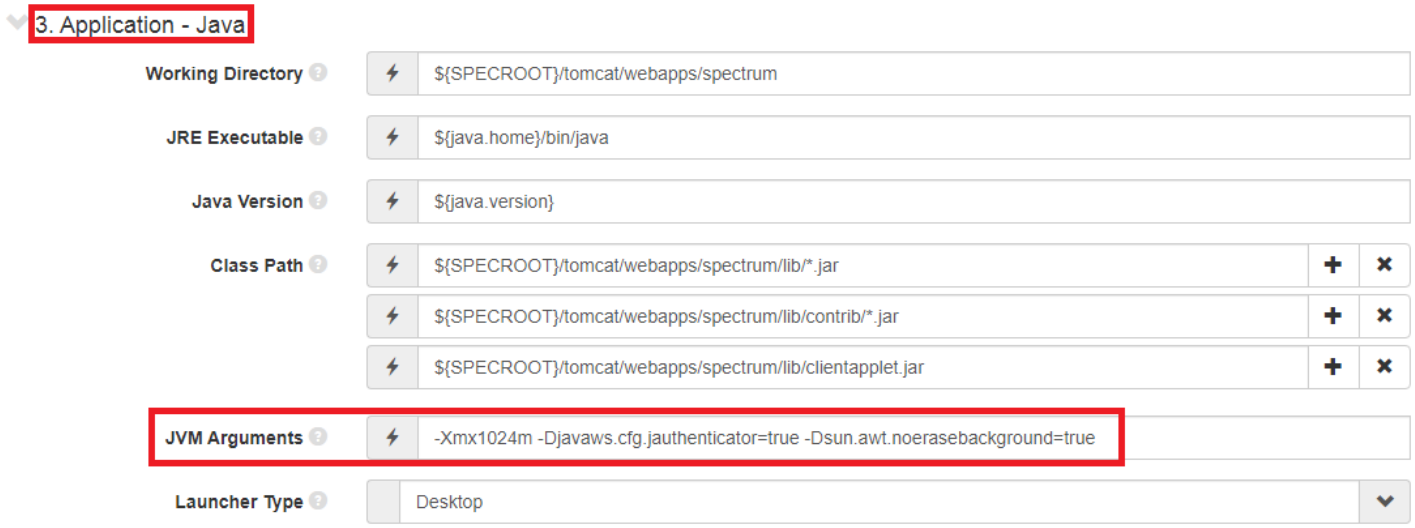
1. Log in to the OneClick WebApp administration page. The default URL is:
   `https://<webapp-hostname>:<webapp-port>/spectrum`
2. Log in with the **spectrum/spectrum** username/password credentials and select **Manage**.



3. Select **Show Config**, to view the configuration.



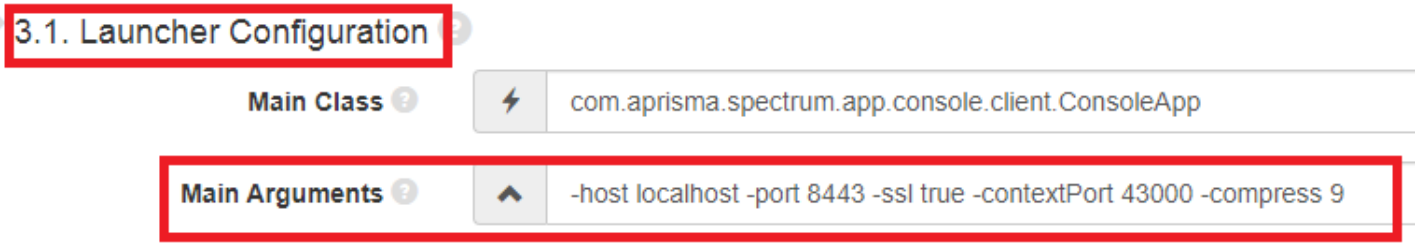
4. Add the following for the JVM Arguments under the **Application – Java** section after the `-Dsun.awt.noerasebackground=true` entry:
   `-Djavax.net.ssl.trustStore=${SPECROOT}/custom/keystore/cacerts-Djavax.net.ssl.trustStorePassword=changeit`



Cross verify these values with the OneClick tomcat server.xml configuration (only if SSL is enabled).

NOTE
Do not set the ${SPECROOT} to an absolute path. However, change the path/filename of the keystore (the default is cacerts) and password (the default is changeit) if they are not the default entries.

5. Navigate to the **Launcher configuration>Main Arguments** section and select the OneClick Hostname, OneClick port, and the SSL values, if SSL is enabled, change the –ssl to true.



NOTE
These values should be in sync with the OneClick details. The SSL port should be the same as your original Tomcat SSL port, that is 8443 (if SSL is enabled). If you changed the OneClick port, change it.

6. After you have made the changes, select **Apply** on the top left corner and re-launch the OneClick WebApp from the administration page.

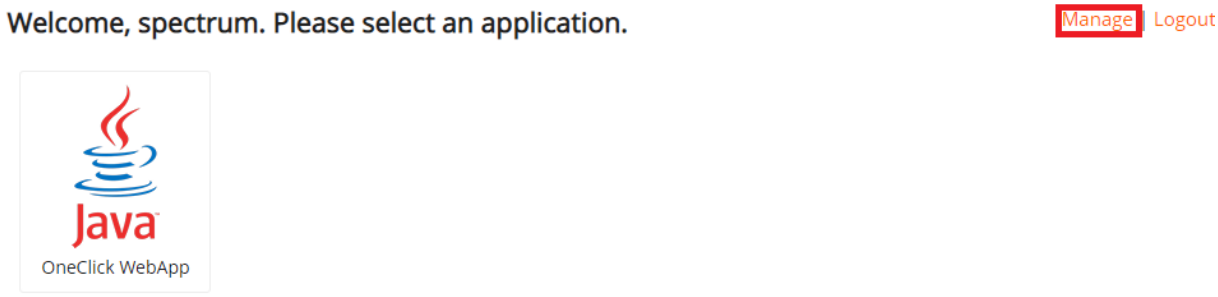
7. Launch the OneClick Admin page and select the OneClick WebApp option, to launch the OneClick WebApp application.

CAC Support for the OneClick WebApp

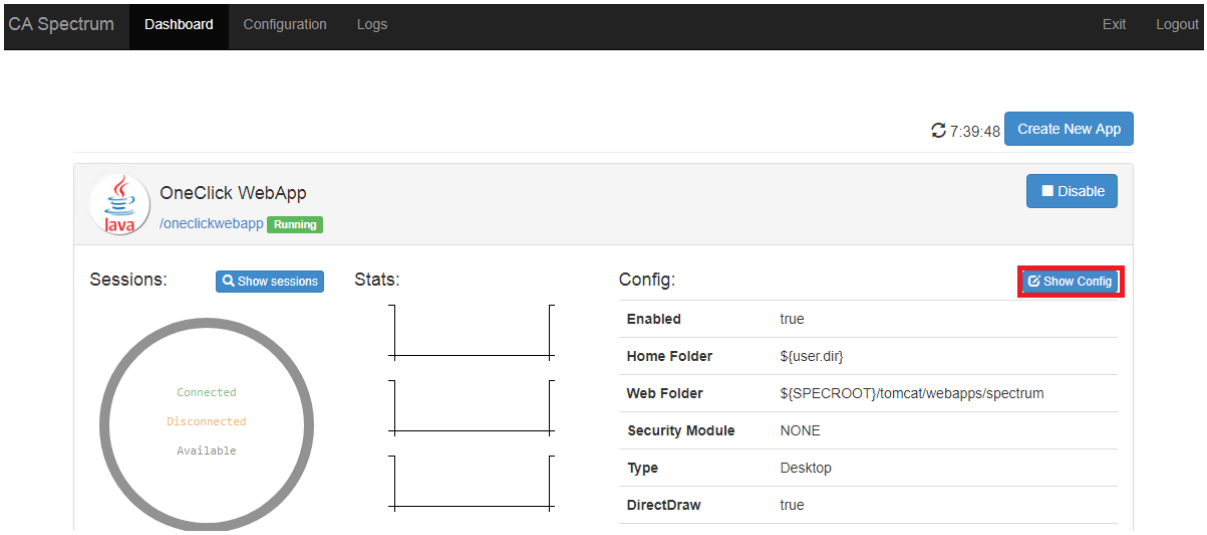
After configuring SSL, configure Common Access Cards (CAC) authentication on the OneClick WebApp.

Follow these steps

1. Configure SSL for the OneClick WebApp.
2. Configure CAC for DX NetOps Spectrum OneClick, see How to Configure DX NetOps Spectrum for SSL and CAC Authentication.
3. Log in to the OneClick WebApp administration page. The default URL is:
   `https://<webapp-hostname>:<webapp-port>/spectrum`
4. Log in with the **spectrum/spectrum** username/password credentials and select **Manage**.

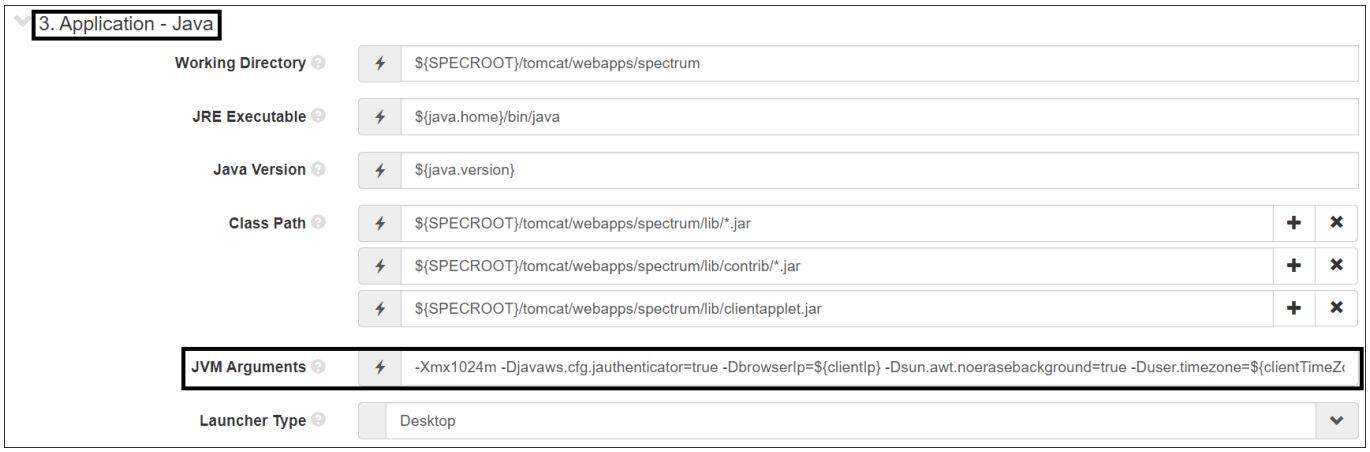


5. Select **Show Config**, to view the configuration.



6. Add the following for the JVM Arguments under the **Application – Java** section after the `-Djavax.net.ssl.trustStorePassword=changeit` entry:

```
-Djavax.net.ssl.keyStore=${SPECROOT}/custom/keystore/cacerts -Djavax.net.ssl.keyStorePassword=changeit
```



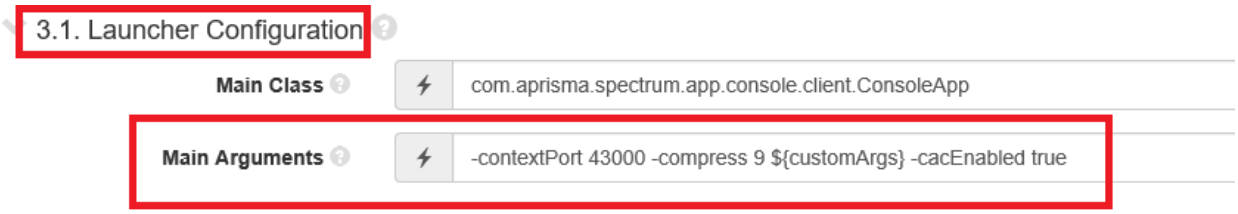
Cross verify these values with the OneClick tomcat server.xml configuration (only if SSL is enabled).

7. Verify that your JVM arguments are as follows:

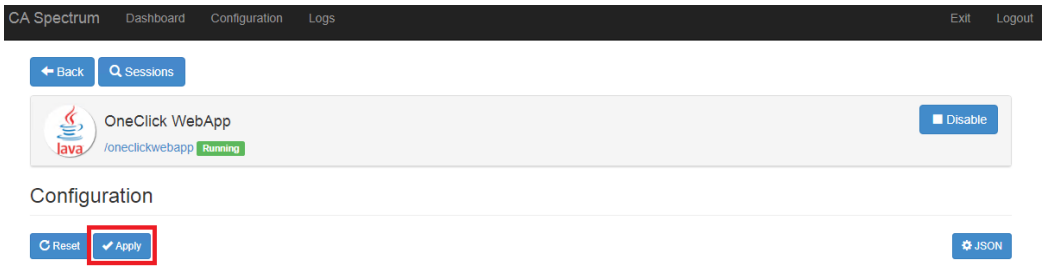
```
--Xmx1024m -Djavaws.cfg.jauthenticator=true
-DbrowserIp=${clientIp}
-Dsun.awt.noerasebackground=true
-Duser.timezone=${clientTimeZone}
-Djavax.net.ssl.trustStore=${SPECROOT}/custom/keystore/cacerts -Djavax.net.ssl.trustStorePassword=changeit
-Djavax.net.ssl.keyStore=${SPECROOT}/custom/keystore/cacerts
-Djavax.net.ssl.keyStorePassword=changeit
```

NOTE
Do not set the ${SPECROOT} to an absolute path. However, change the path/filename of the keystore (the default is cacerts) and password (the default is changeit) if they are not the default entries.

8. Navigate to the **Launcher configuration>Main Arguments** section and add `-cacEnabled true` to the end of the entry.



9. After you have made the changes, select **Apply** on the top left corner and re-launch the OneClick WebApp from the administration page.



10. Launch the OneClick Admin page and select the OneClick WebApp option, to launch the OneClick WebApp application.

(Optional) Configure WebApp User Session Timeout

When a session is inactive for a specific duration, the session automatically logs out after the defined time. You can configure the user session timeout for WebApp users. By default, the session timeout option is disabled. You can enable the session timeout and set the inactive time after which the session must be timed out.

Follow these steps:

1. Log in to the OneClick WebApp administration page.
   Default URL: https://<webapp-hostname>:<webapp-port>/spectrum
2. Select Manage.
3. Select Application, Config.
4. Navigate to the **Application - Session** section.
5. Enter a duration for which session must be active, in the **Session Timeout** field.
   Default: 300 (seconds)
6. Toggle the **Timeout if Inactive** field to ON or OFF.
7. Click **Apply**, to save your changes.
8. Relaunch the OneClick WebApp.

Troubleshooting OneClick WebApp

This section describes the steps you can take to troubleshoot some common issues that you may face during WebApp configuration.

Troubleshooting Enabling the SSL support

This section discusses the procedure to troubleshoot any error while enabling the SSL Support.

Follow these steps:

1. Log in to the OneClick WebApp administration page. Refer to the $SPECROOT/webtomcat/conf/server.xml file for webapp port details.
   Default URL: https://<webapp-hostname>:<webapp-port>/spectrum
2. Log in with the spectrum/spectrum as a username/password.
3. Select Manage.
4. Check whether the OneClick WebApp is enabled or not. If it is not enabled you see the Enable button on the top right corner.
5. Select **Enable**, if the option is in the disable state.
6. Select Show Config, If it is already enabled. The JVM arguments contain the trustStore path and password under the application.
7. Verify the data with OneClick Tomcat server.xml configuration.
8. Navigate to the Launcher configuration, Main arguments.
9. Verify that arguments point to the localhost, where the SSL port and the -ssl is be set to true.

Troubleshooting Launching/Starting Webtomcat

Follow these steps:

1. Check the **tomcat/conf/server.xml** and the **webtomcat/conf/server.xml** files for any port conflicts (often port conflicts will shut down the port).
2. For Linux, the webtomcat does not start if the XVFB is not installed. Refer to the section on Steps to run OneClick WebApp on Linux on this page.

Common Errors with OneClick and Action Required

Error: Spectrum Tomcat is running in SSL mode, Please configure Spectrum WebTomcat also in SSL mode.

Solution: When OneClick is in HTTPS, WebApp also must be in HTTPS.

Error: Not able to reach OneClick Webapp. The process might be stopped. Please start the Spectrum WebTomcat Process and re-launch.

Solution: In case the WebApp process is down, start the WebApp process.

Error: Request Processing failed. Please refer tomcat log for more details.

Solution: In case of any other issues, WebApp shows an appropriate error. Refer to the tomcat log for more details and take appropriate action.

Error: When I launch the WebApp from OneClick administration page, application gets redirected to Administration page. I see the following errror in the tomcat log.

```
java.lang.reflect.InvocationTargetException
Caused by: java.lang.NoClassDefFoundError: org/webswing/ext/services/ImageService
```

Solution: The error occurred because the webtomcat jars are not properly loaded. Restart the webtomcat (stop and start) to solve the issue.

Managing Network

This section describes how to use this product to manage your network.

ATM Circuit Manager

This section discusses how you can discover, manage, and monitor your ATM network.

ATM and Modeling Concepts

This section explains the ATM network technology, and the ATM network model types available in DX NetOps Spectrum. This section also describes the typical ATM infrastructure scenarios.

ATM Technology

Asynchronous Transfer Mode (ATM) is a connection-oriented, network communication architecture that transmits data through pre-established virtual channels called circuits that are similar to telephone calls. Circuits can be established automatically by switched virtual circuit (SVC) signaling, or they can be set up manually to form permanent virtual circuits (PVCs).

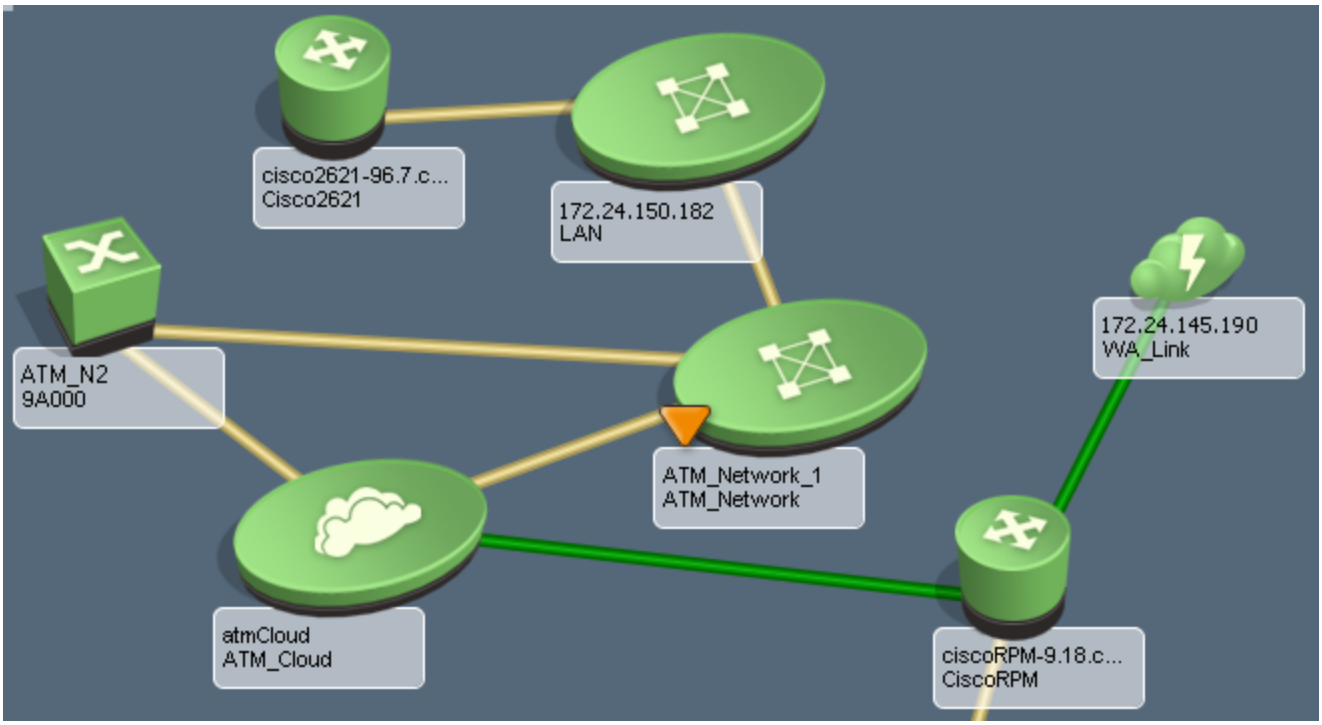
ATM is based on the transmission of fixed-length (53-byte) cells of data. ATM's use of small, fixed-length data cells allows for improved traffic management and traffic shaping. Each ATM cell contains a 5-byte header and 48 bytes of payload. The header includes a virtual path identifier (VPI) and a virtual channel identifier (VCI). These identifiers are used by ATM switches to determine the correct channels on which to transmit particular cells. Transmission is controlled by statistical multiplexing, which awards bandwidth (channels) to devices on a first come, first serve basis.

The combination of small, fixed-length data cells and the efficient use of bandwidth enable ATM switches to communicate time-critical video and audio data, as well as other computer data, across the ATM network. In an end-to-end transmission across a mixed LAN/ATM/LAN network, packets transmitted by a LAN workstation to an ATM switch are segmented into

cells for high speed transmission through ATM channels. At the destination, the cells are then reassembled into packets for use by another LAN workstation.

Overview on ATM Circuit Manager

DX NetOps Spectrum's ATM Circuit Manager lets you model both the physical and logical connectivity of your ATM infrastructure. You can represent an ATM infrastructure that you own and manage, or one that is partially or fully owned and managed by a service provider. The following illustration shows a sample modeled ATM network that includes partial management by a service provider.

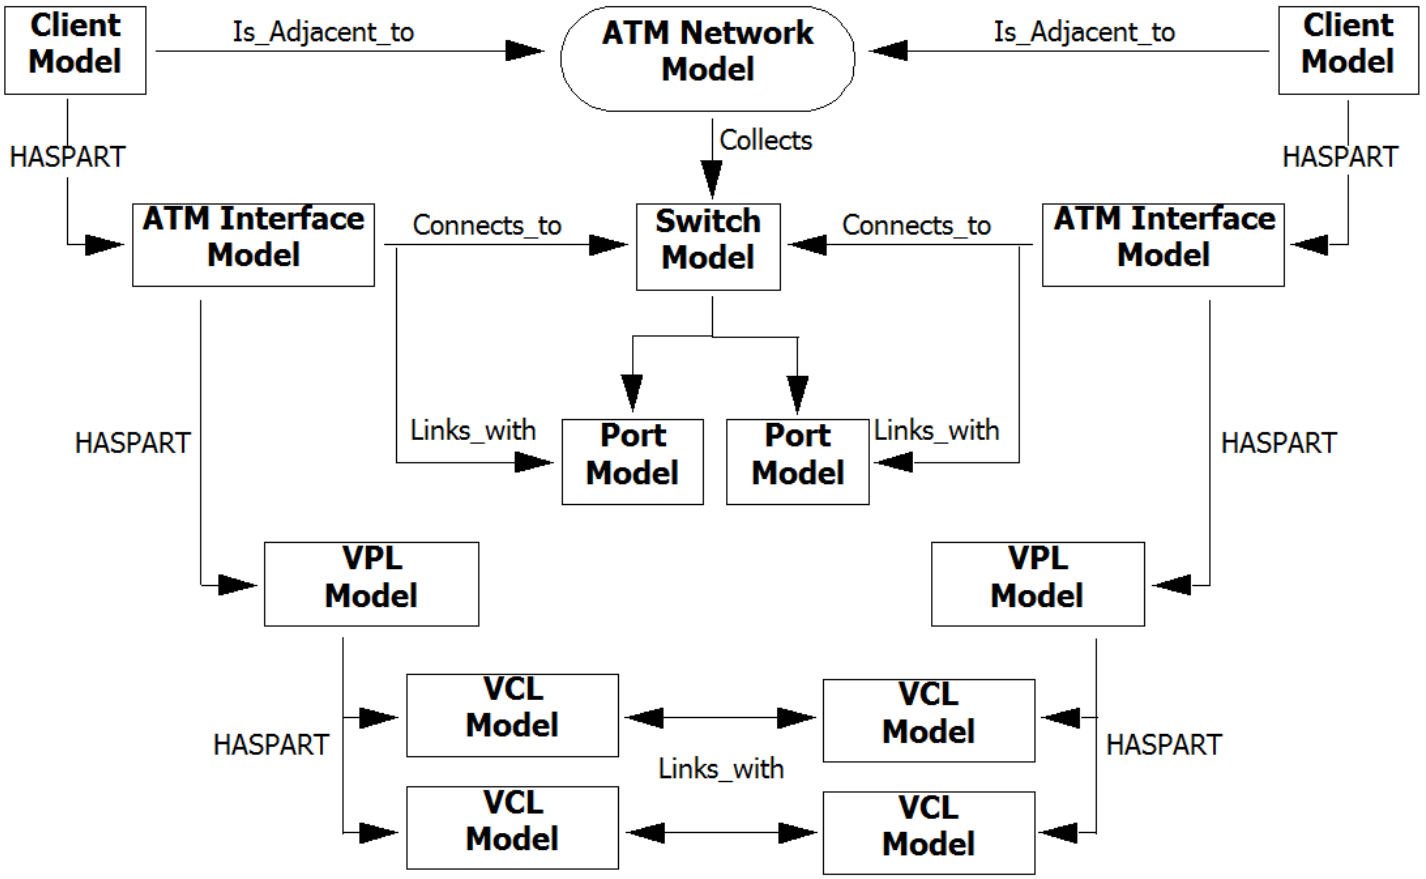


In a fully or partially meshed ATM network, each physical ATM interface may have logical connections with many other ATM devices. However, without ATM Circuit Manager, DX NetOps Spectrum's modeling functionality will only model physical ATM interfaces, leaving logical ATM interfaces unmanaged and limiting connectivity to physical links. Therefore, without ATM Circuit Manager, it is impossible to accurately represent the logical connectivity of the switches and routers in the ATM network.

The physical connectivity of an ATM network is represented by *Connects_to* associations between the ATM physical interface models and the connected device models. This lets you represent true data relay paths between the clients and helps ensure proper fault isolation. You can represent the physical connectivity of the ATM network by connecting a physical ATM interface model to another physical interface model, to a device model, or to an ATM_Cloud model.

The logical connectivity of an ATM network is represented by logical connections between virtual link models. These virtual link models represent the endpoints of a virtual connection. Virtual link models include VPLs (virtual path links, also referred to as virtual path trunks or VPTs) and VCLs (virtual channel links). Virtual link models are associated with a lower-layer interface model using the HASPART relation. The lower-layer interface may be a physical ATM interface model, or, in the case of a VCL, it may be a VPL or VPT model.

The following illustration shows the relationships between the modeled physical and virtual components in an ATM network.



NOTE
An actual ATM network would contain (collect) multiple switches. For simplicity, the illustration shows just one switch.

NOTE
Once you have modeled your ATM network, you can use ATM Circuit Manager to isolate faults within the network, evaluate performance, and monitor quality of service.

ATM Model Types

ATM Circuit Manager uses several model types to enable you to accurately represent your ATM infrastructure. These include ATM_Cloud, ATM_Network, ATMVplLink, ATMVclLink, and UnmanAtmLink.

ATM_Cloud

The ATM_Cloud model type is used in modeling situations where a service provider supplies wide area connectivity to remote sites using ATM links that are leased channels or paths.There is no management access to the service provider's network. In this scenario, management of the ATM links must be provided by the ATM clients also referred to as ATM Edge devices and/or ATM switches connected to the service provider's equipment.

If the devices connected to a cloud have their virtual interfaces modeled (as VPLs/VPTs, VCLs, or both), you can use the interfaces to create logical connections between endpoints.

ATM_Network

The ATM_Network model type is used in modeling situations where the ATM switched fabric is completely managed.

If the devices within the network and the devices connected to it have their virtual interfaces modeled (as VPLs/VPTs, VCLs, or both), you can use the interfaces to create logical connections between endpoints.

ATMVplLink and ATMVclLink

The ATMVplLink model type represents a VPL/VPT, and the ATMVclLink model type represents a VCL. These virtual link models represent the endpoints of a virtual connection, and connectivity between them represents the logical connectivity of the ATM network.

Management of the PVPs and PVCs in the ATM network is achieved by polling the attributes of VPL/VPT and VCL models. DX NetOps Spectrum uses this data to do the following:

- Monitor circuit status and other statistics
- Generate alarms based on the status of a model, for example, when the load on the model exceeds a predefined threshold

In OneClick, you can view a device's physical interface models and virtual link models on the Interfaces tab. The virtual link models in the table are identified by interface type (atmLink and, more specifically, VPL, VPT, or VCL). You can identify the underlying model type of a specific virtual link model by displaying the value for Modeltype_Name using the Attributes tab.

UnmanAtmLink

Some ATM paths or circuits may be manageable from only one endpoint. The device on one side may not have an SNMP agent, may be inaccessible for some reason, or you simply may not have management of the device. If this is the case, you can create a model of type UnmanAtmLink to represent the unmanaged endpoint, and then include the unmanaged model in a logical connection with a managed endpoint.

ATM Network Topologies

There are four typical ATM infrastructure scenarios:

1. You own and administer the switches and clients that comprise the ATM infrastructure.
2. You use a completely leased network through an ATM service provider to provide wide-area connectivity, and you have no management access to the ATM switched fabric.

3. You use a completely leased network through a service provider, and you have a mixture of ATM and Frame Relay interfaces on either side of the leased network.
4. You own and manage your own local area ATM network and lease additional wide-area channels through a service provider's network.

The following subtopics explain how the ATM-related model types are used to represent these different types of ATM infrastructures. For an illustration of the associations that are described, see Overview on ATM Circuit Manager.

A Completely Owned ATM Network

If you own your ATM switches, you will use an ATM_Network model to represent the switched fabric. Switch models will appear within the ATM_Network model and have a *Collects* association with that model. Client models will have an *Is_Adjacent_to* association with the ATM_Network model because the connection between the clients and the switches within the network have been fully modeled at the physical interface level.

A Completely Leased ATM Network

If an ATM service provider supplies wide-area connectivity to remote sites, there is no management access to the service provider's ATM switches. The ATM clients must provide all of the data to monitor the ATM circuits. To support the modeling of this type of network, an ATM_Cloud model is used. All ATM interfaces that connect to the service provider's network will have a *Connects_to* association with the ATM_Cloud model. This modeling association can be established manually as described in Connecting the Physical Interfaces to the Service Provider's Network.

An ATM to Frame Relay Network

It is possible to have a hybrid ATM network that includes multiple Frame Relay to ATM links over a completely leased network. In this scenario, signals transmitted from a local ATM interface through the service provider's network are converted to Frame Relay by a translational bridge before being received by the remote Frame Relay interface, and vice versa. The modeling procedure for this scenario is identical to that for modeling an ATM to ATM logical connection over a completely leased network.

A Completely Owned ATM Switched Fabric with Leased ATM Wide-Area Channels

If you own your local ATM switches, but you connect to a service provider's network for wide-area access, the physical interface(s) of one or more ATM switches may be connected to the ATM_Cloud model. In this case, DX NetOps Spectrum intelligence will automatically create VPL and VCL models to represent the VPLs and VCLs of a physical interface connected to the ATM_Cloud model. If the ATM switches are modeled within an ATM_Network, the ATM_Network model will be adjacent to the ATM_Cloud model.

Modeling the ATM Network

This section discusses how you can accurately model your ATM network.

How to Create an Accurate Model of Your ATM Network

To create an accurate model of your ATM network, you must perform the following high-level tasks:

1. Model the physical elements and physical connectivity in the network using Discovery or manually.
2. Connect the physical ATM interfaces to the service provider's network.
3. Model the logical connectivity between virtual path links (VPLs, also referred to as virtual path trunks or VPTs) and virtual channel links (VCLs).

   NOTE
   This section refers to VPLs and VCLs, collectively, as virtual link models.
4. Create logical connections between the virtual link models. You can create the connections using Discovery (for VCLs on Cisco devices only), create the connections manually, or import them using a file that defines them.

Physical Components Modeling in the ATM Network

To model the ATM circuits correctly, the physical connectivity must be modeled first. You can do this using Discovery or manually. If you use Discovery, you may need to manually customize the results to verify that the model accurately represents the network infrastructure.

Physical Components Modeling Using Discovery

When you use Discovery to model the physical components in an ATM network, and you select in the Protocol Options dialog that ATM protocols be used to map the connectivity between models, Discovery maps the physical connectivity between the ATM devices and places ATM switch models inside ATM_Network container models.

If Discovery does not fully map the physical ATM connectivity of your network, including switch-to-switch and router-to-switch connections, you must rerun Discovery or complete the mapping manually.

> **NOTE**
> Discovery does not create ATM_Cloud models to represent the ATM networks of service providers. After you model your network using Discovery, you must create these models manually and then name them appropriately (for example, Sprint's Network).

If you are using Cisco ATM devices and the VCL interfaces have unique IP addresses, Discovery also resolves the connections between VCL interfaces or between VCL interfaces and Frame Relay DLCI interfaces.

> **NOTE**
> For complete information on modeling using Discovery, see the Modeling and Managing Your IT Infrastructure section.

Once you have modeled the physical components and connections in the ATM network, you can then model the logical connectivity between virtual path links (VPLs, also referred to as virtual path trunks or VPTs) and virtual channel links (VCLs).

Manual Physical Components Modeling

You may need to manually model the ATM infrastructure for various reasons:

- You prefer to manually create all ATM models and connections.
- You have used Discovery to model the devices and map their physical connectivity, but you now need to make some manual modifications to make the network representation fully accurate.
- You have used Discovery to model the ATM infrastructure, but you now need to create ATM_Cloud models to represent the ATM networks of service providers. Discovery does *not* create these models.

After you manually model the devices, you can create connections between container models, device models, and physical interface models. You can connect the physical ATM interface models directly to the switch or client models, but they must be collected by an ATM_Network model to have access to the Logical Connection Table.

> **NOTE**
> For complete information on manually modeling devices and connections, see the Modeling and Managing Your IT Infrastructure section.

After you model the physical components and connections in the ATM network, you can then model the logical connectivity between virtual path links (VPLs, also referred to as virtual path trunks or VPTs) and virtual channel links (VCLs).

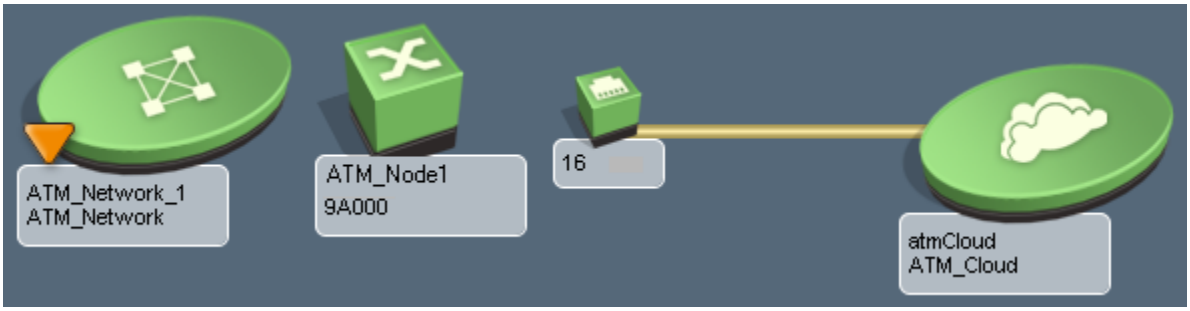
Connect Physical Interfaces to Service Provider's Network

In order for DX NetOps Spectrum to accurately determine the point of an ATM network failure during fault isolation, every physical ATM interface that connects to the service provider's network should be connected to the ATM_Cloud model.

Connecting the physical ATM interfaces to the service provider's network is a manual step regardless of whether you have modeled the ATM network manually or used Discovery.

To connect an ATM interface to the service provider's network

1. On the Interfaces tab of the associated device, select the physical ATM interface to connect to the service provider's network, right-click, and click Start Connection.
2. On the Topology tab, select the ATM_Cloud model that represents the service provider's network, right-click, and click Connect With *<ATM Interface Name>*, where *<ATM Interface Name>* is the name of the interface you selected in the first step.
   A pipe between the ATM_Cloud and the physical ATM interface (and the appropriate network container model) is created to represent the connection. You can double-click the pipe to view the connection between the ATM_Cloud and the physical ATM interface itself, as shown in the following example.



Modeling the Virtual Interfaces in the ATM Network

In DX NetOps Spectrum, physical connections between devices are managed by polling the status and performance data of the endpoints, such as FDDI or HSSI interfaces.

There is no difference between managing logical connections and managing physical connections except that the logical connection endpoints are Virtual Path Links (VPLs) or Virtual Channel Links (VCLs). This section refers to VPLs and VCLs collectively as *virtual links*.

Like physical interfaces, virtual links have objects in a MIB that contain the status, bandwidth, and-depending on the MIB-performance statistics. Physical interfaces, as represented in the MIB-II *ifTable*, have a single-term index, but VPLs have a two-term index, and VCLs have a three-term index.

- A VPL index is in the form *ifIndex.VPI*, where *ifIndex* is the index of the physical interface that the VPL runs on, and *VPI* is the Virtual Path Identifier (the identifier given to the path when it was created).
- A VCL index is in the form *ifIndex.VPI.VCI*, where *VCI* is the Virtual Channel Identifier (the identifier given to the channel when it was created).

Virtual links can be modeled for all ATM clients and switches that have supported ATM MIBs.

Required MIBs

DX NetOps Spectrum can use different sets of SNMP MIBs to manage ATM links and logical connections. When DX NetOps Spectrum creates a device model to represent an ATM device, it also creates an application model based on the ATM MIBs that the device supports.

The following table lists the DX NetOps Spectrum management modules that support ATM devices, the MIBs required to support those devices, and the type of application model that is created to support the required MIBs.

Management Module	MIBs	Application Model Type
CA Spectrum Core Product	ATM-MIB	ATMClientApp
CA Spectrum Core Product	ATM-MIB ATM2-MIB ATM-FORUM-MIB	ATMSwitchApp
Bay Networks Centillion 100 (SM-BAY1001)	CENTILLION-ATMCFG-MIB	CentATMApp
Cisco Catalyst 85xx (SM-CAT1008)	ACCOUNTING-CONTROL-MIB ATM-MIB ATM-FORUM-MIB ATM-RMON-MIB CISCO-ATM-ACCESS-LIST-MIB CISCO-ATM-CONN-MIB CISCO-ATM-IF-MIB CISCO-ATM-IF-PHYS-MIB CISCO-ATM-RM-MIB CISCO-ATM-SERVICE-REGISTRY-MIB CISCO-ATM-SWITCH-ADDR-MIB CISCO-ATM-TRAFFIC-MIB CISCO-PNNI-MIB	CiscoSwitchApp
Cisco LightStream 1010 (SM-CIS1002)	ACCOUNTING-CONTROL-MIB ATM-MIB ATM-FORUM-MIB ATM-RMON-MIB CISCO-ATM-ACCESS-LIST-MIB CISCO-ATM-CONN-MIB CISCO-ATM-IF-MIB CISCO-ATM-IF-PHYS-MIB CISCO-ATM-RM-MIB CISCO-ATM-SERVICE-REGISTRY-MIB CISCO-ATM-SWITCH-ADDR-MIB CISCO-ATM-TRAFFIC-MIB CISCO-PNNI-MIB	LS_Switch_App
Cisco Router (CIS-1000)	CISCO-AAL5-MIB	CiscoAAL5App
Cisco Stratacom BPX8600 and IGX8400 Series (SM-CIS1003)	STRATACOM-MIB	StComATMSwApp
ForeRunner ATM Switch Modules (SM-FOR1000)	Fore-Switch-MIB	ForeSwitchApp
Lucent Ascend CBX (SM-LUC1002)	CASCADE-MIB	CascadeATMApp
Nortel Passport Multiservice Carrier Switch Series (SM-NTL1005)	Nortel-MsCarrier-MscPassport-AtmCoreMIB	PpAtmClientApp
SmartSwitch 9000/9500 Series (SM-CSI1073)	ATM-MIB ATM2-MIB ATM-FORUM-MIB	PredSwitchApp

Specify Virtual Links to Model for a Device

DX NetOps Spectrum models the virtual links (VPLs and VCLs) on ATM devices by periodically reading the MIBs on the devices to determine the virtual links that currently exist. By default, ATM links (VPLs and VCLs) are modeled for ATM clients, and, for performance reasons, they are not modeled for ATM switches.

An exception to this default behavior is when a physical interface of an ATM switch is connected to an ATM_Cloud model. In this situation, the virtual links associated with that interface are modeled. These virtual links are necessary to resolve logical connectivity across the ATM_Cloud.

You can change the configuration of an ATM device so that only VPLs are modeled, both VPLs and VCLs are modeled, or so that no virtual links are modeled at all. The last option is especially useful if the virtual links for a device are dynamic (such as the case when SVCs are in use) and modeling them holds no inherent value.

NOTE
If a particular ATM device has a very large number of VCLs (in the order of thousands), modeling and reconfiguration of the virtual link models can impact SpectroSERVER performance.

To specify the virtual interfaces to model on an ATM device

1. Use the Navigation panel or the Topology tab to locate and select the device.
   Information about the device is displayed in the Component Detail panel.
2. Click the Information tab in the Component Detail panel, expand Reconfiguration, and expand ATM Link Modeling Options and Reconfiguration.
3. Specify whether to model ATM links (virtual interfaces) for the device and, if so, whether to model only VPLs or both VPLs and VCLs:
   – To enable the modeling of ATM links, click set in the 'Create models to represent ATM links' field and select Enabled. Alternatively, if you do not want to model any ATM links, select Disabled instead. (By default, this option is enabled for ATM Client models and disabled for ATM Switch models.)

     NOTE
     If the ATM links for a device are currently modeled, and you disable this option, all existing ATM link models for the device will be deleted after you click 'Reconfigure ATM Link and Virtual Interface Models' in the next step.
   – To enable the modeling of virtual channel links (VCLs), click set in the 'Create models to represent VCLs' field and select Enabled. Alternatively, if you do not want to model VCLs, select Disabled instead.

     NOTE
     This option only controls the modeling of VCLs. If 'Create models to represent ATM links' is set to Disabled, this setting has no effect.
4. Click Reconfigure ATM Link and Virtual Interface Models.
   DX NetOps Spectrum reads the MIBs on the devices to determine the virtual links that currently exist and then creates and destroys the virtual link models according to the settings you specified.

Specify Frequency for Updating Virtual Link Models

DX NetOps Spectrum models the virtual links (VPLs and VCLs) on ATM devices by periodically reading the MIBs on the devices to determine the virtual links that currently exist and then updates the virtual link models accordingly. If desired, you can change the interval at which this read operation is performed.

To specify the frequency for updating virtual link models

1. Use the Navigation panel or the Topology tab to locate and select the appropriate device.
   Information about the device is displayed in the Component Detail panel.
2. Click the Information tab in the Component Detail panel, expand Reconfiguration, and expand ATM Link Modeling Options and Reconfiguration.
3. Click set in the Configuration Discovery Interval (sec) field, type a new time interval in seconds, and press Enter.

Logical Connections Links between Virtual Link Models

Virtual link models can have Links_with associations with other virtual link models to indicate logical connections. A *managed virtual circuit* is a circuit whose virtual link models are associated by a logical connection. ATM circuits run from one client, through the ATM_Network, to another client, or directly between ATM switches within the switched fabric. By default, none of the circuits through the switched fabric are managed.

You can create logical connections (*Links_with* associations) between virtual link models in the following ways:

- Use Discovery (Cisco devices only)
- Manually create the connections
- Import a file that defines the connections to create

DX NetOps Spectrum uses the logical connection information during the fault isolation process.

Logical Connections Links for Cisco Devices Using Discovery

When you run Discovery to model your ATM network, if the VCL interfaces on the Cisco ATM devices have unique IP addresses, DX NetOps Spectrum resolves the connections between these interfaces. If there are connections between Cisco VCL interfaces and Frame Relay DLCI interfaces, DX NetOps Spectrum also resolves these connections.

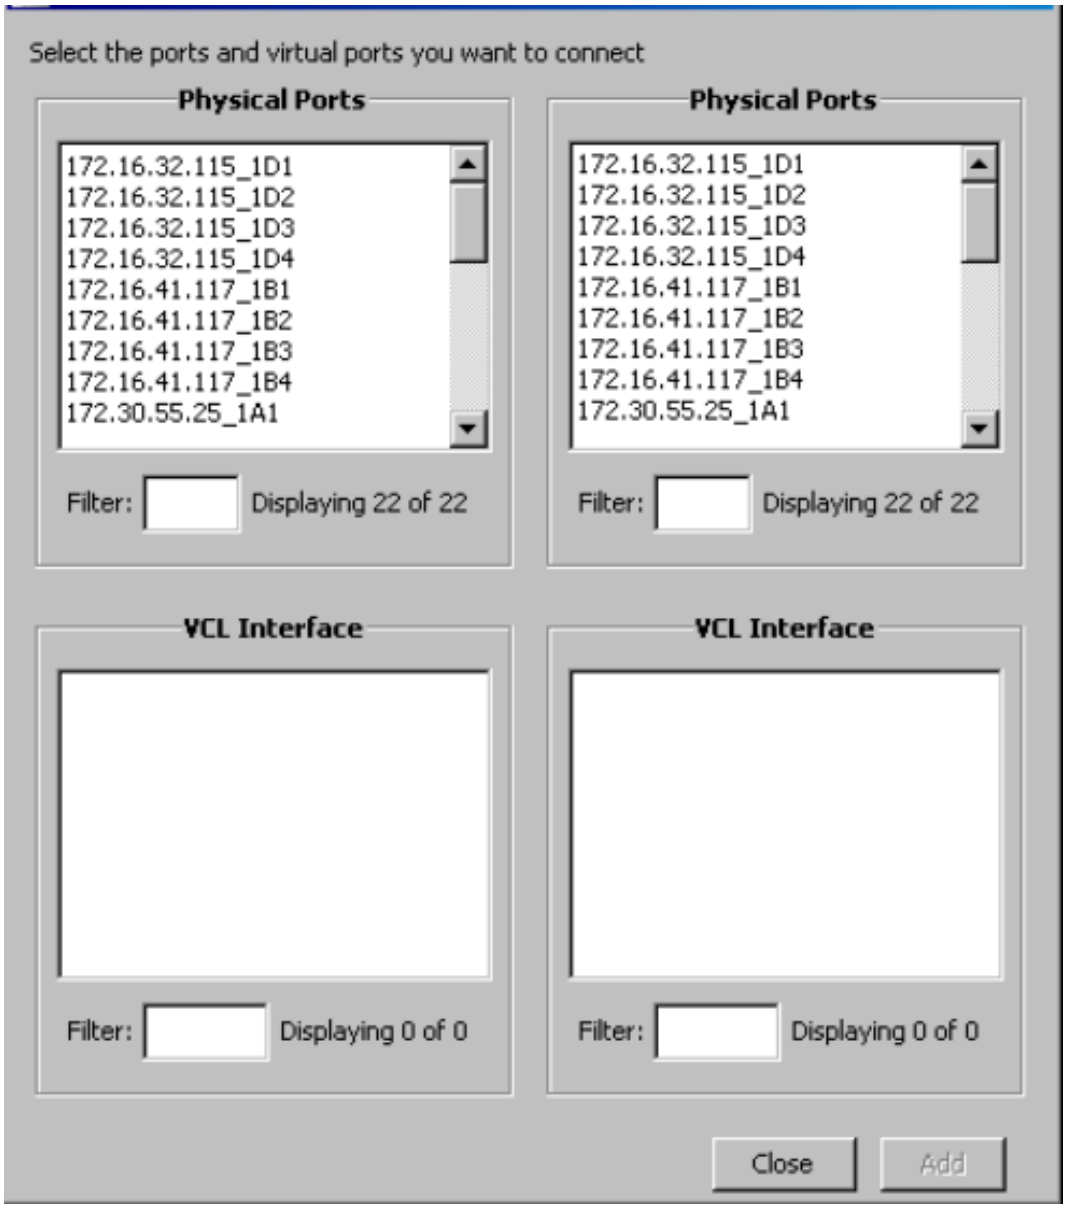
NOTE
For information on using Discovery, see the Modeling and Managing Your IT Infrastructure section.

Create Logical Connections Manually

NOTE
You can include a virtual link in only one logical connection.

To manually create logical connections between virtual link endpoints

1. Use the Navigation panel or the Topology tab to locate and select the ATM_Cloud or ATM_Network model that is connected to or contains the relevant device and interface models.
2. Click the Information tab in the Component Detail panel, expand Logical Connection Table, and click Add. The Logical Connection Manager dialog opens.



The dialog lists the physical ports on the ATM devices connected to the selected cloud, or connected to or contained within the selected network. Only the ports that currently have virtual link models are included in the lists.

3. Select one of the physical ports that contains the virtual link to connect in the left Physical Ports box.
   The virtual interfaces for the selected port are displayed in the left VCL Interface box.
4. Select the virtual link that represents the first endpoint of the logical connection in the left VCL Interface box.
5. Repeat the Step 3 and Step 4 using the right-side boxes to locate and select the virtual interface that represents the second endpoint in the logical connection, and click Add.
   A *Links_with* association is added between the virtual link models, and the logical connection is displayed in the Logical Connection Table.
6. Repeat the preceding steps to create additional logical connections as needed, and click Close.

Create Logical Connections to Unmanaged Models

It is possible for a DX NetOps Spectrum user to be responsible for a circuit but not have SNMP contact with the device on one side. If this is the case, you can still create a logical connection that includes the unmanaged link model and manage the circuit from the other endpoint.

When you create a connection to an unmanaged link model, ATM Circuit Manager creates a model of type UnmanAtmLink and associates it with the ATM_Network or ATM_Cloud model using a *Contains* relation. As with all logical connections, a *Links_with* association between the managed and unmanaged virtual link models is created.

To create a logical connection to an unmanaged link model

1. Use the Navigation panel or the Topology tab to locate and select the ATM_Cloud or ATM_Network model that contains or is connected to the relevant device and interface models.
2. Click the Information tab, expand the Logical Connection Table, and click Add.
   The Logical Connection Manager dialog opens.
3. Under Physical Ports on the left side of the dialog, select the physical port that contains the managed virtual link.
4. Under VCL Interface on the left side of the dialog, select the managed virtual link.
   This virtual link will be the single point of management for the connection.
5. Under Physical Ports on the right side of the dialog, select a physical port on the unmanaged device.
6. Under VCL Interface on the right side of the dialog, select Unmanaged Link, and click Add.
7. Enter the following information about the unmanaged endpoint:
   - **Name**
     The name of the virtual link model. For convenience, the name of the associated ATM_Network container model is used as the default name, so you can easily use it as a prefix for the name you specify.
   - **Component OID**
     The component OID of the unmanaged endpoint (Port_ID.VPL.VCL).
   - **Network Address**
     The network address of the unmanaged interface (if there is one assigned).
   - **Circuit Name**
     The name of the circuit. This can be any name that has meaning, such as “London to Paris link.”
   - **Circuit ID**
     The ID of the circuit. This can be any ID that has meaning, such as “Leased Circuit 119.”
8. Click OK.
   The unmanaged link model is created, and the logical connection between it and the managed link model is also created.

Logical Connections Link in ATM and Frame Relay Models

If you have a mixture of ATM and Frame Relay interfaces on either side of a leased service provider's network, you can create logical connections between their virtual interfaces (VPLs, VPTs, VCLs, and DLCIs) using *Links_with* associations. The procedure for modeling these types of connections is the same as that for ATM-to-ATM logical connections with two exceptions:

- When following the procedure outlined in Connect Physical Interfaces to Service Provider's Network , the physical interface selected in Step 1 will be a Frame Relay interface, such as a serial port.
- When following the procedure outlined in Creating Logical Connections Manually, the virtual interface selected as an endpoint in Step 3 or Step 4 will be a DLCI virtual interface.

It is also possible to use a file to import a list of ATM-to-Frame Relay connections. To do this, you can use the import process described in Importing Logical Connections, but you must access the Logical Connection Import subview that is available on the Information tab of the *VNM model*, not the Logical Connection Table subview that is available on the ATM_Network or ATM_Cloud model.

NOTE
For more information about Frame Relay, see the Standards-Based Protocol Reference section.

Import Logical Connections

You can create logical connections between virtual link models by importing a comma-delimited, ASCII file (text file or XML file) that defines the connections. You can define connections that include two ATM models or an ATM model and a Frame Relay model.

The file in which you define the logical connections must be a comma-delimited, ASCII file (text file or XML file). Use the following syntax to define a connection:

```
<device_IP_1>,<subinterface_OID_1>,<device_IP_2>,<subinterface_OID_2>,
<circuit_name>,<circuit_ID>,<Pipe>
```

The parameters are as follows:

- **device_IP_1**
  Specifies the IP address of the first device in the connection.
- **subinterface_OID_1**
  Specifies the component OID of the first virtual interface in the connection.
- **device_IP_2**
  Specifies the IP address of the second device in the connection.
- **subinterface_OID_2**
  Specifies the component OID of the second virtual interface in the connection.
- **circuit_name**
  (Optional) Specifies the name of the circuit. This can be any name that has meaning.
- **circuit_ID**
  (Optional) Specifies the ID of the circuit. This can be any ID that has meaning.
- **pipe**
  (Optional) Specifies CREATE_PIPE to create a live pipe to graphically represent the connection. Otherwise, specify NO_CREATE_PIPE.

To import the logical connections defined in a file

1. In OneClick, use the Navigation window or the Topology view to select one of the following:
   – The ATM_Network that contains or has connections to the physical interfaces of the virtual link models for which you want to define connections
   – The ATM_Cloud that has connections to the physical interfaces of the virtual link models for you which you want to define connections
2. In the Component Detail window, click the Information tab and expand Logical Connection Table.
3. Click the
   icon 
   This icon helps import a file describing links between virtual interfaces.
4. In the Open dialog, navigate to the file that contains the connection definitions, select the file, and click Open.
   The connection definitions are imported, and the logical connections are created. If the import process fails, you are notified in the Import Results dialog that describes the results of the operation.
5. In the Import Results dialog, click OK.

Note: You can find additional information about the import operation (and previous ones) on the Information tab under the Modeling Gateway subview for the VNM model. This view displays the name of the file that was imported, the location of the log file that was created for the operation, and other information.

Create Pipes Between Virtual Link Models

In some cases, you might want to create pipes (resolved connections) to represent important logical connections between virtual link models. This allows you to monitor the status of a circuit based on the pipe's color in the Topology view.

NOTE
For an introduction to pipes, see the Modeling and Managing Your IT Infrastructure section.

To create a pipe between virtual link models

1. Use the Navigation window or the Topology view to locate the device that contains one of the virtual link models, and select the device.
   Information about the device is displayed in the Component Detail window.
2. In the Component Detail window, click the Interfaces tab.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models. You can right-click the interface to get the Expand All or Collapse All option for your IP address.
4. Select one of the virtual link models you want to connect with a pipe, right-click, and click Start Connection.
5. Select the other virtual link model to connect with the pipe, right-click, and click Connect With *<name of virtual link model>*, where *<name of virtual link model>* is the name of the interface model you selected in the previous step.

NOTE
You can also create pipes when you import a set of logical connections.

Monitoring and Managing the ATM Network

DX NetOps Spectrum lets you set up thresholds, monitor network performance, and diagnose several common network problems.

The management of PVPs and PVCs on ATM switches and ATM clients consists of:

NOTE

If you are monitoring Cisco devices with ATM Circuit Manager, and you are making use of DX NetOps Spectrum's Live Pipes feature or the PortPollStatus attribute to monitor connectivity, it is recommended that you use Cisco's Operation, Administration, and Maintenance (OAM) feature. Turning on this feature helps ensure that you can detect communication problems on a permanent virtual connection (PVC) when network connectivity is lost but the PVC remains up on the end devices. In this situation, if OAM is not configured, and a CiscoATMVclLnk goes down, an alarm is not generated. For more information, see the ATM technical tips on the Cisco web site.

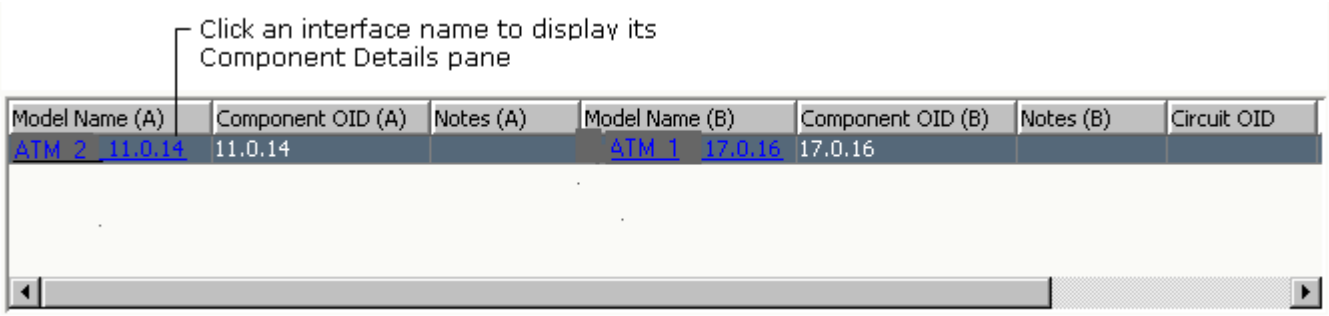
Monitor the Logical Connections Between Virtual Link Models

As you monitor your ATM network, you need to view the logical connections between virtual link models, for example, so you can determine the status of a particular circuit represented by a connection.

To view the logical connections between virtual link models

1. Use the Navigation panel or the Topology tab to locate and select the ATM_Cloud or ATM_Network model that the logical connection you want to view traverses or is a part of.
2. Click the Information tab and expand Logical Connection Table in the Component Detail panel.

The Logical Connection Table opens.



The connection table provides information about each connection; that is, the endpoint models and the logical connections they collectively represent. You can view a circuit's status by moving the scroll bar to the right.

3. To export the list of connections to a CSV, TXT, or HTML file, click

(Export).

4. To delete one or more connections, select them in the table and click

(Delete).

5. To display additional information in the Logical Connection Table, right-click the table heading, select the desired columns in the Table Preferences dialog, and click OK.

Monitor Virtual Link Models

As you monitor your ATM network, you need to view a device's virtual link models, for example, to determine their condition or status.

To view the virtual link models on an ATM device

1. Use the Navigation panel or the Topology tab to locate and select the device.
   Information about the device is displayed in the Component Detail panel.
2. Click the Interfaces tab in the Component Detail panel.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view its associated virtual link models. You can right-click the interface to get the Expand All or Collapse All option for your IP address.
   The interface table identifies the condition, status, and general type of the interface (for example, VPL or VCL), among other information. If the interface is used in a logical connection, the device and port at the other end of the connection are displayed, respectively, in the Device Connected and Port Connected fields.

   NOTE
   You can set the interface IP address as the primary IP address for DX NetOps Spectrum management. To do this, right-click the interface, select Configure Primary Address for Device, and select Use Interface IP as Primary Address.

NOTE
To display additional information in the interface table, right-click the table heading, select the desired columns in the Table Preferences dialog, and click OK.

View Virtual Link Models Performance

You can use the Performance view of a virtual link model to access the following:

- The percentage of the virtual link's utilization for input and output.
- The throughput for input and output using the virtual link.

	Value	Average	Low Value	Low Time	Peak Value	Peak Time
% Utilization	0.0	0.0	0.0	Oct 24, 2007 4:03:21 ...	0.0	Oct 24, 2007 4:03:21 ...
% Input Utilization	0.0	0.0	0.0	Oct 24, 2007 4:03:21 ...	0.0	Oct 24, 2007 4:03:21 ...
% Output Utilization	0.0	0.0	0.0	Oct 24, 2007 4:03:21 ...	0.0	Oct 24, 2007 4:03:21 ...

The current values are the last known values when the associated ATM device was polled. The other values are the average, low, and peak values since the Performance tab was opened.

The interface utilization calculations use the following statistical fields that indicate load:

- For input utilization, the value of the *rcvLoad* attribute
- For output utilization, the value of the *xmtLoad* attribute

The formulae for these attributes are as follows:

```
rcvLoad = rcvCellsPerSecond * 100 / rcvBandwidth
xmtLoad = xmtCellsPerSecond * 100 / xmtBandwidth
```

The *rcvBandwidth* and *xmtBandwidth* attributes are defined by either the Peak Cell Rate (PCR) or Sustainable Cell Rate (SCR) depending on the Quality of Service (QoS) type. For Variable Bit Rate (VBR) circuits, the bandwidth is defined as the SCR. For all other types of service, the bandwidth is defined as the PCR. This means that the load can exceed 100% for VBR circuits.

To always use the Peak Cell Rate (PCR) in bandwidth calculations-even for Variable Bit Rate (VBR) circuits-enable the corresponding setting in the VCL QoS Information view.

The *rcvCellsPerSecond* attribute is calculated by reading the attribute pointed to by *rcvCells_Attr* and the *upTime* attribute over a particular interval, and then subtracting the first values from the second values. This yields a delta of received cells and a delta of elapsed microseconds. By dividing the delta of cells by the delta of microseconds, and then multiplying by 100, the *rcvCellsPerSecond* value is determined.

You can log the values of the *rcvLoad* and *xmtLoad* attributes for historical reports.

NOTE
To use this Performance view, the ATM device must support the ATM2 MIB or one of the supported proprietary MIB extensions. Performance information is not available without the cell counters inherent in this MIB.

To view the virtual link model performance

1. Use the Navigation panel or the Topology tab to locate and select the device that has the virtual link model. Information about the device is displayed in the Component Detail panel.
2. Click the Interfaces tab in the Component Detail panel.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models.

   NOTE
   You can right-click to get the expand all and collapse all option for your IP address.
4. Select the link model for which you want to view performance information, and click

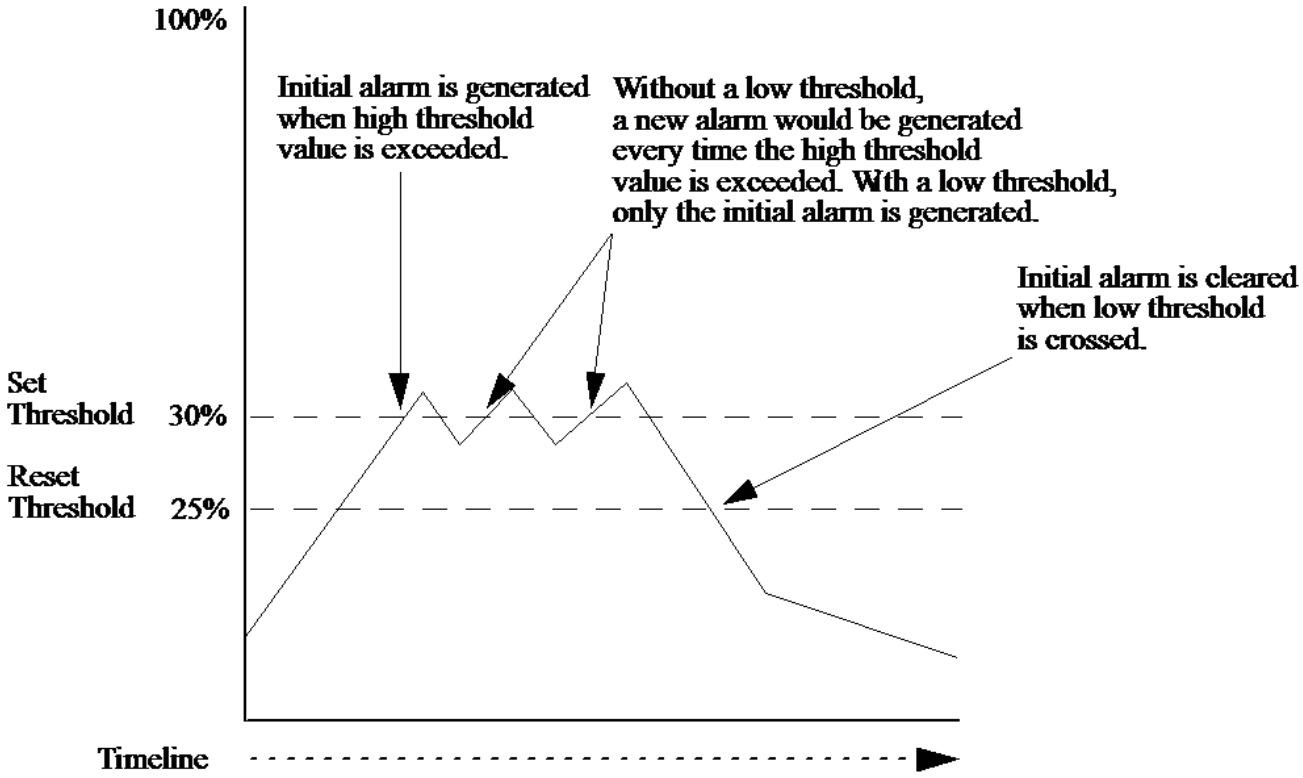
   (View the Component Detail for the selected model).
5. Click the Performance tab in the Component Detail panel.
   The performance information for the selected virtual link model is displayed.

Set Traffic Thresholds for Virtual Link Models

You can establish the levels of activity for virtual link models that will generate alarms. You do this by setting high and low thresholds for the following attributes:

- **Receive Load**
  The average number of bits received by the virtual link model since the last poll.
- **Transmit Load**
  The average number of bits transmitted by the virtual link model since the last poll.

Each high and low threshold has a “set” value and a “reset” value. For the high thresholds, the “set” value is the value that, if exceeded, generates an alarm for the attribute. The “reset” value is the value that, if gone below, automatically clears the alarm for the attribute. The “set” and “reset” values for the low thresholds work in the converse manner. The following illustration further describes the behavior.



By default, the high thresholds are set to 90% and reset at 80%, and the low thresholds are set to 0 and reset at 0. In other words, the low thresholds are disabled. The threshold values are recalculated at every poll cycle and represent the average number per poll.

WARNING
Do not set the “reset” field to “0.” If the “reset” field is set to “0” and the “set” field is crossed, the subsequent alarm is never cleared automatically. If the alarm is cleared manually by the user, the DX NetOps Spectrum threshold intelligence is not reset, and the alarm for that model is not generated again. To reset the threshold intelligence, the SpectroSERVER must be restarted.

NOTE
To use this Threshold view, the ATM device must support the ATM2 MIB or one of the supported proprietary MIB extensions. Thresholds cannot be set for a circuit without the cell counters inherent in this MIB.

To set traffic thresholds for a virtual link model

1. Select the device that has the virtual link model you want to configure from the Navigation panel or the Topology tab. Information about the device is displayed in the Component Detail panel.
2. Click the Interfaces tab in the Component Detail panel.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models.

   NOTE
   You can right-click the interface to get the Expand All or Collapse All option for your IP address.
4. Select the VPL or VCL model that you want to configure, and click

   (View the Component Detail for the selected model).

5. Click the Information tab and expand VCL Threshold Information in the Component Detail panel.
6. Specify a value for any of the thresholds by clicking set, entering the value, and pressing Enter.

Specify Service Information for Virtual Link Models

For reference purposes, you can add information about the service provider for individual virtual link models.

To specify service information for a virtual link model

1. Use the Navigation panel or the Topology tab to locate and select the device that has the virtual link model you want to configure.
   Information about the device is displayed in the Component Detail panel.
2. Click the Interfaces tab.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models.

   NOTE
   You can right-click the interface to get the Expand All or Collapse All option for your IP address.
4. Select the link model that you want to configure, and click

   (View the Component Detail for the selected model).
5. Click the Information tab and expand VPL/VCL Service Information in the Component Detail panel.
6. Enter the service information by clicking 'set,' entering the text, and pressing Enter.
   You can enter the following information:
   - **Provider**
     Specifies the name of the service provider associated with the ATM network.

     NOTE
     ATM customers who use multiple carriers can use this field to indicate the carriers that provide service for specific circuits.
   - **Customer**
     Users who are service providers and manage other companies' ATM networks can use this field to indicate the customer.
   - **Primary Contact**
     Specifies the name, phone number, and email address of the person to contact if there is a problem with the circuit.
   - **Secondary Contact**
     Specifies the name, phone number, and email address of a secondary person to contact if there is a problem with the circuit.
   - **Service Notes**
     Miscellaneous information about the circuit, such as the circuit ID or the monthly cost.

Specify Service Information for unmanATMLink model

NOTE
For reference purposes, you can add information about the service provider for unmanaged virtual link models.

To specify service information for an unmanATMLink model

1. Use the Navigation panel or the Topology tab to locate and select the ATM_Cloud or ATM_Network model where the unmanATMLink in question is defined as an endpoint of a logical connection.
2. Click the Information tab and expand Logical Connection Table in the Component Detail panel.
   The Logical Connection Table opens.

3. Locate the relevant row in the table and click the name of the unmanATMLink to launch the Component Detail for the model.
4. Click the Information tab and expand VPL/VCL Service Information in the Component Detail panel.
5. Enter the service information by clicking 'set,' entering the text, and pressing Enter.
   You can enter the following information:
   - **Provider**
     Specifies the name of the service provider associated with the ATM network.

     NOTE
     ATM customers who use multiple carriers can use this field to indicate the carriers that provide service for specific circuits.
   - **Customer**
     Users who are service providers and manage other companies' ATM networks can use this field to indicate the customer.
   - **Primary Contact**
     Specifies the name, phone number, and email address of the person to contact if there is a problem with the circuit.
   - **Secondary Contact**
     Specifies the name, phone number, and email address of a secondary person to contact if there is a problem with the circuit.
   - **Service Notes**
     Miscellaneous information about the circuit, such as the circuit ID or the monthly cost.

Monitor Quality of Service (QoS) Information for VCLs

If you have configured your network for Quality of Service (QoS), you can use ATM Circuit Manager to view the following QoS information for VCL link models:

- The QoS class of the connection.
- Performance information for the connection, for example, the peak cell rate when receiving and transmitting data.
- The bandwidth used to receive and transmit data on the connection, as well as the parameters used to calculate the bandwidth.

NOTE
For information on how to configure, discover, and manage the QoS elements of your network using DX NetOps Spectrum QoS Manager, see the QoS Manager section.

To monitor QoS information for a VCL

1. Use the Navigation panel or the Topology tab to locate and select the device that has the VCL model that you want to examine.
   Information about the device is displayed in the Component Detail panel.
2. Click the Interfaces tab.

   NOTE
   You can right-click the interface to get the Expand All or Collapse All option for your IP address.

   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models.
4. Select the VCL model that you want to examine, and click

   (View the Component Detail for the selected model).
5. Click the Information tab and expand VCL QoS Information.
   The QoS information for the selected VCL model is displayed.

6. (Optional) Click set in the Use Peak Cell Rate (PCR) for bandwidth calculation field and select Enabled to specify that the peak cell rate (PCR) of the connection is always used in bandwidth calculations.

   NOTE
   Alternatively, you can disable this setting if you want the parameters used in bandwidth calculations to be determined based on the QoS class.

Receive and Transmit QoS Parameters

The VCL QoS Information view displays information on the following receive and transmit parameters:

- **QoS Class**
  The QoS class used for the connection.
- **QoS Peak Cell Rate**
  The maximum number of cells that the connection can receive or transmit per second on the network.
- **QoS Sustained Cell Rate**
  The average number of cells that the connection can receive or transmit per second on the network.
- **QoS Max Burst Size**
  The maximum allowable burst size (in cells) that can be transmitted contiguously at the peak cell rate over this link.
- **QoS Tagging**
  If On (enabled), the Cell Loss Priority (CLP) bit of cells is marked (tagged) because the cells do not confirm to the subscribed QoS contract. Tagged cells have a lower priority than other cells, and they are the first cells to be dropped by the network when traffic is congested.
- **QoS CLPO Peak Cell Rate**
  The maximum number of cells with the CLP bit set that the connection can receive or transmit per second on the network.
- **QoS CLPO Sustained Cell Rate**
  The average number of cells with the CLP bit set that the connection can receive or transmit per second on the network.
- **QoS CLPO Max Burst Size:**
  The maximum allowable burst size (in cells) that can be transmitted contiguously with the CLP bit set at the CLP peak cell rate.

Bandwidth Parameters

The VCL QoS Information view displays the maximum bandwidth that can be used by the connection to receive and transmit data.

Receive Bandwidth Calculations

The *Receive Bandwidth value* is the maximum number of bits per second that can be received by the connection.

By default, if the connection's QoS class is Variable Bit Rate, the Receive Bandwidth value is calculated using the Receive - QoS Sustained Cell Rate as follows:

```
Receive Bandwidth (bits per second) = (Sustained Cell Rate (cells per second) * 53 (bytes per cell)) * 8 (bits per byte)
```

If the connection's QoS class is any other class, the Receive Bandwidth value is calculated using the Receive - QoS Peak Cell Rate as follows:

```
Receive Bandwidth (bits per second) = (Peak Cell Rate (cells per second) * 53 (bytes per cell)) * 8 (bits per byte)
Transmit Bandwidth Calculations
```

Transmit Bandwidth Calculations

The *Transmit Bandwidth value* is the maximum number of bits per second that can be transmitted by the connection.

By default, if the connection's QoS class is Variable Bit Rate, the Transmit Bandwidth value is calculated using the Transmit - QoS Sustained Cell Rate as follows:

```
Transmit Bandwidth (bits per second) = (Sustained Cell Rate (cells per second) * 53 (bytes per cell)) * 8
 (bits per byte)
```

If the connection's QoS class is any other class, the Transmit Bandwidth value is calculated using the Transmit - QoS Peak Cell Rate as follows:

```
Transmit Bandwidth (bits per second) = (Peak Cell Rate (cells per second) * 53 (bytes per cell)) * 8 (bits per
 byte)
```

Using the Peak Cell Rate (PCR) in Bandwidth Calculation

The QoS Information view includes a Use Peak Cell Rate (PCR) for bandwidth calculations setting that you can use to specify how bandwidth calculations are performed.

By default, the setting is disabled, which means that the values for Receive Bandwidth and Transmit Bandwidth are calculated as described previously in this topic. However, if you enable this setting, the bandwidth values are calculated as follows:

- If the receive and transmit values for QoS Peak Cell Rate are specified, the Peak Cell Rate is always used to calculate the bandwidth.
- If the receive and transmit values for QoS Peak Cell Rate and QoS Sustained Cell Rate are not specified, the bandwidth is set to the value of If Speed.

Graphical Representations of ATM Interface Connections

In OneClick, in the Topology tab of your ATM network, you can click any pipe (connection) to view a graphical, port-to-port representation of the connection in the Component Detail panel.

This is helpful when you need to quickly identify the physical interfaces involved in the connection represented by a pipe.

If you have created logical connections between virtual link models and created pipes during the import process, or if you have manually created resolved connections between virtual link models (which automatically creates pipes), this view can also show the logical connections represented by a pipe.

NOTE

In this view, you can click any interface model to display the Interfaces tab for the associated device in the Component Detail panel.

Managing Faults

Once you have created an accurate model of your ATM network, ATM Circuit Manager can detect faults on the ATM circuits, isolate the root cause of an outage or service degradation, and alert the user to a problem using an alarm.

DX NetOps Spectrum uses three different methods to monitor virtual interface models and manage faults across the switched fabric in an ATM environment:

- For devices that support the standard ATM MIB, the status of each virtual link model is monitored using the following MIB objects:
  - atmVclAdminStatus and atmVclOperStatus (for VCL models)
  - atmVplAdminStatus and atmVplOperStatus (for VPL models)

  If a model is determined to be inactive, an alarm is generated.
- You can set high and low traffic thresholds for VPLs and VCLs so that an alarm is generated if the load on a particular circuit falls above or below what what you expect.
- If one endpoint of an ATM circuit is a Cisco router, by default DX NetOps Spectrum periodically initiates a “remote ping” from the router to the IP address on the other side of the circuit. If the ping fails, an alarm is generated.

Fault Management Using Link Status

For devices that support the standard ATM MIB, DX NetOps Spectrum reads the Internal_Link_Status attribute of each virtual link model every polling interval. This attribute is calculated based on the values of the following administrative and operational status objects:

- atmVclAdminStatus and atmVclOperStatus (for VCL models)
- atmVplAdminStatus and atmVplOperStatus (for VPL models)

If the value of the Internal_Link_Status attribute is not active, it is assumed that an error condition has occurred, and an attempt is made to isolate the problem to the model itself or to its parent model. This is done by reading the Internal_Link_Status attribute of the parent model, which could be a trunk or a physical interface.

If the parent model is active, a red alarm is asserted on the inactive model to indicate that the problem has been isolated. If the parent model is *not* active, a gray alarm is asserted on the inactive model to indicate a a suppressed condition, and the fault isolation process continues until the source of the problem is identified.

Manage Faults Using Threshold Alarms

ATM virtual link models have an ATM Threshold view that allows you to specify the levels of activity that generate alarms. This can be useful if a specific amount of traffic on an ATM model is the norm, and you want DX NetOps Spectrum to generate an alarm if less or more traffic occurs (because this indicates a problem exists).

For this functionality to be active, you need to set the virtual link model's PollingStatus attribute to Yes (for TRUE). This attribute is set to No by default to limit management traffic over ATM links.

To set the PollingStatus attribute for a virtual link model

1. Use the Navigation panel or the Topology tab to locate and select the device that has the virtual link model you want to configure.
   Information about the device is displayed in the Component Detail panel.

2. Click the Interfaces tab in the Component Detail panel.
   The physical and virtual interfaces for the device are displayed on the tab.
3. Expand the physical interfaces to view the associated link models.
4. Select the virtual link model that you want to configure, and click
   
   (View the Component Detail for the selected model).
5. Click the Attributes tab in the Component Detail window.
6. Set the PollingStatus attribute to Yes.

> **NOTE**
> For information on using the Attributes tab to change attribute values, see the Modeling and Managing Your IT Infrastructure section.

Fault Management on Cisco Routers

If you have Cisco routers in your ATM network, ATM Circuit Manager uses the CiscoPingApp application model to initiate remote pings to determine the status of ATM PVCs. An inference handler examines the ATM connections for a particular router, and then it instructs the router to ping the IP addresses of the routers on the other side of the ATM PVC. If a ping fails, an event with an event code of 0x02dc0001 is sent to the ATM virtual link model that represents this router's side of the ATM PVC. This generates a red alarm on the model; the alarm includes the probable cause information shown below.

```
REMOTE PING FAILURE MAY INDICATE A PVC FAILURE

SYMPTOMS:

The <ss> initiated a remote ping from one router to another over an ATM PVC. Not all ICMP echos were received
 back by this router.

PROBABLE CAUSES:

The PVC connecting this router to the IP address that was pinged may be down.

RECOMMENDED ACTIONS:

1) Check the Event tab to see what IP address was pinged.
2) Verify that all PVCs on this device are operating normally.
```

If desired, you can change the severity of this alarm or prevent it from being generated using the Event Configuration application.

> **NOTE**
> For information on using the Event Configuration application, see the Event Configuration section.

> **NOTE**
> If the ATM network has redundant paths set up or the OSPF (Open Shortest Path First) routing protocol is being used, remote pinging may return information that is not completely useful in determining the health of the network and, therefore, will use bandwidth unnecessarily.

Also note that the ATM Circuit Manager only initiates 5 remote pings per router at a time until all of the remote pings have been tried. This prevents the possibility of the router becoming overloaded.

Configure CiscoPingApp Application Model

You can configure the following attributes of a CiscoPingApp application model:

- **CommunityNameForSNMPSets**
  The community name that is used when performing SNMP sets. By default, this value is inherited from the CommunityNameForSNMPSets attribute on the device model.
  In order for DX NetOps Spectrum to initiate remote pings from a Cisco router, DX NetOps Spectrum must perform SNMP sets. To allow sets to be performed, the CiscoPingApp application model must have a community name that allows DX NetOps Spectrum to write to the device's MIB (in other words, a community name with read and write capabilities).
  If the value of this attribute for the application model differs from the value for the device model, the value for the application model takes precedence.
  If this attribute is unset on both the device model and the application model, DX NetOps Spectrum uses the value of the Community_Name attribute. Thus, if the value of the Community_Name attribute is a name with read and write capabilities, and the CommunityNameForSnmpSets attribute is unset, remote ping works properly.

  NOTE
  For more information on these attributes, see the Getting Started section.
- **EnableRemotePings**
  Enables and disables remote pinging. If set to No (for FALSE), remote pinging from the router is disabled. The default value is Yes (for TRUE).
- **NumberOfPingPackets**
  The number of ping packets the router will send to the remote IP address.
  Default: 3
- **PingFailuresAllowed**
  The number of ping request failures allowed before an alarm is generated.
  Default: 2
- **PingInterval**
  The interval in seconds between remote ping requests.
  Default: 300
- **PingPacketSize**
  The size in bytes of the ping packet that the router will send to the remote IP address.
  Default: 128

  NOTE
  NumberOfPingPackets, PingFailuresAllowed, and PingInterval, collectively, are used to increase the frequency of remote pinging and the speed of any network fault detection. For example, if PingInterval were lowered to 60, NumberOfPingPackets remained set at 3, and PingFailuresAllowed were decreased to 0, the ping requests would be initiated more frequently, and no failure of any of these requests would be allowed. This would result in the ATM network being more closely monitored for remote link problems, and, if problems were discovered, alarms would be generated more quickly.

To configure one or more CiscoPingApp application models

1. Use the Locater tab to find all models of model type CiscoPingApp.
   The CiscoPingApp models are listed on the Results tab in the Contents panel.
2. Do one of the following:
   – To configure a single model, select it, and click the Attributes tab in the Component Detail panel. Then use the Attributes tab to configure the CiscoPingApp model attributes.
   – To configure multiple models, right-click them all and click Tools, Utilities, Attribute Editor. Add the CiscoPingApp model attributes that you want to configure to the User Defined folder in the Attributes tree, and then use the Attribute Editor to modify the attributes.

NOTE
For more information about using the Attributes tab and the Attribute Editor to change attribute values, see the Modeling and Managing Your IT Infrastructure section.

Fault Isolation Across Switched Fabric

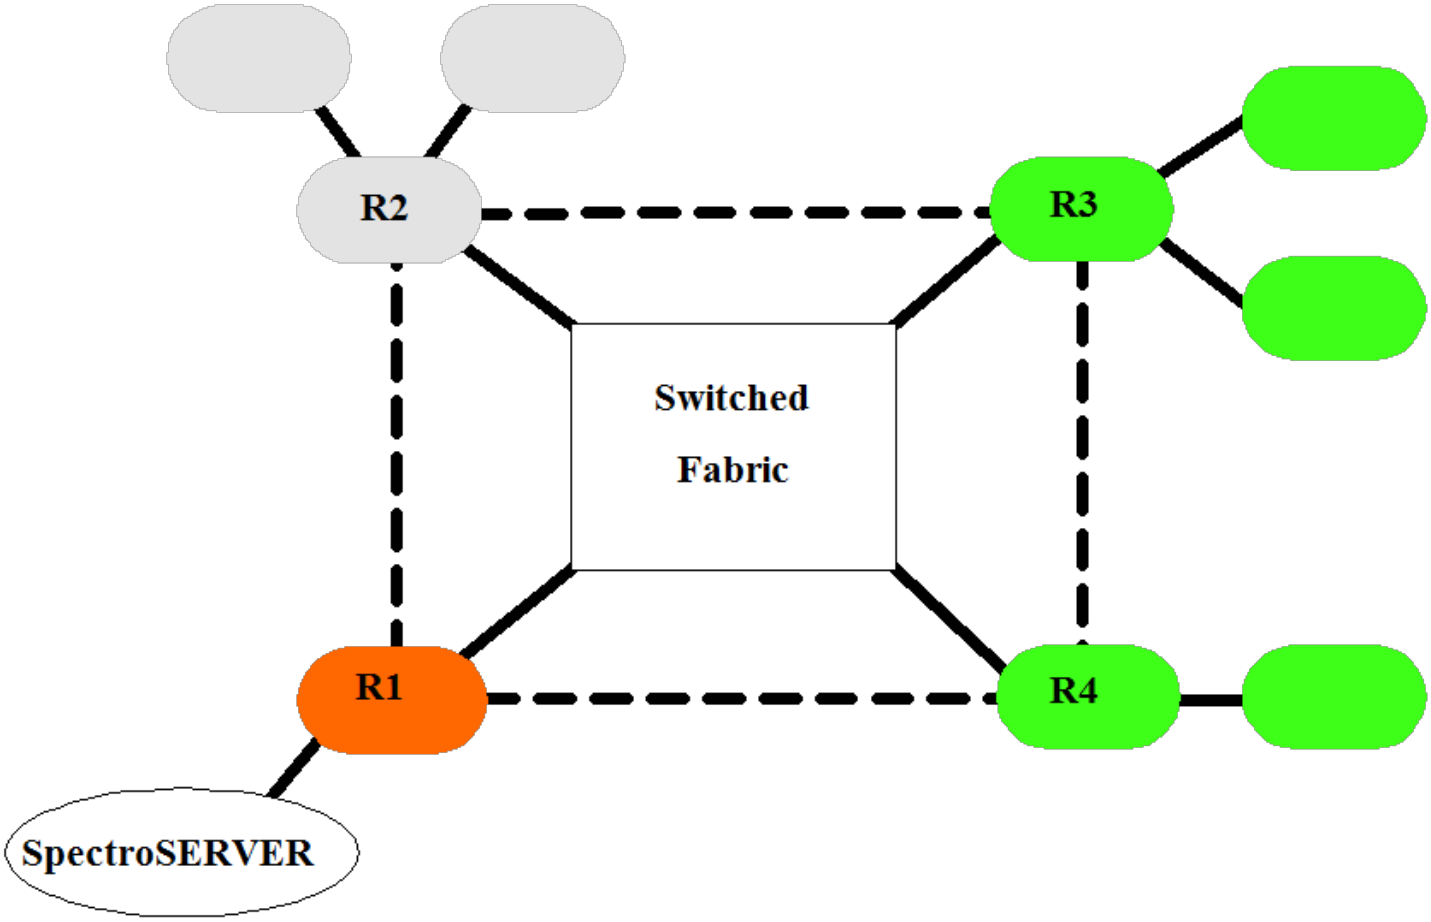
ATM Circuit Manager allows DX NetOps Spectrum to extend its fault isolation capability through the switched fabric of an ATM network. The switched fabric can be part of your own network infrastructure, or it can be part of a leased infrastructure on a service provider's network.

If you are managing your own switched fabric, there will be one or more ATM_Network models in your network topology. The ATM switches that make up the switched fabric are collected inside the ATM_Network model, and the ATM clients (routers, bridges, and so on) will be adjacent to the ATM_Network model. In this scenario, the managed circuits go from one client-through the switched fabric in the ATM_Network model-to another client. The channels and trunks within the switched fabric are not managed unless this functionality has been specified.

If you are leasing channels or trunks through a service provider's network, you will use an ATM_Cloud model in the DX NetOps Spectrum topology to represent the service provider's switched fabric. In this scenario, the managed circuits go from one client-through the switched fabric in the ATM_Cloud model-to another client. The channels and trunks within the switched fabric are not managed.

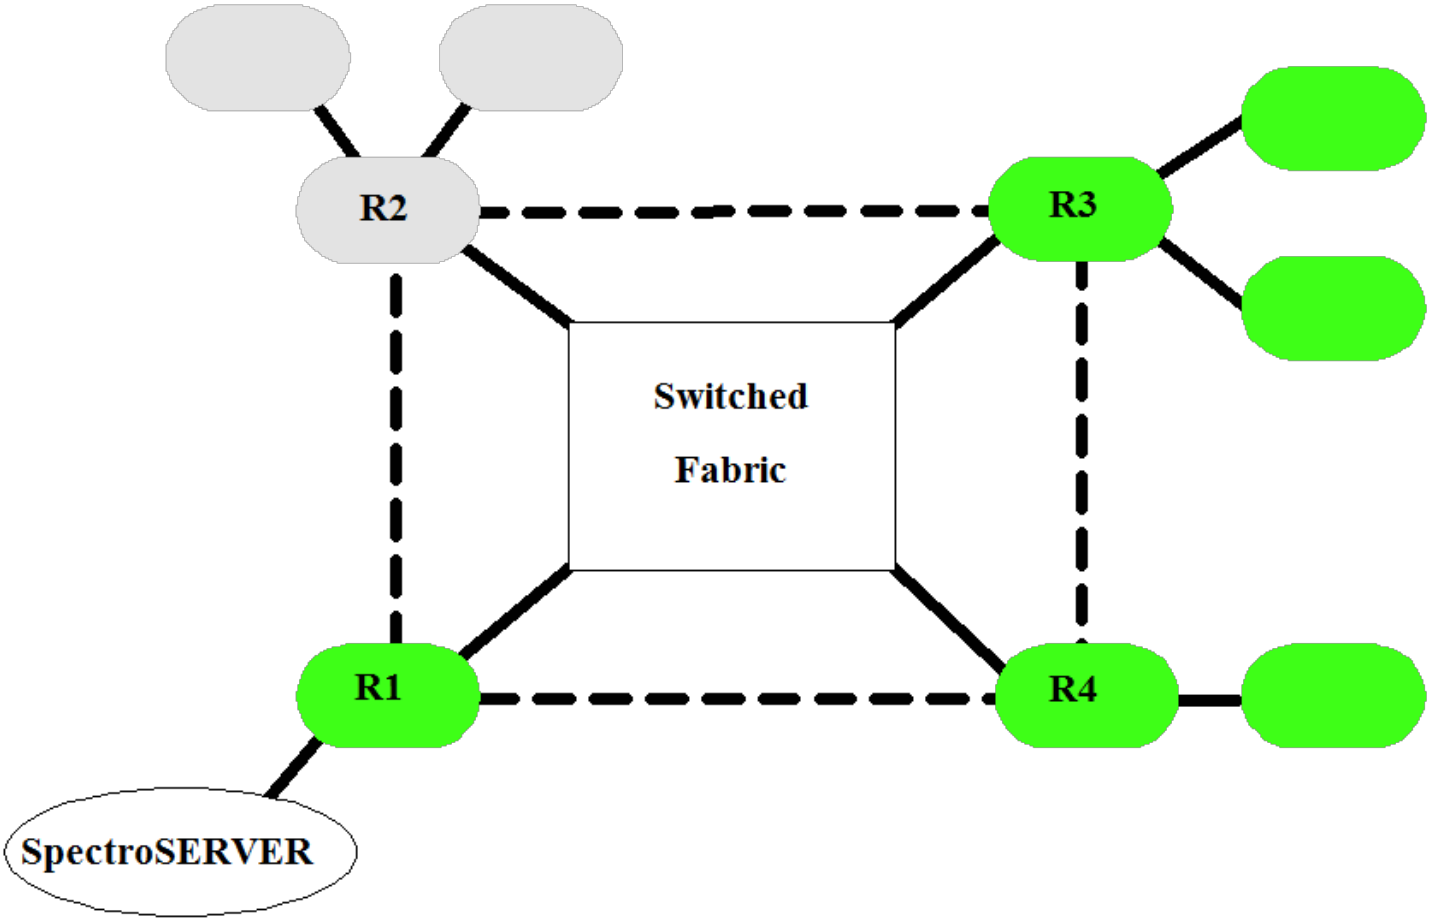
Connections between virtual link models are used to determine an ATM device's neighbors. The neighbors of a device are queried during fault isolation to determine where the source of the problem is located.

As an example, the following illustration shows four routers (R1, R2, R3, and R4) connected across a switched fabric. The logical connections between the routers are indicated by dotted lines, and the physical connections are indicated by solid lines. If the SpectroSERVER has a problem reaching R2, it will check the status of R2's neighbors to isolate the fault. Since the ATM Circuit Manager uses logical connectivity to determine device neighbors, both R1 and R3 will be considered neighbors of R2.



If, for example, R3 responds that it is available, but R1 does not respond, DX NetOps Spectrum creates a red alarm on R1 and changes R2 and the models that depend on its connectivity to gray to indicate a suppressed state.

If ATM Circuit Manager did not have the capability to use logical connectivity to determine device neighbors, it would not be able to isolate the fault to R1. Instead, R2 and its connected devices would change to gray to indicate a suppressed state, and an unresolved red alarm would be created on the generic Fault Management model to indicate the communication problem. The red alarm would be viewable in the Alarms tab in OneClick, but it would not appear linked to any device model in the Topology tab.



Cable Broadband Infrastructure

This section discusses how you can manage and monitor your Cable Broadband network using DX NetOps Spectrum.

Getting Started with Cable Broadband Solution

This section discusses the basic elements of a cable broadband network, cable broadband models available in DX NetOps Spectrum, device-specific MIB support available.

All this information helps you getting started with understanding your cable broadband infrastructure and modeling it in DX NetOps Spectrum.

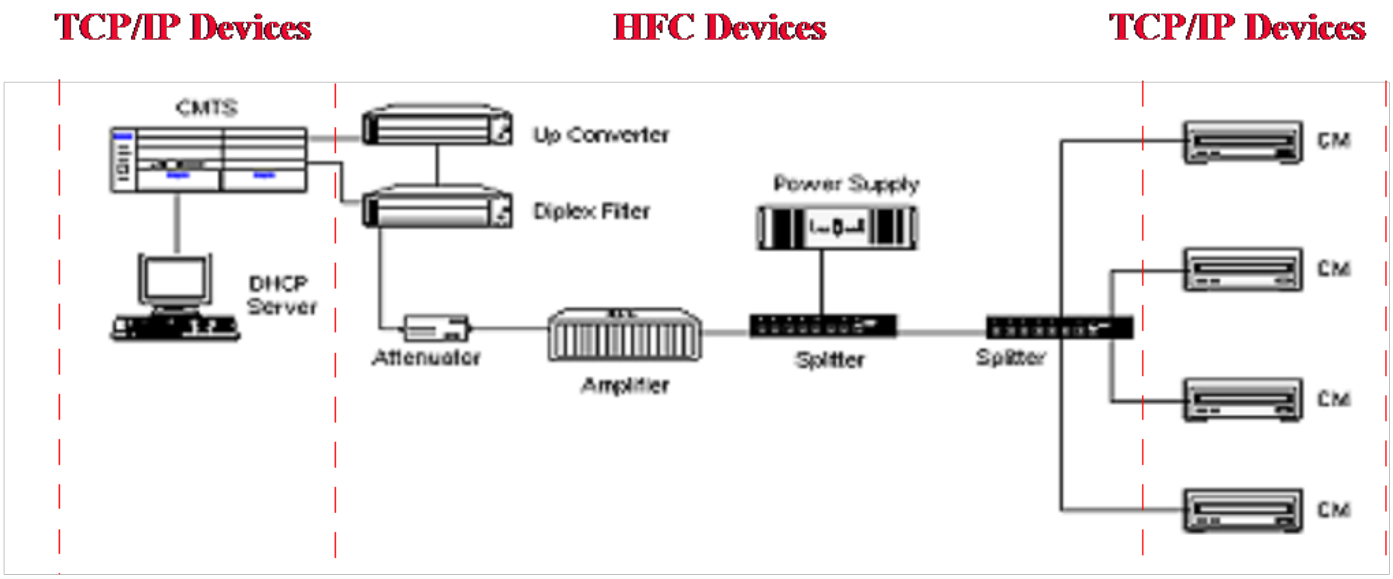
Network Management Factors

This section describes the elements of a broadband network and the Cable Broadband models in the DX NetOps Spectrum Cable Broadband Solution.

For a cable broadband management system to be effective, it must meet the challenge of acquiring an array of information available from a variety of devices diversely deployed to meet the demands of many different business requirements. To be useful to managers, the acquired information must be displayed in a meaningful manner.

The following image provides an example of a simple cable broadband network deployment.

Basic Components of a Cable Broadband Network



The cable broadband network includes Hybrid Fiber Coax (HFC) devices and TCP/IP devices. The HFC devices consist of Up Converters, Diplex Filters, Attenuators, Amplifiers, Splitters, and Power Supplies. The TCP/IP devices consist of DHCP servers, Cable Modem Termination Systems (CMTS), and Cable Modems (CM). The HFC components gather HFC information through proprietary communication methods. The TCP/IP devices gather network information through the Simple Network Management Protocol (SNMP).

In addition to the challenges imposed by the diversity of devices and deployments, an added complexity for network managers is the need to control SNMP traffic. Using SNMP, CMs communicate information to CMTSs over the HFC network using shared channel frequencies. The downstream frequency channel aggregates information from the CMTSs to the CMs and the upstream frequency channels aggregate information from the CMs to the CMTSs. Managers must have visibility into the amount of SNMP traffic that is generated on this shared media in order to maximize network efficiencies, plan for network growth, and have visibility into the operational status of devices for purposes of fault isolation and root cause analysis.

DX NetOps Spectrum's cable broadband network management solution meets the challenges summarized previously by:

- Supporting devices and MIBs produced by a variety of vendors.
- Limiting ICMP and SNMP traffic by introducing modeling techniques designed for cable broadband networks.
- Providing a mechanism for logically grouping device models.
- Providing a means for aggregating alarms from selected devices and setting aggregate threshold values based on mission criticality.
- Providing fault isolation and root cause analysis down to the port level.

Vendor MIB Support

Depending on the management module, vendor-specific information can be found either off the device model or in the Component Detail panel view in the form of an application. The device-specific DX NetOps Spectrum management modules related to cable broadband devices are mentioned in the following list. For example, the AM Communications device type supports the SM-AMC1000 management module.

- **AM Communications**
  SM-AMC1000
- **Arris Cadant C4 CMTS**
  SM-ARS1000
- **Broadband Service Containers**
  SM-BSC1000
- **Cheetah Gateway Integration**
  SM-SFA1000
- **Cisco uBR72xxCMTS**
  SM-CIS1008
- **DOCSIS Applications**
  SM-DCSCMN
- **DOCSIS Devices**
  SM-DCS1000
- **LANCity Cable TV Modem**
  SM-LCH1000
- **Motorola CDLP Cable Router**
  SM-MOT1001
- **RiverDelta BSR 1000/64000**
  SM-RVD1000
- **Riverstone SmartSwitch Router**
  SM-RST1000
- **Scientific Atlanta Explorer HCT**
  SM-SFA1000
- **Telecom CUDA 12000**
  SM-ADC1000
- **Terayon BroadbandEdge2000/TeraLink 1000**
  SM-TRN1000
- **Terayon BW3500 CMTS**
  SM-TRN1001

Device Support

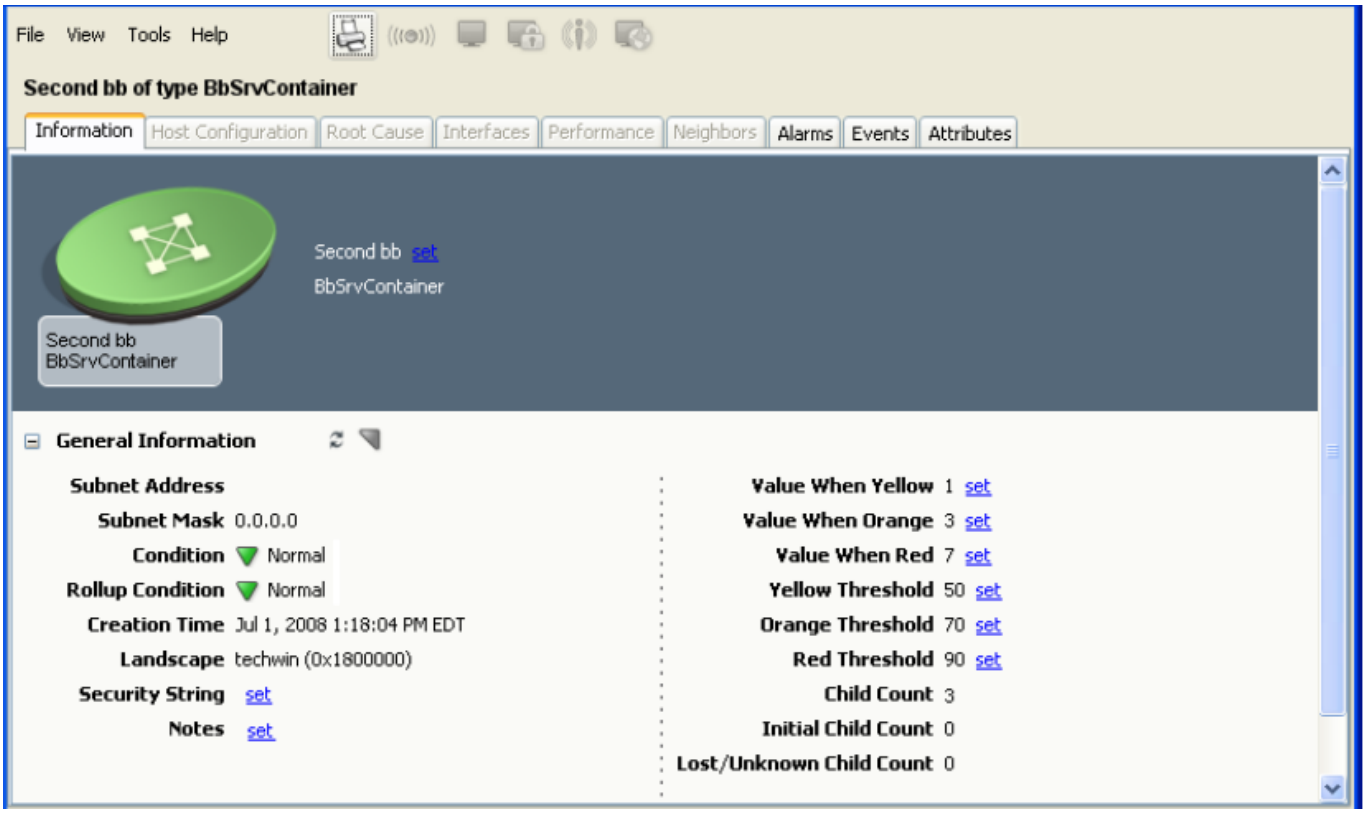
This section describes the cable broadband models and their functionality in DX NetOps Spectrum.

DX NetOps Spectrum provides efficient information gathering by limiting ICMP and SNMP traffic across the cable broadband network. This is accomplished by providing five model paradigms as follows:

- CMTS models provide the full information gathering aspects of a GnSNMPDev model type.
- Lightweight models provide focused information gathering for CMs and set-top boxes.
- Broadband Service Container models provide a method of logically grouping Lightweight models.
- HFC Device Event Modeling
- DOCSIS MIB Support

Each of these models is designed to focus information gathering to meet management's need for useful information, to eliminate distracting information, and to reduce the impact of polling on an efficiently operating cable broadband network.

The following image provides an example of how DX NetOps Spectrum displays cable broadband component details:



CMTS Models

The following section describes DX NetOps Spectrum's support of CMTS devices and DOCSIS-compliant devices.

CMTS Model Device Support

DX NetOps Spectrum supports a variety of CMTS devices from vendors including Cisco, Terayon, Motorola, Nortel LANCity, River Delta (acquired by Motorola), ADC, and Riverstone. The CMTS device models have standard device support including model creation for applications and interfaces, Topology and Device Interface views, interface connectivity/port resolution, Discovery, and fault isolation capabilities. These device models are based on the standard support provided by the GnSNMPDev model type.

CMTS Model DOCSIS Support

DX NetOps Spectrum also supports CMTS devices that comply with DOCSIS.

CMTS Fault Isolation, Polling, and Logging

For information about fault isolation, polling, and logging, see the Modeling and Managing Your IT Infrastructure section.

Lightweight Models

Lightweight models include CMs and set-top boxes. The lightweight model paradigm supports devices that do not require the full functionality that GnSNMPDev models provide.

Lightweight Model Device Support

DX NetOps Spectrum supports the Motorola cable modem, a DOCSIS-compliant cable modem, and the Scientific Atlanta set-top box. A cable broadband network can include thousands of these devices; therefore, the models of these devices are designed as lightweight models. The lightweight series of models provide a way to represent and collect meaningful SNMP data from all cable modems and set-top boxes while limiting the effects of polling on the network.

The implementation of the new lightweight model paradigm has many significant differences over conventional GnSNMPDev models. The lightweight models have increased model capacity on a SpectroSERVER, reduced SNMP traffic, and reduced memory and CPU usage. However, the lightweight models do not create interface models for port resolution, and do not participate in fault isolation. They only communicate SNMP to their real world counterpart, whereas a GnSNMPDev model will also try to use ICMP ping to contact the device.

Lightweight Model DOCSIS Support

Support also includes a generic DOCSIS-compliant CM device model for those vendor devices that DX NetOps Spectrum does not support but which are DOCSIS-compliant.

Lightweight Model Fault Isolation

Because the Lightweight Model Architecture does not participate in fault isolation, there is no value from a fault isolation standpoint of connecting these models by pipes. Also, by default lightweight models do not alarm. If contact with the device via SNMP has been lost, the model will turn gray and go into a suppressed state. This is done to keep the alarm manager from being flooded with red alarms from cable or set-top models losing contact. This functionality is configurable and can be set to alarm or not to alarm.

Lightweight Model Polling and Logging

Lightweight models do not log or poll any attributes. For this reason, they keep in contact with the device at three times the polling interval. This is why lightweight models do not turn active over a polling interval. Lightweight models can only be modeled by model type; you cannot model them using Discovery or by using Model by IP.

> **NOTE**
> Modeling cable modems over the HFC network is not advised. Because most cable modems change IP addresses on a regular basis, there would be too much SNMP traffic generated to update cable modem models.

In the future, DX NetOps Spectrum will contain auto-population features that will create and update cable modem models from the CMTS MIB tables.

Broadband Service Container Models

The broadband service container model (BbSrvContainer) provides a mechanism for the logical grouping of lightweight models. To see how the broadband service container differs from other standard containers, first consider the process used by a standard container to monitor the condition of models it collects.

Standard Container Characteristics

With standard containers, such as a Network or LAN, the container is responsible for summing the condition value of every device (or container) it collects. This sum is written to an attribute called composite condition. The composite condition is then compared to the rollup threshold values of yellow, orange, and red. The rollup thresholds are defined for minor, major, and critical severities. For every severity state, there is a significance level that can be defined. If the

composite condition exceeds a rollup threshold then the rollup condition assumes that threshold condition and color. This process for standard containers is described in detail in the Modeling and Managing Your IT Infrastructure section.

Broadband Service Container Characteristics

In contrast to standard containers, the broadband service container monitors the percentage of models it has collected that have lost contact compared with the total sum of models, excluding any model still in the initial state. The percentage thresholds are defined for minor, major, and critical severities. For every severity state, there is a significance level that can be defined. However, when a threshold has been violated, the broadband service container assumes the condition associated with the threshold. The broadband service container assumes a condition to reflect the condition of the network represented by the devices grouped in the container. This is done because the alarms on the individual cable or set-top models are suppressed.

The container model's General Information subview contains the following two attributes which determine the condition shown on the container in the Topology view: Condition Value and Lost/Unknown Child Count.

The Lost/Unknown Child Count displays the percentage of the devices collected by this container that have lost contact. The value of Lost/Unknown Child Count is compared with the rollup thresholds. If the value of Lost/Unknown Child Count exceeds a threshold, the container will set the Condition Value attribute to that criticality. The table below shows possible condition values.

Once the Condition Value of the Broadband Service Container assumes a criticality of yellow, orange, or red, the significance levels are taken into consideration by DX NetOps Spectrum. That is, the current Condition Value of the BbSrvContainer is compared with the significance level values and the significance value of the BbSrvContainer is then set, based on this comparison.

Models of cable modems and set-top boxes should never be directly connected in DX NetOps Spectrum to models of CMTS devices. To help ensure proper fault isolation for CMs and set-top boxes, the broadband service container model must be used to group models of these lightweight devices.

HFC Device Event Modeling

DX NetOps Spectrum does not model HFC devices. Most HFC devices communicate with a Headend Communications Controller (HEC). The communication protocol between the HEC and HFC devices is usually proprietary. For example, Acterna (Cheetah) and AM Communications developed a software application to communicate with their respective HECs. These software applications are capable of sending SNMP traps. DX NetOps Spectrum collects and processes these traps (sent from either software application) using the Southbound Gateway.

When an SNMP trap is sent from the software application, the Southbound Gateway analyzes the data and creates a new event model, if one has not already been created. From that point forward, traps sent from the application are mapped to that event model. The traps will be further processed and events and alarms created on the event model.

DOCSIS MIB Support

Support also includes a generic DOCSIS-compliant CMTS device for those vendor devices that DX NetOps Spectrum does not support but are DOCSIS-compliant. In the case of these devices, the CMTS models will have the DOCSIS information available in the application view as applications. There is an application for each of the DOCSIS MIBs shown in the following table that will discover automatically if the device supports the MIB.

DOCSIS MIB Listing	1.0 Standard	1.1 Standard	2.0 Standard	Supported by DX NetOps Spectrum
RFC 2669: Cable Device MIB	Yes	Yes	Yes	Yes
RFC 2670: Radio Frequency Interface	Yes	Yes	Yes	Yes

RFC 3083: Baseline Privacy Interface	Yes	Yes	Yes	Yes
Quality of Service	No	Yes	Yes	Yes
Baseline Privacy Interface Plus	No	Yes	Yes	Yes

Broadband Service Container Model

This section describes how to model broadband network devices and access MIB attribute information from the BbSrvContainer model's General Information subview.

Create a Broadband Service Container Model

The following procedure describes how to create a Broadband Service Container model.

> **NOTE**
> For more information about creating models and container models, see Modeling and Managing Your IT Infrastructure section.

To create a Broadband Service Container model

1. In the Explorer tab of the OneClick Navigation panel, select the Universe topology view where you want to add the new container.
   The selected topology view appears in the Topology tab of the Contents panel.
2. In the Topology tab of the Contents panel, click
   
   (Creates a new model by type) in the Topology tab toolbar.
   The Select Model Type dialog opens.
3. Click 'BbSrvContainer' in the Containers tab and click OK to add the container to the Topology tab.
   The 'Create Model of Type BbSrvContainer' dialog appears.
4. Type a Name and Security String for the container and click OK.
   The container is added to the Topology view and you can view details in the Component Detail panel.

> **NOTE**
> You can create more than one container model to separately monitor different parts of a network. A container model can be created inside other container models, and it can be copied and pasted into the topology on an appropriate interface to provide port resolution for the broadband devices. Where and how you model containers and devices depends on your network configuration and how you want to view it in DX NetOps Spectrum.

Model Devices

Once the Broadband container model has been created, you can model devices in its Topology view as needed. The following procedure describes how to do so manually. For more detailed information about creating models and container models, see the Modeling and Managing Your IT Infrastructure section.

To manually add device models to the Broadband Service Container

1. In the Explorer tab of the OneClick Navigation panel, select the broadband service container to which you want to add new device models.
   The selected topology view appears in the Topology tab of the Contents panel.

2. Click
   
   (Creates a new model by type) in the Topology tab toolbar.
   The Select Model Type dialog opens.
3. Select the desired model type and click OK.
   The 'Create Model of Type' dialog appears.
4. Complete the fields as needed and click OK.
   The device model is added to the Topology view and you can view details in the Component Detail panel.

General Information Subview

From the Broadband container model's General Information subview you can access information about the status of the model and its children, its rollup thresholds, and its significance levels. It contains the settings listed here and in the following sections.

- **Condition**
  Reflects the current contact or alarm status of the model itself.
- **Rollup Condition**
  Applies to container models; reflects the composite status of all the other models in the container, which are sometimes referred to as its children. The percentage of devices in the container that are down, excluding those devices whose models were never active.
  The following table shows possible Rollup Condition values:

Condition Value	Alarm Status	Label Color
0	Normal	Green
1	Minor	Yellow
2	Major	Orange
3	Critical	Red

- **Child Count**
  Specifies the total number of devices in the container, which includes active, Initial Child, and Lost Child models.
- **Initial Child Count**
  Specifies the number of devices in the container whose models are in the Initial state.
- **Lost/Unknown Child Count**
  Specifies the number of devices in the container that were active but have lost contact with the network.

Significance Levels

Significance levels for the BbSrvContainer model weigh the importance of the model for each possible alarm severity the model may reach.

In the case of the BbSrvContainer model, the significance levels represent the importance of the cable modems and set-top models. When a BbSrvContainer model is collected by a parent container and the BbSrvContainer model reaches a particular alarm severity, the significance value will be used to calculate the parent container's alarm severity.

- **Value When Yellow**
  Specifies the point value of a Yellow alarm condition existing in a child towards the rollup alarm threshold value for the parent container.

Default: 1

- **Value When Orange**
  Specifies the point weight of an Orange alarm condition existing in a child towards the rollup alarm threshold value for the parent container.
  Default: 3
- **Value When Red**
  The point weight of a Red alarm condition existing in a child towards the rollup alarm threshold value for the parent container.
  Default: 7

Rollup Thresholds

The rollup thresholds are three read-write values that control when the BbSrvContainer model's rollup condition icon changes color and also controls when alarms are triggered. Each of the threshold values represents the percentage of active devices in the BbSrvContainer that have gone down. When the actual percentage of devices that are down equals or exceeds a threshold value, the BbSrvContainer model's rollup condition icon changes to the color associated with that threshold and a commensurate alarm is triggered.

Expressed mathematically, the rollup threshold value is:

```
Lost Child Count divided by (Child Count - Initial Child Count) x 100
```

In other words, models that have never been active are excluded from the percentage value.

You can set the thresholds to suit your requirements or use the default values. Recommendations for each threshold value are as follows:

- **Yellow Threshold**
  Minor alarm threshold. Specifies the minimum points needed to trigger a Yellow rollup alarm for a container. You might use this threshold to indicate a network condition that is less than optimum but does not threaten service.
  Default: 50
- **Orange Threshold**
  Major alarm threshold. Specifies the minimum points needed to trigger an Orange rollup alarm for a container. You might use this threshold to indicate a network condition that should be examined before it threatens service.
  Default: 70
- **Red Threshold**
  Critical alarm threshold. Specifies the minimum points needed to trigger a Red rollup alarm for a container. You might use this threshold to indicate a network condition that has a serious impact on service.
  Default: 90

  NOTE
  Change threshold levels carefully; you may see an increase in generated alarms if threshold levels are set lower, or a decrease in generated alarms if levels are set higher.

Certifications

This section explains the concepts of DX NetOps Spectrum Device Certification:.

Out-of-the-Box Certification Support

This section discusses how DX NetOps Spectrum provides out-of-the-box support for devices, interfaces, and applications. This section also discusses how DX NetOps Spectrum models a device using the device certification, how you can reconfigure existing models with new certification support.

Overview on Certification

Support for monitoring many devices is provided out-of-the-box in DX NetOps Spectrum. Basic monitoring support is supplied through simple or enhanced certifications:

- **Simple Support -** The device is modeled using the DX NetOps Spectrum generic certification. This level of certification provides core DX NetOps Spectrum capabilities, including discovery, identification, standard MIB and trap support, and standard views. Simple support also includes interface modeling and participation in fault isolation and root cause analysis.
- **Enhanced Support** - The device is modeled using one of the DX NetOps Spectrum enhanced certifications, which extend simple certification support. At a minimum, enhanced certification support indicates that support for this device has been extended with proprietary MIB and trap support. Typical extensions include proprietary OneClick views, CPU and memory device thresholding, and serial number support.

About Generic Certification

DX NetOps Spectrum provides a generic certification to represent an SNMP-compliant network device that lacks a corresponding DX NetOps Spectrum enhanced certification. Management Information Bases (MIBs) support SNMP-compliant devices. MIBs are SNMP structures that describe particular devices. MIBs are imported into the DX NetOps Spectrum database and made available through device, application, and interface model types.

Note: For more information about simple and enhanced certification support, see the Standards-Based Protocol Reference section. For more information about enhanced certification support, see the Device Management Reference section, Cisco Device Management section, and Host System Resources Management section.

The generic model type, GnSNMPDev, can represent a broad range of devices by creating the following models:

- A model to represent the device.
- Application models to represent each of the standard (IETF) MIBs that the device supports.
- Interface models to represent device ports.

GnSNMPDev lets DX NetOps Spectrum dynamically create models to manage devices when a specific management module is unavailable.

GnSNMPDev rapidly queries the device to determine its characteristics and capabilities and then creates a model to represent the device. GnSNMPDev also creates the following models:

- Submodels, referred to as application models, to represent each of the standard MIBs that the device supports.
- Interface models to represent each device port that is defined in the standard MIB-II interface table.

The application and interface models are associated with the GnSNMPDev device model. Together, they provide management capabilities for the device.

Devices that are modeled with the GnSNMPDev model type can be used with all DX NetOps Spectrum management tools. GnSNMPDev models participate fully in DX NetOps Spectrum root cause analysis, fault isolation, and downstream alarm suppression algorithms. As a result, they can alert users to network and device problems.

Device Modeling

When modeling a device using Discovery or the Model by IP Address icon, DX NetOps Spectrum automatically chooses the GnSNMPDev model type when an enhanced certification for the device is not available. You can also model a device using the GnSNMPDev model type when you use the Model by Type feature.

You can map the connectivity of interface models automatically using Discovery, or you can map connectivity manually.

The GnSNMPDev model type supports the Cisco Proprietary Discovery Protocol (CDP). A CiscoCDPApp application model is created for Cisco devices that are modeled with GnSNMPDev and that support CDP. This application model lets DX NetOps Spectrum use the Proprietary Discovery tables for the device when discovering device connectivity information.

NOTE
For more information, see the Modeling and Managing Your IT Infrastructure section.

How DX NetOps Spectrum Identifies the Device Type

When modeling a device, DX NetOps Spectrum assigns a descriptive identifier or device type. The device icon shape and label reflect device functionality in OneClick.

The DeviceType attribute (0x23000e) is a text string that identifies the type of device being modeled. In OneClick, this string is displayed below the device icon. DX NetOps Spectrum lets you search, filter, and report on device models using the DeviceType attribute.

The following process describes how DX NetOps Spectrum determines the device type to assign to a device model:

1. If the device type setting is locked, DX NetOps Spectrum does not reevaluate the device model. The device type that is set for the device model remains.
2. If the device type setting is not locked, DX NetOps Spectrum runs custom intelligence for some models to set the device type name.
3. DX NetOps Spectrum checks the System Object Identifier-to-Device Type mapping list. If a device type name (for example, “Cisco 2621”) is found for the device System Object Identifier, it becomes the model device type. If no match is found, DX NetOps Spectrum extracts the device enterprise ID from the System Object Identifier. DX NetOps Spectrum uses the enterprise ID to identify the manufacturer.
4. DX NetOps Spectrum then checks device capabilities and appends an abbreviation (for example, Rtr or Bdg) to the manufacturer name. This entire string becomes the device type name in OneClick (for example, “Cisco Rtr”).
5. If DX NetOps Spectrum cannot determine an appropriate device type, the default value “SNMP DV” is assigned.

How DX NetOps Spectrum Identifies the Model Class

DX NetOps Spectrum evaluates the model class when a device is modeled for the first time and when you reconfigure a device model.

The following process describes how DX NetOps Spectrum determines the model class to assign to a device model:

1. If the model class setting is locked, DX NetOps Spectrum does not reevaluate the device model. The model class that is set for the device model remains as is.
2. If the model class setting is not locked, DX NetOps Spectrum checks device model support for a specific MIB object. If DX NetOps Spectrum detects that a device model supports a certain MIB object, the model class for that device model is set to a specified value.
3. If the search for a supported MIB object fails, DX NetOps Spectrum attempts to determine the model class for the device model. DX NetOps Spectrum uses the mappings in the Device Certification utility in this search. This utility provides a mapping from System Object ID (which is more general than a MIB object) to Model class.
4. If Device Certification does not contain any model class mappings for a device, DX NetOps Spectrum defaults to setting the model class based on whether the device appears to be routing (“Router”), switching (“Switch”), both switching and routing ("Switch-Router”) or simply repeating (“Repeater”).

When assigning the icon and label for a device model, DX NetOps Spectrum uses the icon for the model class that is assigned as described here. This icon appears throughout OneClick.

Support for Chassis Devices

When a device model uses a DX NetOps Spectrum certified proprietary chassis MIB or the Entity MIB, DX NetOps Spectrum identifies that device model as a chassis device. DX NetOps Spectrum models and arranges all the identified chassis devices with their components or modules under the **Chassis Manager** node in the navigation pane of OneClick. This arrangement is based on the vendor names of your chassis devices.

From 10.4.2, you can discover the Cisco FEX module. The FEX module is displayed under the Chasis Manager view.

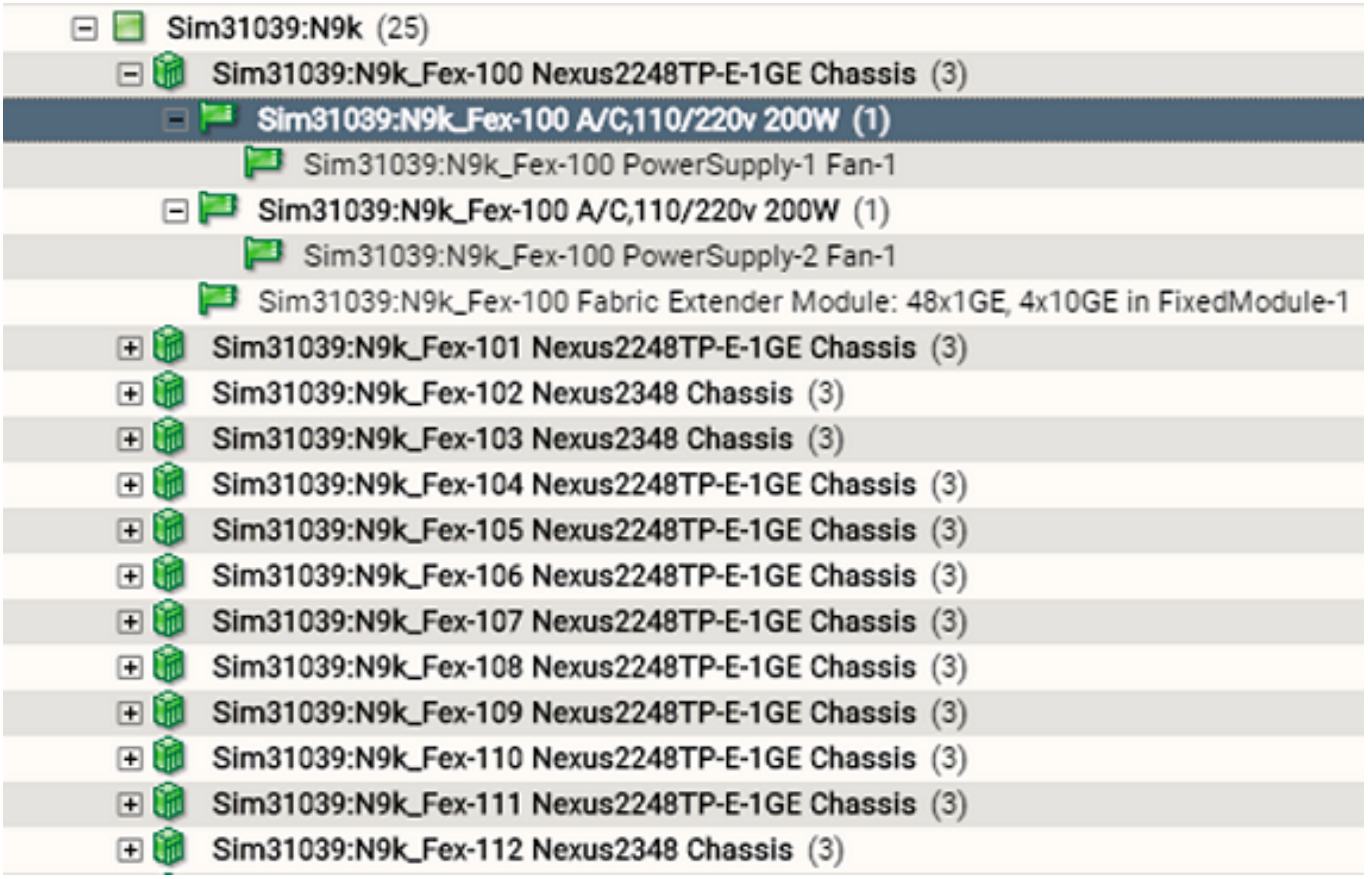
The following CISCO FEX devices are supported:

- Nexus 5596
- Nexus 7000
- Nexus 5000
- Nexus 6001
- Nexus 5672

> **NOTE**
> For active-active FEX configuration, both monitoring devices display all the FEX modules because both entity MIBs contain all the FEX modules.

For example, devices of "Cisco" that are identified as chassis devices are arranged in a folder with the name "Cisco". Similarly, devices of "Juniper" identified as chassis devices are arranged in the "Juniper" folder.

The following image shows how chassis devices are modeled and arranged under the **Chassis Manager** node. Each vendor folder contains its chassis devices:



As a result, you can monitor the health of your chassis devices and their modules at one place in OneClick, the **Chassis Manager** node. This node provides a consolidated location to view and manage chassis devices that are modeled in the Universe topology. After selecting a chassis device from this node and then accessing chassis views from the Component Detail pane, you can view the status of all interfaces, and can assess the health of each module. For more information about the chassis views that give detailed information about each module of your chassis device, see Chassis Views.

Identification of Chassis Devices

DX NetOps Spectrum identifies your device as a chassis device based on the following two types of MIBs:

- **Proprietary MIB**
  When a device supports a DX NetOps Spectrum certified proprietary chassis MIB, it is identified as a chassis device. For example, when a "Juniper" device supports the "jnxBoxAnatomy", it is identified as a chassis device based on that MIB.

  NOTE
  DX NetOps Spectrum always prefers the DX NetOps Spectrum certified proprietary chassis MIB to the Entity MIB of a device model for its identification as a chassis device. Only when the proprietary chassis MIB is absent, the device model is identified as a chassis device using the Entity MIB.

  NOTE

  An attribute(createChassisModules) is added (available on device) to enable or disable modeling of Slots/ Chassis Modules for Juniper devices. By default, this attribute is set to True and all the chassis modules are discovered and modeled for Juniper devices. To disable modeling of chassis modules, set this attribute value to False and perform reconfiguration on the device.
- **Entity MIB**
  When a device model supports the Entity MIB and the value of the "**EnableEntityModuleModeling**" attribute is "Yes" for that device model, it is identified as a chassis device. By default, the value of this attribute is "Yes" on a case-by-case basis for the following reasons:
  – Some vendors do not implement this MIB indexing scheme correctly.
  – Some vendors support the Entity MIB even for non-chassis devices.

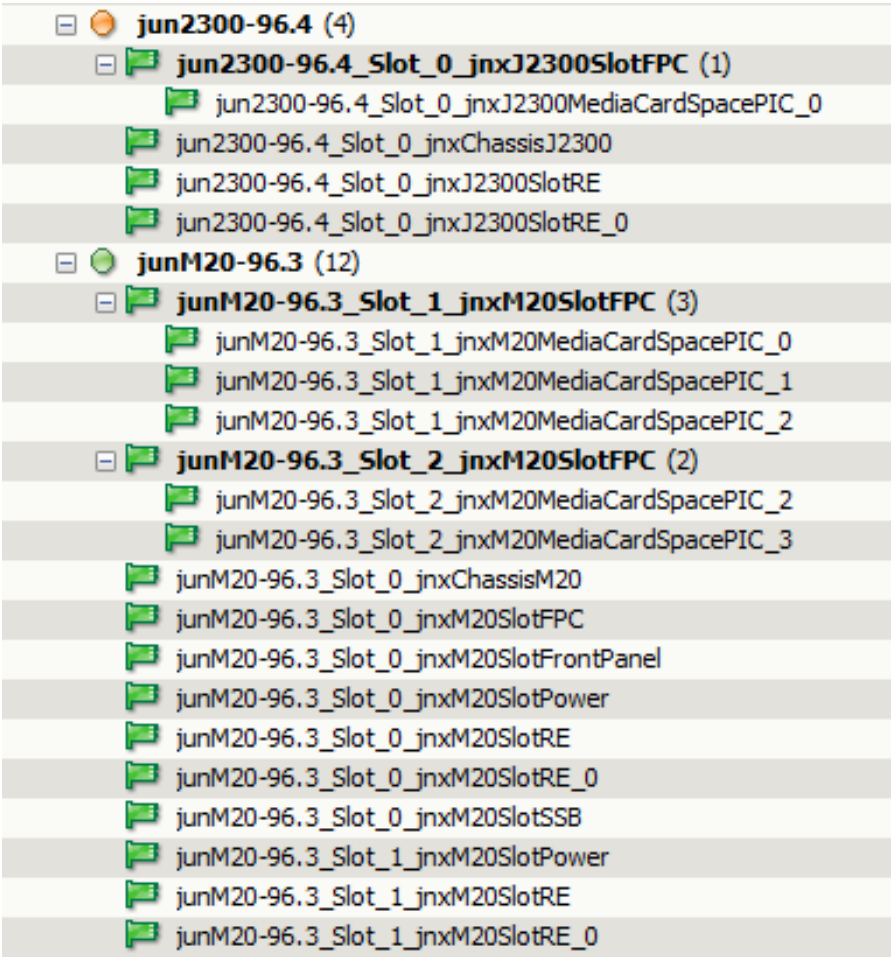
  NOTE
  If you do not want DX NetOps Spectrum to identify a device model as a chassis device, set the value of this attribute to "No" and reconfigure the model.

Chassis Views

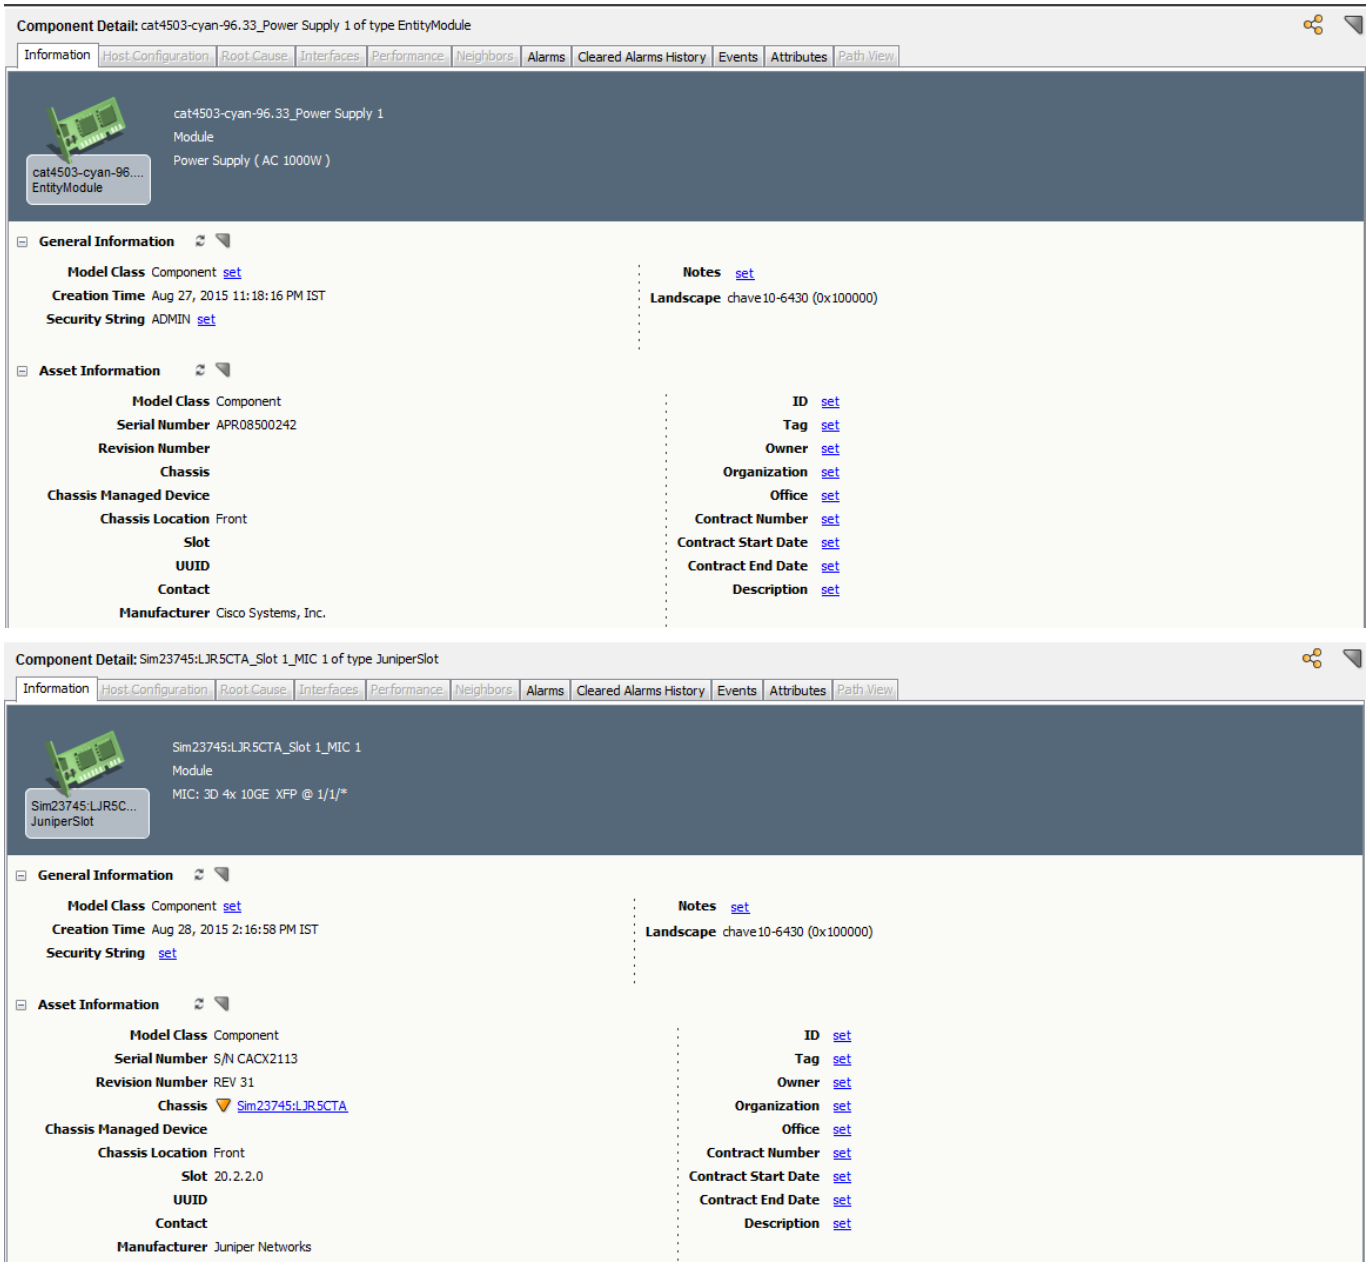
To view the details of your chassis devices, DX NetOps Spectrum displays the following three types of chassis views in OneClick:

- **The Basic Module-Level View**
  This view of your chassis device can be viewed at the Chassis Manager node. This view gives you visibility into your chassis device by displaying all the modules of it. The following image shows the various modules displayed under a Cisco chassis device:

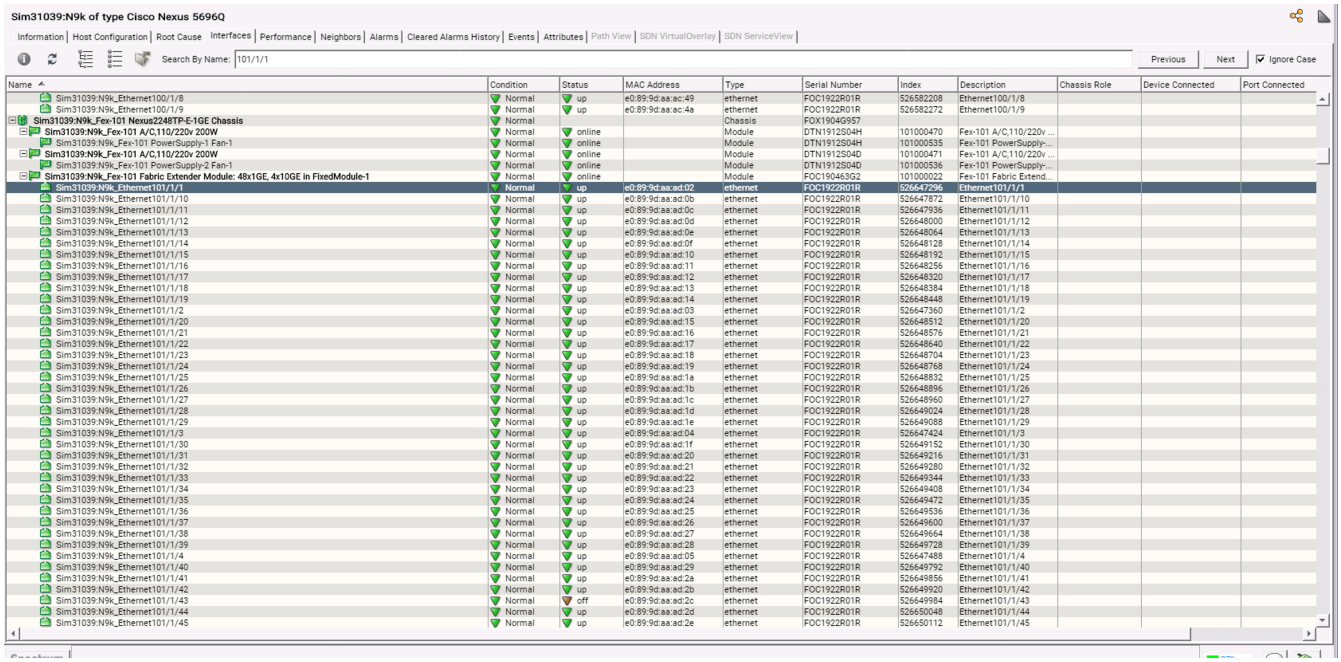
  The following image shows the various modules displayed under a Juniper chassis device:



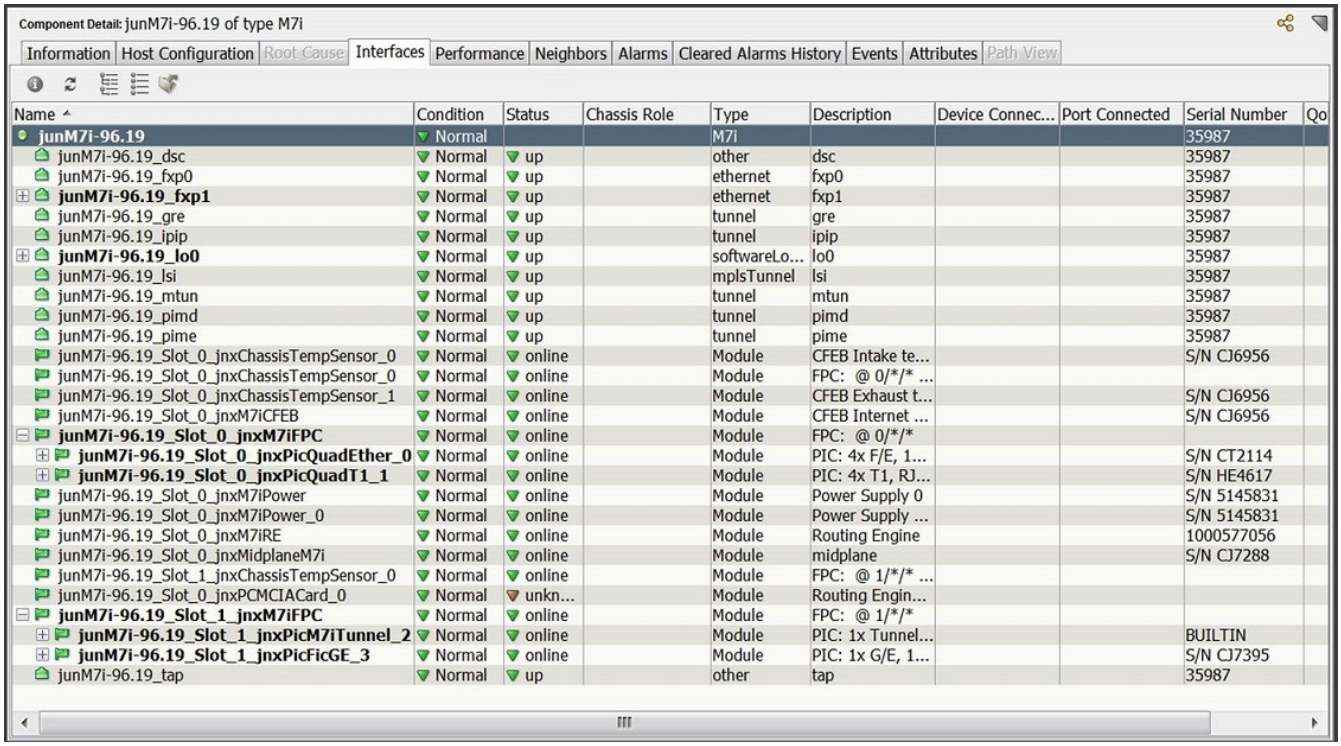
If you select a particular module under any chassis device, you can see the hardware description of that module. The hardware description lets you know whether the module is Fan, Linecard, Power Supply, Routing Engine, PIC, MIC, and so on. The following images show how the hardware description of a Cisco and Juniper module is displayed in the **Component Detail> Information:**



- **The Interfaces View**
  This view is an elaborated view of all interfaces present in each module of your chassis device. For a selected chassis device, this view shows all of its interface modules, interfaces within each module, the status of modules and its interfaces, and other information under the Interfaces tab of the Component Detail pane. From 10.4.2, all the FEX down ports are listed under the FEX modules. The following image shows how a "Cisco" chassis device is populated under the Interfaces tab:

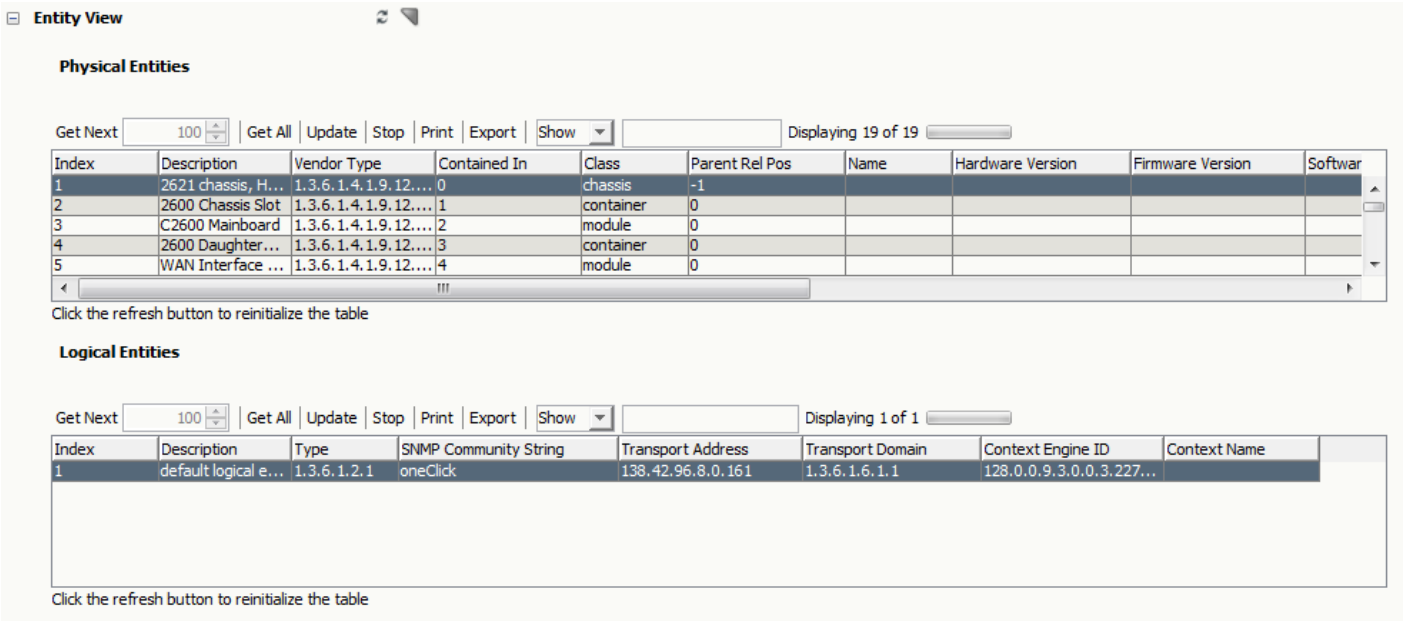


The following image shows how a "Juniper" chassis device is populated under the interfaces tab:



- **The Entity View**
  DX NetOps Spectrum populates this view only for those chassis devices which support the Entity MIB. The **Entity View** is populated when you expand the "**Entity View**" under the **Information** tab of the **Component Detail** pane. This view has the following two sections:
  - **Physical Entities**
    This section populates the information about each module that exists in your chassis device.
  - **Logical Entities**

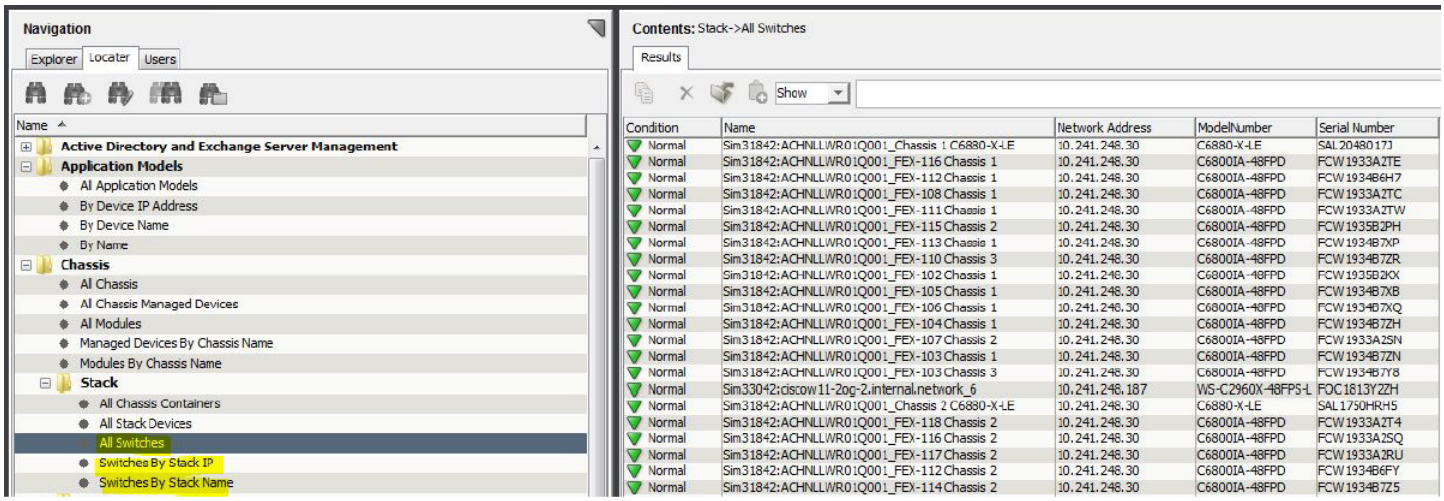
This section populates the information about the logical entities that exist in each module of your chassis device. The following image shows how the **Entity View** is populated for a selected "Cisco" chassis device view under the Chassis Manager node:



The Locater Search

DX NetOps Spectrum allows you to find all your modeled chassis devices and their modules in the **Chassis** node of the Locater tab in the Navigation pane. To find all your modeled chassis devices and their modules, use the following five search criteria available under the **Chassis** node:

- **All Chassis**
  This search criteria finds all your chassis devices that are modeled and arranged under the **Chassis Manager** node of your landscape. The result of this search lists all of your modeled chassis devices.
- **All Chassis Managed Devices**
  This search criteria finds each SNMP capable device model existing on all your modeled chassis devices. The result of this search lists each SNMP capable device model with name of its chassis device.
- **All Modules**
  This search criteria finds all your existing modules that are modeled and arranged under each modeled chassis device. The result of this search lists all modeled modules existing in each modeled chassis device.
- **All FEX Modules**
  This search criteria finds all your existing modules that are modeled and arranged under each modeled chassis device. The result of this search lists all modeled modules existing in each modeled chassis device.
- **Managed Devices By Chassis Name**
  This search criteria finds each SNMP capable device model by the name of its chassis device. The result of this search lists all SNMP capable devices that are mounted on the chassis device you specify.
- **Modules by Chassis Name**
  This search criteria finds each modeled module by the name of its chassis device. The result of this search lists all the modeled modules of the chassis device you specify.
- **Stack**
  From Spectrum 10.3.2 onwards, the 'All switches' option (as shown in the screenshot) fetches details such as the ModelName, Serial Number, ModelNumber, IPAddress of all the switches in a selected landscapes, including the details of the members of the stack devices.



Chassis Alarms

When DX NetOps Spectrum identifies a device model as a chassis device, the **Chassis Fault Domain** is associated with that chassis device. This condition correlation domain correlates various alarms on a chassis device and its modules to raise different root cause alarms. For more information about condition correlation domains, see Condition Correlation section. The existing alarm modules take care of the FEX down scenarios.

The following alarms are the Chassis Fault Domain alarms:

- **Chassis Down (0x00010f69)**
  This alarm is raised when the contact with a chassis device is lost. This alarm is the root cause alarm that suppresses the following alarms that are raised on a chassis device:
  – ContactLost_Red (0x00010d35)
  – Blade Status Unkown (0x00010f71)
  – InferConnectorContactLost_red (0x00010d90)
  – Linkdown (0x00010d11)
- **Blade Status Unkown (0x00010f71)**
  This alarm is raised when DX NetOps Spectrum is not able to contact the chassis on-board agent. This alarm is the root cause alarm that suppresses the following alarms that are raised on a module of a chassis device:
  – Catalyst Dev Module Failed (0x011c0488)
  – Dev Module Failed (0x00010f70)
  – Dev Module Offline (0x00010f86)
  – Dev Module Pulled (0x00010f6b)
  – Module Offline (0x00010f87)
  – Module Pulled (0x00010f6d)
- **Module Offline (0x00010f87)**
  This alarm is raised when the state of a Module is reported as "Offline". This alarm is the root cause alarm that suppresses the following alarms that are raised on a module of a chassis device:
  – ContactLost_Grey (0x00010d36)
  – ContactLost_red (0x000103d5)
  – Physical Host Down (0x056e000c)
- **Module Pulled (0x00010f6d)**
  This alarm is raised when a Module is pulled out from the chassis. This alarm is the root cause alarm that suppresses the following alarms that are raised on a module of a chassis device:

- ContactLost_Grey (0x00010d36)
- ContactLost_red (0x000103d5)
- Physical Host Down (0x056e000c)

Reconfigure Existing Models with New Certification Support

Existing models do not reevaluate their model class and device type at server startup. Therefore, new mappings that are available in a patch or with an upgrade are not applied to existing models. To pick up the new mappings, reconfigure your existing models.

Follow these steps:

1. Select the device models to update in any OneClick view.
2. Right-click the selected models and select Reconfiguration, Reconfigure Model.
   The selected models are reevaluated. If more current certifications for the models exist, the models are reconfigured.

Interface Modeling

GnSNMPDev creates an interface model for every instance in the MIB-II Interface table. Interface models are instantiated and associated with the device during DX NetOps Spectrum modeling. They represent the physical or logical connections on a device.

The device model Interfaces tab in the Component Details panel shows all of the interfaces that DX NetOps Spectrum has discovered on a device. The view shows interface status (UP or DOWN) and other information.

Connections between devices can be mapped to the port level, which lets DX NetOps Spectrum isolate faults with more granularity. For example, if a port on a device goes down, an alarm is generated on the individual interface model rather than at the device level. Interface model statistics can be polled and logged, letting you monitor and manage device performance with detailed data.

Potential interface model types include the following types:

- Gen_If_Port
- Serial_If_Port
- VLAN_IF
- FrameRelayPort

If Frame Relay Manager is installed and the device supports either of the Frame Relay standard MIBs (RFC1315 or RFC2115), the DLCI circuits are modeled using the DLCI_port model type.

NOTE
For more information, see the Standards-Based Protocol Reference section.

If ATM Circuit Manager is installed and the device supports the ATM MIB RFC1695, the ATM logical connections are modeled using the ATMVclLink or ATMVplLink model types.

Note: For more information, see the ATM Circuit Manager section.

Application Modeling

When a device is modeled with GnSNMPDev, DX NetOps Spectrum creates application models to represent each of the standard (IETF) MIBs that the device supports. Application models are instantiated and are associated with the device during DX NetOps Spectrum modeling.

For example, GnSNMPDev intelligence detects that a modeled device performs routing functions (a routing MIB is present). A Routing Application model is created and associated with the device model. Non-routing devices are not

burdened with the functionality and attributes that are required to manage routers; each device model carries only the required functionality.

Additional support for standard or proprietary MIBs can be added to the GnSNMPDev model type by customizing the GnSNMPDev management module.

The Locater tab in OneClick lets you search for and access the application models that are associated with a given device model. Several predefined searches are available for application models, but you can also perform a search using custom criteria.

NOTE
For information about standard MIB applications and accessing their views in OneClick, see the Standards-Based Protocol Reference section and the Host System Resources Management section. For information about creating a search, see the OneClick Administration section.

Traps, Events, and Alarms

The following table summarizes the trap support that is available with the GnSNMPDev management module for the six generic traps:

Trap Name	OID	Variable Binding	Event Generated	Alarm Generated	Alarm Severity
coldStart	0.0	N/A	0x10306	N/A	N/A
warmStart	1.0	N/A	0x10307	N/A	N/A
linkDown	3.0	1.3.6.1.2.1.2.2.1.1 1.3.6.1.2.1.2.2.1.2 1.3.6.1.2.1.2.2.1.3 1.3.6.1.2.1.2.2.1.7 1.3.6.1.2.1.2.2.1.8	0x220002	0x220001	Yellow alarm on the device (can be configured per port); red alarm on the port
linkUp	2.0	1.3.6.1.2.1.2.2.1.1 1.3.6.1.2.1.2.2.1.2 1.3.6.1.2.1.2.2.1.3 1.3.6.1.2.1.2.2.1.7 1.3.6.1.2.1.2.2.1.8	0x220001	N/A	N/A
authenticationFailure	4.0	N/A	0x1030a	0x1030a	Yellow
egpNeighborLoss	5.0	1.3.6.1.2.1.8.5.1.2	0x1030b	0x1030b	Yellow

In addition, the GnSNMPDev model type supports various RFC and IEEE standard applications traps. This model type also supports any traps that are defined at the global level. You can enhance this support to include other traps and event processing.

NOTE
For more information about global traps, see the Event Configuration section.

Access the Device Certification Database Online

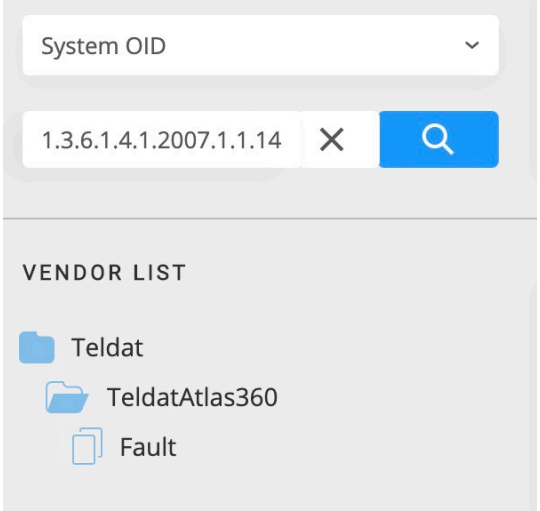
An application on the CA Technical Support website lets you search on all DX NetOps Spectrum certified devices. You can determine whether DX NetOps Spectrum supports a specific device model and filter by firmware version and release. You can also determine whether a device is supported with a Simple certification or an Enhanced certification.

Follow these steps:

1. Access the Device & Technology Certification page.
2. Click the 'Search All Certified Devices' link.

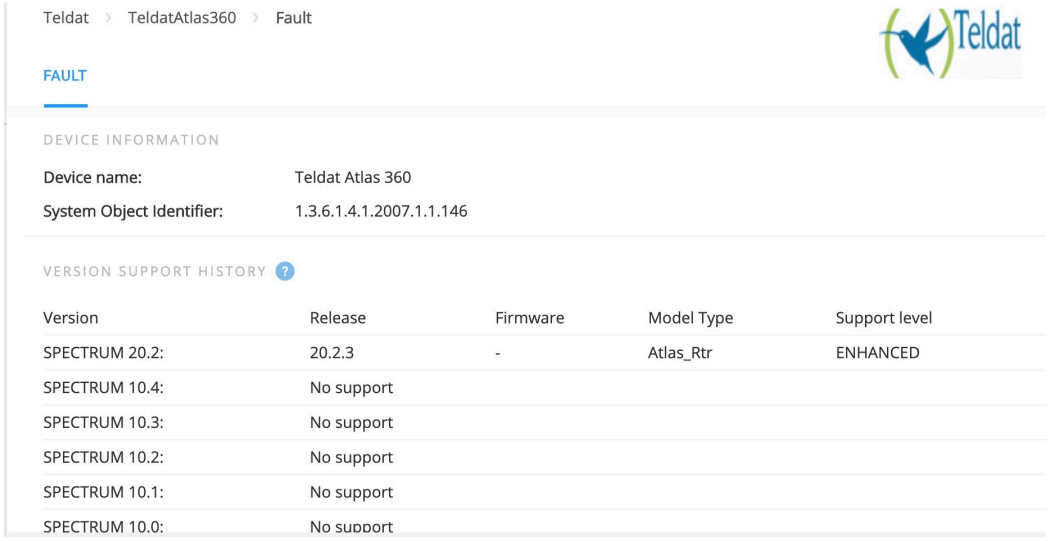
The Certification Web Database Search application appears.

3. Select Spectrum from the Product Line dropdown.



4. Complete the following search criteria fields as needed to locate your device:
   - **Certified Vendors**
     Corporations or organizations that manufacture one or more devices that DX NetOps Spectrum has certified. A vendor filter limits your search to all devices owned or acquired by the selected vendor.
   - **Keyword Search**
     Searches in the Device Type Name field of each device. A keyword search limits your search to all devices that contain the specific keyword in the Device Type Name field.
   - **System Object Identifier**
     Searches for a System Object Identifier, or a portion of the System Object Identifier. All devices containing the sequence you enter are returned.
     For example, 1.3.6.1.4.1.9.1.685 identifies the Cisco 1240AP device.

     NOTE
     Not all devices have a unique System Object Identifier. In addition, some devices lack a System Object Identifier.
   - **Support Level**
     Indicates the current level of DX NetOps Spectrum certification support. Two levels of certification support are available. For more information, see the Overview on Certification section.
5. Click the Search Database button to initiate a search based on your search criteria.
   Results are displayed, one line per device. Details at this level include the device name and model, System Object Identifier and Support Level.
6. Click a specific entry in the results table.
   Detailed information about the selected device appears, as shown:



Self-Certification

You can extend and customize the DX NetOps Spectrum simple or enhanced certification support. The following options are available:

- modifying attribute settings
- customizing identification with Device Certification
- managing MIBs and traps with MIB Tools
- developing new certifications

The subsequent sections discuss customizing identification with Device Certification, managing MIBs and traps with MIB Tools, and developing new certifications.

> **NOTE**
> For more information about customizing certification support, see the Event Configuration section, the Watches section, and the OneClick Customization section.

Adding Trap Support

DX NetOps Spectrum uses traps, events, and alarms to notify you about significant occurrences in your infrastructure. These terms apply to specific DX NetOps Spectrum entities, as described in the following list:

- Traps are alerts that are sent from SNMP-compliant devices. DX NetOps Spectrum receives traps and converts them into events for further processing.
- An alert is an unsolicited message that a managed node on a network sends. The management protocol affects the specific implementation of alerts. In general, DX NetOps Spectrum uses SNMP as the management protocol to communicate with devices on a network.
- An event indicates that something significant has occurred. Events are generated for observed behavior within DX NetOps Spectrum itself or in the managed environment. DX NetOps Spectrum events always occur in relation to a

model. When a managed element on the network generates an alert, it is mapped to a DX NetOps Spectrum event in the appropriate AlertMap file. The event is then generated with the event code specified in the AlertMap.

- An alarm indicates that a user-actionable, abnormal condition exists on a model. A model usually detects an abnormal condition when an event occurs and the EventDisp file states that an alarm is generated.

By default, the GnSNMPDev model type supports various traps, events, and alarms.

You can also add support for additional traps using the MIB Tools application and the Event Configuration application in OneClick. The high-level process is as follows:

1. Identify the MIB that contains the desired trap definitions.
2. In MIB Tools, import the MIB into the MIB Tools database.
3. Map the traps to events using MIB Tools. Specify the events that generate alarms and alarm severity.
   MIB Tools automatically creates and installs the appropriate event and alarm support files.
4. Launch Event Configuration directly from MIB Tools:
   a. In the Trap Support table, select the mapped traps whose events and alarms you want to configure.
   b. Edit traps for selected items in the trap support table.
5. Complete the configuration of the events and alarms in Event Configuration.
   For example, specify the symptoms, probable causes, and recommended actions for each alarm. The corresponding messages are displayed in OneClick when the alarms are generated.
   You can also add optional event processing for one or more events. For example, set up logging and create event rules that determine whether the event clears an alarm or generates another event.
   In addition, you can customize the default event message that is displayed in OneClick when the events are generated.

   NOTE
   For more information, see the Event Configuration section.

Watches to Monitor and Manage Model Conditions

You can create one or more watches for a particular model. A *watch* is a mechanism for adding thresholds for model attributes. Watches let you monitor network elements, such as routers, with a high level of detail. They also provide current data that can be used with other DX NetOps Spectrum tools in network analysis.

Set up a watch to monitor and analyze the changing internal and external attribute values of a model. Watches can include expressions that incorporate one or more attribute values. These attribute values, or an expression that is derived from these values, can then be measured against a defined threshold value. DX NetOps Spectrum evaluates the attribute values defined in a watch by polling the attributes when they are updated or when the watch value is read. Results can be used to generate events and alarms. Results can be logged for historical tracking and report information or sent to script files.

Keep in mind that watches can have an impact on network traffic and system resources. Delete watches that are no longer useful.

NOTE
For more information, see the Watches section.

Lock the Device Type Setting for a Device Model

You can lock the device type setting for a model so that the type is not reevaluated when you reconfigure a device. By default, the device type setting is not locked.

Follow these steps:

1. Locate the device model in the Topology tab of the Contents panel.

2. Select the device model whose device type setting you want to lock.
3. Click the Information tab in the Component Detail panel.
4. Expand the DX NetOps Spectrum Modeling Information subview.
5. Click 'set' in the Lock Device Type field, and select Yes.
   The device type setting is locked for the selected device model.

Lock Device Model Settings

You can lock settings for a device model. Locked settings are not reevaluated when you reconfigure a device. Both the device type setting and the model class setting for a device can be locked. By default, neither setting is locked.

Follow these steps:

1. Locate device models in the Topology tab of the Contents panel.
2. Select the device model whose device type or model class setting you want to lock.
3. Click the Information tab in the Component Detail panel.
4. Expand the DX NetOps Spectrum Modeling Information subview.
5. Take one or both of the following steps:
   – Click 'set' in the Lock Device Type field, and select Yes.
   – Click 'set' in the Lock Model Class field, and select Yes.
   The setting is locked for the selected device model.

Customizing Identification with Device Certification

This section describes the Device Certification component of OneClick. This section also discusses concepts and operations that are performed to customize the identity of a device using the Device Certification component of OneClick.

Device Certification in OneClick

The Device Certification component of OneClick lets you view, create, and edit Device Certification entries. DX NetOps Spectrum maps the System Object ID to the device type, model class, and model type. Device certification mappings appear in the Device Certification dialog.

Device certification entries let DX NetOps Spectrum initialize the device type, model type, and model class attributes on models during Discovery, Modeling, and device creation. You can create Device Certification entries for devices not directly supported in OneClick.

You can search, filter, and report on device models using the following attributes from the Device Certification list:

- Device Type attribute (0x23000e)
- Model Class attribute (0x11ee8)
- Model Type attributes (0x10000 for Modeltype_Name and 0x10001 for Modeltype_Handle)

These attributes provide a fine level of granularity when managing your network infrastructure.

Device Certification supports a distributed SpectroSERVER environment. Consistent device model identification occurs across a distributed deployment.

> **NOTE**
> To access and edit the device certification entries, log in as an administrator with read and write permissions.

Open the Device Certification Dialog

You can open the Device Certification dialog by taking one of the following steps:

- Open the Device Certification dialog from OneClick by selecting Tools, Utilities, Device Certification.
  The Device Certification dialog opens, displaying device type mappings for all modeled devices.
- Open the Device Certification dialog within the context of a device model. Select the model in the Explorer tab or the List tab of the Navigation panel, or in the Topology tab of the Contents panel. Right-click the selected device and select Utilities, Device Certification.
  The Device Certification dialog opens. The entry for the selected device type is highlighted.

About the Device Certification Dialog

The Device Certification dialog lets you maintain a custom list of system object identifiers and their corresponding device type name, model type, and model class. When you create or modify one of these entries, the corresponding attribute for all device models with the given system object ID is set to your customized value. This setting is applied to both existing and future device models. Used with the GnSNMPDev model type, this feature lets you model and monitor any SNMP-compliant device in the network. Devices that lack a specific DX NetOps Spectrum management module can also be modeled.

The Identification list in the Device Certification dialog also contains unregistered devices. An "unregistered" device has been modeled using Discovery or Model by IP. Such a device has system object IDs but lacks a device type name, model type, or model class.

You can use the unregistered devices in the Identification list to set up entries for all devices that are modeled with GnSNMPDev. Instead of trying to determine which devices use the GnSNMPDev model type, first model the devices. Once the devices are modeled, their system object IDs are added to the Identification list. You can then filter and sort the list and specify device type names for the unregistered devices that are modeled with GnSNMPDev.

> **NOTE**
> The mappings in the Device Certification dialog are preserved during upgrades and database migrations.

You can open the Device Certification dialog from the OneClick Tools menu or from a device model context:

- Select Tools, Utilities, Device Certification.
  The Device Certification dialog displays device type mappings for all modeled devices.
- Right-click a device model in OneClick. Find the model in the Explorer tab or the List tab of the Navigation panel, or in the Topology tab of the Contents panel. Select Utilities, Device Certification.
  The Device Certification dialog highlights the entry for the selected device type.

Device Certification Table

The Device Certification dialog lists the mappings of the device type name to System Object Identifier (sysObjectID or system OID), model classes, and model types. This list includes all standard DX NetOps Spectrum predefined mappings, all user-defined mappings, and any unregistered mappings. The list *does not* include mappings that have specialized device type name handling.

The Device Certification table displays the following information about each mapping:

- **Vendor Name**
  Displays the name of the company that manufactures the device, such as Cisco Systems.
- **System Object ID**
  Displays the MIB II sysObjectID entry that was retrieved from the device.
- **Device Type Name**

Displays the Device Type value that is mapped to the associated system OID.

- **Model Type**
  Identifies the name of the specific model type. If the system OID is supported with a simple certification (the system OID is *not* associated with a specific model type), displays “GnSNMPDev”. By default, this column is not visible.
- **Model Class**
  Identifies the model class (such as Router, Switch-Router, or Port) for the device model. If no model class is mapped to the system OID, "Auto" is displayed.
- **Modification**
  Identifies the mappings that have been modified in the current DC session.
- **Support Level**
  Identifies whether the device for the system OID has a simple or enhanced certification (MM). If the system OID is modeled with the GnSNMPDev model type, the support level is "Simple." If the system OID has a specific certification, the support level is "Enhanced."
- **Author**
  Identifies the user who created the mapping. This column is hidden by default.

You can modify the table display using the standard OneClick table preferences and column sorting methods. You can export the data in the Device Certification table to a file in either a comma-separated (.CSV), tab-delimited (.txt), or web page (.HTML) format.

NOTE
For more information, see the Using OneClick section.

Search Device Certification Mappings Using Filters

You can search for specific text or numeric strings in the Device Certification table by typing them in the Filter field. As you type in the Filter field, only the mappings that contain matching character strings appear in the table.

NOTE
The Filter field searches only the *visible* columns.

Use this feature to search for the following attributes:

- **Vendor Name:** Type the name of a specific vendor to display all supported system OIDs for that vendor. This information can help you determine whether DX NetOps Spectrum supports a specific model.
- **Custom mappings:** Enter "custom" in the Filter field to view only the mappings that you or someone else has modified using Device Certification.
- **Unregistered devices:** Enter "unregistered" in the Filter field to view only mappings of unregistered devices in the table.

Device Certification Changes

Once you have created or modified a mapping and have applied the changes, all device models in your distributed SpectroSERVER (DSS) environment is updated if they have Device Certification mapping changes. The updated device type names, model classes, and model types appear in the Topology views, the Navigation panel, and the List views for all landscapes.

The DX NetOps Spectrum modeling catalog is also updated so that all future device models with this system OID are assigned the corresponding device type, model class, and model type values.

Device Mappings

Device Certification categorizes device mappings into the following types:

- **CA mappings:** The predefined mappings that are included with DX NetOps Spectrum.
- **Custom mappings:** The mappings that are created or customized using the Device Certification utility.
- **Unregistered mappings:** Entries that do not have a mapping.

  NOTE
  The mapping type appears in the Author column in the Device Certification dialog.

Custom Device Type Mappings

You can customize any mapping, or you can create new mappings to improve any of the following administrative settings:

- Modify device type names to be more descriptive.
- Modify model classes to more accurately reflect the type of a device.
- Modify the model type to acquire functionality that is associated with a more appropriate model type.
- Add new mappings to accommodate devices.
- Assign device names to unregistered devices that DX NetOps Spectrum has identified on your network.

Modify Device Certification Entries

You can modify the device type name of an existing Device Certification mapping. You can also map the model type name and model class of a device.

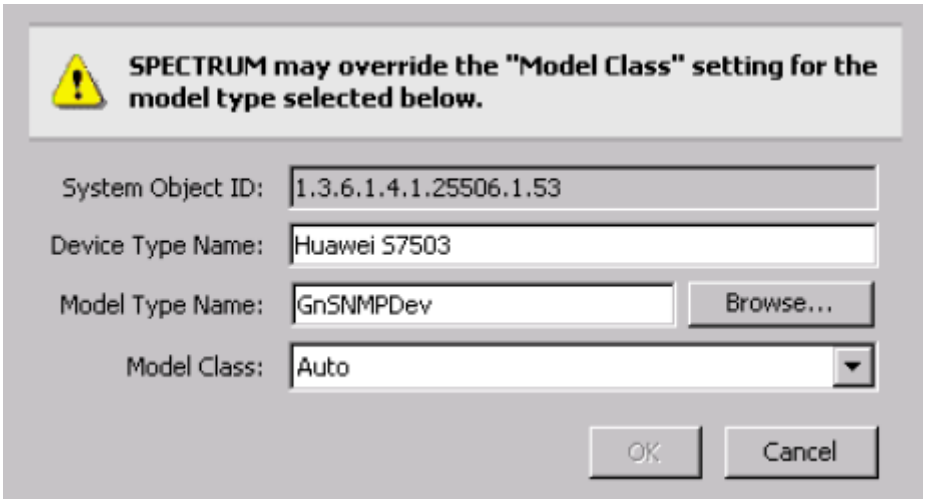
If you modify the device type name of an existing Device Certification mapping, or if you map the device OID to the appropriate model type name or model class, you create a custom mapping. Custom mappings override original mappings.

However, the original mapping remains intact on the system. If you delete a custom mapping with a modified device type name, model type name, or model class value, the original mapping reappears in the table.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Select an entry to modify, and click the edit
   icon 
   The DC: Edit Mapping dialog opens.

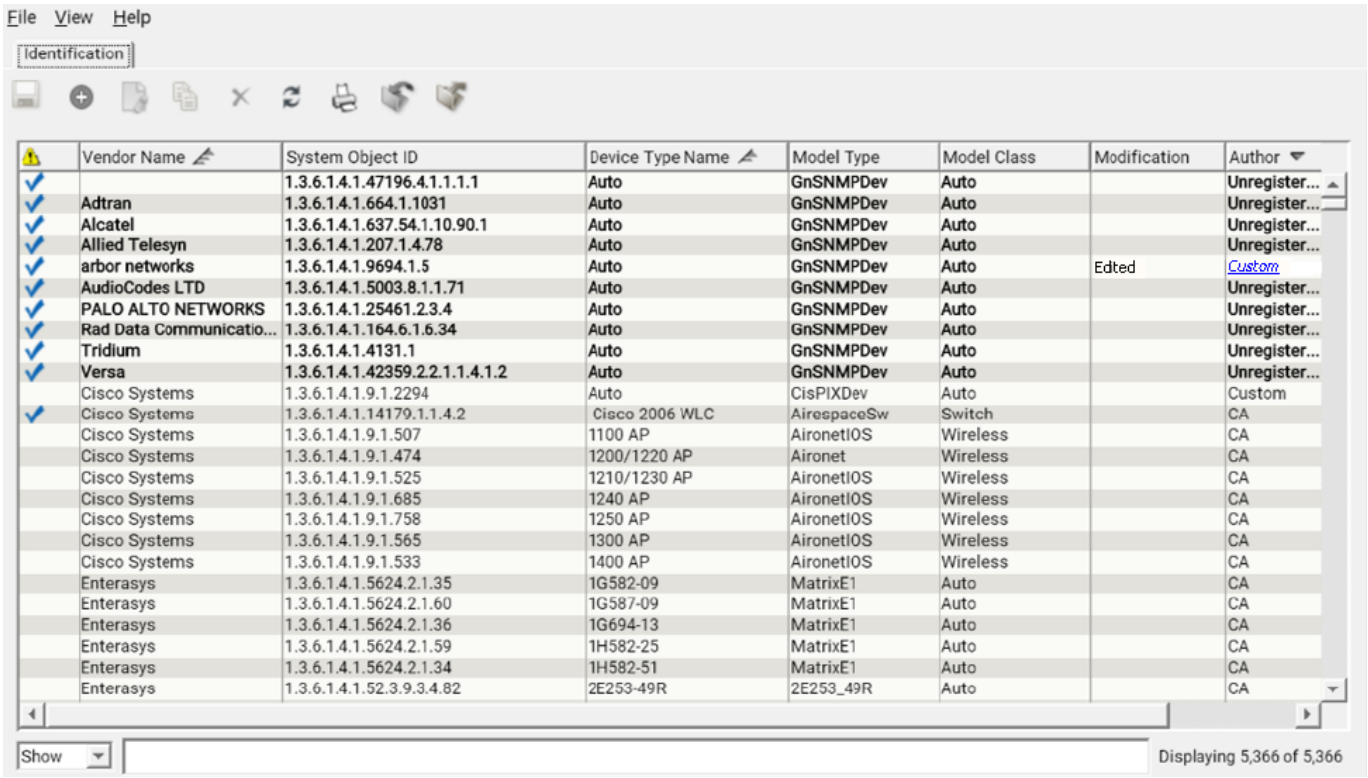
   NOTE
   For some models, DX NetOps Spectrum overrides your custom settings. In these cases, a warning message appears.



– Edit the following fields, and click OK.

  - Device Type Name
  - Model Type Name
  - Model Class

  Your changes to the selected model appear in the table on the Identification tab.



3. Click Save.
   Your changes are saved and are immediately applied to all device models. When complete, the DC: Operation Results dialog displays the results, either successful or unsuccessful, for each landscape in a DSS environment.
4. Click Close.
   Your selected Device Certification mapping is updated.

View Default Values Masked by Custom Device Certifications

Default device certifications are set up during the initial DX NetOps Spectrum modeling. When you customize a device certification mapping, your values mask the default values. After customizing your mapping values, you can view the default values that your custom mapping is obscuring. Viewing this information can be useful when determining whether your custom values are still required.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Locate the custom device certification, and click the 'Custom' link.

   The DC: Custom Mapping Details dialog opens. This dialog displays the custom values and the default values for each modified device certification mapping.

Copy Device Certification Mappings to Create New Mappings

You can create a new device certification mapping by copying an existing device certification mapping. Using the existing mapping can be more efficient when your new mapping is very similar, because the System Object ID, device type, model class, and model type values are prefilled.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Select the entry to copy and click the copy
   icon 
   The DC: Copy Mapping dialog opens.

NOTE
For some models, DX NetOps Spectrum overrides your custom settings. In these cases, a warning message appears.

3. Edit the following fields, as needed, and click OK.
   - System Object ID
   - Device Type Name
   - Model Type Name
   - Model Class

   Your new device certification mapping appears in the table on the Identification tab. The Modification column specifies "New," and the Author column specifies "Custom."
4. Click Save.
5. Click Close.
   Your new device certification mapping is created and is added to the Device Certification table.

Your changes are saved and are immediately applied to all device models. When complete, the DC: Operation Results dialog displays the results, either successful or unsuccessful, for each landscape in a DSS environment.

Map Unregistered Devices

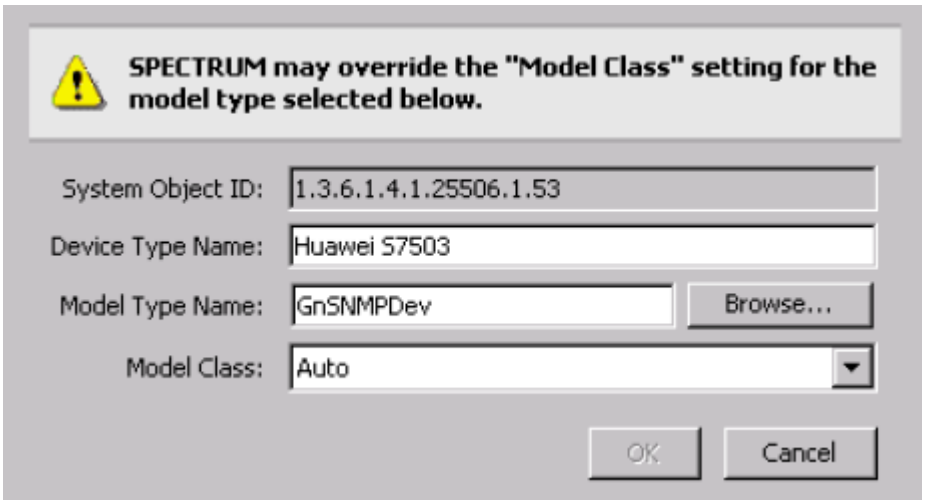
Unregistered devices lack a matching device type, model class, or model type entry. Any unregistered devices appear in bold in the Device Certification dialog, and "Unregistered" appears in the Author column.

To map unregistered devices, know the system OID of the unregistered devices on your network.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Select the unregistered device entry to be mapped, and click the edit icon 
   The DC: Edit Mapping dialog opens.

   NOTE
   For some models, DX NetOps Spectrum overrides your custom settings. In these cases, a warning message appears.



- Edit the following fields, as needed, and click OK.
  - Device Type Name
  - Model Type Name
  - Model Class

  Your changes to the selected model appear in the table on the Identification tab. "Custom" appears in the Author column, and "P" appears in the Modification column.

OneClick Views

A device that is modeled with the GnSNMPDev model type offers access to all OneClick views, such as Information, Performance, and Alarms.

NOTE
For more information about OneClick views, see the Using OneClick section.

Delete Custom Device Certification Mappings

You can delete custom mappings from the Device Certification table. However, default CA Technologies mappings cannot be deleted. When you delete a custom mapping that overrides a default mapping, the default mapping displays after the delete operation completes.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Select the entry to delete and click the delete icon 

   NOTE
   The Delete button is not available if the selected entry cannot be removed. For example, a default CA Technologies Device Certification cannot be deleted.

   The entry is flagged for removal from the list.

3. Click Save.
   Your changes are saved and are immediately applied to all device models. When complete, the DC: Operation Results dialog displays the results, either successful or unsuccessful, for each landscape in a DSS environment.
4. Click Close.
   Your selected Device Certification mapping is deleted.

Import the Uncertified Devices

From 10.4.1, you can import the uncertified devices and certify them yourself instead of waiting for the next version of the DX NetOps Spectrum to release a new list of certified devices.

Follow these steps:

1. Open the Device Certification dialog.
   The Device Certification dialog displays the device certification mappings on the Identification tab.
2. Click the **Import the file** icon 
   The Open File dialog is displayed.

3. Browse and select the required CSV (comma-separated values) file.
   Importing the file, update all the unregistered sysoids and update model type of existing sysoids. The updated list of devices is shown in the Device Certification dialog.

   NOTE
   For more information, see **Self Certify the Unregistered Devices** section in Uncertified Devices.

   You have successfully imported the unregistered devices.

Distributed SpectroSERVER Support

The Device Certification utility supports a distributed SpectroSERVER (DSS) environment. Device Certification detects multiple primary SpectroSERVERs in a DX NetOps Spectrum environment and alerts you when it cannot communicate with a SpectroSERVER. Device Certification queries all SpectroSERVERs for Device Certification table entries. Conflicts among SpectroSERVERs for user-specified mappings are detected.

NOTE
When you open the Device Certification utility in a DSS environment, a warning message appears if any of the primary SpectroSERVERs are down. Any unavailable SpectroSERVERs do not receive the Device Certification mapping changes that you make. Custom Device Certification mapping conflicts occur after all SpectroSERVERs are back online.

Resolve Device Certification Mapping Conflicts

Conflicts in Device Certification mappings can occur in an environment when a sysObjectID has more than one device type, model class, or model name defined. Conflicts usually happen when:

- **User customizations are mismatched across SpectroSERVERs** -- This situation can occur when one or more SpectroSERVERs are down prior to starting Device Certification. This situation can also occur when one or more SpectroSERVERs go down after starting Device Certification but before applying changes to custom mappings.
- **Predefined mappings are mismatched across SpectroSERVERs** -- This situation occurs when the device certification mappings provided by DX NetOps Spectrum are updated on some SpectroSERVERs but not others. For example, bringing a new SpectroSERVER online that has a more recent release of DX NetOps Spectrum can lead to differences in the predefined mappings between SpectroSERVERs.

For mismatched predefined mappings, verify the software installation on all SpectroSERVERs so that they use the same device certification table. You can resolve conflicts with customized mappings using the Device Certification dialog.

Follow these steps:

1. Open the Device Certification dialog.
   If conflicting Device Certification mappings are detected when you start the Device Certification utility, a Conflicts Encountered dialog opens.

   WARNING
   Resolve the conflicts so that Device Certification can open.
2. Click the Resolve Conflicts button.
   The Resolve Conflicts dialog opens.
3. Select the appropriate name from the Device Type Name drop-down list for each System Object ID, then click OK.
   The Device Certification mapping conflicts are resolved. The Device Certification dialog displays the device certification mappings on the Identification tab.

   NOTE
   If the Device Certification utility identifies a Device Certification entry that is present on some, but not all, of the servers in the DSS environment, the entry is automatically applied to all servers that lack it. This condition is different from a conflicting entry condition.

Device Certification Changes are Not Saved

Symptom:

I updated my Device Certification mappings, but some of my device models were not updated when I clicked Save. Now the Save button is disabled. Why were some devices not updated, and how can I apply my changes?

Solution:

DX NetOps Spectrum is unable to successfully save the updated Device Certification mappings on the first save attempt in the following cases:

- **A server in a distributed SpectroSERVER (DSS) environment cannot be contacted and does not receive the mapping update.**
  In this case, DX NetOps Spectrum warns you that one or more servers were down before the mappings were applied, or that some of the mappings were not applied on one or more servers.
  To resolve this problem, take the following steps:
  a. Close the Device Certification dialog.
  b. Resolve the communication issue with the server.
  c. Open the Device Certification dialog.
  The Device Certification dialog notifies you that conflicts exist and you must resolve them.
  d. Resolve all conflicts, then click Apply.
  The server synchronizes with your Device Certification mappings and reapplies them to all affected models.
- **Updated mappings are applied to all SpectroSERVERs, but some device models did not reevaluate their Device Certifications.**
  This situation can occur when the model classes or device types are locked. Network failure, stopping a server, or losing contact with the Device Certification client during an update can also cause this scenario. In this case, the SpectroSERVERs are properly updated -- the *device models* did not update -- so the Device Certification dialog does not notify you about conflicts.
  To force individual device models to reevaluate their Device Certification mappings, take the following steps:
  a. Use a Locater search to find all device models that did not update.

  NOTE
  You can check the Device Type Name or Model Class columns for device models that did not update.

  b. Verify that the device types and model classes are not locked.
  c. Select all affected device models and reconfigure the models.

Change the Model Type for a Single Device Type Using a Script

You can use the NewMM.pl post-installation script to automatically change the model type for a single device type. Many key attributes, relationships, and other elements are preserved.

This procedure changes the model type for all models with the specified system Object ID *and* the specified starting model type.

WARNING
Do not perform this procedure until you modify the model type mapping for the device type in the Device Certification utility. Otherwise, your changes are not communicated to the SpectroSERVER database and you see unexpected alarms.

Follow these steps:

1. Verify that the SpectroSERVER is running.
2. Run the following command from the <*$SPECROOT*>/Install-Tools/PostInstall/ directory:

```
NewMM.pl -m
```

NOTE
On Windows, run all necessary scripts from a bash shell. They do not run as expected from a DOS command prompt.

3. Enter the host name or IP address of the VNM and press Enter.
4. Enter the SpectroSERVER landscape handle when prompted.
5. Enter the system Object ID for the model when prompted.
6. Enter the current model type of the model when prompted.
7. Enter the new model type when prompted.
   The model type is changed.
   The log file, NewMM_Log_<*DATE*>, is created in the <*$SPECROOT*>/Install-Tools/PostInstall/ directory.

   NOTE
   Verify that the model type converted successfully by checking the log file, NewMM_Log_<*DATE*>.

Device Certification and Fault-Tolerant Environments

If you are working in a fault-tolerant environment, Device Certification differentiates between a primary and a backup server. For Device Certification to operate, it must be able to connect to the primary SpectroSERVER. The application cannot connect to the backup server.

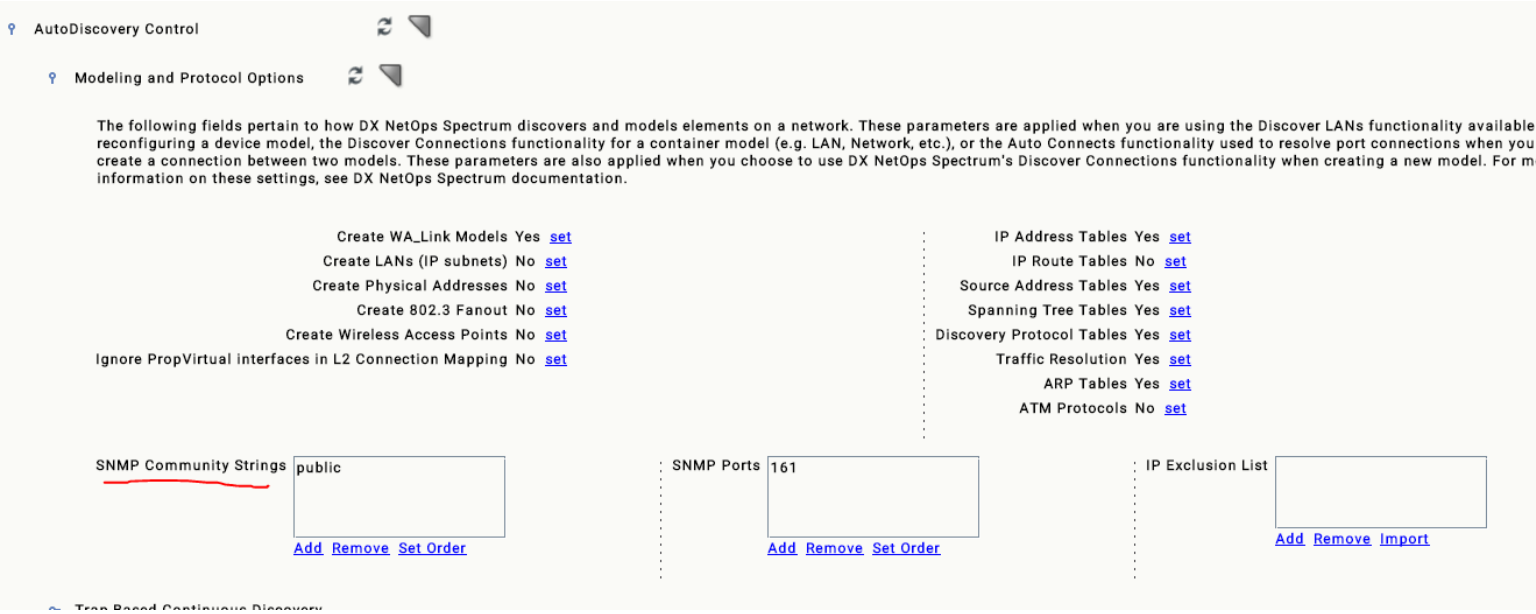
The backup SpectroSERVER obtains the Device Identifier List update and device model updates from the primary SpectroSERVER during the Online Backup procedure.

NOTE
For more information, see the Distributed SpectroSERVER Administration section.

Uncertified Devices

The current release simplifies the certification of uncertified OIDs to an existing model type. The device certification tool has a new option to import CSV files. The CSV file must have the mapping of the OIDs to be certified and model type. Importing the CSV updates the device certification tool with the new OID and corresponding model type. Previously, the device certification tool provided a consolidated list of all certified and uncertified SyOIDs. With this improved search option in this release, you can now fetch only the uncertified devices and self-certify those devices.

Ensure that you add the **SNMP Community String** options of the GnSNMP devices under the VNM Model, AutoDiscovery Control, Modeling and Protocol Options.



Self-Certify the Uncertified Devices

From 10.4.1, you can import the uncertified devices and can certify them yourself instead of waiting for the next version of DX NetOps Spectrum to release a new list of certified devices.

Follow these steps:

1. Ensure that you import the uncertified devices from the CSV file provided by Product Management.
   For more information, see the **Import the Uncertified Devices** section in Device Mapping.
2. Right-click the **Uncertified Devices** option in Locater and select **Certify**.

   DX NetOps Spectrum lists the uncertified devices in the dialog and prompts you to confirm the certification.
3. Click **Yes** to certify.
   DX NetOps Spectrum identifies all the GnSNMP devices for which the model type has been updated with the import, deletes them, and recreates.

   NOTE
   Manually created connections are lost and must be recreated.

Managing MIBs and Traps With MIB Tools

This section explains the MIB Tools utility of OneClick. This section also describes various concepts of a MIB and operations that are performed to manage MIBs and traps using the MIB Tools utility.

The MIB Tools Utility

The MIB Tools utility lets you compile, import, and browse Management Information Bases (MIBs). In addition, this utility can issue SNMP requests to network elements and can customize the mapping of MIB objects and traps in DX NetOps Spectrum. Use the MIB Tools to create, customize, and troubleshoot network element management in DX NetOps Spectrum.

SNMP and MIBs form the structure of network element management in DX NetOps Spectrum. DX NetOps Spectrum communicates with modeled network entities using SNMP. A MIB is a type of network device database that represents a device as a hierarchical collection of objects. A MIB object represents an individual unit of information in a MIB, such as device uptime. MIBs themselves are text files with special syntax.

MIB Tools include two self-certification tools. First, MIB Tools lets you map MIB objects to attributes in the DX NetOps Spectrum database. You can create OneClick views to display the values of those MIB objects, create Watches on the attributes, and set thresholds to send alarms. Second, the MIB Tools utility lets you add support for traps that your devices send.

DX NetOps Spectrum complies with the following RFCs regarding MIBs and SNMP:

- RFC 1155: Structure and Identification of Management Information for TCP/IP-based Internets
- RFC 1157: A Simple Network Management Protocol
- RFC 1213: Management Information Base for Network Management of TCP/IP-based Internets

DX NetOps Spectrum uses the following standard MIBs for link discovery to establish connectivity with neighboring devices:

- LLDP MIB
- Bridge MIB
- Q-Bridge MIB (if VLAN is configured)
- IP MIB (This MIB takes care of IP-Forwarding tables also)

NOTE

Information!

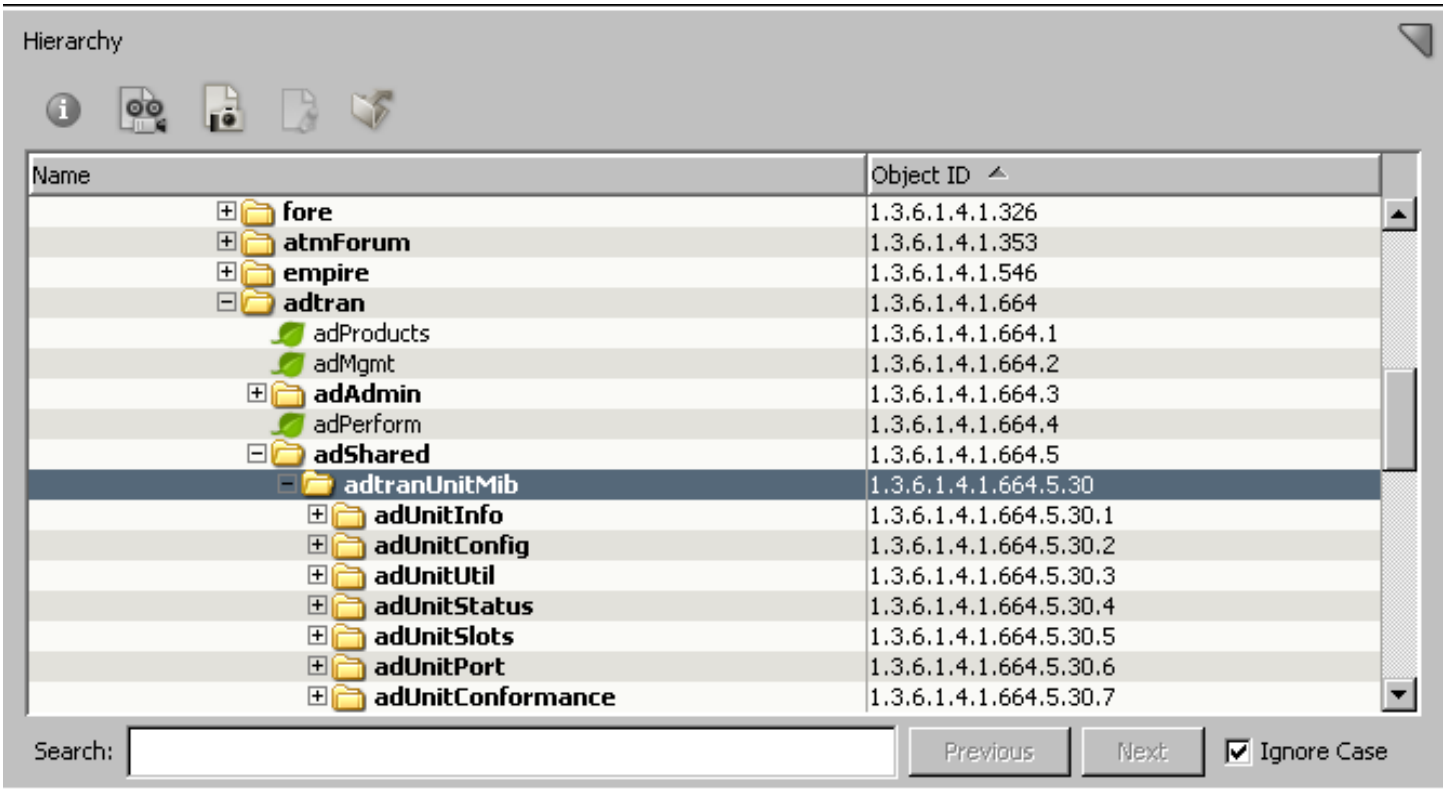
- When a device is certified in Spectrum, it is verified that these standard MIBs are supported by the respective device. If yes, then the connections with neighboring devices get established automatically.
- If these MIBs are supported by the device and still relevant information is not available in those MIBs, then it might be a problem with device configuration or vendor issue.
- If device populates these MIBs information, and yet the connections are not being established then further troubleshooting is required from Spectrum end.
- If these MIBs are not supported by the device and relevant information is available in proprietary MIB (like CDP MIB), then you need to add specific intelligence for these types of devices as part of the enhanced certification.

How a MIB Is Organized

The International Standards Organization (ISO) supplies a standard tree format for the organization of network device management information. This tree structure branches out into subtrees that are organized into branches (groups of related information) and leaves (the individual pieces of information, or objects).

Each layer of this tree is numerically encoded. A unique number, an Object Identifier (OID), identifies each group and object. This identifier lets an SNMP agent locate the object in a device MIB. An ASCII name is also assigned to each branch or OID to identify management objects.

The following image illustrates MIB objects in the MIB Tools Hierarchy with the name and OID. MIB Tools uses folders, acorns, and leaf icons to show branches, traps, and objects within a MIB. Each folder in the display indicates that more objects are contained in that level of the tree structure.



MIB Tools Database

MIB Tools maintains a MIB database on the OneClick web server. The default database consists of standard and proprietary MIBs. You can add MIBs to this database by importing them.

OneClick MIB Tools Overview

MIB Tools is a multifunctional MIB utility. Use it to browse MIBs, issue SNMP requests to network elements, import MIBs, and add MIB object and trap mapping support to DX NetOps Spectrum. You can use MIB Tools to retrieve supported information directly from a given device to aid in troubleshooting and managing that device. You can customize your DX NetOps Spectrum network management environment by using MIB Tools to import the MIBs of network elements that are not yet supported in DX NetOps Spectrum.

The MIB Tools utility lets you complete the following tasks:

- Compile and import MIBs into the MIB Tools database.
- Browse MIBs for details of MIB objects and traps.
- Directly query and set values for MIB objects of network elements.
- Export MIB query result values for use in troubleshooting and creating simulations.
  You can export the data that is displayed in MIB Tools into several different file formats. You can export data from the Results, Attribute Support, and Trap Support tables.
- Create custom network element support in DX NetOps Spectrum by mapping new traps and MIB objects.
- Delete custom MIBs from MIB Tools database. Standard or proprietary MIBs cannot be deleted.

Start MIB Tools

You can start the MIB Tools utility from the Tools menu. Or you can start it within the context of a selected device model.

To open the MIB Tools utility without the context of a specific device model, click Tools, Utilities, MIB Tools without selecting a device model. The MIB Tools dialog shows the progress of retrieving and loading the MIB Tools database.

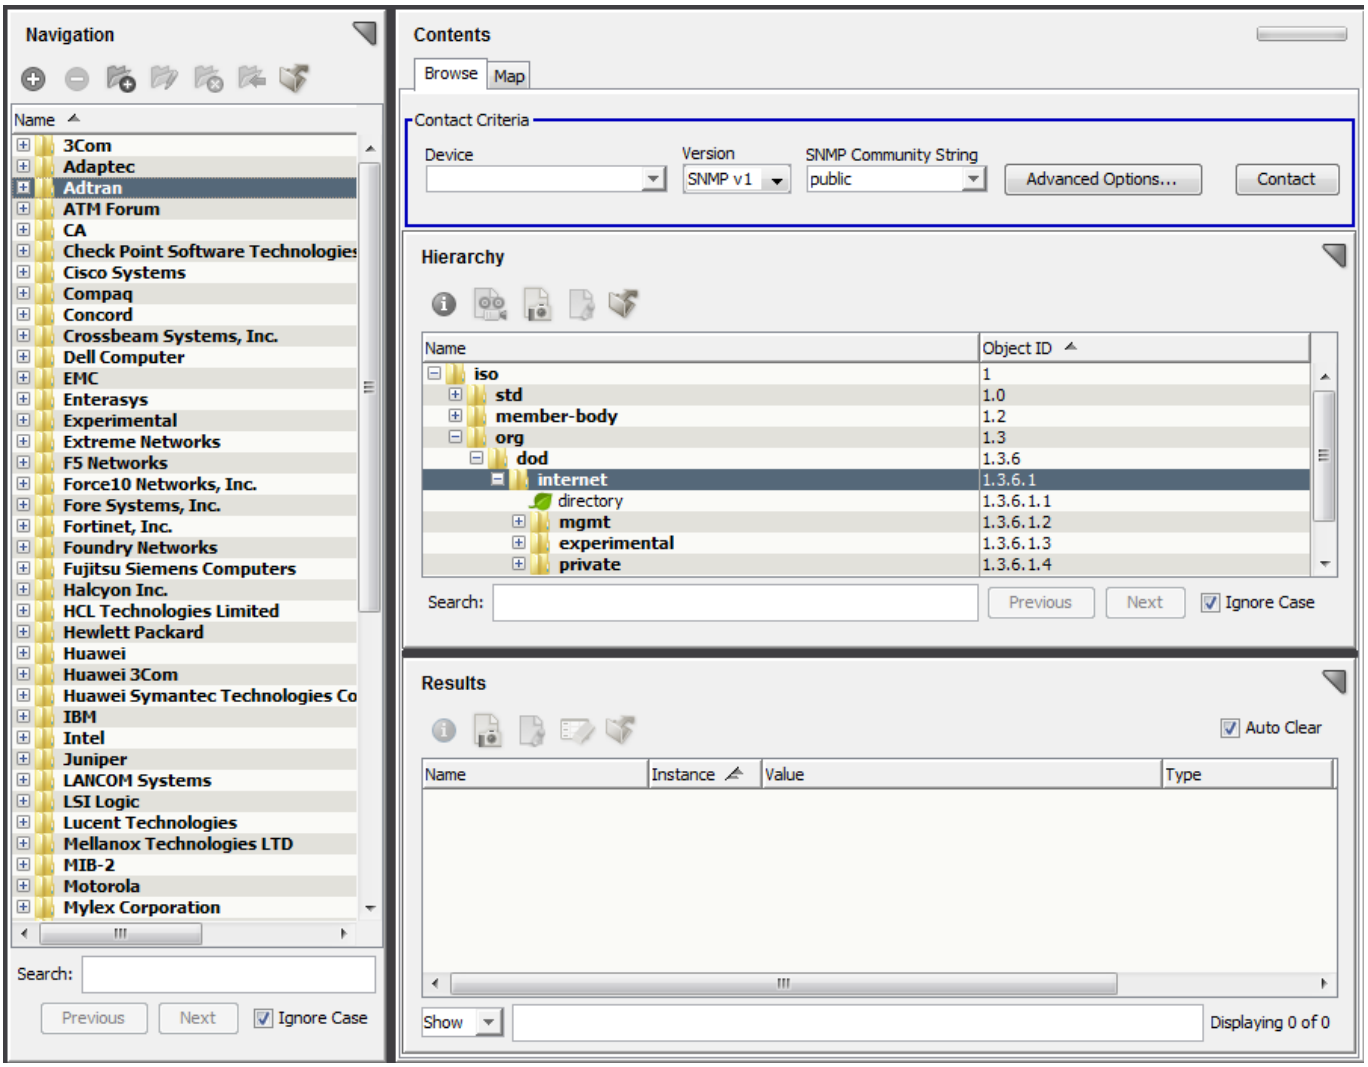
You can also start MIB Tools in the context of a specific device model. This method lets you communicate with the device and perform SNMP queries on the model, whose contact criteria are automatically displayed.

Follow these steps:

1. In the OneClick Console, locate the device model you want to investigate with MIB Tools.
   Locate a model in either the Explorer tab of the Navigation Panel or the Topology tab of the Contents panel.
2. Right-click the device model and click Utilities, MIB Tools, or click Tools, Utilities, MIB Tools from the main menu.
   The MIB Tools utility opens.
   The Contact Criteria display the SNMP contact information for the selected device.
   MIB Tools attempts to contact the device.
   If the attempt fails, an error message appears.
   If the attempt succeeds, the Contact Status indicator turns green.
   A status dialog shows the progress of retrieving and loading the MIB Tools database.

MIB Tools User Interface

The MIB Tools user interface has two panes that let you find MIBs and view MIB information: the Navigation pane and the Contents pane.



Locate and select MIBs in the Navigation pane. You can view a list of the compiled MIBs in the MIB Tools database. By default, MIBs are organized by vendor and are displayed alphabetically. Sorting is supported on table columns. You can also delete custom MIBs that you select in the Navigation pane.

The Contents panel has two tabs:

- **Browse tab**
  Lets you browse MIBs in the MIB Tools database and query devices on your network to obtain or set MIB object values. The Browse tab has three main sections: Contact Criteria, Hierarchy, and Results.
  Perform the following tasks from the Browse tab:
  - Contact a device.
  - View the name, object ID, or access type of an MIB object in the Hierarchy section.
  - View the results of a query in the Results section.
- **Map tab**
  Identifies the objects and traps for a selected MIB that DX NetOps Spectrum supports. You can see the DX NetOps Spectrum Attribute ID for an object and the Event code for a trap. Unsupported objects lack an Attribute ID or Event code.
  Perform the following tasks from the Map tab:

- Create attributes in the DX NetOps Spectrum database from MIB objects.
- Map traps in DX NetOps Spectrum.
- Identify the MIB objects that have been previously mapped to attributes in the DX NetOps Spectrum database using MIB Tools.
- Identify all trap support in DX NetOps Spectrum.

MIB Tree Hierarchy Table

When you select a MIB in the Navigation panel, its details appear in the Hierarchy tree table in the Browse tab of the Contents panel.

The default view of the Hierarchy tree table displays the entire MIB Tools database starting at the iso branch.

Browse MIBs

You can browse the MIB Tools database and view detailed information for each group, object, and trap. For trap objects, you can view variable binding details. To browse an individual MIB, select the MIB in the Navigation panel and use the Hierarchy tree table to navigate the MIB folders, groups, objects, and traps.

Search MIBs

You can search the Hierarchy tree table for a text string by entering it into the Search field. The Next and Previous buttons let you scroll through each successive instance of the search string.

The Hierarchy tree table displays the following information:

- **Name**
  Displays the name of the MIB object.
- **Object ID**
  Displays the Object ID of the MIB object.
- **Access**
  (Hidden by default) Displays the access type for the object. The type is read-only, read/write, read-create, or not-accessible.

NOTE
For more information, see the Using OneClick section.

The Hierarchy toolbar provides the following functionality:

Button	Description
	**Information/ Component Detail button**: Opens a dialog with details about a selected item. This information is taken directly from the MIB.
	**Query button:** Retrieves a subtree of management values using SNMP GET_NEXT requests. All of the objects returned have an OID that is prefixed by the OID of the branch that you select for the query.
	**GET button:** Performs an SNMP GET of a selected scalar object. If a scalar object is not selected, lets you build an SNMP GET or SNMP GET_NEXT request.
	**SET button:** Sets the value of the selected MIB object on a specific device.
	**Export button**: Exports the table contents to an external file

Attribute Support Table

When you select a MIB in the Navigation panel, its attribute support details appear in the Attribute Support table. Find this table in the Map tab of the Contents panel. The Attribute Support table displays information for MIB objects and DX NetOps Spectrum attribute support.

> **NOTE**
> The table does not reflect the DX NetOps Spectrum attribute support from the DX NetOps Spectrum model type catalog. Only the DX NetOps Spectrum attribute support that is created using MIB Tools is included.

The Attribute Support table displays the following information:

- **Name**
  Is the name of the object in the MIB.
- **Object ID**
  Is the object ID in the MIB.
- **Attribute ID**
  Specifies the attribute ID value. If the object is not supported in DX NetOps Spectrum, this field is blank. The word 'Conflict' can appear to indicate a conflict with the assigned attribute ID for the object in a DSS environment.
- **Landscapes**
  Indicates whether the attribute is supported on some, all, or none of your landscapes.
- **Needs Update**
  Indicates whether the attribute requires an update. For example, if the enumerations in the MIB do not match entries in the DX NetOps Spectrum database, the entry needs an update. A checkmark indicates that an update is needed.

The toolbar in the Attribute Support table includes the following functionality:

Button	Description
	**Information/ Component Detail button**: Opens a dialog with details about a selected item. This information is taken directly from the MIB.
	**Create Attributes button:** Creates DX NetOps Spectrum Attribute IDs for the objects that are selected and that lack support in DX NetOps Spectrum. If you do not select any objects in the Attribute Support table, and no attributes are currently mapped, creates attributes for *all* objects in the table. This button is disabled if the selected entry is already mapped, or if no items are selected and any of the entries are already mapped.
	**Export button**: Exports the table contents to an external file

Trap Support Table

When you select a MIB in the Navigation panel, its trap support details appear in the Trap Support table in the Map tab of the Contents panel.

The Trap Support table lets you view the traps defined in the MIB selected in the Navigation panel and all default and custom DX NetOps Spectrum event codes mapped to them.

The Trap Support table displays the following trap and DX NetOps Spectrum event information:

- **Name**
  Specifies the name of the trap in the MIB.
- **Object ID**
  Specifies the trap object ID in the MIB.
- **Event Code**
  Specifies the event code. If the trap is available for only select DX NetOps Spectrum models, the event code appears as ‘Partial.’ If the trap has different event codes mapped on different SpectroSERVERs in a DSS environment, the event code appears as ‘Conflict.’
- **Landscapes**
  Indicates if the attribute is supported on some, all, or none of your landscapes.
- **Event Type**
  Indicates whether the trap has a default mapping, a custom mapping, or both. Default mappings show ‘CA’ in this column; custom mappings show ‘Custom.’ However, if a custom trap mapping is obscuring, or shadowing, a default trap mapping, this column shows a ‘Custom’ link. Click 'Custom' to see the disposition details of the custom mappings.

The toolbar in the Trap Support table includes the following functionality:

Button	Description
	**Information/ Component Detail button**: Opens a dialog with details about a selected item. This information is taken directly from the MIB.
	**Map Traps button:** Maps traps for the selected item or items. If no objects in the Trap Support table are selected and no traps are mapped, creates traps for *all* objects in the table. Does not apply if the selected entry is already mapped, or if no items are selected that lack mappings.
	**Remove Traps button:** Removes the custom trap mappings from the selected item or items in the Trap Support table. When you unmap a trap from an event code, the corresponding "EvFormat" and "Pcause" files are deleted, and that event code is deleted from the database.
	**Edit Traps button:** Opens the Event Configuration application, which lets you edit the mapped trap selected in the Trap Support table. Does not apply to unmapped traps, whose entries lack event codes. For more information, see the Event Configuration section.
	**Export button**: Exports the table contents to an external file
Remap All Conflicts	**Remap All Conflicts check box:** Remaps traps that are partially supported in DX NetOps Spectrum, or that have inconsistent, conflicting support across SpectroSERVERs in a DSS environment. Remapping traps makes the traps available to all model types on all SpectroSERVERs.

Import and Export MIBs

You can add MIBs to the MIB Tools database individually using the MIB Import feature. You can also import multiple MIB files using a script at the command line. Import MIBs into the MIB Tools database for the following reasons:

- To view new MIB objects in a MIB that is not imported.
- To retrieve MIB objects from a device whose MIB is not imported.
- To build OneClick views or create Watches based on MIB objects that are not already supported in DX NetOps Spectrum.

> **NOTE**
> Importing MIBs is only the first step to using them in OneClick. The second step involves mapping the MIB objects.

You can also export data that is displayed in MIB Tools for use outside of MIB Tools and OneClick. You can export data that is displayed in the Results, Attribute Support, and Trap Support tables into several different file formats.

Import Individual MIBs

You can import individual MIBs into the MIB Tools database. The MIBs that you import are stored in the following directory on the OneClick web server:

```
<$SPECROOT>/MibDatabase/userContrib
```

When you import a new MIB using the MIB Tools, DX NetOps Spectrum stores it as a custom MIB.

To import a MIB into MIB Tools, the MIB file must be on a file system that is accessible from the OneClick Console. You can only compile text-formatted MIB files. Files in Microsoft Word or rich text formats (containing control characters) cannot be compiled and are ignored.

> **NOTE**
> If you have many MIBs to import, you can import multiple files in bulk using the BulkMibImport command. The MIB files that are referenced by MIB Tools can only contain a single MIB. This restriction includes the MIB that is being compiled and any dependent or imported MIBs that are in the same directory. If a referenced file contains multiple MIBs, break each MIB into a separate file.

When you import a MIB file, MIB Tools recursively checks the MIB file for any IMPORTS statements that reference other MIBs. MIB Tools identifies any dependent or imported MIBs in files that are in the same directory as the MIB that is being compiled. As long as they are in the same directory, the MIB files that resolve IMPORTS statements are also compiled and are placed in the following directory on the OneClick web server:

```
<$SPECROOT>/MibDatabase/Dependent
```

These files are therefore available for subsequent import requests.

After you locate and compile a referenced MIB, the MIB Tools utility no longer has to locate and compile it each time another MIB file references it.

Follow these steps:

1. Click Utilities, MIB Tools from the main menu.
   MIB Tools opens.
2. On the Navigation panel, click the Add MIB
   icon 
   The ‘MIB Tools: Add MIB’ dialog opens.
3. Click Browse to locate and select the file that contains the MIB that you want to import. Or manually enter the complete path and filename in the MIB File Name field
4. Click Open.
5. Click Compile.

A message appears in the Compiler section of the dialog, relating to the status of the compile request.
On success, a message states that the file was successfully compiled.
Otherwise, errors or warnings that were generated during the compilation appear. You cannot import a MIB that contains errors. Click Show Editor to edit the MIB file and correct any errors.

6. Once the MIB compiles successfully, click Add to add the MIB and keep the 'MIB Tools: Add MIB' dialog open so that you can add additional MIBs, or click Add & Close to add the MIB and close the dialog.
   The MIB is added to the MIB Tools database, the 'MIB Tools: Add MIB' dialog closes, and the MIB is added to the list in the Navigation panel. If the MIB references a new vendor, a new folder appears for that vendor.

   NOTE
   If you import an updated copy of an existing standard MIB, the MIB Tools adds that MIB as a unique custom MIB under the same vendor folder by appending MIB-MODULE-NAME<n>. For example, when you update the ADTRAN-AOS MIB and import it, MIB Tools adds it as ADTRAN-AOS1 after the existing ADTRAN-AOS MIB. You can delete the ADTRAN-AOS1 MIB as it is a custom MIB.

Delete Individual MIBs

You can delete previously imported custom MIBs from the MIB Tools database. When you delete an MIB all the corresponding mapped attributes and events that are associated with traps remain mapped.

Follow these steps:

1. Click Utilities, MIB Tools from the main menu.
   The MIB Tools opens.
2. Expand the required vendor folder, and select the required custom MIB.
3. On the Navigation toolbar,
   click 
   The " Delete Custom MIBs" dialog opens.
4. Click OK.
   The MIB Tools deletes the MIB from its database.

Editing MIBs

MIB Tools includes an editor that lets you locate and correct errors that are identified during the compilation of a MIB file. To troubleshoot compiler errors, click Show Editor in the 'MIB Tools: Add MIB' dialog. You can then view the MIB file in the editor and make changes to remove errors. You can search the file for alphanumeric strings, locate specific lines in the file, and save the changes that you make.

Import Multiple MIBs

Use the BulkMibCompile command to import large numbers of MIB files into the MIB Tools database. This command lets you migrate existing MIBs without using the MIB Tools interface. BulkMibCompile is located in the default DX NetOps Spectrum installation directory on the OneClick server:

```
<$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh
```

This command uses the following format:

```
BulkMibCompile [-u <MYSQL USER>] [-p <MYSQL PASS>] -d <MIB DIRECTORY> [-f <FILE MASK>] [-skip_search] [-standard_mibs]
```

- **-u**
  Specifies the MYSQL username. If you do not specify a username, BulkMibCompile uses the default MYSQL username 'root'. This parameter is not required if the default username is correct.
- **-p**

Specifies the MYSQL password. If you do not specify a password, BulkMibCompile uses the default MYSQL password, 'root'. This parameter is not required if the default password is correct.

- **-d**
  Specifies the directory containing the MIBs to import.
  – If you are running a Windows Cygwin bash shell, use the following format for specifying a directory:
  ```
  <$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh -d c:\\MibDirectory
  ```
  NOTE
  The double backslash (\\) is required. A single backslash (\) is an escape character in this environment.
  – Otherwise, use the following format:
  ```
  <$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh -d /usr/MibDirectory
  ```
- **-f**
  Specifies the file mask. Use a file mask that includes all of the MIB files that you want to import in a directory. Examples of file masks include:
  ```
  RFC*
  *RFC*
  *.mib
  ```
- **-skip_search**
  Speeds up the import process by instructing the compiler to resolve IMPORTS statements. Use this option if the MIBs that are referenced in IMPORTS statements in the MIB files that you are importing are in the MIB directory that you specified and are named using their MODULE-NAME.
  If you do not use -skip_search, the BulkMibCompile code searches each MIB for IMPORTS statements and attempts to resolve them. This process is repeated during the compilation of each MIB.
- **-init**
  Reinitializes the MIB Tools database, clearing the database of all MIBs.
- **-standard_mibs**
  Specifies that all the MIBs being imported into the <MIB DIRECTORY> will be added as standard MIBs.

  NOTE
  If you run the "BulkMibCompile" command without this option at the CLI, all the imported MIBs will be added as custom MIBs. Custom MIBs can be deleted.

Example: Import All MIBs in a Directory

To import all MIBs in a directory, use the following syntax:

```
<$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh -d /usr/MibsToCompile
```

A MIB that has been successfully compiled is added to the database. The imported MIB overwrites any existing MIBs with the same MIB MODULE-NAME. Any compilation errors are displayed, and compilation continues with the next MIB that is imported.

Example: Reinitialize a MIB Tools Database

To reinitialize a MIB Tools database, use the following command:

```
<$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh [-u <MYSQL USER> ] [-p <MYSQL PASS> ] -init
```

Example: Populate the MIB Tools Database of Another OneClick Server from the Primary OneClick Server

To populate the MIB Tools database of another OneClick server from the primary OneClick server, take the following steps:

1. Copy the contents of *<$SPECROOT>*/MibDatabase and *<$SPECROOT>*/MibDatabase/Dependent on the primary OneClick server to the same directories on the secondary OneClick server.
2. On the secondary OneClick server, run BulkMibCompile to import the MIBs that you copied into the *<$SPECROOT>*/MibDatabase:

```
<$SPECROOT>/MibDatabase/scripts/BulkMibCompile.sh -d <$SPECROOT>/MibDatabase
-skip_search
```

After the script has completed, the databases on the original and destination OneClick servers are identical.

Create Attribute Support

You can add support for MIB objects that DX NetOps Spectrum does not currently support. Create attribute support for a MIB that you have imported into the MIB Tools database.

To create support for MIB objects in the DX NetOps Spectrum database, create an attribute identifier (ID) for the MIB objects. Attribute IDs are used to create mappings between the DX NetOps Spectrum database and MIB objects. You can use the attribute information to develop custom views, Watches, or leverage other features to manage network devices.

Follow these steps:

1. In the Navigation panel of MIB Tools, select the MIB for which you want to create attribute support.
   The list of MIB objects appears in the Attribute Support table.
2. Check the columns for MIB objects that lack corresponding Attribute IDs.
3. Select a MIB object, and click the Create Attributes icon 
4. Click OK to continue creating the attributes on all SpectroSERVERs.
   The 'MIB Tools: Attribute Creation Results' dialog shows the status, including the number of attributes created for each landscape.
5. Click Close.
   The Attribute Support table now shows the Attribute ID that was created for each object. The new attributes are available for use by all SNMP-capable models in DX NetOps Spectrum.

Modifying MIB Objects in the MIB Tools Database

After you have imported a MIB object into the MIB Tools database and have mapped the object by configuring attribute support, the object definition is locked. The only part of the object definition that you can change is the enumerations.

WARNING
Do not edit a MIB object that has been mapped. Modifications to any parameters other than enumerations (such as name or data type) are not supported. In addition, you cannot use MIB Tools to delete attributes that have already been mapped.

WARNING
The only way to modify a MIB object that has been mapped is to re-import the MIB into the MIB Tools database. For more information, see Import Individual MIBs.

Query (GET_NEXT), GET, and SET Requests

You can run queries (GET_NEXT) and perform GET and SET operations for MIB objects to retrieve and set information about network devices.

You must know the Object IDs of the objects to query. You can query a device that is not modeled in DX NetOps Spectrum.

Query a Subtree of Objects

You can query a MIB object in the MIB database on a network device. You can perform a query to repeatedly perform a request to find multiple instances of a MIB object as long as the objects returned have an OID that is prefixed by the OID of the branch you selected to do the query on.

Follow these steps:

1. Establish contact with the device to query.
2. Navigate to the MIB object you want to query.

   NOTE
   Select an inaccessible object (folder) or a table leaf object to perform the SNMP GET_NEXT query. Performing an SNMP GET_NEXT query on a scalar leaf object yields an empty result set.
3. In the Hierarchy tree table toolbar, click the Query/GET_NEXT icon  .

   NOTE
   The Query/GET_NEXT button is available when a readable object is selected in the Hierarchy tree table.

   The query results appear in the Results table.

   NOTE
   If you select a group object (contains other groups and individual objects) or a table object (contains multiple instances of the same object) in the Hierarchy tree table and click the GET icon, the SNMP GET dialog opens. Change the request type to a GET_NEXT in the Request Type drop-down menu before proceeding. Performing a GET request on a group object fails.

Query an Object

You can query a MIB object in the MIB database. You can perform a query to search for a single instance of an accessible MIB object. You can also perform a query to repeatedly request multiple instances of a MIB object. But the objects that are returned must have an OID that is prefixed by the OID of the branch where you run the query.

Follow these steps:

1. Establish contact with the device to query.
2. Navigate to the group object or leaf that you want to query.
3. In the Hierarchy tree table toolbar, click the GET icon  .

   NOTE
   The GET button is available after you select a readable object in the Hierarchy tree table.

   One of the following things occurs:
   - If a scalar leaf object is selected, the GET request is performed.
   - If a table leaf object is selected, the SNMP GET dialog opens.
4. To retrieve a particular instance of the table object, specify an instance identifier and click OK.

   NOTE
   If the device contains multiple instances of the MIB object, enter the value of the instance to query in the Instance field.

   If the query is successful, the result appears in the Results table.
   If the query fails, an error message appears, indicating the reason for the failure.

If no results appear in the Results table, the object is not supported by the device, the object is not accessible, or the device is unreachable.

Set an Object

You can set the value of a MIB object on a network device. The MIB objects that you modify must have write access, such as read/write. View the access value for MIB objects in the Hierarchy tree table Access column.

Follow these steps:

1. Establish contact with the device on which you want to set the value of the MIB object.
2. Navigate to the MIB object that you want to modify.
3. In the Hierarchy tree table toolbar, click the SNMP SET icon 
   The 'MIB Tools: SNMP Set' dialog opens.
4. Take the following steps:
   - Verify that the correct MIB object is selected in the dialog. Or for a MIB object that is not in the MIB Tools database, enter the OID for the object that you want to modify.
   - Enter the Instance of the object that you want to modify.
   - Enter the new Value for the object instance.

   NOTE
   Depending on the object type, you can often select a value from a list in the 'MIB Tools: SNMP Set' dialog.
5. Click OK.
   A dialog opens, indicating whether the SET action was successful. If the action was unsuccessful, a reason is provided.

If the SET action fails, use the following checklist for troubleshooting:

1. Verify that the device is reachable. Try to contact the device from the Contact Criteria section of the Browse tab.
2. If you can contact the device, verify that you can perform a GET action on the device for the MIB object.
3. Verify that the MIB object has read/write access by checking the value for the Access parameter in the Hierarchy tree table.

   NOTE
   If the MIB is not part of the MIB Tools database, use the MIB itself to verify that the MIB object has read/write access.
4. Finally, verify that the SNMP community string in the Contact Criteria is the correct one for writing to the device. You can verify the community string value in the DX NetOps Spectrum Modeling Information subview in the OneClick Component Detail panel.

Device Query and SET Results

The Results section of the Browse tab displays the results of SNMP GET_NEXT, GET, and SET requests in a table.

The available columns include the following:

- **Name**
  Displays the name of the MIB object queried.
- **Instance**
  Displays the instance of the object queried.
- **Type**
  Displays the object type, such as Integer, Counter, IP Address, Octet String, Gauge, Time Ticks, and so on.
- **Value**

Displays the value of the MIB object read from the device.

- **Object ID**
  Displays the Object ID of the object.
- **Access**
  (Hidden by default) Displays the access type for the object. The access type can be read-only, read/write, read-create, or not-accessible.

NOTE
For more information about setting table preferences, see the Using OneClick section.

The Results toolbar provides the following functionality:

Button	Description
	
	**SNMP GET button:** Retrieves the value of the selected MIB object on a specific device. Take this step after a SET action because the values in the Results table are not automatically updated.
	**SNMP SET button:** Sets the value of the selected MIB object on a specific device. Available only for objects that have read/write access. Take this step after a SET action because the values in the Results table are not automatically updated.
	**Clear button:** Clears the contents of the Results table.
	
Auto Clear	**Auto Clear check box:** Clears the contents of the Results table each time you query a device. To view sequential SNMP queries, clear this check box.
Filter	**Filter text box:** Filters the Results table. Only results that contain the text string that you supplied as a filter appear in the table.

Export Query Results To Support Troubleshooting

To aid in troubleshooting a problem, CA Technical Support sometimes asks you to provide a .sim file. Exported from MIB Tools, this file contains information to build a simulation of your device. You can use a query to obtain a detailed SNMP snapshot of your device to provide to CA Technical Support.

Follow these steps:

1. Perform a query on the device for which you require support (typically from the ‘internet’ branch).
2. In the Results table toolbar, click the Export
   icon 
   The ‘Export table data to file’ dialog opens.
3. Select Simulation (*.sim) from the 'Save as type' list.

   NOTE
   We recommend using the name of the device in the filename for easier recognition.
4. Save the file to your local file system.

The query results are exported.

Custom Vendor Folders

Create Custom Vendor Folders

You can create custom vendor folders to organize your compiled MIBs. You can edit these folders to change their names and can also delete these folders.

Note: A star icon indicates custom vendor folders. You can only modify or delete custom vendor folders, not the predefined vendor folders.

Follow these steps:

1. In MIB Tools, click

   (Creates a new folder) in the Navigation panel.
   The 'MIB Tools: Create Vendor' dialog opens.
2. Enter a name for the vendor folder you want to create and click OK.
   The new folder appears in alphabetical order in the Navigation panel.

Edit Custom Vendor Folders

You can change the name of custom vendor folders.

Note: A star icon indicates custom vendor folders. You can only modify or delete custom vendor folders, not the predefined vendor folders.

To edit a custom vendor folder

1. In MIB Tools, select a custom vendor folder in the Navigation panel and click

   (Edit Folder).

   NOTE
   The 'MIB Tools: Edit Vendor' dialog opens.
2. Edit the name of the folder and click OK.

   NOTE
   The name of the folder is changed.

Delete Custom Vendor Folders

You can delete the custom vendor folders that you created.

Note: A star icon indicates custom vendor folders. You can only modify or delete custom vendor folders, not the predefined vendor folders.

Follow these steps:

1. In the MIB Tools utility, select a custom vendor folder in the Navigation panel and click
   
   (Delete Folder).
   A confirmation dialog opens.
2. Click Yes to confirm the deletion.
   The custom vendor folder is deleted.

   NOTE
   Any MIBs that were in the deleted folder are automatically moved back to their original predefined vendor folders.

Move MIBs to Custom Vendor Folders

You can move a MIB from a predefined vendor folder to a custom vendor folder. You can also move a MIB from a custom vendor folder back to its default folder.

Follow these steps:

1. In MIB Tools, expand the folder where the MIB you want to move exists, select the MIB, and then click
   
   (Move MIB).
   The 'MIB Tools: Move Selected MIB' dialog opens.
2. Select the custom vendor folder where you want to move the MIB, and click OK.
   The MIB appears in the custom vendor folder in the Navigation panel.
3. (Optional) Move the MIB back to its predefined folder.
4. Expand the custom folder, select the MIB, and click Move MIB.
   The 'MIB Tools: Move Selected MIB' dialog opens.
5. Select the predefined vendor folder where the MIB was originally stored and click OK.
   If you select multiple MIBs to move, an [ORIGINAL VENDOR FOLDER] option appears. Click this option to move multiple MIBs to their respective default vendor folders.
   The MIB reappears in the predefined vendor folder in the Navigation panel.

Contact a Device Using MIB Tools

You can contact a device using MIB Tools. The utility lets you specify parameters for the SNMP query that is sent. SNMP security information information is required.

Follow these steps:

1. Open MIB Tools and click the Browse tab.
2. Complete the following fields in the Contact Criteria section:
   - **Device**
     Specifies the IPv4 or IPv6 address or the hostname for the device.

     NOTE
     Check the Device list to see the last ten devices that were successfully contacted.
   - **Version**
     Specifies the version of SNMP you want to use.
   - **SNMP v3 Profile**

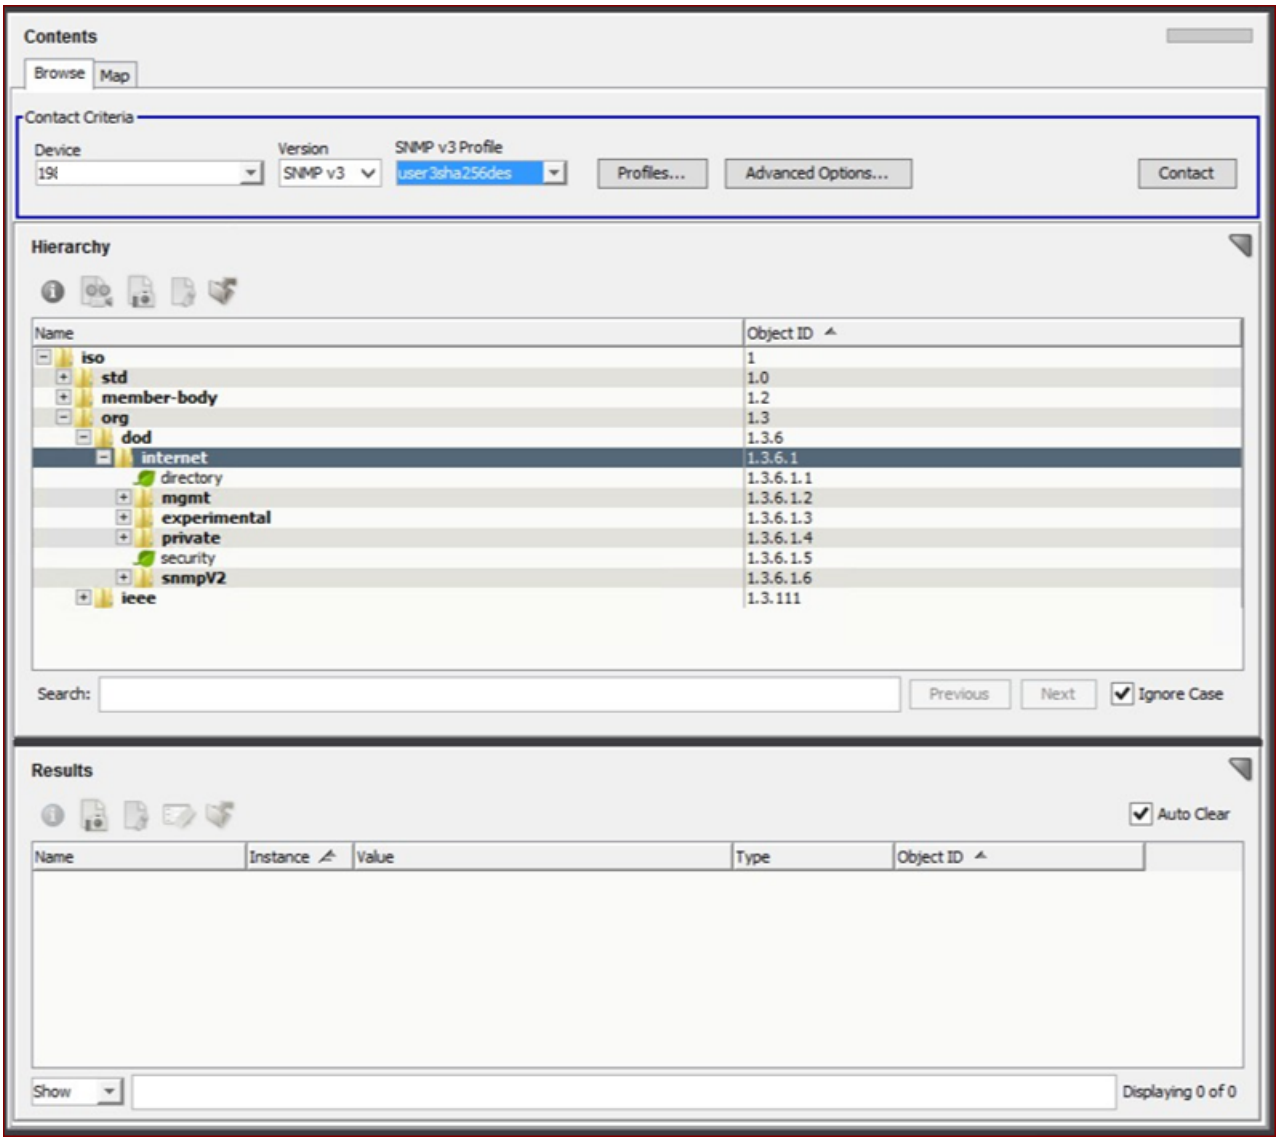
If you are using SNMPv3, select the profile required to contact the device from the SNMP v3 Profile drop-down. If you want to create a profile, click the Profiles button.

NOTE
In 10.4.2, the SNMPv3 profile creation supports SHA-256 and SHA-512 as authentication protocols. Therefore, you can now select those profiles, too.

- **SNMP Community String**
  Specifies the SNMP community string used to access the device.

3. (Optional) If you are using Secure Domain Connector, or if you want to change any of the default values for SNMP to use in contacting the device, click Advanced Options and complete the following fields:
   - **Landscape**
     Specifies the landscape from which the SNMP request should be initiated, if you have a Distributed SpectroSERVER (DSS) environment.
   - **Secure Domain**
     Specifies the secure domain to which the SNMP request should be forwarded, if you have the Secure Domain Manager add-on application installed with secure domains configured.
   - **Port**
     Specifies the value of the UDP port to contact the device on.
     Default: 161
   - **Retry Count**
     Specifies the number of times to retry contacting the device before MIB Tools stops attempting to contact the device.
     Default: 3
   - **Timeout (ms)**
     Specifies the amount of time, in milliseconds, to wait before trying to contact the device again.
     Default: 3000
4. Click Contact to initiate contact with the device.
   The color of the line surrounding the Contact Criteria section indicates the status of contact with the device. The following defines the contact status indicator colors.
   - **Blue:** Contact with the device has not been initiated.
   - **Yellow:** Contact with the device is in progress.
   - **Green:** Contact with the device was successful.
   - **Red:** Contact with the device was unsuccessful.

The following screenshot shows the required information:



Search for a MIB

You can search for MIBs in the Navigation panel of the MIB Tools utility.

Follow these steps:

1. Enter a text string in the Search field in the Navigation panel.

   NOTE
   Wildcards are not supported.
2. (Optional) Select the Ignore Case check box to make the search case-insensitive.
3. Press Enter to search.
   The Next and Previous buttons let you scroll through each successive instance of the search string.
   When a match is found, it is highlighted in the Navigation panel. The Contents panel is populated with the information about the selected MIB.

Trap Support for MIB Objects

The MIB Tools utility lets you create custom traps and modify traps. You can create trap support for MIB objects that are not currently supported by DX NetOps Spectrum. The first step is importing the MIBs.

You can also create support for traps that are defined in the MIBs that you have imported. And you can customize traps for the MIBs that you have imported into the MIB Tools database. Finally, you can add custom trap support for new devices that are not yet supported in DX NetOps Spectrum.

Custom Trap Support File Details

When you map traps using MIB Tools, entries are generated in the following files on all SpectroSERVERs in your DSS environment:

```
<$SPECROOT>/custom/Events/EventDisp
<$SPECROOT>/custom/Events/AlertMap
```

The mapping information for a trap in these files overrides any previous mapping information for that trap in other SpectroSERVER files or directories. And when you map traps, files are generated in the following directories on the OneClick server to which you are connected:

- *<$SPECROOT>*/custom/Events/CsEvFormat -- An Event Format file applies to each DX NetOps Spectrum event. These files define the event text that appears in the OneClick Alarm and Event lists.
- *<$SPECROOT>*/custom/Events/CsPCause -- A Probable Cause file defines the text for each DX NetOps Spectrum alarm that appears in the OneClick Alarm Details view. Select an Alarm Severity level when you map a trap to enable Probable Cause.
- *<$SPECROOT>*/custom/Events/CsEvFormat/EventTable -- An Event Table file determines each varbind sent with a trap that includes enumerated definitions in the MIB.

Manually copy these directories from your primary OneClick server to other OneClick servers in a multiple OneClick server environment.

If you use the CLI commands 'show alarms' or 'show events', or if you deploy DX NetOps Spectrum Alarm Notification Manager (SANM), copy the contents of these directories to all SpectroSERVERs in *<$SPECROOT>*/SG-Support.

> **NOTE**
> The Getting Started section and the Event Configuration section provide information about DX NetOps Spectrum alarm and event support files.

Create Trap Support

You can add support for MIB objects that DX NetOps Spectrum does not currently support by creating trap support. The MIBs must have already been imported into the MIB Tools database.

You can create support in DX NetOps Spectrum for traps that are defined in MIBs and are imported into the MIB Tools database. You can add custom trap support for new devices that are not supported in DX NetOps Spectrum. Or you can change the way that a trap is supported.

In a fault-tolerant SpectroSERVER environment, MIB Tools does not map traps on a secondary SpectroSERVER when the primary SpectroSERVER is down. If you have multiple primary SpectroSERVERs, then at least one of your primary SpectroSERVERs can be available to create trap support.

Follow these steps:

1. Select Tools, Utilities, and MIB Tools from the OneClick main menu.
2. Select MIB in the Navigation panel.

A list of traps for each MIB appears in the Trap Support table. TheMap Traps icon is only enabled if some traps lack DX NetOps Spectrum support.

NOTE
Use multiselect to select specific traps. Support is created only for the traps you select.

WARNING
Any traps with partial support appear in the Trap Support table with Partial in the Event Code column. To create global trap support for these traps, remap these traps before continuing. For more information, see the Modeling and Managing Your IT Infrastructure section.

3. Click the Map Traps icon  .
   The MIB Tools: Assign Trap Alarms dialog opens.
4. Click set in the Alarm Severity column to select the severity for the alarm that DX NetOps Spectrum generates when it receives the trap.
5. Click OK to map the traps on all SpectroSERVERs.
   The MIB Tools: Trap Support Results dialog displays the status of the Map Traps action. When the action completes, the results list the number of traps that were created for each landscape.
   You can use Show Advanced Options when mapping traps to DX NetOps Spectrum events. For more information, see Show Advanced Options for Mapping Traps.
6. Click Close.
   The Trap Support table shows the event code for each trap. The new events are now available for use by all model types in the DX NetOps Spectrum modeling catalog.
   DX NetOps Spectrum processes the trap accordingly.

Review Custom Trap Mapping Information

You can use MIB Tools to determine whether a trap has a default mapping, a custom mapping, or both.

Follow these steps:

1. In MIB Tools, select the MIB in the Navigation panel whose trap support you want to verify. Click the Map tab.
   The list of traps for the MIB appears in the Trap Support table.
2. Right-click the Trap Support table column header.
   The Table Preferences dialog opens.
3. In the Columns tab, select the Event Type check box, and click OK.
   The Event Type column is added to the Trap Support table.
   Default mappings have 'CA' in the Event Type column.
   Custom mappings have 'Custom' in the Event Type column. If a custom trap mapping is obscuring, or shadowing, a default trap mapping, the Event Type column displays a ‘Custom’ hyperlink.
4. Click the ‘Custom’ link.
   The MIB Tools: Custom Trap Mapping Details dialog opens.
5. Review the Custom Disposition Details and the CA Disposition Details for the trap to determine whether to Remove Custom Trap Mappings.
6. Click Close.
   The dialog closes.

Remove Custom Trap Mappings

You can remove custom mappings from traps in MIB Tools.

Follow these steps:

1. In MIB Tools, select the MIB in the Navigation panel whose custom trap support you want to remove. Click the Map tab.
   The list of traps for the MIB appears in the Trap Support table.
   The Remove Traps button is available if at least one item with a custom mapping is selected.
2. Click the Remove Traps
   icon 
   The MIB Tools: Delete Trap Mappings dialog opens.
3. Click OK to confirm the removal of this custom mapping.
   The MIB Tools: Trap Support Results dialog shows the status of the Remove Traps action.
   The results show the number of traps that were removed for each landscape.
4. Click Close.
   If no default mapping exists, the Trap Support table shows a blank entry in the Event Code column. However, if the custom mapping was shadowing a default mapping, the event code of the default mapping is displayed.

Remove Partial Mappings From Traps

You can identify when a trap is only supported on select model types in the DX NetOps Spectrum modeling catalog. You can also change trap support to include all model types.

When a trap is globally supported in DX NetOps Spectrum, it is available for use by all model types. The event code value for a globally supported trap appears in the Event Code column in the Trap Support table.

When a trap is partially supported in DX NetOps Spectrum, it is available for use by certain model types only. The event code value for a partially supported trap appears in the Event Code column in the Trap Support table as ‘Partial.’

We recommend not modifying partially supported traps. However, you can remap a trap to make it globally supported in DX NetOps Spectrum.

> **WARNING**
> If you remap a trap, you can disable useful DX NetOps Spectrum functionality. Proceed with caution.

To change partial trap support to global trap support, remove the partial mapping and then remap the trap.

Follow these steps:

1. In MIB Tools, click the Map tab.
2. Click ‘Partial’ in the Event Code column of the Trap Support table for the trap you want to remap.
   The ‘MIB Tools: Partial Trap Support’ dialog opens, displaying the trap event code, the landscapes it is available on, the MIB object name, and the object ID.
3. Click Remap.
   The ‘MIB Tools: Confirm Remap’ dialog opens.
4. Click Yes to continue remapping the trap.
   The remapped trap appears in the Trap Support table with the previous partial mapping removed; there is no event code value and ‘Partial’ no longer appears in the Event Code column.
5. (Optional)Remap these traps globally.
   The partial mapping is removed.

To remove a partial mapping from all traps in a MIB, select the Remap All Conflicts check box.

Follow these steps:

1. In MIB Tools, select the MIB that contains the traps whose partial support you want to remove in the Navigation panel. Click the Map tab.
   The traps with partial support appear in the Trap Support table.

2. Select the Remap All Conflicts check box.
   All partial trap support is removed for the traps.
3. Verify that the traps lack an event code and that 'Partial' no longer appears in the Event Code column.
   The previous partial mapping is now removed.
4. (Optional) Remap these traps globally.
   The partial mapping is removed.

Show Advanced Options for Mapping Traps

You can use Show Advanced Options when mapping traps to DX NetOps Spectrum events. This option lets you select the event codes to assign to new trap mappings. You can also export the events and alarms to a specific directory.

Follow these steps:

1. Select Tools, Utilities, and MIB Tools from the OneClick main menu.
2. Select MIB in the Navigation panel.
   A list of traps for each MIB appears in the Trap Support table. TheMap Traps icon is only enabled if some traps lack DX NetOps Spectrum support.

   NOTE
   Use multiselect to select specific traps. Support is created only for the traps you select.

   WARNING
   Any traps with partial support appear in the Trap Support table with Partial in the Event Code column. To create global trap support for these traps, remap these traps before continuing. For more information, see the Modeling Your IT Infrastructure section.
3. Click the Map Traps icon 
   The MIB Tools: Assign Trap Alarms dialog opens.
4. Click Show Advanced Options.
   The following advanced options are available in MIB Tools:
   - **Starting Event Code**
     Lets you specify the first code to use for events.
     By default, DX NetOps Spectrum automatically calculates and assigns event codes for new trap mappings. A read-only event code appears in the Starting Event Code field and in the selected Use Default check box.
     However, you can specify a starting event code to assign to new trap mappings. Clear the Use Default check box to enable the Starting Event Code text box. DX NetOps Spectrum then automatically calculates and assigns the event codes that are based on the new starting event code.

     NOTE
     Select a unique starting event code.
   - **Install Trap Support**
     Installs the event and alarm support files in the DX NetOps Spectrum installation area, providing immediate support for the new trap mappings.
   - **Export Trap Support**
     Lets you specify the directory where the event and alarm support files are exported. Selecting this option does *not* provide support for the new trap mappings in DX NetOps Spectrum.

MIB Tools Support for Multiple SpectroSERVERs

The MIB Tools utility offers the following features to supports a Distributed SpectroSERVER (DSS) environment:

Offline SpectroSERVERs: MIB Tools can recognize that a SpectroSERVER is offline while attempting to create Event Codes and Attribute IDs for MIB objects. You receive a notification.

- **Incomplete Trap and Attribute Support:** MIB Tools can identify situations where MIB objects are supported on some, but not all, SpectroSERVERs.
- **Resolve Incomplete Support:** MIB Tools can resolve incomplete trap support.
- **Conflicting Support:** MIB Tools can identify MIB objects that have conflicting Event Code or Attribute ID mappings on multiple SpectroSERVERs.
- **Resolve Trap Conflicts:** MIB Tools can resolve trap disposition conflicts.

MIB Tools Synchronization in a DSS Environment

Use the following guidelines to maintain synchronization among SpectroSERVERs in a DSS setup:

- Do not create attribute or trap support if any of the SpectroSERVERs are down. A warning dialog appears in this situation.
- Always create consistent support for attributes and traps on all SpectroSERVERs.
- Always resolve trap disposition conflicts when they appear.

Attribute Conflicts

When inconsistent support for an attribute occurs in a DSS environment, an attribute conflict condition exists. Usually, this results when an attribute is mapped to different attribute IDs on one or more SpectroSERVERs.

The Attribute ID value for the attribute in the Attribute Support table indicates that a conflict has been detected. To see the landscape and the attribute ID for the attribute, click the 'Conflict' link in the table. At least one SpectroSERVER has a different attribute ID, or no attribute ID, for the attribute in conflict situations.

To resolve attribute conflicts, synchronize the modeling catalogs on your SpectroSERVERs.

NOTE
For more information, see the Distributed SpectroSERVER Administration section.

Create Consistent Support Across a DSS Environment

When a trap or attribute is supported on some, but not all, SpectroSERVERs in a DSS environment, the value 'Some' in the Landscapes column. Click the 'Some' link to see the mapping of the attribute ID or event code to a landscape for a MIB object. Landscapes where the selected MIB object is not mapped lack a value.

Create consistent support across your DSS environment for traps and attributes that are supported on some of your SpectroSERVERs. Remap the traps and recreate the attributes once all SpectroSERVERs are running.

You can create consistent attribute support and consistent trap support across a DSS environment.

Follow these steps:

1. Select the MIB containing the attributes for which you want to create consistent support in the Navigation panel of MIB Tools.
2. Click the Map tab, and verify that attributes appear in the Attribute Support table with the value 'Some' in the Landscapes column.
3. Click Create Attributes 
4. Click OK to confirm.

   The MIB Tools: Attribute Creation Results dialog displays the status and results of the Create Attributes action.
5. Click OK.

The value ‘All’ appears in the Landscapes column for all the attributes.

Follow these steps:

1. In MIB Tools, select the MIB containing the traps for which you want to create consistent support in the Navigation panel.
2. Click the Map tab and verify that traps appear in the Attribute Support table with the value 'Some' in the Landscapes column.
3. Click Map Traps 
   The MIB Tools: Assign Trap Alarms dialog opens.
4. (Optional) Click set in the Alarm Severity column to select the alarm severity for the alarm that DX NetOps Spectrum generates when it receives the trap. Or select None if the trap does not generate an alarm.
5. Click OK to map the traps on all SpectroSERVERs.
   The MIB Tools: Trap Support Results dialog shows the status of the Map Traps action. The results list the number of traps that were created for each landscape.
6. Click Close.
   The Trap Support table shows the event code for each trap.

Synchronize and Update MIB Databases and Support Files on Multiple OneClick Servers

When you import MIBs into the MIB Tools database and create trap and attribute support, information is written to each SpectroSERVER in your DSS environment. However, information required by OneClick to support the traps and attributes is written only on the OneClick server to which you are connected.

If you have multiple OneClick servers in your environment, maintain synchronicity among the MIB Tools databases and support files for new attribute and trap support.

You can synchronize and update MIB databases and support files on multiple OneClick servers.

Follow these steps:

1. Designate one of your OneClick servers as the primary server that contains the primary MIB Tools database.
2. Import all MIBs and create attribute and trap support on this primary OneClick server.
3. Distribute the MIB Tools database to other OneClick servers from the primary server.
4. Distribute OneClick support files created for events and alarms from the primary OneClick server to the other OneClick servers.

Trap Disposition Conflicts

When inconsistent support for a trap occurs in a DSS environment, a trap disposition conflict condition exists. Inconsistent trap support includes the following situations:

- A trap is mapped to different event codes on one or more SpectroSERVERs.
- A trap is disposed differently on one or more SpectroSERVERs.
  - For example, a trap is disposed to a minor alarm on one SpectroSERVER, and a major alarm on another.
  - A trap is using an event rule for complex processing, but another instance of the trap is not using that rule.

When a trap disposition conflict exists, the Event Code value for that trap in the Trap Support table reads ‘Conflict.

Resolve Trap Disposition Conflicts Remap the Trap

You can resolve a trap disposition conflict by remapping the trap on all SpectroSERVERs in your DSS environment. Resolving trap disposition conflicts creates consistent support for the trap on all SpectroSERVERs. Each SpectroSERVER in your DSS environment must be running to resolve a trap disposition conflict.

Follow these steps:

1. In MIB Tools, click the Map tab and locate the trap in conflict in the Trap Support table.
2. Take one of the following steps:
   - For multiple trap disposition conflicts, select Remap All Conflicts.
   - For a single trap, click Conflict in the Event Code column.
     The Trap Disposition Conflict dialog lists each landscape and the event code for the trap.
     Click Remap, and then click Yes to confirm.
     The trap now has a value of 'Some' or 'None' in the Landscape column of the Trap Support table.
3. Click
   
   (Map Traps) to create an event code for the trap on all SpectroSERVERs in the DSS environment.
   The traps are remapped.

Resolve Trap Disposition Conflicts Edit the AlertMap and EventDisp Files

You can resolve a trap disposition conflict by editing the AlertMap and EventDisp files for the trap. Such conflicts occur in a DSS environment when, for example, a trap is mapped to different event codes on one or more SpectroSERVERs.

Follow these steps:

1. In MIB Tools, click the Map tab and locate the trap in conflict in the Trap Support table.
2. Click Conflict in the Event Code column.
   The Trap Disposition Conflict dialog lists each landscape and the event code for the trap.
3. Locate the desired mapping by reviewing the Event details.
4. Synchronize the conflicting events on the other SpectroSERVERs in your DSS environment by editing the appropriate EventDisp file and AlertMap file with a text editor.

   NOTE
   The AlertMap files and EventDisp files are located in the <*$SPECROOT*>/SS/CsVendor directory.
5. Issue a command on each SpectroSERVER to reload its events and alerts.
   For more information, see the Event Configuration section.

Troubleshooting for Trap Mappings missing in MIB Tools

Symptom:

Trap mappings missing after compiling NGD_G42.MIB file in Spectrum MIB Tools.Trap mappings missing after compiling NGD_G42.MIB file in Spectrum MIB Tools. Specifically the trap mappings for the dpsRTUp8177nSet, dpsRTUp8180nSet and dpsRTUp8183nSet traps. The NGD_G42.MIB file has the following NOTIFICATION-TYPE configuration for these traps:

```
dpsRTUp8177nSet NOTIFICATION-TYPE

                OBJECTS { sysDescr, sysLocation, dpsRTUDateTime,
```

```
                                                                dpsRTUAPort,
 dpsRTUCAddress, dpsRTUADisplay, dpsRTUAPoint,
                                                                dpsRTUAPntDesc,
 dpsRTUAState }
                STATUS current
                DESCRIPTION "Granular point 8177 is set."
                ::= { dpsRTU 8177 }

dpsRTUp8180nSet NOTIFICATION-TYPE
                OBJECTS { sysDescr, sysLocation, dpsRTUDateTime,
                                                                dpsRTUAPort,
 dpsRTUCAddress, dpsRTUADisplay, dpsRTUAPoint,
                                                                dpsRTUAPntDesc,
 dpsRTUAState }
                STATUS current
                DESCRIPTION "Granular point 8180 is set."
                ::= { dpsRTU 8180 }

dpsRTUp8183nSet NOTIFICATION-TYPE
                OBJECTS { sysDescr, sysLocation, dpsRTUDateTime,
                                                                dpsRTUAPort,
 dpsRTUCAddress, dpsRTUADisplay, dpsRTUAPoint,
                                                                dpsRTUAPntDesc,
 dpsRTUAState }
                STATUS current
                DESCRIPTION "Granular point 8183 is set."
```

```
                ::= { dpsRTU 8183 }
```

Cause:

The NGD_G42.MIB file contains a NOTIFICATION-TYPE configuration for these traps but does not contain a TRAP-TYPE configuration for these traps.

Resolution:

Follow the steps:

1. Edit the NGD_G42.MIB file
2. Add the TRAP-TYPE configurations for the dpsRTUp8177nSet, dpsRTUp8180nSet and dpsRTUp8183nSet traps. The following is an example for the dpsRTUp8177nSet trap:

```
dpsRTUp8177Set TRAP-TYPE

        ENTERPRISE  dpsRTU

        VARIABLES {     sysDescr, sysLocation, dpsRTUDateTime,

                                    dpsRTUAPort, dpsRTUCAddress, dpsRTUADisplay,
 dpsRTUAPoint,

                                    dpsRTUAPntDesc, dpsRTUAState }

        DESCRIPTION "Generated when discrete point 177 is set."

        ::=  8177
```

Fetch MIBs Information of a Device Using a Script

10.3 introduces a new script (Monitoring_Profile.pl) to fetch MIBs information of a selected device. A user can use this script to fetch the following information of a device:

- List of MIBs
- Trap details
- Pollable Attributes
- Events and Alarms information of a device

Running the Monitoring Script

Following is the procedure to run the Monitoring Profile Script:

Prerequisites:

Following are the prerequisites to run the Monitoring_Profile.pl script:

1. Ensure you log in the SpectroSERVER as one of the DX NetOps Spectrum users. A user should be present in the DX NetOps Spectrum users list to run LogPollAnalyzer.exe , which fetches the attributes list. If the user should be present in the DX NetOps Spectrum users list for the LogPollAnalyzer.exe to work.
2. Ensure that the Tomcat Server and the SpectroSERVER are up and running.

To run the script, follow these steps:

1. Navigate to $SPECROOT/Install-Tools/PostInstall/ directory
2. Open a bash shell and run the following script for a model handle of a device.

   ```
   ./Monitoring_Profile.pl <device model handle> <OneClick host name> <port>
   ```

   Script prompts for the user name and password of OneClick.
   The script contacts vnmsh directory to fetch the MIBs information.
3. If you have the SSL option, select 'Yes' to enable the https support.

   NOTE

   Now fetch MIB information using scripts with HTTPs support with the new Spectrum 10.3.1 release.
4. The script generates following files in the $SPECROOT\SS-Tools folder.
   a. trap_details_<model handle>.csv - lists MIBs and corresponding Traps, Trap OID, Event Code, Alarm Severity, Alarm Name, and Alarm PCause Code details.
   b. pollable_attributes_<model handle>.csv - lists the attributes which are being polled the selected device.

      NOTE

      The attributes to be polled are fetched from the existing feature LogPollAnalyzer.exe.

Enhancement Support for Monitoring Profile in Spectrum 10.3.1

10.3.1 introduces enhancements to support the Monitoring Profile features present in the previous release. These enhancements include:

1. MIB Description, Dynamic Alarm Titles, Event Text, and Event Procedures: A REST API fetches the trap information of a MIB such as the MIB name and the landscape handle is passed as parameters such as the Alarm Titles, Event Text and Event Procedures.

2. Custom AlertMaps: An action code supports the custom AlertMaps that dumps all the custom OIDs, event code and the pcause code.
3. Support for all MIBs

Known Issues

- Conditional alarms are not listed in the output files.
  For example: The script supports only the EventDisp strings in the format like 0x01165306 E 50 A 2,0x01165305
  The script does not support EventDisp strings like 0x0116912a E 20 A { v 4 Ctron_Gen_HOST.alertCurrentStatus },0x0116912a

Developing a New Certification

This section describes various concepts and operations to develop a new or customized certification for your device for managing it properly.

New Certification Management

To model a device, DX NetOps Spectrum uses a device model type and its associated interface and application model types. You can add device model types or you can enhance the functionality of the GnSNMPDev device model type. To enhance device management with DX NetOps Spectrum, a solid understanding of the functional components of a device is required.

The GnSNMPDev device model type and the interface and application models that are known to the GnSNMPDev model type support many device functions. Supported functions comprise both proprietary and standard MIBs. Identify the functionality of the device that GnSNMPDev already supports. For example, if device interfaces map one-to-one with physical ports on a single board, GnSNMPDev supports this device without enhancement. GnSNMPDev includes native support for MIB-II interfaces in the Snmp2_Agent application model.

To test GnSNMPDev device support, use an IP address to model the device in OneClick. DX NetOps Spectrum automatically finds the model type most appropriate for the device. If a specific model type is lacking, DX NetOps Spectrum selects the GnSNMPDev model type and instantiates a GnSNMPDev model to represent the device. You can then evaluate the type of support that DX NetOps Spectrum can provide for your device by default.

Once you have established the default support, consider the required customizations. You can then more easily decide if further customization is necessary to manage your device properly. The following sections outline some scenarios in which expanded support is required.

Additional MIB Support

If device management in your environment requires access to additional MIBs, MIB objects can be made available to a device model. The following methods let you increase access to MIBs:

- (Recommended) Import the new MIB directly into the SpectroSERVER using the import mechanism provided in MIB Tools.
- Create a device model type to represent your device and include the necessary MIBs in the device model type.
- Create an application model type that provides access to the new MIB.

Unique Trap Mapping

Create a device model type if the device that you are modeling requires unique trap processing in response to a common trap. For example, assume that you want core routers to generate a major alarm in response to an authentication failure. However, all other devices generate a minor alarm in response to the same failure.

By default, DX NetOps Spectrum generates a minor alarm in response to an authenticationFailure trap. You can create a device model type, and you can configure support for the trap in the event and alert configuration files for this device model type. This support overrides DX NetOps Spectrum default processing for the authenticationFailure trap for this model type only.

Unique Watches

You can generate events and alarms that are based on the results of a watch. The GnSNMPDev model type provides a number of predefined watches that can be enabled for individual models.

You can customize the watch implementation on the models that represent your device for each applicable GnSNMPDev model. However, you can avoid repeating this customization on each model by creating your own device model type to implement the customized watch.

All of the information that makes up a watch is stored as attributes in the model type specified in the watch. The only exception is the probable cause information that is created for an alarm that results from the watch. This information is stored in the ProbCause model type .

Because you have not created the ProbCause model type with your Developer ID, you lack permission to export and distribute it with your management module. As a result, the probable cause information for the watches that you have created is not distributed. To solve this problem, derive a new model type from the ProbCause model type. The probable cause information for any watches for any of your management modules is automatically stored in this derived model type. Because you have created this derived model type, you can distribute it with your management module.

NOTE
For more information, see the Watches section.

Interface Model Creation

If your device does not advertise interface (port) information in the MIB-II standard interface table but instead uses information from a proprietary MIB, DX NetOps Spectrum cannot model the associated interfaces.

Without interface models, you cannot resolve connections to the interface level, nor can you monitor the status of each interface. To work around this problem, create a new application model type that includes support for the proprietary MIB with the interface information.

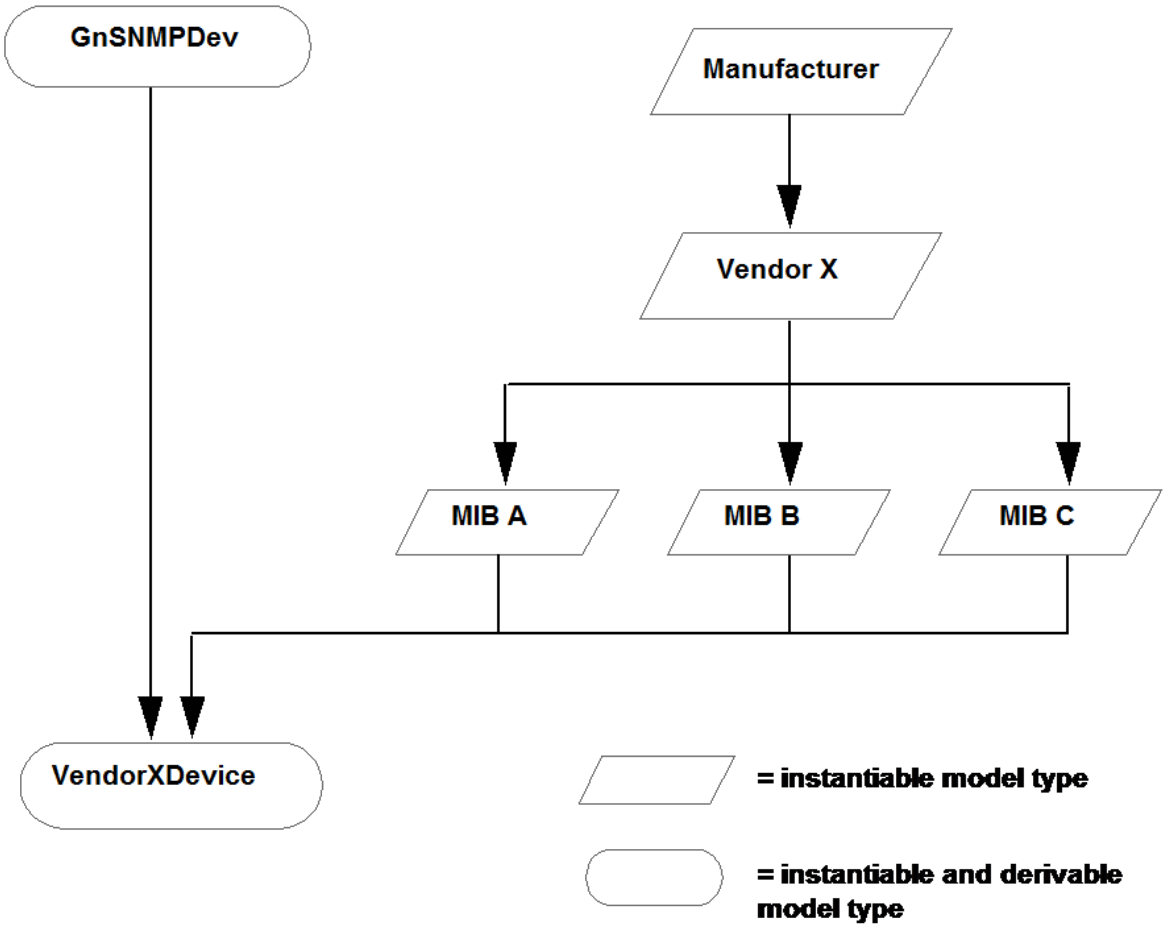
New Device Model Type

DX NetOps Spectrum offers multiple options for creating device model types. The topics in this section describe some of the factors to consider. A new device model type requires some or all of the following tasks:

- Understanding the database derivation and MIB requirements
- Creating the model type and setting required attributes
- Selecting discovery and identification mechanisms
- Making desired customizations
- Making the new model type distributable to other DX NetOps Spectrum hosts

New Device Model Type Design

The device model type database architecture for developing new device model types organizes all of the proprietary MIBs that you import into separate MIB model types. These MIB model types can then be derived directly into the device model type, as shown in the following diagram:



This scheme has the following advantages:

- A single MIB can be derived into multiple model types. For example, you can use the same MIB to create multiple device model types or a device and an application model type while maintaining the attribute IDs.
- Vendor MIBs can be organized in a single collection.
- Convenient access to MIB information is available directly from the device model. For example, you can access OneClick views, watches, and logging and polling information about proprietary vendor attributes from the device model.

If the new device model requires access to additional MIBs from DX NetOps Spectrum, the simplest method is the MIB import mechanism that is available in MIB Tools. This mechanism creates attributes from these objects and makes them available to all models that represent a device in the SpectroSERVER database.

NOTE
For more information, see the Device Management Reference section. The MIB import mechanism distributes the new MIB across all SpectroSERVERs in a distributed environment.

New Device Model Type Creation

After selecting a database scheme, use the Model Type Editor to create your model types. Derive all device model types from the GnSNMPDev model type.

Note: For more information, see the Model Type Editor section.

NOTE
When you are using the Model Type Editor to create a device model type, remember to set the model type flags correctly for the new model type.

New Device Model Type Configuration

A few steps are involved in configuring a new device model type. Complete the following tasks:

- Set model type flags
- Set attribute values
- Map a device or a device family to the new device model type
- Configure serial number handling

The following sections provide high-level information about these configuration steps.

For more information, see the Model Type Editor section.

Model Type Flags Setting

Set the values of model type flags so that models of the new model type behave as expected. Each flag represents a Boolean value and can either be selected (set to TRUE) or not (set to FALSE).

In most cases, you set the Visible, Instantiable, and Derivable flags to TRUE.

- **Visible flag**
  Makes the model type visible to all Model Type Editor users. If set to FALSE, the model type is only visible to a user with the same Developer ID as the one used to create the model type.
- **Instantiable flag**
  Lets you instantiate a model of this model type in OneClick.
- **Derivable flag**
  Lets this model type be used as a base for other model types.

In most cases you should set the No Destroy, Unique, and Required flags to FALSE.

- **No Destroy flag**
  If set to TRUE, prevents users from destroying a model of this type in OneClick.
- **Unique flag**
  If set to TRUE, only lets one model of this model type be instantiated in OneClick.
- **Required flag**
  If set to TRUE, a model of this model type must always exist in the SpectroSERVER database.

Attribute Values Setting

Once you have created your device model type, use the Model Type Editor to set the default value of several attributes. Some of these settings are used to configure built-in capabilities that are inherited by deriving from the GnSNMPDev model type. The following section describes the attributes and settings.

- **CompanyName**
  Is the name of the company that developed the management module.
- **Description**
  Is an attribute that exists in the MMDeveloper group and in the CommonInfo group. The Description attribute in the MMDeveloper group has a default value of Generic SNMP Device Management Module. We recommend resetting this default value to a description of your management module. The Description attribute in the CommonInfo group can be similarly reset or left empty.
- **Desc_Key_Word**

Enables resolution of multiple device model types. If the System_Desc_Verify or Vendor_Object_ID discovery mechanisms identify multiple device model types, a search of sysDescr looks for a substring match for the value of this attribute.

- **DeviceSerialAttr**
  Is the device serial number. Set the value to the attribute ID of the external attribute that contains the serial number. When the model is created, it reads this external attribute and writes it into Serial_Number.
- **DeviceType**
  Identifies the device. A default value is required for this description attribute when the DeviceNameList mechanism is not used for identification. Setting the default value guarantees that a value is present for displaying, sorting, and filtering.
- **DeviceTypeDiscEnable**
  Enables or disables DeviceType naming intelligence. The default value (true) is appropriate for most device model types. However, set this value to false under either of the following conditions:
  – A new device model type has been derived from a base model type other than GnSNMPDev. The new type has specialized DeviceType naming intelligence that is inappropriate for the derived device model type.
  – A more appropriate DeviceType name can be set in the catalog for the derived model type.
- **Disposable_Precedence**
  Is evaluated during device model type discovery when multiple model types are identified as candidates. The higher value is the chosen model type.
  This value is also evaluated when a model is created with the same MAC address as a previously existing model. In this case, the disposable_precedence attributes of both models are evaluated. The model with the higher value replaces the existing model by appropriating its CONNECTs associations.
- **Enable_IH_Enterprise_Disc**
  Enables or disables the automated setting of the Manufacturer and App_Manufacturer attributes based on the enterprise ID term of the device sysObjectID.
  The default value, true, is appropriate for GnSNMPDev because it is used to model devices from various manufacturers. However, for a new device model type that is derived from GnSNMPDev with a known device manufacturer, we recommend setting the value of Enable_IH_Enterprise_Disc to false. With that attribute set to false, set the default values of the Manufacturer and App_Manufacturer attributes to the appropriate names.
- **Manufacturer**
  Is the name of the vendor that manufactures the device.
- **MMName**
  Is the name of the management module.
- **MMPartNumber**
  Is the part number that you plan to assign to the management module.
- **System_Desc_Verify**
  Provides a device model type discovery mechanism that parses the sysDescr for firmware version information. Clear this default value if you are not using this discovery mechanism. It interferes with the other discovery methods if enabled.
- **System_Oid_Verify**
  Is a legacy attribute. Refer to SysOIDVerifyList.
- **SysOIDVerifyList**
  Used in conjunction with DeviceNameList. Populating this list attribute with sysObjectID values enables device model type discovery intelligence to match the list against the device sysObjectID value. If a match is found, this model type is selected as a possible candidate for modeling.
- **Vendor_Name**
  Is the name of the company developing the management module.
- **Vendor_Object_ID**
  Provides a device model type discovery mechanism by which a partial sysObjectID match identifies a device model type.
- **VendorIDVerifyList**

Maps devices to device model types based on whether the device supports specific MIB objects. Used during Discovery with VendorOIDVerifyList.
Specify the list of enterprise IDs to compare against the device to model. If a match is found, the corresponding MIB object specified in VendorOIDVerifyList is read from the device.

- **VendorOIDVerifyList**
  Maps devices to device model types based on whether the device supports specific MIB objects. Used during Discovery with VendorIDVerifyList.
  Specify the list of attribute IDs for the MIB objects to read from the device.
- **Verify_Mismatch_Model**
  Causes DX NetOps Spectrum to perform checks for a device model type match with the device that is modeled. Set this attribute to true.

Device Mapping

Each device on the network requires a unique identifier. Most commonly the MIB-II object sysObjectID provides this unique identifier. Vendors typically assign a unique sysObjectID value for a device, creating a one-to-one mapping. Vendors often advertise this information in a product MIB, where you can find the mapping of sysObjectID to device model type.

You can use the Model Type Editor to identify a device in several ways:

- If your device provides a unique sysObjectID value, use the process described in Map Using Unique sysObjectID Values.
- If your device does not provide a unique sysObjectID but does provide a unique substring within sysDescr, use the process described in Map Using sysObjectID and Strings in sysDesc.
- If your device does not provide a unique sysObjectID but does provide a firmware version text string in sysDescr, use the process described in Map Using Firmware Version Strings in sysDesc.
- If your device does not provide any of the previously described information, you can map the device to a device model type based on whether the device supports specific MIB objects in a proprietary MIB. Refer to Map Using a MIB Object.

Map Using Unique sysObjectID Value

If your device has a unique sysObjectID value, you must relate your new device model type to the sysObjectID to help ensure that DX NetOps Spectrum selects the new device model type to represent the device. To do this, add the sysObjectID value to the SysOIDVerifyList model type attribute. If the new device model type represents a family of devices, then add each sysObjectID value.

> **NOTE**
> If another model type contains the same sysObjectID value in its SysOIDVerifyList attribute, it is possible that DX NetOps Spectrum will choose the other model type to represent a device with this sysObjectID. If this occurs, you should change the disposable_precedence attribute value on your device model type to a higher value than that of the other model type. For example, if the other model type has a disposable_precedence value of 10, change the disposable_precedence value on your model type to 11.

To provide identification to your model, configure the model type to display a different device name for each of the devices that the model type is designed to support. For example, assume your device model type represents the 8480 series of switches made by MySwitch, Inc. Instead of seeing the device name MySwitch_8480XX for all of the switches in the 8480 family, you want to display the model number of the switch, as appropriate. If DX NetOps Spectrum is modeling an 8480-09 switch, the model should display the device name MySwitch_8480-09. If DX NetOps Spectrum is modeling an 06 switch, the model should display the device name MySwitch_8480-06.

Follow these steps:

1. Set the SysOIDVerifyList attribute equal to the sysObjectID(s) of the devices that the model type represents.

2. Set the DeviceNameList attribute equal to the device names that apply to each sysObjectID listed in the SysOIDVerifyList attribute.
3. Specify the same number of names in the DeviceNameList attribute as there are sysObjectIDs listed in the SysOIDVerifyList attribute. List the names in the same order as their corresponding sysObjectIDs.
4. Clear the System_Desc_Verify default value.
   The DeviceNameList attribute only works for device model types that use the SysOIDVerifyList attribute model type discovery mechanism. Verify that both lists have the same number of entries. Otherwise, the DeviceType attribute is not set correctly.

Map Using sysObjectID and Strings in sysDesc

If your device does not provide a unique sysObjectID, a partial or complete match of the sysObjectID in combination with a sysDescr substring can provide unique identification.

You can set up the relevant attributes to enable this functionality on the model type.

Follow these steps:

1. Set the Vendor_Object_ID attribute equal to the partial or complete sysObjectID value returned by your device. Only the first seven terms up to the enterprise ID are used for comparison.
2. Set the Desc_Key_Word attribute equal to the unique, partial sysDescr value returned by your device.
3. Set the DeviceType attribute to be equal to the desired identification string.
4. Clear the System_Desc_Verify default value.

Map Using Firmware Version Strings in sysDesc

If your device does not provide a unique sysObjectID or a unique sub-string within sysDescr, check whether sysDescr provides a unique firmware version. This discovery mechanism searches the sysDescr value for either “Version” or “Revi.” If one of these strings is found, the value of System_Desc_Verify is compared against the text that follows these key words. If a match is found, the device model type is selected. In the case where multiple model types have the same System_Desc_Verify value, a substring in sysDescr can be compared by setting the Desc_Key_Word.

You can set up the relevant attributes to enable this functionality on the model type.

Follow these steps:

1. Set the System_Desc_Verify attribute to be equal to the contents of sysDescr that follow the key text noted above.
2. Set the Desc_Key_Word attribute to be equal to the unique, partial sysDescr value returned by your device.
3. Set the DeviceType attribute to be equal to the desired identification string.

Map Using a MIB Object

If your device does not provide a unique sysObjectID or a unique sub-string or firmware version within sysDescr, check if it supports a proprietary MIB. You can map the device to a device model type based on whether the device supports specific MIB objects.

This discovery mechanism compares the enterprise ID of the device against each enterprise ID specified in the VendorIDVerifyList attribute. If a match is found, the MIB object specified in the same instance of the VendorOIDVerifyList attribute is read from the device. If the SNMP read succeeds, this model type is added to the list of model type candidates (from which the model type with the highest disposable_precedence attribute value is ultimately selected). The enterprise ID match mechanism is implemented for performance reasons: the SNMP read is only initiated for targeted devices.

You can set up the relevant attributes to enable this functionality on the model type.

Follow these steps:

1. Add the enterprise ID of the device to model with this model type to the VendorIDVerifyList attribute.

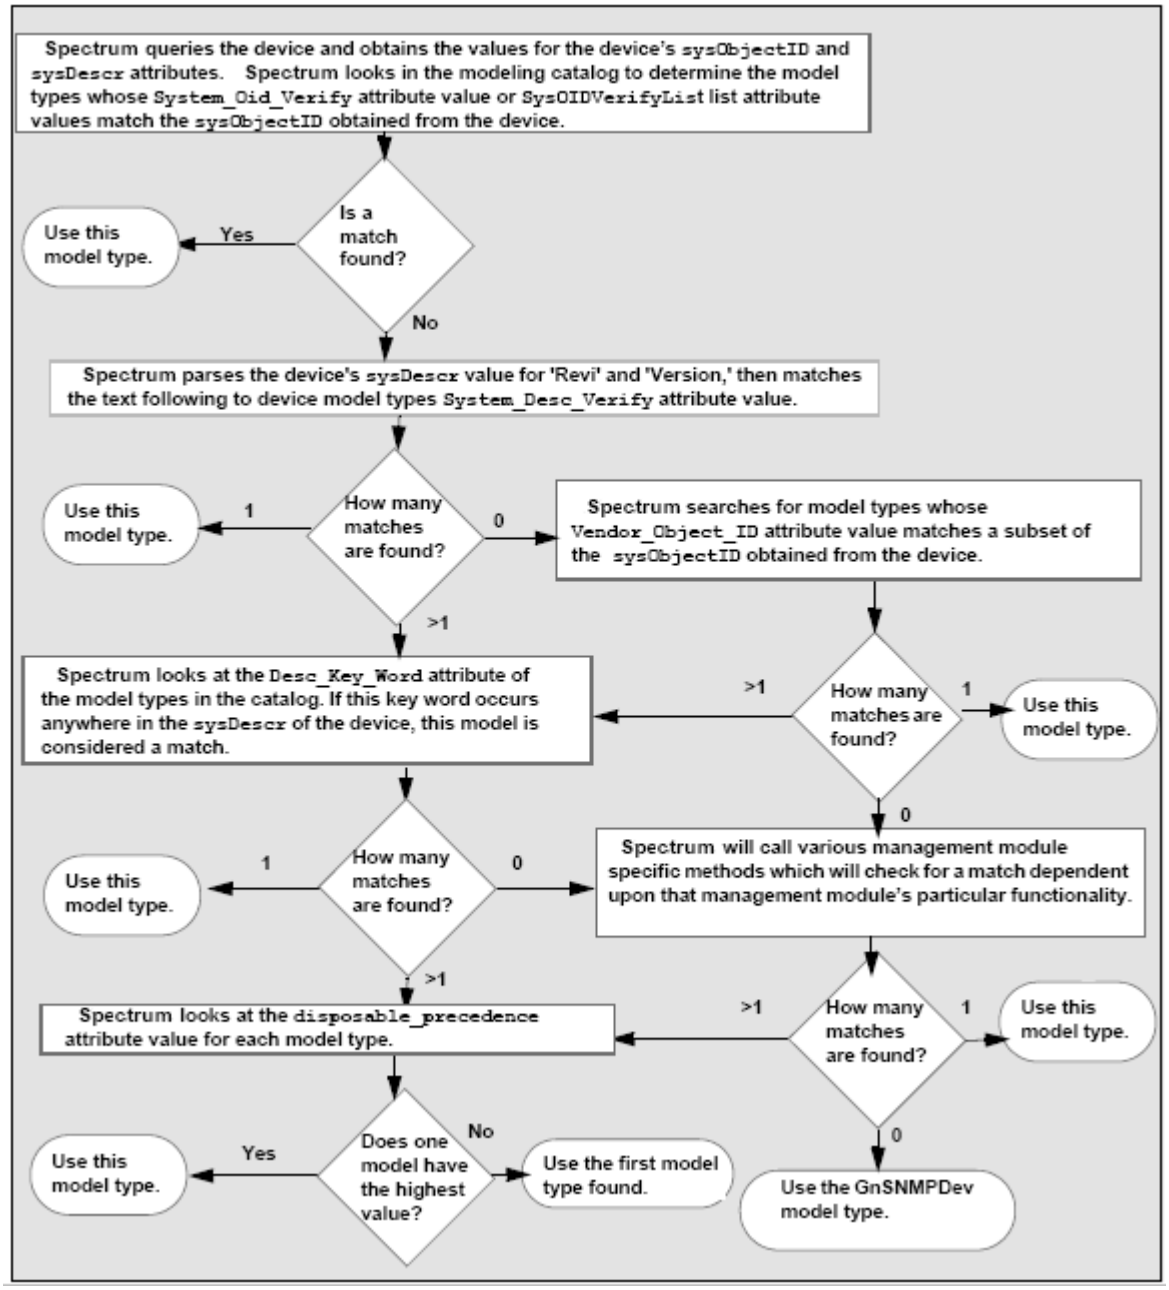
2. Add the attribute ID of the MIB object to read from the device as the corresponding instance in the VendorOIDVerifyList attribute.
3. Repeat the preceding steps for each enterprise ID/attribute ID pair to evaluate in conjunction with one another.
4. Set the DeviceType attribute equal to the desired identification string.

Discovery and Identification Flowchart

This flowchart identifies the steps that DX NetOps Spectrum takes to determine the device model type to represent a device. The flowchart includes discovery and identification mechanisms:

- Using unique values in sysObjectID
- Using strings in sysObjectID and sysDesc
- Using firmware version strings in sysDesc

You can also map a device (or a device family) to a new device model type based on whether the device supports specific MIB objects in a proprietary MIB.



Configure Serial Number Handling

Device model types contain an attribute for setting and displaying the serial number of the modeled device: Serial_Number (0x10030). Enter the appropriate serial number value in any of the views where the attribute is displayed. Or, if the serial number is available as an external device attribute, you can configure the model type to retrieve this value and set the Serial_Number attribute.

Follow these steps:

1. Verify that the external attribute that contains the serial number is not a list attribute and is of type TEXT_STRING or OCTET_STRING.

2. Set the value of the DeviceSerialAttr (0x3d0063) attribute for this device model type in the Model Type Editor. Make this value equal to the ID of the external attribute that contains the serial number.
   When a model of this model type is instantiated, DX NetOps Spectrum sets the Serial_Number attribute so that the value is equal to the value of the external attribute.

Creating a New Application Model Type

This section describes how to expand support for a device using application model types. All application model types are derived from a series of standard model types, called *derivation points*. An Application often corresponds to the functionality of a MIB.

Derivation Points and Model Fragments

Select derivation points and use them as base model types for new application model types. Derivation points have the functionality to support different types of applications. When you derive a new model type from one or more of these derivation points, the model type inherits the derivation point functionality.

Some derivation points require the use of model fragments. The available model fragments are model types with attached inference handlers. These inference handlers provide the model fragments with certain behaviors and intelligence, such as the ability to create port or board models. To use the functionality from these inference handlers, map attribute IDs from the model type that represents the MIB to specific model fragment attribute values.

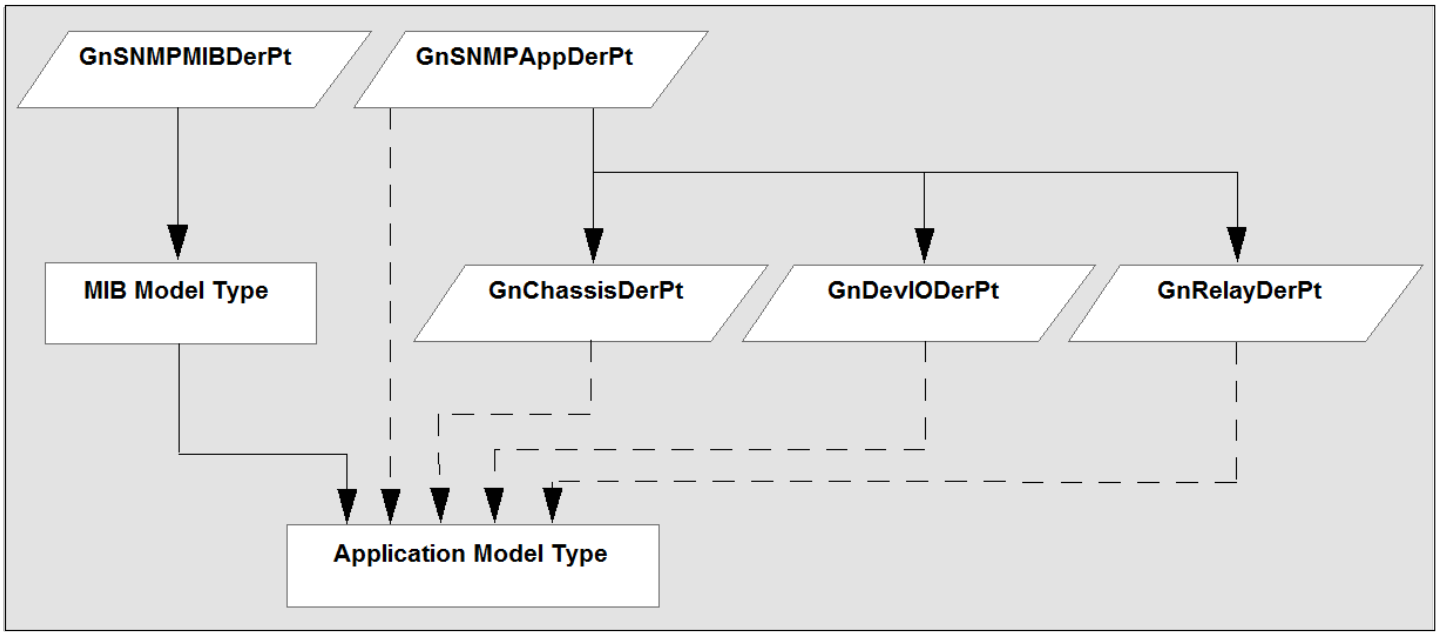
Model fragments are typically included as base model types for the GnSNMPDev derivation points that require them. However, it can be necessary to add a model fragment as a base model type to a new model type to gain the capabilities of the inference handler that is attached to the model fragment.

The following model types can be used as application derivation points:

- GnSNMPMibDerPt
- GnSNMPAppDerPt
- GnChassisDerPt
- GnDevIODerPt
- GnRelayDerPt

The following figure shows the application derivation point hierarchy and sample derived model types. The lines connecting the model types denote the inheritance structure.

NOTE
Select only one of the dotted line paths for the derivation hierarchy of your new application model type.



The derivation points for application model types are all designed to provide specific functionality. The GnChassisDerPt, GnDevIODerPt, and GnRelayDerPt derivation points have model fragments that enhance this functionality. The following table shows each derivation point, the application model type that it creates, and its associated model fragments.

Derivation Point	Model Type	Associated Model Fragment
GnSNMPMibDerPt	MIB Model Type	N/A
GnSNMPAppDerPt	Application model type with no requirement to manage ports or boards.	N/A
GnChassisDerPt	Application model type to model chassis functionality. Provides management for ports and boards.	GnChassis_MF
GnDevIODerPt	Application model type for devices that require port management but not board management (such as switches or terminal servers).	GnDeviceIO_MF
GnRelayDerPt	Application model type for repeater functionality	GnDataRelay_MF

Derivation Point

GnSNMPAppDerPt includes the functionality that is required for an application model type. GnChassisDerPt, GnDevIODerPT, and GnRelayDerPt are derived from GnSNMPAppDerPt and therefore inherit this functionality. Each also includes some specialized functionality for managing ports and boards.

If your device does not manage ports and boards and you are only interested in expanding support, use GnSNMPAppDerPt to derive your application model type.

If your device uses other MIBs to extend the functionality of MIB-II to manage ports and boards, use GnChassisDerPt, GnDevIODerPt, or GnRelayDerPt. Each of these derivation points uses model fragments that contain the attributes and

intelligence to create port models. The topic titled Board and Port Considerations explains how to select an appropriate derivation point for your port or board model type.

Board and Port Considerations

If you are modeling a chassis (a device with multiple modules or boards that can be inserted and removed), create the application model type from the GnChassisDerPt and GnRelayDerPt derivation points. These derivation points are used to model both the boards and ports in the device. The intelligence of these derivation points creates both board and port models.

If the device you are modeling is not a chassis, build your application model type from the GnDevIODerPt derivation point. The intelligence of this derivation point creates only port models (no boards) that are associated with the device model.

The structure and content of the relevant MIBs is important to consider. Chassis and data relay MIBs generally have a standard structure. A chassis MIB usually has a slot and board table. The index of the table represents the slot in the chassis where the board is plugged in.

A data relay MIB usually has two tables: a board table and a port table. The board table is indexed by the slot where the board is plugged in. The port table typically has two indexes: a board index and a port number. And vendors have devised several variations to the standard structures.

Port-Oriented Devices

Use the GnDevIODerPt to model port-oriented, non-chassis devices. Most MIBs for these port-oriented devices conform to the structural requirements to use GnDevIODerPt. The MIB must contain a port table, with at least one index, the port number. The derivation point executes a read_next (which is analogous to the get_next SNMP call) on this attribute. For each successful read of the index attribute, a port model with the appropriate instance ID is instantiated.

Chassis Devices

The structure of the MIBs that are associated with chassis devices is highly varied. We recommend reviewing the requirements of the GnChassisDerPt and the GnRelayDerPt derivation points. You can thus examine the variations and how they affect the modeling of the device.

GnChassisDerPt

The GnChassisDerPt is used to create an application model type that becomes the chassis manager application. This application is responsible for the creation and management of board models in the SpectroSERVER database. This chassis manager relies on three attributes (usually list attributes) for the information it needs:

- slot index
- board type
- board label

A single chassis manager application can be instantiated or managed by the main device model. The chassis manager intelligence expects the MIB to have a slot or board table that is indexed by an integer value. This value represents the slot into which a particular board is plugged. The intelligence performs a read_next on this slot index attribute. For each successful read, the intelligence creates a model in the database to represent that board. Because the intelligence can only reference one index value, all boards in the chassis require an entry in this single table of the chassis MIB.

In addition to finding the slot where a board is plugged in, the manager intelligence must determine the board type and label the board correctly. The board type and board label attributes determine this information. These attributes do not have to exist in the same table as the slot index attribute. The attributes must only exist in a table that uses the same indexing scheme as the table used to discover the boards.

The MIB can have all the board information in non-list attributes rather than in a table. In this case, the information that is supplied within the MIB applies to a single board. The slot index value is not an index into a table, but simply an integer

attribute that returns the slot where the board is located. The chassis manager intelligence tests the slot index attribute. For a non-list attribute, a read is used instead of a read_next to get the board number. If the slot index attribute is not a list attribute, the board type and board label attributes are not list attributes.

GnRelayDerPt

The GnRelayDerPt derivation point is used to model the ports on a chassis. You can use this derivation point with GnChassisDerPt to create one application model. Or you can use it on its own to create an application model that is separate from the chassis manager.

The term *chassis support application* describes an application that was built using GnRelayDerPt. This derivation point provides support to the chassis manager application (such as modeling the ports for each board). Unlike the chassis manager application, multiple chassis support applications can be instantiated under the main device model. This ability lets you model a chassis whose boards support different protocols.

Although all the boards can show up in the slot table of the chassis, a MIB that corresponds to the appropriate protocol can manage the data relay component of each board. Each of these protocol-dependent MIBs must be modeled as separate application models (built from the GnRelayDerPt derivation point). The ports on each board can then be discovered and modeled.

The typical structure of a data relay MIB has two tables: a board table and a port table. Do not confuse the board table with the slot table that is used with the chassis manager. In some cases, they can be the same table. However, the board table in the data relay MIB has an entry for each board that the MIB supports. Typically the board table is indexed by the position of the board in the chassis. For example, if the data relay MIB is an Ethernet MIB, any board that supports the Ethernet protocol (typically a repeater board) has an entry in the board table of this MIB. If a FDDI board is plugged into the chassis, the board creates an entry in the common slot table. However, this new board does not appear in the board table of the Ethernet MIB. Instead, it appears in the board table of the FDDI MIB.

In addition to the board table, the data relay MIB has a port table. For each port that the MIB supports, this table contains a corresponding entry. The tables often contain the status and statistical information for each port. The port table contains two indices: a board index and a port index. Because the port table contains a board index, the chassis support intelligence can associate the port models with the appropriate board models; the board index supplies the mapping of a port to a board.

GnDataRelay_MF is the model fragment within the GnRelayDerPt derivation point, which contains the attributes and intelligence to model the ports of each board and associate those port models with the appropriate board model. The GnDataRelay_MF model fragment intelligence works with only one board table and one port table. This requirement matches the typical structure of a data relay MIB. If your data relay MIB contains sets of tables - for example, a set of board and port tables for each of the major protocols - you must separate these MIB tables or groups into separate model types. Use each model type as a base for the appropriate application that is built with the GnRelayDerPt.

In some cases, the data relay MIB lacks the typical structure: both a board table and a port table, with the port table indexed to provide the physical mapping of ports to boards. For example, the chassis device uses a MIB with a different indexing scheme for accessing the port information. The FDDI MIB indexes the port table by the SMTIndex and the PortIndex. The SMTIndex is not used to identify the board where the FDDI port is physically located.

This situation can also be created if a vendor reuses a MIB from another device. The original device that the MIB was designed to manage was a port-oriented device (no boards, only ports). The vendor supplies the same functionality in a board that can be plugged into its chassis, and has used the original MIB to manage the ports on that board. The port table does not contain a board index; the device does not identify which board has a given port.

In such a case, implement the DataRelay_MF model fragment functionality as you would with a port-oriented device.

Application Model Types

Complete the following tasks when you create an application model type:

- Import the required MIBs.
- Derive the application model type.
- Set up application model discovery.
- Set the model name.
- Map the model fragments.
- Set the model type flags.

Use the Model Type Editor to accomplish each of these tasks. The following sections explain why these tasks are required.

NOTE
For more information, see the Model Type Editor section.

Required MIBs Import

When you create an application model type, in some cases the MIB model type already exists in DX NetOps Spectrum. Or you might need to provide access to the new MIB. To provide access to the new MIB, you have two options:

- Use the Model Type Editor to import the MIB directly into the new application model type.
- Create a MIB model type.

If the MIB will be derived into multiple model types, consider deriving the MIB into a separate model type that can be used as a derivation point. The attribute IDs can then be maintained across the model types. Organizing this MIB model type under a new or existing vendor model type maintains database organization.

To create a MIB model type, derive a new model type from GnSNMPMibDerPt. Import the compiled MIB, and supply the SMI (Structure of Management Information) path.

NOTE
If the wrong SMI Path is used, the Model Type Editor does not produce an error. However, when you view imported attributes, the OID Prefix value is incorrect.

Application Model Type Derivation

To derive an application model type, use the Model Type Editor to set the GnSNMPAppDerPt model type as the current model type. Then create a new derived model type.

After you have created the new application model type, add any MIB model type that you created as a base model type to the new application model type.

The new application model type now contains two base model types:

- GnSNMPAppDerPt model type
- custom MIB model type

Application Model Discovery

When a device model for a specific device is instantiated, DX NetOps Spectrum queries the Model Type catalog. Most application model types that are derived from GnSNMPAppDerPt are queried. The query retrieves the value of the default_attr or default_attr_list attribute of each of these model types. DX NetOps Spectrum then queries those attributes on the device MIB. When a match is found between an attribute value retrieved from the application model type and the corresponding attribute value retrieved from the MIB, DX NetOps Spectrum instantiates a model of this model type.

You can use either the default_attr_list or default_attr to specify attribute IDs from attributes of a MIB model type. DX NetOps Spectrum queries the attributes whose attribute ID is contained in the default_attr or default_attr_list. If default_attr_list is used, DX NetOps Spectrum goes through the list of attribute IDs. The first supported attribute ID that is found is used to instantiate that application model to represent the MIB functionality.

Set the Default Attribute Values

The default_attr_list attribute lets you specify multiple attribute IDs, and the default_attr attribute lets you specify one attribute ID. Each attribute lets DX NetOps Spectrum identify the application model type that represents the MIB functionality.

The default_attr_list attribute is helpful when you have one device that supports a single table in a MIB rather than the entire MIB, and another device that supports other objects in the same MIB, but not in the particular table that the other device supports. In this scenario, use the default_attr_list attribute to specify multiple attribute IDs. This step ensures that the application model type that represents the MIB is instantiated for both devices even though they do not support the same MIB objects.

NOTE
Set the default_attr or default_attr_list in all application model types. When choosing a value, we recommend using an attribute from the MIB model type that represents a mandatory, non-list, external MIB variable. Using such an attribute is especially important when you create a chassis application.

Specify a value for default_attr.

Follow these steps:

1. Find the MIB attribute for the application model type with which you are working.
2. Use the attribute ID of this attribute to set the value of the default_attr attribute in the application model type.
   Look specifically at the attributes of the model type that represents the MIB. You can find the attribute IDs of the attributes of a model type on the Attributes tab in the Model Type Editor.

Specify values for default_attr_list.

Follow these steps:

1. Find the MIB attributes for the application model type with which you are working.
2. Use the attribute IDs of these attributes to specify values in the default_attr_list attribute in the application model type.

   NOTE
   Find the attribute IDs of the attributes of a model type on the Attributes tab in the Model Type Editor.
3. Set the Model_Group attribute to the decimal value of the model type handle of the application model.
4. Verify that the value of Model_Group is set appropriately.
   If Model_Group is set to 0, DX NetOps Spectrum only uses the default_attr attribute to identify the application model type that represents the MIB functionality.

Model Name Setting

Set the Model_Name attribute of the application model type to the appropriate value. By default, this value is used as the model name for any application model of this type.

Model Fragment Mapping

If your new application model type is derived from GnChassisDerPt, GnDevIODerPt, or GnRelayDerPt, use the model fragments that correspond to these model types. This practice ensures correct operation of port and board management. For a model fragment to function properly, use the Model Type Editor to map MIB attribute values from the application model type to model fragment attribute values. The model fragment gains access to information from the MIB that it uses to create and manage ports, boards, and interfaces.

For example, the boardIndex_Attr is one of the required attributes for the GnChassis_MF model fragment, which is used with the GnChassisDerPt derivation point. This attribute lets the model fragment discover the boards that are present in a chassis. The boardIndex_Attr must be set to the index attribute value in the board (group) table of the chassis or repeater MIB. The index attribute usually returns an integer value or a series of values that represents a board number.

Certain derivation points have associated model fragments. The attributes that are associated with that model fragment are available to any model type that was based on these derivation points. To gain the functionality of a model fragment that is not included with one of your base model types, include that model fragment as a base model type.

Model Type Flags Setting

When creating an application model type, set the value of a few different flags to ensure that models of this model type work correctly. These flags are available on the Flags tab of the current model type in the Model Type Editor. Each flag represents a Boolean value and can either be selected (set to TRUE) or deselected (set to FALSE).

In most cases, set the Visible, Instantiable, and Derivable flags to TRUE.

- If the Visible flag is set to TRUE, the model type is visible to all Model Type Editor users. Otherwise, the model type is only visible to a user with the developer ID that was used to create the model type.
- If the Instantiable flag is set to TRUE, you can instantiate a model of this model type in OneClick.
- If the Derivable flag is set to TRUE, this model type can be used as a base for other model types.

The No Destroy, Unique, and Required flags are typically set to FALSE.

- If the No Destroy flag is set to TRUE, users cannot destroy a model of this type in OneClick.
- If the Unique flag is set to TRUE, only one model of this model type can be instantiated in OneClick.
- If the Required flag is set to TRUE, a model of this model type must always exist in the SpectroSERVER database.

Modeling Ports and Boards

When you create application model types from GnChassisDerPt, GnDevIODerPt, and GnRelayDerPt, these applications create the port and board models that are required to represent your device. DX NetOps Spectrum generally uses two model types to model these boards and ports: GnModule and GnPort. You can derive new model types from these model types for customization purposes.

In OneClick, you can view the ports for a device on the Interfaces tab in the Component Details panel. To view the boards for a device, use the Locater tab to search for the boards by model type name.

Modeling Boards with GnModule

Typically a board is modeled for one reason: to be a container for the port models that are physically located on it. In the chassis support of GnSNMPDev, the GnModule model type models many different types of boards.

Derive all new board model types from the GnModule model type. Two GnModule attributes help to define the type of board that a particular model represents:

- **gnType**
  This attribute provides the board type as read from the chassis slot table. When each GnModule model type is instantiated, the chassis manager intelligence supplies the gnType attribute.
- **gnName**
  This attribute is supplied by the chassis manager, which uses information in the chassis slot table when the board is first created.

Modeling Ports with GnPort

Port models are very similar to board models. GnSNMPDev provides one port model type that is sufficient for most modeling needs. The GnPort model type is the default model that is used to model ports using the GnSNMPDev chassis support.

Port and Board Model Information

This following information is not necessary for modeling your ports and boards. We provide this information to help you understand how the information for each board and port is read and displayed in OneClick.

All external attributes that are associated with the boards and ports are read through the application models that support the board and port models. The application models are used because they contain the MIB model types and thus the external attributes that are associated with the boards and ports.

In OneClick, you can view the ports for a device on the Interfaces tab in the Component Details panel. To view the boards for a device, use the Locater tab to search for the boards by model type name.

How to Add Support for Additional Traps

DX NetOps Spectrum notifies you about significant occurrences on your network using traps (alerts from SNMP-compliant devices), events, and alarms.

- An *alert* is an unsolicited message sent out by a managed node on a network. A more specific definition of an alert depends on the management protocol that is used to report the alert. In general, DX NetOps Spectrum uses SNMP as the management protocol to communicate with network devices. Alerts that an SNMP-compliant device generates are called *traps*. DX NetOps Spectrum receives traps and converts them to events for further processing.
- An *event* is an object in DX NetOps Spectrum that indicates that something significant has occurred within DX NetOps Spectrum itself or within the managed environment. Events always occur in relation to a model. When a managed element on the network generates an alert, this alert is mapped to a DX NetOps Spectrum event in the appropriate AlertMap file. The event is then generated and takes on the event code that is specified in the AlertMap file.
- An *alarm* is an indication that a user-actionable abnormal condition exists on a model. A model usually detects an abnormal condition when an event occurs, and the EventDisp file indicates that an alarm is generated.

When you create a model type, typically you add support for additional traps, events, and alarms. You can do this using the MIB Tools application and the Event Configuration application in OneClick. The high-level process is as follows:

1. Enable the OneClick preference that lets you select whether to install or to export the event and alarm support files from MIB Tools:
   a. Click View, Preferences in the OneClick Console.
      The Set Preferences dialog opens.
   b. Expand the MIB Tools folder in the left panel and select Show Advanced Map Options.
   c. Select Yes from the drop-down list.

   Enabling this option lets you use MIB Tools to export the files that support trap, event, and alarm processing to a user-defined directory. You can then package the files in your new management module.
2. Identify the MIB that contains the desired trap definitions.
3. In MIB Tools, import the MIB into the MIB Tools database.
4. Also in MIB Tools, map the traps to events, and specify the events that generate alarms (and the severity of the alarms).
5. While you are still in the Assign Trap Alarms dialog in MIB Tools, take the following steps:
   a. Under Advanced Options, select Export Trap Support.
   b. For Starting Event Code, enter the event code for the first trap that you have mapped.
      The event code is a 4-byte integer that is expressed in hexadecimal format. The first 2 bytes contain the developer ID, and the last 2 bytes identify the event with a unique number. You specify the event code for the first trap. The codes for the remaining traps are assigned sequentially based on the first.

      NOTE
      To identify your custom event codes in OneClick, and to prevent potential conflicts with other DX NetOps Spectrum event codes, we recommend using a starting event code that begins with your CA-assigned developer ID.

c. For Directory, click Browse, navigate to the directory where the event and alarm support files are exported , select the directory, and click Open. For example, browse to C:\win32app\<*vendor_name*>.

6. Click OK in the Assign Trap Alarms dialog.
   MIB Tools creates the appropriate event and alarm support files and exports them to the directory you specified.
7. In Event Configuration, complete the configuration of the events and alarms.
   For example, specify the symptoms, probable causes, and recommended actions for the alarms. These messages are displayed in OneClick when the alarms are generated.
   You can also specify event processing for one or more events, such as logging the event, using the event to clear an alarm, or generating another event using event rules.
   In addition, you can customize the default event message that is displayed in OneClick when the events are generated.

   NOTE
   For more information, see the Event Configuration section.

Distributing a New Certification

After you have created and customized model types, use the DX NetOps Spectrum Extension Integration (SEI) Toolkit to create a virtual CD (VCD) for distributing the new model types to other DX NetOps Spectrum hosts.

The SEI toolkit includes command-line tools for creating required files and for assembling and packaging extensions into a management module that you can distribute. The toolkit helps you create a management module that is compatible with software from CA and other third-party developers. It lets you install a module in your existing DX NetOps Spectrum environment with minimal installation or integration issues.

NOTE
For more information about the DX NetOps Spectrum Extension Integration toolkit, see the Extension Integration (SEI) Developer Reference section.

Cisco Device Management

This section explains how DX NetOps Spectrum supports Cisco device management.

Cisco Device Support Overview

The DX NetOps Spectrum Cisco device certifications provide Cisco MIB and trap support, descriptive device identification, OneClick views, Cisco technology support. The DX NetOps Spectrum Cisco device certifications also provide DX NetOps Spectrum standard capabilities for specific devices and firmware.

Examples of device-family certifications include Catalyst, PIX Firewall, Wireless LAN Controller, and Aironet.

Examples of firmware-based certifications include Cisco IOS, CatOS, and Unified Computing System (UCS).

If no specific device-family certification is available for your Cisco device, then one of the following firmware-based model types is used:

- Rtr_Cisco -- Models Cisco routers that are running IOS firmware.
- SwCiscoIOS -- Models Cisco switches that are running IOS firmware.
- RtrCatOS -- Models Cisco routers that are running CatOS firmware.
- SwCatOS -- Models Cisco switches that are running CatOS firmware.
- CiscoNXOS -- Models Cisco Nexus devices that are running NX-OS firmware.
- GnCiscoDev -- Models Cisco devices that are not running IOS or CatOS firmware.

MIB Sources

Depending on the Cisco device firmware, chassis and board or module information is found in the following MIB sources:

- **OLD-CISCO-CHASSIS-MIB**
  Cisco has deprecated this MIB. Therefore, the information can be incomplete. To view the contents of this MIB, see the Cisco Chassis View subview in OneClick.
- **CISCO-STACK-MIB**
  The CatOS devices support this MIB. This MIB is deprecated in favor of the ENTITY-MIB. To view the contents of this MIB, see the MIB Tools utility.

  NOTE
  For more information about MIB Tools, see the Certifications section.
- **ENTITY-MIB**
  This MIB contains the latest board or module information for new devices. Older devices, however, do not populate this MIB correctly. To view the contents of this MIB, see the Entity View subview in OneClick.

Cisco Unified Computing System

Cisco Unified Computing System (UCS) comprises a set of specialized devices working together, including the blades of the chassis and server. UCS supports the data center by delivering a dynamic IT infrastructure and by unifying network, computing, and virtualization resources.

DX NetOps Spectrum provides visibility into the following key components of Cisco UCS:

- **UCS Manager**
  A web services agent running on a Fabric Interconnect switch. The Cisco UCS manager supports an XML-based API for client interaction.
- Fabric Interconnect (FI) Switch
  - Typically two per UCS system; Cisco recommends a redundant configuration
  - Runs NX-OS
  - Hosts the UCS manager
- **Chassis**
  An agentless, switchless, blade server enclosure, with a maximum configuration of 40 chassis per UCS manager. Each chassis supports 8 half-width or 4 full-width server blades.
- **Blades**
  A server platform that serves as a virtualization host.
- **Service Profiles**
  Logical views of blade servers. Stored in the FI switch, they contain the blade server personality (identity and network information).

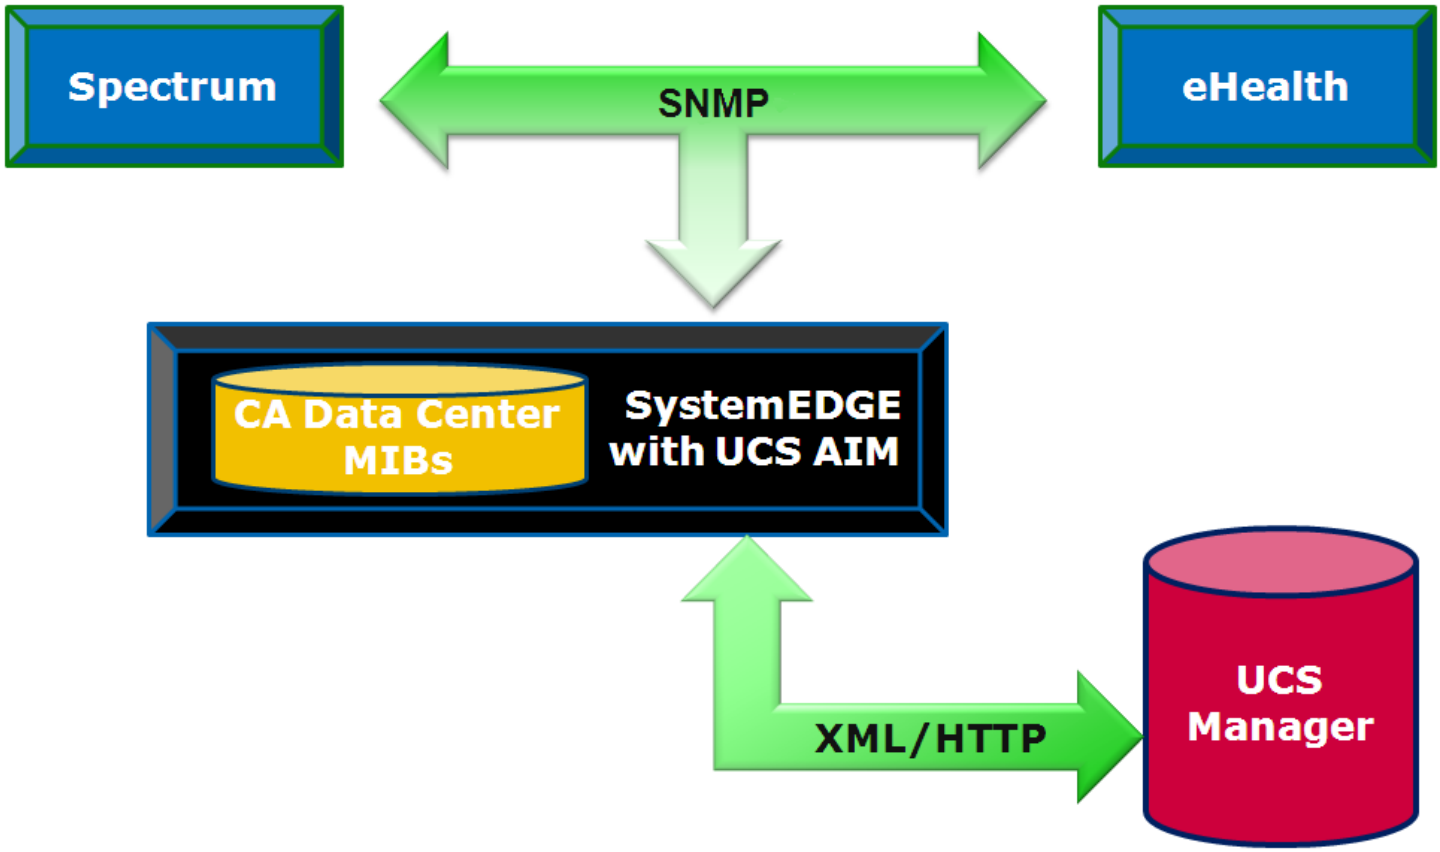
Solution Architecture for Managing Cisco UCS

You can enable DX NetOps Spectrum support for Cisco UCS by employing a specialized CA eHealth SystemEDGE Application Insight Module (AIM). This AIM communicates with the UCS XML-based API to obtain information about the UCS managed environment. The data is then written to a pair of CA-developed MIBs. This solution lets other SNMP clients, such as CA eHealth, leverage the AIM.

The UCS AIM is an extension of the CA eHealth SystemEDGE SNMP agent and can support multiple UCS systems. The CA-developed MIBS are:

- Generic data center MIB (CADATACENTERA)
- UCS-specific data center extension MIB (CACUCSEXTENSIONA)

As the following diagram shows, CA products such as DX NetOps Spectrum and CA eHealth use SNMP to connect to the CA eHealth SystemEDGE that hosts the UCS AIM to obtain Cisco UCS details. The UCS AIM leverages XML/HTTP to connect to the UCS Manager.



UCS Certification Features

DX NetOps Spectrum UCS certification features include:

- Automated device discovery and modeling -- Creates models for UCS components and maintains associations between blade models and any resident ESX hosts
- Connectivity -- Generates accurate physical (Layer 2) topology map of UCS system components
- Enhanced fault management -- Recognizes and suppresses symptomatic alarms, and aids fault isolation with proxy management
- Dedicated UCS views -- Provides visibility into UCS-specific data
- Intelligent trap forwarding -- Enables alarm generation on individual UCS components
- Chassis management (non-UCS-specific) -- Leverages the rich chassis management feature set of DX NetOps Spectrum

Automated Device Discovery and Modeling

The certification automatically models UCS system components on creation of the Host_SystemEDGE model that hosts the UCS AIM. This model can be identified as the Cisco UCS Manager. It creates an application model type of

cacucsaimApp when a UCS AIM MIB is detected. In turn, this application model creates UCS system components such as Fabric Interconnects, chassis, blades, service profiles, and more.

NOTE
Not all UCS components are modeled, such as fabric extenders, power supplies, media adapters, or interfaces.

Next, a search is performed for previously modeled ESX hosts on any of the blades. An association is created between the corresponding blade and ESX models to provide visibility into this hardware-to-software relationship.

Last, container models to represent each UCS system are created. These models reside in the same container (for example, Universe) as the CA eHealth SystemEDGE host. Each container provides a logical topological grouping of the UCS system components.

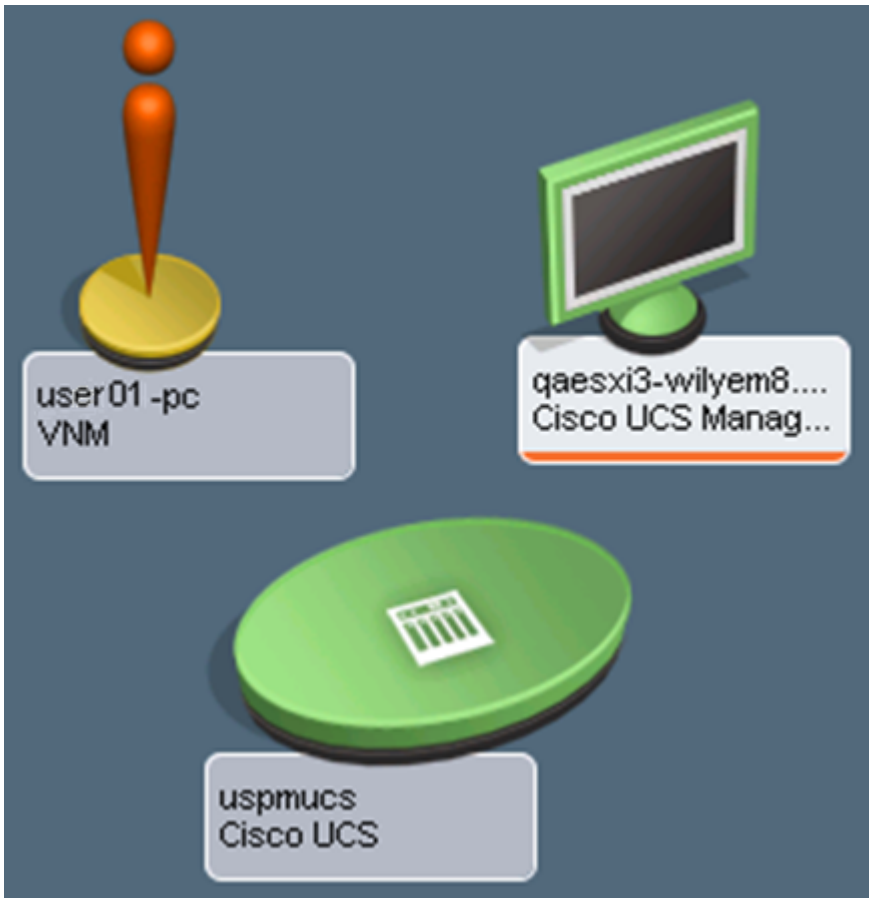
The UCS AIM MIB is polled regularly to collect status and modeling information from the UCS environments. For more information about configuring the polling interval, see Control Cisco UCS AIM Polling.

WARNING
In a given landscape, you cannot model multiple Host_SystemEDGE models whose UCS AIMs monitor the same UCS system. This configuration is not supported. If the Host_SystemEDGE that hosts a UCS AIM is a virtual device, model it before modeling the Host_SystemEDGE that hosts the corresponding virtual technology AIM. Otherwise, UCS containers can be incorrectly created inside a physical host container of the virtual technology. This situation disrupts the DX NetOps Spectrum fault-isolation algorithms.

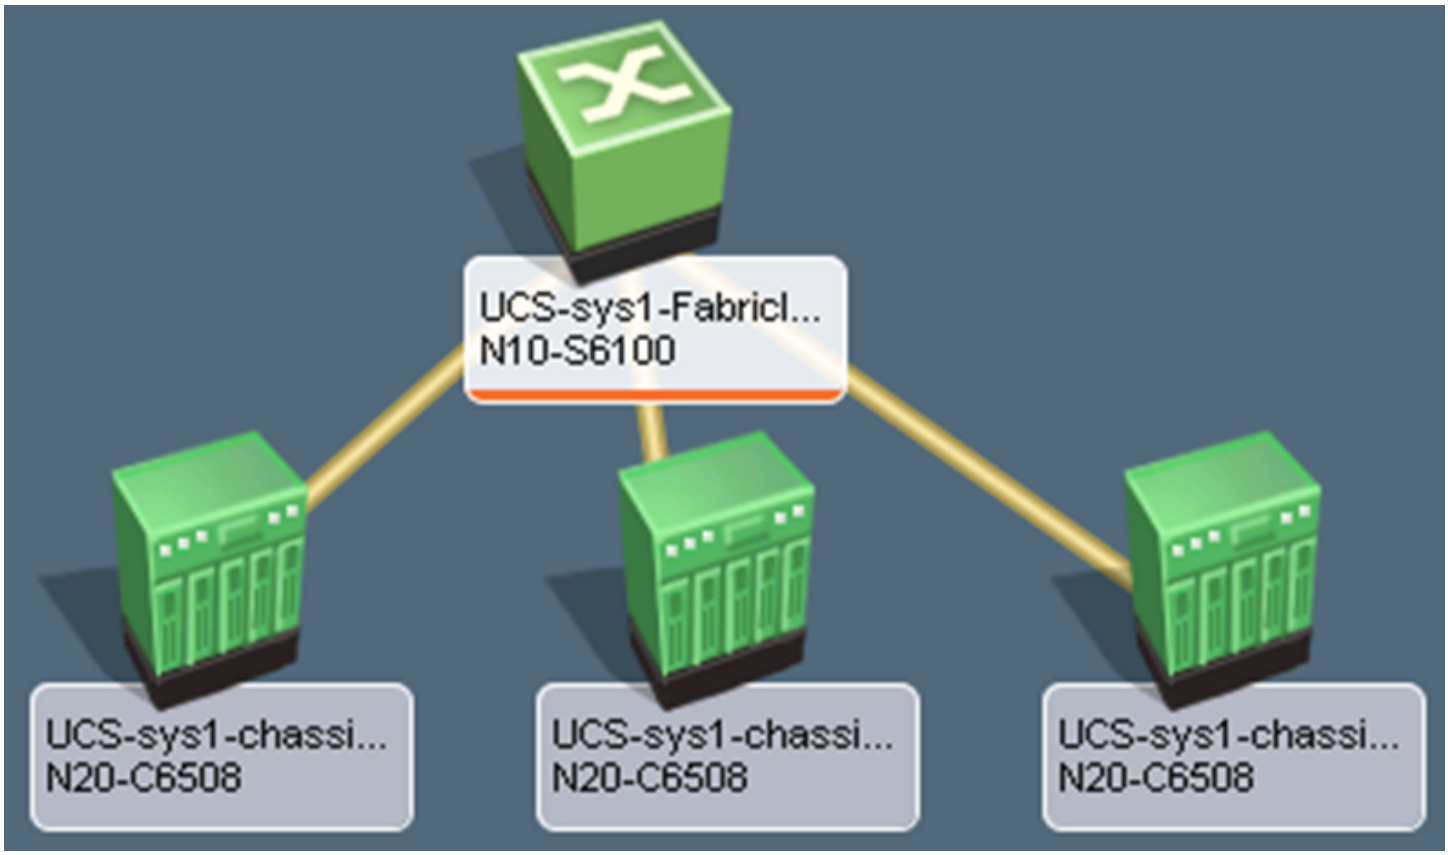
UCS Container Models

To represent a UCS container, DX NetOps Spectrum uses the standard container icon with a chassis logo. UCS containers have a model type of CiscoUCSContainer. Each container gathers together all the topologically significant models of a single UCS system (up to 2 FIs and 40 chassis). The contents of a UCS container cannot be modified.

UCS containers are displayed as in the following image:



The following image shows an example of the contents of a UCS Container:



UCS Fabric Interconnect Models

UCS Fabric Interconnects use the standard switch icon of DX NetOps Spectrum. If this device is modeled through IP address or through discovery, and if its NX-OS SNMP agent is enabled (it is disabled by default), a model of type CiscoUCSFabricInterconnect is created. Otherwise, automated UCS discovery creates a Pingable model. This model includes no device interfaces nor connectivity to upstream devices. Note that the IP address modeling can occur after UCS discovery, in which case the CiscoUCSFabricInterconnect model replaces the Pingable model.

UCS Fabric Interconnect models support dedicated UCS OneClick views and are the target models for UCS Fabric Interconnect traps and alarms.

UCS Chassis Models

UCS chassis use the standard chassis icon of DX NetOps Spectrum and have a model type of CiscoUCSChassis. The Interfaces tab in the Component Details panel of OneClick is enhanced for UCS chassis: the blades within the chassis are displayed to help with blade management.

UCS chassis also extend the fault isolation functionality of DX NetOps Spectrum to provide alarm correlation of collocated hardware resources.

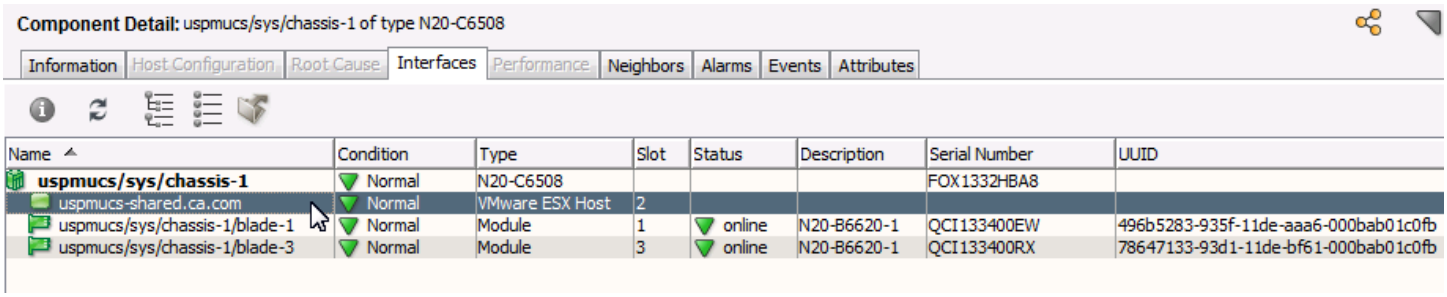
UCS chassis models support dedicated UCS OneClick views and are the target models for UCS chassis traps and alarms.

UCS Blade Models

UCS blades are modeled in DX NetOps Spectrum but, unlike Fabric Interconnect switches and chassis, are not visible inside their parent UCS container nor in any other location of the DX NetOps Spectrum topology. However, the UCS blades for each chassis are listed in the Interfaces tab of the chassis. UCS blades have a model type of CiscoUCSBlade.

DX NetOps Spectrum automatically makes associations between a blade and an ESX host resident on that blade. This association is done by performing a search for previously modeled ESX hosts and obtaining the UUID (Universally Unique Identifier) value. The blade UUIDs are then examined. When a match is found, the ESX host model is associated with the blade model. Only ESX hosts are supported for automatic association. DX NetOps Spectrum understands this blade (hardware)-to-ESX host (software) relationship and leverages it through enhanced fault isolation. You see meaningful alarm details, such as when the ESX host is out of contact because its blade failed.

Once the association is made, the ESX host model takes the place of the blade model in the Interfaces tab of the chassis model.



You can manually associate UCS blades with corresponding SNMP agent models to gain visibility into the blade (hardware)-to-agent (software) relationship.

UCS blade models support dedicated UCS hardware-based OneClick views, which include the following types of information:

- Statistical information such as CPU load, memory, and storage utilization
- Image inventory (BIOS & Firmware) and BIOS H/W configuration
- Physical interfaces of the blade server
- Service profile details

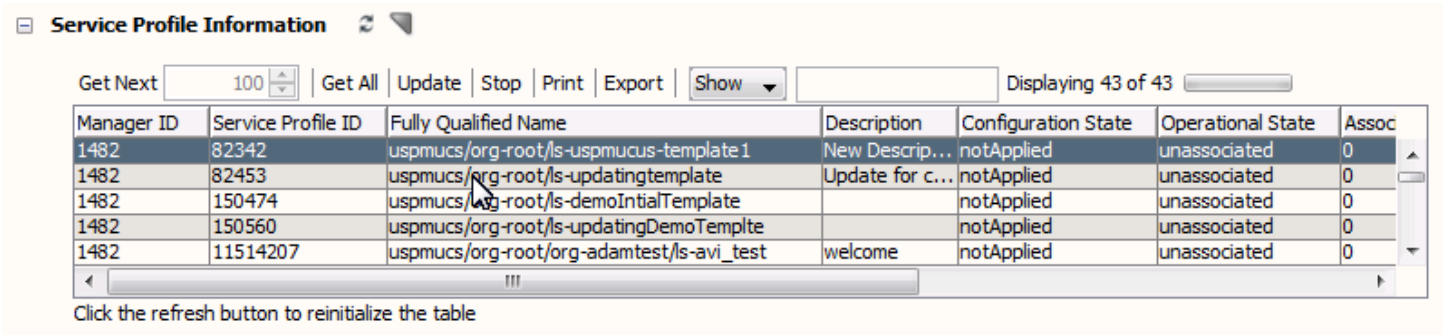
The UCS blade models are the target models for UCS blade traps and alarms.

UCS Service Profile Models

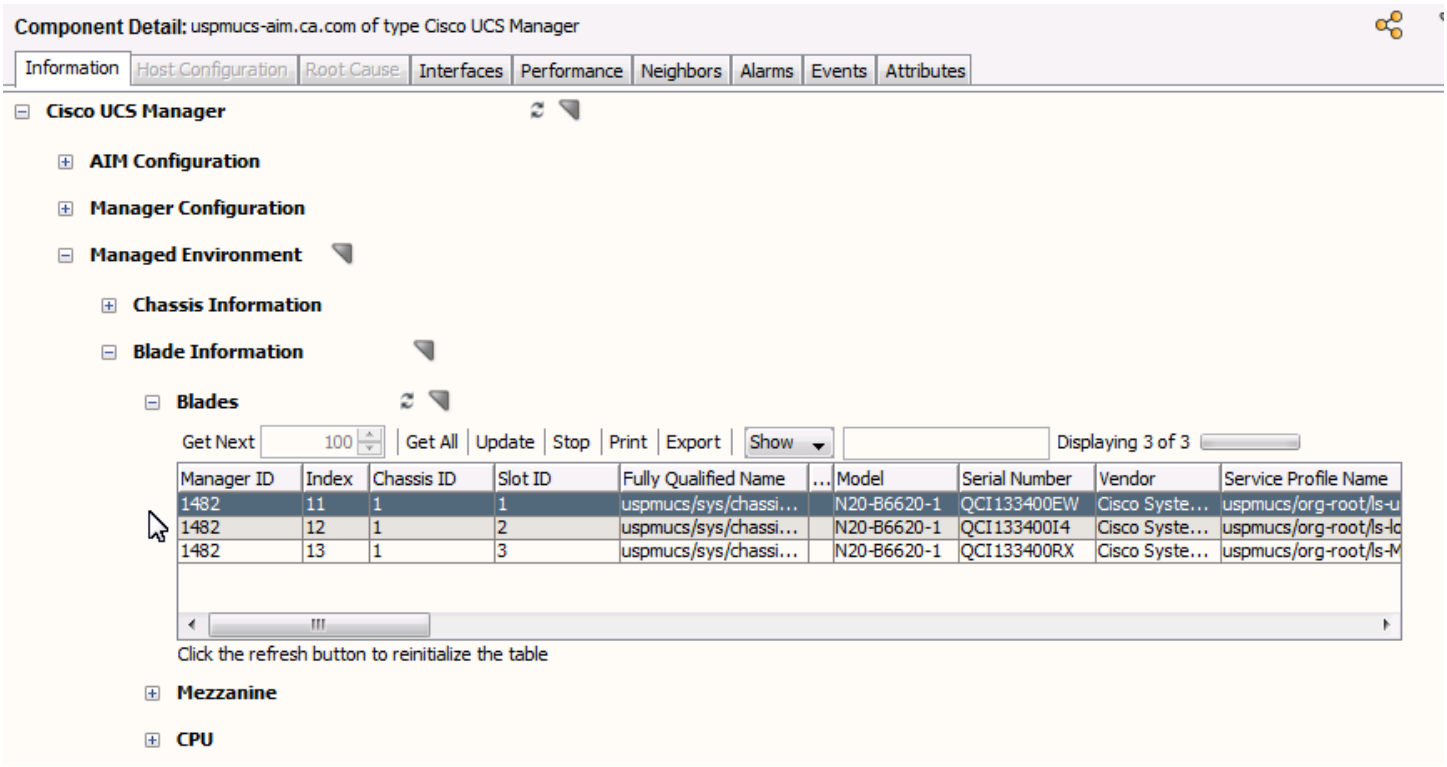
Blade servers that are provisioned in the Cisco Unified Computing System are specified by a service profile. A service profile is a software definition of a server and its LAN and SAN network connectivity. UCS service profiles have a model type of CiscoUCSServiceProfile.

Server, network, and storage administrators create service profiles. Service profiles are stored in the Cisco UCS 6100 Series Fabric Interconnects. When a service profile is deployed on a blade server, the UCS manager automatically configures the blade server, its network adapters, fabric extenders, and fabric interconnects to support the configuration specified in the service profile.

DX NetOps Spectrum creates models for each service profile that is defined by a UCS Manager. They can be viewed from the OneClick Locater tab which now includes a Service Profile Model Class search option. In addition, service profile details are displayed in various OneClick views. Select the Cisco UCS Manager, Managed Environment and the Service Profile Information option on the Host_SystemEDGE model that is hosting the UCS AIM. You can then see the name, ID, description, associated blade, and various states of all the service profiles in the UCS systems that the Host_SystemEDGE manages.



DX NetOps Spectrum also displays the service profile that is associated with each blade that is installed in each UCS Manager Chassis.



The UCS service profile models are the target models for UCS service profile alarms.

Connectivity

UCS Fabric Interconnect models participates in connectivity by providing the boundary switching node between the upstream devices and the blade servers in the chassis.

Upstream from the UCS Fabric Interconnect

The upstream connections from the Fabric Interconnect interface are done through standard bridging tables. These connections require the following steps:

- Enabling the native NX-OS SNMP agent in the Fabric Interconnect .
- Modeling the device ,either by IP address or through discovery.

Downstream from the UCS Fabric Interconnect

The downstream FCoE connections from a UCS Fabric Interconnect to its constituent chassis are shown as standard DX NetOps Spectrum L2 connections. These connections are created programmatically and not through standard bridging tables nor the UCS MIBs.

Enhanced Fault Management

Enhanced Fault Management for UCS involves two types of alarms:

- Fault Alarms
  - Indicate a problem with L2 availability
  - Are enhanced with special correlation logic
- Proxy Lost Alarms
  - Indicate that updated UCS information cannot be obtained from the CA eHealth SystemEDGE UCS AIM host
  - Include a Proxy Unavailable alarm for the host itself

UCS Fault Management enhancements also include chassis- and blade-level availability alarms and trap-generated alarms that indicate infrastructure and environment issues.

UCS leverages the benefits of alarm correlation:

- Pinpoint root cause
- Suppress extraneous alarms
- Correlate symptoms to root cause
- Show impact

UCS alarm correlation occurs at both the chassis level and the UCS System level.

Chassis-Level alarm correlation uses a domain that includes a chassis, its blades, and all SNMP blade agent models in the case of fault (loss of contact) alarms. If contact is lost for each of these domain entities (in other words, the chassis, the blades and the SNMP blade agents) a single Chassis Down alarm is generated on the chassis. The entire set of Contact Lost alarms is correlated with it.

In the case of proxy lost alarms, chassis-level alarm correlation uses a smaller domain that includes a chassis and its blades. Here, Proxy Lost alarms for all blades are correlated with the chassis Proxy Lost alarm.

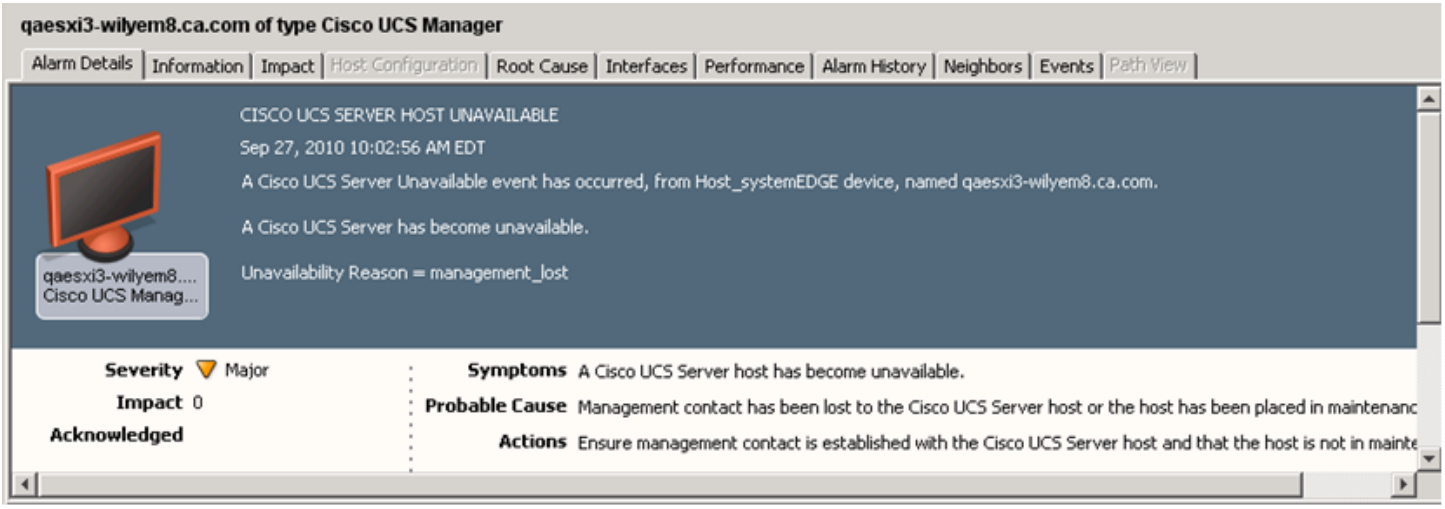
UCS System-Level alarm correlation uses a domain that includes the CA eHealth SystemEDGE host, the FIs, and the child chassis and blades. If communication is lost between DX NetOps Spectrum and the CA eHealth SystemEDGE host, a Proxy Lost alarm is present on all the FIs, chassis, and blades. A Proxy Unavailable alarm is present on the host.

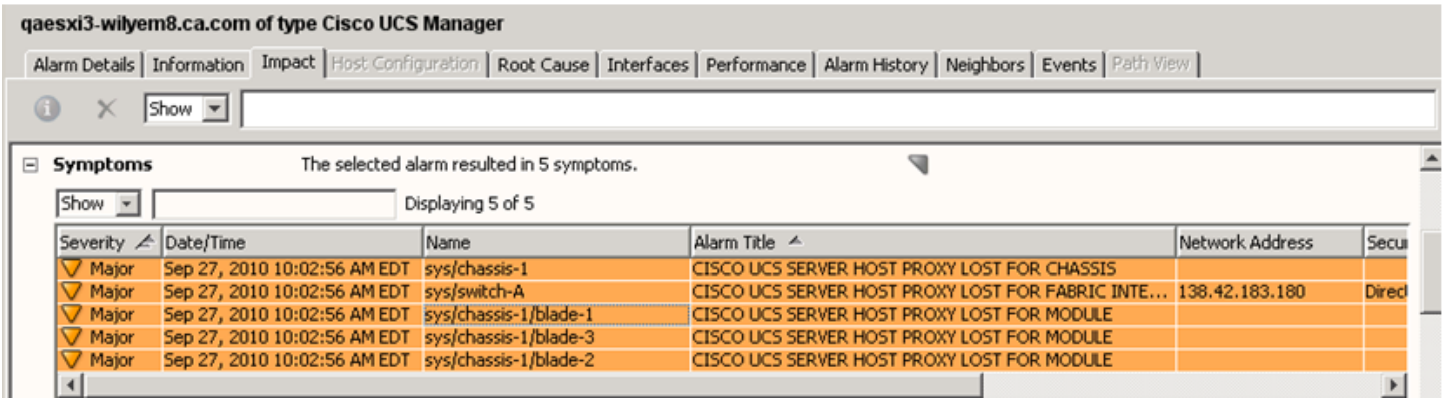
The Proxy Lost alarms for all the components are correlated with the host Proxy Unavailable alarm. These correlations are performed hierarchically. The Proxy Unavailable alarm is itself correlated with the alarm that indicates the reason for the communication failure. For example, it indicates contact lost, management lost, or maintenance mode. This top-level, overarching alarm is then visible to you in the alarm window.

Root Cause Isolation Examples

Root cause isolation resembles the following examples:

- A UCS chassis is inadvertently powered off, affecting the blades (and services running on them). Therefore, the individual Contact Lost alarms on all blades are correlated with the Chassis Down alarm to point the fault to the chassis.
- DX NetOps Spectrum loses contact with the CA eHealth SystemEDGE host. Therefore, the Proxy Lost alarms on all FIs, chassis, and blades are hierarchically correlated with the host’s Proxy Unavailable alarm.





Chassis and Blade Availability Alarms

Chassis availability alarms include Chassis Down and Blade Status Unknown (which is correlated with Chassis Down).

Blade availability alarms include Blade Removed and Blade Failed (the blade is present but has a failed status). Both of these alarms are correlated with an existing Blade Status Unknown alarm on the parent chassis. Note that blade models are subject by default to a two-hour age-out to allow for blade replacement.

Service Profile Alarms

Not only do we display all the service profile details, we also create DX NetOps Spectrum models for each service profile. DX NetOps Spectrum actively monitors the state of the service profile and generates events and alarms based on the operational state of each service profile.

Trap-Generated Alarms

UCS supports trap-generated alarms that indicate infrastructure and environment issues. Discrimination is used where appropriate. Examples include Blade Added, Blade Removed, Power Supply Inoperable, and Temperature Warning.

Dedicated UCS Views

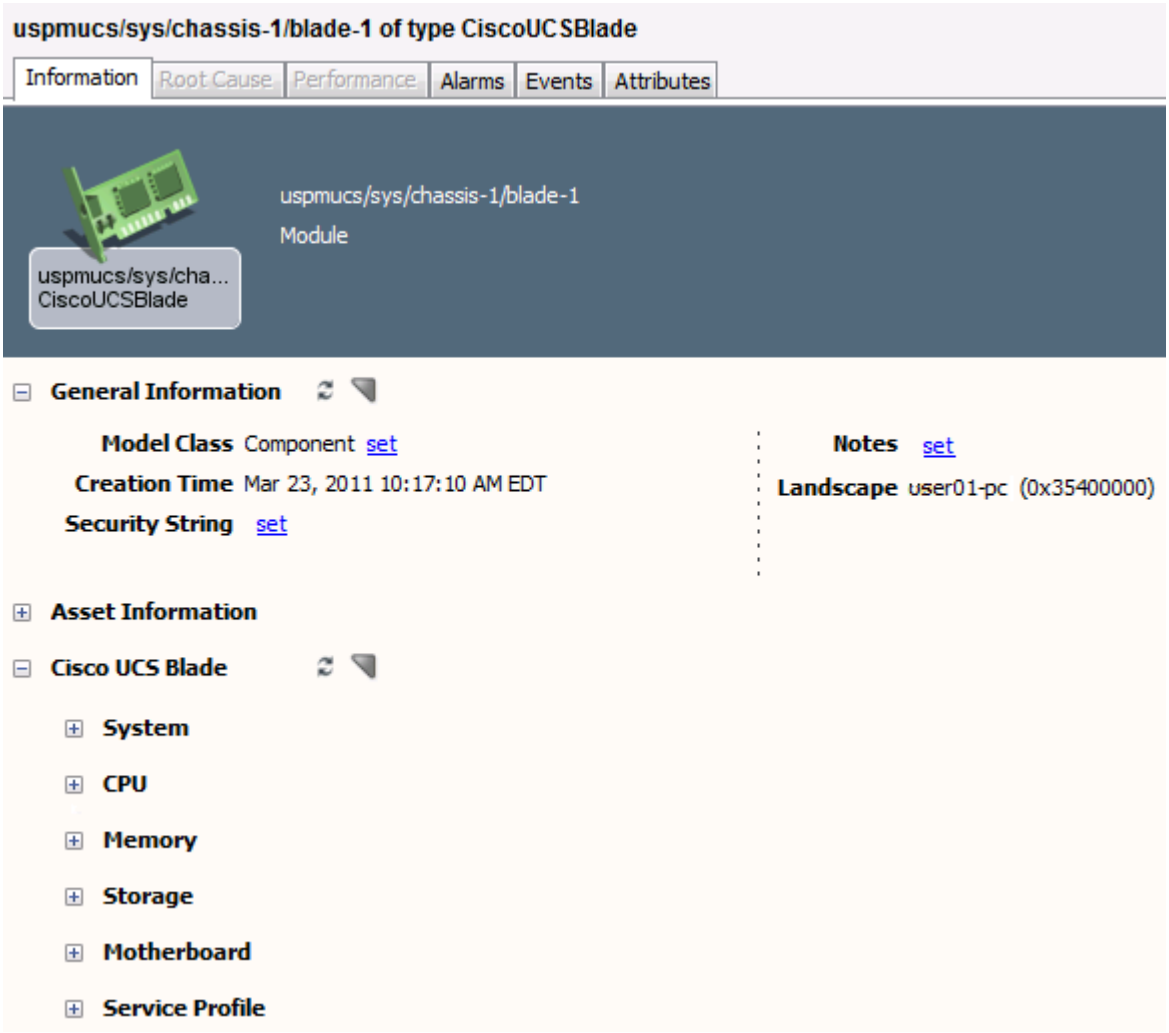
Dedicated UCS views are available for the following device types (indicated in parentheses):

- CA eHealth SystemEDGE host (Cisco UCS Manager)

This view includes table views of the managed environment.

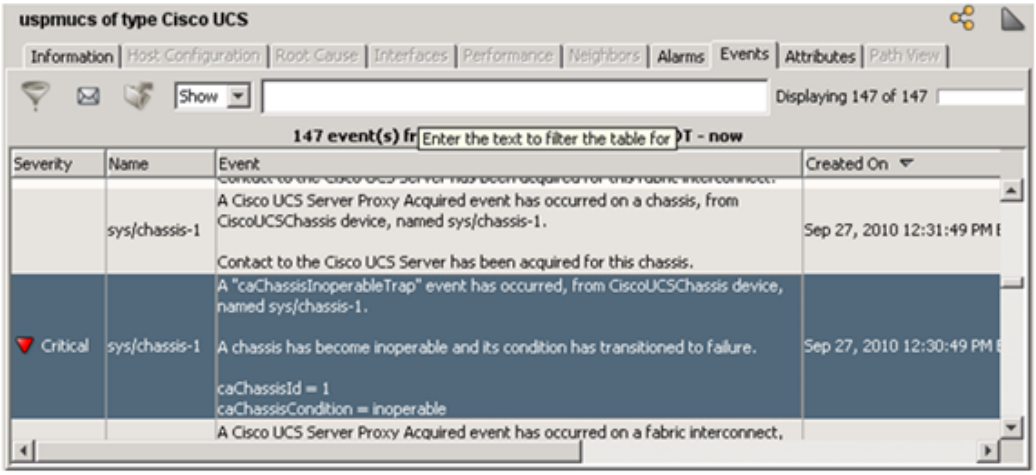
- Fabric Interconnect (Cisco UCS Switch)
- Chassis (Cisco UCS Chassis)
- Blade (Cisco UCS Blade)
- Service Profile (N/A)

OneClick views show hardware details, such as memory DIMMs, mezzanine cards, fabric interconnect extenders, and interfaces.



Intelligent Trap Forwarding

All UCS traps are generated from the UCS AIM and thus arrive into DX NetOps Spectrum from the CA eHealth SystemEDGE host. Therefore, DX NetOps Spectrum employs a forwarding mechanism to generate the event or trap on the correct UCS component. Determination of the correct component is achieved through examination of trap variable values. If the applicable component cannot be found, the trap event is asserted on the CA eHealth SystemEDGE host.



Chassis Management

UCS leverages the rich set of chassis management features that are available in DX NetOps Spectrum:

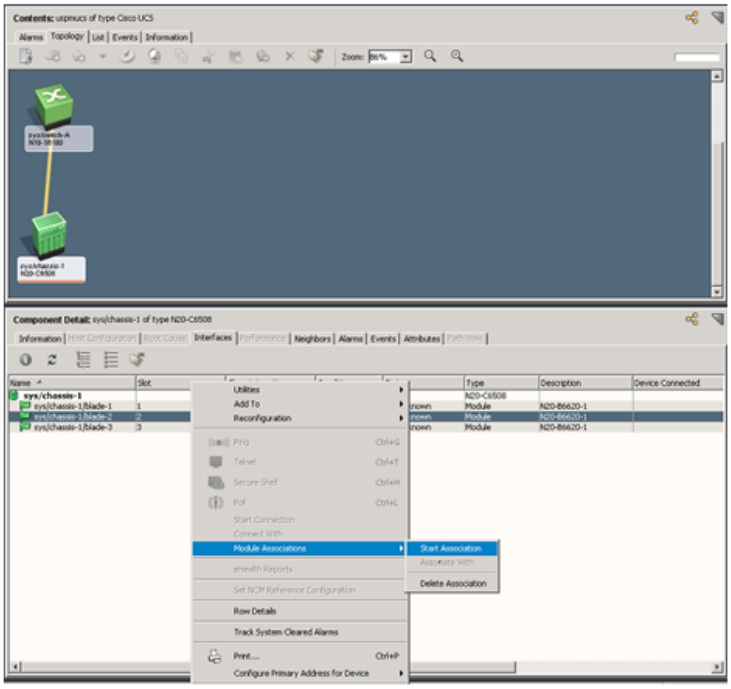
- Manual blade/SNMP device association
- Blade and managed device visibility
- Locater searches

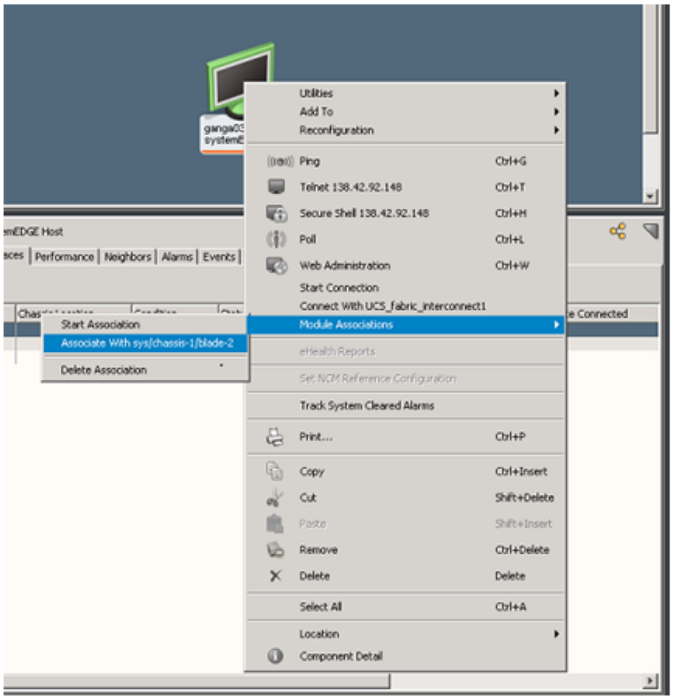
For more information, see the Support for Chassis Devices section of Certifications.

Manual Blade/SNMP Device Association

Manual blade/SNMP device association binds one blade of a chassis to an SNMP-capable blade agent model. This association enables quick determination of the system/chassis location from the agent model. The SNMP model is not moved into the UCS container, but it takes the place of the blade in the Interfaces tab of the chassis.

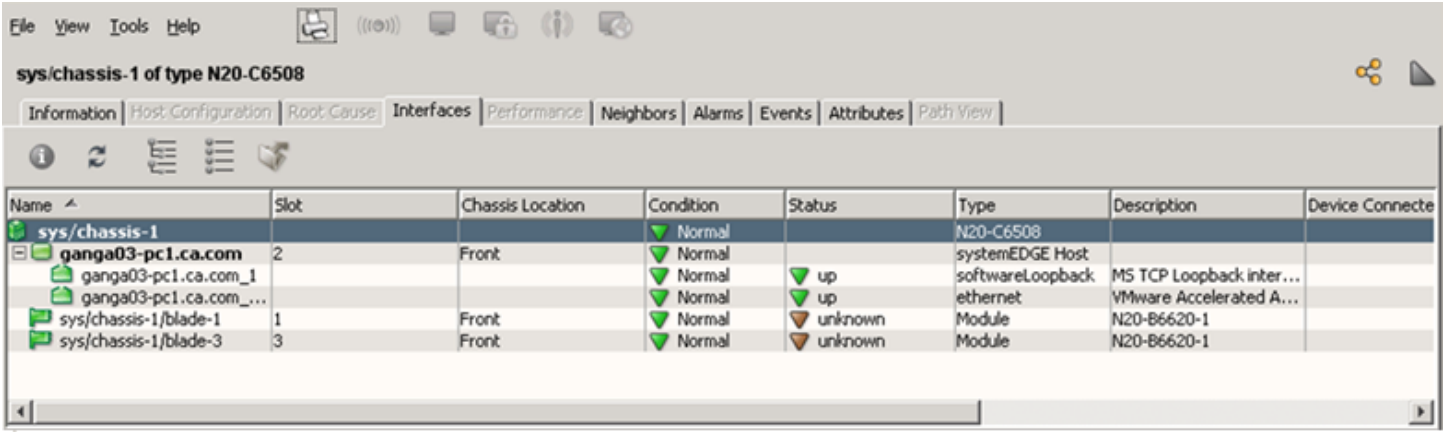
To bolster this integration, the SNMP agent model is incorporated into chassis fault correlation. Blade/agent association also enables SNMP model identification through chassis-based Locater searches.





Blade and Managed Device Visibility

Through the inclusion of associated SNMP devices, the extended Interfaces tab offers visibility into the blades of the chassis and managed devices.



Locater Searches

Chassis-based searches are listed under the Chassis node on the Locater tab. These searches facilitate the quick location of chassis and their components.

Searches include:

- All Chassis
- All Chassis Managed Devices
- All Modules
- Managed Devices By Chassis Name
- Modules By Chassis Name

Control Cisco UCS AIM Polling

When troubleshooting networking issues or tuning the Cisco UCS Manager performance, change the Cisco UCS AIM (cacucsaimApp) polling rate to increase or decrease the frequency. You can configure the polling rate by setting the Poll_Interval attribute on the Cisco UCS AIM application model.

Follow these steps:

1. Open OneClick and select Locater in the Navigation pane.
2. Expand Application Models, and double-click 'By Device IP Address'.
   The Search dialog opens.
3. Enter the IP address of your Cisco UCS Manager in the Device IP Address field, and click OK.
   A list of application models for the Cisco UCS Manager appears in the Contents panel.
4. Select the cacucsaimApp application model.
   The application model details appear in the Component Detail panel.
5. Select Information in the Component Details pane.
6. Expand DX NetOps Spectrum Modeling Information.
7. Click 'set' in the Poll Interval (sec) field, enter a new value, and press Enter.
   Note: Changing the Polling Interval value from any number to 0 also sets the Polling field to Off, disabling UCS AIM polling. If you set the Polling Interval to 0 and the Polling field to On, UCS AIM polling continues, using the polling interval that is set for the Cisco UCS Manager device.
   The Cisco UCS AIM polling rate is configured.

Cisco Catalyst

DX NetOps Spectrum supports Catalyst device families 1200, 1400, 1900, 2820, 3000, 3200, 4000, 4500, 5000, and 6500 with multiple enhanced certifications.

For the Catalyst 2900 and Catalyst 3500 device families, the specific enhanced certification is dependent on the supported MIB set.

DX NetOps Spectrum models Catalyst 2900 series devices as follows:

- The HubCat29xx model type models Catalyst 2900 series switches that run the IOS firmware and support the CISCO-C2900-MIB.
- The SwCiscoIOS model type models Catalyst 2900 series switches that run the IOS firmware, but does not support the CISCO-C2900-MIB. Catalyst 2970 and Catalyst 2948g devices fall into this category.
- The SwCat4xxx model type models Catalyst 2900 series switches that run the CatOS firmware.

DX NetOps Spectrum models Catalyst 3500 series devices as follows:

- The HubCat29xx model type models Catalyst 3500 series switches that run the IOS firmware and support the CISCO-C2900-MIB.
- The SwCiscoIOS model type models Catalyst 3500 series switches that run the IOS firmware, but does not support the CISCO-C2900-MIB. Catalyst 3550 series falls into this category.

Cisco Catalyst Board Fault Isolation Overview

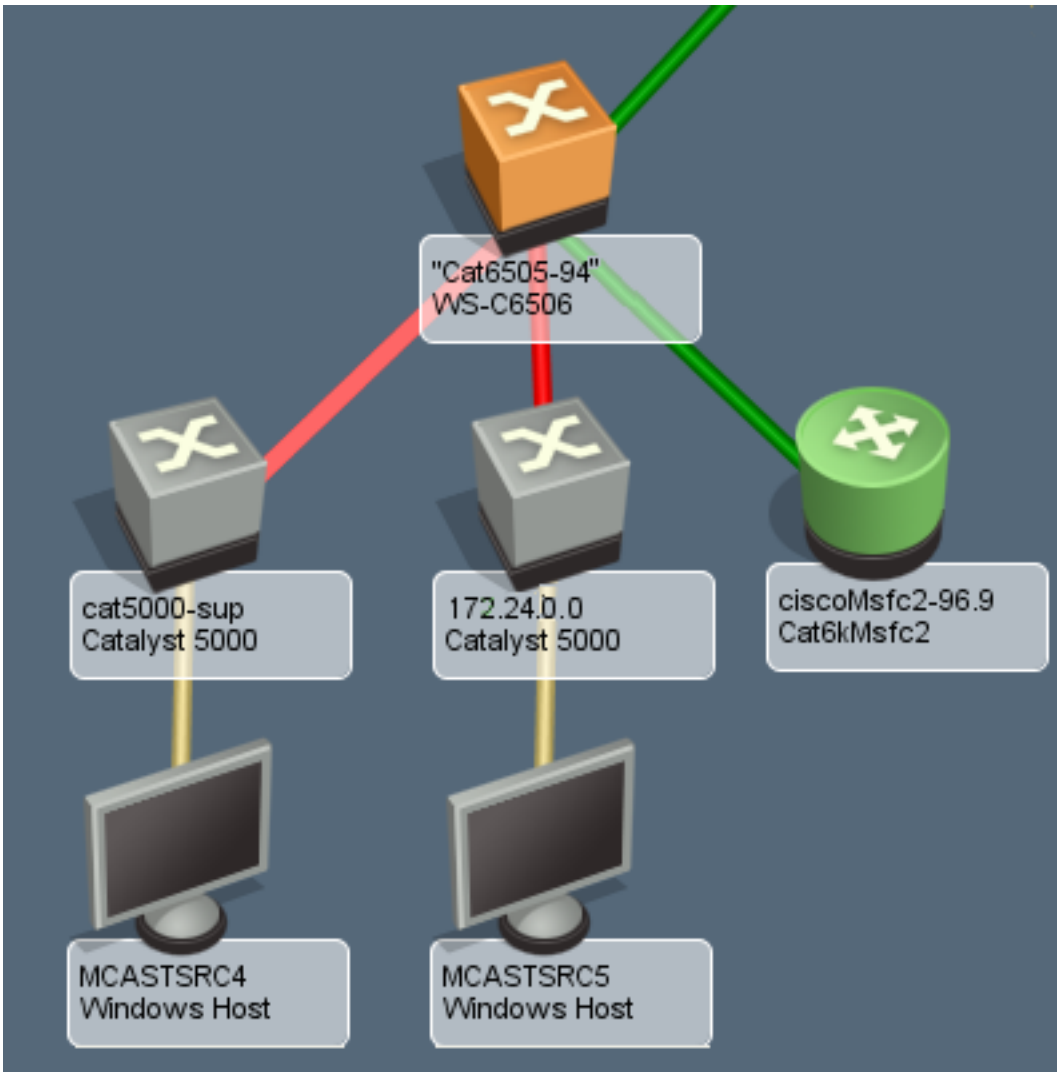
DX NetOps Spectrum supports boards being pulled or failing.

In a traditional fault isolation scenario, when a board in a chassis-based device fails, DX NetOps Spectrum generates critical alarms on all downstream device models. The device model that has the failed board retains its normal condition. However, this behavior does not give an indication as to which device is actually the fault.

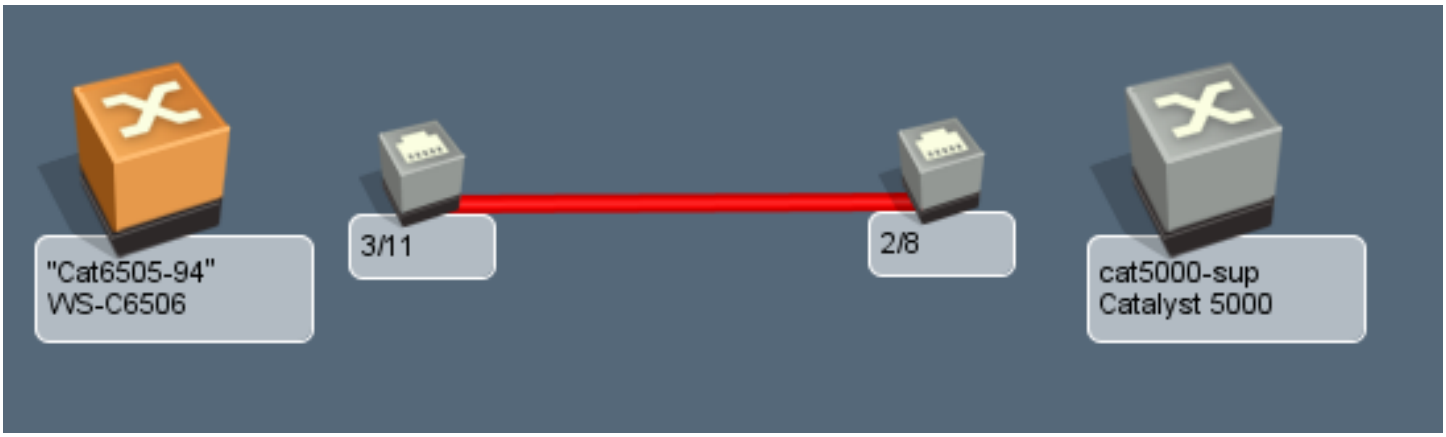
In the same scenario, Catalyst chassis-based devices that support the CISCO-STACK-MIB have enhanced fault isolation functionality to suppress the downstream device models, generate a major alarm on the device model which has the failed board, and generates a critical alarm on the board model. The ports that are associated with the board model are also suppressed giving a clear indication to not only which device is at fault, but also the board that is at fault.

The Catalyst Device with Downstream Devices Example

In the following example, the connected devices have Enable Live Links set to TRUE. When the Catalyst board is pulled, the devices that are connected to ports through that board go down. This event triggers DX NetOps Spectrum to determine the cause of the fault. In this example, two downstream switches and hosts are affected.

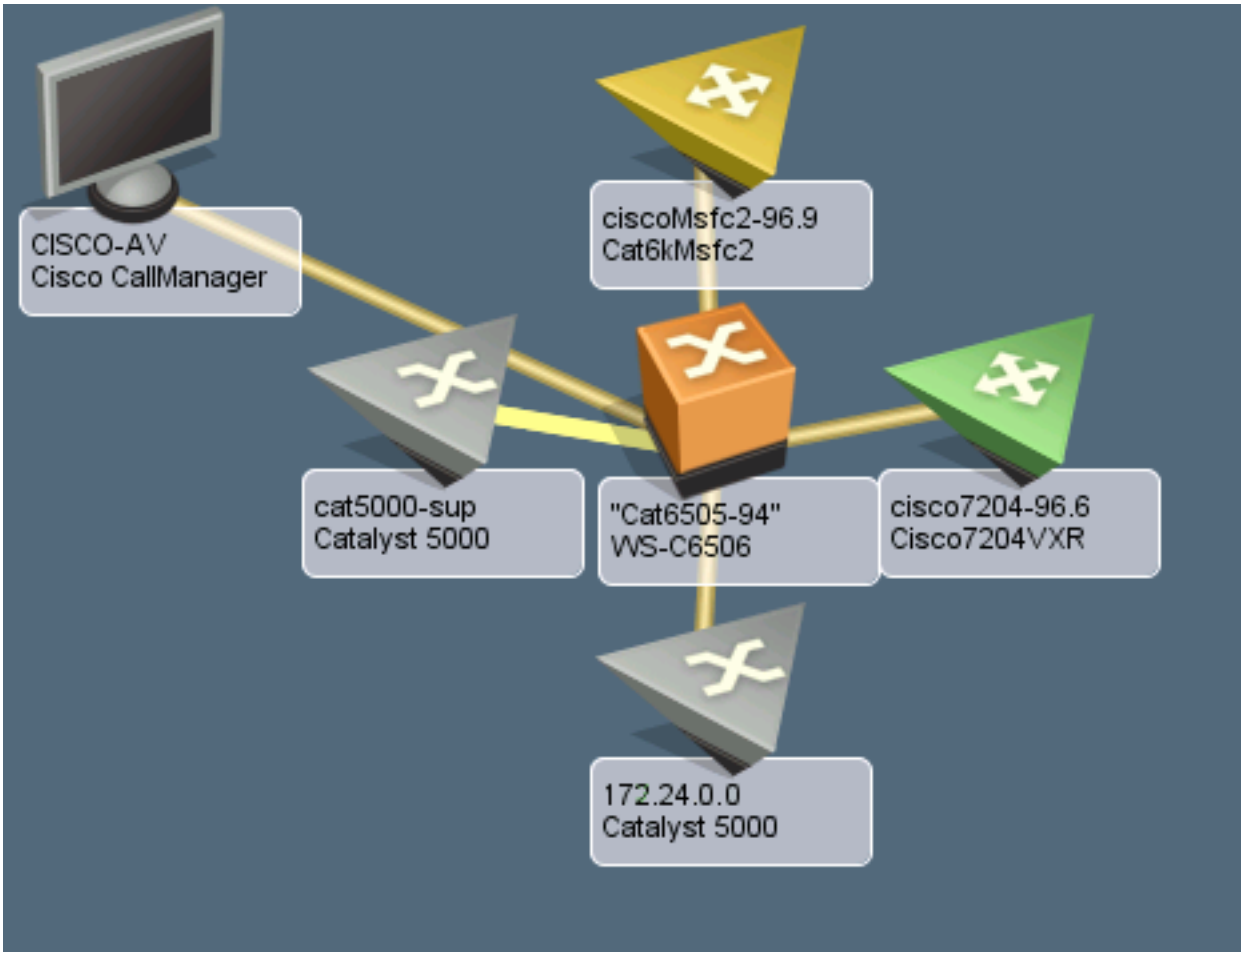


The following illustration shows the Link Information view. The Link Information view shows the root cause of the alarm.

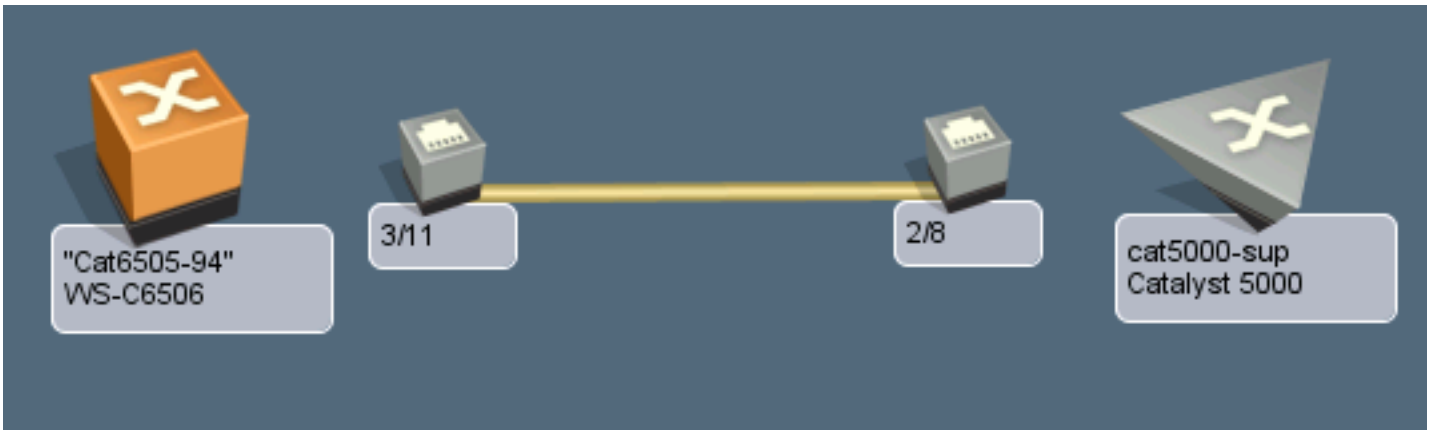


Example of a Catalyst Device with Downstream Devices

In the following example, the connected devices have Enable Live Links set to FALSE. Traps are received when the Catalyst board is pulled, and the devices that are connected to ports through that board go down. This event triggers DX NetOps Spectrum to determine the cause of the fault. In this example, two downstream switches (off-page references) and hosts (not in view) are affected.

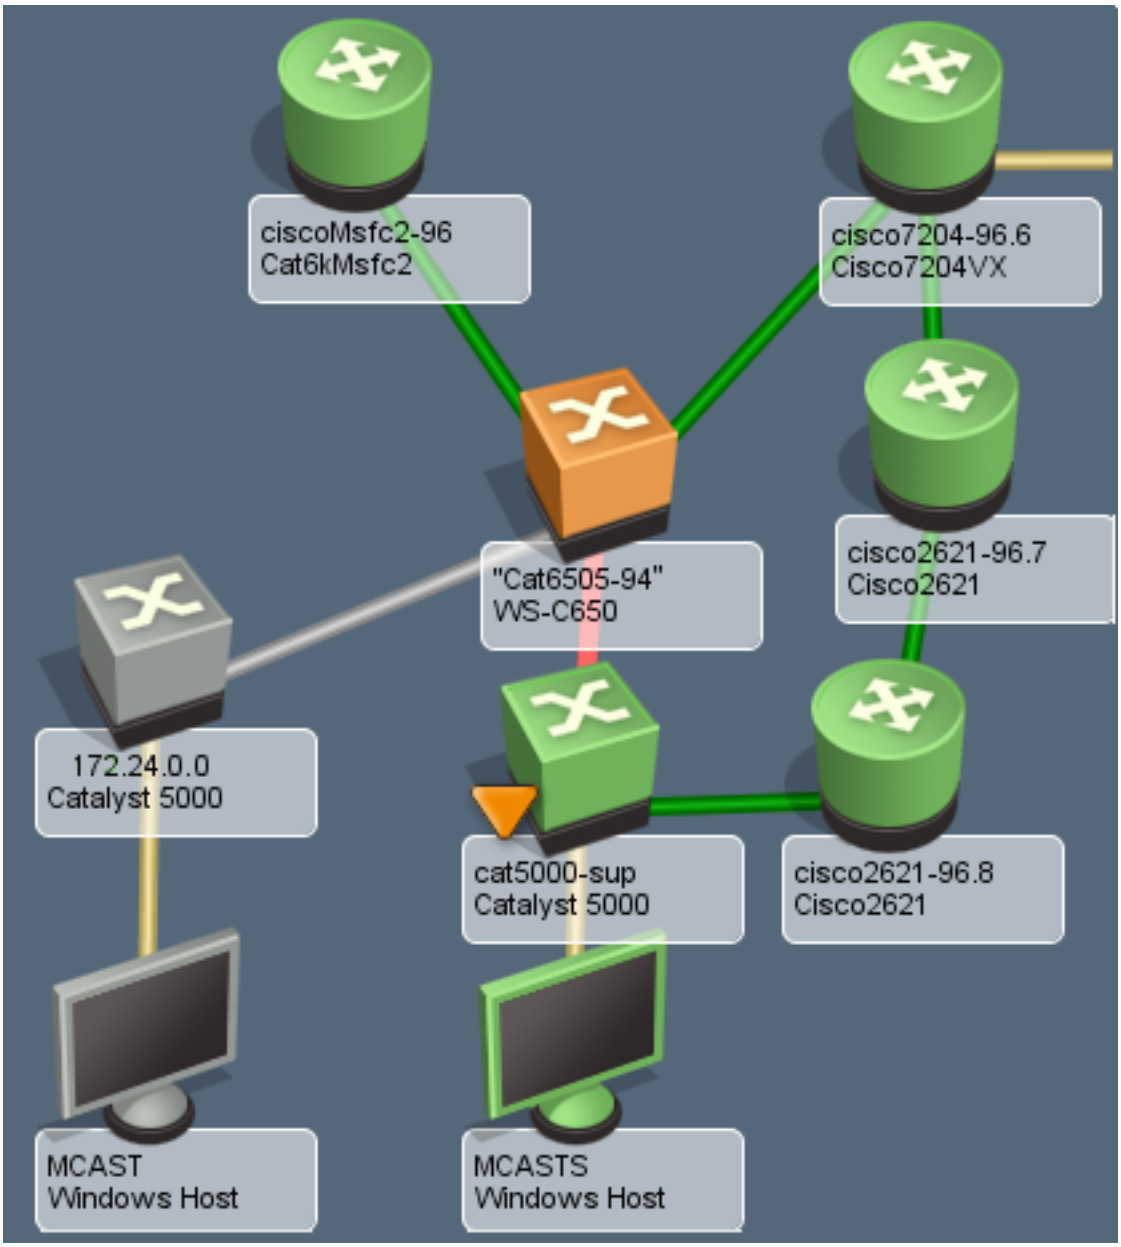


The following illustration shows the Link Information view. The Link Information view shows the root cause of the alarm.



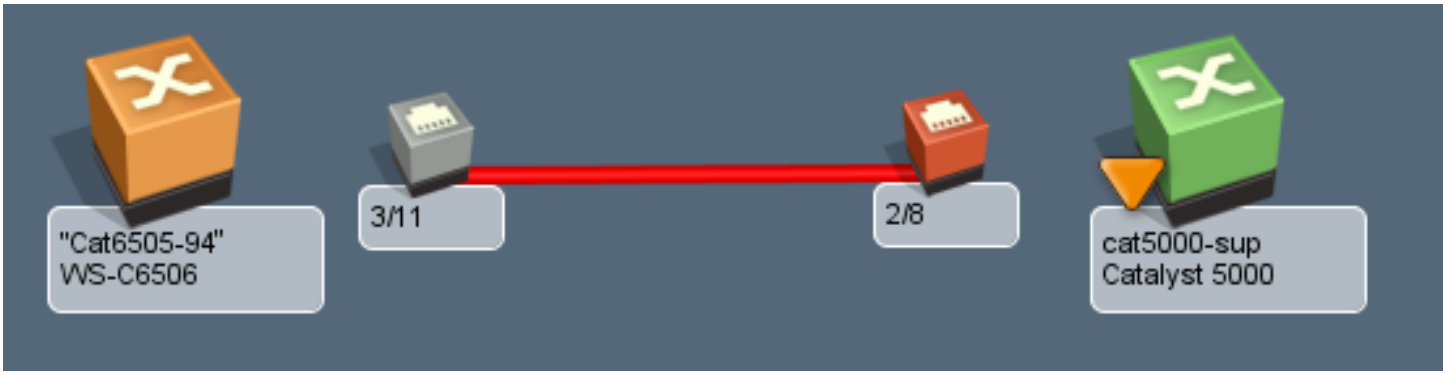
The Catalyst with Downstream Devices with Multiple Management Paths Example

In the following example, the connected devices have Enable Live Links set to TRUE. When the Catalyst board is pulled, the devices that are connected to ports through that board go down. This event triggers DX NetOps Spectrum to determine the cause of the fault. In this example, one downstream switch and host are affected.



NOTE
The switch with the second management path stays contacted and alarms its port.

The following illustration shows the Link Information view. The Link Information view shows the root cause of the alarm.



Cisco Technology Support

This section discusses how DX NetOps Spectrum supports the following Cisco technologies:

- Router Redundancy
- SNMPv3 Device Discovery
- Syslog Trap Support
- Tunnel Interface Modeling
- VLAN Indexing Support
- Virtual PortChannel Support
- Virtual Switching System (VSS) Support

Router Redundancy

The CISCO-HSRP-MIB lets you manage Cisco IOS proprietary Hot Standby Router Protocol (HSRP).

HSRP lets the host appear to be using a single router and maintain the connectivity even if the actual first hop router fails. Multiple routers participate in this protocol. Together, they simulate a single virtual router with a static IP address that is known as the virtual IP address. The end hosts forward their packets to the virtual router.

The router that forwards packets is known as the active router. If the active router fails, the standby router replaces the active router. HSRP provides a mechanism for determining the active and standby routers, using the IP addresses on the participating routers. If an active router fails, the standby router takes over without a major interruption in the connectivity of the host.

HSRP Group Modeling

DX NetOps Spectrum creates models for every Hot Standby Router Protocol (HSRP) group that it discovers. DX NetOps Spectrum identifies them by the virtual IP address. This virtual IP address is added to the Redundancy Excluded Address of the active router of the HSRP group. Each HSRP group model knows the active and standby routers in the HSRP group.

OneClick gives the visibility in the HSRP group membership, using the following router redundancy spotlight methods:

- **Explorer Search**
  Provides a view that highlights HSRP group members with Active and Standby labels, as applicable. You can select a container in the Explorer tab, select the Topology tab in the Contents panel, click the spotlight icon, and select Router Redundancy.
- **Locater Search**

Displays the available searches for HSRP group models. You can open the Router Redundancy directory in the Locater tab. For each model, the Contents panel contains information about the HSRP group model, including Virtual IP, Group ID, and group membership.

HSRP Group Membership

DX NetOps Spectrum monitors each Hot Standby Router Protocol (HSRP) group, looking for state and membership changes. DX NetOps Spectrum polls the HSRP group tables of the active router using the polling interval of the active router device model. DX NetOps Spectrum also responds to the state change traps that the device sends.

If a router fails over, a major alarm is asserted on the HSRP group model, indicating that Router Redundancy has been lost and a standby router is no longer available. DX NetOps Spectrum clears this alarm when a new standby router is detected.

Note: The Information tab for the group model provides a Report Election Change setting. If you enable this setting, DX NetOps Spectrum generates an alarm every time a new active router is selected. DX NetOps Spectrum does not clear this alarm.

Change the State of the HSRPMode Attribute

Limit the volume of SNMP requests to the network devices that are running with the HSRP deployment to prevent a degradation of network performance. You can set the state of the HSRPMode attribute to one of the following three states:

- **Off**
  The HSRP table is not polled.
- **Passive**
  The HSRP table is polled once at the activation. Otherwise, DX NetOps Spectrum relies on updates from traps to update this information.
- **Active**
  The HSRP table is polled every poll interval in addition to the passive processing.

Follow these steps:

1. From the Locater tab, expand Application Models.
2. Select By Name.
   The Search dialog opens.
3. In the Search dialog, type 'CiscoHSRPApp' in the Model Type name text box.
   A list of all of the CiscoHSRPApp devices is displayed.
4. Select all of the devices in the list and right-click to select Utilities, Attribute Editor.
   The Attribute Editor dialog opens.
5. In the left pane, expand User Defined and click the add hyperlink.
   The Attribute Selector dialog opens.
6. Type 'HSRPMode′ in the filter tex box and click OK.
   The attribute HSRPMode is added under User Defined.
7. Select HSRPMode, and click the right arrow to move it to the right pane.

   NOTE
   You can now set the state of the HSRPMode attribute in the right pane.
8. In the left pane, expand SNMP Communication to select *Poll Interval (sec),* and click the right arrow to move it to the right pane.
   You can now set a value for the Poll Interval in the right pane.
9. In the right pane, clear No Change, and set a value for the Poll Interval and set the state of the HSRPMode to Off, Passive, or Active.

You have changed the state of the HSRPMode and set the value for the Poll Interval on all the device models in your landscape.

SNMPv3 Device Discovery

When you discover SNMPv3 devices on the Cisco switches with VLANs, you cannot use the community_string@VLAN_ID format to an index bridging information for each VLAN. Create the contexts instead.

The following configurations are to be done on the Cisco devices. For detailed instructions, refer to the respective Cisco switch configuration guides.

For DX NetOps Spectrum to read the bridging information, create these contexts using the following format:

```
vlan-<VLAN_ID>
```

Example: Create an SNMP v3 User

This example creates an SNMPv3 user context, using the format DX NetOps Spectrum can read:

```
(enable) set snmp user <level1-vlan> nonvolatile

(OUTPUT) Snmp user was set to level1-vlan authProt no-auth  privProt no-priv
```

Example: Create an SNMP Group

This example creates an SNMP group context, using the format DX NetOps Spectrum can read:

```
(enable) set snmp group <v3-level1-vlan> user <level1-vlan> security-model v3 nonvolatile

(OUTPUT) Snmp group was set to v3-level1-vlan user level1-vlan and version v3, nonvolatile.
```

Example: Create an SNMP Access Group

This example creates an SNMP access group context, using the format DX NetOps Spectrum can read:

```
(enable) set snmp access <v3-level1-vlan> security-model v3 noauthentication read <defaultUserView> write
 <defaultUserView> notify <defaultUserView> nonvolatile

(OUTPUT) Snmp access group was set to v3-level1-vlan version v3 level noauthentication, readview
 defaultUserView, writeview defaultUserView, notifyview defaultUserView context match: exact, nonvolatile.

(enable) set snmp access <v3-level1-vlan> security-model v3 noauthentication read <defaultUserView> write
 <defaultUserView> notify <defaultUserView> context <vlan> prefix nonvolatile

(OUTPUT) Snmp access group was set to v3-level1-vlan version v3 level noauthentication, readview
 defaultUserView, writeview defaultUserView, notifyview defaultUserView context: vlan, context match: prefix,
 nonvolatile.
```

Syslog Trap Support

The System Message Log (syslog) protocol lets you send text messages from the Cisco devices to the network management software. The text messages are sent to the DX NetOps Spectrum Event Manager as SNMP traps. Syslog trap support lets the router device identify the text messages and escalate them to alarms as required. Syslog trap support also lets the Cisco Router model icon communicate alarm severity information.

If an alarm occurs as indicated by the Cisco device icon, the DX NetOps Spectrum Alarm Severity and a syslog message appear in the Alarm Log.

The syslog messages are classified based on the severity that ranges from 0 to 7 (most severe to least severe). The alarms display in the Alarm Log. Because these alarms are associated with Cisco device models, the corresponding model icon changes color and flashes, depending on the alarm severity.

The following table lists the severity codes and their descriptions:

Severity	Description
0	Emergency -- System is unusable
1	Alert -- Immediate action required
2	Critical -- Critical condition
3	Error -- Error condition
4	Warning -- Warning condition
5	Notification -- Normal but significant condition
6	Informational -- Informational message only
7	Debugging -- Message that appears during debugging only

The following table maps syslog message severity to the DX NetOps Spectrum alarm severity:

Alarm Severity	Color
0-1	Red
2-3	Orange
4	Yellow

Messages with an alarm severity of 5 through 7 do not generate an alarm because they are of a minor importance. Facility(hardware device, protocol, or a module or system software) lists the messages.

A facility code is an abbreviation of the facility to which the message refers. A facility can be a specific hardware device, a protocol, or software. Within each facility, messages are listed in terms of the severity, from the highest (0) to the lowest (7). A *mnemonic* is an uppercase string that uniquely identifies the message.

An explanation and a recommended action follow each message. Messages appear only when the system remains operational. The following line is an example of a syslog message:

01/01/2001,18:31:15:SYS-5-MOD_INSERT:Module 5 has been inserted.

This message is interpreted as follows:

- 01/01/2001,18:31:15 is the date and time of the error (this information appears if set for system log messaging).
- SYS is the facility type.
- 5 is the severity level, indicating it is a normal but significant condition.
- MOD_INSERT is the mnemonic that uniquely identifies the message.
- "Module 5 has been inserted" is the message text that describes the condition.

The System Message Log (syslog) program saves the system messages in a log file or directs the messages to other devices. Syslog software lets you do the following functions:

- Save logging information for monitoring and troubleshooting
- Select the type and destination of the logging information

By default, the switch logs normal but significant system messages to its internal buffer and sends these messages to the system console. You can specify how system messages must be saved based on the type of facility and the severity level. Messages can be time-stamped to improve real-time debugging and management.

Add Syslog Trap Mappings to DX NetOps Spectrum

DX NetOps Spectrum includes three text files that SpectroSERVER uses to map Cisco syslog traps to DX NetOps Spectrum events.

The following table shows the syslog text files:

Device Syslog Message	Text File
Cisco Router	<$SPECROOT>/SS/CsVendor/Cisco_Router/Rtr.txt
Catalyst Switch	<$SPECROOT>/SS/CsVendor/Ctron_CAT/Switch.txt
Cisco PIX	<$SPECROOT>/SS/CsVendor/CiscoPIX/Pix.txt

Each line of these text files contains information to map syslog messages to DX NetOps Spectrum events. The lines have the following format (for each field, a single space is the delimiter):

```
<facility> <severity> <mnemonic> <event code>
```

Follow these steps:

1. Add a line to the file that contains the previous information.
   For example, to add support for the %SPE-3-SM_DOWNLOAD_FAILED syslog message for Cisco Routers, add the following line to the Rtr.txt file: SPE 3 SM_DOWNLOAD_FAILED 0xffff0001, where 0xffff0001 is an arbitrary code that you select.
2. Create Event Format and the Probable Cause files for the event and alarm.
   In this case, create Eventffff0001 and Probffff0001. You can enter any text in these files. The following variable data can be read from the Event Message and displayed in the Event Format file:
   ```
   {S 1}- Facility
   {T T1_210017 2}- Severity
   {S 3}- Mnemonic
   {S 4} - Message
   ```
3. Add the event-to-alarm mapping. Using the previous example, add the following line:
   0xffff0001 E 50 A 2,0xffff0001

   NOTE
   You must have an EventDisp file in the same directory as the Rtr.txt file.

   An orange alarm is generated if SpectroSERVER receives this syslog trap.

   NOTE
   You can do this configuration while the SpectroSERVER is running. The SpectroSERVER checks for changes to the *.txt files every minute.

Syslog Message Filter

The Cisco Syslog Message Filter OneClick view lets you filter unwanted syslog messages. Filtering syslog messages blocks unwanted alarms or events. SS/CsVendor/SYSLOG contains eight files that correspond to different filter categories. To select the filter category to which a facility belongs, move the facility to the required SS/CsVendor/SYSLOG file.

The following table shows SS/CsVendor/SYSLOG files and corresponding filters:

File	Corresponding Filter
Syslog0	Protocol_Filter
Syslog1	System_Filter
Syslog2	Environment_Filter

Syslog3	Software_Filter
Syslog4	Security_Filter
Syslog5	Hardware_Configuration_Filter
Syslog6	Connection_Configuration_Filter
Syslog7	PIX_Firewall_Filter

NOTE
The facilities are interchangeable with any of the filters.

The filters are as follows:

- **Protocol_Filter**
  Affects the Syslog0 file. Set this filter to True to filter all syslog messages whose facilities deal with protocols. For example, BGP, OSPF, SNMP, SPANTREE.
- **System_Filter**
  Affects the Syslog1 file. Set this filter to True to filter all syslog messages whose facilities deal with the system. For example, CBUS, MEMSCAN.
- **Environment_Filter**
  Affects the contents of the Syslog2 file. Set this filter to True to filter out all syslog messages that deal with environment variables. For example, LCFE, LCGE.
- **Software_Filter**
  Affects the contents of the Syslog3 file. Set this filter to True to filter out all syslog messages that deal with internal software. For example, PARSER, RSP, GRPGE.
- **Security_Filter**
  Affects the contents of the Syslog4 file. Set this filter to True to filter out all syslog messages that deal with the security of the system. For example, RADIUS, SECURITY.
- **Hardware_Configuration_Filter**
  Affects the contents of the Syslog5 file. Set this filter to True to filter out all syslog messages that deal with the hardware configuration of the device. For example, IOCARD, MODEM, DIALSHELF.
- **Connection_Configuration_Filter**
  Affects the contents of the Syslog6 file. Set this filter to True to filter out all syslog messages that deal with connection configuration of the device. For example, MROUTE, ISDN, X25.
- **Pix_Firewall_Filter**
  Affects the contents of the Syslog7 file. Set this filter to True to filter out all syslog messages that deal with the Cisco PIX Firewall device.

Tunnel Interface Modeling

DX NetOps Spectrum supports the Cisco IPSec tunnel interface management for the Cisco devices that support CISCO-IPSEC-FLOW-MONITOR-MIB and CISCO-IPSEC-MIB. These MIBs are available for Cisco firmware versions 12.1 (4) or later.

DX NetOps Spectrum supports the following IPSEC VPN management features:

- The modeling of tunnel interfaces (site-to-site)
- The automatic connectivity mapping
- The interface model identification
- The interface model aging
- Link down trap correlation
- Status monitoring of tunnel interfaces

The following attributes control IPSEC VPN management:

- CreateTunnelLIf
- Interface_Polling_Interval

Configure CreateTunneLIf

The CreateTunnelLIf attribute indicates if tunnel interface models are created for each IPSec tunnel that is defined on the device. If TRUE, it specifies that DX NetOps Spectrum reads the external tables during the interface reconfiguration. These external tables define the tunnel interfaces present. DX NetOps Spectrum creates appropriate tunnel interface models as a subinterface of the related physical interface.

Follow these steps:

1. Navigate to the Locater tab, expand the Application Models folder, and double-click By Device IP Address. The Search dialog opens.
2. Enter the IP address of the Cisco IPSec-capable device you want to configure and click OK. The device appears in the Contents panel.
3. Select the CiscIPSecExtAp device in the Contents panel.
4. Select the Attributes tab in the Component Detail panel.
5. Select CreateTunneLIf in the left pane and click the right arrow button to move it to the right pane.
6. Double-click CreateTunneLIf in the right pane to change its value.

NOTE
Setting CreateTunneLIf to No disables Cisco IPSec tunnel modeling.

Configure Interface_Polling_Interval

The Interface_Polling_Interval attribute defines the tunnel table polling interval in seconds. If set to 0, the table is not polled.

Follow these steps:

1. Navigate to the Locater tab, expand the Application Models folder, and double-click By Device IP Address. The Search dialog opens.
2. Enter the IP address of the Cisco IPSec-capable device you want to configure and click OK. The device appears in the Contents panel.
3. Select the device in the Contents panel.
4. Select the Attributes tab in the Component Detail panel.
5. Select Interface_Polling_Interval in the left pane and click the right arrow button to move it to the right pane.
6. Double-click Interface_Polling_Interval in the right pane to change its value.

VLAN Indexing Support

DX NetOps Spectrum can test whether the VLAN indexing community string is supported on a particular Cisco device. The VLAN indexing community string prevents authentication failure traps.

If a Cisco device supports the VLAN indexing community string, the VLANIndexingSupported (0x4a0037) attribute value is set to Supported 1.

If a device of Cisco does not support the VLAN indexing community string, the VLANIndexingSupported (0x4a0037) attribute value is set to an enumeration NotSupported 0. Further VLAN index reads are not made. This configuration prevents authentication failure traps from being generated.

Test the device, if a Cisco device was not tested due to lack of VLANS information for the device. Perform a Discovery on that device, or to enable the VLAN overlay, set the VLANIndexingSupported (0x4a0037) attribute value to Test 2.

If the configuration of a device changes to support the VLAN indexing community string, change the attribute value to VLANIndexingSupported (0x4a0037) on the Transparnt_App model for that device through the Attribute Editor.

Virtual PortChannel Support

Introduction to Virtual PortChannel Technology

Virtual PortChannels (vPCs) allow links that are physically connected to two different Cisco switches to appear to a third downstream device as coming from a single device and as part of a single port channel. The third device can be a switch, a server, or any other networking device that supports IEEE 802.3ad PortChannels. For more information about vPC, see the Cisco documentation.

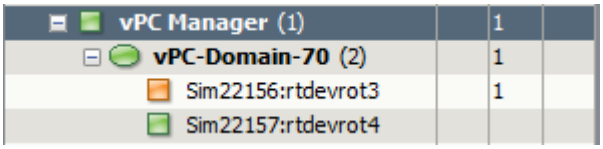
Identification of vPC Configuration

DX NetOps Spectrum monitors vPC domains formed by vPC-enabled Cisco Nexus 7000 series switches with firmware version 6.2.2 that support the CISCO-VPC-MIB. The following vPC parameters are monitored for a particular vPC domain:

- Peer link status
- Peer-keepalive status
- vPC role status
- vPC dual-active status
- vPC PortChannels configured

The monitoring of vPC domains is enabled by creating vPC domain container models (vPC domain model) under vPC Manager node in the Navigation pane of OneClick. Each vPC domain model contains two peer switches that form that vPC domain. All vPC specific alarms and information are displayed at the vPC domain level in OneClick.

The following image shows how a vPC domain model containing two peer switches is arranged in OneClick:



NOTE

As shown in the image, **vPC-Domain-70** is created which contains two peer switches, the value 70 indicates the domain id. The peer switches shown here are simulated, and not real-time switches. If you want to give other meaningful name to a vPC domain model, you can edit its name.

vPC Events, Alarms, and Correlation

The following table lists the events that are generated on a vPC domain:

Events Code	Event Description	Alarm Raised or Cleared
0x00210def	VPC DOMAIN HOST LINK STATUS CHANGE EVENT	Major alarm is raised.
0x00210df1	VPC HOST LINK CLEAR EVENT	Major alarm is cleared.
0x00210df2	VPC DOMAIN ROLE STATUS CHANGE EVENT	Alarm is not raised.
0x00210df3	VPC DOMAIN KEEP ALIVE STATUS CHANGE EVENT	Major alarm is raised.

0x00210df4	VPC PEER KEEP ALIVE CLEAR EVENT	Major alarm is cleared.
0x00210dfa	VPC DOMAIN DUAL ACTIVE STATUS CHANGE EVENT	Major alarm is raised.
0x00210dfb	VPC DOMAIN DUAL ACTIVE CLEAR EVENT	Major alarm is cleared.
0x00210df9	DETECTED ANOTHER DEVICE EVENT	Minor alarm is cleared.
0x00210dfd	PEER DEVICE NOT RESPONDING TO POLLS EVENT	Critical alarm is raised.
0x00210dfe	PEERDEVICE_RESPONDING TO POLLS EVENT	Critical alarm is cleared.

When monitoring your vPC environment, vPC domain models display an alarm state for the following conditions:

Peer Link is Down

The attribute "cVpcStatusPeerLinkStatus" is polled to monitor this condition. A major alarm is raised when the value of this attribute is "down". The alarm is cleared when the value is "up".

Peer-keepalive Link is Disabled or PeerUnreachable or suspendedasdestipunreachable or misconfigured

The attribute "cVpcPeerKeepAliveStatus" is polled to monitor this condition. A major alarm is raised for this condition. The alarm is cleared when the value of this attribute is "Alive".

Dual Active Detected

The attribute "cVpcDualActiveDetectionStatus" is polled to monitor this condition. A critical alarm is raised if the value of this attribute is "True". In this case, the two alarms that are mentioned before are made symptoms to this critical alarm. The alarm is cleared when the value changes to "False".

Third Device found with the same vPC Domain ID

A minor alarm is raised when a third device is found the same domain id.

vPC Peer Switch is Down

This condition applies to the peer switch when it stops responding to polls. In this case, a critical alarm is raised.

> **NOTE**
>
> Non-vPC alarms (like NCM, SPM, so on) are not rolled to vPC domain container models. Alarms are raised only for the vPC conditions that are mentioned here.

vPC Views in OneClick

For each vPC domain model, the **Alarms**, **Events**, and **List** tab in the **Contents** pane displays alarms, events, and details of peer switches. The **Information** tab displays the following information under the **Virtual Port Channel (vPC)** view:

Configured Primary

This field displays the peer switch that is configured as primary.

Configured Secondary

This field displays the peer switch that is configured as secondary.

Current Primary

This field displays the peer switch that is operationally primary.

Host Link status

This field displays the following information for each peer switch:

Host-Link Interfaces Index

This field displays the interface index.

Host-Link Interface Name

This field displays the PortChannel configured on the corresponding interface index.

Host-Link Interface Status

This field displays the status of the interface index.

Spotlight View for vPC Domains

From the **Universe** topology, you can use the **Spotlight** view to directly view the vPC specific details of all vPC domains.

Follow these steps:

1. Select **Universe** container from the Navigation pane.
2. Click **Spotlight View** from Topology tab, and Select **vPC Domains**.
   The vPC Domains List dialog appears.
3. Select the required vPC domain from the list, and select **Hide Icons**.
   You can see the two vPC peer switches of that domain.

Locater Search for vPC Peer Models

You can find vPC peer switches using the **Locater** search from the Navigation pane. The **Locater** search includes the **vPC Manager** folder for this purpose. You can find vPC peer switches using the following two options:

All vPC peer Models using vPC Domain ID

Use this option to find by the Domain ID. If there are multiple vPC domains, click the **List** button to enter Domain IDs using the available delimiters. You can also import a text file that contains a list of Domain IDs (use newline, comma, space, or semi-colon as the delimiter).

All vPC peers

Use this option to find by Landscapes.

Troubleshooting Tips

If vPC domains and their vPC peer models are not created in the Oneclick, consider the following points:

1. Check whether the firmware version that is running on the vPC devices is below 6.2, and upgrade to leverage the vPC support. CISCO-VPC-MIB is supported only from firmaware version 6.2 and above.
2. After an upgrade, you must reconfigure the vPC enabled devices in OneClick using the reconfigure option.

Virtual Switching System (VSS) Support

Overview

VSS devices are support from the 10.0 release. Virtual Switching System (VSS) is a network system virtualization technology, it pools two Cisco Catalyst Switches into one virtual switch. VSS helps in increasing operational efficiency by boosting nonstop communications. VSS simplifies the network by reducing the number of network elements and hiding the complexity of managing redundant switches and links.

One virtual switch member chassis act as an Active virtual switch, while the other member is in Standby state. Even though one member is in Standby mode both chassis act as active and forward the traffic. When one of the virtual switch members fails, there is no convergence of protocols in the network and no disruption occurs to the traffic flowing through the VSS.

DX NetOps Spectrum supports the following Cisco VSS devices:

Device Type Name	System Object ID
Cat 65xx Virtual Switch	1.3.6.1.4.1.9.1.896
Cisco C68xx Virtual Switch	1.3.6.1.4.1.9.1.1934

NOTE

Contact CA Support for information on other Cisco Catalyst VSS device support.

Monitor VSS devices

Once the VSS device is modeled in DX NetOps Spectrum, Chassis container models are created for the VSS device in the Cisco folder under the Chassis Manager. DX NetOps Spectrum detects the role of Chassis container models as Active and Standby. The Active Chassis container model is shown in solid green () color and the Standby chassis container model is shown in light green () color. By expanding the chassis container models you can see the associated modules.

Use the following navigation to view the virtual switches under the Chassis Manager.

OC Navigation -> Chassis manager -> Cisco -> <VSS> ->Chassis containers (Active and Standby)

The Interfaces tab in the Component Detail pane shows the Chassis container models, associated modules and interfaces.

NOTE

After DX NetOps Spectrum upgrade, the VSS Chassis container models of the Cat 65xx Virtual Switch (System Object ID: 1.3.6.1.4.1.9.1.896), which is modeled in the earlier release are not displayed. To view these VSS Chassis container models you must model the Cat 65xx Virtual Switch again after upgrade to the current release.

Cisco Virtual Switch Information view

When you select the VSS device from Explorer tab, the Information tab under the Contents pane shows the Cisco Virtual Switch Information.

You can expand the Cisco Virtual Switch Information to see the following sub views:

- Chassis Information
- VSL Port Statistics
- VSL Statistics
- VSL Connection Information
- Core Switch Configuration

You can expand each sub view for detailed information.

VSS Chassis Information

This view is shown for VSS Chassis containers models. The Information tab under the Component Details pane shows the VSS Chassis Information along with its General Information and Asset Information.

You can expand the VSS Chassis Information to the following details:

- Chassis Switch ID
- Chassis Uptime
- Chassis Role
- Chassis CoreSwitchPriority
- Chassis CoreSwitchPreempt

Locater Search for VSS Models

You can find VSS devices using the **Locater** search from the Navigation pane. Under the Locater tab the Chassis folder contains the sub folder VSS. You can find VSS models using the following two options:

All Chassis Containers

Use this option to find the Chassis container models of VSS devices.

All VSS Devices

Use this option find all VSS Devices.

VSS Alarms and Correlation

When monitoring your VSS environment, VSS models display an alarm state for the following conditions:

VSS CONFIGURATION PROBLEM

It is a critical alarm. Spectrum raises this alarm when it detects a problem in VSS setup. The alarm is cleared when the Spectrum detects the setup is back to normal.

CHASSIS CONTACT LOST

It is a critical alarm. Spectrum raises this alarm when one of the VSS Chassis container model is down. The alarm is cleared when the VSS Chassis is up.

Correlation:

The CHASSIS CONTACT LOST alarm is correlated to VSS CONFIGURATION PROBLEM alarm.

VSS DUAL ACTIVE DETECTED

It is a critical alarm. Spectrum raises this alarm when a dual active detected trap “cvsDualActiveDetectionNotif” is sent by a VSS device. The alarm is automatically cleared when the VSS setup is back to normal.

Correlation:

The VSS DUAL ACTIVE DETECTED alarm is correlated to CHASSIS DOWN alarm.

The CHASSIS CONTACT LOST Critical Alarm and VSS CONFIGURATION PROBLEM critical Alarm is correlated to VSS DUAL ACTIVE DETECTED Critical Alarm.

VSL CONNECTION DOWN

It is a minor alarm. Spectrum raises this alarm when ‘cvsVSLConnectionChangeNotif’ trap is received with ‘cvsVSLConnectOperStatus’ as down. The alarm is cleared when the ‘cvsVSLConnectionChangeNotif’ trap is received with ‘cvsVSLConnectOperStatus’ as up.

Event id: 0x210df5

This event is generated when the VSS Chassis container model changes its role.

Cisco Nexus devices that support Virtual Device Context (VDC)

Overview

The Cisco Nexus devices, with NX-OS software which support Virtual Device Contexts (VDCs), allow the partitioning of a single physical Nexus device into multiple logical devices. This logical separation provides the following benefits:

- Independent Administrative and Management capability
- Change and failure domain isolation from other VDCs
- Isolation of Address, VLAN, VRF, and vPC

The virtual device context allows for the partitioning of a single physical device into more than one logical device. A Cisco Nexus device can support one Admin VDC and multiple non-default VDCs. Each VDC is a virtual entity that can be provisioned, configured and managed like a single physical chassis device.

You need to discover and model each VDC in DX NetOps Spectrum using their individual IP management address. For each device that supports VDC, a container is created and the VDCs within the device will be grouped within the same container in the Universe hierarchy. In 10.2, the CiscoVDC container contains all the VDCs that Spectrum discovers and models, specific to the device whose management IP you have used for discovery and modeling.

If the Cisco VDC Container is initially named after the non-admin/ default VDC context, the container name is updated to reflect the Admin VDC context, once the Admin VDC devices are identified.

From the 10.2.1 release, the container hierarchy creation is no longer created within the Universe hierarchy. A new Virtual Device Manager hierarchy is created in the Explorer view, where all the Cisco Nexus devices that support virtual device context are discovered, modeled and are named based on the Admin VDC context. The existing hierarchy functionality is carried forward from 10.2, while individual devices are still visible in the Universe hierarchy.
This change was made as creating the CiscoVDC container within the Universe hierarchy was blocking the overall topology view of the device along with the connectivity with the neighboring devices of the VDCs. As a result, router connectivity with particular VDC/ devices was not visible in the Universe view and neighboring connections were displayed to the CiscoVDC container rather than the actual VDC, until the user actually drilled down to the VDC container.

> **NOTE**
>
> Till 10.2 the container (CiscoVDC) containing the Cisco VDC devices was created within the Explorer view, from 10.2.1, the Virtual Device Manager container is created and all Cisco nexus devices which support VDC and have a virtual context are discovered and modeled under this Virtual Device Manager hierarchy.

Topology View

In DX NetOps Spectrum, each Cisco Nexus device which supports VDC, is represented by a container. The container will be named on the first modeled VDC. Once the Admin VDC is discovered, the container will be renamed to the Admin VDC context.

If you are upgrading to 10.2.1 from 10.2 and have discovered and modeled Cisco VDC devices with a virtual context in 10.2, after the upgrade is complete, the CiscoVDC container will be removed/ deleted from the Universe hierarchy and all Cisco Nexus devices with a virtual context will be discovered and modeled under the Virtual Device Manager hierarchy in the Explorer view. You can still see individual Cisco Nexus devices under the Universe view.

From 10.2.2, the Topology view for CISCO VDC container is not available, as the contexts are placed under Universe and connectivity details are shown in the Universe topology.

If you have already modeled the Cisco Nexus devices in 10.2.0 and have the Cisco VDC container in Universe hierarchy, after upgrading to 10.2.1. To move the Cisco VDC devices out of VDCContainer into Universe, remove VDCContainer, follow these steps

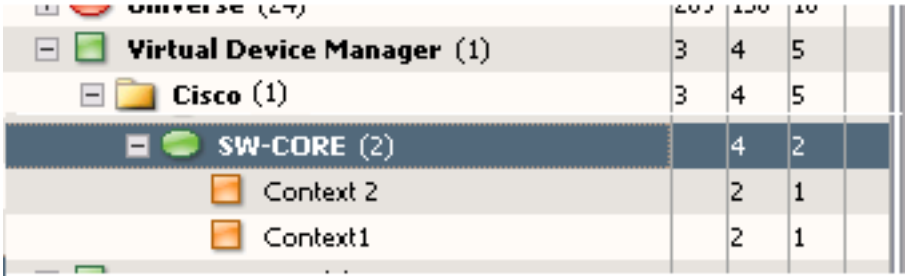
1. Download the following script:
   150
2. Unzip the UpgradeVDC.zip into the <SPECROOT> directory on each SpectroSERVER.
3. Run the script from the command line with no options.
   ```
   ./UpgradeVDCpl.pl
   ```
4. Please run the script on all SpectroSERVERs (that have Cisco Nexus devices modeled.) in a DSS environment. The Cisco VDC container hierarchy is deleted from the Universe view, and the Cisco Nexus devices are now available/ modeled in the Virtual Device Manager hierarchy.

Once you have completed running the script, a summary of actions performed by the script is displayed. See the sample below:

```
####### Summary Report #######
Total CiscoNXOS Models Found:
Actual Models in VDC container:
Total parent associations destroyed:
Total child associations destroyed:
Total VDC App models:
Total VDC App models having Cisco VDC Type null or 0:
Total VDC App models deleted:
Total VDC Container models deleted:
```

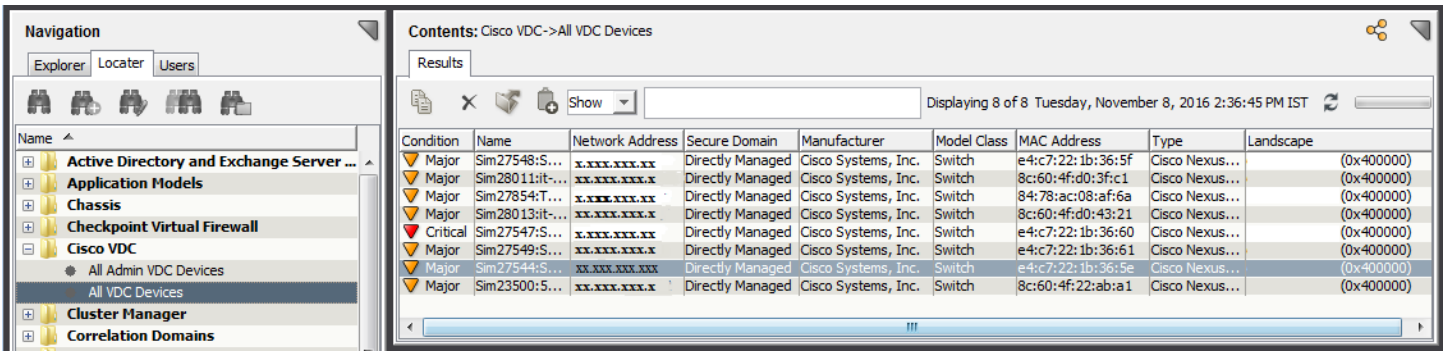
To view the models (related to Cisco Nexus devices that support VDC) in its relevant context, follow these steps:

In the OneClick Console, **Explorer View**, navigate to the **Virtual Device Manager** > select VDC container.



Locater Search for Cisco VDC

You can use pre-configured searches to locate VDC (Virtual Device Context) entities related to Cisco Nexus devices (that support VDC), in the DX NetOps Spectrum database quickly. The searches are grouped under the **Cisco VDC** folder in the **Locater** tab of the **Navigation** panel, as shown below:



The following searches are specific to Cisco VDC models:

Cisco VDC

Locates all devices that are modeled in the DX NetOps Spectrum database that has been identified as serving the specified role in one of the following searches:

- **All Admin VDC Devices**: This search will return all Admin VDC devices
- **All VDC Devices**: This search will return all VDC devices discovered and modeled

Follow these steps, to view VDCs associated to Cisco Nexus 7000 Series devices:

1. Navigate to **Locater** tab, **Cisco VDCs**, and select one of the following:
   – All Admin VDC Devices:
   – All VDC Devices:
2. Select the landscapes you wish to search against, in the Select Landscapes to the Search dialog box.
3. Click OK.
   The results matching your query are displayed in the Contents pane.

Alarm Correlation

After modeling of the logical VDCs is complete, DX NetOps Spectrum monitors the virtual entities normally as independent switch / physical chassis devices. As a result, when any number of VDC's go down within the Cisco Nexus VDC container, the corresponding number of alarms is generated on Spectrum.
Accordingly, if the container is down and assuming that the VDC's are functioning independently as per functionality, all VDCs will go down and raise separate alarms. However, if all the VDCs within the container go down, using its correlation domain capabilities, DX NetOps Spectrum suppresses the alarms for all VDCs and generates a single alarm on the container.

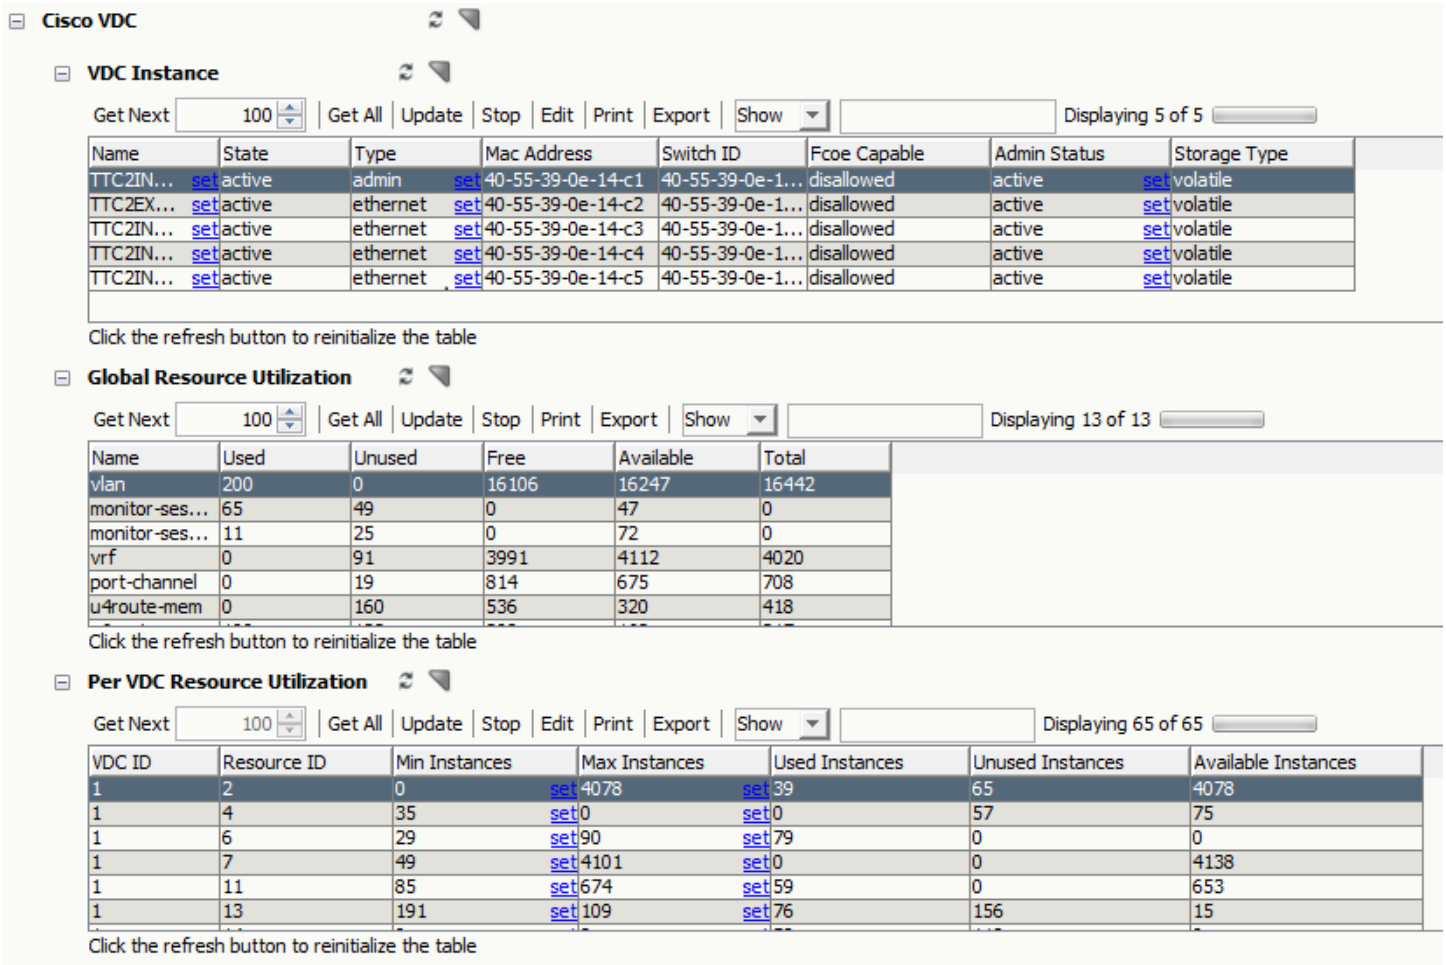
Cisco VDC Information Tab

To view the Cisco VDC Information, navigate to the **VDC context > Information Tab> Cisco VDC** (under the container which represents the physical device in DX NetOps Spectrum.)
Information is displayed under the following categories:

- **VDC Instance**
- **Global Resource Utilization**
- **Per VDC Resource Utilization**

NOTE

The container will be named on the first modeled VDC, which is renamed to the Admin VDC context after the Admin and child contexts are identified/ discovered.



VDC Instance

Field	Description
Name	The human-readable name of the instance. This name uniquely identifies the VDC Instance in the system.
State	This object indicates the current operational state of the virtual device.
Type	This object indicates whether the VDC instance is in Admin or non-admin context.
MACID	This object indicates the router MAC address of the virtual device
SwitchID	This object indicates the MAC address of the device where the virtual device instance is created.
fcoe Capable	This object indicates the FCoE capabilities of the virtual device
Admin Status	This object indicates whether the Admin status for the device is enabled or suspended.
Storage Type	This object specifies the storage type for this conceptual row.

NOTE

The following columnar objects are allowed to be writable when the storageType of this conceptual row is permanent(4):none

Global Resource Utilization

Field	Description
Name	This object indicates the name of the resource on the device.
Used	This object indicates the number of instances of a particular resource that is currently in use.
Unused	This object indicates the number of instances of a particular resource that are reserved, and currently not in use
Free	This object indicates the number of instances of a particular resource that still remain to be used.
Available .	This object indicates the number of instances of a particular resource that are available to be allocated
Total	This object indicates the total number of a particular resource

Per VDC Resource Utilization

Field	Description
VDC ID	A unique value, greater than zero, that uniquely identifies a type of resource.
Resource ID	A unique value, greater than zero, that uniquely identifies a type of resource.Min Instances
Min Instances	This object specifies the minimum number of instances of a particular resource that needs to be allocated to a particular VDC.
Max Instances	This object specifies the maximum number of instances of a particular resource that allows being allocated to a particular VDC.
Used Instances	This object indicates the number of instances of a particular resource that is currently in use for a particular VDC.
Unused Instances	This object indicates the number of instances of a particular resource that are reserved, and currently not in use for a particular VDC.
Available Instances	This object indicates the number of instances of a particular resource that is available to be allocated for a particular VDC.

Cisco ASA (Adaptive Security Appliance) Devices Failover

Cisco Adaptive Security Appliance (ASA) device family delivers enterprise-class firewall capabilities for ASA devices in an array of form factors - standalone appliances, blades, and virtual appliances - for any distributed network environment. ASA software also integrates with other critical security technologies to deliver comprehensive solutions that meet continuously evolving security needs. Cisco ASA devices offers a combination of enterprise-class stateful firewalls with a comprehensive range of next-generation network security services.

With respect to Cisco ASA (Adaptive Security Appliance) devices failover, DX NetOps Spectrum has the following capabilities:

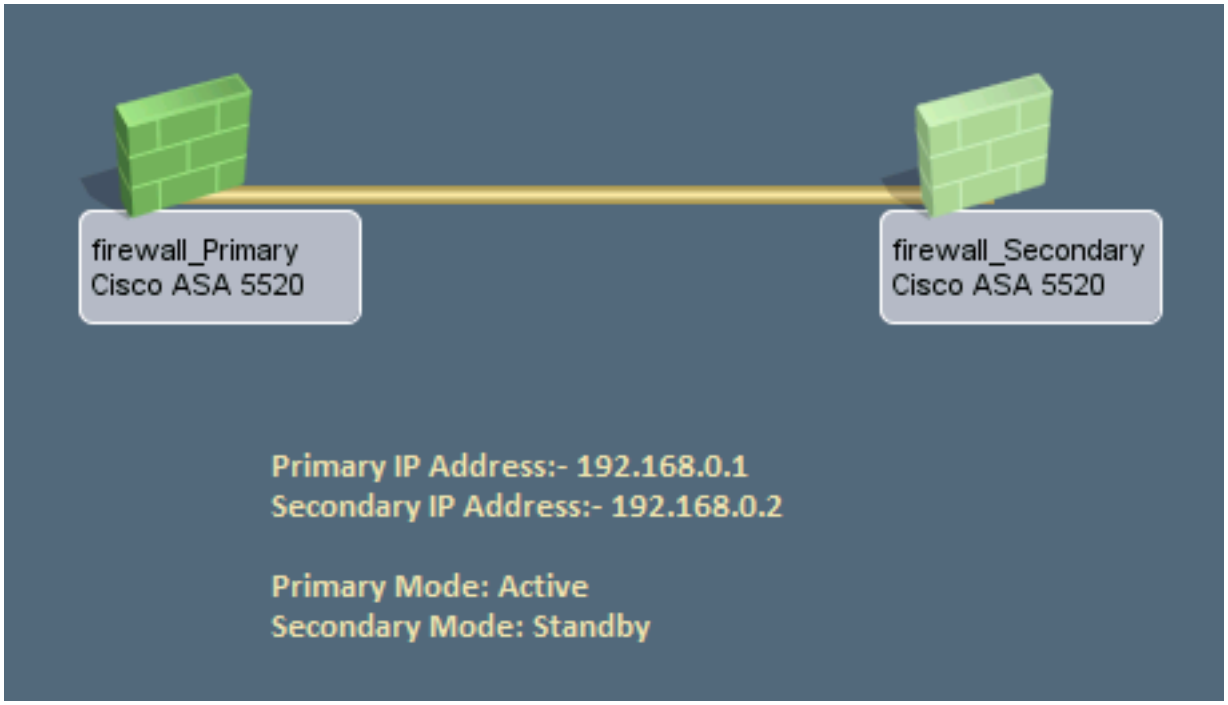
- Identifies Primary and Secondary device and appends the text to model name.
- Generates alarm if the Primary device goes to standby.
- Changes the ASA device status to Active/Standby or Active/Active.
- Polls and discovers changes of Failover States of Cisco ASA Firewalls
- Discover Connections and update the topology, when the failover occurs

NOTE

DX NetOps Spectrum does not support the Network Configuration Manager (NCM) capabilities for Cisco ASA firewall devices.

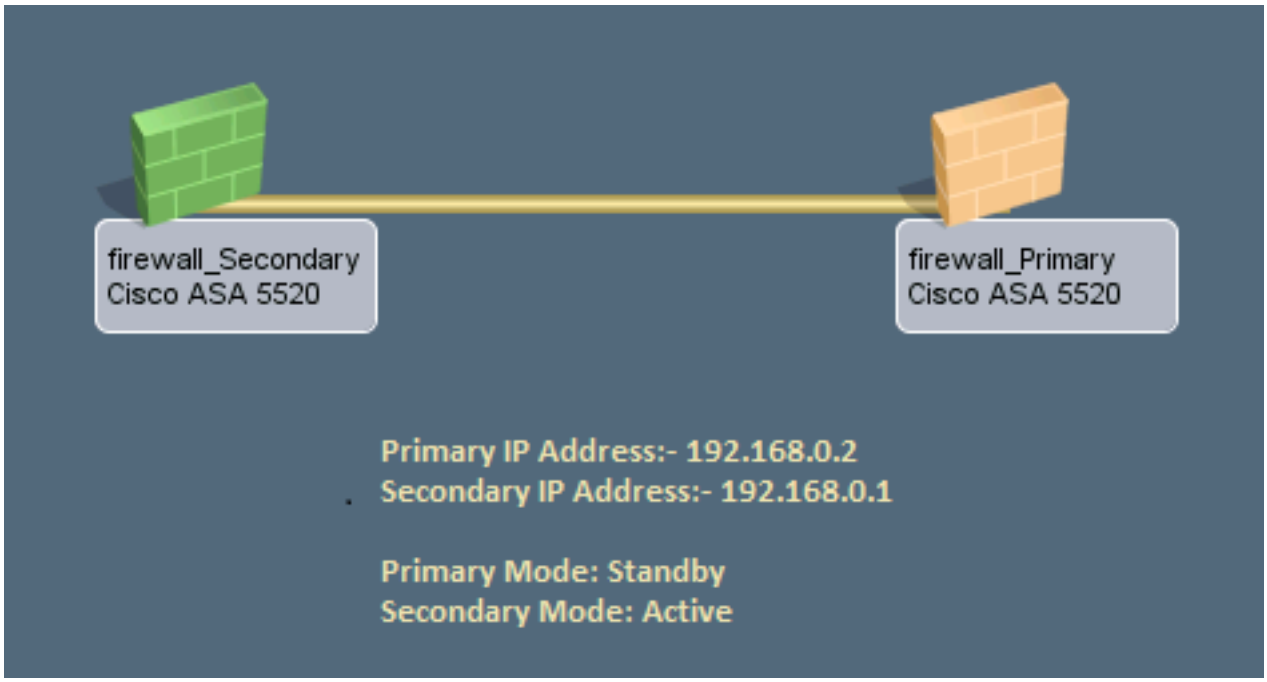
Prerequisites to Cisco ASA Firewall devices Failover Scenario:

- The Spectrum model type must be Cisco ASA. This functionality does not exist on the GnSNMPDev modeltype. To confirm:
  a. Open the Spectrum Modeling Information subview in the Component Detail of your device.
  b. Review the “Model Type Name” field on the right hand side. If it shows as GnSNMPDev (and the device is a Cisco ASA), you need to self certify your system object id from GnSNMPDev to Cisco ASA. Refer to the Self Certification Documentation.
- The two Cisco ASA Firewalls are in a **Primary** and **Secondary** Mode, which ideally means that Primary Firewall is **Active**, whereas the Firewall in secondary mode is in **Standby**.
  See image below for reference: The ASA device on the left is the Primary (Active) device, while the one on the right is the Secondary (Standby) device.



- When a failover happens, the two Firewall devices switch their configuration.
- This means that they switch their Management IP Address as well. This Management IP Address is used to model both devices in Spectrum.
- The MAC Addresses for active interfaces are also switched.

As a result, when such a Failover occurs, the modeling information in Spectrum is no longer accurate because of the IP Address switch.

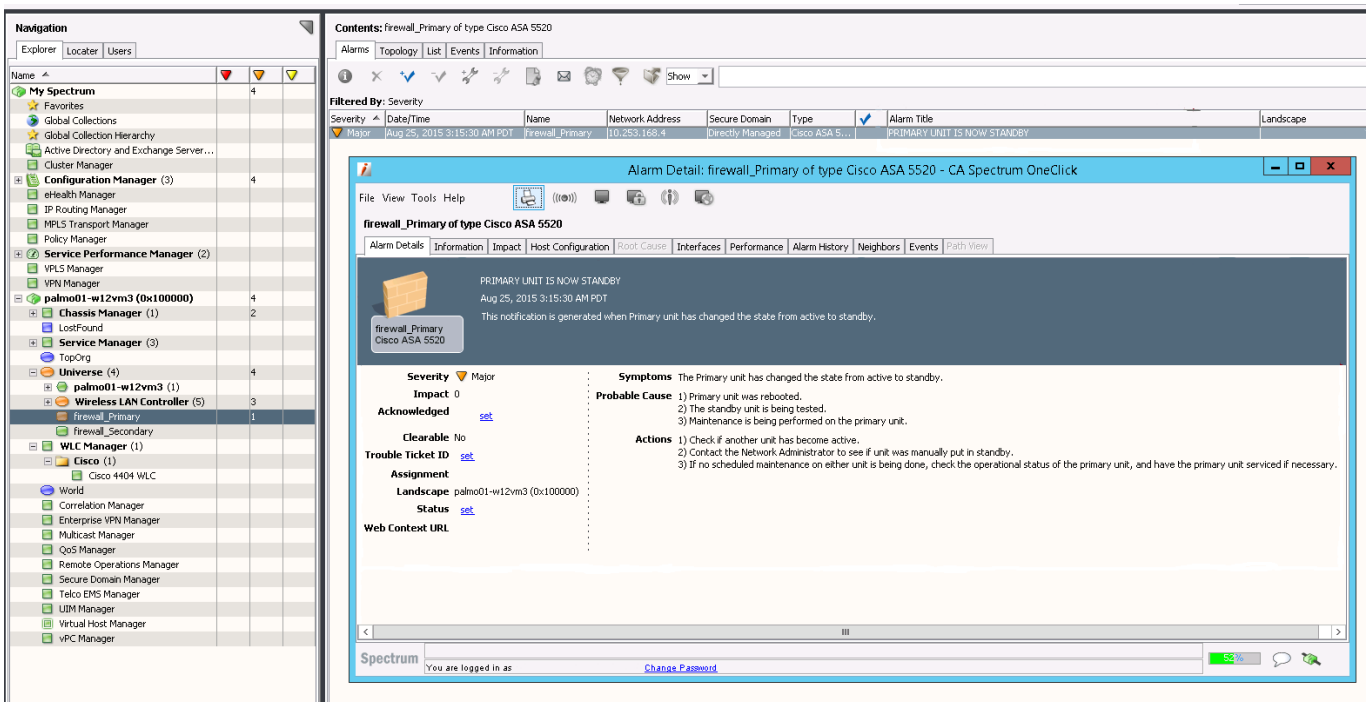


Expected Result:

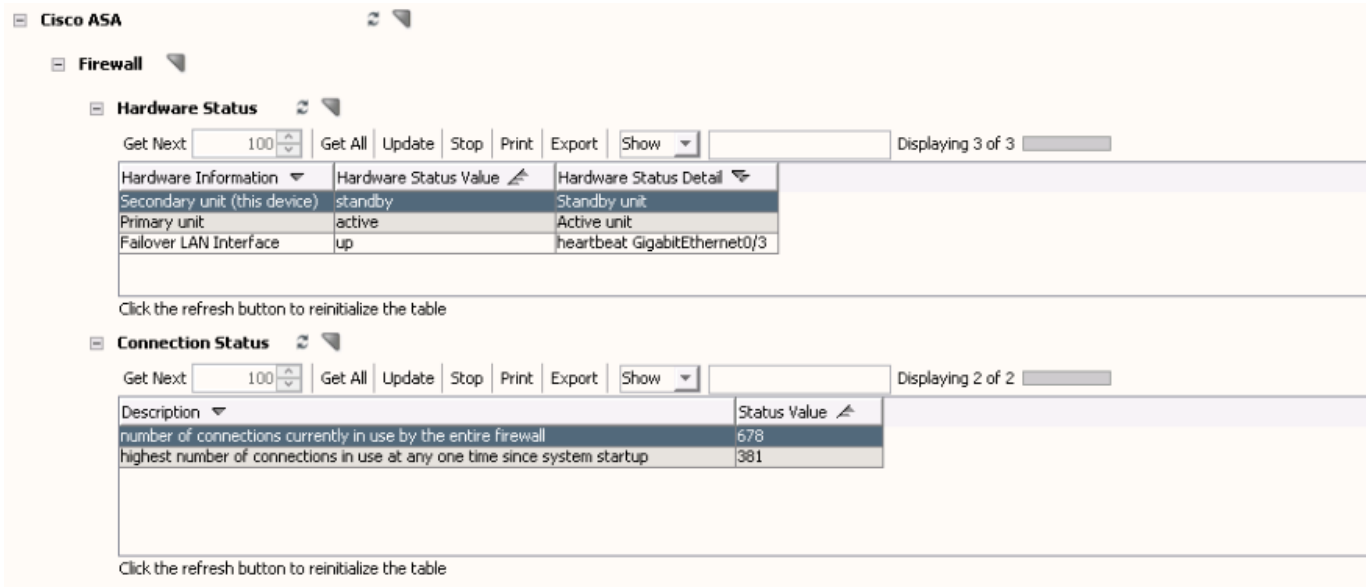
- When failover occurs on the primary device, secondary firewall device should become **Active** and primary firewall device becomes **Standby**.
- The following text: "**_Primary**" & "**_Secondary**" is appended to the model name automatically in the topology view, if the the default value is set to True.

When a Cisco ASA firewall device state goes down or is turned to standby by an Admin user manually, the following sequence of events occurs:

1. The Primary ASA device state turns from **Active** to **Standby**.
2. A major alarm "**PRIMARY UNIT IS NOW STANDBY**" is triggered on the primary device.



3. Once the the Primary ASA device is **UP** again or is brought back to **Active** state, manually.
   The Alarm "**PRIMARY UNIT IS NOW STANDBY**" is cleared on the primary device.
4. To observe Hardware status of the device, navigate to the selected **Primary Cisco ASA device** > **Information Tab** and expand the **Cisco ASA** > **Firewall** sub-view.
   Based on the hardware status we can identify if the device is **Active**/**Standby**.
   The following information is displayed for Cisco ASA devices, in **Component Detail** > **Information Tab** > **Cisco ASA.**



5. Model names are appended (with **_primary** or **_secondary**) to the device name after every polling interval, if the the default value is set to True.

NOTE

Default Polling Interval is changed to 60 seconds from 300 for Cisco ASA devices. If ***Poll Interval (sec)*** attribute value is changed from 60 to 300, the model name changes will only reflect after 300 seconds.

NOTE

The 10.2.2 release introduces an attribute suffixFWModeToModelName/0x00215325. The default value for this attribute is set as TRUE on the device model type CiscoASA, which allows for the existing functionality of the appended firewall mode (_Primary/_Secondary) to the device model name remain same.

If this value is set to FALSE, the appended firewall mode (_Primary/_Secondary) will not be added to the device model name. Therefore if the firewall mode is already added to the device model name, it will be removed from the device model name in the next polling cycle.

SNMP Support for Cisco Meraki Solutions

10.3.1 introduces SNMP support for a range of Meraki solutions including wireless appliances and switches. These include:

- **Cloud Managed Wireless**
  - Access Points
  - Oid 1.3.6.1.4.1.29671.2.1 till 29
  - Controller
    Oid 1.3.6.1.4.1.29671.1
- **Cloud Managed Appliances**
  - Oid 1.3.6.1.4.1.29671.2.100 till 124
- **Cloud Managed Switches**
  - Oid 1.3.6.1.4.1.29671.2.300 till 349
  - Oid 1.3.6.1.4.1.29671.2.356

Condition Correlation

This section discusses Condition Correlation, its various components, and how you can use Condition Correlation in DX NetOps Spectrum to achieve fault management and root-cause analysis.

About Condition Correlation

DX NetOps Spectrum Condition Correlation supports events, troubleshooting, and root-cause analysis. The Condition Correlation component lets you set up a system in DX NetOps Spectrum to determine the root-cause alarm from a heterogeneous group of managed infrastructure resources (models). You can use Condition Correlation to select the criteria that identify a causal problem event. Such events precipitate a specific set of events, which are in turn identified as symptoms. You can select a set of resources (models) for the correlation to consider and define it as the correlation domain.

Condition Correlation provides the following benefits:

- Respond to the real problem efficiently. Spend less time responding to symptomatic problems.
- Track problem trends and interdependencies.
- Respond quickly to changes in the infrastructure. You can manage multiple Condition Correlation implementations from a single landscape.

Condition Correlation Components

You can use Condition Correlation to construct a system of components that define fault indicators. You can use these components to create a process for fault association. Fault indicators specify the resources that are evaluated by the system. The following components are available to you:

- Conditions
- Rules
- Policies
- Correlation Domains

Before you begin configuring Condition Correlation, we recommend reviewing the predefined component settings. You can see these in the Condition Correlation Editor.

Conditions

Conditions are fundamental building blocks of the correlation system. A condition, like a DX NetOps Spectrum alarm, is a transitory occurrence on a resource, such as status change. A condition exists as long as the criteria that produced the condition are met. As with an alarm, a *set* event always initiates a condition, and a *clear* event clears a condition. When you define a condition, you identify the set and clear event types.

A 'set' event creates an alarm that is associated with the condition. Therefore, a condition can be cleared when the associated alarm is destroyed. Similarly, a condition is also cleared when a rule creates the condition (through its 'set' event), and no set of conditions still fulfills the rule. In this case, the condition is cleared automatically. A condition that a rule created through its set event is an *implied condition*.

You can define the conditions that correspond to DX NetOps Spectrum alarms. If the 'set' event of the condition is same as the set event of the alarm, the condition instance is instantiated after the alarm is generated. The alarm itself is linked within the correlation system. This link lets Condition Correlation hide symptomatic alarms from the main alarm list in OneClick and relate symptomatic alarms to root-cause alarms. The symptomatic alarms are listed in the Symptoms list of the root-cause alarm under the Impact tab.

> **WARNING**
> Alarms that are available at startup are not correlated.

You can also define the parameters for a condition that are used to establish correlation criteria when you create correlation rules. A *parameter* can be any event variable data or any model attribute of the model that is associated with the condition. You can create new parameters, or you can create modified versions of existing parameters.

> **NOTE**
> A correlation condition has no relationship with the condition attribute for a DX NetOps Spectrum model.

Rules

A *rule* defines the relationship between two or more conditions when specific criteria are met. You can define a rule to stipulate that one condition is a symptom of, or the cause of, another.

For example, you can associate a symptomatic SPM test threshold violation condition to a root-cause port LinkDown condition. You can apply this rule in a policy, to a set of SPM test and port models in a domain. In addition, you can create a rule to indicate that one or more conditions imply that another exists.

Rule Patterns

You can express rules in any of the following patterns:

- **Caused By**
  Condition Z causes Condition X or a set of conditions.

A correlation is made when all of the symptom conditions exist, the rule criteria apply, and the root cause condition Z exists. If Z is associated with an alarm, all symptomatic alarms are hidden under that alarm. The condition (color) of the model remains the same as before. For example, if one yellow alarm on the model hides another red alarm on the model, the other model remains red with no alarms displayed.

NOTE
When any of the conditions are cleared, the correlation is not broken.

- **Implies**
  Condition X or a set of conditions implies Condition Z.
  When all of the symptoms exist and the rule criteria apply, the root cause Condition Z is created. A 'set' event is therefore created for Condition Z, which can then create an alarm. Condition Z is only cleared if any of the symptoms are subsequently cleared, and if no other set of conditions still supports the rule. But if the condition creates an alarm, the alarm is only cleared if the condition has a 'clear' event, which must clear the alarm. Therefore, the alarm can remain, depending on its configuration.
- **Implied Cause**
  Condition X or a set of conditions is the implied cause of Condition Z.
  The Caused By and Implies pattern combines both of the previous patterns.

WARNING
Correlation using the same condition as the symptom and the cause fails.

You cannot set up a correlation using the same condition (such as implied cause) as both symptom and cause. However, you can create another condition with the same set or clear events and can use the condition as the root cause.

Example

Set up Condition A, and Rule A implies Caused by A on the correlation domain. When Alarm A is created on a device in the domain, you can see that another Alarm A is created on the correlation domain model. However, the Alarm A on the device does not become a symptom of the domain alarm.

To make the alarm a symptom of the domain alarm, you can create a B condition, similar to A, with a rule that Condition A implies Caused by B on the correlation domain.

Other Patterns

Condition Correlation lets you construct more granular rule patterns using more rule criteria that must be met before a correlation is established between two conditions. You can specify the criteria by comparing the parameters of one condition with another or in terms of specific values.

For example, an instance of a LinkDown condition on a port model can be caused by an instance of a BoardPulled condition on a board. This relationship can occur if the slot number of the port is equal to the slot number of the board, and both the port and the board are from the same device.

Policies

A *policy* is a set of one or more rules. You can group any number of rules in a policy. You can apply one or more policies to any number of resource groups (in a domain).

Use policies to simplify the implementation of rules for multiple domains. All implementations of a policy are updated after you add, edit, or remove rules from a policy.

Correlation Domains

A *correlation domain* is a group of resources that is created as a DX NetOps Spectrum container model. Condition Correlation assesses these resources collectively. This assessment is based on the rules in the policies that are applied to it. A domain can include any number of models of various model types and can have any number of policies applied. Therefore, when you select the resources in a domain, you are also deciding what is evaluated by the policy or policies that are applied to it.

You have multiple options for creating a correlation domain and populating it with resources. You can add resources on a per-resource basis. Or you can create a domain from a service or Global Collection model, which are entities that represent collections of resources.

The Condition Correlation Editor

The Condition Correlation Editor window lets you create and manage correlation system components. The window also lists and provides access to all predefined and custom (user-defined) components.

The Condition Correlation Editor window contains the following tabs:

- **Conditions**
  Lists the predefined and custom conditions. Select a condition to see a list of corresponding parameters.

  NOTE
  Not all conditions include parameters.
- **Rules**
  Lists the predefined and custom rules. When you select a rule, the corresponding correlation criteria of that rule are listed in the Rule Criteria tab.
- **Policies**
  Lists the predefined and custom policies. Select a policy to see the corresponding rules of that policy on the Rules tab.
- **Domains**
  Lists the predefined and custom domains. When you select a domain, the corresponding policies of that domain and resources are listed in the Policies tab and the Resources tab respectively.

The Condition Correlation Editor provides buttons to let you create, edit, copy, and delete conditions, rules, policies, or domains.

Use the Filter field to specify the condition, rule, policy, or domain entries to display in the editor window.

Open the Condition Correlation Editor

The Condition Correlation Editor lets you configure all Condition Correlation component settings. You must have OneClick administrative privileges to access the Condition Correlation Editor.

Follow these steps:

1. Log in to OneClick.
2. Select Tools, Utilities, and then Condition Correlation Editor.
   The Condition Correlation Editor window opens. By default, it displays the Conditions tab list and any parameters that are defined for the selected condition.

Condition Correlation Import and Export Features

You can import or export correlation data using the Import or Export features in the Condition Correlation editor. The following options are available in the Condition Correlation editor:

- **Export**
  Exports the correlation data and saves it to an XML file.
- **Import**
  Imports the correlation data from an XML file. The three scenarios that can occur while you import the data are as follows:
  - **SKIP**
    Defines the entry that already exists. The skipped entries are prefixed with [SKIP].
  - **REPLACE**

Replaces the existing entry of the same name and type only if you enable the Replace Existing option. The replaced entries are prefixed with [REPLACE].

– **IMPORT**
Defines all other entries that are not prefixed with SKIP or REPLACE. These entries are prefixed with [IMPORT].

NOTE
The import and export of domains is not supported.

How to Create a Condition Correlation Domain

Deploying a correlation system to a particular group of managed infrastructure resources is synonymous with creating a correlation domain. Once the domain is created on a landscape, the correlation system is in effect.

NOTE
Condition correlations are implemented in a SpectroSERVER or in multiple SpectroSERVERs. Therefore, condition correlations are not affected if you start or stop the OneClick web server.

Verify the following information before configuring the required domain parameters:

- A domain has at least one policy that is applied to it.
- The policy includes at least one rule.
- The rule criteria are logically appropriate for the conditions it evaluates for a correlative association.

WARNING
Attempt to produce a problem to manage and test the correlation system before you deploy the system in a production environment.

Perform the following tasks to create a condition correlation domain:

1. Create a domain and add the resources that you want include in it. In a later step, you can apply one or more correlation policies to the domain.
   Once you have created a domain, you can add resources to it and can remove resources from it at any time.
2. Create one or more conditions that you want to be evaluated by correlation rule criteria.

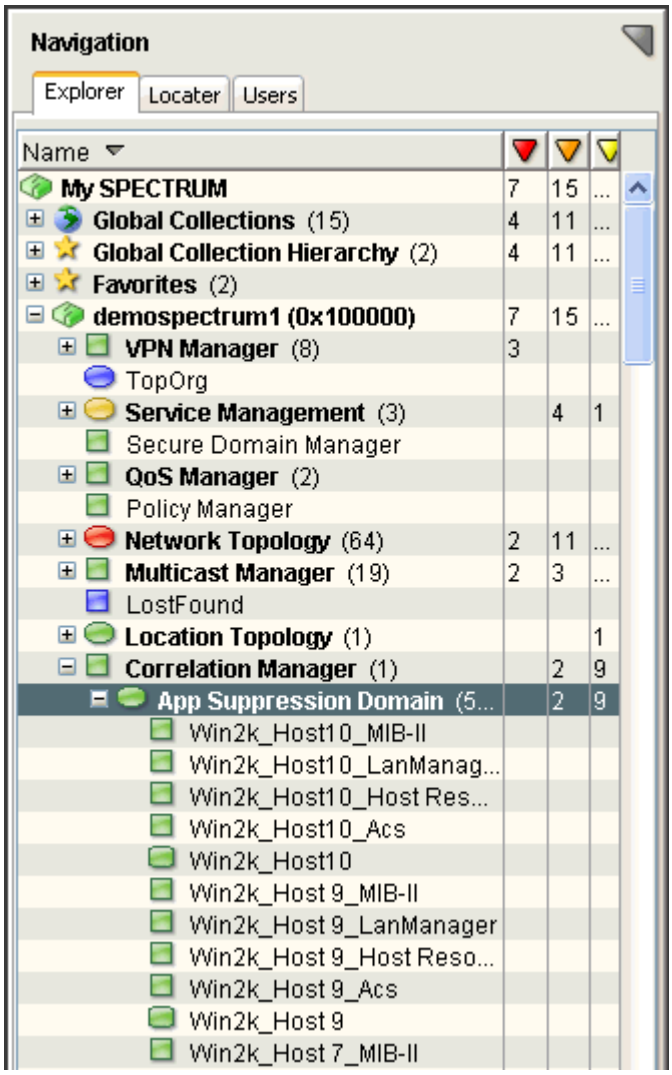
   NOTE
   If you want to use available conditions, skip this step.
3. Create the rule or rules that establish root-cause condition and symptomatic condition associations if criteria specified by the rules are met.

   NOTE
   If you want to use available rules (such as rules that specify predefined conditions), skip this step.

   A rule evaluates two or more conditions. If rule criteria are met, Condition Correlation identifies one condition as the root-cause condition and the other conditions as symptomatic of the root-cause condition. Once you have created a rule, you can modify its criteria or the conditions it evaluates at any time.
4. Create the policy or policies that contain the correlation rules to associate with the domain.
   Note: If you want to use available policies, skip this step. You can add rules to or can remove rules from a policy at any time.
5. Apply one or more policies to the domain.

   NOTE
   Existing correlation domains adjust to policy changes automatically, keeping the correct correlation state.

   The Condition Correlation process is in effect for the resources that are included in the domain. The domain is modeled as a correlation domain container in OneClick.
   The following image is an example for domain container and the resources included in it:



Creating and Managing Conditions

This section explains how to create and manage conditions using the Condition Correlation Editor. Creating a condition involves creating parameters. Managing parameters and conditions involves editing, copying, or adding new and deleting old parameters (values) or conditions.

Create a Condition

Conditions are fundamental building blocks of the correlation system. A Condition, like a DX NetOps Spectrum alarm, is a transitory occurrence on a resource, such as status change. A condition exists as long as the criteria that produced the condition are met. As with an alarm, a set event always initiates a condition, and a clear event clears a condition.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Conditions tab.
   A list of conditions is displayed.

3. Click the Create icon  .
   The Create Correlation Condition dialog opens.
4. Specify a value for the following condition properties:
   - **Condition Name**
     Defines the condition. For example, supply the names Power_Outage and Battery_On.
   - **Set Event Code**
     Identifies the DX NetOps Spectrum event code that is associated with the condition. When you define a condition, the set and clear event types are identified
5. (Optional, for an advanced correlation only) In the Parameters section, to specify parameters, click the Create icon  .
   The Create Parameter dialog opens. You can create parameters for the conditions as desired. For more information, see Create Parameter.
6. Click OK.

A new condition is created and added to the Conditions tab list. The Author property identifies you as the condition author.

Create a Parameter

A condition *parameter* can be any event variable data or any model attribute of the model that is associated with the condition.

Parameter values are filled in at the time the condition is created, from the event that created it, or from the model where the event was created. These parameters are then available in the Advanced Rule Criteria section.

For count conditions, a *count* parameter is available automatically, after you select that condition type in the rule.

Follow these steps:

1. Click 
   (Create) in the Parameters section.
   The Create Parameter dialog opens.
2. Provide a value for the following parameter properties:
   - **Parameter Name**
     Identifies the parameter. Provide a name that indicates the parameter type.
   - **Parameter Type**
     Specifies the type of parameter. Choose *one* of the following options:
     - Model Attribute: Specifies a model attribute parameter type.
     - Var Bind: Specifies a Var Bind parameter type.
     - Predefined: Specifies a Model, Model Type, or Device Model.
   - **Parameter ID**
     Identifies the type of parameter.
     If you select Model Attribute, click Attribute to open the Attribute Selector dialog and select the appropriate Model Attribute ID.
     If you select Var Bind, enter the Var Bind variable number that is associated with the trap for the model.
     If you select Predefined, select *one* of the following attributes from the adjacent Parameter Type drop-down list:

- Model: Enter the Model_Handle associated with the condition (Attribute ID 0x129fa).
- Model Type: Enter the Model_Type_Handle of the model that is associated with the condition (Attribute ID 0x10001).
- Device Model: Enter the Device_Mdl_Handle of the model that is associated with the condition (Attribute ID 0x10069).

– **Use as discriminator**
Designates the parameter as a discriminator. This setting lets you clear only the 'set' events that include parameter values that match the values in the 'clear' event. You can designate multiple parameters as discriminators. When condition parameters are designated as discriminators, the condition maintains the parameter values that were in place when the set event produced the condition. A condition can only be cleared if the 'clear' event contains parameter values that match the values in the 'set' event.

NOTE
To use different discriminators for special situations, you can use the same condition discriminators that the associated alarm uses. If you use the same condition discriminators as the alarm, the conditions match the alarms and clear accordingly.

3. Click OK.
The parameter is created.

Manage a Parameter

You can edit, copy, and delete the parameter values of all parameters that are listed in the Parameters section.

Follow these steps:

1. Select the parameter in the Parameters section and click

(Edit).
The Edit Parameter dialog opens.
2. To copy a parameter,
click 
(Copy).
The Copy Parameter dialog displays the property conditions of the parameter you selected.

NOTE
The Parameter Name is suffixed with _COPY because the new parameter is copied from an existing parameter and contains a unique name. If the name is already in use, a Name already exists message appears.

3. Edit the properties of the parameter as necessary, and click OK.
4. To delete a parameter, click

(Delete).
The selected parameters are removed from the Condition Parameters list.

NOTE
You cannot delete a parameter that is still in use by a rule.

Manage a Condition

In the Condition Correlation Editor window, you can edit, copy, and delete a condition from the list of predefined (CA-authored) and custom (user-authored) conditions. You can permanently delete user-authored conditions, but you cannot delete predefined conditions. If you or another user has edited and assumed ownership of a predefined condition, you can delete it temporarily. The Condition Correlation Editor restores the predefined condition with its default settings when you restart the OneClick server. You cannot delete a condition that is in use by a rule.

> **WARNING**
> Any changes that you make to existing conditions forces Condition Correlation to drop all current conditions of the same type.

Follow these steps:

1. Click the Conditions tab in the Condition Correlation Editor window.
   A list of conditions is displayed.
2. Select the condition to edit and click
   
   (Edit).
   The Edit Condition dialog opens displaying the property settings of the condition you selected.
3. Edit the values for the following condition properties:
   - **Set Event Code**
     Identifies the DX NetOps Spectrum event code that is associated with the condition.
   - **Clear Event Code**
     (Optional) Identifies the DX NetOps Spectrum clear event code that is associated with the condition.
4. (Optional, for an advanced correlation only) Specify parameters for the selected condition.
   Update one or more parameters that can be used to determine a correlation that is made between instances of the specified condition.
5. To copy a condition, click
   
   (Copy).
   The Copy Condition dialog opens, displaying the property settings for the condition you selected.

   > **NOTE**
   > The Condition Name is suffixed with _COPY because the new condition is copied from an existing condition and contains a unique name. If the name is already in use, a "Name already exists" message appears.
6. To delete a condition, click
   
   (Delete).
   Condition Correlation removes the conditions from the Conditions tab.

Creating and Managing Rules

This section explains how to create and manage rules.

Create a Rule

A rule defines the relationship between two or more conditions when specific criteria are met. You can define a rule to stipulate that one condition is a symptom of, or the cause of, another condition. For example, you can associate a

symptomatic condition with a root-cause condition. You can apply this rule in a policy or to a set of models in a domain. In addition, you can create a rule to indicate that one or more conditions imply that another condition exists.

Follow these steps:

1. Open the Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Rules tab.
   A list of rules is displayed.
3. Click
   
   (Create).
   The Create Rule dialog opens.
4. Enter a name for the rule in the Rule Name field.
5. (Optional) Click set in the Type column of each item you select, specify the symptom condition to belong to a correlation domain, and select one of the following options:
   - **Exists:** The condition is in the correlation domain.
   - **Not Exists:** The condition is not present in the correlation domain. This option lets you create rules that can only be satisfied if the condition does not exist in the correlation domain.
   - **Counts:** The condition is in the correlation domain, and it enables totals/limits/range comparisons using the Advanced Rule Criteria section of the Create Correlation Rule dialog. This option lets you create rules only if a particular condition exists, reaches a limit, or is in a user-defined range.
     When using a condition for counting, a new parameter is automatically created for that condition named "Condition Count." This count can be used in the Advanced Rule Criteria section, as shown in the following example:
     ```
     TestCondition.Condition Count GREATER_THAN 10.
     ```
     No other parameter can be used for counted conditions. Because multiple copies are present, Condition Correlation cannot determine the condition from which to derive the parameter value.
6. Select one or more symptom conditions in the Symptom Condition(s) list.

   NOTE
   The rule is created based on the selected symptom conditions.
7. Select *one* of the following values from the Relationship drop-down list to specify the relationship between symptomatic conditions and the root cause condition.
   - **Caused By:** The alarm that is associated with the root cause condition caused the associated symptomatic conditions. When the rule is met, OneClick suppresses the alarms for symptomatic conditions and lists them as symptoms under the Alarms view Impact tab in OneClick.
   - **Implies:** The symptomatic conditions suggest the existence of another condition that can be unknown to the management system. When the rule is satisfied, the set event of the implied condition is processed on the target model. This condition can raise an alarm on the target model, but OneClick does not suppress the alarms for symptomatic conditions.
   - **Implied Cause**: This rule incorporates the logic of both the Caused By and Implies rules. The symptomatic conditions are indicative of another condition. The set event of this implied condition is processed on the target model. If this event raises an alarm on the target model, OneClick suppresses the alarms that are associated with the symptomatic conditions. The suppressed alarms are listed as symptoms of the root cause alarm under the Impact tab in OneClick.

     NOTE
     If you select Implies or Implied Cause, the Root Cause Target selection box is displayed on the Correlation Rule dialog. Root Cause Target lets you specify the alarm that can be generated on the correlation domain with which the rule is associated or on one of the symptomatic conditions.

To associate the implied alarm (event) with a model, add the predefined "Model" parameter to the condition that you know is created on the target model. Then select this condition and the "Model" parameter as the root cause target from the Root Cause Target section.
You can imply the condition (event/alarm) on a model where you do not have an alarm and include the model in the correlation. Consider the following examples:

- For a container, select the Model Active condition for that model, and add some rule criteria to identify the correct Model Active condition.
- For a port alarm, add the Device Model parameter to the port condition and add a criterion in the rule that specifies "Model Active.Model EQUAL TO PortCondition.Device Model". The implied condition is created on the desired model. The "Model Active" condition is created once for each model participating in the correlation domain.

NOTE
If you select Implies or Implied Cause, the Clear Symptom condition if Implied Condition is cleared check box is displayed.

8. Select a condition from the Root Cause Condition dialog that caused, or was the implied cause, of the symptomatic conditions.

   NOTE
   You can select only one root cause condition for a rule.
9. (Optional) Select the Clear Symptom condition if Implied Condition is cleared check box.
   The symptom conditions are cleared when the implied condition is cleared. This feature works with a chain of implications similar to the following scenarios:
   – ConditionA implies ConditionB, and ConditionB implies ConditionC
   – You assert ConditionA, and the SpectroSERVER then asserts ConditionB and ConditionC
   – You clear ConditionC, and the SpectroSERVER then clears ConditionB and ConditionA
10. (Optional) Click Show Advanced.
    The Advanced Rule Criteria workspace opens. You can use advanced rule criteria when you have specified condition parameters and you want to establish correlation criteria that are based on parameter or topology values. In addition to the parameter comparison, you can also include topology information (association between models).
11. Click OK.
    A new rule is created and added to the Rules tab list. The Author property identifies you as the author of the rule.

Manage a Rule

In the Condition Correlation Editor, you can edit, copy, and delete rules from the list of predefined and custom rules.

Follow these steps:

1. Click the Rules tab in the Condition Correlation Editor window.
   A list of rules is displayed.
2. Select the rule that you want to edit and click

   (Edit).
   The Edit Rule dialog opens.

   NOTE
   You cannot edit a rule name when the rule is specified in a policy.

3. To copy a rule, click
   
   (Copy).
   The Copy Rule dialog displays the property settings for the rule.

   NOTE
   The suffix _COPY is appended to the Rule Name to provide a unique name for the new rule. A unique name is required.
4. To delete a rule, click
   
   (Delete).
   Condition Correlation removes the selected rules from the list on the Rules tab.
5. Edit the properties of the rule as necessary, and click OK.
   The Condition Correlation Editor saves your changes.

Topology Information

The Advanced Rule Criteria let you specify topology information when you create a rule. Topology rules create associations between models that are used in the correlation rules. You can insert regular parameter criteria, topology criteria, or both. The topology rule criteria, like parameter criteria, are applied to the parameters of conditions. These condition parameters must be the model handles or must be convertible to model handles.

The operator that is used on condition parameters is a relation procedure. The relation procedure lets the rule verify the existence of the relationship between the two models. The operator stands for the type of relationship.

The Topology operator stands for the following relations:

- **Regular Relations**
  Represent regular associations. The rule criteria evaluate to TRUE when the left model is associated with a topology relation to the right model. The following regular relations operators are used:
  – Connects_to
  – HasPart
  – Manages
  – Collects
  – Correlates
- **Special Relation**
  Represents special associations. The rule criteria evaluate to TRUE when the left model is a port of the device model on the right. One special topology relation operator is available: IsPortOf.

Update Topology Operators in Configuration Files

The topology operator is a relation procedure that checks whether the relationship exists between two models. You can use all available topology operators in your correlations. DX NetOps Spectrum also lets you update the topology operators in the configuration files.

Follow these steps:

1. Copy the topology association configuration file, *$SPECROOT*/tomcat/webapps/spectrum/WEB-INF/event/config/topology-criteria- operator-choices.xml, to the *$SPECROOT*/custom/event/config area.

   NOTE
   Create the *$SPECROOT*/custom/event/config directory if it does not exist.

2. (Optional) Update the configuration file to add, delete, or modify a topology operator.
   Note: You can add or remove any number of topology operators from the configuration files.
3. Restart the Tomcat web server.
   The updates take effect when you reopen the Condition Correlation Editor.

Example: Add an 'IsAdjacent_to' topology operator

This example adds the IsAdjacent_to topology operator in the configuration file.

```
<criteria-choice>
 <relation-choice>
    <name>IsAdjacent_to</name>
      <verbose>is adjacent to</verbose>
   <relation-id>0x00010007</relation-id>
  </relation-choice>
</criteria-choice>
```

The code has the following parameters:

- **name**
  Indicates the name of the relation as defined in DX NetOps Spectrum.
- **verbose**
  Indicates the verbose text that is shown for the relation name.
- **relation-id**
  Indicates the relation ID as defined in the database.

  WARNING
  Set the relation-id properly. Otherwise, the correlation does not work.

Creating and Managing Policies

This section discusses how to create and manage policies using the Condition Correlation Editor in OneClick.

Create a Policy

A policy is a set of one or more rules. Create the policy or policies that contain the correlation rules to associate with the domain. Apply the policies to domains to create correlation domains.

Follow these steps:

1. Open Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Policies tab.
   The Condition Correlation Editor window displays a list of policies.
3. Click
   
   (Create).
   The Create Correlation Policy dialog opens.
4. Supply a value for each of the following policy properties:
   - **Policy Name**
     Defines the policy (such as Power_Outage, DiskPolicy).
   - **Policy Rule(s)**
     Includes the rules for the policy. You can use the arrow buttons to add rules from the Available Rules list to the Policy Rule(s) list, or to remove rules from the Policy Rule(s) list.

5. Click OK.
   A new policy is created and added to the Policies tab list. The Author property identifies you as the author of the policy.

Manage a Policy

In the Condition Correlation Editor window, you can edit, copy, and delete a policy from the list of predefined and custom policies.

Follow these steps:

1. Click the Policies tab in the Condition Correlation Editor window.
   The Condition Correlation Editor window displays a list of policies.
2. Select the policy to modify, and click
   
   (Edit).
   The Edit Policy dialog opens.

   NOTE
   If the policy is applied to a correlation domain, you cannot edit that policy name.
3. To copy a policy, click
   
   (Copy).
   The Copy Policy dialog opens, displaying the property settings for the policy you selected.

   NOTE
   The suffix _COPY is appended to the Policy Name to create a unique name for the new policy. A unique name is required.
4. Edit policy properties as necessary, and click OK.
   The Condition Correlation Editor saves your changes.
5. To delete a policy, click
   
   (Delete).
   A confirmation dialog opens.
6. Click Yes.
   The Condition Correlation Editor removes the selected policies from the Policies tab list.

Creating and Managing Domains

This section discusses the concept of a "Correlation Domain", and discusses how to create and manage a domain using the Condition Correlation Editor in OneClick.

About Correlation Domains

You can create *correlation domains* that contain different correlation policies for various types of managed resources and alarm events. This section describes how to create correlation domains and edit domain settings.

WARNING
The volume of correlation processing that is required for large domains can affect DX NetOps Spectrum performance.

In the Condition Correlation Editor, you can create a domain, or you can copy a domain and modify it.

You can also create a domain from the context of a device, service, or Global Collection model that you want to add to the domain. Use the OneClick ‘Add To’ feature to create a domain in context.

> **NOTE**
> If you plan to add resources to the correlation domain from multiple landscapes, create the domain on the Main Location Server.

Create a Domain in the Condition Correlation Editor

In DX NetOps Spectrum, a *domain* is a group of resources. DX NetOps Spectrum Condition Correlation evaluates these resources collectively. You can apply policies to domains to create correlation domains. The rules in the policies that are applied to the domain are executed on all resources in the domain.

Follow these steps:

1. Open Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Domains tab.
   The Condition Correlation Editor window displays a list of any domains that users have created. Condition Correlation does not include default domains.
3. Click
   
   (Create) to create a domain.
   The Create Domain dialog opens.
4. Provide a value for each of the following domain properties:
   - **Domain Name**
     Defines the domain (such as Backup_Power, DiskMonitor).
   - **Landscape**
     Defines the landscape for the domain.
5. Move one or more policies from the Available Policies box to the Domain Policies box. If you are creating another version of an existing domain, remove policies as required from the Domain Policies box.
6. Add or remove resources from the domain by taking the following steps:
   a. Click the Resources tab, and click Create.
      The Locate Resources dialog opens.
   b. Search for the resources to add to the domain in the ‘Search using’ panel.
   c. Select the resources to add to the domain from the search list, click ‘Add Selected to Correlation Domain,’ and click Close.
      The resources that you added appear under the Resources tab in the Create Correlation Domain dialog.

      > **NOTE**
      > To add a device model and some port models for the device, add each individual model to the domain. Adding the device model does not add its component models to the domain.
7. Click OK.
   The Condition Correlation Editor saves the new domain to the Domains tab list.

Create a Domain in the OneClick Console

You can use the OneClick 'Add To' feature to create a domain from the context of a device, service, or Global Collection model.

Follow these steps:

1. Select the model in OneClick that you want to use to create a domain.
2. Right-click the model, and select Add To Correlation Domain.
   The Add to Correlation Domain dialog opens.
3. Perform one of the following actions:
   – To create a domain, enter a name for the domain and specify the landscape where you want to create the domain in the 'Create a new correlation domain' section.
   – To include the device, service, or Global Collection model in an existing domain, select the existing domain from the list in the 'Select an existing correlation domain' section.
4. Click OK.
   A domain is created or edited. You can add policies to the domain. For more information, see Create a Domain in the Condition Correlation Editor.

Manage a Domain

In the Condition Correlation Editor, you can copy and modify domains from the list of predefined and custom domains. You can delete domains that were created by any user.

Follow these steps:

1. Click the Domains tab in the Condition Correlation Editor window.
   The Condition Correlation Editor displays a list of domains.
2. Select the domain to edit and click
   
   (Edit).
   The Edit Domain dialog opens.
3. To copy a domain, click
   
   (Copy).
   The Copy Domain dialog opens.
4. Edit the Domain properties as necessary, and click OK.
5. (Optional) Remove resources from a domain that you are copying by taking the following steps:
   a. Select the resources that you want to remove from the Resources tab list in the Edit Correlation Domain dialog.
   b. Click Delete.
      The selected resources are removed from the Resources tab list.
   The Condition Correlation Editor saves your changes.
6. To delete a domain, click
   
   (Delete).
7. Click Yes in the confirmation dialog that opens.
   Condition Correlation Editor removes the selected domains from the Domains tab list.

Testing and Debugging

DX NetOps Spectrum Condition Correlation provides advanced capabilities to enhance the functionality of the base product. When you create or customize the conditions, rules, and policies, that compose a condition correlation system, testing is required. We recommend staging the deployment of each new system to enable testing and debugging.

The topics in this section describe the testing and debugging process in Condition Correlation and recommend some best practices.

How to Develop and Test Correlations

This section describes the design and development process for Condition Correlation. The lifecycle of a condition correlation follows typical software development methodology. Perform the following tasks in this recommended order to create a correlation:

- Create conditions
- Create rules
- Create policies
- Create correlation domains and add models to the domains

> **NOTE**
> Use the same order to develop new correlations using the Condition Correlation Editor.

After creating the condition correlation system, test and debug it. The testing and debugging process for a new correlation includes the following tasks:

1. Simulate the symptom condition on the appropriate model.
2. Verify that the appropriate alarm or event is raised in the OneClick Alarm View.
3. Verify that the condition is recognized by the correlation domain.
4. Simulate the root-cause condition of the appropriate model(s) in the correlation domain.
5. Verify that the condition is recognized by the correlation domain.
6. Verify that the root-cause alarm is raised correctly and that the symptom condition is hidden in the OneClick Alarm View.

Guidelines and Best Practices

Verify the following guidelines and best practices before starting the development process:

- Become familiar with the preconfigured Condition Correlation components, such as the conditions, rules, and policies that are installed with DX NetOps Spectrum. Use the correlation components when required. You can create copies and can edit the preconfigured correlation components. For more information, see Condition Correlation Components.
- Start with simple conditions and rules to build a more complex system.
- Design the rules for easier testing. Use the techniques to test Condition Correlations that are explained in this document.
- Start testing rules and conditions from the bottom of the hierarchy and move up the hierarchy.

Testing a Correlation

After you design and develop a Condition Correlation system, test the system elements before deploying the correlation in a production environment. Multiple methods are available to perform the validation and verification process. The most robust method is to use a live environment. In certain circumstances, this method is not possible. For example, some DX NetOps Spectrum operators and developers cannot bring down infrastructure resources for testing a correlation.

A lab environment can provide a suitable test-bed for this type of verification. However, a lab can lack some of the resources that are required to test the correlation and simulate the scale of the deployment.

The simplest way to test a new Condition Correlation system is to create artificial events on DX NetOps Spectrum models. The following methods are available to test the Condition Correlation system:

- Test the Correlation with the Command Line Interface
- Test the Correlation with the Web Services API

NOTE
The Web Services API method provides more capability with greater complexity.

Test the Correlation with the Command-Line Interface

Use a simple command from the DX NetOps Spectrum Command-Line Interface (CLI) to test a new correlation. All events in DX NetOps Spectrum have an ID that is used to identify the event when it is processed. To know the type of the event that you are creating, an event-type-id is required. The event-type-id can be obtained from any of the following sources:

- The Condition Correlation Editor
  Note: The event is typically defined in an existing condition.
- The Event Configuration tool.
- The EventDisp file that refers the specific event and how it is handled.

Follow these steps:

1. Select Start, Programs, and Command Prompt.
   The DOS prompt appears, ready to accept CLI commands.
2. Start the SpectroSERVER to which you want to connect.
3. Navigate to the following vnmsh directory in the DX NetOps Spectrum installation directory:
   ```
   $ cd $SPECROOT/vnmsh
   ```
4. Open the connection using the following command:
   ```
   $ connect
   ```
   You are connected to the CLI session.

   NOTE
   On a UNIX platform, you can start a CLI session from the shell prompt. You can also start a CLI session from a bash shell prompt on Windows platform. For more information, see the Command Line Interface section.
5. Execute the following CLI command to test the correlation:
   ```
   create event type=event-type-id text=event-text mh=model-handle
   ```
   An event is created on the model with the given mode handle.

Example

To simulate the Chassis Down event on a model (with the model handle of 0x10234), use the following command:

```
create event type=0x10f69 text="Chassis is Down" mh=0x10234
```

NOTE
This command works for some situations. However, it does not let you deliver event variables in the event message. To generate a more complicated event, use the web services method.

Test the Correlation with the Web Services API

Use the DX NetOps Spectrum RESTful Web Services API to test the correlation. The DX NetOps Spectrum RESTful Web Services lets you generate events that include event variables. This method requires a REST client that supports XML input, for example, WizTools RESTclient (on Windows 7).

Follow these steps:

1. Download and install the WizTools REST client.
   For more information, see *http://code.google.com/p/rest-client/.*
2. Determine whether event variables are required to create the event.

3. Verify the syntax in the CsEvFormat file for the relevant event.
   You can view this file through Event Configuration or by accessing the file directly, using bash shell or your preferred text editor.
   For example, to find the file for event type 0x10f96, use the following path:
   ```
   $SPECROOT/SG-Support/CsEvFormat/Event00010f96[language_pack]
   ```
   NOTE
   The language pack extension is used for releases 9.3.0 or later. The extension for US English is '_en_US'.
4. Review the contents of this file. It does not contain event variables. It contains the following text:
   ```
   The <ss> physical Memory has exceeded 2.5 Gigabytes for more than 300 seconds.
   ```
5. If you do not see event variables in the event message, use the template that lacks event variables. For more information, see REST Examples for Correlation Testing.
6. For event type 0x5180302, verify the text for the following message:
   ```
   The BGP Peering session from S 1 to S 2 has been Lost.
   ```
   The event variables in italics are required for the event to be generated correctly. In this example, following event variables are applicable:
   - **S 1**
     Represents the device model name.
   - **S 2**
     Represents the Provider_Cloud model name.

   The context of these parameters is determined by reviewing the actual events that have been generated.
7. Use the template to generate an event with the appropriate event variables. For more information, see REST Examples for Correlation Testing.
   An event is generated.

Verify the Simulated Events

You can verify the simulated events that are generated through the CLI or web services. After the test tools are configured, you can verify the events in the Event View for the target model.

Follow these steps:

1. Open the Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Select a DX NetOps Spectrum model in one of the views.
   For example, select a view from the Navigation, List, Topology, or Search Results pane.
3. Select the Event tab for that model.
   All events are displayed for the selected model.
4. Enter text in the event filter dialog to search for events that contain relevant text.
   For example, if you are simulating a Border Gateway Protocol (BGP) backwards transition event, type 'BGP' as the keyword in the filter dialog.
5. Verify that the event is correctly displayed in the event window.
6. Verify that the event variables contain valid values.
   Note: Perform Step 6 only if the correlation requires specific event variables to be set or modified. For more information, see REST Examples.
   The simulated event is verified.

Debugging Correlations

Debugging is an essential component of the process to design, develop, and validate a new condition correlation system. Multiple built-in tools are available to help you debug a condition correlation. This section discusses the development prerequisites and the debugging tools that are available to debug the correlation system.

Debugging Prerequisites

Review the following prerequisites before debugging a Condition Correlation system. In our testing, we have frequently seen preventable errors that are related to these factors:

- The correlation domain has at least one policy that is applied to it.
- The correlation domain contains the models where a correlation is likely to occur. Verify that the model has not been deleted from the correlation domain.
- Rules are set up with the correct relationships.
- Symptom conditions are set up with the correct event types.
- Symptom and root-cause conditions are not reversed.
- Rules or symptoms are set up correctly to suppress the alarms.
- Conditions or policies exist in the correlation domain.

Debugging Tools

Condition Correlation is one of the most complex systems in DX NetOps Spectrum. As a result, various tools and techniques are available to debug a correlation system. The Condition Correlation debugging tools are specific actions that are sent to specific models. The following model support actions are available for the Condition Correlation debugging tools:

- Correlation Domain (custom - possibly multiple per landscape)
- Correlation Manager (predefined - only one model per landscape)

You can send these actions through the DX NetOps Spectrum CLI or Web Services. Both APIs let you create actions on models with optional parameters. A prerequisite for each approach is to find the model handle of the target model. Use the following syntax for CLI-based actions:

```
update action=0xffff0102 mh=CorrelationDomain_mh
```

All debug output, whether it is initiated through the DX NetOps Spectrum CLI or Web Services, appears in the Control Panel message window. The debugging messages are captured in the following VNM.OUT file:

```
$SPECROOT/SS/VNM.OUT
```

> **NOTE**
> Before you attempt the debugging actions, we recommend verifying the events that are produced and checking the configuration of symptoms and rules. Review the debugging prerequisites before you start the process.

Debugging Actions Correlation Domain

The following debug actions can be sent to the Correlation Domain Model through the CLI. You can see the output on the server console. The model handle of the target model is a prerequisite.

Action Code	Outputs	Usage
0xffff0102	List of existing conditions	Verify that expected conditions appear
0xffff0103	Detailed list of existing conditions	Verify that expected condition details match
0xffff0104	Condition definitions	Verify that expected conditions appear active
0xffff0105	Rule definitions	Verify that expected rules appear active
0xffff0106	Detailed Rule definitions	Verify that expected rule details match CCE
0xffff0107	Correlation hierarchy - models in domain	Verify that the target models are in domain
0xffff0202	Count conditions existing in domain	Verify that the count is an expected value
0xffff0203	Details for all count conditions	Verify that the count is an expected value

0xffff0900	Start runtime debug	Enable runtime debugging of domain
0xffff0901	Stop runtime debug	Disable runtime debugging

NOTE
Disable runtime debugging when it is not required to reduce the impact on performance and disk space.

Debugging Actions Correlation Manager

The following debug actions can be sent to the Correlation Manager through the CLI. You can see the output on the server console. The model handle of the target model is a prerequisite.

Action Code	Outputs	Usage
0xffff0100	All condition definitions	Verify that expected condition appears
0xffff0101	All condition definitions - detailed	Verify that expected condition details match
0xffff0110	All rule patterns	Verify that expected rule appears
0xffff0111	All rule patterns - detailed	Verify that expected rule details match
0xffff0120	All policies	Verify that expected policy appears
0xffff0200	All condition registrations	Verify that target model registrations are present
0xffff0300	Condition engine condition table	Verify that active conditions are represented
0xffff0401	Reload shipped condition definitions	Restore initial conditions
0xffff0402	Reload shipped rule definitions	Restore initial rules
0xffff0403	Reload shipped policy definitions	Restore initial policies
0xffff0900	Enable Condition Correlation Mgr debug	Verify initialization, registration, and notification
0xffff0901	Disable Condition Correlation Mgr debug	Disable when not required
0xffff0910	Enable condition engine debug	Verify event and alarm registrations received
0xffff0911	Disable condition engine debug	Disable when not required

NOTE
Disable runtime debug when it is not required to reduce the impact on performance and disk space.

Condition Correlation Examples

This appendix provides a workflow and examples to help you implement Condition Correlation in your environment.

NOTE
All of the fictitious instances of alarms and Condition Correlation components that are referenced in the following examples are enclosed in double quotation marks (“ ”). References to actual events and alarms that are defined in DX NetOps Spectrum are not enclosed in quotation marks.

The following scenarios are discussed as Condition Correlation examples:

- Power Outage
- Disk Full
- WAN Link Failure

How to Configure a Condition Correlation for a Power Outage

DX NetOps Spectrum Condition Correlation can be configured to determine the root-cause alarm and manage trouble-prone segments of your infrastructure. Predefined correlation systems are available in Condition Correlation Editor. However, you can use Condition Correlation to select the criteria that identify a causal problem event. With the help of Condition Correlation components (such as Conditions, Rules, Policies, and Correlation Domains), you can pinpoint the root-cause alarm and can pay less attention to symptomatic alarms.

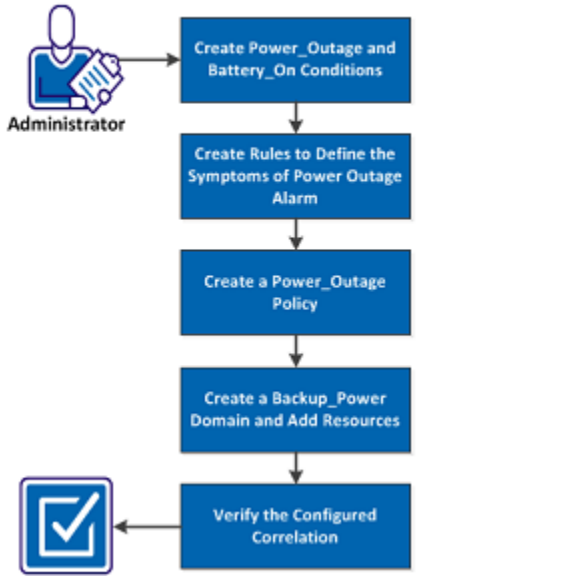
DX NetOps Spectrum includes many predefined correlations. For example, ContactLost_Red (caused by) Chassis Down, LinkDown (caused by) Chassis Down, Dev Module Pulled (caused by) Blade Status Unknown are a few predefined correlations that are available in Condition Correlation Editor.

In a power outage scenario, managed UPS systems generate traps indicating that they have switched to backup battery power. If the backup battery power fades, the systems generate traps that indicate low battery power. When the batteries fail, managed devices that are connected to the UPS systems go down. These devices trigger a flood of events and alarms from the affected area. The volume of events makes it difficult to identify and address the underlying problem.

As an administrator, you can configure a correlation system for a power outage. Create one or more conditions that can be evaluated by correlation rule criteria. If rule criteria are met, Condition Correlation identifies one condition as the root-cause condition and the other condition as symptomatic of the root-cause condition. Create a policy that contains the correlation rules to associate with the domain and apply the policy to the domain. The Condition Correlation process is in effect for the resources that are included in the domain

The following diagram illustrates the process to configure a Condition Correlation for a power outage:

How to Configure a Condition Correlation for a Power Outage



Create Power_Outage and Battery_On Conditions

Conditions are the building blocks of the correlation system. Create Power_Outage and Battery_On conditions in the Condition Correlation editor to configure a correlation system for a power outage. The Power_Outage condition uses the set event code and the clear event code that are associated with the Power Outage alarm. The Battery_On condition uses the set event code and the clear event code that are associated with the UPS trap. You can also use this procedure to create conditions to handle alarms from other root causes.

NOTE
To access Condition Correlation Editor, you require OneClick administrative privileges.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens. For more information, see The Condition Correlation Editor.
2. Click the Conditions tab.
   A list of conditions is displayed.
3. Click
   
   (Create).
   The Create Correlation Condition dialog opens.
4. Specify a value for the following condition properties:
   - **Condition Name**
     Defines the condition. For example, supply the names Power_Outage and Battery_On.
   - **Set Event Code**
     Identifies the DX NetOps Spectrum event code that is associated with the condition. For example, use the following set event codes:
     - Set event for Battery_On: 0x0116905a
     - Set event for Power_Outage: 0x01169431
5. Click OK.
   Power_Outage and Battery_On conditions are created.

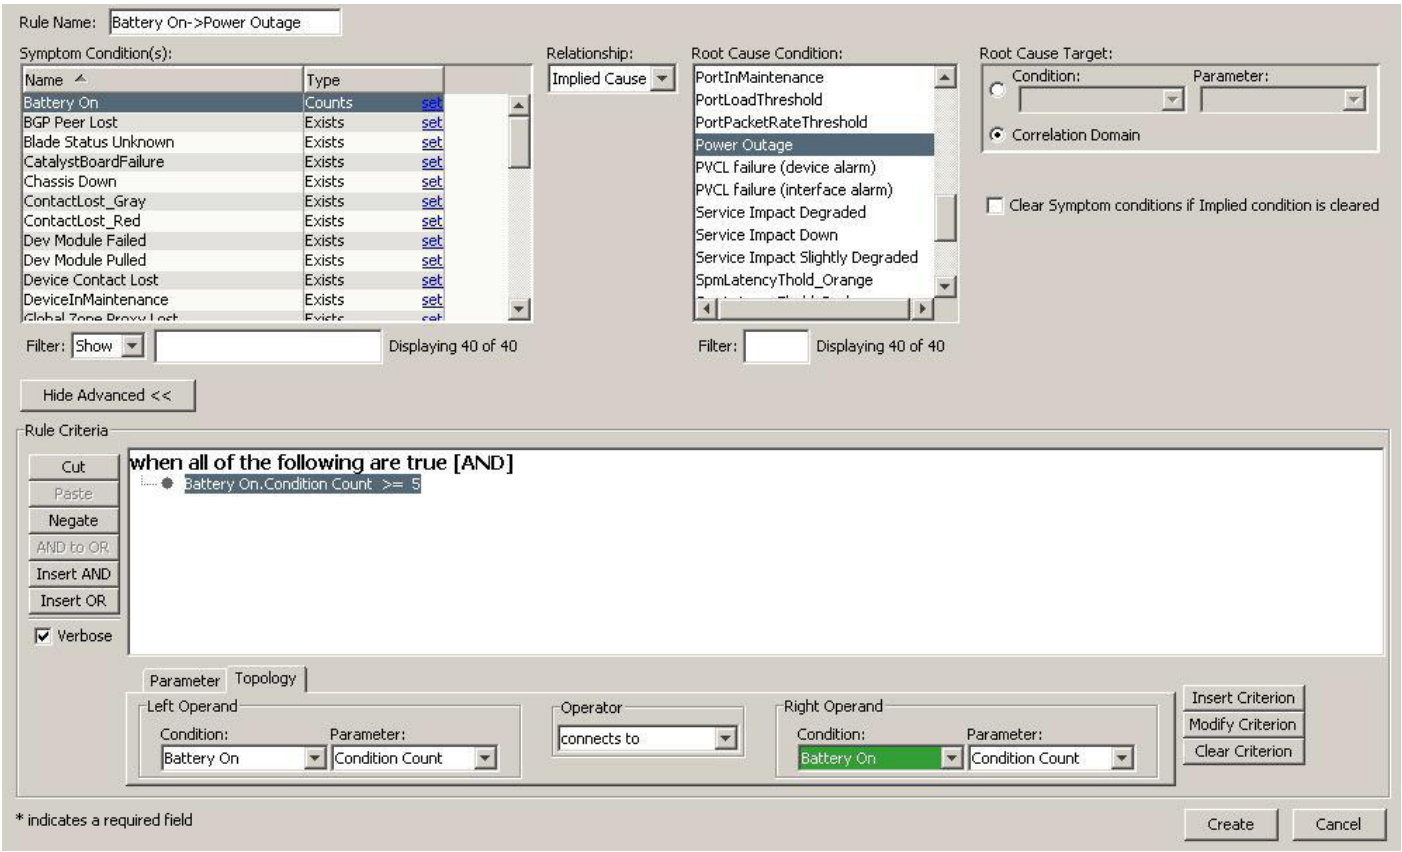
Create Rules to Define the Symptoms of the Power Outage Alarm

A rule is defined to stipulate that one condition is a symptom or a cause of another condition. Create rules to define the symptoms of the Power Outage alarm. You can create the following three rules for Power Outage:

- **Battery On -> Power Outage**
  Specifies that if five or more power systems go on battery power, the Power Outage condition is the implied cause.
- **ContactLost_Red -> Power Outage**
  Specifies that if the ContactLost_Red condition (predefined) is caused by the Power Outage condition, the critical (red) Contact Lost alarm is suppressed as a symptom of the Power Outage alarm.
- **ContactLost_Gray -> Power Outage**
  Specifies that if the ContactLost_Gray condition (predefined) is caused by the Power Outage condition, the (gray) Contact Lost alarm is suppressed as a symptom of the Power Outage alarm.

Follow these steps:

1. Open Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Rules tab.
   A list of rules is displayed.
3. Click the Create
   icon 
   The Create Rule dialog opens.
4. Enter a name for the rule in the Rule Name field.
   The following image illustrates the configuration in Advanced Rule Criteria:



5. Click Create.
   Rules for Power Outage are created in Correlation Editor.

Create a Power_Outage Policy

A policy is a set of one or more rules. To configure a condition correlation system for a Power Outage, create a Power_Outage policy and add the Power Outage rules to the Policy rules list. All implementations of the policy are updated after you add rules.

Follow these steps:

1. Open Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Policies tab.
   The Condition Correlation Editor window displays a list of policies.
3. Click

   (Create).
   The Create Correlation Policy dialog opens.
4. Supply a value for each of the following policy properties:
   - **Policy Name**
     Defines the policy. For example, supply the name Power_Outage.
   - **Policy Rule(s)**
     Includes the rules for the policy. You can use the arrow buttons to add rules from the Available Rules list to the Policy Rule(s) list, or to remove rules from the Policy Rule(s) list.

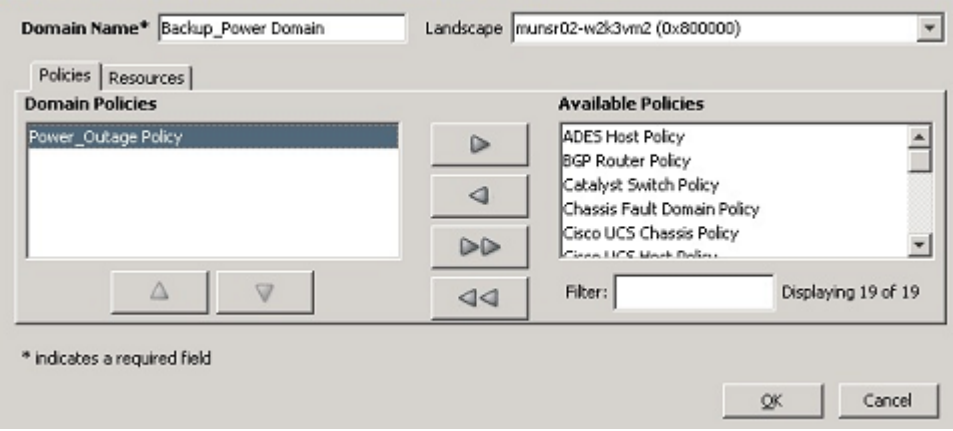
A Power_Outage policy is created that includes the Battery On -> Power Outage, ContactLost_Red -> Power Outage, and ContactLost_Gray -> Power Outage rules.

Create a Backup_Power Domain and Add Resources

A *domain* is a group of resources. You can create a Backup_Power domain for the condition correlation system for a Power Outage. UPS models and the device models (that connect to the power supplies) are the resources of the correlation domain. These resources are added and the Power_Outage policy is applied to the domain. You can include multiple models of various model types and can apply multiple policies.

Follow these steps:

1. Open Condition Correlation Editor.
   The Conditions tab is displayed by default.
2. Click the Domains tab.
   The Condition Correlation Editor window displays a list of any domains that users have created. Condition Correlation does not include default domains.
3. To create a domain, click the Create icon 
   The Create Domain dialog opens.
4. Provide a value for each of the following domain properties:
   - **Domain Name**
     Identifies the domain. For example, supply the name Backup_Power.
   - **Landscape**
     Defines the landscape for the domain.
5. To add the Power_Outage policy to the Domain Policies box, move the Power _Outage policy from Available Policies to the Domain Policies box.
   If you are creating another version of an existing domain, remove policies as required from the Domain Policies box.
   The following image illustrates the Power_Outage policy that is added to the Domain Policies box.



6. Click the Resources tab to add or remove resources from the domain. For more information, see the Creating and Managing Domains section.
7. Click OK.
   The Backup_Power domain is created.

Verify the Correlation

As a best practice, verify the correlation that you configured before you deploy it. When a correlation is correctly configured, the symptom alarms are hidden while the root cause alarm is active.

Follow these steps:

1. Log in to the OneClick console.
2. Click the Alarms tab.
   The Alarms window opens.
3. Verify the status of the symptom alarms (such as ContactLost_Red, ContactLost_Red, Battery_On) and the root cause alarm.
   The symptom alarms are hidden and the root cause alarm is displayed in Alarms tab.
   The correlation is appropriately configured.

Disk Full Scenario

A disk monitor alarm appears on many models multiple times. However, the total number of these alarms is required rather than every instance of each alarm. For an instance, less than five disk monitor alarms are acceptable, but once there are at least five alarms, you want to see a minor alarm. Similarly, if there are more than ten alarms, you want to see a major alarm. If there are more than 15 alarms, then you can see a critical alarm. The following process explains the concept of condition correlation for a Disk Full scenario:

- If any of the DiskFull events are generated on the host devices with different values for the disk (variable binding 4), they are displayed on-screen, as long as their overall number goes up to four. Once a fifth alarm is generated on a model of the correlation domain, the MinorDiskProblemRule instantiates and the MinorDiskProblem alarm is created on the correlation domain. The five DiskFull alarms are hidden as symptoms under the MinorDiskProblem alarm.
- If one or more DiskFull alarms are cleared, the MinorDiskProblem alarm clears, showing the previously hidden other four or fewer DiskFull alarms. By contrast, if more DiskFull alarms are generated and their number reaches ten, the MajorDiskProblem alarm is generated. The minor alarm, which covers 5-9 alarms, disappears. All DiskFull alarms can be the symptoms of the major alarm.
- If the DiskFull alarm total does not reach ten, you can see the MinorDiskProblem alarm. Similarly, if the DiskFull alarm total exceeds 14, you can see the CriticalDiskProblem alarm.

EventDisp Entries

You can use the following EventDisp entries for setting up Condition Correlation. These alarms use variable binding 4 as a discriminator so that multiple alarms can exist on the same device.

test alarm (disk full)

```
0xffff0000 E 50 A 1,0xffff0000,4
0xffff0001 E 50 C 0xffff0000,4
```

5 to 9 test alarms, minor problem with disks

```
0xffff0010 E 50 A 1,0xffff0010
0xffff0011 E 50 C 0xffff0010
```

10 to 14 test alarms, major problem with disks

```
0xffff0020 E 50 A 2,0xffff0020
0xffff0021 E 50 C 0xffff0020
```

more than 15 test alarms, critical problem with disks

```
0xffff0030 E 50 A 3,0xffff0030
0xffff0031 E 50 C 0xffff0030
```

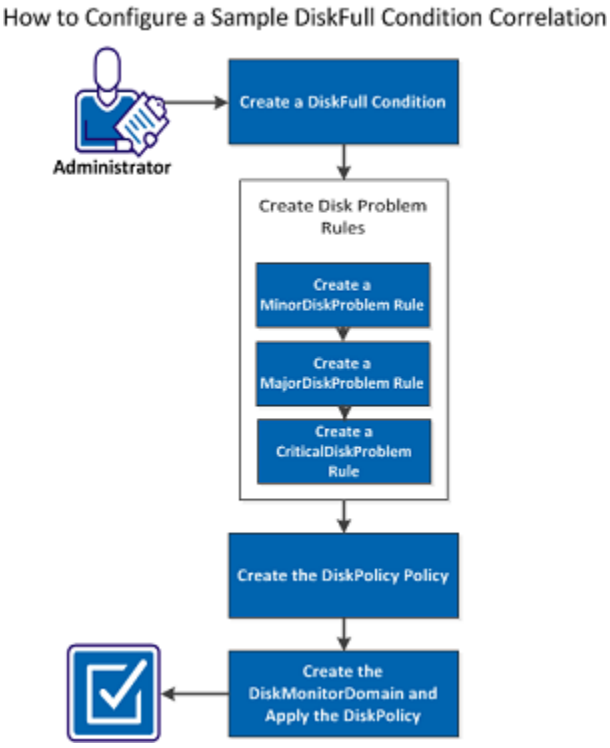
> **NOTE**
> You can create event format and alarm probable cause files. For more information, see the Event Configuration section.

How to Configure the Sample DiskFull Condition Correlation

Condition Correlation determines the root-cause alarm by selecting a criterion to identify a casual problem event. You can use the predefined components to configure a correlation. With the help of Condition Correlation components (such as Conditions, Rules, Policies and Correlation domain), you can pinpoint the root-cause alarm and symptomatic alarms.

As an administrator, you can configure the sample Disk Full Condition Correlation by creating DiskFull condition and Disk Problem rules. After creating the conditions and rules, you can create a DiskPolicy policy and apply it to a DiskMonitor Domain. DiskFull events are generated on the host devices with different values for the disk. Each time the disk problem alarms are cleared, all the existing DiskFull alarms become symptoms of the respective disk problem alarm.

The following diagram illustrates the process to configure a Disk Full Condition Correlation:



Perform the following tasks to configure the sample DiskFull Condition Correlation:

1. Create a DiskFull Condition
2. Create Disk Problem Rules
   a. Create a MinorDiskProblem Rule
   b. Create a MajorDiskProblem Rule
   c. Create a CriticalDiskProblem Rule
3. Create the DiskPolicy Policy
4. Create the DiskMonitorDomain and Apply the DiskPolicy

Create Disk Conditions

You can create disk conditions in Condition Correlation Editor. You can specify the condition name with the set event and clear event codes associated to the condition.

Follow these steps:

1. Open Condition Correlation Editor.

The Condition Correlation Editor window opens.
2. Click the Conditions tab.
   A list of predefined and user-created conditions is displayed.
3. Click Create.
   The Create Correlation Condition dialog opens.
4. Create the following disk conditions:
   – DiskFull Alarm (including Disk parameter):
     • Condition Name: DiskFull
     • Set Event Code: 0xffff0000
     • Clear Event Code: 0xffff0001

     Because a model can have multiple occurrences of these conditions, you must also add a parameter to distinguish them. The alarms are distinguished by variable binding 4. Therefore, use 4 for this parameter as well.
     • Parameter Name: Disk
     • Parameter Type: Var Bind
     • Parameter ID: 4
     • Use as discriminator: Yes
   – Minor Disk Problem:
     • Condition Name: MinorDiskProblem
     • Set Event Code: 0xffff0010
     • Clear Event Code: 0xffff0011
   – Major Disk Problem:
     • Condition Name: MajorDiskProblem
     • Set Event Code: 0xffff0020
     • Clear Event Code: 0xffff0021
   – Critical Disk Problem:
     • Condition Name: CriticalDiskProblem
     • Set Event Code: 0xffff0030
     • Clear Event Code: 0xffff0031
5. Click OK.
   Conditions are created and added to the Conditions tab.

Create Disk Problem Rules

You can create Disk Problem Rules to configure a Disk Full Condition Correlation. Minor, Major, and Critical Disk Problem rules are created in Condition Correlation Editor with specific rule criteria.

You can create the following disk problem rules:

- Create a MinorDiskProblem Rule
- Create a MajorDiskProblem Rule
- Create a CriticalDiskProblem Rule

Create a MinorDiskProblem Rule

You can create a MinorDiskProblem rule in Condition Correlation Editor. You can specify the rule name and the rule criteria for the DiskFull condition.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Rules tab.

A list of rules is displayed

3. Create a rule using the following properties:
   – Name: MinorDiskProblemRule
   – Symptom Condition(s):
     • Name: DiskFull
     • Type: Counts
   – Relationship: Implied Cause

     NOTE
     The MinorDiskProblem alarm is generated when the rule criteria are satisfied, and causes the rule to hide the DiskFull alarms.
   – Root Cause Condition: MinorDiskProblem
   – Root Cause Target: Select the Correlation Domain option.
4. Click Show Advanced to open the Rule Criteria panel.
5. Create the following rule criteria:
   – 'DiskFull.count GREATER THAN OR EQUAL TO 5':
     • Condition: DiskFull
     • Parameter: Condition Count
     • Operator: GREATER THAN OR EQUAL TO
     • By Value: Yes
     • Value: 5
     • Type: Integer
     • Click Insert Criterion.
   – 'DiskFull.count LESS THAN 10':
     • Condition: DiskFull
     • Parameter: Condition Count
     • Operator: LESS THAN
     • By Value: Yes
     • Value: 10
     • Type: Integer
6. Click Insert Criterion.
7. Click Create.
   The new rule is added to the Condition Correlation Editor Rules tab.

Create a MajorDiskProblem Rule

You can create a MajorDiskProblem rule for the DiskFull condition in Condition Correlation editor. After creating the rule, you can specify the rule criteria.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Rules tab.
   A list of rules is displayed.
3. Create a rule using the following properties:
   – Name: MajorDiskProblemRule
   – Symptom Condition(s):

    - Name: DiskFull
    - Type: Counts
  - Relationship: Implied Cause
  - Root Cause Condition: MajorDiskProblem
  - Root Cause Target: Select the Correlation Domain option.
4. Click Show Advanced to open the Rule Criteria panel.
5. Create the following rule criteria:
  - 'DiskFull.count GREATER THAN OR EQUAL TO 10':
    - Condition: DiskFull
    - Parameter: Condition Count
    - Operator: GREATER THAN OR EQUAL TO
    - By Value: Yes
    - Value: 10
    - Type: Integer
    - Click Insert Criterion.
  - 'DiskFull.count LESS THAN 15':
    - Condition: DiskFull
    - Parameter: Condition Count
    - Operator: LESS THAN
    - By Value: Yes
    - Value: 15
    - Type: Integer
6. Click Insert Criterion.
7. Click Create.
   The new rule is added to the Condition Correlation Editor Rules tab.

Create a CriticalDiskProblem Rule

You can create the CriticalDiskProblem rule after creating MinorDiskProblem and MajorDiskProblem rules in Condition Correlation Editor.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Rules tab.
   A list of rules is displayed
3. Create a rule using the following properties:
  - Name: CriticalDiskProblemRule
  - Symptom Condition(s):
    - Name: DiskFull
    - Type: Counts
  - Relationship: Implied Cause
  - Root Cause Condition: CriticalDiskProblem
  - Root Cause Target: Select the Correlation Domain option.
4. Click Show Advanced to open the Rule Criteria panel.
5. Create the following rule criteria:
  - 'DiskFull.count GREATER THAN OR EQUAL TO 15':

- Condition: DiskFull
- Parameter: Condition Count
- Operator: GREATER THAN OR EQUAL TO
- By Value: Yes
- Value: 15
- Type: Integer

6. Click Insert Criterion.
7. Click Create.
   The new rule is added to the list of rules in Condition Correlation Editor.

Create the DiskPolicy Policy

You can create a DiskPolicy policy in Condition Correlation Editor. After creating the policy, you can add the disk problem rules to the policy rules list.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Policies tab.
   The Condition Correlation Editor window displays a list of policies
3. Create a new policy using the name DiskPolicy.
4. Add the following rules to the Policy Rules list:
   – MinorDiskProblemRule
   – MajorDiskProblemRule
   – CriticalDiskProblemRule
5. Click Create.
   The new policy appears in the list of policies in Condition Correlation Editor.

Create the DiskMonitorDomain and Apply the DiskPolicy

You can create a new correlation domain to accommodate the components. You can apply the DiskPolicy from the policies list to the DiskMonitor Domain.

Follow these steps:

1. Click the Domain tab in Condition Correlation Editor.
2. Click Create.
3. Enter DiskMonitorDomain in the Domain Name text box.
4. Click the Policies tab, select DiskPolicy from the Available Policies list and move it into the Domain Policies list.
5. Click the Resources tab and then select any number of host devices as resources.
6. Click Create.
   The DiskMonitor Domain is added to the list of Domains in the Condition Correlation Editor.

Create a Clear Events Correlation

This section describes some additional functionality that you can implement on this sample DiskFull Condition Correlation.

You can clear the disk problem alarms (such as, major, minor, or critical) from OneClick. However, if you clear the disk problem alarm, all previously hidden disk full alarms reappear. Because the alarm it is correlated to is destroyed. This section describes how you can clear all of these alarms.

Multiple alarms on multiple models can exist. Therefore, the only thing you have is the clear event for one of the disk problem events (minor, major, or critical). You can perform the following tasks to create the clearing events on the correct model:

Create an Additional Parameter for the DiskFull Condition

To add a parameter to the DiskFull condition, you require one additional parameter for the DiskFull condition.

Follow these steps:

1. In the Conditions tab, in the Correlation Editor, select the DiskFull condition and click Edit.
   The Edit Correlation Condition dialog opens.
2. Click Create in the Parameters section.
   The Create Correlation Parameter dialog opens. You need to add the model where the condition (alarm) exists as shown in the following step.
3. From the Parameter Type field, select Predefined.
   The Parameter ID field shows the applicable model handle attribute: 0x129fa.
4. Click Create to add this parameter to the condition.
   This condition parameter can now be used in the clearing rule that you create to assert the clear event on the correct model.

Create an Event Rule to Identify a Cleared Disk Problem Alarm

You can create an event rule to identify when a disk problem alarm is cleared by the user. This rule lets you distinguish between instances when the correlation cleared the alarm (performs automatically when the number of alarms reaches any of the thresholds) and when a user cleared the alarm from the UI, indicating that the user knows about the problem and decides that the problem is resolved.

As you are clearing the alarms from the UI, no direct event code (for example, 0xffff0021) is used. Instead, you can use one of the alarm status events. For example, 0x10706: user has cleared an alarm. In this event, you can find Probable Cause Code of the cleared alarm, in varbind 3. You can use the Probable Cause Code to generate a new event and can use it as a condition to start the clear correlation.

You can create an event rule to generate a event, disk problem alarm has been user-cleared. The 0x10706 event is mapped (by default) in the following file:

```
<$SPECROOT>/SS/CsVendor/Cabletron/EventDisp
```

The syntax to add an event action is as follows:

```
0x00010706 E 50 R CA.EventCondition, \
   " { v 3 } == { H 0xffff0010 } ", 0xffff0100, \
   " { v 3 } == { H 0xffff0020 } ", 0xffff0100, \
   " { v 3 } == { H 0xffff0030 } ", 0xffff0100
```

Log and Add an Event to Clear the DiskFull Alarms

Optionally, you can log the event in the custom EventDisp file using the following syntax:

```
0xffff0100 E 50
```

You can add an event to clear the disk full alarms, regardless of their discriminator value. Use the following clear all (‘A’) alarm clear flag syntax:

```
0xffff0002 E 50 C 0xffff0000, A
```

This event lets you clear all disk full alarms on a model, even if you do not know the values for their discriminator attributes.

Create the Conditions Required for the Clear Correlation

Reload the EventDisp files so that you can set up the clear correlation. The following procedure describes the steps.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Conditions tab.
   A list of conditions is displayed.
3. Click Create.
   The Create Correlation Condition dialog opens.
4. Create the following condition to start the clear correlation:
   – DiskProblemAlarmUserCleared:
     - Condition Name: DiskProblemAlarmUserCleared
     - Set Event Code: 0xffff0100
     - Clear Event Code: 0xffff0100

       NOTE
       The DiskProblemAlarmUserCleared condition is no longer required after it starts the clear correlation. You can clear this condition after the clear correlation has completed. You can use the same clear event as the set event to generate the condition. This condition is cleared after the completion of clear correlation and is therefore temporary.
5. Create the following condition to clear the DiskFull alarms:
   – DiskFullAlarmClear:
     - Condition Name: DiskProblemAlarmUserCleared
     - Set Event Code: 0xffff0002
       (The Set Event Code indicates that this event can be generated when the condition is generated by an implied rule.)
     - Clear Event Code**:** 0xffff0002
       (The Clear Event Code indicates that the condition is self-clearing, as does the condition in Step 1.)

   DiskProblemAlarmUserCleared condition is created.

Create a Rule to Clear DiskFull Alarms

You can create a rule that clears all DiskFull alarms when a user clears one of the disk problem alarms.

Follow these steps:

1. Open Condition Correlation Editor.
   The Condition Correlation Editor window opens.
2. Click the Rules tab.
   A list of rules is displayed.
3. Create the following rule:
   – Name: DiskFullUserClearRule
   – Symptom Condition(s):

    - DiskProblemAlarmUserCleared
    - DiskFull
  - Type: Exists
  - Relationship: Implies
  - Root Cause Condition: DiskFullAlarmClear
  - Root Cause Target: DiskFull.Model

    NOTE
    This rule ensures that the clear event is generated on each model where a DiskFull alarm exists, enabling the alarm to be cleared.
4. Save the rule.
5. Add the new rule to the “DiskPolicy” policy.
   This rule triggers when any one of the three disk problem alarms is cleared by the user, generating event 0xffff0100.

The setup is complete. Anytime the user clears any one of the three disk problem alarms (minor, major, or critical), all individual DiskFull alarms are cleared. The condition is paired with each DiskFull alarm, and generates the DiskFullAlarmClear condition on the model of the DiskFull alarm. Thus, all of the DiskFull alarms are cleared.

WAN Link Failure Example

The WAN Link Failure example describes the process that Condition Correlation uses to pinpoint the root-cause alarm and symptomatic alarms among a barrage of alarms that are generated for different resources, as a result of a WAN link failure.

WAN Link Scenario

In many WANs, primary connections have a backup. The backup connection typically provides less bandwidth than the primary connection. In this example, a 384K Frame Relay link is backed up by a 128K ISDN link. Also, a DX NetOps Spectrum Service Performance Manager (SPM) test is measuring latency across the WAN link.

When the Frame Relay link goes down, the ISDN link takes over and the SPM test exceeds the latency threshold due to the reduced bandwidth. DX NetOps Spectrum generates two alarms (Critical Alarm - Frame Relay Link Down occurs on the Frame Relay link model; Minor Alarm - SPM Test Exceeded Threshold occurs on the SPM Test model) and one event (ISDN Backup Active occurs on the device).

WAN Link Correlation Strategy

It may not be apparent to network management personnel that all the three conditions are related and they are likely to focus their effort on the critical alarm even though there are other important alarms in the infrastructure.

You can apply the following conditions to the domain including the resources that can be compromised by a primary WAN link failure:

- The two alarms and the ISDN event can be correlated to generate a new primary link down, reduced bandwidth condition that produces a major alarm because the WAN is still working, but with a decreased performance.
- The failed Frame Relay link can be correlated with the Dialup Link Active event and can imply that the primary WAN link is down with reduced bandwidth, if the backup link bandwidth is less than the primary link bandwidth.
- The SPM test can be correlated with the primary WAN link down, reduced bandwidth condition with a rule that stipulates SPM Test Threshold Exceeded is caused by primary WAN link down, reduced bandwidth condition.

This correlation system produces the following alarm and event information: the single major alarm for the WAN link being down. There is also an SPM test threshold exceeded alarm and the ISDN backup active event, but these alarms are hidden under the single major alarm. This lets troubleshooters focus their efforts on the most important alarms. A second rule could be created to produce a minor alarm if the active backup link has the same bandwidth as the failed primary link.

WAN Link Failure Configurations

You can configure the correlation system using the following process:

- In DX NetOps Spectrum, a new “Primary WAN Link Down, Reduced Bandwidth” alarm is created. A set event and clear event for the new alarm is required.
  You can create alarms and can edit event configuration files. For more information, see the Event Configuration section.
- Create the following conditions:
  – A “Primary_WAN_Link_Down_Reduced_Bandwidth” condition using the set and clear event codes from the “Primary WAN Link Down, Reduced Bandwidth” alarm.
  – A “Dialup_Link_Active” condition using set event 0x022ffff6, “Dialup link has been activated,” and clear event 0x022ffffc, “Dialup link is inactive.” This condition is not linked to a DX NetOps Spectrum alarm. However, it infers that the backup, or secondary, link is up and running.
- Create the following rules:
  – A “PrimaryFrameRelay_Red -> LinkDown” rule states that if the “Primary_WAN_Link_Down_Reduced_Bandwidth” and “Dialup_Link_Active” conditions occur, then the implied cause is the “Primary_WAN_Link_Down_Reduced_Bandwidth” condition and the critical (red) Frame Relay Link Down alarm is suppressed by the “Primary WAN Down, Decreased Bandwidth” alarm (orange).
  – An “SPMLatencyThreshold_yellow -> Violated” rule states that the SPM latency threshold violation is caused by the “Primary WAN Link Down, Reduced Bandwidth” condition, and suppressed yellow SPM latency threshold violation alarms.
- A “WAN_Link_Failure” policy is created that includes the “PrimaryFrameRelay_Red -> LinkDown” and “SPMLatencyThreshold_yellow -> Violated” rules.
- A “WAN_Primary_Backup_Links” domain is created. It includes the primary WAN link interfaces, the backup link, and any SPM tests that can be impacted by the lower bandwidth of the backup. The “WAN_Link_Failure” policy is applied to the domain.

Special Topics

This section discusses special topics that are related to Condition Correlation capabilities and implementation.

Condition Correlation and Fault Isolation

If a managed device stops responding to polls, the DX NetOps Spectrum fault isolation algorithm determines whether to create a critical alarm for the device or suppress its alarm state. The unreachable device is the root cause of the alarm. Condition Correlation supports setting up a correlation between a device in the Contact Lost condition and some other condition in your environment. For example, DX NetOps Spectrum receives a trap from a BGP router that is reporting a lost session with a peer router. If the peer router is already in the Contact Lost state in DX NetOps Spectrum, the BGPLost Session alarm can be a symptom of the Contact Lost alarm on the peer router model.

If the peer router in the Contact Lost state has a critical Device Has Stopped Responding to Polls alarm, the correlation is trivial. If the fault state of the peer router is suppressed by the DX NetOps Spectrum fault isolation algorithm, no root cause alarm exists on this model.

You cannot correlate the actual root cause alarm with the Peer Lost alarm without special consideration from Condition Correlation. However, in Condition Correlation, the Device Contact Lost condition receives special consideration. This condition remains in force whenever a device is in the Contact Lost state, regardless of whether the device model is suppressed or has an alarm. If the device model in question is suppressed, the correlation engine locates the isolated alarm and uses it as the root cause for any correlation rules.

About Transfer Rules

DX NetOps Spectrum recognizes a Model Active condition that can be used in a correlation rule. The Model Active condition is used when a port model is added or removed from a correlation domain. This condition can be used for special rules, such as transferring alarms from devices to ports, because the Model Active condition is present for each correlated port. This usage eliminates the requirement for the port to have an alarm to participate in a correlation. Attributes on the condition can then be used to create a rule that transfers alarms to the correct port. The correct port can be identified by using the following parameters from the Model Active condition:

- Component OID of the port.
- Model handle of the parent device of the port.
- Model type of the port.

Condition Correlation provides a default transfer rule: transfer PVCL alarm from the device to interface. It reacts to the PVCL failure condition (alarm 0x210048 - PVCLs Failure Notification) on the device model by extracting the Interface ID of the affected port from the PVCL failure condition. Then it locates the port model by comparing the Interface ID from the PVCL failure condition with the Component_OID parameter of the Model Active condition on the port. A new PVCL failure (0x210c0c - PVCLs Failure Notification) alarm is created on the port. This failure alarm is identified by the Model parameter of the Model Active condition. The PVCLs Failure Notification alarm for the device is made a symptom of the new PVCLs Failure Notification alarm on the port.

Advanced Correlations and Data Type Comparisons

Verify the following information before you configure advanced correlations, which involve comparisons between different data types:

- Condition Correlation converts the right-hand value to the left. This conversion can be problematic; it is unlikely that a real number conversion produces the same text string that you have for a comparison.
- SNMP represents both real text strings (such as, messages, and information), and octet strings (such as, Mac addresses) with no indication of the actual usage. Therefore, in some cases it is impossible for the automatic conversion process to convert to the actual type which you need for a comparison. Because, Condition Correlation does not have the meta-information.
- Condition Correlation does not attempt to convert list types.

REST Examples for Correlation Testing

This section contains examples to help you test and debug custom correlation systems that you have created.

Two examples of simulated events are provided to help you test correlations. In the following XML examples, replace the [model_handle] field with the actual model handle of the target model. You can perform this task through the DX NetOps Spectrum CLI (using show models) or through the attribute browser, by reading the value of the Model_Handle attribute with attribute ID of 0x129fa.

RESTful Web Services XML Example - No Event Variables

The following XML example lets you generate an event for testing purposes without event variables (for example, Event00010220, the model has gone into Maintenance Mode). Use this event template as a framework to develop simulation and testing tools for Condition Correlation testing.

```
<?xml version="1.0" encoding="UTF-8"?>
<rs:event-request throttlesize="10"
xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
```

```
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/Request.xsd">
<rs:event>
<!-- target model of event -->
<rs:target-models>
<rs:model mh="0x100000"/>
</rs:target-models>
<!-- event ID -->
<rs:event-type id="0x10220"/>
</rs:event>
</rs:event-request>
```

RESTful Web Services XML Example - with Event Variables

The following sample XML generates an artificial event for testing with event variables. Use this event template as a framework to develop simulation and testing tools for Condition Correlation testing:

```
$SPECROOT/RestfulExamples/xml/Events/CreateEventByModelHandleList.xml
<?xml version="1.0" encoding="UTF-8"?>
<!--
This sample event request will create an event of type
0x10f06 (generates a High Memory Utilization alarm).
->
<rs:event-request throttlesize="10"
xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/Request.xsd">
<rs:event>
<!-- target model of event -->
<rs:target-models>
<rs:model mh="0x100000"/>
</rs:target-models>
<!-- event ID -->
<rs:event-type id="0x10f06"/>
<!-- attributes/varbinds -->
<rs:varbind id="0">75</rs:varbind>
<rs:varbind id="1">99</rs:varbind>
<rs:varbind id="3">mem_instance</rs:varbind>
<rs:varbind id="5">ModelName</rs:varbind>
</rs:event>
</rs:event-request>
```

NOTE
Replace the 0x100000 in the modelmh field with the correct model handle (while retaining the double quotes).

NOTE
You can also edit the attribute varbinds to reflect the number of varbinds (or event variables), their index, and value. This example specifies the following four varbinds:

- Event Variable 0: Value = 75 (memory threshold)
- Event Variable 1: Value = 99 (actual memory utilization)
- Event Variable 3: Value = mem_instance (Memory Instance)
- Event Variable 5: Value = name (Memory Instance Name)

Other events can have a different number of varbinds. But this XML example can be edited as appropriate to have the correct number of varbinds.

Configure WizTools RESTClient

Configure the WizTools REST client to work in a DX NetOps Spectrum environment. The following steps illustrate how the REST client can be configured before sending the XML request to the OneClick web server.

> **NOTE**
> Any REST client can be used to interact with the DX NetOps Spectrum web services. However, in this document, we describe how to configure a specific REST client application. We selected this particular client for its simplicity and ease of use.

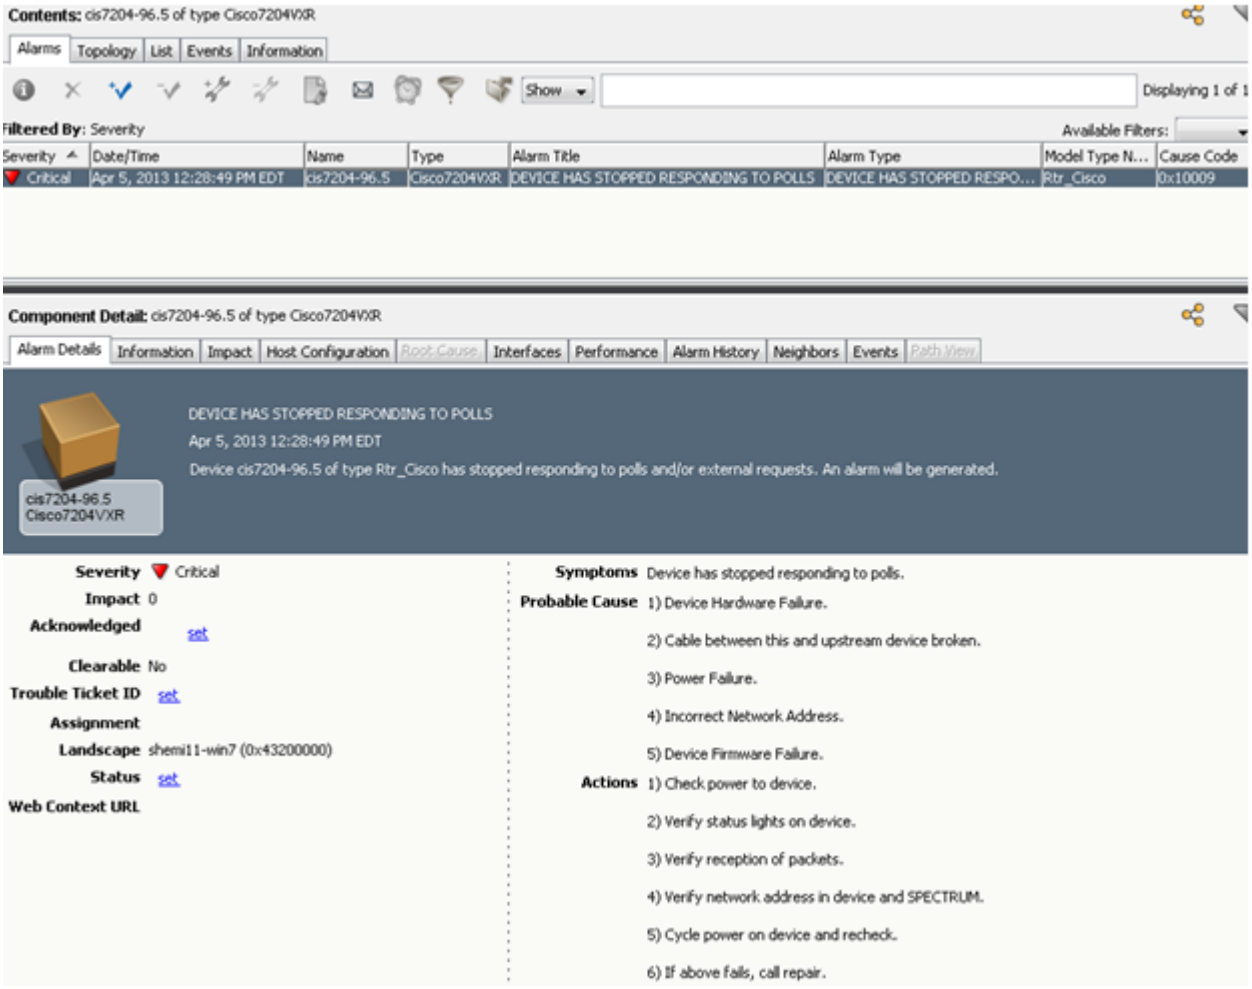
Follow these steps:

1. Add the following string to the URL dialog:
   ```
   http://OneClick web server hostname/spectrum/restful/events
   ```
2. Click the Method tab and select Post.
3. Click the Body tab and select String Body from the list.
   The Body Content-type dialog opens.
4. Supply 'application/xml' for the Content Type.
5. Leave the Charset at 'UTF-8'.
6. Paste the XML contents into the String Body field.
7. Click the Auth tab and select BASIC from the list.
8. Supply values for the following parameters:
   - **Host**
     Specifies the hostname of the OneClick web server.
   - **Realm**
     Identifies the type of authentication.
     Note: Leave this field blank.
   - **Username**
     Indicates the username of the operator who is authorized to access OneClick.
   - **Password**
     Indicates the password.
9. Click Go (>>).
   The WizTools REST client is configured.

Create and View Simulated Alarms An Example

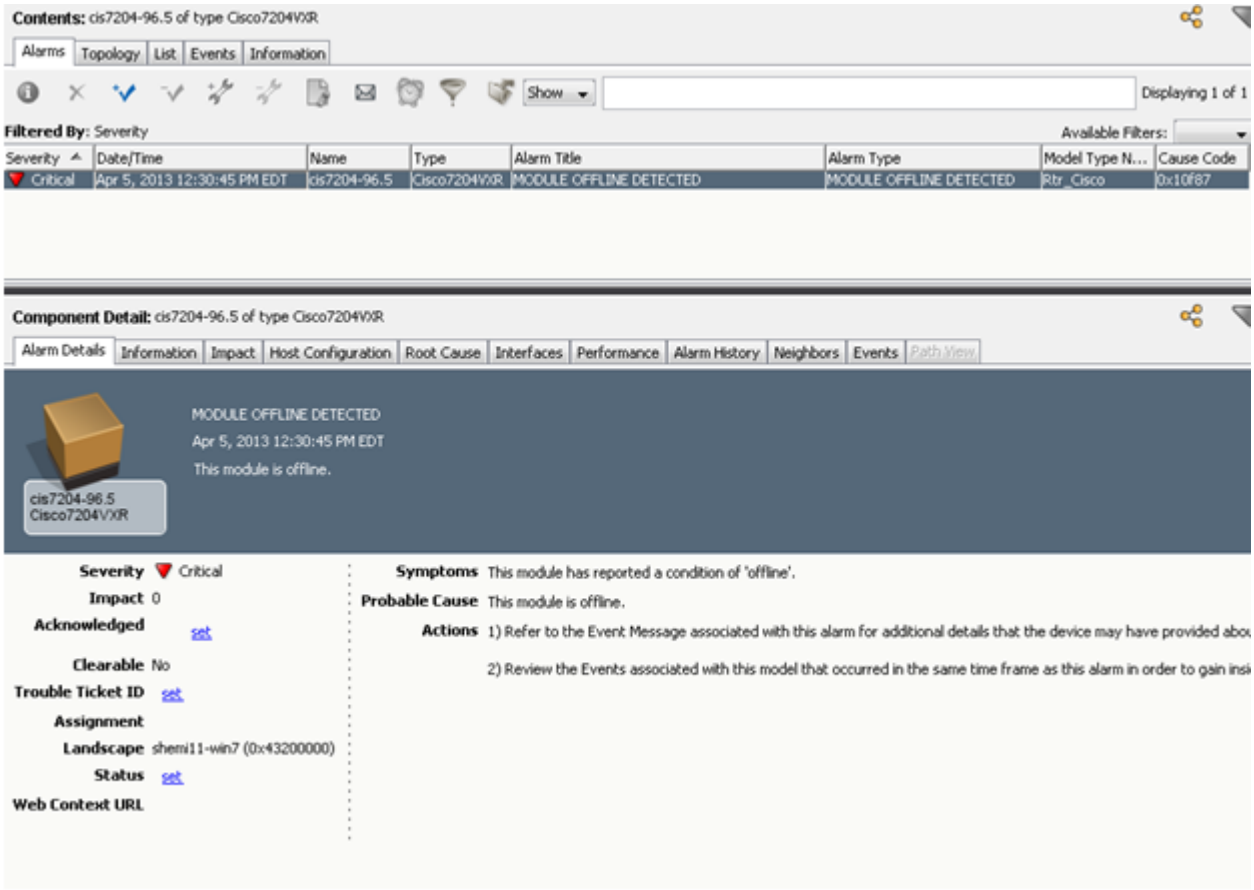
The simulated alarms that you create using the DX NetOps Spectrum CLI or web services can be viewed in the model Alarm View. Create the appropriate events on a managed entity, where DX NetOps Spectrum simulates that an alarm condition exists (although no actual condition exists). DX NetOps Spectrum treats the simulated alarm as if it were an actual alarm on the managed entity. The same intelligence is executed, and the same alarms are displayed in OneClick.

For example, the following image illustrates a simulated Device Contact Lost alarm:



The ModuleOffline event that is created causes the ContactLost alarm to be hidden.

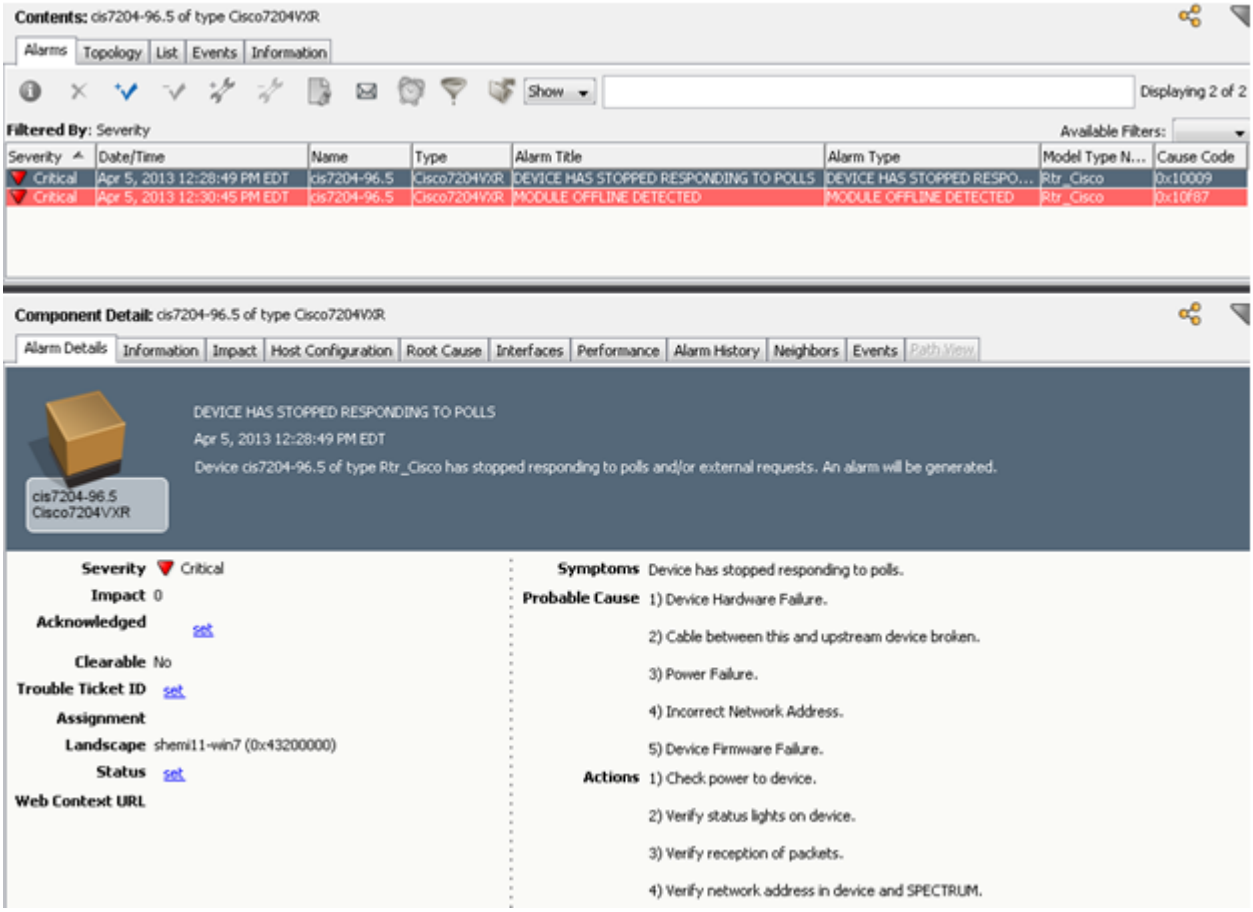
The following image illustrates the ModuleOffline event:



If the Alarm View alarm filter state is changed from its default setting to Show Symptoms, the following alarms are displayed.

- Symptom Alarm: Contact Lost
- Root-Cause Alarm: ModuleOffline

The following image illustrates the Symptom and Root-Cause alarms:



You can clear these alarms by creating the following Clear events:

- ModuleOffline Clear: Event 0x00010f89
- ContactLost Clear: Event 0x00010d30

Device Management Reference

This section introduces DX NetOps Spectrum Device Management documentation for the following devices (presented alphabetically):

AM Communications

This section introduces the DX NetOps Spectrum Device Management documentation for the AM Communications Integration.

Supported Devices

AM Communications develops network management products for non-SNMP broadband components. They monitor RF (Radio Frequency), HFC (Hybrid FIber Coax) components. The NetMentor software package of Cheetah, with optional SNMP Agent Module, converts their proprietary events into SNMPv1/v2 alarms and traps. This management module uses the Generic Southbound Application Gateway integration to provide a place for trap reception and event creation.

This management module supports the Omni2000 Proxy Agent. Omni2000 Proxy Agent is the HFC component monitoring solution of AM Communication.

The DX NetOps Spectrum Model

No specific AM Communications model types are created. The Southbound Gateway provides the model types EventAdmin and EventModel. These model types are used to manage the information that the Omni2000 Proxy Agent sends to DX NetOps Spectrum.

EventAdmin is a container model type that is used to represent the Omni2000 Proxy Agent. EventModels represent unique sources of trap information that the Omni2000 Proxy Agent passes to DX NetOps Spectrum. EventModels are automatically placed in a topology view that you can access by drilling down from the EventAdmin model. These icons do not show any connectivity with one another because they represent an event source, not necessarily a physical device or component.

When the EventAdmin model receives a trap from the Omni2000 Proxy Agent, it maps the trap to a DX NetOps Spectrum event. It then sends the event to the appropriate EventModel for processing. If an EventModel that represents the unique source of trap information does not exist, it is automatically created.

The SouthBound Gateway Toolkit contains instructions for creating an EventAdmin model. Use the EventAdmin model to represent the AM Communications management application.

When you create this model, select a Manager Name of Omni2000.

Traps, Events, and Alarms

This section describes how the AM Communication Integration sends the traps. It also describes how the EventAdmin and EventModels process and manage these traps.

As the Omni2000 Proxy Agent sends traps to DX NetOps Spectrum, the EventAdmin model receives them, and maps them to a DX NetOps Spectrum event. These events are sent to an EventModel that represents the trap source. The value of the NEModelNumber variable binding that is sent in the trap identifies the trap source. This variable binding is from the AMC-MIB**.** If an EventModel representing the trap source does not exist, it automatically is created.

When the EventModel receives the event, it is processed and can be used to create or clear an alarm. The following table displays how each trap is mapped to a DX NetOps Spectrum event and how the event is processed.

trap	alarm	event code	description
NewNEFound		0x3eb0001	HFC Proxy detected new Network Element.
Communicatio-nsStatus		0x3eb0002	HFC Proxy lost or restored communication with Network Element.
Configuration Change	orange	ox3eb0003	Configuration of a single variable of any type was changed (via any interface).
StatusChange		0x3eb0004	An active alarm was cleared.
Alarm	orange	0x3eb0005	An ALARM is detected by a proxy agent.
ToBeSendQue-ueOverflow	orange	0x3eb0006	SNMP agent's TrapToBeSendQueue is full.
NewNELost	orange	0x3eb0007	HFC Proxy Detected New Network Element Lost.

Ceterus Universal

This section describes common deployment scenarios for the Ceterus Universal Transport System devices and how to model them in DX NetOps Spectrum.

Trap Processing

You can configure the Remote Ceterus device to forward traps through its EOC channel to the Local device. In this configuration, the Local device acts as a gateway and forwards these traps. For more information about this feature, see the Ceterus documentation.

You can also configure the Remote device with an SNMP target IP address. In this configuration, the device sends traps through its management port.

If both of these capabilities are configured simultaneously, DX NetOps Spectrum receives duplicate traps. The Ceterus management module is designed to handle this case. It evaluates the incoming Ceterus traps and asserts those traps on the most appropriate DX NetOps Spectrum device model. The management module selects the appropriate model by comparing the Ceterus device community string in the trap with the value of the device sysName.

> **WARNING**
> DX NetOps Spectrum relies on the community name of the device to make this determination. As a result, the community name and the sysName must be synchronized. Polling of sysName occurs every 5 minutes by default. Changing the TID can affect the handling of the trap until sysName has been properly updated through a poll. When an administrator changes the TID (sysName) on a given Ceterus device from “Device A” to “Device B,” the device sends traps to that model. In this case, DX NetOps Spectrum can no longer process the traps. Trap processing does not recommence until the sysName is updated (up to a maximum of 5 minutes by default).

Cheetah Gateway

This section describes DX NetOps Spectrum support for monitoring Cheetah™ network management products.

Supported Devices

Cheetah™ products, including CheetahNet™ (formerly NetMentor™) are network management products for non-SNMP broadband components. They monitor RF (Radio Frequency), and HFC (Hybrid Fiber Coax) components. The CheetahNet/NetMentor software package, with an optional SNMP Agent Module, converts their proprietary events into SNMPv1/v2 alarms and traps. This management module uses the DX NetOps Spectrum Southbound Gateway integration to enable traps to be received and events to be created in DX NetOps Spectrum.

This management module provides an integration between the CheetahNet/NetMentor management application, including the SNMP agent module, and DX NetOps Spectrum. This integration can report events on the following types of HFC devices:

- Power Supply
- Amplifier
- Line Monitor
- Test Point
- Fiber Node
- HEFiber

The DX NetOps Spectrum Model

No specific Cheetah model types are created. The Southbound Gateway provides the EventAdmin and EventModel model types. These model types are used to manage the information that NetMentor sends to DX NetOps Spectrum.

The EventAdmin is a container model type that is used to represent the NetMentor management application. EventModels represent unique sources of trap information that the CheetahNet/NetMentor application passes to DX NetOps Spectrum. EventModels are automatically placed in a topology view that can be accessed by drilling down from the EventAdmin model. These icons do not show any connectivity with one another because they represent an event source, not necessarily a physical device or component.

When the EventAdmin model receives a trap from the CheetahNet/NetMentor application, it maps the trap to a DX NetOps Spectrum event. The EventAdmin also sends the event to the appropriate EventModel for processing. If an EventModel that represents the unique source of trap information does not exist, it is automatically created.

Creating the EventAdmin Model

The SouthBound Gateway Toolkit section contains instructions for creating an EventAdmin Model. Use the EventAdmin model to represent the CheetahNet/NetMentor management application. When you create this model, select a Manager Name of NetMentor.

Traps, Events, and Alarms

This section describes how the EventAdmin and EventModel process and manage traps that are sent by the CheetahNet/NetMentor integration.

As CheetahNet/NetMentor sends traps to DX NetOps Spectrum, the EventAdmin model receives these traps and maps them to a DX NetOps Spectrum event. These events are sent to an EventModel that represents the trap source. The value of the **CNAlarmResource** and the **CNAlarmSubResource** variable bindings that are sent in the trap identify the trap source. Each of these variable bindings is from the CNAlarmsMib (CheetahNet Alarms MIB)**.** If an EventModel representing the trap source does not exist, it is automatically created.

When the EventModel receives the event, it is processed and can be used to create or clear an alarm. The following table describes how each trap is mapped to a DX NetOps Spectrum event and how the event is processed.

Trap OID	Trap Name	Event Generated	Alarm Generated or Cleared	Alarm Severity
1.3.6.1.4.1.1283.10.6.1	Device added	0x3e00001	NA	NA
1.3.6.1.4.1.1283.10.6.2	Device deleted	0x3e00002	NA	NA
1.3.6.1.4.1.1283.10.6.3	Configuration changed	0x3e00003	0x3e00003	Orange
1.3.6.1.4.1.1283.10.6.4	Clear Alarm	0x3e00004	Clears 0x3e00003, 0x3e00005, 0x3e00006, 0x3e00007, 0x3e00008	NA
1.3.6.1.4.1.1283.10.6.5	Warning alarm	0x3e00005		Yellow
1.3.6.1.4.1.1283.10.6.6	Minor alarm	0x3e00006		Yellow
1.3.6.1.4.1.1283.10.6.7	Major alarm	0x3e00007		Orange
1.3.6.1.4.1.1283.10.6.8	Critical alarm	0x3e00008		Red

HP BladeSystem c-Class

This section describes DX NetOps Spectrum support for monitoring the Hewlett-Packard (HP) BladeSystem c-Class device family.

Overview

Support for the HP BladeSystem c-Class device family is available in DX NetOps Spectrum with an enhanced certification. The top-level management uses the model of the HP BladeSystem Onboard Administrator (OA). This device family is modeled and represented in the topology with a OneClick icon representing a chassis.

DX NetOps Spectrum> chassis device management includes the following features:

- Support for the C7000 and C3000 chassis types.
- OA support, represented in DX NetOps Spectrum with a unique model type and chassis icon.
- Automatic blade modeling. After OA modeling, a nontopological module model is created for each occupied chassis slot. These models represent the hardware level view of an occupied slot.
- Automatic chassis identification of previously modeled device models, or managed devices, either pingable or SNMP capable, that are running on a blade.
- Enhanced Interface tab to show the hierarchy view of blades and interfaces for a given chassis. Chassis, managed devices, module models, and interfaces each have a unique icon in the hierarchy.
- Managed devices can be manually associated (or disassociated) with their chassis using a right-click menu option.
- Jump-to navigation from a managed device model to its chassis.
- Jump-to navigation from a module model to its managed device if it exists.
- Support of several chassis-based OneClick views.
- Chassis-based Locater searches.
- Enhanced Fault Isolation capabilities ensure that a single alarm is generated on a chassis-wide failure, eliminating a multiple alarm scenario.

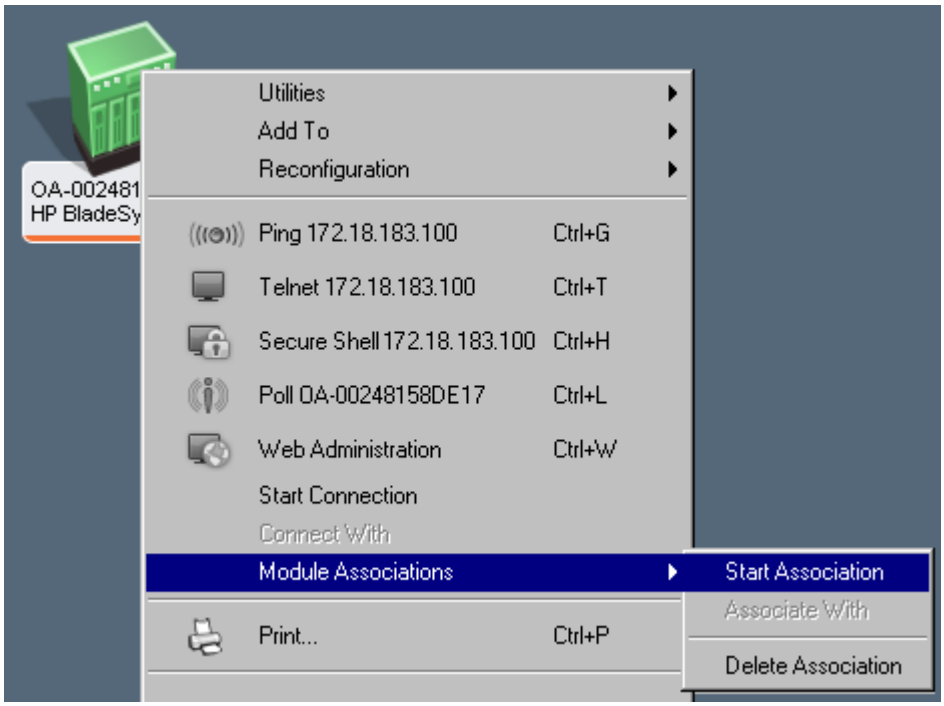
Configuration

Analysis of the chassis modeling environment occurs, by default, every 5 minutes. You can change the polling discovery interval for server and interconnect blades by modifying the *configInterval* attribute. This attribute is located on separate application models that are associated with the HPBladeOnboardAdmin model. For server blades, the relevant application model is HPServerBladeApp. For interconnect blades, the relevant application model is HPNetworkBladeApp.

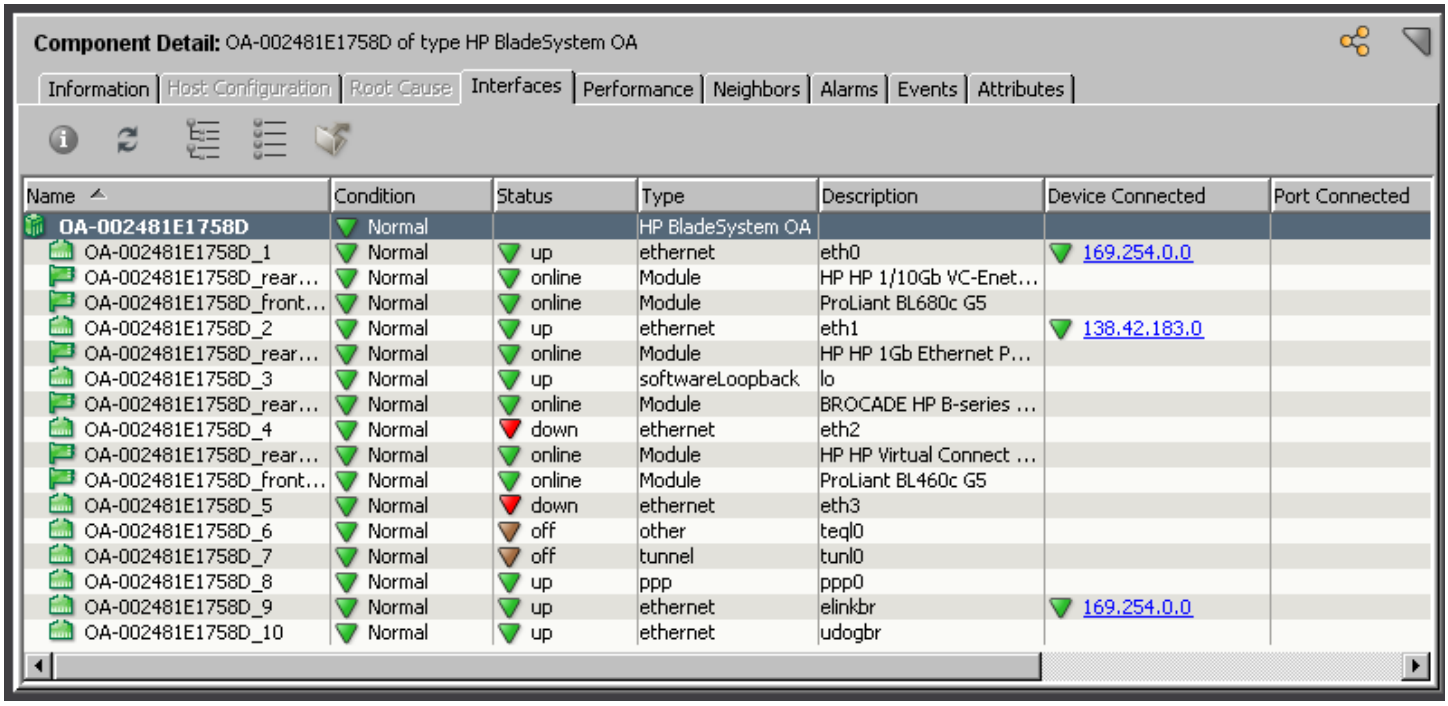
Use the 'By Device IP Address' Locater tab search under Application Models to locate and select the relevant application model. You can modify the *configInterval* attribute using the Attributes tab in the Component Detail panel of OneClick.

Managing Module Associations

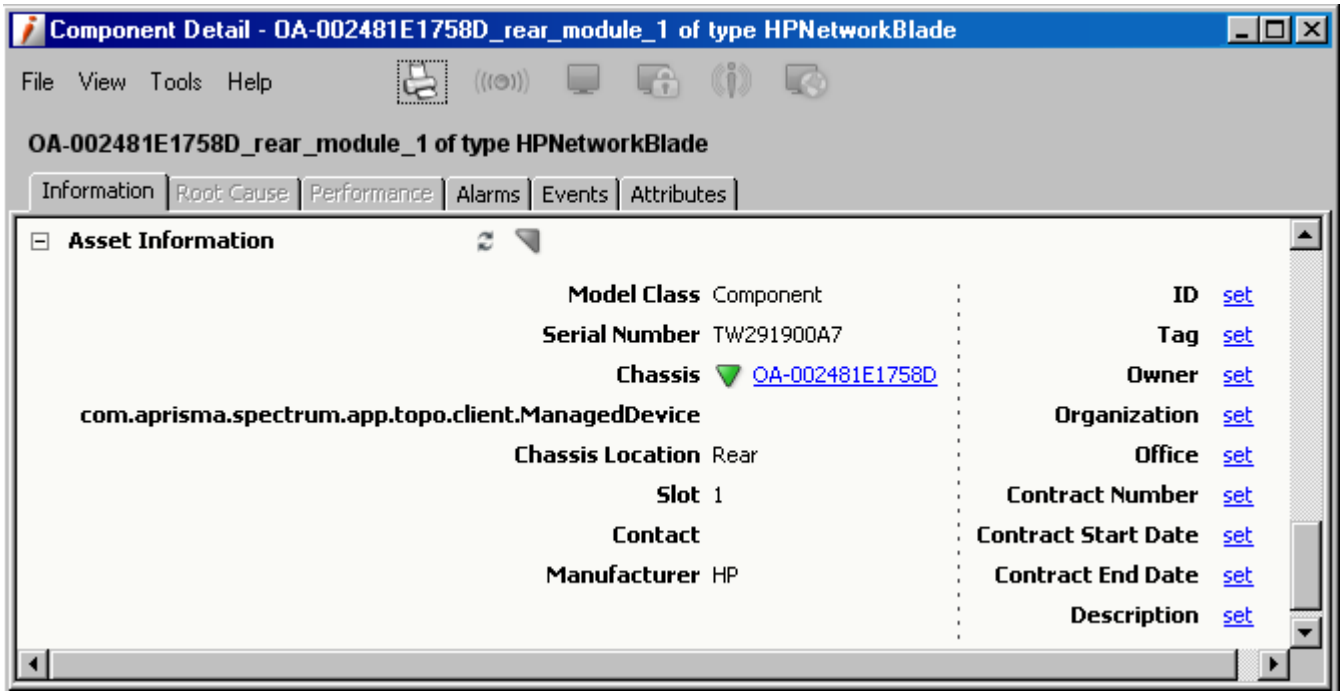
Modeling the OA initiates automated module modeling and creates associations between the modules and the chassis. Existing managed device models that can be identified through a serial number are automatically associated with the chassis. HP Insight Manager Agents do provide the required serial number; they are the recommended configuration. Otherwise, use manual association through the 'Module Associations' menu option. Subsequent Module Association menu options let you manage your association with options such as 'Start Association', 'Associate With', or 'Delete Association'.



You can view the contained modules and their associated interfaces through the OA Interfaces tab. Supported columns provide the chassis location (front or rear), slot number, module type, and description. The module icon helps you identify the type of hardware.

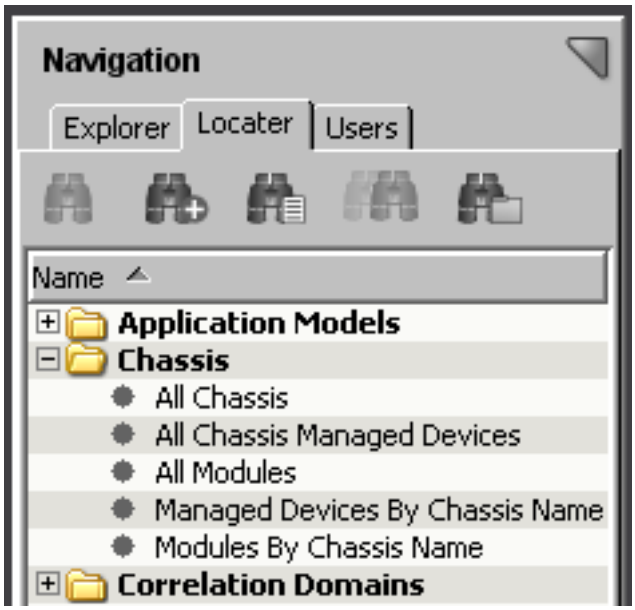


From the perspective of a module model, you can identify the parent chassis using the Chassis navigation link in the Asset Information OneClick view. You can also identify an associated managed device, if one exists, using the Managed Device link in the same view.



Locating Chassis

From the Locater tab of the Navigation panel, you can now see the following Chassis search menu options. This feature assists you in changing the polling discovery interval.

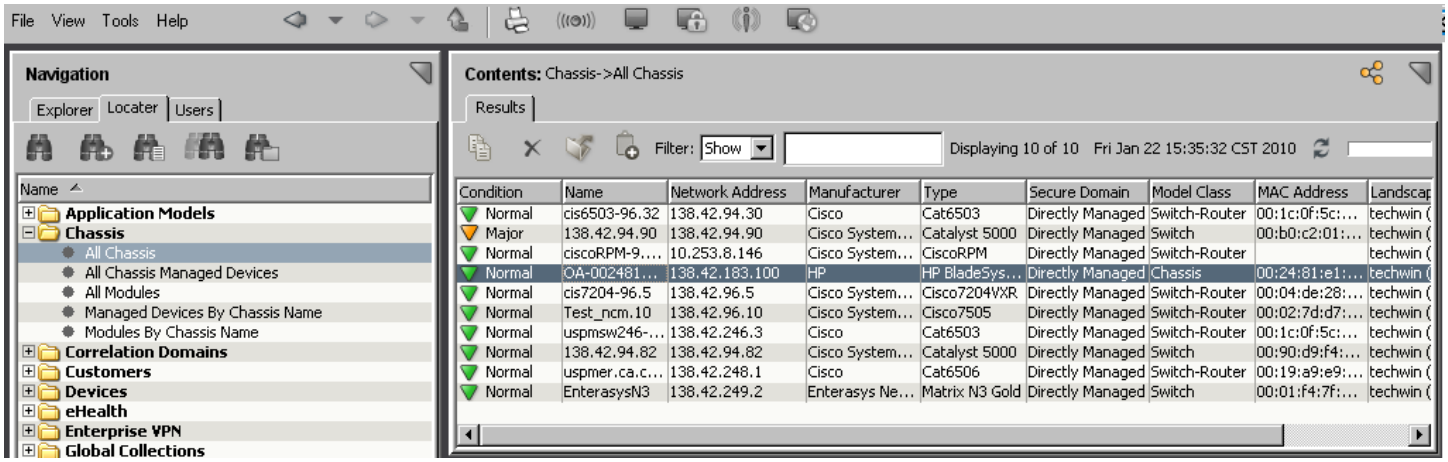


- **All Chassis**
  Displays all chassis models (HP OA model, for example)
- **All Chassis Managed Devices**

Displays all device models that are managed through DX NetOps Spectrum that are running on a blade. This search only includes pingable or SNMP-capable device models. The module models that are created for every occupied slot in a chassis are not included.

- **All Modules**
  Displays all module models, one for every occupied slot in a chassis. The search does not include the managed devices (SNMP- or ICMP-capable). They represent the hardware-level view of an occupied slot.
- **Managed Devices by Chassis Name**
  Displays all device models that DX NetOps Spectrum manages and that are running on a blade on a specified chassis. A subsequent window lets you enter the specific chassis name whose associated devices you want to view.
- **Modules by Chassis Name**
  Displays all module models for the specified chassis. A subsequent window lets you enter the specific chassis name whose associated modules you want to view.

As an example, select the 'All Chassis' chassis search option. The following results appear in the Contents panel:



Juniper M Series

This section describes the Redundant Component Monitoring intelligence available for support of JnprRedundRtr (M20, M40e, and M160) routers in DX NetOps Spectrum.

Redundant Component Monitoring Intelligence

Juniper M20, M40e, and M160 routers support the Redundant Component Architecture. Redundant components include those pieces of hardware that are necessary for proper routing functionality. The following specific components for these routers are passive monitoring and active monitoring.

> **NOTE**
> All Juniper M Series routers can be modeled, without this functionality, by type as a JNPR_Mxxx. This feature provides basic modeling functionality as is described for the JNPR_Mxxx model type.

When either Passive Monitoring or Active Monitoring is invoked, they check for status changes in each type of redundant component. The redundant components of Juniper M Series routers differ based on the following router models:

- **Juniper M20 -** System and Switch Board(s), Routing Engine(s).
- **Juniper M40e** - Routing Engine(s), Miscellaneous Control System(s), System and Forwarding Module(s), PFE Clock Generators.
- **Juniper M160** - Routing Engine(s), Miscellaneous Control System(s), System and Forwarding Module(s), PFE Clock Generators.

Passive Monitoring

Passive Monitoring intelligence reports changes in the status of redundant components only after DX NetOps Spectrum has lost contact with the router. When contact is reestablished with the device, DX NetOps Spectrum queries the device. The query determines whether component status changes have occurred. Passive Monitoring is always on, but it only checks for component status changes in the previously mentioned case.

> **NOTE**
> When contact is reestablished with the device, the components are not always in a “steady” state. The components take a few minutes to reach their steady state. Each router type (M20, M40e, or M160) takes a different amount of time to reach its steady state. As a result, Passive Monitoring waits 60, 90, or 120 seconds before checking the states of the M20, M40e, or M160 components.

Active Monitoring

Active monitoring is used to report changes in the status of redundant components. The value of the Active Polling Interval determines the frequency of active monitoring. This interval determines how often (in seconds) the Active Monitoring intelligence queries the device to find component status changes. The field is read/write. For example, if the Active Polling Interval is set to 60, the device is queried every 60 seconds for component status changes. When Active Monitoring is enabled, it works in addition to the functionality provided by Passive Monitoring.

You have several other options for enabling or disabling this functionality. First, you can set the Active Polling Interval to 0 to disable active polling. Change the value to a value in seconds to enable this functionality when the Active Monitoring attribute is set to True. Changing the Polling Status of the device model to False also disables Active Monitoring.

Setting the Polling Interval of the device model to 0 also disables Active Monitoring. Changing Polling Status to True or changing the Polling Interval to a nonzero value does not reenable Active Monitoring, when Active Monitoring is disabled.

Never set the Active Polling Interval to a value that is less than the "steady" state time for the given router type. For example, the "steady" state time for an M20 is 60 seconds. Set the Active Polling Interval to a value that is greater than 60.

The following attributes control the Active Monitoring intelligence:

- **ActiveMonitor** - Enables or disables the active monitoring intelligence. The default value is disabled.
- **ActivePollInt** - Determines the frequency (in seconds) of Active Monitoring queries to the device for component status changes.

Juniper SRX Devices

Support for Juniper Logical Systems Route

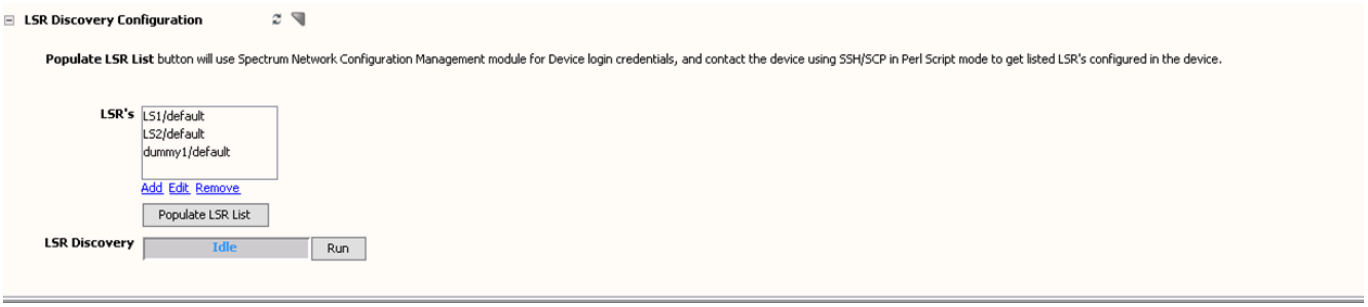
Starting from the 10.2.3 release, DX NetOps Spectrum supports Juniper SRX devices Logical Systems Route. DX NetOps Spectrum uses Network Configuration Management Perl script SSH mode to fetch a list of Logical Systems Routes (LSRs).

DX NetOps Spectrum discovers each LSR as a new Juniper model type. The LSR name is appended with default device name.

After discovery, Spectrum creates an interface for Juniper SRX devices and discovers the connection using the auto-discovery. All LSRs are associated to a container model and placed under the virtual device manager node.

LSR Discovery Configuration

The LSR Discovery Configuration section in the OneClick Interface tab allows you to configure the LSRs in DX NetOps Spectrum.



Using the LSR Discovery Configuration section, you can add, edit, or remove the LSRs in DX NetOps Spectrum.

The 'Populate LSR List' button allows you to get list of LSRs configured in the device using the SSH/SCP in Perl Script mode. It used the Spectrum Network Configuration Management mode for device login credentials.

LSR Discovery

The LSR Discovery option allows you to discover the LSRs configured in a device.

LSR hierarchy in the Explorer tab

After the discovery, a new hierarchy gets created for LSRs under the Virtual Device Manager in the Explorer tab. You can see the discovered devices in the Topology tab.

LSR Locater Search

You can use the Locater Search to search for 'All LSR Devices' and 'All LSR Host Devices'.

Netscreen Firewall

This section describes the Netscreen Tunnel Interface model type (nsTunnelIf) and its functionality.

Tunnel Interfaces

This section describes DX NetOps Spectrum support for monitoring NetScreen Firewall tunnel interfaces.

Model Tunnel Interfaces

Various attributes control whether the site-to-site Tunnel Interfaces are modeled on your Netscreen device. You can model other types of tunnel interfaces by using the following procedure. By default, DX NetOps Spectrum does not model Dialup Tunnels or Tunnels whose monitor state is set to OFF. To enable the modeling of these types of tunnels, use the Model Type Editor.

Follow these steps:

1. Shut down the SpectroSERVER and start the Model Type Editor.
2. To enable modeling of Dialup Tunnels, use the Search text box on the Attributes tab to find the TunnelFilterTypes attribute (0x12a17) of the NSFirewallVPN model type.
3. Remove the value 1 from the list of values for this attribute.
4. To enable modeling of tunnels whose monitor state is OFF, use the Search text box on the Attributes tab to find the TunnelFilterStates attribute (0x12a19) of the NSFirewallVPN model type.
5. Remove the value 0 from the list of values for this attribute.
6. Save your changes in the Model Type Editor, and restart the SpectroSERVER.

7. Reconfigure the Netscreen models using the Manually Poll Device option that is available for each device model. The tunnel interfaces are modeled.

Tunnel Interface “Stacking”

Tunnel interface models are created as subinterfaces of the physical interface whose IP address matches the local address of the tunnel. This behavior is indicated in the VPN-MON.mib. Because NetScreen devices do not support the ifStackTable, this mechanism for determining the lower-layer interface is necessary and effective.

Automatic Connectivity Mapping

A tunnel interface model activates for the first time during initial device modeling or during an interface reconfiguration. Then, DX NetOps Spectrum searches for a tunnel interface model that represents the other end point of the tunnel. If such a model is found, the connection between these two interfaces is modeled. DX NetOps Spectrum uses the local address and remote address that are indicated in the VPN-MON.mib to find the other end point of the tunnel.

Interface Model Identification

You can identify a Tunnel interface model by its local address and remote address, as indicated in the VPN-MON.mib. This identification method lets DX NetOps Spectrum preserve the interface model if the ifIndex of the interface changes.

Status Monitoring of Tunnel Interfaces

On the NetScreen device, the ifOperStatus of a tunnel interface entry is always "UP until it disappears from the ifTable. If a tunnel model becomes "stale", and no link down trap is processed for the tunnel, DX NetOps Spectrum generates a red alarm on the model.

This alarm is suppressed in the following cases:

- If the physical interface is down (the same case in which a link down trap alarm is suppressed).
- If the "Suppress Linked Port Alarms" setting of the Live Pipes model is set to True, and either of the following conditions are met:
  - The connected device is unreachable (by the SpectroSERVER)
  - The "linked" tunnel interface model has an alarm (red)

This status monitoring functionality is only available when Live Links are enabled for the port that is associated with the tunnel interface. For information about enabling Live Links, see the Modeling and Managing Your IT Infrastructure section.

Nortel Contivity VPN Switches

This section describes DX NetOps Spectrum support for monitoring Nortel Contivity VPN switches.

Tunnel Interfaces

This section describes the Tunnel Interface Filter functionality for Nortel Contivity devices.

Tunnel Interface Filtering

The ContivityVPN device populates the **ifTable** with both user and branch VPN tunnel interface entries. However, thousands of user VPN tunnel interfaces can exist. The ContivityVPN interface filtering functionality filters out user tunnel interfaces and prevents unnecessary modeling of these interfaces.

NOTE
Tunnel interface filtering is only available for models of type **ContivityVPN**.

Enabling and Disabling Tunnel IF Filtering

The following steps enable or disable Tunnel IF filtering:

Follow these steps:

1. In the Model Type Editor, set the default list value for the attribute If_Mtype_Map handle 0x011fb4.
2. Look at the list of values, and locate OID instance 131.
3. Set to a value of 0. This setting prevents the interface type from being modeled.
4. To disable the tunnel interface filtering and enable model creation, set this value to 220013.

Modeling of Tunnel Interfaces

The Create Sub-Interface attribute of the Contivity device model controls the creation of models to represent site-to-site or branch tunnel interfaces. No models are ever created to represent "user" tunnels. This behavior is consistent with previous versions.

Tunnel Interface "Stacking"

Tunnel interface models are created as sub-interfaces of the physical interface. The IP address of the physical interface matches the local address of the tunnel as indicated in the Tunnel MIB. The Contivity devices do not support the ifStackTable. As a result, this mechanism of determining the lower-layer interface is necessary and effective.

Automatic Connectivity Mapping

A tunnel interface model activates for the first time during initial device modeling or during an interface reconfiguration. Then DX NetOps Spectrum searches for a tunnel interface model that represents the other end point of the tunnel. If such a model is found, the connection between these two interfaces is modeled. DX NetOps Spectrum uses the local address and remote address that are indicated in the Tunnel MIB (rfc2667) to find the other tunnel end point.

Interface Model Identification

You can identify the Tunnel interface models by their local address and remote address, as indicated in the Tunnel MIB (rfc2667). This identification lets DX NetOps Spectrum preserve the interface model even if the ifIndex of the interface changes.

Interface Model Aging

During an interface reconfiguration, any interface model that is no longer represented in the MIB is marked as "stale" instead of being destroyed. This feature lets DX NetOps Spectrum retain the connectivity modeling between tunnel interfaces and other devices while the tunnel is down. The connectivity information can then be used for the event correlation and fault suppression.

On subsequent reconfigurations, the port age-out time of the device model is compared with the time period that the interface model has been stale. If the interface does not reappear in the MIB, the interface model is destroyed after it ages out. If the interface does reappear in the MIB, the interface model is marked as "current." The port is marked as stale by setting the "isStale" attribute to True. You can set the port age-out time per device Set the "PortAgeOutTime" on the device to a number of minutes. The default age-out time for the Contivity device is two hours (120 minutes).

Link Down Trap Correlation

To avoid sending multiple alarms for a single network outage, link down traps for "tunnel" interface models are correlated with other conditions. The alarms for link down traps are suppressed when the lower layer (that is, the physical interface)

is down. When the "Suppress Linked Port Alarms" setting of the Live Pipes model is set to True, the alarms for the link down traps are suppressed. The alarms are suppressed under the following conditions:

1. The connected device is unreachable (by the SpectroSERVER).
2. The "linked" tunnel interface model has an alarm (is red).

Status Monitoring of Tunnel Interfaces

On the Contivity device, the ifOperStatus of a tunnel interface entry is always "UP" until it disappears from the ifTable. When a tunnel model becomes "stale" and link down traps have not been processed for the tunnel, DX NetOps Spectrum generates a red alarm on the model. The red alarm is suppressed in the same cases in which a link down trap alarm is suppressed. The red alarm is suppressed when the lower layer (that is, physical interface) is down. When the "Suppress Linked Port Alarms" parameter of the Live Pipes model is set to True, this alarm is suppressed.

The alarm is suppressed under the following conditions:

1. The connected device is unreachable (by the SpectroSERVER).
2. The "linked" tunnel interface model has an alarm (red).

Contivity Management Settings

The following Contivity settings are recommended.

Enable Tunnel MIB

We recommend enabling the Tunnel IP MIB on all managed Contivity devices. This setting lets DX NetOps Spectrum create models to represent the tunnel end points on the device. This MIB can be enabled and disabled from the ADMIN->SNMP section of the Contivity web management pages.

Enable Link Up/Down Traps

We recommend enabling link up and link down traps for physical interfaces and for "Nailed-Up" branch tunnels. This setting gives DX NetOps Spectrum immediate notifications of link state changes. Our testing has shown that link traps for "OnDemand" tunnels do not provide much value. The tunnel must be down for approximately 15 minutes before the trap is sent.

Nail-Up Your Monitored Tunnels

We recommend that all tunnels for which connection monitoring is important be "Nailed-Up". DX NetOps Spectrum does not alarm "OnDemand" tunnels when they go down. Specifically, the Alarm on LINK down Trap attribute of the Tunnel_If model determines whether it responds to link down traps or changes to the isStale attribute. A value of Always (1) causes DX NetOps Spectrum to process these events; a value of Never (0) causes DX NetOps Spectrum to ignore them. When DX NetOps Spectrum creates the Tunnel_If models for the Contivity, it sets this attribute to Always for "Nailed-Up" branch tunnels, and Never for "OnDemand" tunnels.

Change the Alarm on LINK down setting from the Configuration tab of the Global Attribute Editor. We recommend leaving it as DX NetOps Spectrum has set it.

Management Settings

The following DX NetOps Spectrum management settings are recommended.

Automatically Reconfigure Interfaces

Set this attribute to True for the Contivity models if you want DX NetOps Spectrum to manage the branch tunnels of the device. For the devices that only support "User" tunnels, set this attribute to False. When set to True, DX NetOps Spectrum reconfigures the interface models whenever the ifNumber object of the SNMP agent changes on the device.

Reconfigure on LINK change

We recommend setting this attribute to False for all Contivity models. When it is set to True, DX NetOps Spectrum performs an interface reconfiguration after every link up or every link down trap is received.

Discovery after Reconfigure

We recommend retaining the default value of False for the Discovery after Reconfigure attribute for all Contivity models. DX NetOps Spectrum models connections between newly found tunnels regardless of this setting. The DX NetOps Spectrum autodiscovery process adds little or no value after most link state changes, especially for Contivity devices. For these devices, most link state changes represent tunnels coming up and going down, and not the configuration of new router or bridge ports.

Create Sub-Interfaces

Set this attribute to True for Contivity models if you want DX NetOps Spectrum to monitor the branch tunnels. If this attribute is set to False, DX NetOps Spectrum does not create models for the tunnel interfaces.

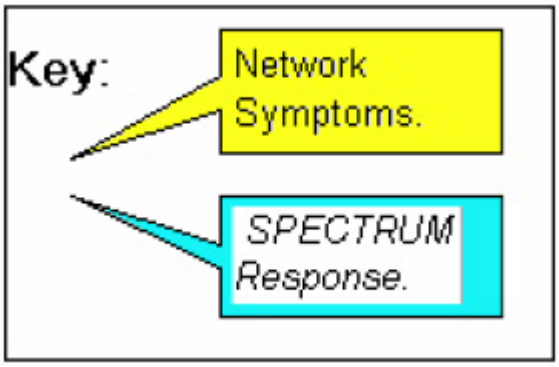
Suppress Linked Port Alarms

We recommend setting this attribute of the Live Pipes model to True. This setting suppresses port alarms when either the connected device is unreachable or the linked port model already has an alarm.

Contivity Fault Scenarios

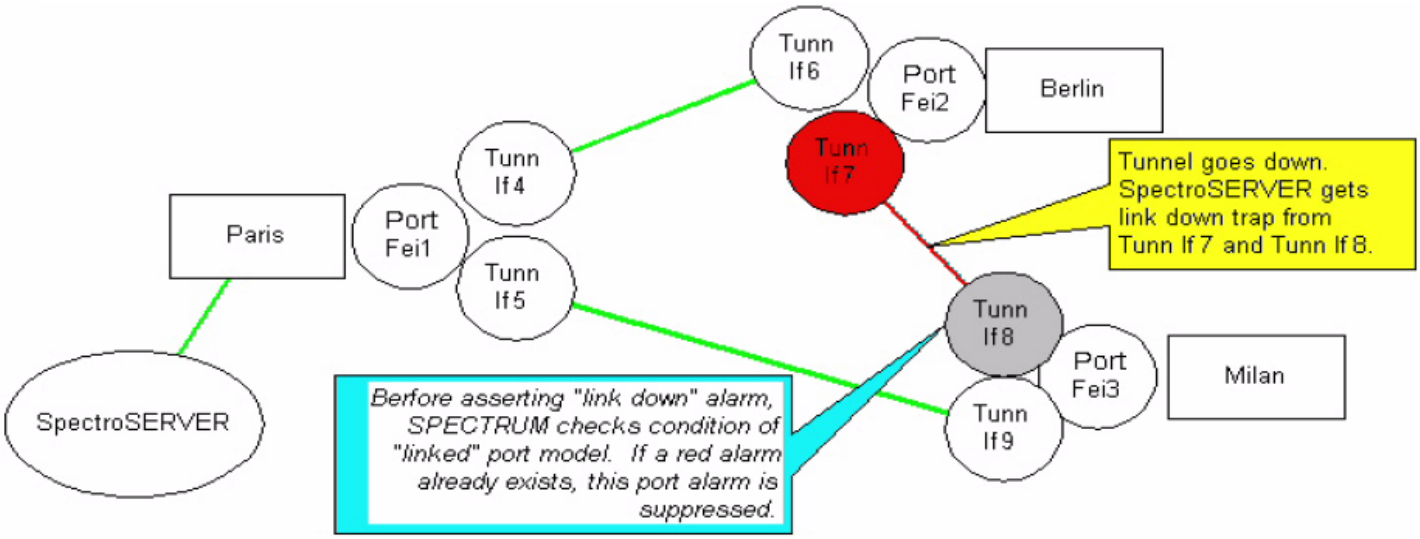
This section describes fault scenarios that are likely in a VPN environment and the DX NetOps Spectrum response to each scenario.

The following key applies to each of the diagrams in this section:



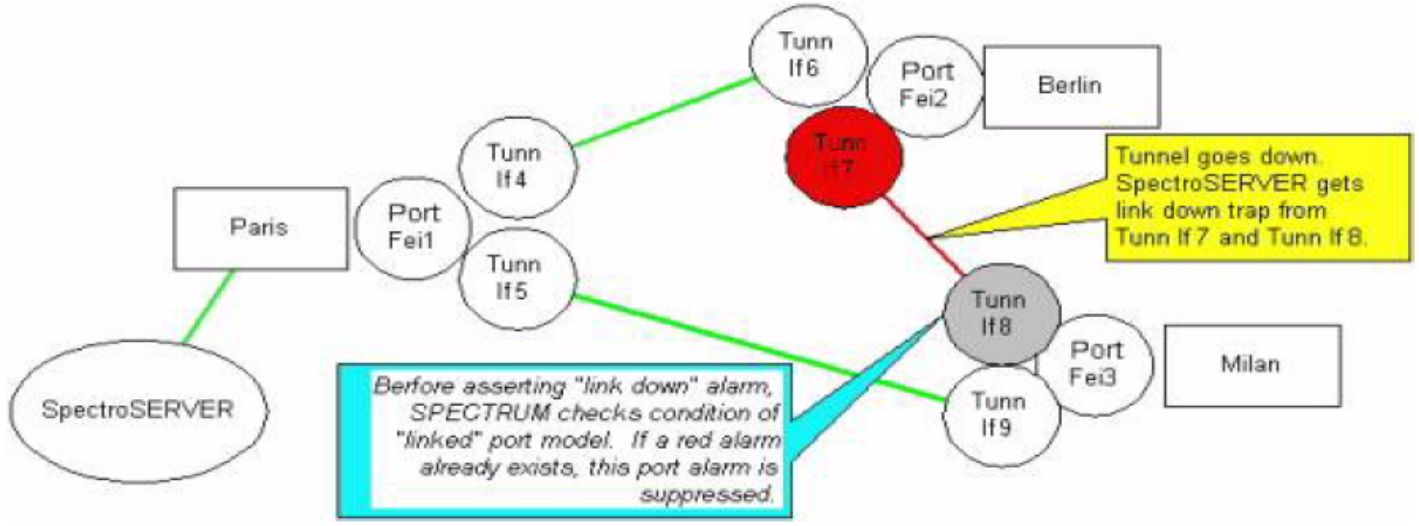
Two Link Down Traps for One Down Tunnel

In the following scenario, the SpectroSERVER retains contact to all managed elements in this meshed environment, but a tunnel between two devices goes down. DX NetOps Spectrum receives two link down traps. One tunnel interface alarms; the other alarm is suppressed.



Loss of Contact and Link Down Trap

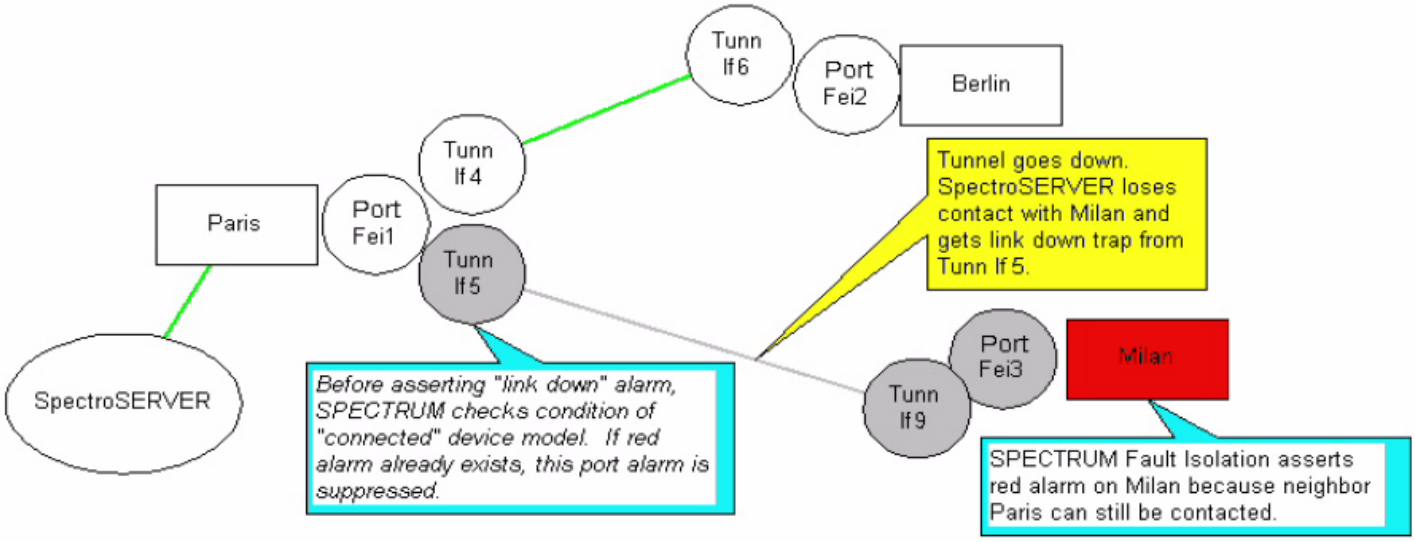
In the following scenario, DX NetOps Spectrum loses contact with a "spoke" Contivity in a hub and spoke network. DX NetOps Spectrum also receives a link down trap from the hub, indicating the tunnel to the lost device. DX NetOps Spectrum sends an alarm for the lost device and suppresses the alarm on the tunnel interface that is indicated by the trap.



Physical Port Down, Loss of Contact, and Link Down Traps

In the following scenario, a physical port of a Contivity goes down or loses its link to the public network. DX NetOps Spectrum gets link down traps for the physical port and tunnels of the Contivity, and loses contact with remote the

Contivity devices. The link down alarms on the tunnel interface models are suppressed, but DX NetOps Spectrum fault isolation creates red alarms on the lost Contivity device models because they have an "up" neighbor.



Known Anomalies - Nortel Contivity

DX NetOps Spectrum contains the following known anomalies.

Sub-Interfaces

When Create Sub-Interfaces is changed from True to False for a Contivity model after tunnel interface models have been created, the tunnel interface models are not destroyed immediately after an interface reconfiguration. Instead, these models go stale and start aging out. To enable tunnel monitoring for a subset of Contivity devices, set the default value of Create Sub-Interfaces to False. Then set Create Sub-Interfaces to True for the individual models of Contivity devices that require tunnel monitoring.

Autodiscovery and Public Address

Generally, the public addresses on the Contivity devices in a VPN are in different subnets because multiple routers separate them. The Contivity devices with public interfaces can be on the same subnet. In this case, autodiscovery can attempt to map the connectivity of the public interfaces. The result would be a LAN container in the same topology view as the Contivity models with pipes to the Contivity models. A fanout model without the LAN would be connected to the public interface models of the Contivity devices.

Port Aging

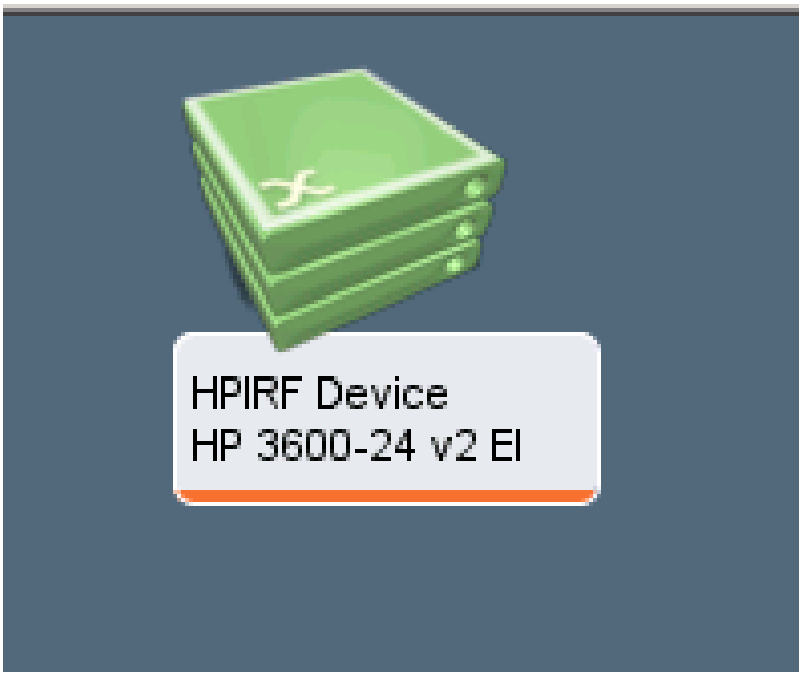
DX NetOps Spectrum port aging is not aggressive. When a tunnel becomes inactive, the tunnel interface model is marked as "Stale". Any future reconfiguration that occurs after the "portAgeOutTime" of the device causes that tunnel model to be destroyed. However, if no future reconfigurations of the device occur, the "Stale" tunnel interface model remains.

For example, consider a polling interval of 5 minutes and a portAgeOutTime of 30 minutes. If a tunnel goes down at 10:27 and DX NetOps Spectrum polls at 10:30, DX NetOps Spectrum detects an ifNumber change and performs and interface reconfiguration. During this process, the tunnel interface is marked as stale. If the tunnel does not come back up, the tunnel interface model is destroyed at 11:00. When ifNumber does not change again for a week, interface reconfiguration cannot run again for a week. This tunnel interface model remains stale for one week and is then destroyed.

HP IRF Device Enhancements

- Modeling of physical devices is successful: After HP IRF device is modeled, double click on the device model to view the physical devices and port level connectivity from the physical devices to neighbor devices.
- EnableChassisTopology option: To show physical devices on the Topology view, enable the attribute 'Enable_Chassis_Topology=Yes'. To enable the attribute to Yes, Navigate to **Topology or List Tab**> **Attribute**> Select the **Enable_Chassis** and set the attribute to '**Yes**'. By default value of Enable_Chassis_Topology is No. This option is applicable only for HPIRF Stack device
- Naming Convention: Appended serial numbers to the master and slave devices in the interface tab, allows for easy differentiation

Icon & device type is displayed: To differentiate the HP IRF stack devices, the icon of devices, now looks as shown in the following screenshot:



There is a change of icon, which is (M) for the master member and (S) for the slave member to help identify the device on the topology.

The master and the slave devices in chassis manager and the interface tab, can now be clearly identified.

NOTE

If a master or slave device is deleted manually then you must reconfigure the model to retrieve the connections.

Limitations:

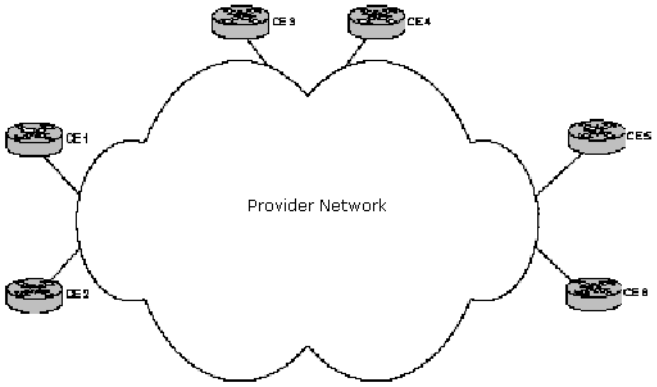
- Changes made to the master and slave devices in OneClick Topology edit mode does not work.
- The interface tab for the HP IRF stack device displays duplicate interfaces (group by IRF stack member and on the stack device).
- The Locater search for stack devices shows a 'no models found' error.
- HP IRF support will not be enabled by default on existing models, after upgrading to 10.3.

Enterprise VPN Manager

About Enterprise VPN Manager

Enterprise VPN Manager is a OneClick application that lets you discover, model, and monitor a provider-provisioned VPN. Your enterprise network ends at your customer edge (CE) devices. When lack access to performance statistics from provider core (P) or provider edge (PE) routers, you can infer service health by monitoring the behavior at the edges of the provider network, where enterprise CE devices exist.

The following illustration shows a typical provider-provisioned VPN from an enterprise customer perspective:



Model the links and devices (the CE routers) connected to a service provider using the Enterprise VPN Manager discovery, manual modeling, or import functionality. The Enterprise VPN Manager component then continuously monitors health and the service that is delivered by a service provider. The Provider_Cloud model represents the service that is provided to you by a service provider. The Outage events are processed and rolled-up into the health of the service provider which is reflected on the Provider_Cloud model. The Outage events are detected by actively polling CE routers for an availability and by polling the status of interfaces on CE routers which are connected to a service provider. Enterprise VPN Manager supports Layer 3 Multiprotocol Label Switching (MPLS) VPN networks for discovery, modeling, and monitoring. In addition, it can also model (manually or by importing the information) and monitor Layer 2 Virtual Private LAN Service (VPLS).

In addition to active polling, Enterprise VPN Manager supports Service Assurance (SA) Ping tests. Set up these tests to monitor service delivery and compliance with response time service-level agreements (SLAs). Ping tests offer the strongest option for service monitoring because they measure end-to-end response time.

NOTE

All elements that are connected to a given service provider must be modeled on a single SpectroSERVER.

Access Enterprise VPN Manager

You can access the Enterprise VPN Manager in the OneClick Navigation panel. Expand the appropriate landscape in the Explorer tab and select Enterprise VPN Manager.

Model information is displayed in the Contents and Component Detail panels.

Discovery and Modeling in Enterprise VPN Manager

Provider_Cloud Model

The Provider_Cloud model represents the service that is offered to you by a service provider. Enterprise VPN Manager offers several methods to model network entities and services, such as Discovery, import, and manual modeling functionality to accommodate the unique needs of your enterprise.

Existing Device Models

If the CE devices with BGP4_App modeled in DX NetOps Spectrum, you can run Enterprise VPN Discovery to detect their connections to the service provider. Otherwise, you can delete and remodel the devices or run Application Reconfiguration on those devices. Once the necessary application models are present, you can run Enterprise VPN Discovery.

Add Autonomous System Numbers (ASNs) to the DX NetOps Spectrum Database

By default, DX NetOps Spectrum includes over two thousand officially registered Service Provider ASNs. You can add additional Service Provider ASNs to the DX NetOps Spectrum database with the Model Type Editor by modifying the ASNamesList attribute of the EntVpnManager model type.

NOTE
For more information about editing model type attributes, see the *Model Type Editor .*

Enterprise VPN Discovery Prerequisites

Model the physical components of your network, before using the Enterprise VPN Manager Discovery functionality.

NOTE
For information about modeling your network, see the *Modeling and Managing Your IT Infrastructure Administrator* and the *Modeling Gateway Toolkit .*

At minimum, verify that your CE routers are modeled in DX NetOps Spectrum.

On CE routers, verify that BGP peering to the service provider is properly configured. If your devices do not support BGP peering, Enterprise VPN Manager supports import from a CSV text file that is based on Autonomous System Numbers (ASN) and manual modeling.

Access Enterprise VPN Discovery Configuration

The Enterprise VPN Discovery subview contains discovery controls and configuration.

Follow these steps:

1. Expand the appropriate landscape in the Explorer tab of the Navigation panel. Select Enterprise VPN Manager. Information and configuration appear in the Information tab of the Contents panel.
2. Expand the Configuration subview, and then expand the Enterprise VPN Discovery subview.
   The Enterprise VPN Manager Discovery options display:
   - Run Discovery
   - Import Config File
   - Provider Name Filter Type
   - Provider Name Filter
   - Discover On Activation
   - Create On Trap
   - Enable Background Discovery
   - Background Discovery Interval (minutes)
   - ASN Mapping

Configure Automatic Discovery on Model Activation

You can configure Enterprise VPN Manager to discover provider networks and CE interfaces automatically using the Discover On Activation option. When Discover On Activation is enabled, an Enterprise VPN Discovery is initiated each time DX NetOps Spectrum activates a device model. This process occurs on initial device model creation or on a SpectroSERVER restart. Determine whether this processing load (during these times) is appropriate in your environment. If not, disable this attribute.

Follow these steps:

1. Expand the Enterprise VPN Discovery subview as described in Access Enterprise VPN Discovery Configurations. Enterprise VPN Discovery options appear.
2. Click set next to Discover On Activation. Select Yes to enable. The option is disabled by default.
   Discover On Activation is set. The value that you selected is displayed next to Discover On Activation.

Configure Enterprise VPN Manager for a bgpEstablished Trap

Several devices that are configured with BGP4_App send a bgpEstablished trap when they establish a connection (a new peering session). You can configure Enterprise VPN Manager to discover provider networks and CE interfaces automatically in response to a bgpEstablished trap. When Create On Trap is enabled, an Enterprise VPN Discovery is initiated each time a bgpEstablished trap is received.

The Create On Trap option offers an alternative to Background discovery. Determine whether this Discovery option is appropriate in your environment. If this behavior is not desired, disable this attribute.

Follow these steps:

1. Expand the Enterprise VPN Discovery subview as described in Access Enterprise VPN Discovery Configurations.
   Enterprise VPN Discovery options appear.
2. Click set next to Create On Trap and select Yes.
   Enterprise VPN Manager runs Discovery when it receives a bgpEstablished trap.

Enable Background Discovery

You can configure Enterprise VPN Manager to discover provider networks and CE interfaces automatically using the Background Discovery option. When Enable Background Discovery is enabled, an Enterprise VPN Discovery is initiated based on the Background Discovery Interval. This process lets you determine the frequency of Discovery in your network. Determine whether this processing load (during these times) is appropriate in your environment.

Follow these steps:

1. Expand the Enterprise VPN Discovery subview as described in Access Enterprise VPN Discovery Configurations.
   Enterprise VPN Discovery options appear.
2. Click set next to Enable Background Discovery and select Yes.
   Background Discovery is enabled and recurs according to the frequency that you set in the Background Discovery Interval.

Configure the Background Discovery Interval

If you enable background Discovery, you can configure the frequency for background Discovery. Enable Background Discovery must be set to Yes to enable the value for the Background Discovery Interval parameter.

Follow these steps:

1. Expand the Enterprise VPN Discovery subview as described in .
   Enterprise VPN Discovery options appear.
2. Click set next to Background Discovery Interval.
3. Enter a value (in minutes).
   The Background Discovery interval is set.

Run an On-Demand Enterprise VPN Discovery

Enterprise VPN Discovery is the simplest method of modeling your network. Meet the prerequisites, before running an on-demand Enterprise VPN Discovery.

Follow these steps:

1. Expand the Enterprise VPN Discovery subview.
   Enterprise VPN Discovery options appear.
2. Click Run.
   The Enterprise VPN Discovery runs, and Discovery status is displayed in the window next to the Run button.

Run Enterprise VPN Discovery on Selected Models

You can configure the Enterprise VPN Network Services Discovery from the OneClick views that display models.

Follow these steps:

1. Select the models.
2. Click Tools, Utilities, Network Services Discoveries, Enterprise VPN Discovery.
   The Discovery process is initiated. You can check the status in the Configuration subview.

Configuring Enterprise VPN Discovery During Modeling

DX NetOps Spectrum lets you configure Network Services Discoveries, including Enterprise VPN Discovery, during modeling. As a part of modeling configuration, you can specify the network service discoveries to run with the modeling process.

NOTE
For more information, see *Modeling and Managing Your IT Infrastructure*.

Filter Service Provider Names During Discovery

The Enterprise VPN Manager lets you filter the Service Provider names during Discovery run.

Follow these steps:

1. Select Enterprise VPN Manager in the Explorer tab.
2. Select the Information tab in the Contents panel.
   The configuration options for Enterprise VPN Manager display.
3. Expand the Enterprise VPN Discovery subview.
   The Discovery options are available, including these options:
   - **Provider Name Filter Type**
     Determines whether the Provider names in the 'Provider Name Filter' field are included or excluded from modeling. Select from the following options:
     - Exclusive
     - Inclusive
   - **Provider Name Filter**
     Lists the Service Provider names to be included or excluded when the Enterprise VPN Discovery is run. This field is used together with the 'Provider Name Filter Type' field.

     NOTE
     Add Service Provider names to the Provider Name Filter field to filter and save them. If the Provider Name Filter Type is Inclusive and the Provider Name Filter is empty, all Provider Names are discovered.

Import Peer/Provider Information

Enterprise VPN Manager enables you to import service provider information from MPLS and VPLS VPNs to create Provider_Cloud models. If BGP peering is not used to communicate with your provider, import lets you associate your Provider_Cloud models with sites. The import file must be in a comma-separated value (CSV) formatted file. You can create a CSV file with a text editor or can export it from another application. Know the service provider ASN and the IP Address for MPLS VPNs or the Interface Model Name for VPLS VPNs of your CE Interfaces.

NOTE
Devices and interfaces must be modeled in DX NetOps Spectrum before importing a CSV-formatted text file.

The following parameters are supported for a line entry in an import file:

ProviderASN,SiteIfIdentifier,ProviderName,Region,SiteName,SitePriority

- **ProviderASN**
  Specifies the Autonomous System Number of the provider. Required parameter.
- **SiteIfIdentifier**
  Specifies the IP Address for MPLS VPNs or the Interface Model Name of the site interface for VPLS VPNs. SiteIfIdentifier is required.
- **ProviderName**
  Specifies the Name of the service provider.
- **Region**
  Lets you define Alarm Domains. This option is helpful when users have regional responsibility. The following values are available:
  - Unavailable = Unavailable
  - Arin = United States and Canada
  - Lacnic = Latin America
  - Ripe = EMEA
  - Afrinic = Africa
  - Apnic = Asia Pacific
- **SiteName**
  Specifies the name of the Provider_Cloud model.
- **SitePriority**
  Specifies an integer from 1 to N where 1 represents the primary connection and 2 through N represent backup connections.

The following text is an example of a CSV import file:

1234,138.42.14.143,ProvName,Lacnic,SiteName,3

Follow these steps:

1. Expand the Enterprise VPN Discovery subview as described in Access Enterprise VPN Discovery Configurations.
   The Enterprise VPN Discovery options display.
2. Click Import.
   The Import File dialog opens.
3. Locate your import file and click Open.
   Your peer or provider information is imported.

Create a Service Provider Model

Enterprise VPN Manager lets you manually model the connections to a service from your provider. Manual modeling is an alternative method of modeling devices that do not support the BGP4_App MIB, which is required to run Enterprise VPN Discovery. Manually modeling the connections to your service provider requires significant time and maintenance.

NOTE
For more information about manual modeling, see the *Modeling and Managing Your IT Infrastructure*.

Follow these steps:

1. In the OneClick Universe Topology tab, in the Topology toolbar,
   click 
   The Select Model Type dialog opens.
2. In the All Model Types tab, select Provider_Cloud and click OK.
   The Create Model of Type dialog opens.
3. Fill in the appropriate information that is requested in the dialog and click OK.
   This model represents the network of the provider.

4. Create models of your CE devices.
5. Select a CE model in the Topology view.
6. Select the Interfaces tab of the Component Detail panel.
7. Locate the interface that is connected to the provider.
8. Right-click the interface and select Start Connection.
9. Return to the Universe Topology view.
10. Right-click the Provider_Cloud model and select Connect with <interfaceName>.
    This operation associates the interface of CE router with the provider.
11. Repeat for each CE interface that must be manually connected to the provider.

Service Monitoring Configuration

Overview

Enterprise VPN Manager can gather information about your provider network by pinging or polling. Ping tests offer the strongest measurement of service health because they measure end to end, while a port polling is focused on a single resource (a device or interface). However, the Ping tests have resource requirements that can affect on your network and equipment. Specifically, the Ping tests require the following additional resources:

- Processing time in DX NetOps Spectrum
- Network bandwidth to set up the tests
- Processing time in the CE routers
- Network bandwidth to execute the tests

Despite the resource requirements of Ping tests, they provide a valuable addition to your management capabilities. We recommend enabling the Ping tests.

Note: An SNMP read or write community name is required to provision SNMP polling.

Polling Configuration

Polling for port status serves as an alternative to Ping testing. Polling does not create as much of a network strain as Ping testing. SNMP secure information is not required to enable polling.

Port Polling

Enterprise VPN Manager uses the port status of the connected interfaces to update the status of the Provider_Cloud model. If port polling is disabled, the status is not updated. We recommend leaving port polling enabled (the default).

NOTE
Port polling includes all BGP sessions (active and inactive).

Follow these steps:

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the Information tab.
3. Expand the Configuration subview.
4. Expand the Management Configuration subview.
5. Locate Enable Port Polling, click set, and select Yes.
   Port Polling is now enabled.

Peer Session Polling

You can configure Enterprise VPN Manager to poll the status of peer sessions. When Peer Session Polling is enabled, Enterprise VPN Manager looks for changes to PeerState. The total number of operative and inoperative BGP peering sessions is used to compute the percentage of peering failures. This metric is evaluated when Enterprise VPN Manager determines the Provider_Cloud status.

NOTE
For more information about enabling alarms on failed peering sessions, see Modeling and Managing Your IT Infrastructure.

Follow these steps:

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the Information tab.
3. Expand the Configuration subview.
4. Expand the Management Configuration subview.
5. Locate Enable Peer Session Polling and click set.
6. Select Yes to enable peer session polling.

Ping Test Requirements

Verify that the following requirements are met to enable Ping tests:

- Devices must support Cisco RTTMON MIB or RFC2925.
- Devices must be modeled with a read/write community name.

Configure at least one site with one of the following options:

- Ping from Site.
- Ping to/from Site.

Configure at least one (other) site with one of the following options:

- Ping to Site.
- Ping to/from Site.
- Ping Test Interval, Ping Test Timeout, and Response Time Threshold, set to appropriate values.
- The 'Enable Ping Tests' parameter must be enabled on each Provider_Cloud model that participates in the ping test.
- The 'Enable Ping Tests' parameter must be enabled on the Enterprise VPN Manager model.

Ping Test Scalability

The scalability of Ping tests must be considered in large environments where fully meshed testing is performed. Performance testing has shown that full mesh testing beyond 50 sites greatly increases network traffic. Enterprise VPN Ping tests are therefore disabled by default. The number of Ping tests (and the resource requirements) can be efficiently managed by organizing your Ping tests.

We recommend selecting a relatively small number of important sites to perform Ping testing. When the number of sites (or remote offices) exceeds 50, let larger regional offices test back to corporate headquarters or test among themselves. For example, in an enterprise environment that consists of several regional offices and a corporate headquarters, configure your corporate headquarters as Ping to Site and your larger regional offices as Ping from Site to reduce the network load.

Configure Ping Tests

Configure Ping Tests in Enterprise VPN Manager.

Follow these steps:

1. Access Enterprise VPN Manager.
2. Select the List tab in the Content panel and select the Provider_Cloud model.
3. Select the Information tab in the Component Detail panel and expand the Ping Test Configuration subview.
   The following Ping test configurations are available:
   – **Ping Test Interval (sec)**
   Determines ping test frequency. Raise the value to reduce network traffic.
   Default: 1200 seconds

   NOTE
   Lower values for the Ping Test Interval attribute can cause a severe performance impact.
   – **Ping Test Timeout (sec)**
   Sets the timeout value before an event is generated for Ping tests. An event is generated if the ping response is not received before the timeout.
   Default: 5 seconds
   – **Response Time Threshold (ms)**
   Sets the event threshold for the response time of a successful Ping test.
   Default: 250 milliseconds

Configure Ping Source and Destination

Remote sites typically communicate more efficiently with a central location than with each other. You can select the interfaces that send and receive a ping. By default, interfaces are set to Ping from Site. Therefore, no testing occurs until at least one interface is set to either Ping to Site or Ping to/from Site.

The following settings are available:

- **Ping Disabled**
  Indicates that ping is not enabled for this interface.
- **Ping from Site**
  Indicates that this interface can only originate a ping.
- **Ping to Site**
  Indicates that this interface can only receive a ping.
- **Ping to/from Site**
  Indicates that this interface can originate and receive a ping.

Follow these steps:

1. Select the appropriate Provider_Cloud model to change all relevant interfaces or select an individual Interface model to make an individual change.
2. Open the Attribute Editor.
3. Click Add next to the User Defined folder.
   The Attribute Selector dialog opens.
4. In the left panel of the Attribute Selector, select the Port folder.
5. In the right panel of the Attribute Selector, locate and select the PingTestEnable attribute and click OK.
   PingTestEnable is now displayed in the right panel of the Attribute Editor.
6. Select the appropriate value in the PingTestEnable list.
   Click OK.

   NOTE
   For more information on the Attribute Editor, see Modeling and Managing Your IT Infrastructure.

Collapse BiDirectional Ping

Collapsing the BiDirectional pings reduces network traffic by eliminating potentially redundant ping tests. If one site can receive responses from another, the network between them functions properly. Therefore no test is sent in the opposite direction if BiDirectional tests are collapsed. By default, Collapse BiDirectional Ping is enabled.

Follow these steps:

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the Information tab.
3. Expand the Configuration subview.
4. Set the value of Collapse BiDirectional Ping to Yes.

Enable or Disable Ping Tests

Ping tests involve additional resource requirements on your network and equipment. As result, these tests are disabled by default. Ping tests are not conducted until:

- Ping source and destination for all Interfaces participate in the ping is configured
- Enable Ping Tests is set to Yes for each Provider_Cloud participating in the Ping test
- Enable Ping Tests is set to Yes on the Enterprise VPN Manager model

To enable or disable ping tests on the Enterprise VPN Manager model

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the Information tab.
3. Expand the Configuration subview.
4. Expand the Ping subview.
5. Set the value of Enable Ping Tests to Yes to enable ping testing. The default value is No.

To enable or disable ping tests on a Provider_Cloud model

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the List tab.
3. Select the appropriate Provider_Cloud model.
4. In the Component Detail panel, select the Information tab.
5. Expand the Ping Test Configuration subview.
6. Set the value of Enable Ping Tests to Yes to enable ping testing. The default value is No.

Manage Provider VPN Services

Managing Provider VPN Services

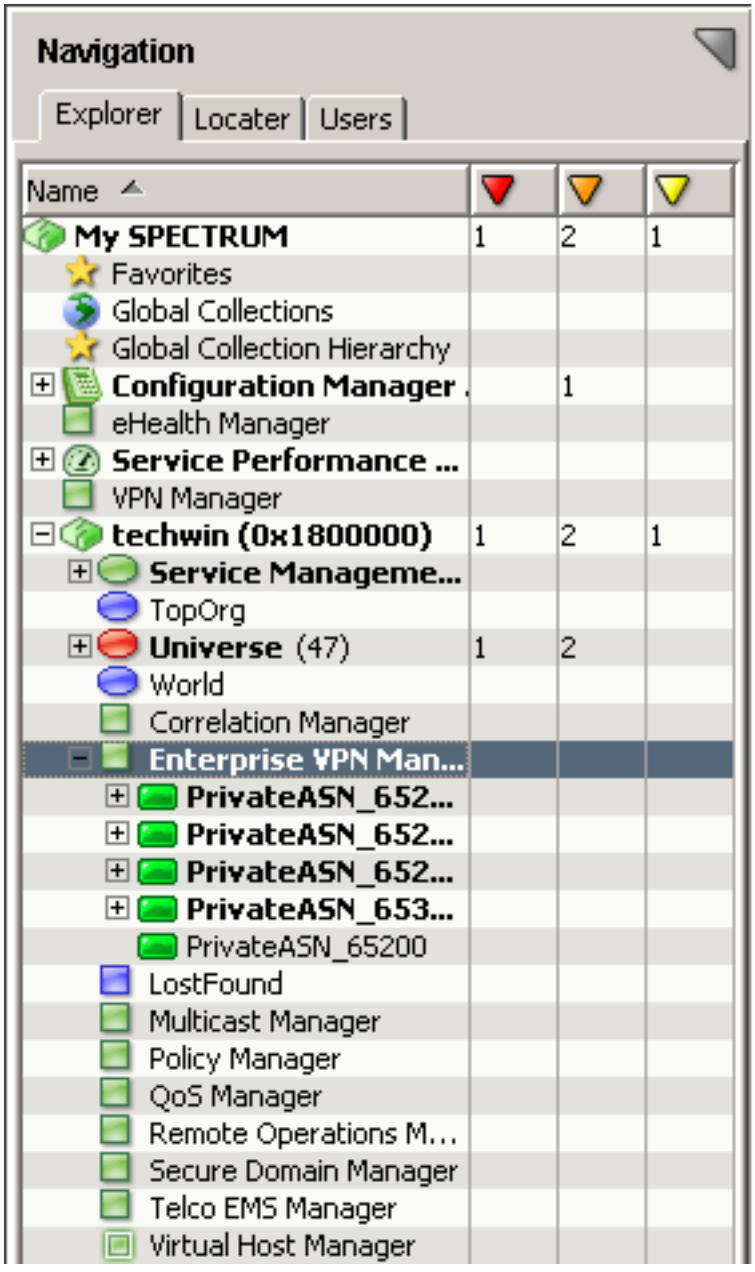
Enterprise VPN Manager Services

Enterprise VPN Manager enables you to continuously monitor the services that are provided to you by your service provider. You can see events and alarms pertaining to the health of various sites and the overall health of your provider. Enterprise VPN Manager lets you monitor the service across the three hierarchal levels (Enterprise VPN Manager model, Provider_Cloud model, and the individual interface/site models) of your provider network.

Enterprise VPN Manager Navigation

The OneClick Navigation panel displays a hierarchal view of your network. The Enterprise VPN Manager model exists within a particular landscape.

Expand the Enterprise VPN Manager model to see your providers and the sites that are connected to your providers, as shown in the following image:



Conduct an Enterprise VPN Search

You can access Enterprise VPN searches through the Locater tab. The Enterprise VPN search results, which appear in the Contents tab, help you access views that present management, performance, and configuration information. The Component Detail panel displays information about the device that is selected in the Contents panel. The following Enterprise VPN searches are available:

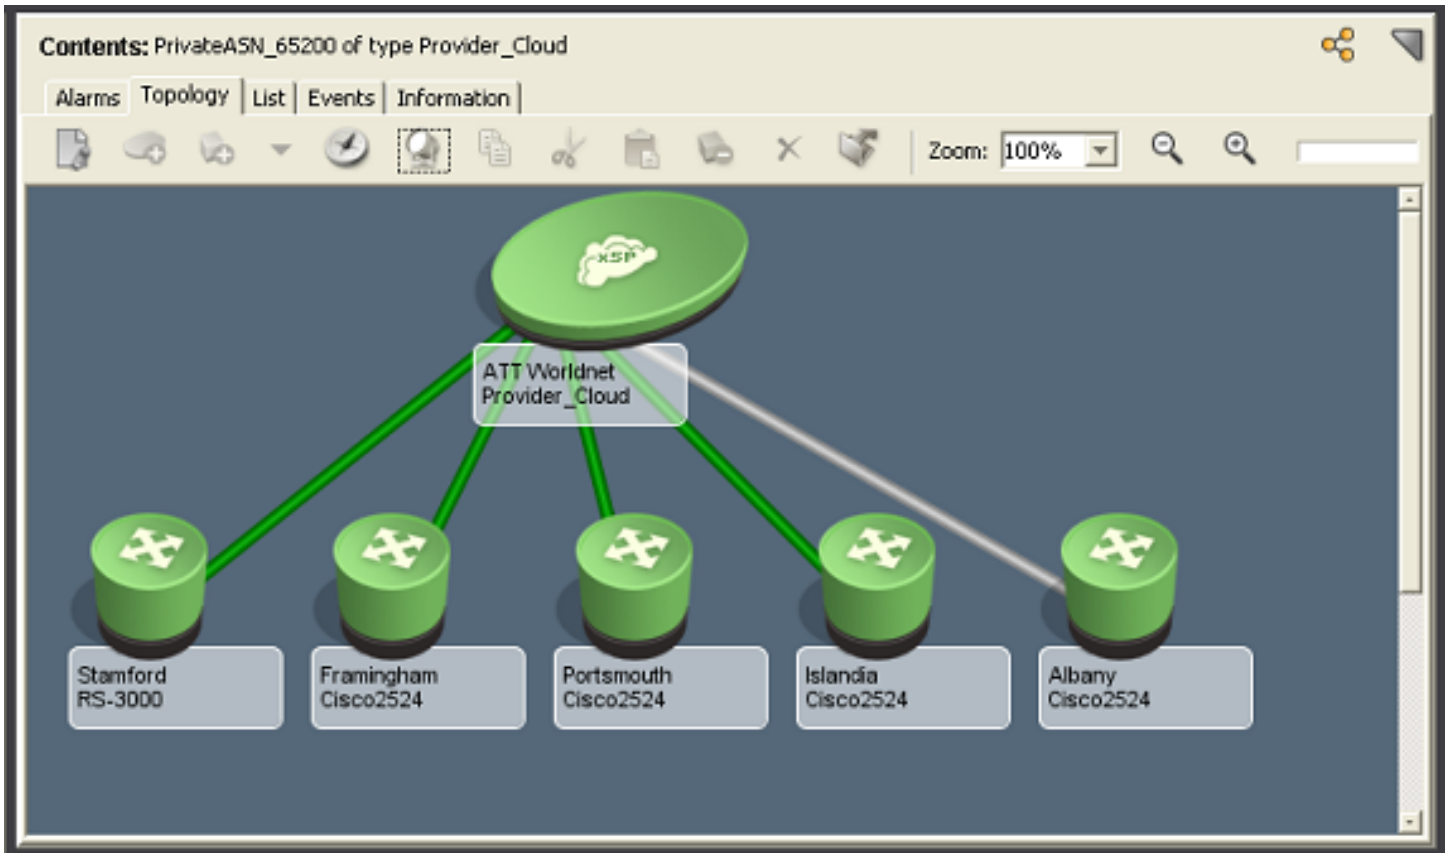
- All CE Devices by Provider
- All CE Interfaces by Provider
- All Enterprise VPN Managers
- All Providers

View Provider_Cloud Topology

The Provider Topology view displays the CE devices that are connected to a Provider_Cloud model. Selecting the Provider_Cloud or an interface model icon displays model information in the Component Detail panel.

Follow these steps:

1. Select the appropriate landscape from the Explorer tab in the OneClick Navigation panel.
2. Expand the Enterprise VPN Manager subview.
3. Select the appropriate Provider_Cloud model.
4. Select the Topology tab in the Contents panel.
   The Provider Topology resembles the following example:



View Events and Alarms

Events and Alarms that are generated on a selected Provider_Cloud model display in the Events tab and Alarms tab of the OneClick Contents panel.

NOTE
For more information about the Contents panel, Using OneClick .

Execute OnDemand Ping Test

Enterprise VPN Manager lets you provision an OnDemand Ping test between two sites. The OnDemand Ping tests are a good way to troubleshoot connectivity between two sites without the resource requirements that are necessary to provision background Ping tests in a large environment.

Follow these steps:

1. Activate the Topology view for the appropriate Provider_Cloud model.
2. Click Select OnDemand Ping Start Point from the right-click menu of the interface model icon from which you would like to initiate the Ping test.
3. Right-click the interface model icon that is the destination of Ping test, and select Ping Test From <source_model_name>. This process starts the on-demand Ping test.
   The results of the Ping test appear in a dialog after the Ping test completes.

   NOTE
   You can execute an on-demand Ping test using interface models in the Navigation panel.

Provider_Cloud Condition

Enterprise VPN Manager provides information about the status or condition of a Provider_Cloud model. The following types of information contribute to status reporting:

- Status of the interfaces that are connected to the Provider_Cloud
- Results of the automated service assurance tests (Ping and Response Time)

WARNING
To enable calculation of the VPN Manager Provider_Cloud condition, verify that the Live Pipes field is enabled. VPN status is not properly updated when Disabling Live Pipes are disabled.

The total number of operative and inoperative BGP peering sessions is used to compute the percent of peering failures. The percent of peering failures is evaluated when Enterprise VPN Manager determines the Provider_Cloud status.

NOTE
For more information on BGP peering sessions, see Modeling and Managing Your IT Infrastructure .

The default thresholds are available in the Information tab of the Provider_Cloud model. The thresholds and their default value are:

- Critical Alarm Threshold % - 5%
- Major Alarm Threshold % - 3%
- Minor Alarm Threshold % - 1%

Provider_Cloud Roll-Up Condition

The aggregate condition of the interfaces contributes to the roll-up condition of the Provider_Cloud. For example, if 100 interfaces (or sites) are connected to a provider and 4 of those interfaces are unreachable by DX NetOps Spectrum, the condition is calculated as follows:

4 of 100 interfaces (4 percent) are unreachable.

This provider has a condition of Major Alarm because the 4 percent outage is above the default Major Alarm Failure threshold of 3 percent.

Service Assurance Test

Automated service assurance tests provide the best indication of provider health. These tests assure not only that the interface and the BGP peering session is operating but that the endpoints are able to pass traffic. An additional test

verifies that the traffic passing through the network of the provider can reach the endpoint within the time thresholds that are specified in the service agreement.

Hide Symptomatic Alarms

Hiding symptomatic alarms reduces the number of alarms that are presented to you. You can configure Enterprise VPN Manager to generate a single alarm when a percentage of your interfaces that are connected to a service provider lose connectivity. When a significant number of sites are experiencing simultaneous problems, the provider is typically the root cause. The Minor Alarm Threshold is a point where Enterprise VPN Manager suppresses multiple site alarms and it instead generates an alarm on the Provider_Cloud model.

For example, you model a network with ten CE devices that are connected to a Provider_Cloud model. The alarm thresholds have the following settings:

- Critical Alarm Threshold %: 35
- Major Alarm Threshold %: 25
- Minor Alarm Threshold %: 15

> **NOTE**
> These settings are usually high and are not recommended for operational use.

When one CE device (10 percent of the devices that are connected to the service provider) becomes unreachable by DX NetOps Spectrum, a red alarm is raised on the device model and the status of the Provider_Cloud model remains green. The status of the Provider_Cloud model remains green because 10 percent falls below the 15 percent Minor Alarm Threshold. When a second CE device (20 percent) becomes unreachable, the Minor Alarm Threshold is violated. The status of the Provider_Cloud model is Minor Alarm and the alarms on the device models are hidden. The status of the two unreachable devices remains critical, but no Contact Lost alarms appear in the alarm log.

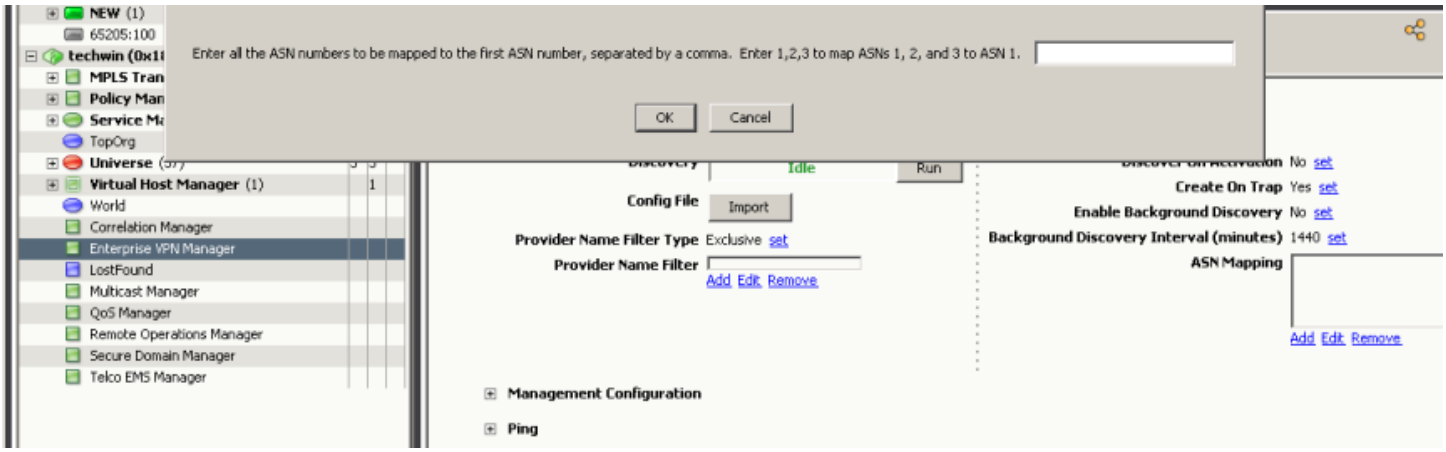
Follow these steps:

1. Locate the appropriate Enterprise VPN Manager model.
2. In the Contents panel, select the List tab.
3. Select the appropriate Provider_Cloud model.
4. In the Component Detail panel, select the Information tab.
5. Expand the Configuration Information subview.
6. Specify the following thresholds:
   - **Critical Alarm Threshold (%)**
     Specifies the threshold for hiding Critical alarms.
     Default: 5
   - **Major Alarm Threshold (%)**
     Specifies the threshold for hiding Major alarms.
     Default: 3
   - **Minor Alarm Threshold (%)**
     Specifies the threshold for hiding Minor alarms.
     Default: 1
7. Select the Impact tab.
8. Expand the Symptoms subview.
   You can view the affected device sites.

Map Multiple Autonomous System Numbers to a Single Provider

The DX NetOps Spectrum MultipleASNLists attribute is now a list rather than a text string. This list lets you easily map multiple Autonomous System Numbers (ASNs) to a single provider.

This option is available when you select Configuration from the Enterprise VPN Manager and then edit the ASN Mapping field. DX NetOps Spectrum displays a List Renderer that lets you easily add, edit, or remove each list of ASNs that are mapped to the first ASN in the list, as shown in the following image:



Enterprise VPN Manager Events

Enterprise VPN Manager Events

Enterprise VPN Manager events enhance management of provider based services. Most of these events mirror the roll-up and service assurance methods of provider status calculation.

Roll-Up Method

The events in the roll-up method approach reflect the health of the service provider, infrastructure, which is modeled using the Provider_Cloud model type. The supported events are listed in the following table:

Event	Event ID	Description
InitialEvent	0x5180400	Provider is Initial
MinorEvent	0x5180401	Provider is Minor (% sites down)
MajorEvent	0x5180402	Provider is Major (% sites down)
CriticalEvent	0x5180403	Provider is Critical (% sites down)
GoodEvent	0x5180404	Provider is Good (all sites up)
MinorAlarmEvent	0x5180405	Provider Minor Alarm (% sites down)
MajorAlarmEvent	0x5180406	Provider Major Alarm (% sites down)
CriticalAlarmEvent	0x5180407	Provider Critical Alarm (% sites down)

Service Assurance Method

Multiple events are generated using the condition calculation method. They can be classified in several ways:

- Scope
  - Single test between a Pair of Sites
  - Tests from a Site to all its Destinations
  - Tests from all Sites to all their Destinations connected to the Provider
- Test Type

  - Connectivity (Did the Ping Succeed)
  - Response Time (Did the Ping Succeed within the threshold)
- Test Phase
  - Test Model Creation
  - Test Setup
  - Ping Test Operation
  - Response Time Threshold

Test Phases

Events occur at each phase of test creation, setup, or execution. The results that are reported attempt to determine the most likely root cause. Events that are caused by other events are typically excluded. An example of this result is shown in the following test phases:

1. Test Model Creation
2. Test Setup
3. Ping Test Operation
4. Response Time Threshold

Each successive test phase builds on the previous one. For example, if the Test Model cannot be created, none of the other phases are attempted. Therefore, you see a Test Creation Event (SingleTestCreateFailed) instead of multiple Ping Failure and Response Time Failure events (and alarms). The same is true for the Ping Test Operation and Response Time Threshold phases. If the Ping connectivity test fails (the timeout is 5 seconds), a Response Time failure is not reported. The default value for critical Response Time threshold is 250 milliseconds. Conversely, the Ping test can succeed but the Response Time threshold fails. The event sequence shows the following events:

Event	Event ID
SinglePingTestGood	0x5180604
SingleRTThreshFailed	0x5180607

Assume that you manage 100 sites and have modified the Ping values of minor, major, and critical thresholds to 5, 10 and 20 percent respectively. Next assume that 21 percent of the Ping tests from a site fail. A critical alarm is raised because it exceeds the value of the critical alarm threshold. There are 79 tests that have succeeded. Of these remaining successful ping tests, there are nine Response Time threshold violations. The calculation is done using 9 of 79 tests leading to a failure rate of 11 percent; this percentage is a major alarm status because it exceeds the major alarm threshold. The event sequence that is displayed in this case is as follows:

Event	Event ID
SiteTotalPingTestsCritical	0x5180621
SiteTotalRTThreshMajor	0x5180624

The example demonstrates how the success of each succeeding phase depends on the results of the previous phase. An event sequence can have the following events:

Event	Event ID
SiteTotalPingTestsGood	0x5180618
SiteTotalRTThreshCritical	0x5180625

Single Test Between Sites

The following events are generated for a single site-to-site test.

Event	Event ID	Description
SingleTestCreateGood	0x5180600	Individual test created successfully
SingleTestCreateFailed	0x5180601	Individual test creation failed
SingleTestSetupGood	0x5180602	Individual test setup succeeded
SingleTestSetupFailed	0x5180603	Individual test setup failed
SinglePingTestGood	0x5180604	Individual ping test succeeded
SinglePingTestFailed	0x5180605	Individual ping test failed
SingleRTThreshGood	0x5180606	Individual RT test succeeded
SingleRTThreshFailed	0x5180607	Individual RT test failed

The following tests are part of each event cycle:

- Ping Connectivity
- Ping Response Time

A Ping cycle can pass the Ping Connectivity test but can fail the Response Time test when the ping response returns outside the specified response time window. In this case, the user sees SinglePingTestGood event followed by a SingleRTThreshFailed event.

Summary from One Site to All its Destinations

The following events are generated for a test from a single site to all of its destinations.

Event	Event ID	Description
SiteTotalCreatesGood	0x5180610	All of the site-to-site test that were created are good
SiteTotalCreatesMajor	0x5180612	Major % of site-to-site tests that were created failed
SiteTotalSetupsGood	0x5180614	All of the site-to-site test setups are good
SiteTotalSetupsMajor	0x5180616	Major % of site-to-site test setups failed
SiteTotalPingTestsGood	0x5180618	All of the site-to-site pings are good
SiteTotalPingTestsMinor	0x5180619	Minor % of site-to-site pings failed
SiteTotalPingTestsMajor	0x5180620	Major % of site-to-site pings failed
SiteTotalPingTestsCritical	0x5180621	Critical % of site-to-site pings failed
SiteTotalRTThreshGood	0x5180622	All of the site-to-site RT thresholds are good
SiteTotalRTThreshMinor	0x5180623	Minor % of site-to-site RT thresholds violated
SiteTotalRTThreshMajor	0x5180624	Major % of site-to-site RT thresholds violated
SiteTotalRTThreshCritical	0x5180625	Critical % of site-to-site RT thresholds violated

Summary for All Sites to All Destinations in Provider

The following events are generated for tests from all sites to all destinations in a provider.

Event	Event ID	Description
TotalTestCreatesGood	0x5180700	All Ping tests for provider were created successfully
TotalTestCreatesMinor	0x5180701	Minor % of tests that were created for provider failed
TotalTestCreatesMajor	0x5180702	Major % of tests that were created for provider failed
TotalTestCreatesCritical	0x5180703	Critical % of tests that were created for provider failed
TotalTestSetupsGood	0x5180704	All Ping tests for provider setup ran successfully
TotalTestSetupsMinor	0x5180705	Minor % of test setups for provider failed
TotalTestSetupsMajor	0x5180706	Major % of test setups for provider failed
TotalTestSetupsCritical	0x5180707	Critical % of test setups for provider failed
TotalPingTestsGood	0x5180708	All Ping tests for provider executed successfully
TotalPingTestsMinor	0x5180709	Minor % of Ping tests for provider failed
TotalPingTestsMajor	0x5180710	Major % of Ping tests for provider failed
TotalPingTestsCritical	0x5180711	Critical % of Ping tests for provider failed
TotalRTThreshGood	0x5180712	All RT tests for provider executed successfully
TotalRTThreshMinor	0x5180713	Minor % of RT Threshold for provider violated
TotalRTThreshMajor	0x5180714	Major % of RT Threshold for provider violated
TotalRTThreshCritical	0x5180715	Critical % of RT Threshold for provider violated
DevTestCreatesGood	0x5180800	All RT tests for provider executed successfully
DevTestCreatesMinor	0x5180801	Minor % of tests created for provider failed
DevTestCreatesMajor	0x5180802	Major % of test created for provider failed
DevTestCreatesCritical	0x5180803	Critical % of tests created for provider failed
DevTestSetupsGood	0x5180804	All Ping tests for provider setup successfully
DevTestSetupsMinor	0x5180805	Minor % of test setups for provider failed
DevTestSetupsMajor	0x5180806	Major % of test setups for provider failed
DevTestSetupsCritical	0x5180807	Critical % of test setups for provider failed
DevPingTestsGood	0x5180808	All Ping tests for provider executed successfully
DevPingTestsMinor	0x5180809	Minor % of Ping tests for provider failed
DevPingTestsMajor	0x5180810	Major % of Ping tests for provider failed
DevPingTestsCritical	0x5180811	Critical % of Ping tests for provider failed

DevRTThreshGood	0x5180812	All RT tests for provider executed successfully
DevRTThreshMinor	0x5180813	Minor % of RT Threshold for provider violated
DevRTThreshMajor	0x5180814	Major % of RT Threshold for provider violated
DevRTThreshCritical	0x5180815	Critical % of RT Threshold for provider violated

Event Configuration

DX NetOps Spectrum Event and Alarm Concepts

This section provides a brief overview of conceptual information about Events and Alarms.

About Alarms and Events

DX NetOps Spectrum is a services and infrastructure management system that notifies you of faults on managed elements within the network infrastructure. DX NetOps Spectrum receives alerts from problem areas within the managed infrastructure. DX NetOps Spectrum converts alerts into events and alarms, which are displayed in OneClick event and alarm views. Alerts, events, and alarms let DX NetOps Spectrum notify you about significant occurrences in your IT infrastructure.

Alerts

An *alert* is an unsolicited message from a managed element on a network. A more specific definition of an alert depends on the management protocol that is used to report the alert. In general, DX NetOps Spectrum uses SNMP as the management protocol to communicate with devices on a network. Alerts that an SNMP-compliant device generates are named *traps*.

You can configure managed elements that have enabled the SNMP traps to direct their traps to the host that is running DX NetOps Spectrum. The host receives a trap DX NetOps Spectrum and identifies the model in the DX NetOps Spectrum database that is associated with the managed element, using the source IP address. Next, DX NetOps Spectrum maps the trap to a DX NetOps Spectrum event. The event is then generated and processed.

DX NetOps Spectrum applies special handling to traps that are not mapped to specific DX NetOps Spectrum events. Traps that occur on managed elements that are not modeled at the time the trap is received are also handled differently. For more information, see Modeling and Managing Your IT Infrastructure .

> **NOTE**
> You map the traps from a managed element to specific DX NetOps Spectrum events using the MIB Tools application in OneClick. Perform these mappings before you can create and modify the events and associated alarms using Event Configuration. For more information, see Certifications .

Events

An *event* is a DX NetOps Spectrum object that indicates that something significant has occurred within DX NetOps Spectrum itself or within the managed environment. Events always occur in relation to a model. When DX NetOps Spectrum receives an alert from a managed element on the network, in response, it generates a DX NetOps Spectrum event for the corresponding model if the received trap is mapped to an event.

DX NetOps Spectrum also generates some events automatically. For example, DX NetOps Spectrum generates an event when models are created or destroyed or when DX NetOps Spectrum connects or disconnects from a device application. DX NetOps Spectrum also generates an event when contact with a managed element is established or lost.

DX NetOps Spectrum uses the configuration of the underlying event to process an event instance. For example, the Archive Manager in the Distributed Data Manager (DDM) database can log an event instance. Or an event instance can clear an alarm or can generate another event using an event rule.

Network operators can view the list of current events in a landscape on the OneClick Events tab. For a specific event, you can also view information such as a description of the event and the time it was created.

To map the traps from a device to specific DX NetOps Spectrum events, use the MIB Tools application in OneClick. Then complete event customization using Event Configuration. In Event Configuration, define event processing rules, create the event message to display to users, and set other parameters.

Event Codes

Every event has a unique event code. The event code is a 4-byte integer that is expressed in hexadecimal format.

An event code has two parts:

- The first 2 bytes contain the developer ID of the developer who created the event
- The last 2 bytes identify the event with a unique number relative to all other event codes for that developer

DX NetOps Spectrum assigns event codes to all events created using MIB Tools or Event Configuration. The next available event code is always used as the default code. In Event Configuration, you have the option of overriding the default code and specifying a different one.

> **NOTE**
> The event code 0x10000 represents a null event. This event cannot be generated. However, the null event can be used in an event rule that requires an event code as a parameter.

Alarms

An *alarm* is a DX NetOps Spectrum object that indicates that a user-actionable, abnormal condition exists in a model. DX NetOps Spectrum generates an alarm when a DX NetOps Spectrum event -- typically generated as a result of a received trap -- specifies an alarm creation. DX NetOps Spectrum can generate an alarm that is based on the results of a watch. DX NetOps Spectrum can also send an event in response to an abnormal situation that did not send an event. (For example, a model loses the connection to its managed element).

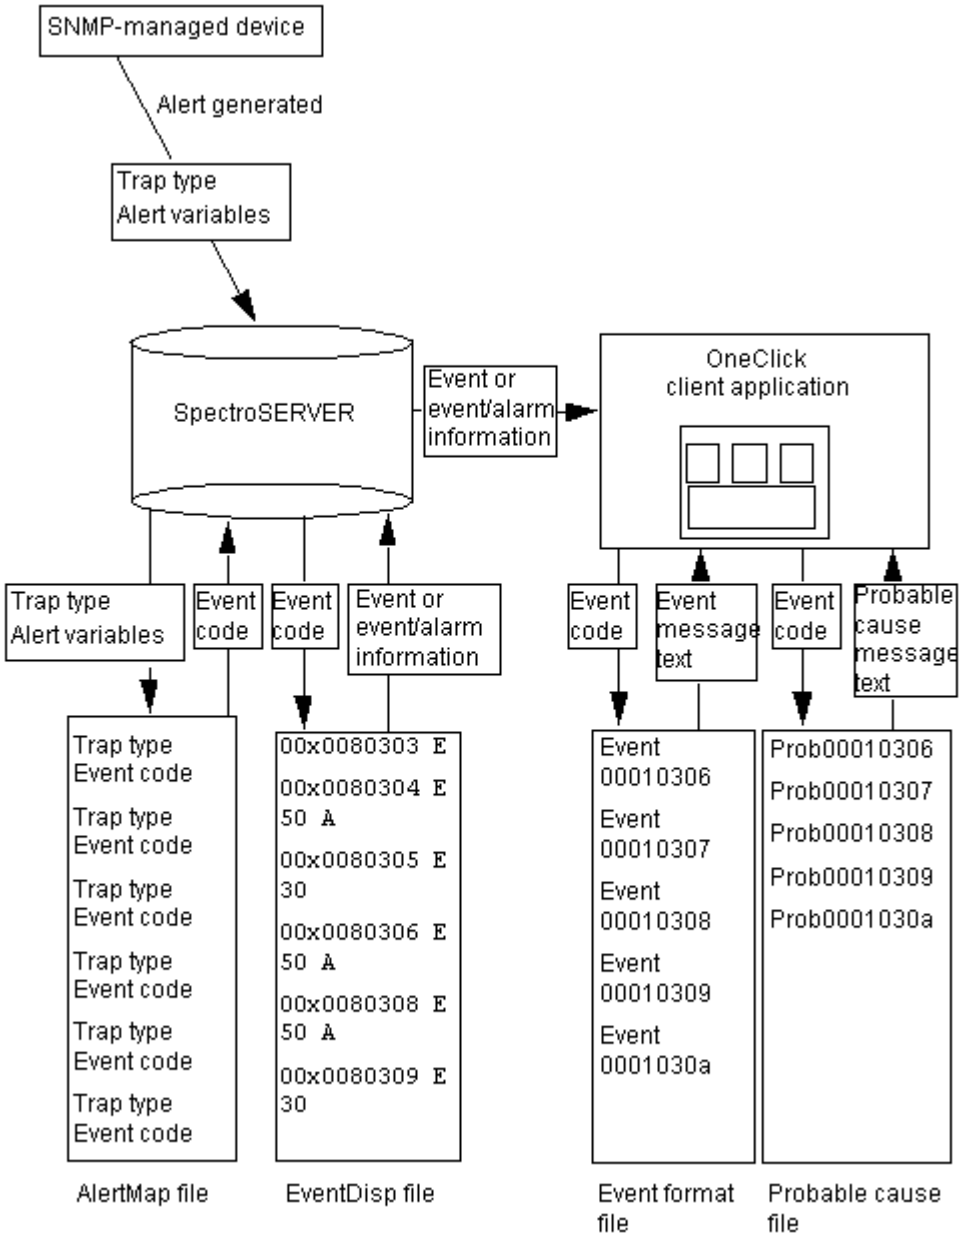
Network operators are alerted to alarms in multiple ways that depend on OneClick configuration. For example, the icon representing the model of the managed element (or a container model for the managed element model) can change color. Or an audio message can announce the new alarm.

Operators can view the current list of alarms in a landscape on the OneClick Alarms tab. For a specific alarm, you can also view detailed information. For example, you can see whether a user has acknowledged the alarm, its symptoms, probable causes, and the recommended corrective actions.

When the abnormal condition that caused the alarm ends, another event automatically clears the corresponding alarm. You can clear the alarm manually and also send any Alarm notifications to external third-party or internal DX NetOps Spectrum applications as appropriate.

You can specify whether an event generates an alarm (and alarm severity) in MIB Tools when you map a trap to an event. However, you use Event Configuration to set more alarm parameters and to change the alarm severity.

The following figure illustrates the flow of alerts, events, and alarms within DX NetOps Spectrum.



Getting Started with Event Configuration

Before You Begin

Before you begin using Event Configuration to create events and alarms, follow any of these steps:

- Obtain a developer ID from CA.
- Map the traps to new DX NetOps Spectrum events using MIB Tools first, if you are adding trap support for a device. (Which is not supported by default in DX NetOps Spectrum).

Obtaining a Developer ID

The first 2 bytes of any event code contains a developer ID. By default, this portion of the event code is the default developer ID that is provided with DX NetOps Spectrum. However, if you are creating events and alarms to support a new device management module, or you are creating a Southbound Gateway integration; we recommend obtaining a unique registered developer ID from CA. A registered developer ID lets you specify event codes for your events that begin with your unique ID. You can easily recognize your custom code in OneClick and avoid potential conflicts with other DX NetOps Spectrum event codes.

To obtain a developer ID, contact CA Support. To be eligible for a developer ID, you must have purchased the Level 1 Toolkit.

NOTE
For information about the toolkit, see Spectrum Integrator. To activate your developer ID, use **SSdbload** with the **-d** option. For more information, see Database Management on loading developer information in.

Mapping Traps to DX NetOps Spectrum Events

When you are creating a management module for a device that is not supported by default in DX NetOps Spectrum. We recommend using MIB Tools to map the traps that the device sends to new DX NetOps Spectrum events. The new events are automatically created when the trap mappings are defined. Follow these steps before you begin using Event Configuration. You can then launch Event Configuration directly from MIB Tools to complete the configuration of the events and associated alarms.

If you create new events using Event Configuration instead of MIB Tools, you cannot use MIB Tools to map traps to them. Instead, you need to manually specify the mappings in the *$SPECROOT*/custom/Events/AlertMap file on each SpectroSERVER in your environment. This rule applies because the process of mapping traps to events using MIB Tools automatically creates new events with unique event codes. You cannot use MIB Tools to map traps to *existing* events that were previously created using Event Configuration.

AlertMap files are ASCII files that store the following Mappings:

- Mappings between the traps that a device sends and DX NetOps Spectrum events
- Mappings between the variable bindings that are sent with a trap and the event variables thatDX NetOps Spectrum generates on a model when the trap is received. Variable bindings can store attribute values in a MIB table, OIDs, or integer bit values.

NOTE
For more information about using MIB Tools to map traps to events, see Certifications .

Preserving Customizations Across Upgrades of DX NetOps Spectrum

Several types of event and alarm configuration files support event and alarm processing in DX NetOps Spectrum, such as: alert mapping files, event disposition files, event format files, event table files, and probable cause files.

The files that are provided with DX NetOps Spectrum to support CA-authored events and alarms are installed in subfolders of the following folders:

```
<$SPECROOT>/SS/CsVendor
<$SPECROOT>/SG-Support
```

When you are customizing CA-authored events and alarms or creating your own events and saving the customizations to one or more landscapes; the event and alarm configuration files that define your customizations are installed in the following folder or in one of its subfolders:

```
<$SPECROOT>/custom/Events
```

Following this procedure ensures that the support files for your custom events and alarms are not overwritten or affected when you upgrade to a newer version of DX NetOps Spectrum.

Starting the Event Configuration Application

You can start Event Configuration from the following locations:

- OneClick Console
- MIB Tools

Starting the Event Configuration Application from the OneClick Console

To load all events that are supported in the landscape (or landscapes in a distributed environment) into the application, start Event Configuration from the OneClick Console.

You can start Event Configuration from the OneClick Console.

Follow these steps:

1. Launch the OneClick Console from the OneClick home page.
2. From the Tools menu, select Utilities, Event Configuration.

Starting the Event Configuration Application from MIB Tools

To add trap support for a device that is not currently supported in DX NetOps Spectrum use MIB Tools, You must map the traps to new DX NetOps Spectrum events and specify those events to generate alarms. After you do the mapping, typically you further customize the events and alarms, which you must do in Event Configuration. For this reason, you can start Event Configuration directly from MIB Tools.

When you start Event Configuration from MIB Tools, only the events that are associated with the traps you select are initially loaded into the application.

You can start Event Configuration from MIB Tools.

Follow these steps:

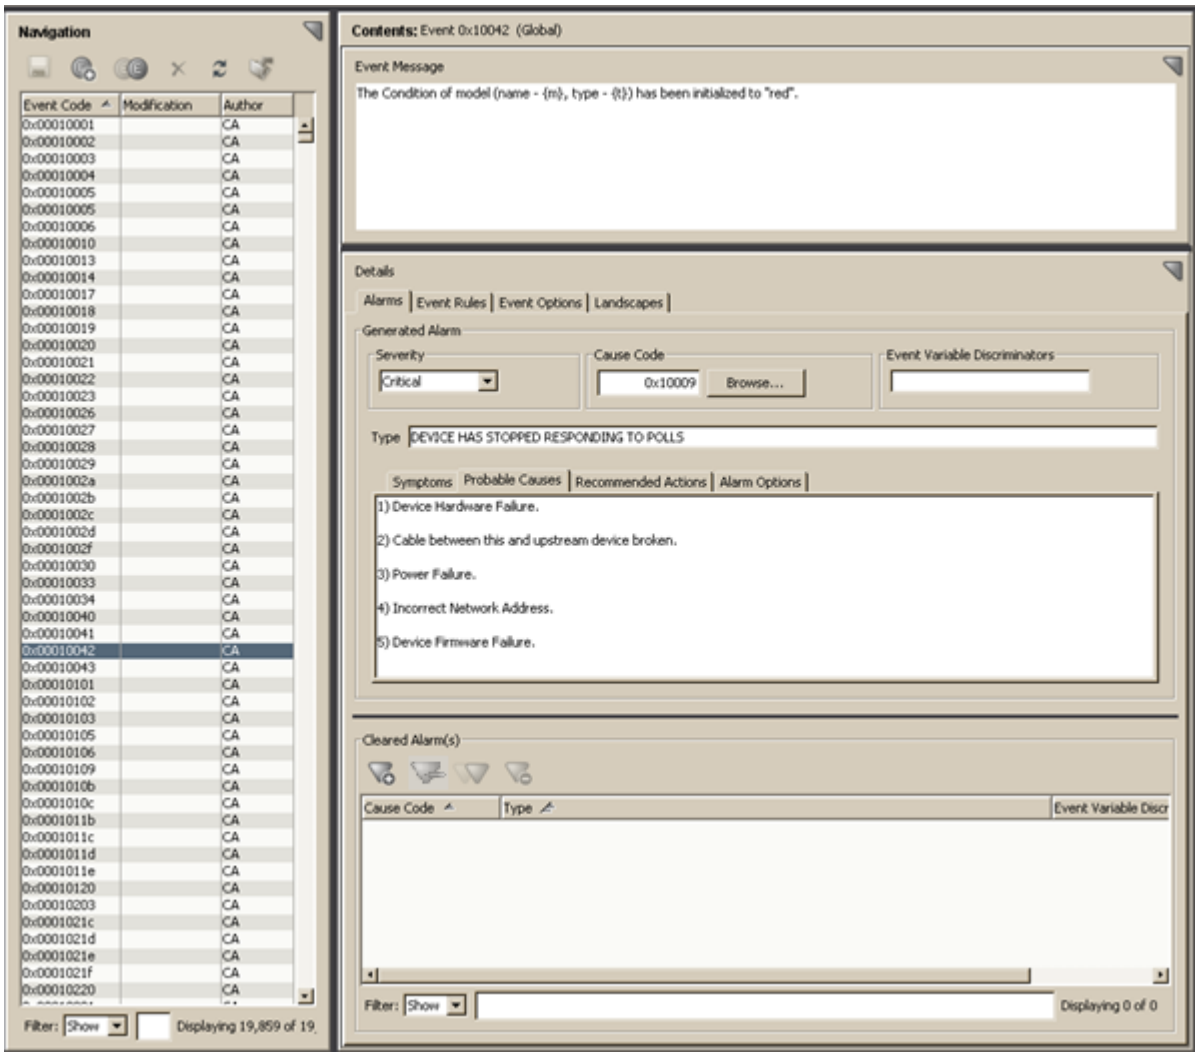
1. In the Navigation panel in MIB Tools, select the MIB containing the traps that have been mapped to the events that you want to configure.

   NOTE
   Map traps to DX NetOps Spectrum events in MIB Tools before you can configure the associated events in Event Configuration. For more information, see information about trap support in Certifications .
2. In the Contents panel, click the Map tab.
3. In the Trap Support table, select the mapped traps for which you want to configure events, and click the edit iconto edit traps for selected items in the trap support table.
   The Event Configuration application is started, and the events that are associated with the traps that you selected display by event code in the Navigation panel.

   NOTE
   Click the Reloads the list of events icon on the Navigation panel, to load all events that are supported in the landscape or landscapes (in a distributed environment).

Overview of the User Interface

You can perform all event and alarm configuration tasks in the Event Configuration main window.



The window is divided into three panels:

- **Navigation:** The Navigation panel lists all of the events that are currently loaded into Event Configuration. The Modified column displays a checkmark next to any event that you have created or modified but not yet saved to a landscape. For more information, see Saving Events to Landscapes.
- **Contents:** The Contents panel displays a customizable event message in the Events tab in OneClick for the event that is selected in the Navigation panel.
- **Details:** The Details panel provides access to the configuration information for the event that is selected in the Navigation panel. If the event generates an alarm, you can also configure the alarm in this panel.

NOTE
You can click the server connection icon to access connection status information for all landscapes in the environment.

Loading All Events from All Landscapes

In order to, load or reload all of the events that are supported in the landscape (or landscapes if the environment is distributed).

On the Navigation panel, to reload the list of events,

click  .

NOTE
Click the Reloads the list of events icon if you start Event Configuration from MIB Tools to work with a limited set of events, and now require access to all events supported in all landscapes.

Save Events to Landscapes

When you save new or modified events (and their disposed actions, such as alarms and event rules) to a landscape, Event Configuration updates the event disposition (EventDisp) files that define them on the SpectroSERVER. The SpectroSERVER flushes all existing event and alarm instances and reloads them using the most recent configuration information.

You can save all events or only selected ones. You can also save the changes to the local landscape only or, in a distributed environment, to some or all of the landscapes.

NOTE
You must save your changes to one or more landscapes before exiting Event Configuration, else the changes you have made are discarded when you exit the application.

WARNING
The save process flushes and reloads all event rules including those event rules that are in the middle of processing. As a consequence, the processing of events by active event rules is aborted, and all associated data (for example, counts for occurrences of contributing events) is lost.

You can save events to the landscape in a single SpectroSERVER environment.

Follow these steps:

1. Do one of the following:
   - To save all modified or created events (and associated alarms) click Save All on the File menu.
   - To save only specific events (and associated alarms) select the events in the table in the Navigation panel and then click Save Selected on the File menu.
2. Click Yes.

You can save events to one or more landscapes in a Distributed SpectroSERVER (DSS) environment.

Follow these steps:

1. Do one of the following:
   - To save all modified or created events (and associated alarms), click Save All on the File menu.
   - To save only specific events (and associated alarms), select the events in the table in the Navigation panel, and then click Save Selected on the File menu.

   If one or more SpectroSERVERs are unavailable. A relevant notification is displayed so you that can cancel the process if wish to.

   NOTE
   If any SpectroSERVERs are unavailable and cannot receive the changes, you can synchronize the events and alarms on all landscapes later.
2. Click Yes to save the events and alarms to available SpectroSERVERs. Alternatively, click No to cancel the process. The Select Landscapes dialog opens. By default, all available SpectroSERVERs are listed in the left list , which means that all available SpectroSERVERs receive the updated events and alarms.
3. If there are available landscapes to which you do not want to save the changes, select them in the left list and click the right-arrow button to move them to the right list.
4. Click OK.

Synchronizing Events in a Distributed Environment

If you are running DX NetOps Spectrum in a distributed environment, update events and alarms using Event Configuration and saving them to landscapes, do any of the following tasks:

- Update the SpectroSERVERs in the environment that do not have the most current events and alarms.
  See Synchronizing Event Disposition Files on SpectroSERVERs.
- Copy the event and alarm support files to all of the OneClick web servers in the environment. See Synchronizing Event and Alarm Support Files on OneClick Web Servers.

Synchronize Event Disposition Files on SpectroSERVERs

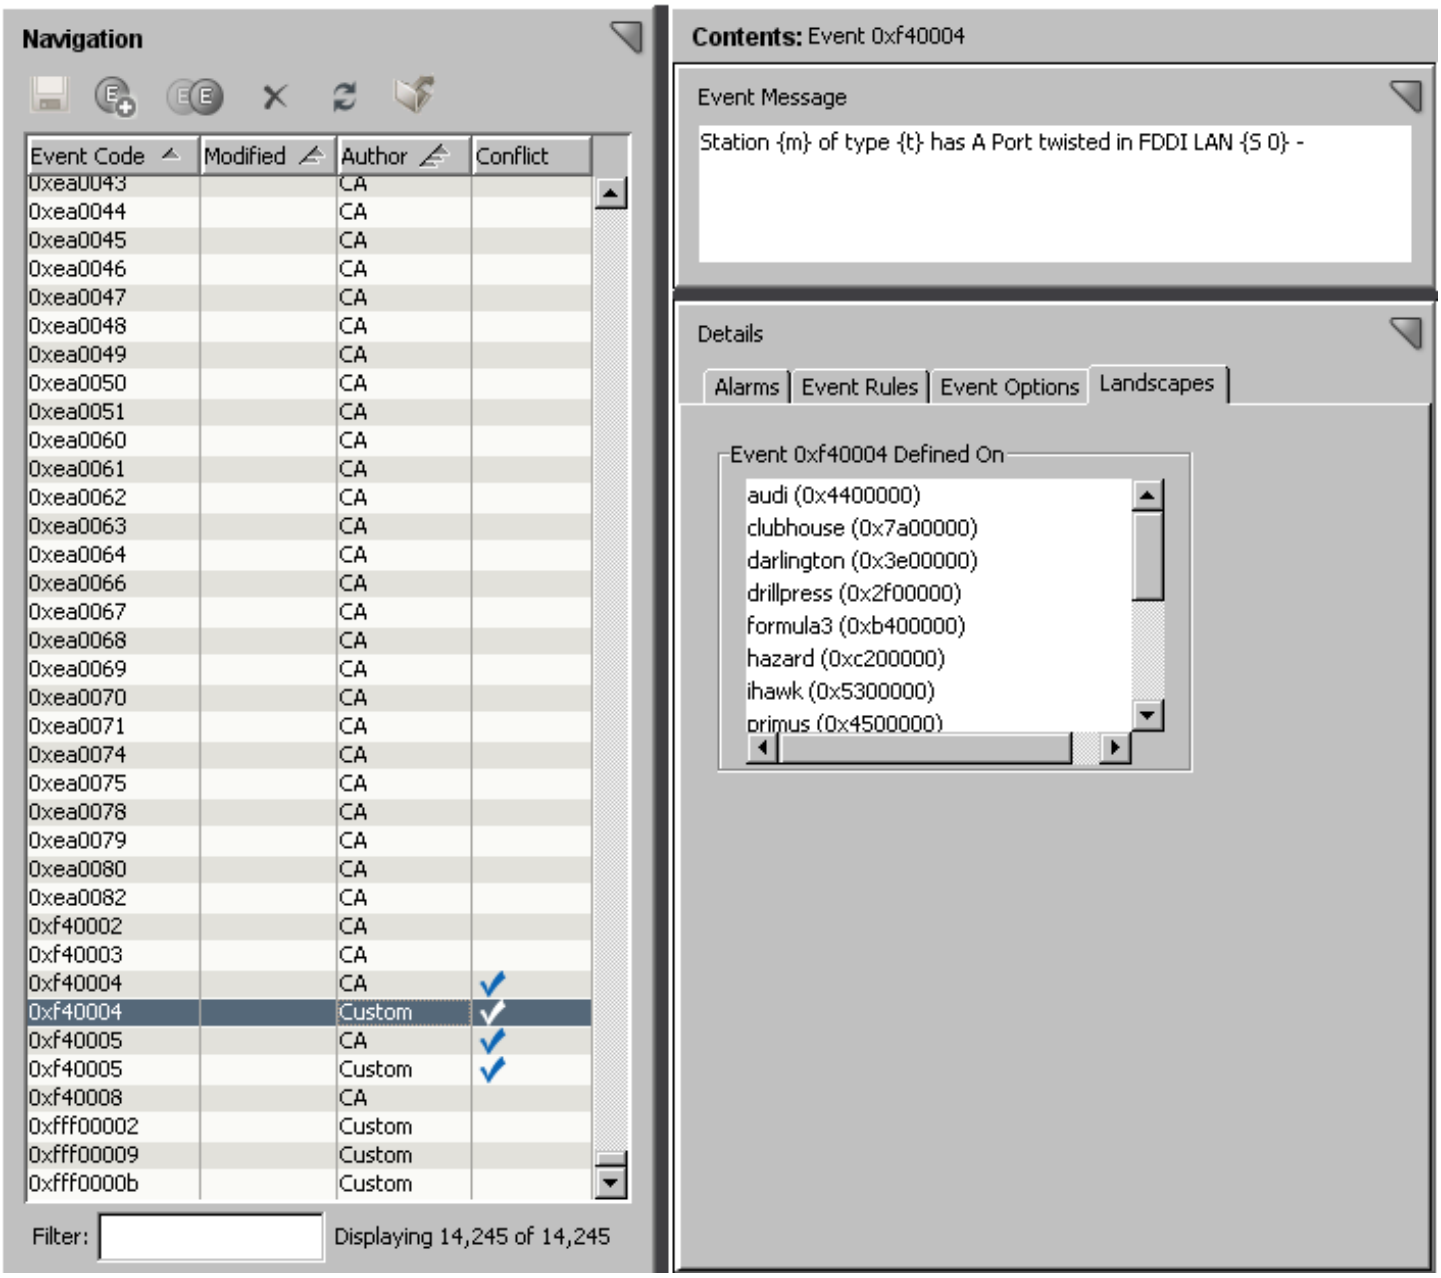
Event and alarm changes are saved to the SpectroSERVERs in a Distributed SpectroSERVER (DSS) environment only when, for example, a server is unavailable. As a result, conflicts in event and alarm configurations arise across the landscapes. Resolve these conflicts by saving the changes to the unavailable servers when they become available. You can perform this task using the synchronization features in Event Configuration.

To begin resolving event (and alarm) conflicts across landscapes, first add the Conflict column to the table of events in the Navigation panel.

Next, examine the Conflict column and note any select marks  .

DX NetOps Spectrum detects an event that is configured differently across two or more landscapes because it finds different event maps for the event in the event disposition files on the SpectroSERVERs. An event with multiple event maps is loaded into Event Configuration once for each unique event map in the DSS environment. The select mark notifies you of each event that has different configurations.

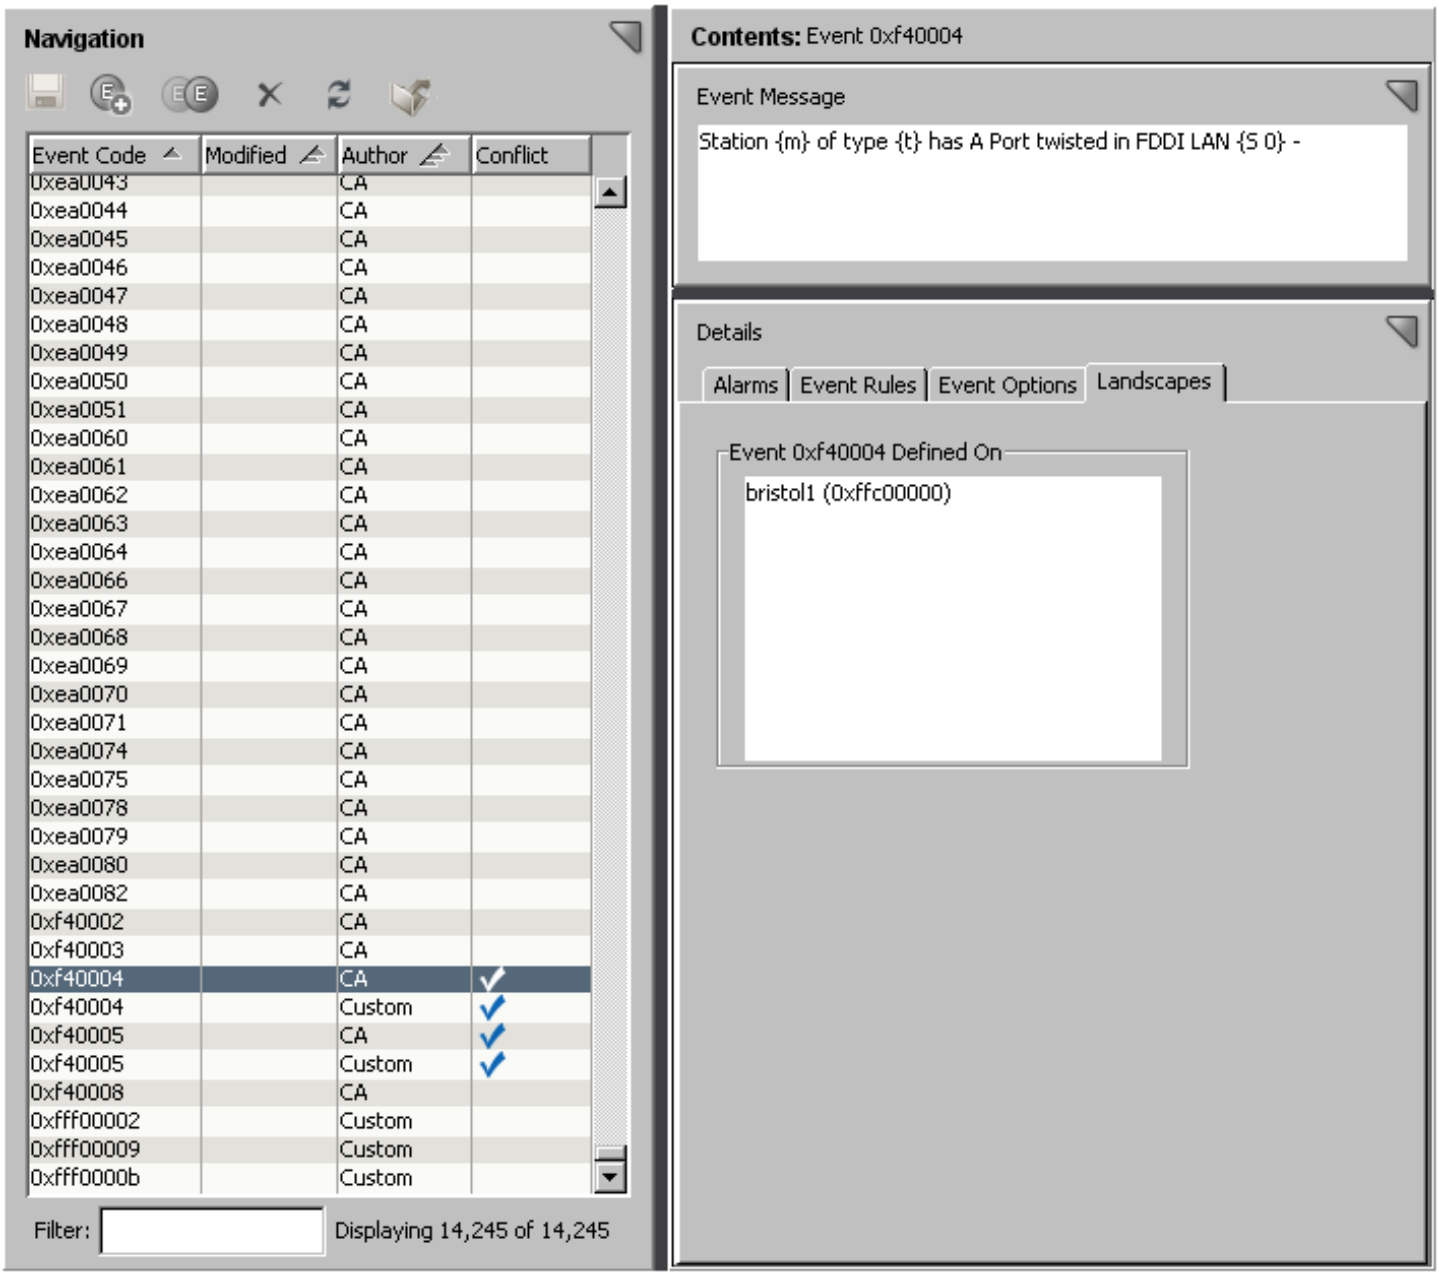
As an example, note the two instances of event 0xf40004 in the following image.



The image shows the result of customizing a predefined event (event 0xf40004) and saving the customization to some but not all landscapes.

You can identify the landscapes to which the custom event has been saved. Select the custom event 0xf40004 and examine the Landscapes tab (displayed automatically in a DSS environment) in the Details panel.

Similarly, you can identify the landscapes to which a predefined event has been saved. Select predefined event 0xf40004 and examine the Landscapes tab. The following image shows the Landscapes tab for the predefined event.



Compare the following information:

- The configurations of the conflicting events
- The landscapes to which the conflicting events have been saved

This information helps you identify the events to save and the landscapes where they are saved to resolve a conflict. Once you have identified these factors, synchronize the landscapes.

Synchronizing the landscapes updates the event disposition (EventDisp) files on one or more SpectroSERVERs. Once updated, they match the event disposition file on the main location server in the DSS environment. Use the Save command if the main location server does not have the event disposition file that you want to use to update the rest of the SpectroSERVERs. For more information, see Saving Events to Landscapes.

Note: You manually designate a main location server when you install DX NetOps Spectrum. For more information about location servers, see Distributed SpectroSERVER Administration .

Follow these steps:

1. Select Synchronize on the File menu.
   The landscapes with event disposition files that differ from the file on the main location server are listed.
2. To synchronize with the main location server, select the landscapes, and click OK.

NOTE
Synchronize the event and alarm support files on the OneClick web servers in the environment.

NOTE
You can also synchronize event and alarm support files between fault-tolerant servers. For more information, see Distributed SpectroSERVER Administration .

Synchronize Event and Alarm Support Files on OneClick Web Servers

Support files are created when you create and configure events and alarms and save them to one or more landscapes using Event Configuration.
The following types of files are created and updated automatically on only the OneClick web server to which you are connected:

- **Event format files**
  Store the event messages that are displayed in OneClick. Every event that DX NetOps Spectrum creates has an event format file.
- **Probable cause files**
  Store the alarm messages that are displayed in OneClick. Every alarm that DX NetOps Spectrum creates and that appears on the Alarms tab in OneClick has a probable cause file.

If you are running multiple OneClick web servers, copy the folders containing the event format files and the probable cause files to the other OneClick servers in your distributed environment. Copy the following folders:

$SPECROOT/custom/Events/CsEvFormat

$SPECROOT/custom/Events/CsPCause

Also copy the contents of these same directories to a custom directory on all of the SpectroSERVERs in your environment in the following circumstances:

- Use the command-line interface (CLI) commands showalarms or showevents.
- Use DX NetOps Spectrum Alarm Notification Manager (SANM).

Updating the Overall Alert and Event System for a Landscape

As described in Saving Events to Landscapes, you can update only the events (and their disposed actions, such as alarms or event rules) on one or more landscapes using the Save commands available on the File menu.

However, to update the overall alert and event system more broadly for a given landscape, in OneClick, click Update Event Configuration on the SpectroSERVER Control subview of the Information tab on the VNM model. This action reloads the following:

- The alert maps that are defined in all custom and predefined AlertMap files.
- The event maps (including event rules) defined in all custom and predefined event disposition files.
- The event procedures that are defined in all custom and predefined event procedure definition files.
- The severity maps defined in all custom and predefined severity mapping files (which are used for alarms that are assigned an alarm severity level of Conditional).
- The event-related resource settings that are defined in the.vnmrc file for the SpectroSERVER.

NOTE
For information about these settings, see Logging Event-Related Errors. For more information about the.vnmrc resource file, see Distributed SpectroSERVER Administration .

- The parse maps defined in all custom and predefined parse map files.

NOTE
For *information about* parse map files, see Host System Resources Management .

WARNING
This update process flushes and reloads all event rules, including those event rules that are in the middle of processing. As a result, the processing of events by active event rules is aborted, and all associated data (for example, counts for occurrences of contributing events) is lost.

Add and Remove Columns from the Events Table

You can modify the event information that is displayed in the table of events in the Navigation panel by adding or removing columns from the table.

For example, if you are working in a Distributed SpectroSERVER (DSS) environment, it can be helpful to add the Conflict column to the table. This information lets you identify whether existing events are configured differently on different landscapes.

NOTE
To filter the events in the table that is based on a specific event property, the corresponding event property column must be displayed. The filtering mechanism checks the text string that you specify against only the text in the *displayed* columns.

Follow these steps:

1. Right-click any column heading.
   The Table Preferences dialog opens.
2. Click the Columns tab, and select the columns that you want to display.

   NOTE
   You can also change the table sort order and font using the controls on the Sort and Font tabs.
3. Click OK.

Logging Event-Related Errors

When you create and configure events and alarms using Event Configuration and then save them to a landscape, the event and alarm processing instructions are written to configuration files referred to as event disposition files.

To help you resolve errors in event disposition files, which result in errors in event processing, you can write errors of different types to log files. You specify which types of errors to log, and the log files to which to write them, using several parameters in the VNM resource file (.vnmrc file) for the SpectroSERVER. see subsections that follow for details on each parameter.

Several types of errors, such as syntax errors, are typically the result of *manual* modifications to event disposition files. To minimize these types of errors, it is recommended that you use Event Configuration, not a manual process, to create and configure events and alarms.

WARNING
If the SpectroSERVER encounters an error in an event map while parsing an event disposition file, that event map is ignored. The event map cannot, therefore, be used to process the associated event.

NOTE
If you modify the event-related.vnmrc parameters that are described in this section, you must reload the parameters on the SpectroSERVER using the Update Event Configuration command on the Information tab

of the VNM model for the changes to take effect. For more information, see Updating the Overall Alert and Event System for a Landscape. Or you can restart the SpectroSERVER, which reloads all of the parameters in the .vnmrc file, not only the event-related ones. For more information about the.vnmrc file, see Distributed SpectroSERVER Administration .

event_disp_error_file

If you set this parameter to the name of a text file, DX NetOps Spectrum writes any syntax errors or other errors that it encounters while parsing an event disposition file to that text file. Use the following syntax:

```
event_disp_error_file=<file name>
```

The text file is created in the *$SPECROOT*/SS folder.

Or you can set the value as follows:

```
event_disp_error_file=stderr
```

This command sends the output to the console window in the DX NetOps Spectrum Control Panel and to the *$SPECROOT*/SS/VNM.OUT file.

NOTE
For more *information about* syntax errors, see Syntax Errors in EventDisp Files.

event_custom_override_warnings

If you set this parameter to TRUE, when DX NetOps Spectrum encounters an event map for an event in a custom event disposition file, and an event map for the same event also exists in an event disposition *file that is provided* with DX NetOps Spectrum, it logs a warning to the text file specified in the event_disp_error_file parameter (if a file is specified). The default value is FALSE.

Setting this parameter to TRUE can be helpful if you must determine which CA-authored events are overridden by your custom events, for example, for troubleshooting purposes. Use the following syntax:

```
event_custom_override_warnings=TRUE
```

NOTE
To set this parameter, you must manually add it to the .vnmrc file.

enable_event_variable_warnings

By default, DX NetOps Spectrum does not log any warnings that are encountered while copying event variable values from one event to another during event rule processing. You can override this default behavior by setting the value of this parameter to TRUE. Use the following syntax:

```
enable_event_variable_warnings=TRUE
```

NOTE
To set this parameter, you must manually add it to the.vnmrc file.

event_duplicate_action_warnings

By default, when DX NetOps Spectrum encounters *identical* (and, therefore, duplicate) event maps for an event within an event disposition file or across multiple event disposition files on a SpectroSERVER, it logs a warning to the text file specified in the event_disp_error_file parameter (if a file is specified).

Typically, this default behavior is desirable. However, you can override it by setting the value of this parameter to FALSE. Use the following syntax:

```
event_duplicate_action_warnings=FALSE
```

NOTE
To set this parameter, you must manually add it to the .vnmrc file.

event_disp_default_log

For the events that you create and manage using Event Configuration, you specify whether they are logged in the Distributed Data Manager (DDM) database using the Store Event in Historical Database event option in Event Configuration. See Specify Event Options for more information.

By default, events that do not have event maps in event disposition files are logged in the DDM database. You can override this default behavior by setting the value of this parameter to FALSE. Use the following syntax:

```
event_disp_default_log=FALSE
```

Typically, most events have event maps in event disposition files. However, there are situations where this behavior is not true. For example, if you mapped a trap to a DX NetOps Spectrum event *manually* instead of using the recommended method of using MIB Tools, and then you inadvertently neglected to define an event map for the event in an event disposition file, the event is still logged in the DDM database depending on the value of this **.vnmrc** parameter.

procedure_error_file

If you set this parameter to the name of a text file, DX NetOps Spectrum writes any errors that it encounters while parsing a procedure file to that text file. Use the following syntax:

```
procedure_error_file=<file name>
```

The text file is created in the *$SPECROOT*/SS folder.

Alternatively, you can set the value as follows:

```
procedure_error_file=stderr
```

This sends the output to the console window in the DX NetOps Spectrum Control Panel and to the *$SPECROOT*/SS/VNM.OUT file.

If the event_disp_error_file parameter is set, the errors that are encountered in procedures that are executed from events are written to the file specified in event_disp_error_file instead of to the file specified in this parameter. Errors that are encountered in other types of procedures, for example, in procedures used for diagnostics, are still written to the file specified in this parameter.

> **NOTE**
> To set this parameter, add it to the.vnmrc file manually.

Event and Alarm Concepts

This section provides a brief overview of conceptual information about Events and Alarms.

About Alarms and Events

DX NetOps Spectrum is a services and infrastructure management system that notifies you of faults on managed elements within the network infrastructure. DX NetOps Spectrum receives alerts from problem areas within the managed infrastructure. DX NetOps Spectrum converts alerts into events and alarms, which are displayed in OneClick event and alarm views. Alerts, events, and alarms let DX NetOps Spectrum notify you about significant occurrences in your IT infrastructure.

Alerts

An *alert* is an unsolicited message from a managed element on a network. A more specific definition of an alert depends on the management protocol that is used to report the alert. In general, DX NetOps Spectrum uses SNMP as the management protocol to communicate with devices on a network. Alerts that an SNMP-compliant device generates are named *traps*.

You can configure managed elements that have enabled the SNMP traps to direct their traps to the host that is running DX NetOps Spectrum. The host receives a trap and identifies the model in the DX NetOps Spectrum database that is associated with the managed element, using the source IP address. Next, DX NetOps Spectrum maps the trap to a DX NetOps Spectrum event. The event is then generated and processed.

DX NetOps Spectrum applies special handling to traps that are not mapped to specific DX NetOps Spectrum events. Traps that occur on managed elements that are not modeled at the time the trap is received are also handled differently. For more information, see Modeling and Managing Your IT Infrastructure .

> **NOTE**
> You map the traps from a managed element to specific DX NetOps Spectrum events using the MIB Tools application in OneClick. Perform these mappings before you can create and modify the events and associated alarms using Event Configuration. For more information, see Certifications .

Events

An *event* is a DX NetOps Spectrum object that indicates that something significant has occurred within DX NetOps Spectrum itself or within the managed environment. Events always occur in relation to a model. When DX NetOps Spectrum receives an alert from a managed element on the network, in response, it generates a DX NetOps Spectrum event for the corresponding model if the received trap is mapped to an event.

DX NetOps Spectrum also generates some events automatically. For example, DX NetOps Spectrum generates an event when models are created or destroyed or when DX NetOps Spectrum connects or disconnects from a device application. DX NetOps Spectrum also generates an event when contact with a managed element is established or lost.

DX NetOps Spectrum uses the configuration of the underlying event to process an event instance. For example, the Archive Manager in the Distributed Data Manager (DDM) database can log an event instance. Or an event instance can clear an alarm or can generate another event using an event rule.

Network operators can view the list of current events in a landscape on the OneClick Events tab. For a specific event, you can also view information such as a description of the event and the time it was created.

To map the traps from a device to specific DX NetOps Spectrum events, use the MIB Tools application in OneClick. Then complete event customization using Event Configuration. In Event Configuration, define event processing rules, create the event message to display to users, and set other parameters.

Event Codes

Every event has a unique event code. The event code is a 4-byte integer that is expressed in hexadecimal format.

An event code has two parts:

- The first 2 bytes contain the developer ID of the developer who created the event
- The last 2 bytes identify the event with a unique number relative to all other event codes for that developer

DX NetOps Spectrum assigns event codes to all events created using MIB Tools or Event Configuration. The next available event code is always used as the default code. In Event Configuration, you have the option of overriding the default code and specifying a different one.

> **NOTE**
> The event code 0x10000 represents a null event. This event cannot be generated. However, the null event can be used in an event rule that requires an event code as a parameter.

Alarms

An *alarm* is a DX NetOps Spectrum object that indicates that a user-actionable, abnormal condition exists in a model. DX NetOps Spectrum generates an alarm when a DX NetOps Spectrum event -- typically generated as a result of a received trap -- specifies an alarm creation. DX NetOps Spectrum can generate an alarm that is based on the results of a

watch. DX NetOps Spectrum can also send an event in response to an abnormal situation that did not send an event. (For example, a model loses the connection to its managed element).

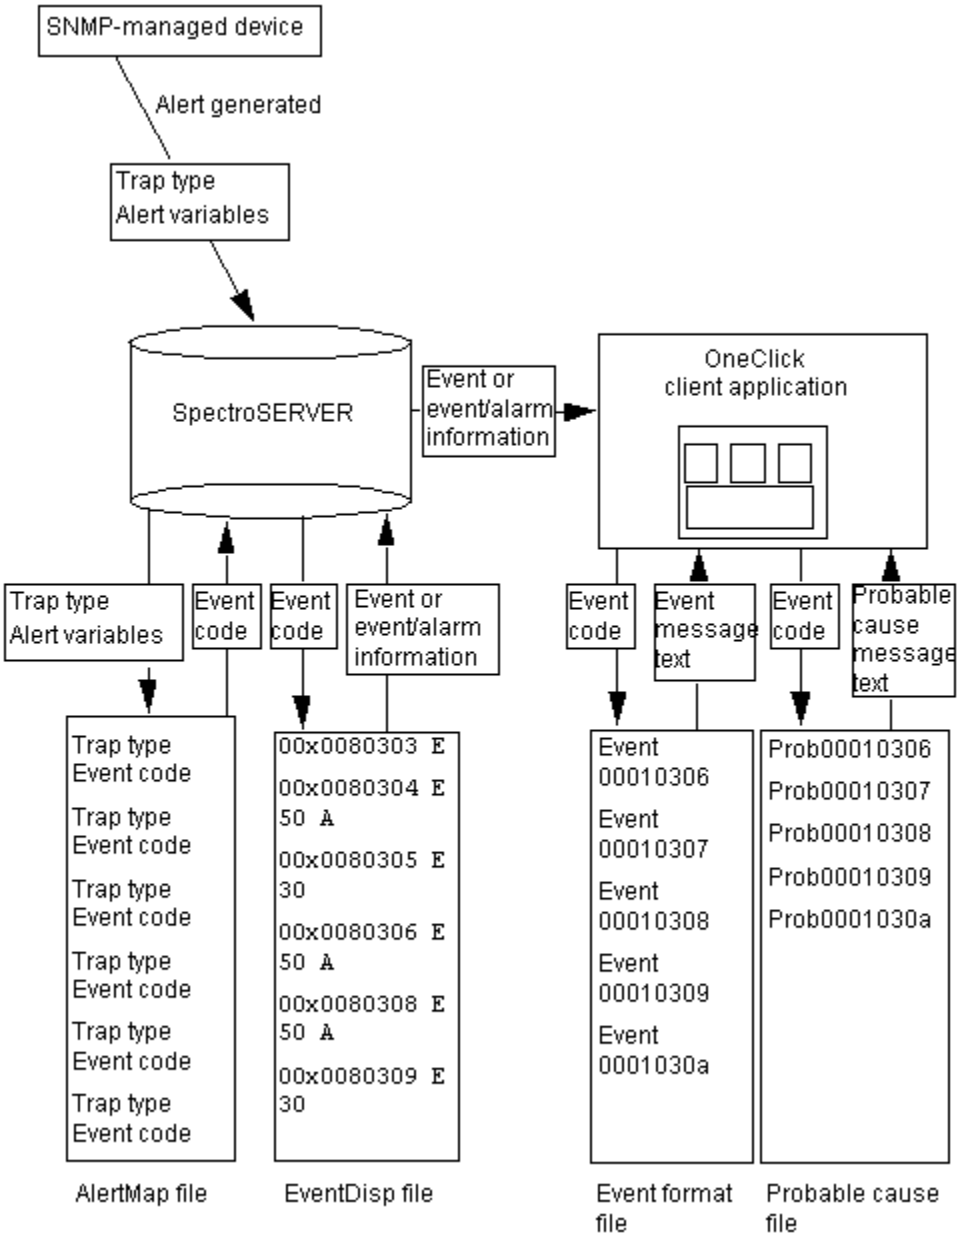
Network operators are alerted to alarms in multiple ways that depend on OneClick configuration. For example, the icon representing the model of the managed element (or a container model for the managed element model) can change color. In addition, an audio message announces the new alarm in both thick client and WebApp.

Operators can view the current list of alarms in a landscape on the OneClick Alarms tab. For a specific alarm, you can also view detailed information. For example, you can see whether a user has acknowledged the alarm, its symptoms, probable causes, and the recommended corrective actions.

When the abnormal condition that caused the alarm ends, another event automatically clears the corresponding alarm. You can clear the alarm manually and also send any Alarm notifications to external third-party or internal DX NetOps Spectrum applications as appropriate.

You can specify whether an event generates an alarm (and alarm severity) in MIB Tools when you map a trap to an event. However, you use Event Configuration to set more alarm parameters and to change the alarm severity.

The following figure illustrates the flow of alerts, events, and alarms within DX NetOps Spectrum.



Working with Events and Alarms

The following sections details all the features and options that you face while working with Events and Alarms in DX NetOps Spectrum.

Finding Events

To find an event, you can filter the list of events in the Navigation panel to include only events with displayed property values that include a specific text string. For example, *if the Type column is displayed*, you can enter “timeout” to filter the

list to include only events that generate alarms that include the word (in uppercase or lowercase) in the alarm type text string (alarm title).

An event that is mapped to a Trap has the Trap Event column checked.

To find events.

1. If necessary, click the Reloads the list of events icon to update the event table in the Navigation panel to include all events in the distributed environment.

   NOTE
   Typically, you must reload the list of events if you started Event Configuration from MIB Tools. Starting Event Configuration in this manner only loads into Event Configuration the specific events you selected in MIB Tools.
2. Verify that the event properties that you want to search against are displayed in the events table. If not, add the appropriate table columns as described in Adding and Removing Columns from the Events Table.

   NOTE
   Only visible table columns are included in the filtering process.
3. In the Filter field, enter the text string to search for in the event table.
   The list of events in the table is filtered to include only those events that have the text string you specified in the displayed property values.

Create Events from Scratch

You can create new events from scratch.

NOTE
Creating a management module for a device that DX NetOps Spectrum does not support by default; use MIB Tools to map traps sent by the device to new DX NetOps Spectrum events before using Event Configuration. (Events are automatically created when you define the trap mappings). You can then launch Event Configuration directly from MIB Tools to configure the events and associated alarms.

NOTE
For more information, see Mapping Traps to DX NetOps Spectrum Events.

To create a new event.

1. In the Navigation panel, click the Creates an event icon
   
   The Create Event dialog appears.
2. Enter an event code or accept the default event code.

   NOTE
   The event code is a 4-byte integer that is expressed in hexadecimal format. The first 2 bytes contain the developer ID, and the last 2 bytes identify the event with a unique number. While the default code is unique, it is recommended that you enter a code beginning with your CA-assigned developer ID. This ID lets you easily recognize your custom code in OneClick and prevents potential conflicts with other DX NetOps Spectrum event codes. The event code 0x10000 represents a null event. This event cannot be generated. However, the null event can be used in an event rule that requires an event code as a parameter.
3. Enter an event message as described in Entering an Event Message. (You can also modify the message after the event is created.)
   Remember that most of the information that a OneClick user receives about an event is through the message text that is affiliated with that event. For this reason, provide as much information about the event as possible in the message.
4. (Optional) Enter the Vendor to specify the developer, vendor, or manufacturer.

NOTE
The Vendor is available in the directory under <$SPECROOT>/custom/Events that contains the EventDisp file. The event options (and other event processing information) are stored in event configuration files referred to as event disposition files.

5. Click OK.
   The new event is added to the table of events in the Navigation panel. The event is displayed in bold. The Modification column displays *New*.

   NOTE
   The event is marked *New*. However, the event is not saved. You can make more updates such as create more events, modify existing events, or delete events, and save all the updates at one time.
6. Configure the event, as described in Configuring Events.
7. (Optional) Add event rules to the event, as described in Creating an Event Rule.
8. Save the changes to one or more landscapes, as described in Saving Events to Landscapes.
   The events appear in the normal font and are not marked in the Modification column.

Create Events from a Copy

You can create new events by copying existing events.

NOTE
Creating a management module for a device that DX NetOps Spectrum does not support by default, use MIB tools to map the traps that are sent by the device to new DX NetOps Spectrum events (automatically created when the trap mappings are defined) before using Event Configuration. You can then launch Event Configuration directly from MIB Tools to configure the events and associated alarms.

NOTE
For more information, see Mapping Traps to DX NetOps Spectrum Events.

To create an event from a copy.

1. In the Navigation panel, select the event that you want to copy, and click the Copies the selected event icon
   
   The Copy Event dialog opens.
2. Enter an event code or accept the default event code.

   NOTE
   The event code is a 4-byte integer that is expressed in hexadecimal format. The first 2 bytes contain the developer ID, and the last 2 bytes identify the event with a unique number. Though the default code is unique (even regarding the event that you are copying), it is recommended that you enter a code beginning with your CA-assigned developer ID. This ID lets you easily recognize your custom code in OneClick and prevents potential conflicts with other DX NetOps Spectrum event codes. The event code 0x10000 represents a null event. This event cannot be generated. However, the null event can be used in an event rule that requires an event code as a parameter.
3. Revise the event message as appropriate for the new event, as described in Entering an Event Message. (You can also modify the message after the event is created.)
   Remember that most of the information that a OneClick user receives about an event is through the message text which is affiliated with that event. For this reason, provide as much information about the event as possible in the message.
4. Click OK.
   The new event is added to the table of events in the Navigation panel. The event displays in bold. The Modification column displays *New*.

NOTE
The event is marked *New*. However, the event is not saved. You can make more updates such as create more events, modify existing events, or delete events, and save all the updates at one time.

5. Configure the event, as described in Configuring Events.
6. (Optional) Add event rules to the event, as described in Creating an Event Rule.
7. Save the changes to one or more landscapes, as described in Saving Events to Landscapes.
   The events appear in the normal font and are not marked in the Modification column.

About Configuring Events

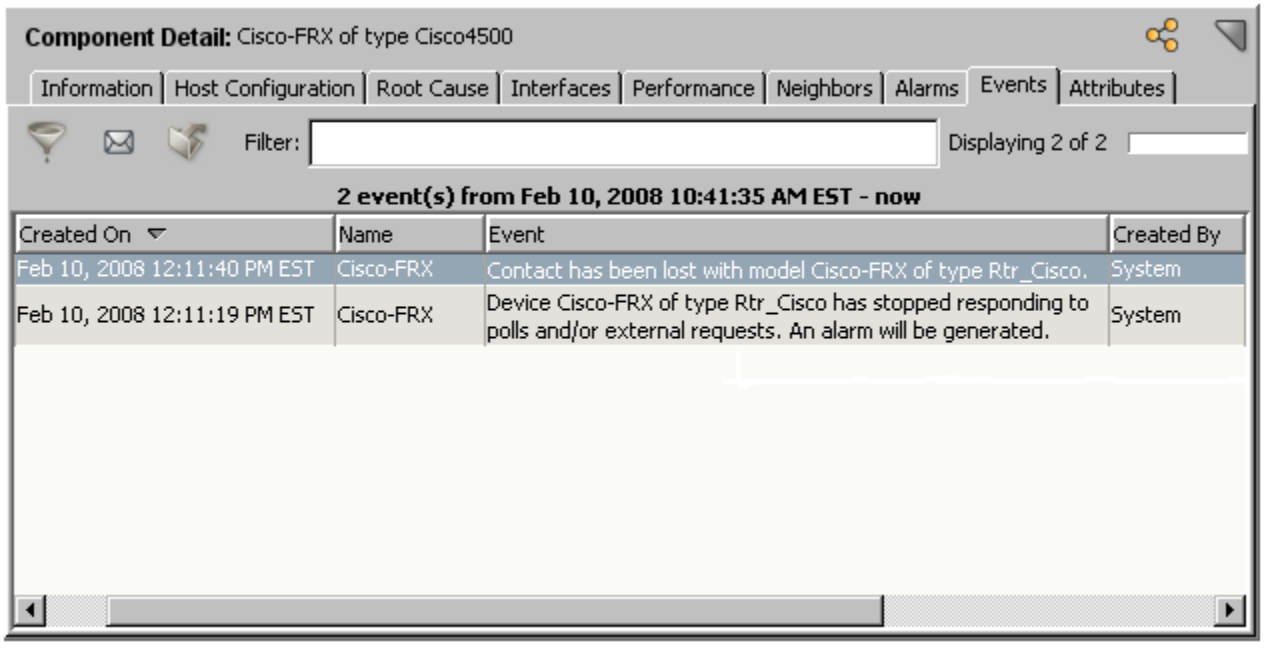
To configure an event, specify the following:

- The message that is displayed to users in OneClick when the event occurs. See Entering an Event Message.
- The scope of the event (global or model type-specific) and whether the event is logged in the Distributed Data Manager (DDM) database by the Archive Manager for historical and reporting purposes. See Specifying Event Options.
- Whether the event generates an alarm. See Configuring Events to Generate Alarms.
- Whether the event clears one or more alarms. See Configuring Events to Clear Alarms.

NOTE
You can also create event rules that are activated (triggered) by an event. For example, some types of events can be tolerated and do not indicate problems if the frequency at which they are generated does not reach a specific threshold, within a specific amount of time. You can create a rule that watches for this scenario, and when it occurs, generates another event (and associated alarm) in response.

Event Messages

The *event message* is the message that is displayed on the Events tab in OneClick when the event occurs.



When you compose an event message, you can use plain text and variables that reference specific data about the generated event. For the descriptions of each variable and the proper syntax to use when including them, see the subsections that follow.

NOTE
The event messages are stored in event configuration files referred to as event format files.

Variable Descriptions and Syntax

This section provides information about the event variables that you can use when you define event messages. When you include an event variable in a message, use the syntax that is defined here.

In the sections that follow, the # sign represents the event variable ID that is mapped to the OID of the variable binding that is sent with the trap. This assignment is made in the OID map in an AlertMap file that MIB Tools automatically creates when you map a trap to an event.

You can construct any type of message using event variable IDs. The only requirement is that the variables that you use in the message are of the proper data type.

NOTE
0x12a63 is a reserved event variable ID that is used for a web context URL.

- **{d “%w- %d %m-, %Y - %T”}**
  This variable is for the date string. This variable must be included in every event message. By including this variable exactly as shown, you tell DX NetOps Spectrum to capture the time and date that the alert is received.

  NOTE
  You do not need to include this variable if you are entering the event message using Event Configuration, as the application automatically inserts the variable in the event format file that it creates when you save the event to a landscape.

  Date/Time specifier options:
  - **%u**
    Use GMT time not local time. Must appear first in format.
  - **%%**
    Writes % to buffer.
  - **%d**
    Writes day-of-month 01..31 to buffer.
  - **%d-**
    Writes day-of-month 1..31 to buffer.
  - **%D**
    Writes date dd/mm/yy to buffer.
  - **%H**
    Writes hour-of-day 00..23 to buffer.
  - **%h**
    Same as %m.
  - **%j**
    Writes day-of-year 1..366 to buffer.
  - **%m+**
    Writes full month name to buffer.
  - **%m-**
    Writes abbreviated month name to buffer.
  - **%m***
    Writes month index 1..12 to buffer.
  - **%m**
    Writes month index 01..12 to buffer.
  - **%M**

Writes minute 00..59 to buffer.
  - **%S**
    Writes second 00..59 to buffer.
  - **%T**
    Writes time hh:mm:ss to buffer.
  - **%w+**
    Writes full weekday name to buffer.
  - **%w-**
    Writes abbreviated weekday name to buffer.
  - **%w**
    Writes weekday index 1..7 to buffer.
  - **%y**
    Writes year 00..99 to buffer.
  - **%Y**
    Writes year 0000..9999 to buffer.
- **{t}**
  This variable inserts the model type name in the message. The (t) variable is defined internally and is not configurable.
- **{m}**
  This variable inserts the model name in the message. The (m) model name variable is defined internally and is not configurable.
- **{e}**
  This variable inserts the event code in the message. The (e) variable is defined internally and is not configurable.
- **{u}**
  This variable inserts the user name in the message. The (u) variable is defined internally and is not configurable.
- **{T <event table file name> #}**
  Inserts a text string that is associated with a MIB table attribute value. The association between the attribute value and the text string is defined in an event table file that MIB Tools creates automatically when you map the trap to the event. For more information, see Referencing Attribute Values in a MIB Table.
- {Y <event table file name> #}
  Inserts a text string that is associated with an OID. The association between the attribute value and the text string is defined in an event table file that MIB Tools creates automatically when you map the trap to the event. For more information, see Referencing OIDs.
- **{Z <event table file name> #}**
  Inserts a text value that is associated with an integer bit value. The association between the integer bit value and the text string is defined in an event table file that MIB Tools creates automatically when you map the trap to the event. For more information, see Referencing Integer Bit Values.
- **{o #}**
  Inserts an object ID.
- **{O #}**
  Inserts an octet string.
- **{X #} or {x #}**
  Inserts an octet string that is displayed in hexadecimal format.
- **{S #}**
  Inserts a text string.
- **{B #}**
  Inserts a Boolean value. Zero denotes false. Any other value denotes true.
- **{I #}**
  Inserts an integer.string that is displayed.
- **{L #}**

Inserts a Counter64 counter.

- **{U #}**
  Inserts an unsigned integer or Counter64 counter.
- **{R #}**
  Inserts a real number in the range: 10E37 to 10E37.
- **{H #}**
  Inserts a 32-bit hex number with a 0x prefix.
- **{K #}**
  Converts a DateAndTime attribute value from an octet string to a text string, and inserts the formatted text string.
- **{G #}**
  Calculates and inserts the device up time that is based on the value of the event variable (#). The value is displayed as days+hours:mins:secs.
- **{D #}**
  Used with an event variable (#), which contains an integer representing the number of seconds from 1969. Converts that value to a string that represents the date and time.
- **{T #}**
  Inserts a date and time.
- **{a #}**
  Inserts an attribute ID.
- **{A #}**
  Inserts an IP address.
- **{V #}**
  Inserts the value of a variable.

Referencing Attribute Values in a MIB Table

If a variable binding that is sent with a trap contains an attribute value from a MIB table, you can use it in an event message. To use it in an event message, apply proper syntax and reference the following information:

- The event variable to which the OID of the variable binding is mapped.
- The event table file that contains the enumerated attribute values and the associated text strings to use in event messages. (MIB Tools automatically creates the Event table files when you map traps to new DX NetOps Spectrum events.)

As an example, assume that you have an event table file that is named BeaconType that associates the following attribute values with corresponding text strings:

```
0x00000001 Reconfiguration
0x00000002 Signal-Loss
0x00000003 Bit-Streaming
0x00000004 Contention-Streaming
0x000000ff None
```

To reference these values in an event message, use the following syntax:

```
{T BeaconType 2}
```

- **T**
  Indicates that you are inserting a MIB table attribute whose values are enumerated in an event table file.
- **BeaconType**
  Specifies the name of the event table file that contains the enumerated values.
- **2**
  Specifies the event variable number that is mapped (in the AlertMap file) to the OID of the variable binding that is sent with the trap. DX NetOps Spectrum takes the value of the event variable and retrieves the corresponding text

string that is defined in the event table file. For example, if the event variable above, 2, stored the value 3, the text “Bit-Streaming” would be rendered in the event message.

Referencing OIDs

If a variable binding that is sent with a trap contains an OID, you can use it in an event message. To use it in an event message,use the proper syntax and reference the following:

- The event variable to which the OID of the variable binding is mapped.
- The event table file that contains the enumerated OID values and the associated text strings to use in event messages. (MIB Tools automatically create Event table files when you map traps to new DX NetOps Spectrum events.)

As an example, assume that you have an event table file that is named NewTable that associates the following attribute values with corresponding text strings:

```
1.3.6.1.4.1.1563.1.2.1.1.3.2.36.2.6 dot6
1.3.6.1.4.1.1563.1.2.1.1.3.2.36.2.5 dot15
1.3.6.1.4.1.1563.1.2.1.1.3.2 dot7
```

To reference these values in an event message, use the following syntax:

```
{Y NewTable 2}
```

- **Y**
  Indicates that you are inserting the value of a variable binding whose possible OID values are enumerated in an event table file.
- **NewTable**
  Specifies the name of the event table file that contains the enumerated values.
- **2**
  Specifies the event variable number that is mapped (in the AlertMap file) to the OID of the variable binding that is sent with the trap. DX NetOps Spectrum takes the value of the event variable and retrieves the corresponding text string that is defined in the Event Table file. For example, if the event variable above, 2, stored the value 1.3.6.1.4.1.1563.1.2.1.1.3.2, the text “dot7” would be rendered in the event message.

Referencing Integer Bit Values

If a variable binding that is sent with a trap contains an OID, you can use it in an event message. To use it in an event message,use the proper syntax and reference the following:

- The event variable to which the OID of the variable binding is mapped.
- The event table file that contains the enumerated integer bit values and the associated text strings to use in event messages.

  NOTE
  When you map traps to new DX NetOps Spectrum events MIB Tools automatically created Event table files.

As an example, assume that you have an event table file that is named NewBitTable that associates the following integer bit values with corresponding text strings:

```
1 dsx1NoAlarm
2 dsx1RcvFarEndLOF
3 dsx1XmtFarEndLOF
4 dsx1RcvAIS
```

To reference these values in an event message, use the following syntax:

```
{Z NewBitTable 2}
```

- **Z**

Indicates that you are inserting the value of a variable binding whose possible integer bit values are enumerated in an event table file.

- **NewBitTable**
  Specifies the name of the event table file that contains the enumerated values.
- **2**
  Specifies the event variable number that is mapped (in the AlertMap file) to the OID of the variable binding that is sent with the trap. DX NetOps Spectrum takes the value of the event variable and retrieves the corresponding text string that is defined in the Event Table file. For example, if the event variable above, 2, stored the value 4, the text “dsx1RcvAIS” would be rendered in the event message.

Example Event Message

The following message is a sample event message:

```
{d "%w- %d %m-, %Y - %T"} A device {m} of type {t} has reported a Firewall trap has occurred. {S 1} contains
 the name of the last trap sent via fw. - (event [{e}])
```

When the message is displayed on the Events tab in OneClick, it is rendered as follows:

- {d "%w- %d %m-, %Y - %T"} is replaced with the date and time
- {m} is replaced with the model name
- {S 1} is replaced with a string value (S for string data type) from a variable binding
- {t} is replaced with the model type
- {e} is replaced with the event code.

Specify Event Options

You can specify the following options for an event:

- Whether the event is logged in the Distributed Data Manager (DDM) database by the Archive Manager for historical and reporting purposes.
  Events for a model that are not logged in the DDM database are displayed on the Events tab in OneClick only if they are generated while the Events tab for that model is displayed.
- Whether the event is global or specific to one or more model types.
  Global events are those that are generated for all models of all model types regardless of the developer who created the model type. Examples of global events include “link down” or “cold start” events.
  If an event is *specific to a model type*, it is generated only for models of specific model types (for example, for a device model type that supports a proprietary MIB).
- The Vendor field appears only for those events that are defined for a vendor. The Vendor field appears as read-only only for events that are defined under a vendor directory. This field is configurable for a new event until the event has been saved, then it appears as read-only.

  NOTE
  The Event options (and other event processing information) are stored in event configuration files referred to as event disposition files.

To specify options for an event.

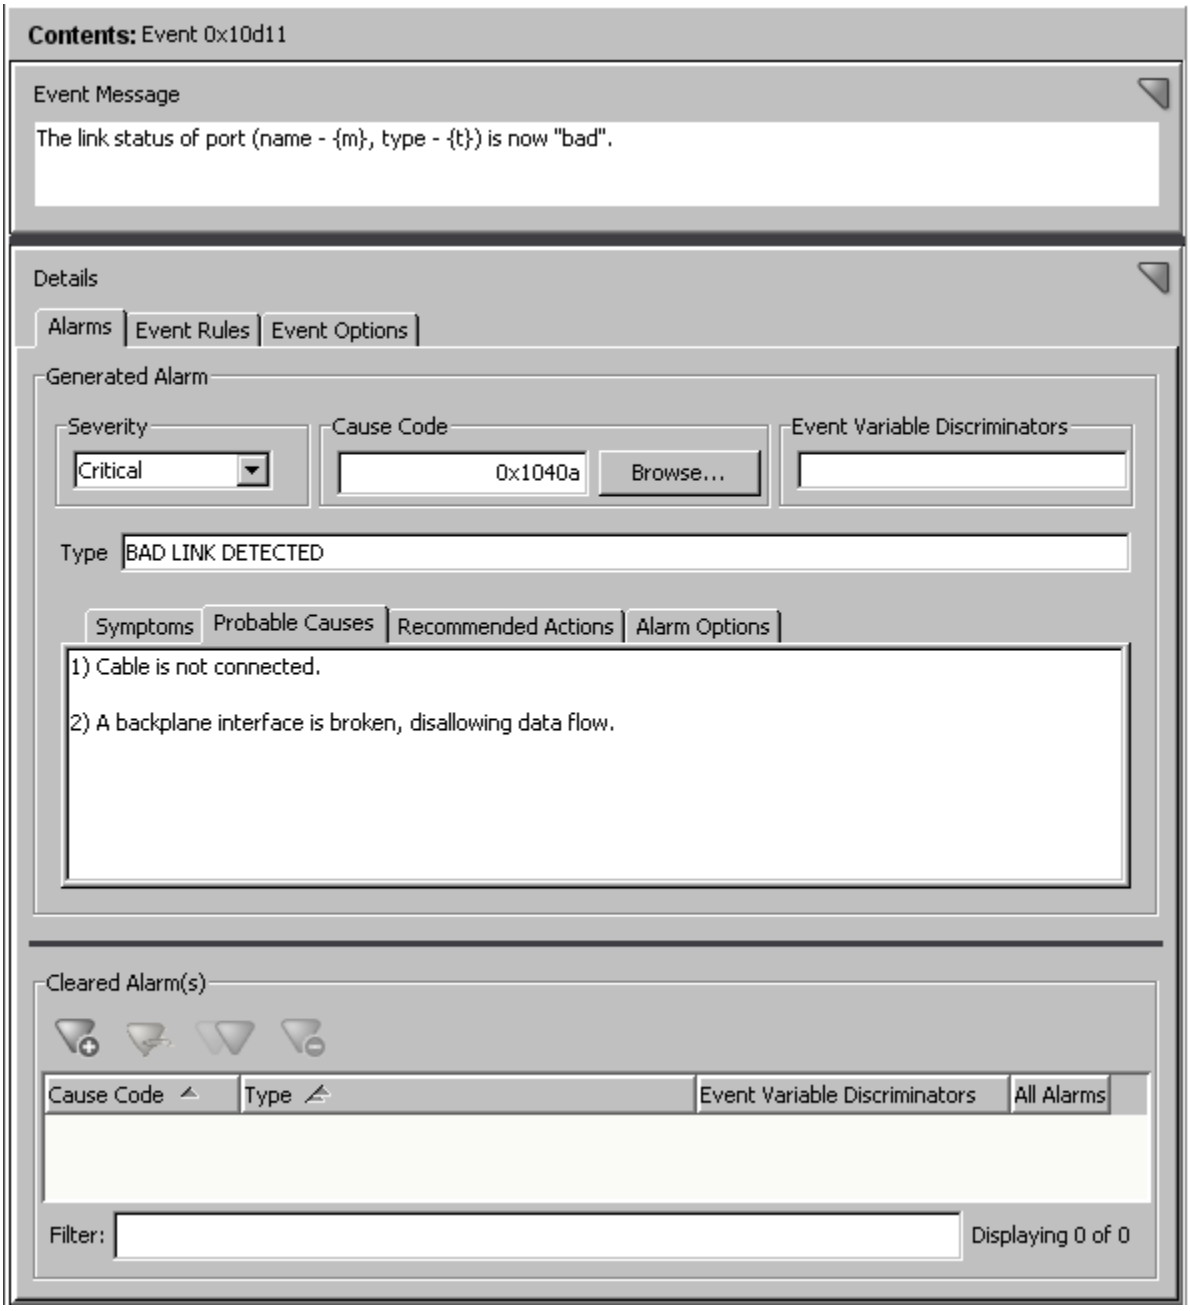
1. Select the event in the Navigation panel.
2. In the Details panel, click the Event Options tab.
3. If you want the event to be logged in the Distributed Data Manager (DDM) database by the Archive Manager, select Store Event in Historical Database.
4. Under Scope, specify the scope of the event:

- If the event is global, select Global.
- If the event is specific to a model type, select Model Type. Then, in the Select Model Type dialog, select the name of one or more model types to which the event applies, and click OK. (Use the CTRL key to select multiple model types.)

  NOTE
  Changing the scope of an event does not modify the event; instead, a duplicate event with the same event code but a different event scope is automatically created. As a result, when you save both events to a landscape, two event maps in two different event disposition files are created. This feature lets you specify event processing for the event and apply those instructions globally, and then override those processing instructions, for the same event, for specific model types. When DX NetOps Spectrumprocesses an event, the event maps in model type-specific event disposition files take precedence over the event maps for the same events in global event disposition files. If you change the scope of an event and you do not require the original event, you can delete it if it is a custom event.

Configure Events to Generate Alarms

You can specify that the currently selected event generates an alarm, and you can configure the alarm itself using the Alarms tab in the Details panel. The Details panel is shown in the following image:



When you configure an event to generate an alarm and then save that change to a landscape, you create a mapping between the event and the alarm in a configuration file, an *event disposition file*.

Follow these steps:

1. Select the event in the Navigation panel, and then click the Alarms tab in the Details panel.

   NOTE
   Under Generated Alarm, the value for Severity is None, indicating that the event does not generate an alarm.
2. Select an alarm severity other than None from the Severity list. For more information, including descriptions of the different severity levels, see Specifying an Alarm Severity.

3. (Optional) For Cause Code, change the alarm cause code (the 8-digit, hexadecimal code that identifies the cause of the alarm). For more information, see Specifying an Alarm Cause Code.

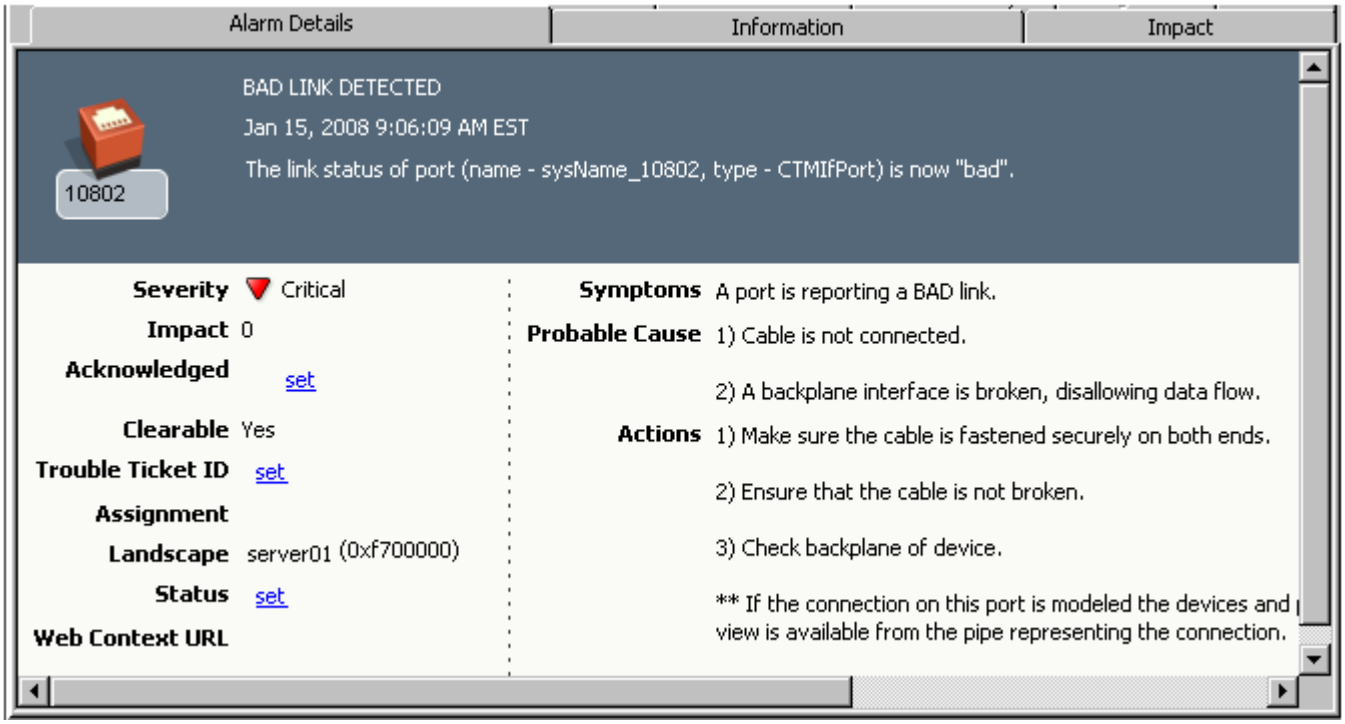
   NOTE
   Events that generate alarms typically use their event codes as alarm cause codes. The event code of the event is, therefore, the default alarm cause code of the alarm.

4. For Event Variable Discriminators, enter a comma-separated list of event variable IDs if you want to use the values of the variables in the event to determine whether to generate the alarm.
   Enter each ID separately; ranges of IDs are not supported.

   NOTE
   By default, DX NetOps Spectrum does not generate a new alarm each time the same event occurs if an alarm already exists for that event on the model. You can use event discriminators or alarm options to change this default behavior.

   For example, if the event generates alarm 0x3b10011, and you enter “1,3” for Event Variable Discriminators, and if an alarm 0x3b10011 already exists on the model, a new alarm is generated ONLY if the values for *both* event variables 1 and 3 are *different* in the new event instance as compared to current alarms on the model generated from the same event.
   For more help with this step, see Using Event Variable Discriminators to Generate Alarms.

5. For Type, enter a text string that identifies the type of the alarm, for example, “BAD LINK DETECTED.”
   The text string that you enter for Type is displayed as the alarm title in OneClick, as shown in the following image. For enhanced readability in OneClick, enter the text string in capital letters.



6. Specify the symptoms, probable causes, and recommended corrective actions for the alarm, respectively, on the Symptoms, Probable Causes, and Recommended Actions tabs. This information is displayed on the Alarm Details tab in OneClick, as shown in the preceding image.

   NOTE
   For more information, see Specifying Symptoms, Causes, and Recommended Actions.

7. Click the Alarm Options tab, and specify advanced options for the alarm. For more information, see Specifying Alarm Options.

8. To configure the selected event to also *clear* one or more alarms, specify the alarms in the Cleared Alarms area of the Contents panel.
   For more information, see Configuring an Event to Clear Alarms.

Specify an Alarm Severity

The following lists the alarm severity levels that are used in DX NetOps Spectrum. Each severity level is associated with a color-coded condition that is displayed on the model. When an alarm of the specified severity is asserted on a model, the condition color is displayed on the model's icon to reflect the alarm status.

- **Normal (0)**
  Color-coded condition: Green
  Indicates that:
  – Contact has been made with the device, and the device is operating typically.
  – A Normal Alarm is generated.
  – If an event generates an alarm but a severity for the alarm is not specified (for instance, if you have created the supporting EventDisp configuration file manually and inadvertently omitted a severity), DX NetOps Spectrum assigns normal severity status to the alarm.
- **Minor (1)**
  Color-coded condition: Yellow
  Indicates that an abnormal situation exists, but no immediate action is required. This level of severity is also used for alarms created only to convey information, such as "Duplicate IP."
- **Major (2)**
  Color-coded condition: Orange
  Indicates that a loss of service has occurred or is impending. Action is required within a short period.
- **Critical (3)**
  Color-coded condition: Red
  Indicates that a loss of service has occurred and immediate action is required.
- **Maintenance (4)**
  Color-coded condition: Brown
  Indicates that the device has been taken offline for maintenance purposes.
- **Suppressed (5)**
  Color-coded condition: Gray
  Indicates that the device cannot be reached due to a known error condition that exists on another device.
- **Initial (6)**
  Color-coded condition: Blue
  Indicates that contact with the device has not yet been established.
- **Variable**
  Color-coded condition: N/A; evaluates to a severity that has a color-coded condition.
  Lets you assign an alarm severity that is based on the value of a variable binding. For example, if the value of the variable binding is 1, then the alarm is assigned a severity level of Minor.
  To use this option, do the following:
  – For Severity, select Variable.
  – For Event Variable, specify the ID of the event variable that stores the variable binding value to use to determine the severity level of the alarm. You must specify a variable whose possible values are enumerated and directly correspond to the numeric severity levels used by DX NetOps Spectrum (identified in the first column in this table).
- **Conditional**
  Color-coded condition: N/A; evaluates to a severity that has a color-coded condition.
  Lets you assign an alarm severity that is based on the value of a variable binding. You can also select the set of enumerated values and corresponding DX NetOps Spectrum alarm severity levels to use. The Color coded condition is useful if, for example, the variable binding defines a set of alarm severity levels that differ from those used in DX NetOps Spectrum.

To use this option, do the following:

- For Severity, select Conditional.
- For Event Variable, specify the ID of the event variable that stores the variable binding value to use to determine the severity level of the alarm. Specify a variable whose possible values are enumerated. The actual value in the event variable is used as the key to look up a corresponding DX NetOps Spectrum alarm severity level in a severity mapping file.
- Below the severity level drop-down list, select the file that contains the user-defined mappings of variable binding values and DX NetOps Spectrum alarm severity levels.

Enable or Disable Alarms of a Severity Type

Alarms use a large number of resources such as memory and processing time. DX NetOps Spectrum lets you disable an alarm of a severity type to reduce the impact on system performance. The disabled alarm is available internally but you cannot view it in the user interface. The disabled alarm does not support alarm attributes like discriminators. By default, alarm types with severity levels Initial and Suppressed are set as disabled. All other alarm types continue to exist as regular alarms.

Note: Normal severity alarms do not support discriminators.

To disable an alarm of a severity type:

1. Select the VNM Model.
2. Click the Information tab and expand the Alarm Management section.
3. Right-click the alarm and select Disable.
   The alarm is disabled and the change takes effect immediately. The existing alarms of the selected severity type continue to be regular or internal alarms until they are cleared.

To enable an alarm of a severity type:

1. Select the VNM Model.
2. Click the Information tab and expand the Alarm Management section.
3. Right-click the alarm and select Enable.
   The alarm is enabled and the change takes effect immediately. The existing alarms of the selected severity type continue to be regular or internal alarms until they are cleared.

- Even after enabling alarms, verify that the client-side filters are adjusted, before you can view the alarm in the client applications.
- We do not recommend enabling the Suppressed alarm type as it can affect performance adversely.

Specify an Alarm Cause Code

An *alarm cause code* is an 8-digit, hexadecimal code that identifies the probable cause of the alarm. As you save the event and associated alarm to a landscape, a mapping between the event code and the associated alarm code is added to the event configuration file that determines how to process the event, referred to as the event disposition file. This mapping is the mechanism by which DX NetOps Spectrum identifies whether or not to generate an alarm for an event, and if so, which one.

As a convention, events that generate alarms typically use their event codes as alarm cause codes, and for this reason, the event code of the event is the default alarm cause code of any alarm. However, you can change the alarm cause code if desired. For example, you want to change the alarm cause code, if you have a more generic existing alarm and want it to be generated whenever the event occurs.

The alarm cause code is also used to name the underlying probable cause file that contains the alarm-related messages (symptoms, causes, and recommended actions) to display in OneClick when the alarm occurs. Each probable cause file is named Prob<alarm_cause_code>, where <alarm_cause_code> is the code you specify on the Alarms tab in Event Configuration.

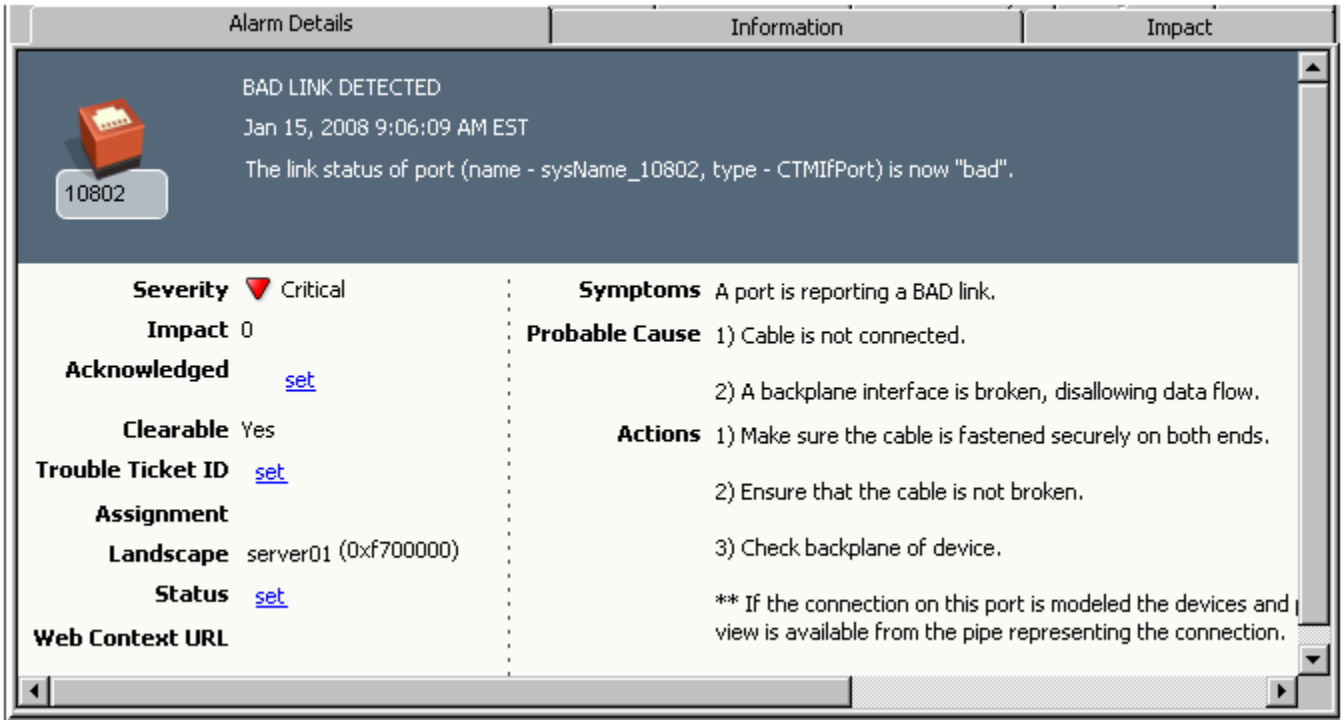
To specify an alarm cause code, do one of the following:

- Accept the default code, which readily identifies the alarm with the event that generates it. If the supporting probable cause file does not exist, it is created automatically by Event Configuration when you save the event and alarm changes to a landscape.
- Click Browse, and in the Select Alarm Cause Code dialog, select an existing code. The displayed list includes all of the alarm cause codes for all loaded events that generate alarms. In this case, the supporting probable cause file is updated automatically when you save the event and alarm changes to a landscape.
- Enter a new 8-digit, hexadecimal value. If the supporting probable cause file does not exist, it is automatically created by Event Configuration while saving the event and alarm changes to a landscape.

NOTE
If you create an alarm-generating event, save it to one or more landscapes and later, change the alarm cause code to a new code and then save the changes to the landscapes. Event Configuration automatically creates a new probable cause file that is named based on the new alarm cause code. However, to remove the probable cause file that is named using the old code (if it is not used by any other alarm-generating events), you must remove it manually.

About Specifying Symptoms, Causes, and Recommended Actions

If an event generates an alarm, you must supply several plain text messages that describe the symptoms, probable causes, and recommended corrective actions for the alarm. These messages are displayed on the Alarm Details tab in OneClick, as shown in the following image.



The text messages that you enter for the symptoms, probable causes, and the recommended corrective actions for an alarm, are stored in an alarm configuration file referred to as a probable cause file. The fields that support traps get auto-populated. For example, when you create a new alarm the trap-specific Alarm Title is auto-populated assuming the MIB in which the trap is defined is found in the MIB database.

Specify Alarm Options

You can specify the following advanced options for an alarm:

- **Alarm is Persistent**
  If this option is selected, the alarm is retained in memory, in case the SpectroSERVER is shut down and restarted.
- **Alarm is User Clearable**
  If this option is selected, users can clear the alarm
- **Generate a Unique Alarm for Each Event**
  By default, DX NetOps Spectrum does not generate a new alarm each time the same event occurs if an alarm already exists for the event on the model.
  If this option is selected, a unique alarm is generated each time the same event occurs.

Using Event Variable Discriminators to Generate Alarms

When an event triggers an alarm in a model, DX NetOps Spectrum does not generate a separate alarm if the same event recurs on the model. This default behavior prevents an event that can occur multiple times due to the same condition. You can, however, configure multiple alarms to occur when the conditions of the event change. You can specify this behavior using event variable discriminators.

Event variable discriminators are numeric values that refer to the IDs of the event variables in an event. In turn, the event variable IDs are mapped (in the AlertMap file) to the OIDs of the variable bindings that are sent with the trap. The discriminators let DX NetOps Spectrum determine to generate alarms for multiple instances of the same event, that is based on the values of variable bindings that are sent with the traps.

You can configure an event to generate an alarm and also specify one or more discriminators. The alarm is generated when the values of the referenced event variables are *different*. You can thus, specify alarms to be generated for distinct event instances (with the same event code) in spite of an existing alarm in the model.

For example, to generate alarm 0x3b10011 you have configured event 0x3b10011, and have specified that event variables 1 and 3 are event variable discriminators. This configuration means that, if an alarm 0x3b10011 already exists on the model, another alarm is not generated.

However, if the following condition is met, a new alarm is generated:

The values for *both* event variables 1 and 3 in the new event instance are *different* compared to current alarms on the model that is generated from the same event.

When you are configuring an alarm, specify the event variable discriminators by entering a comma-separated list of IDs, for example:

```
1,3,5
You must enter each ID; ranges of IDs are not supported.
```

> **NOTE**
> The Event discriminators cannot be specified for normal, maintenance, suppressed, or initial severity alarms.

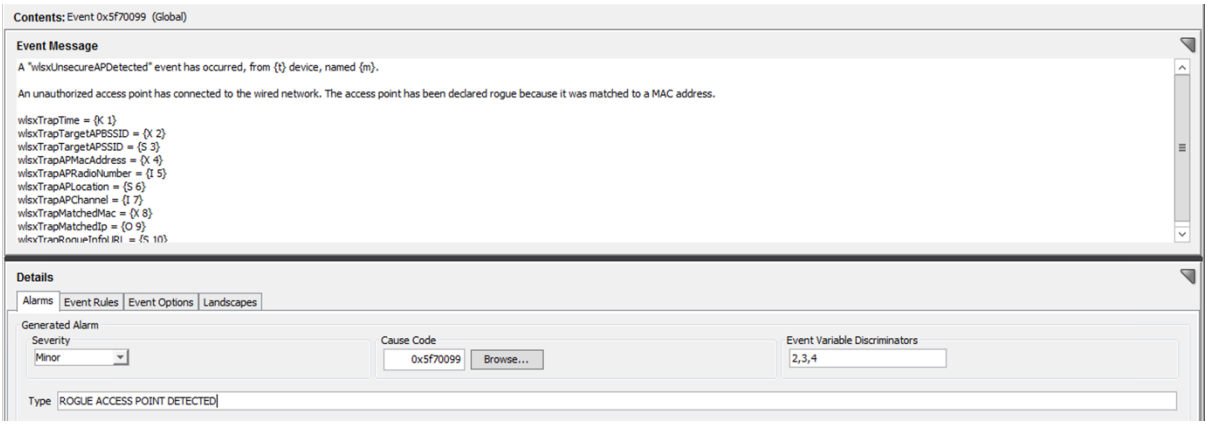
Creating Dynamic Alarm Title

You can modify the alarm to include the event variables in the alarm title. You need not update the event configuration or restart the spectroSERVER after modifying the alarm title. The updated alarm title is applied to the traps that are received after the change. You can only add Event varbinds to alarm title and not DX NetOps Spectrum attribute values. The new alarm title overwrites the dynamic alarm title customizations in EventDisp EventRules.

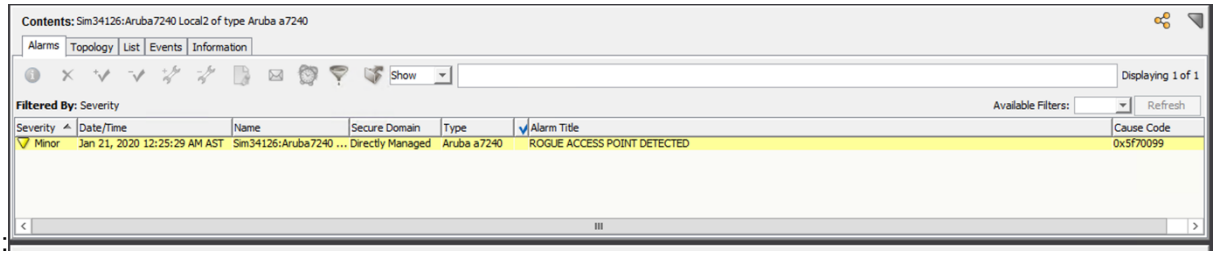
Example: Create a Dynamic Alarm Title

The following example shows how the alarm title looks before and after including trap var binds in the title:

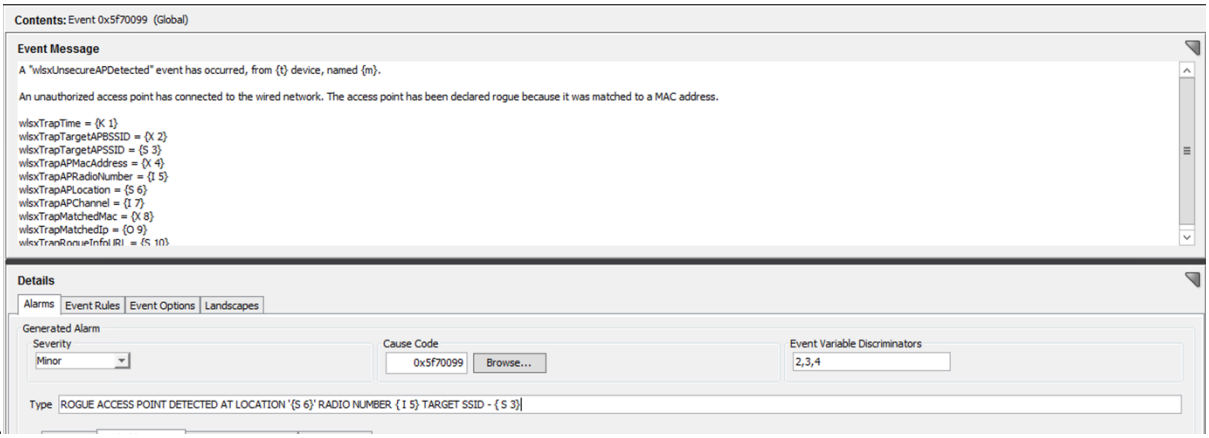
- Default alarm title, before including var binds in the title:



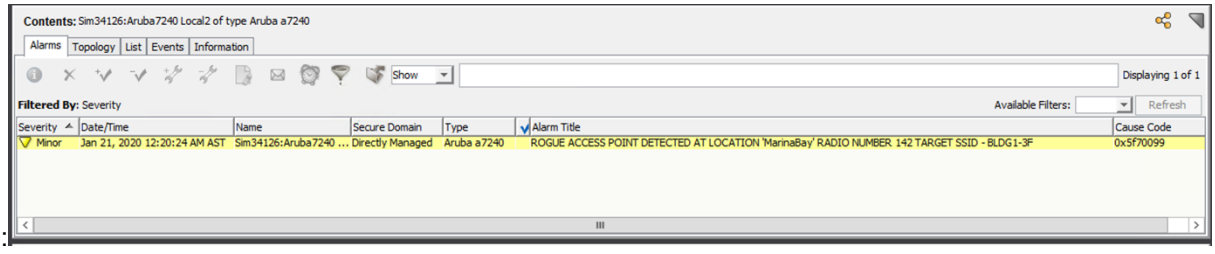
- Alarm title that is created when the trap is received:



- Change the alarm title to include the trap varbinds like ‘SSID’,’ Radio number’ and ‘Location’ in the alarm title. You can include multiple trap varbinds in the alarm title.



- The new alarm title when the new trap is received post-implementation of the change:



Configuring Alarm Severity Mappings for the Conditional Severity Level

A *severity mapping file* is an ASCII file that is used to determine the actual severity of an alarm instance to generate when the alarm configuration specifies an alarm severity of Conditional.

The *Conditional alarm severity* lets you assign the alarm severity that is based on the value of a variable binding that is sent with the trap which triggered the event. It also allows you to select the set of mappings between values and alarm severity levels to use when determining the actual alarm severity.

The severity mapping file defines the mappings between possible variable binding values and DX NetOps Spectrum alarm severity levels. You can create severity mapping files and can customize the ones that are provided by default with DX NetOps Spectrum.

Create Alarm Severity Mappings for the Conditional Severity Level

If you create a severity mapping file, the file is installed in the following location when you save the change to a landscape:

<$SPECROOT>/custom/Events/<vendor_directory>/SeverityMaps/<file name>

Where <vendor_directory> is the directory and <file_name> is the file name that you specified when you created the mapping file using Event Configuration. If you do *not* specify a directory while creating the file, it is installed in the following folder instead:

<$SPECROOT>/custom/Events/CA/SeverityMaps/<file name>

> **WARNING**
> Custom severity mapping files override those Severity files provided with DX NetOps Spectrum, the latter of which are located in <$SPECROOT>/SS/CsVendor/<vendor_directory>/SeverityMaps.

To create an alarm severity mapping file

1. Display the event that generates the alarm, and click the Alarms tab.
2. If you have not already done so, do the following:
   a. For Severity, select Conditional.
   b. For Event Variable, enter or select the event variable that contains the variable binding value to use to determine the alarm severity.
3. Select any severity mapping file and click Configure.
   The Configure Conditional Alarm Severity dialog opens, displaying the contents of the selected severity mapping file.
4. Click
   
   The severity mapping file add dialog opens.
5. Complete the fields as follows:
   – **Directory**
     Specifies the directory in which to save the severity mapping file.
   – **Name**
     Specifies a name for the severity mapping file; ideally the name of the variable binding whose values are enumerated in the file.
6. Add the mappings between the string representations of the variable binding values and DX NetOps Spectrum alarm severity levels (described in Specifying an Alarm Severity) as follows:

   > **NOTE**
   >
   > For Alarm Severity value zero (‘0’), Spectrum generates a normal alarm along with an event. So, if you do not want a normal alarm to be generated for the Severity value zero, do not include the string in the Severity Maps file.

   – To add a mapping, enter a unique string value for String, select a severity for Severity, and click Add.

NOTE
If you want the alarm to be cleared -- instead of generated -- if the corresponding variable binding value is sent, select Clear.

- To change a mapping, select the mapping, change the value for String or for Severity (or both), and click Modify.
- To remove a mapping, select the mapping, and click Remove.

NOTE

DX NetOps Spectrum treats the entries in SeverityMap file as regular expressions. To match the exact variable binding value to a DX NetOps Spectrum alarm severity level, we recommend that you use word boundary characters ('\b') before and after the varbind value string in SeverityMap file.

7. Click OK twice.

Modifying Alarm Severity Mappings for the Conditional Severity Level

You can modify your custom severity mapping files and the mapping files provided by default with DX NetOps Spectrum at any time.

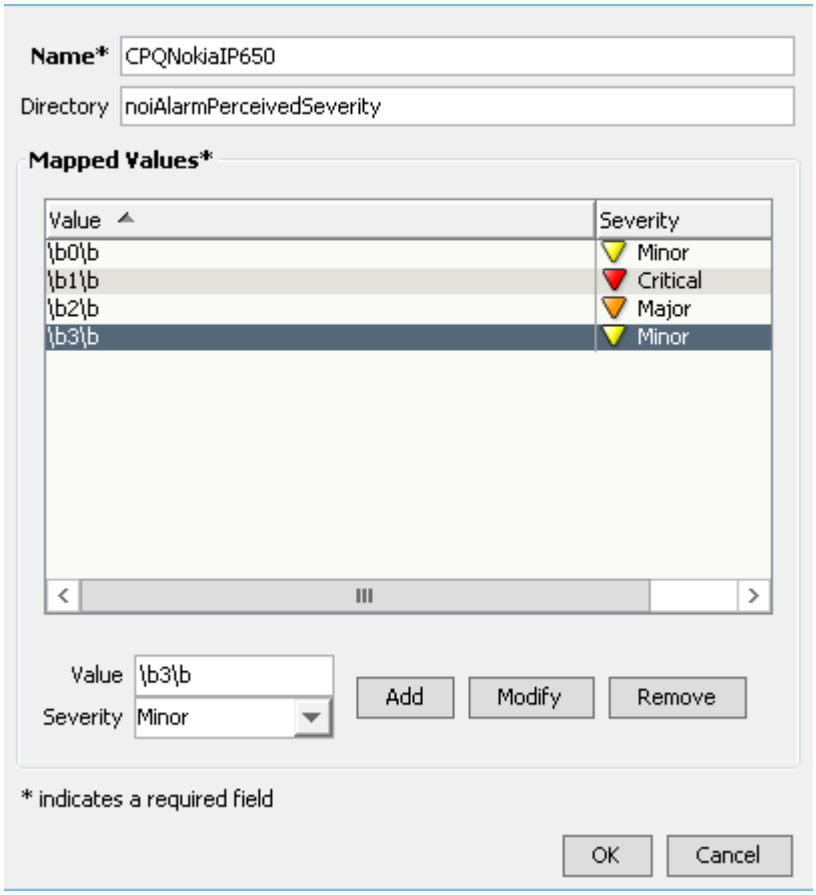
If you modify a severity mapping file provided with DX NetOps Spectrum, a customized version of the file is installed in the following location when you save the change to a landscape:

<$SPECROOT>/custom/Events/<vendor_directory>/SeverityMaps/<file name>

WARNING
Custom severity mapping files override those provided with DX NetOps Spectrum, the latter of which are located in <$SPECROOT>/SS/CsVendor/<vendor_directory>/SeverityMaps.

To modify an alarm severity mapping file, Follow these steps:

1. Display the event that generates the alarm, and click the Alarms tab.
2. If you have not already done so, do the following:
   a. For Severity, select Conditional.
   b. For Event Variable, enter or select the event variable that contains the variable binding value to use to determine the alarm severity.
3. Select the severity mapping file to use to determine the actual severity level of the alarm, and click Configure.
   The Configure Conditional Alarm Severity dialog opens, displaying the contents of the selected severity mapping file.
4. Click
   
   .
   The severity mapping file edit dialog opens.



5. Modify the mappings between the string representations of the variable binding values and DX NetOps Spectrum alarm severity levels as follows:
   - To change a mapping, select the mapping, change the value for String or for Severity (or both), and click Modify.

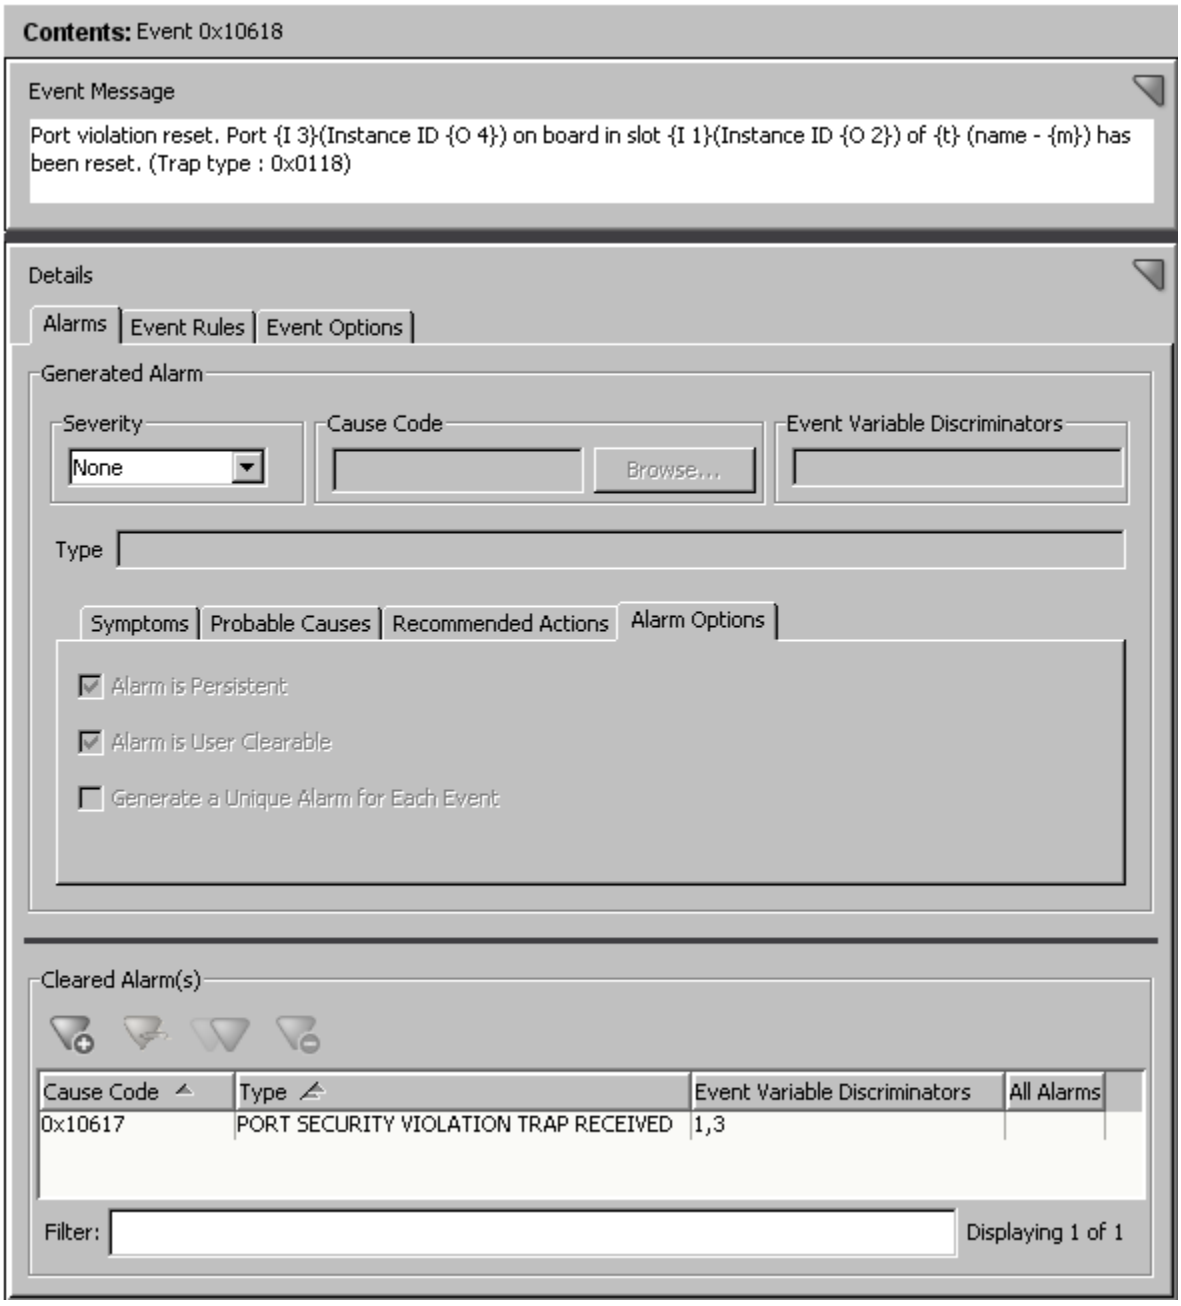
     NOTE
     Select Clear to clear the alarm -- instead of generating it -- if the corresponding variable binding value is sent.
   - To add a mapping, enter a unique string value for String, select a severity for Severity, and click Add.
   - To remove a mapping, select the mapping, and click Remove.

     NOTE

     DX NetOps Spectrum treats the entries in SeverityMap file as regular expressions. To match the exact variable binding value to a DX NetOps Spectrum alarm severity level, we recommend that you use word boundary characters ('\b') before and after the varbind value string in SeverityMap file.
6. Double-click OK.

Configure Events to Clear Alarms

You can specify that the currently selected event clears one or more alarms using the Alarms tab in the Details panel, which is shown in the following image.



When you configure an event to clear alarms and then save that change to a landscape, you create a mapping between the event and the alarms to be cleared in a configuration file referred to as an event disposition file.

Follow these steps:

1. Select the event in the Navigation panel, and then click the Alarms tab in the Details panel.
2. Under Cleared Alarm(s), click the Adds an alarm to the list icon

   The Add Cleared Alarm dialog displays the alarm cause codes for all alarms that are loaded into Event Configuration.
3. Click Browse, and in the Select Alarm Cause Code dialog, select the alarm cause code of the alarm to clear.

To help you identify the desired alarm, enter a text string in the Filter text box. The list is filtered to include only the alarms with displayed properties that contain the text string.

4. Click OK.
5. If the alarm that you want to clear was generated based on event variable discriminators, select Clear Options, and then specify how the alarm is cleared. Select one of the following options:
   - **All Alarms**
     The event clears all existing instances of the alarm, regardless of whether the values in the alarm-clearing event match the values that are stored in the alarm instances.
   - **Event Variable Discriminators**
     The event clears existing instances of the alarm that is based on the values of the alarm variables (which are copied from the alarm-generating event to the alarm when the alarm is generated). Then enter a comma-separated list of event variable IDs (for example: 1,3,5). You must enter each ID separately; ranges of IDs are not supported. If the values in event match the values stored in the alarm, the alarm-clearing event clears the alarm.

     NOTE
     For examples of using event discriminators to clear alarms, see Clearing Alarms.
6. Click OK.
7. (Optional) Repeat the preceding steps to add additional alarms to be cleared.

Modify Events

You cannot delete the events that CA authors and provides with DX NetOps Spectrum. However, you can customize them to meet your requirements simply as you would any other events.

In addition, you can undo any customizations that you make to a CA-authored event by deleting the event. *For CA-authored events only*, this action does not delete the event but instead reverts it to its default configuration.

When you delete (revert) a CA-authored event, the author of the event changes from “Custom” back to “CA.” To identify the author of an event, add the Author column to the table of events in the Navigation panel, as described in Adding and Removing Columns from the Events Table.

To modify events.

1. Select the event in the Navigation panel.
   The event details are displayed in Contents and Details panels.
2. Modify the event details.
   The event is displayed in bold. The Modification column displays *Edited.*

   NOTE
   The event is marked *Edited.* However, the event is not saved. You can make more updates such as create more events, modify existing events, or delete events, and save all the updates at one time.
3. Do *one* of the following:
   a. Go to File, Save All.
      All marked events in the Navigation panel are saved.
   b. Select the desired events in the Navigation panel, and go to File, Save Selected.

      NOTE
      You can select multiple events using the Shift key.

      The selected events are saved.

   The events are modified. The events appear in the normal font and are not marked in the Modification column.

Delete Custom Events

You can delete any event that CA did not author. To identify the author of an event, add the Author column to the table of events in the Navigation panel.

WARNING
Do not delete an event until you are certain it is no longer required. If you delete an event that generates a needed alarm, DX NetOps Spectrum is unable to inform you about a problem in the network infrastructure.

To delete events.

1. To delete events, select the event in the Navigation Panel, and click the delete icon

   The event is displayed in italics. The Modification column displays *Deleted.*

   NOTE
   The event is marked *Deleted.* However, the event is not deleted until you save the changes. You can make more updates such as create more events, modify existing events, or delete events, and save all the updates at one time.
2. Do one of the following:
   a. Go to File, Save All.
      All marked events in the Navigation panel are saved.
   b. Select the desired events in the Navigation panel, and go to File, Save Selected.

      NOTE
      You can select multiple events using the Shift key.

      The selected events are saved.

   The events are deleted. The events appear in the normal font and are not marked in the Modification column.

Event and Alarm Customization

DX NetOps Spectrum events and alarms support extensive customization. The files that support the DX NetOps Spectrum predefined events and alarms are installed in subfolders of the following directories:

```
$SPECROOT/SS/CsVendor
$SPECROOT/SG-Support
```

If you customize predefined events and alarms or create your own, and you then save the customizations to one or more landscapes, the event and alarm configuration files that define your customizations are installed in the following folder or in one of its subfolders:

```
$SPECROOT/custom/Events
```

As a result, the support files for your custom events and alarms are not overwritten or otherwise affected when you upgrade to a new version of DX NetOps Spectrum.

WARNING

Do not customize the following list of event codes as this will adversely affect Spectrum's fault isolation algorithms which leads to undesirable results.

LINK_GOOD = 0x00010d10,
LINK_BAD = 0x00010d11,
LINK_DISABLED = 0x00010d12,
LINK_UNKNOWN = 0x00010d13,
LINK_UNREACHABLE = 0x00010d14,
LINK_INITIAL = 0x00010d15,
LINK_BAD_SUPPRESSED = 0x00010d16,
LINK_LL_IN_MAINTENANCE = 0x00010d2e,
LINKED_PORT_BAD = 0x00010d17,

LINKED_DEVICE_BAD = 0x00010d18,
LINK_STATUS_CLEAR = 0x00010d2a,
LINK_DISABLED_AND_BAD = 0x0001040d,
LINK_ALWAYS_DOWN = 0x00010d2f,
LINK_BAD_WA_LINK_BAD = 0x00010d2d
CS_EVENT_ALARM_SET = 0x00010701
CS_EVENT_ALARM_UPDATED = 0x00010703
CS_EVENT_DEVICE_LOST = 0x00010302
DEVICE_CONTACT_STATUS_LOST = 0x00010d35
DEVICE_GATEWAY_UNREACHABLE = 0x00010d36
MGMT_LOST = 0x00010d00
UNRESOLVED_FAULT = 0x00010d05
APPLICATION_LOST = 0x00010d09
APPLICATION_REACTIVATED = 0x00010d0b
MGMT_REACTIVATED = 0x00010d0c
DEV_MNGMNT_NBORS_DOWN = 0x00010d19
LANDSCAPE_CONTACT_STATUS_CLEAR = 0x00010d20
PORT_LOST = 0x00010d66
PORT_REACTIVATED = 0x00010d67
ALARMING_MGMT_LOST_EVENT = 0x10daa

Customizing the above events would have direct impact on Fault Isolation (FI)/ Internal Port Link Status (IPLS).

Working with Event Rules

Event Rules

Event Rules let you specify the evaluation logic determining how DX NetOps Spectrum processes those events to which you are applying the rules. You can also specify what actions to perform in response to the events.

An event rule stipulates the conditions under which an event condition, a pattern of events, a combination of events in a particular order, or over a specific period, sets the generation of another event.

You can create multiple rules for a single event.

> **NOTE**
> The Event rules are stored in event configuration files referred to as event disposition files.

Event Condition Rules

An *event condition rule* creates an event when specific conditions are satisfied. The input to the rule is a list of conditions and associated events. Each condition is evaluated until one condition evaluates to TRUE, and then the corresponding event is created.

The following parameters are applicable:

- The event that starts the evaluation of the rule
- A conditional expression to evaluate
- If the conditional expression is true, the event to generate

An event condition rule can include multiple conditional expressions and corresponding output events.

Event Pair Rules

In some cases, you expect events to happen in pairs, and if the second event does not occur, it could indicate a problem in the computing infrastructure. Based on such a scenario the *event pair rule* creates an event. If one of two expected events are generated but the second event does not follow the first, a new event is generated in response. You can specify the amount of wait time that can elapse before the new event is generated.

NOTE
Other unrelated events can be generated between the first and the second event. They do not affect the execution of this rule.

Event Rate Rules

Some types of events do not indicate a problem unless the frequency at which they are generated reaches a specific threshold within a specific amount of time. An *event rate rule* creates an event based on this scenario. When a number of events of the same type that is, with the same event code are created within a given time period, a new event is created in response.

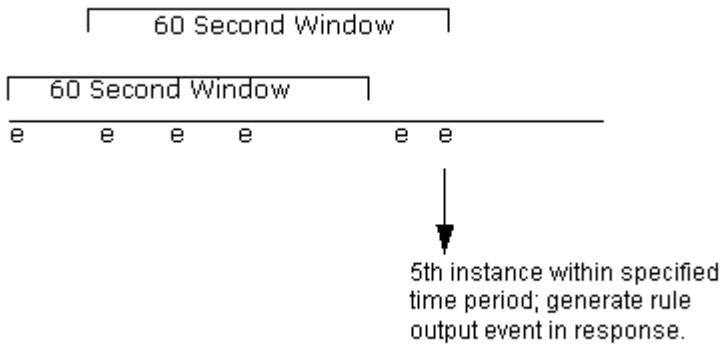
NOTE
Other, unrelated events do not affect rule execution.

Event rate rules never terminate. Once the conditions of the rule are met and a new event is created in response, the rule remains active. However, no additional event is created as long as the frequency at which the evaluated events remains at or above the specified rate in the rule. If the frequency drops below the specified rate, and then subsequently exceeds that rate again, a new event is generated.

An event rate rule can use either of the following methods to define the window of time in which the events must occur:

Sliding Window: With this type of time window, if the specified number of events (or more) ever occurs in any window of the specified time period, the output event is created in response. This type of time window is best suited for accurately detecting a short burst of events.

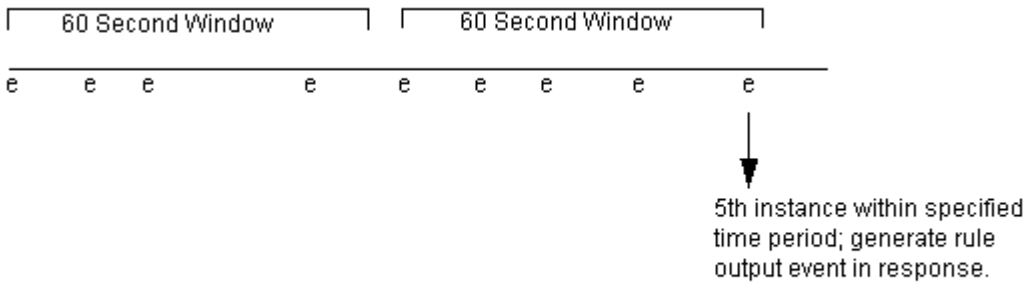
For example, the following illustration shows the sliding time windows that are active for a rule that watches for five instances of a given event (e) within a specified time period.



When a sliding time window is used for a rule, if the rule generates a rule output event, all active time windows are terminated, and a new time window automatically begins.

Sequential Window: When the rule uses this type of time window, non-overlapping time windows are examined, one after another, to determine if the requisite number of events has occurred within the time window. This type of time window is best suited for detecting a long, sustained train of events.

For example, the following illustration shows the sequential time windows that are opened and closed for a rule that watches for five instances of a given event (e) within a specified time period.



If the current time window closes due to time period expiration, or if the rule creates an output event in response, the window is not opened next time until a new event occurrence is detected.

Event Series Rules

An *event series rule* creates an event when a specific event. triggers one or more other events in an ordered or unordered sequence. The combination of events which must occur include any number and type of event. You can specify also the amount of wait time to elapse during which the sequence of events must occur.

Note: Other, unrelated events can be generated during the wait time. They do not affect the execution of a rule.

Event Counter Rules

An *Event Counter rule* counts events. The rule watches for two events, one increasing the count, the other one decreasing it again. An event is generated whenever the count is higher than a threshold, and also once it falls below the set threshold. The Event Counter rule remains instantiated and counts events and does not terminate.

Heartbeat Rules

The *Heartbeat rule* watches for a periodic heartbeat event, and generates a new event when the heartbeat event is missing. You can stop the rule instance using a separate event.

Single Event Rules

The *Single Event rule* watches for a single occurrence of a target event. The Single Event rule reduces an event stream where one event ('up' event) occurs multiple times, before a reset ('down') event is observed. Instead of the multiple 'up' events, a single event which can be reused in other rules, denoting the condition ('up' or 'down')is set. An event is generated the first time the target event is seen. The rule triggers only when the clearing event is seen again. The rule then resets the behavior to the initial state. If needed, a separate event can be generated when the clearing event is seen.

Solo Event Rules

The *Solo Event rule* finds an instance of target event which does not follow or precede any other user-defined event in a defined period.

The time periods are configurable, and there is a separate event to stop the rule.

User-Defined Event Rules

Most of the CA-shipped event rules are supported on the Event Configuration User Interface. However, in some cases, CA can create a special rule or can customize a rule for an individual customer. A customer can also create a rule.

The Event Configuration Editor does not support Event disposition entries using such rules. The displayed event rule is read-only. The rule entry must be edited in a text editor and reloaded in the event disposition files. Such custom event rule entries must have the correct vendor code and rule name, depending on which vendor supplied the rule. For example, a custom rule entry for a rule that is named MyOwnRule' from vendor 'MyOwnVendor' has the following syntax:

0xfff00002 E50 R MyOwnVendor.MyOwnRule, <rule parameters>

NOTE
The xml rule definition file is at $SPECROOT/SS/CsVendor/<Vendor Name>/EventRules/<RuleName>.xml.

Create Event Rules

We recommend that you start the application and examine the rules that CA provides for various events, before creating an event rule.

You can create an event rule in two ways:

- From scratch.
- By copying an existing event rule and modifying the copy. This method is only useful in case the same event triggers the new rule that you want to copy.

NOTE
Event rule definitions are stored in event configuration files referred to as event disposition files.

To create an event rule:

1. In the Navigation panel, select the event that activates (triggers) the event rule.
2. In the Details panel, click the Event Rules tab.
   The list of event rules for the selected event appears.
3. Click the list
   icon  .
4. Select the type of event to create from the drop-down list.

   The configuration dialog for the selected type of event rule opens.
5. Configure the event rule as required.
6. Click OK to save the event rule to the event.

To create an event rule from a copy:

1. In the Navigation panel, select the event that has the event rule that you want to copy.
2. In the Details panel, click the Event Rules tab.
   The list of event rules for the selected event appears.
3. To copy an event rule, select the desired rule and click the copy
   icon  .
   The event rule configuration dialog opens.
4. Modify the configuration of the event rule as required.
5. Click OK to save the event rule to the event.

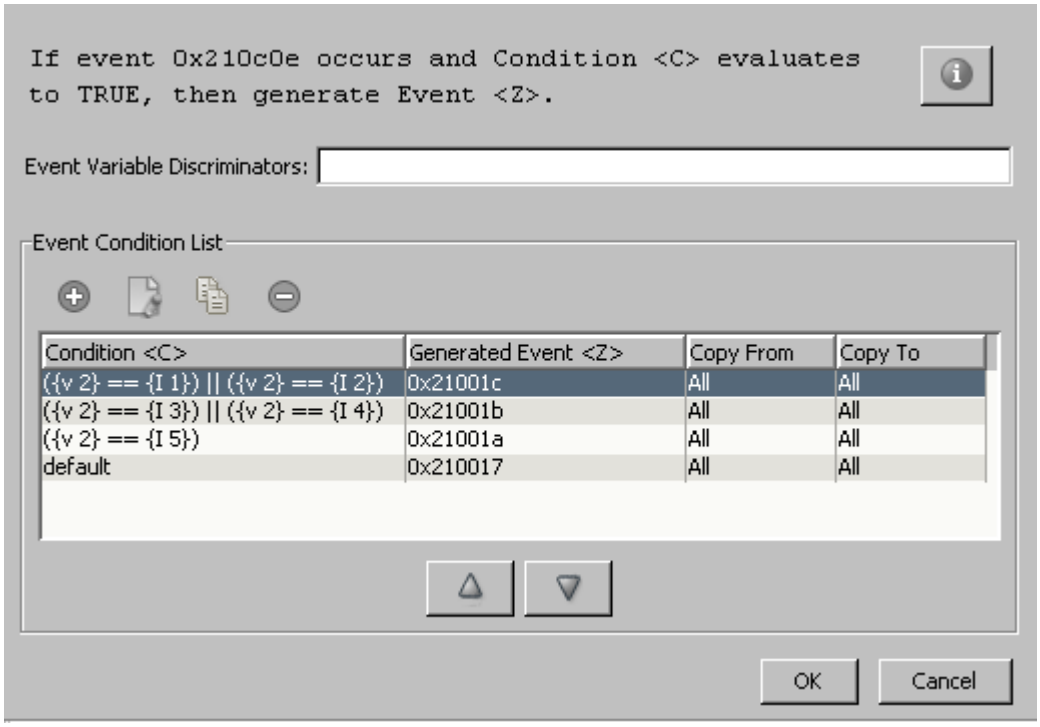
Configuring Event Condition Rule Settings

To create an event condition rule, create one or more conditions to evaluate the event for which you are creating the rule. For each condition, define an event that DX NetOps Spectrum generates if the given condition is met. Optionally, you can also specify that one or more values of the event that triggered the rule is copied to the rule output event.

As an example, assume you want to create the following event condition rule (expressed in pseudo code) for event 0x210c0e:

```
If event 0x210c0e occurs, evaluate the following:
if event variable 2 = 2 or event variable 2 = 2, then generate 0x0021001c,
else if event variable 2 = 3 or event variable 2 = 4, then generate 0x0021001b,
else if event variable 2 = 5, then generate 0x0021001a,
else, generate 0x00210017.
```

This rule requires the four conditional expressions that are shown in the following rule configuration dialog.

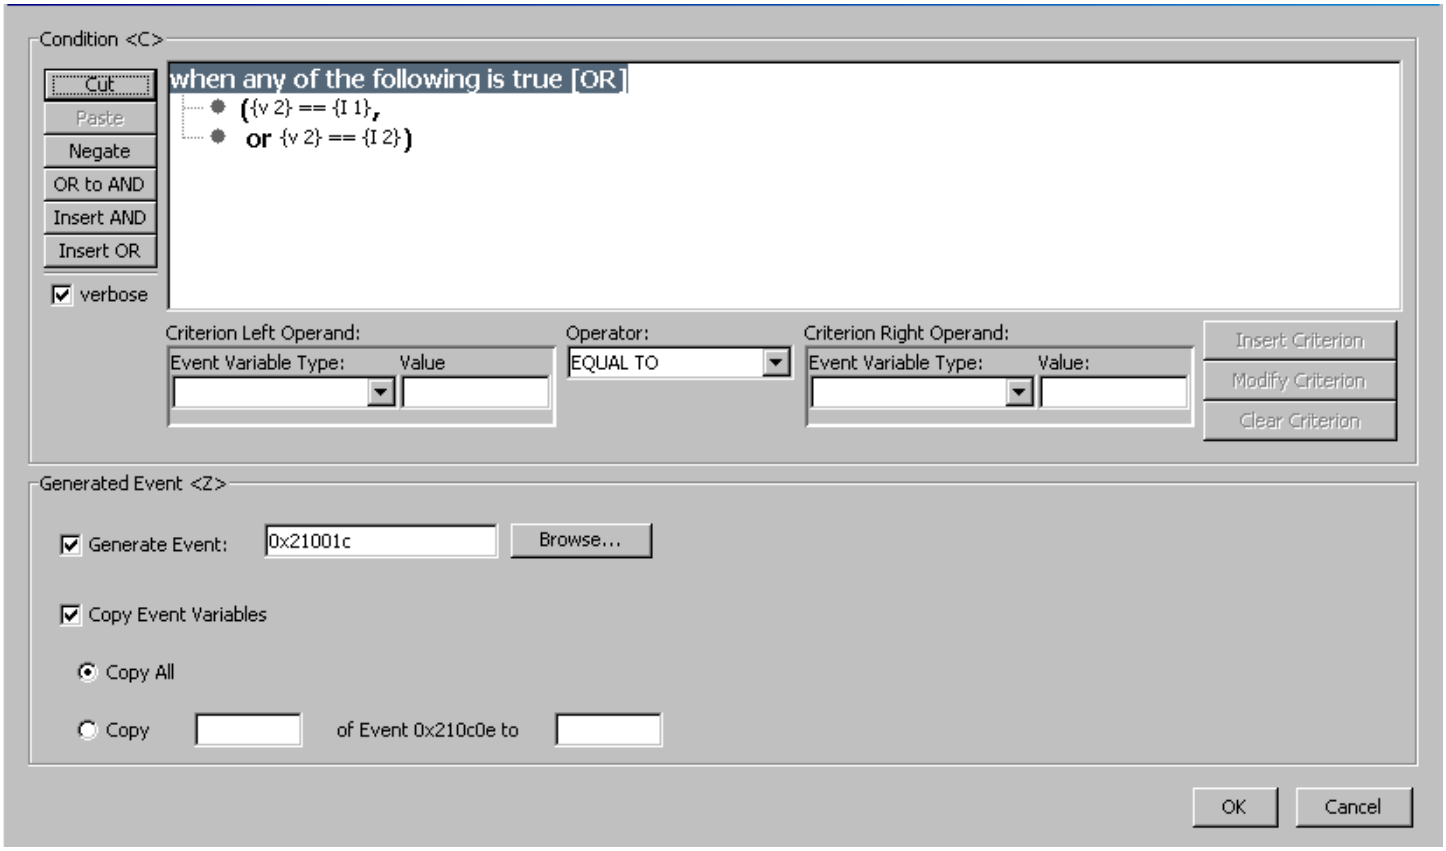


In the dialog, use the buttons above the list of conditions to add new conditions and to modify, copy, and delete a selected condition. To change the sequence in which the conditions are evaluated, use the up and down arrows below the list of conditions.

The rule output event (generated event <Z>) that corresponds to the first condition that evaluates to TRUE is generated.

> **NOTE**
> Event variable discriminators are a general feature available for all types of rules. However, while you can specify discriminators for an event condition rule, a rule of this type currently does not use them during rule processing.

When you add or modify a condition, you define the conditional expression using the following dialog.



The settings in the dialog include the following options:

- **Condition ©**
  The condition to evaluate. To create the expression, use the controls in the top section of the dialog.
  For information about conditional expression syntax, see Event Condition Rule.
- **Generated Event <Z>- Generate Event**
  If the associated condition evaluates to TRUE, the event code of the event to create in response.
  To specify the event code, click Browse, select the event in the Select Event dialog, and then click OK.
- **Generated Event <Z> - Copy Event Variables**
  To copy the values of any event variables in that event which activated the rule to the generated event <Z>, select Copy Event Variables and then do any of the following steps:
  – Select Copy All to copy the values of all of the event variables into the generated event <Z>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values must be copied. Ranges of IDs are also supported, for example, “1-4”.

NOTE
For information about using the proper syntax when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.

NOTE
To create a default condition in the condition configuration dialog evaluating to TRUE; select DEFAULT for Operator and click Insert Criterion.

Configuring Event Pair Rule Settings

The Event Pair dialog provides the following settings:

The settings in the dialog include the following:

- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables in the event to evaluate as a part of the rule.

  NOTE
  Enter each ID separately; ranges of IDs are not supported.
- **Event <Y> - Event Code**
  The event code of the event that, within the specified time period, follows the event that activates (triggers) the rule. Event <Y> is the second event in the pair of events.
  To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events that are loaded into Event Configuration), and click OK.
- **Time <T> - Time Interval**
  The period that begins when the first event is created and during which the second event (event <Y>) occurs.
- **Get Time From Attribute**
  Select this option to use the value of any time attribute whose value is a quantity of time, such as like the polling _interval attribute (0x1134e). The value of the selected time attribute becomes the value of Time <T>. The time unit is seconds.
  The format would resemble the following:
  if Event X occurs and is not followed by Event Y within the time specified in the time- specific Attribute Y, then generate Event Z.
- **Generated Event <Z> - Generate Event**
  The event code of the event to create in response if the second event (event <Y>) does not follow the first event within the specified time interval.
  To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events that are loaded into Event Configuration), and click OK.
- **Generated Event <Z> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <Z>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into generated event <Z>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  NOTE
  For information about the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.

Event Variable Discriminators in Event Pair Rules

The use of discriminators not only lets multiple instances of the rule to be generated due to the same event, but also affects rule processing and termination. More specifically, if discriminators are used, the following occurs:

When the event is generated, if there are active instances of the rule, another instance of the rule is created only if the values of the specified variables are different in the new event when compared to the events that activated the existing rule instances. (If you do not specify any discriminators for a rule and if a single instance of the rule is active, then the subsequent instances of the rule are not generated when subsequent instances of the event occur.)

To terminate the rule without generating the rule output event, the values of all of the specified event variables must be the same in both the first event (that triggered the rule) and the second event (for which the rule is watching) in the pair.

As an example, assume you create an event pair rule that watches for a port down event followed by a port up event, and you specify the event variable that stores the interface ID of the port as an event variable discriminator. As a result, if device A has ports 1 and 2, and port 1 goes down, a rule instance for the event is generated. If port 2 subsequently goes down, another rule instance is also generated due to the same event because the interface ID in the second instance

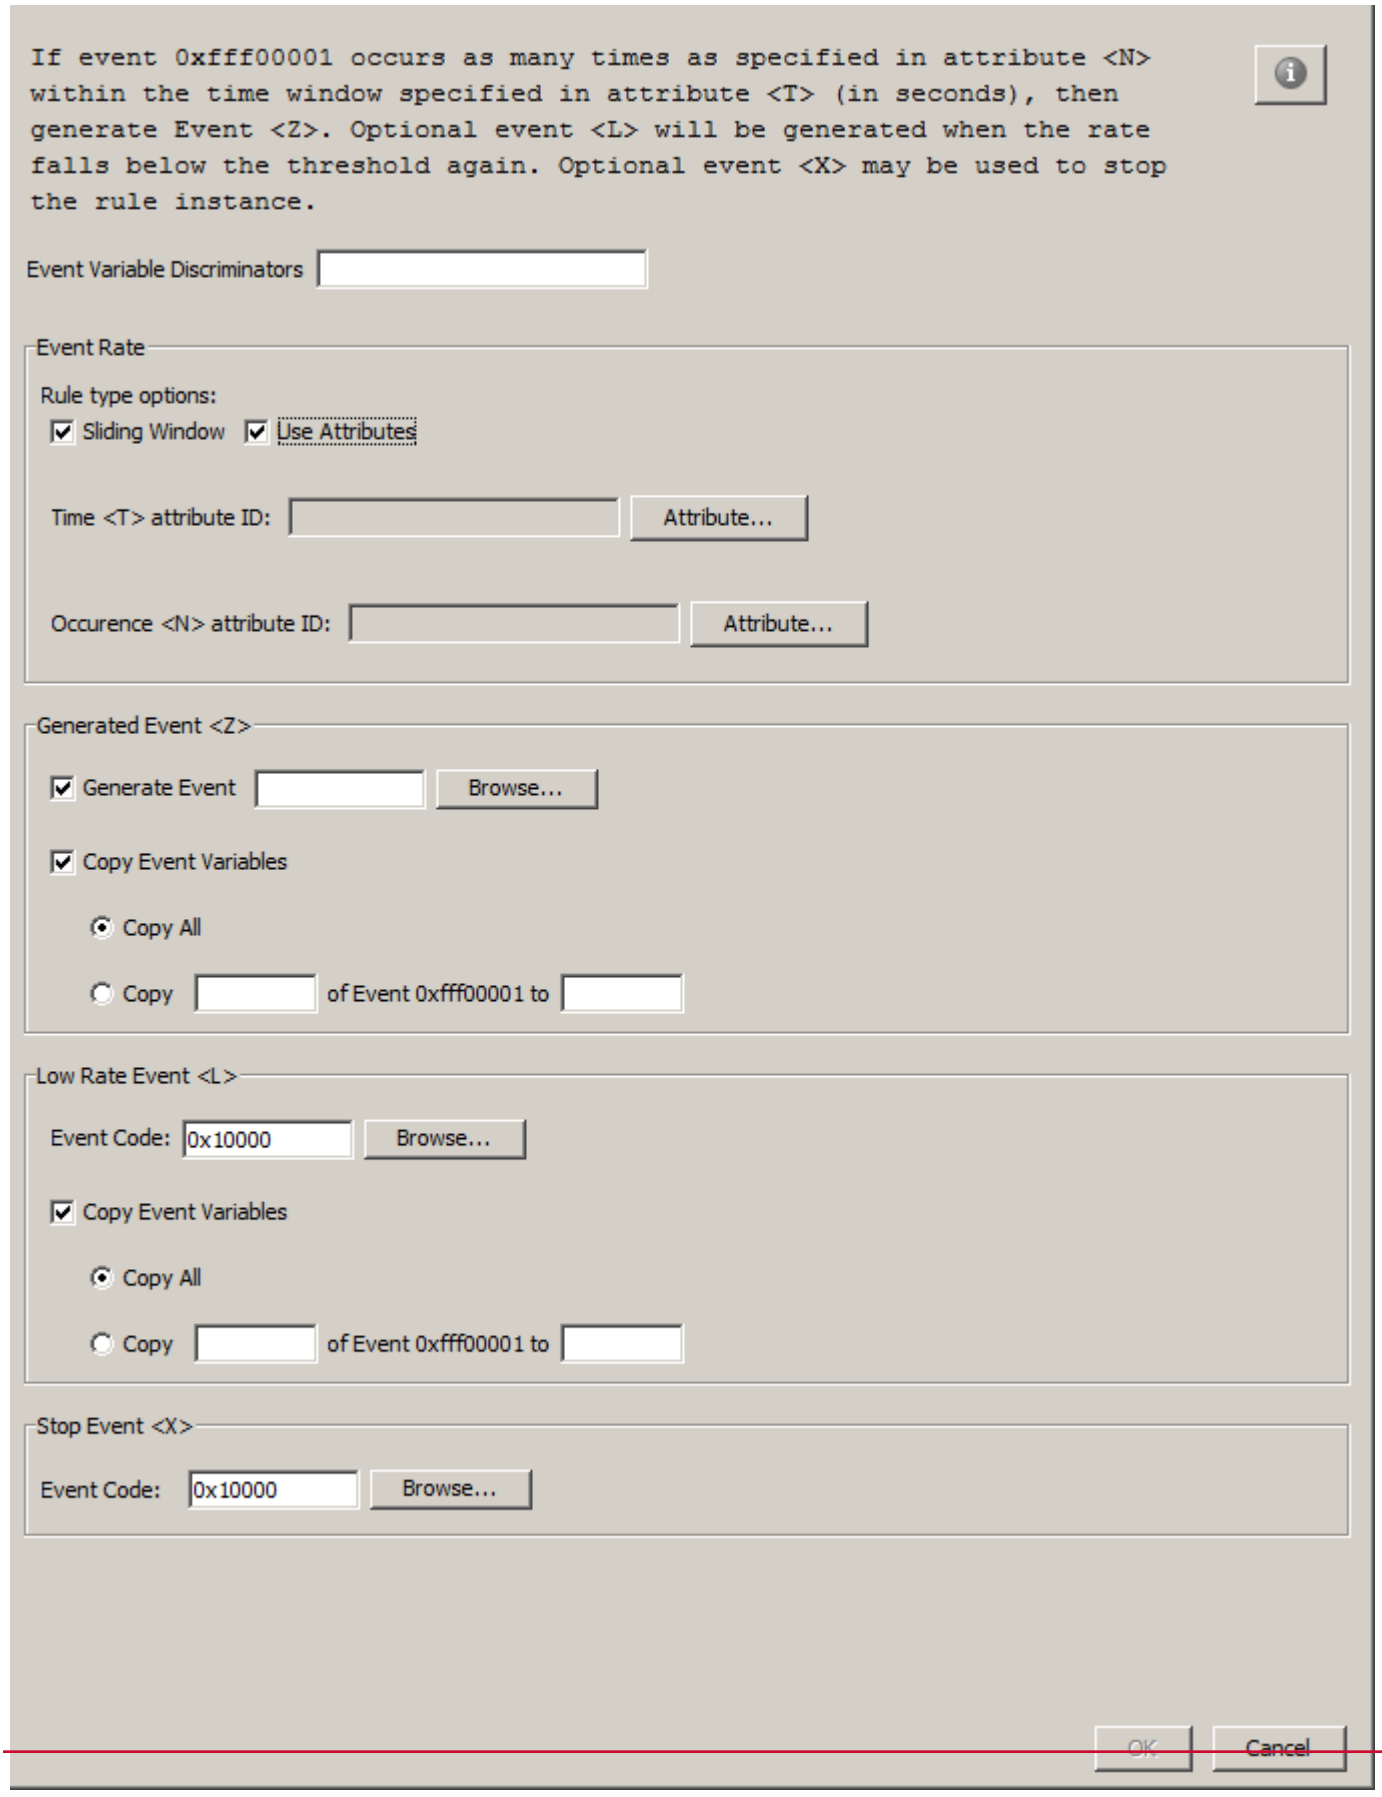
of the event is different. There are now two active instances of the rule due to port down events that are related to two different ports.

To continue the example, if port 2 goes up within the specified time period, the associated rule will immediately terminate without generating the rule output event if the port up event that is generated stores the interface ID of port 2 in the same event variable (that is, the IDs of the event variables in the first event and second event in the pair that store the interface ID are the same). If a similar event is not generated for port 1 within the specified time period, the associated rule terminates by generating the rule output event.

> **NOTE**
> To use event variable discriminators effectively in an event pair rule, the IDs of the event variables in the contributing events must match. That is, the same event variables must store the same variable binding data. If not, you can create an event condition rule that is activated by the first event and copies the data to event variables having the appropriate IDs in the rule output event; you can then use the rule output event as the second event in the pair.

Configuring Event Rate Rule Settings

To configure an event rate rule use the following dialog:



If event 0xfff00001 occurs as many times as specified in attribute <N> within the time window specified in attribute <T> (in seconds), then generate Event <Z>. Optional event <L> will be generated when the rate falls below the threshold again. Optional event <X> may be used to stop the rule instance.

OK
Cancel

The dialog offers the following settings:

- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables that are included in the event. Events in the list are evaluated as a part of the rule.

  NOTE
  Enter individual IDs; ranges of IDs are not supported.

  The use of discriminators not only lets multiple instances of the rule to be generated due to the same event, but also affects rule processing. More specifically, if discriminators are used, the following occurs:
  – When the event is generated, if there are active instances of the rule, another instance of the rule is created only if the values of the specified variables are different in the new event when compared to the events that activated the existing rule instances. (If you do not specify any discriminators for a rule and if a single instance of the rule is active, subsequent instances of the rule are not generated when subsequent instances of the event occur.)
  – To generate the rule output event, the values of the variables must be the same in all instances of the same event (and all other rule conditions must be met).
- **Event Rate - Occurrences <N>**
  The number of instances of the same event that must be created within the specified time period for the rule to generate the output event.
- **Event Rate - Time <T>**
  The period during which <N> occurrences of the same event are required for the rule to generate the output event.
- **Event Rate - Sliding Window**
  The type of time window to use. Select a Sliding Window, or clear Sliding Window to use a *sequential window* of time. For a description of both, see Event Rate Rules.
- **Generated Event <Z> - Generate Event**
  The event code of the event to create if <N> occurrences of the same event occur within the specified period.
  To specify the event code, click Browse, select the event in the Select Event dialog, and click OK.
- **Generated Event - Copy Event Variables**
  To copy the values of any event variables of the event that activated the rule into the generated event <Z>, select Copy Event Variables and do one of the following:
  – Select Copy All to copy the values of all of the event variables into generated event <Z>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values are being copied. Ranges of IDs are also supported, for example, “1-4”.

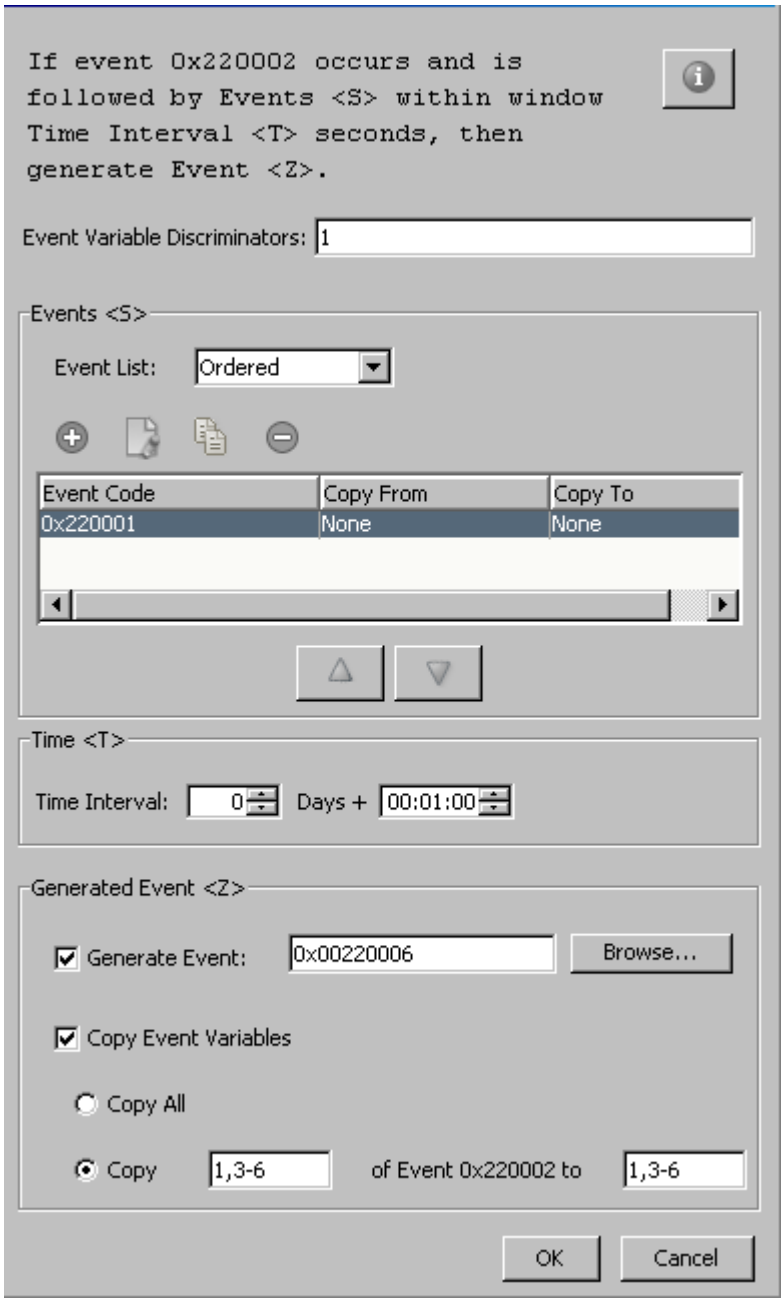
  NOTE
  For information about the proper syntax for specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.
- **Low Rate Event**
  (Optional) Generates a low rate event <L> if the frequency drops below the threshold. The rule generates the high rate event again only when the frequency threshold is crossed again.
- **Stop Event**

  NOTE
  (Optional) Stops the rule with an event. The rule runs continuously unless you set the stop event. In many cases, letting it run continuously is the desired behavior.

NOTE
An event rate rule can also generate a different rule output event when the rate of the trigger event drops below the specified threshold. Manually modify the rule in the event disposition file and specify that rule output event. For more information, see EventRateWindow Rule.

Configuring Event Series Rule Settings

You can configure an event series rule using the following dialog.



The settings in the dialog include the following options:

- **Event Variable Discriminators**

  NOTE
  A comma-separated list of IDs of event variables in the event to evaluate as a part of the rule. Enter each ID manually, ranges of IDs are not supported.

  To allow multiple instances of the rule to be generated due to the same event, use discriminators. The use of discriminators also affects processing and termination of rules. The following conditions apply occur if discriminators are used:

  – In case, there are active instances of the rule during event generation, another instance of the rule is created only if the values of the specified variables are different in the new event as compared to the events activating the existing

rule instances. The subsequent instances of the rule are generated when a single instance of the rule is active, only when you specify any discriminators for a rule.

– To generate the rule output event, the values of the variables must be the same in all contributing events (that is, both, in the event that activated the rule, and in all events that are specified in the series).

NOTE
To use event variable discriminators effectively in an event series rule, the IDs of the event variables in the contributing events must match. That is, the same event variables must store the same variable binding data. Alternately, you can create an event condition rule that a given event triggers and copies the data to event variables having the appropriate IDs in the rule output event. You can then use the rule output event in the series.

- **Events <S> - Event List**
  Select Ordered if the list (series) of events must occur in a specific sequence to trigger creation of the response event. Select Not Ordered if the events in the series can occur in any order.
- **Events <S> - Event Code**
  The series of events that must follow the event that activated the rule for the rule to generate the output event. If the events in the series must occur in a specific order, list them in that order.
  To add, modify, copy, and remove events from the list use the buttons above the table.
  To move an event up or down in the list, select the event, and click the up or down arrow.
  You can add an event to the series, and can specify that one or more of the values in its event variables be copied to the rule output event (generated event <Z>). To select the event in the dialog to add to the series, do any of the following actions:
  – Select Copy All to copy the values of all of the event variables to the rule output event.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values you want to copy. Ranges of IDs are also supported, for example, “1-4”.
- **Time <T> - Time Interval**
  The period during which the series of events must occur for the rule to generate the output event.
- **Generated Event <Z> - Generate Event**
  The event code of the event to create, in response to a series of events occurring within the specified period and in the specified order.
  To specify the event code, click Browse, select the event in the Select Event dialog (displaying all events that are loaded into Event Configuration), and click OK.
- **Generated Event <Z> - Copy Event Variables**

To copy the values of any event variables in that event which first activated the rule to the generated event <Z>, select Copy Event Variables, and perform any of the following steps:

Select Copy All to copy the values of all of the event variables into the generated event <Z>.

- Select Copy, and specify a comma-separated list of specific variable IDs whose values are copied. Ranges of IDs are also supported, for example, “1-4”.

NOTE
For information about the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.

To generate an event in response to a specific series of events, where one of several events triggers that same series first. To satisfy this scenario, create the same event series rule for all events that triggers the series.

Alternatively, you want to watch for any combination of a series of events and in any order, inclusive of the event that triggers the series. To satisfy this scenario, we recommend that you create the following rules:

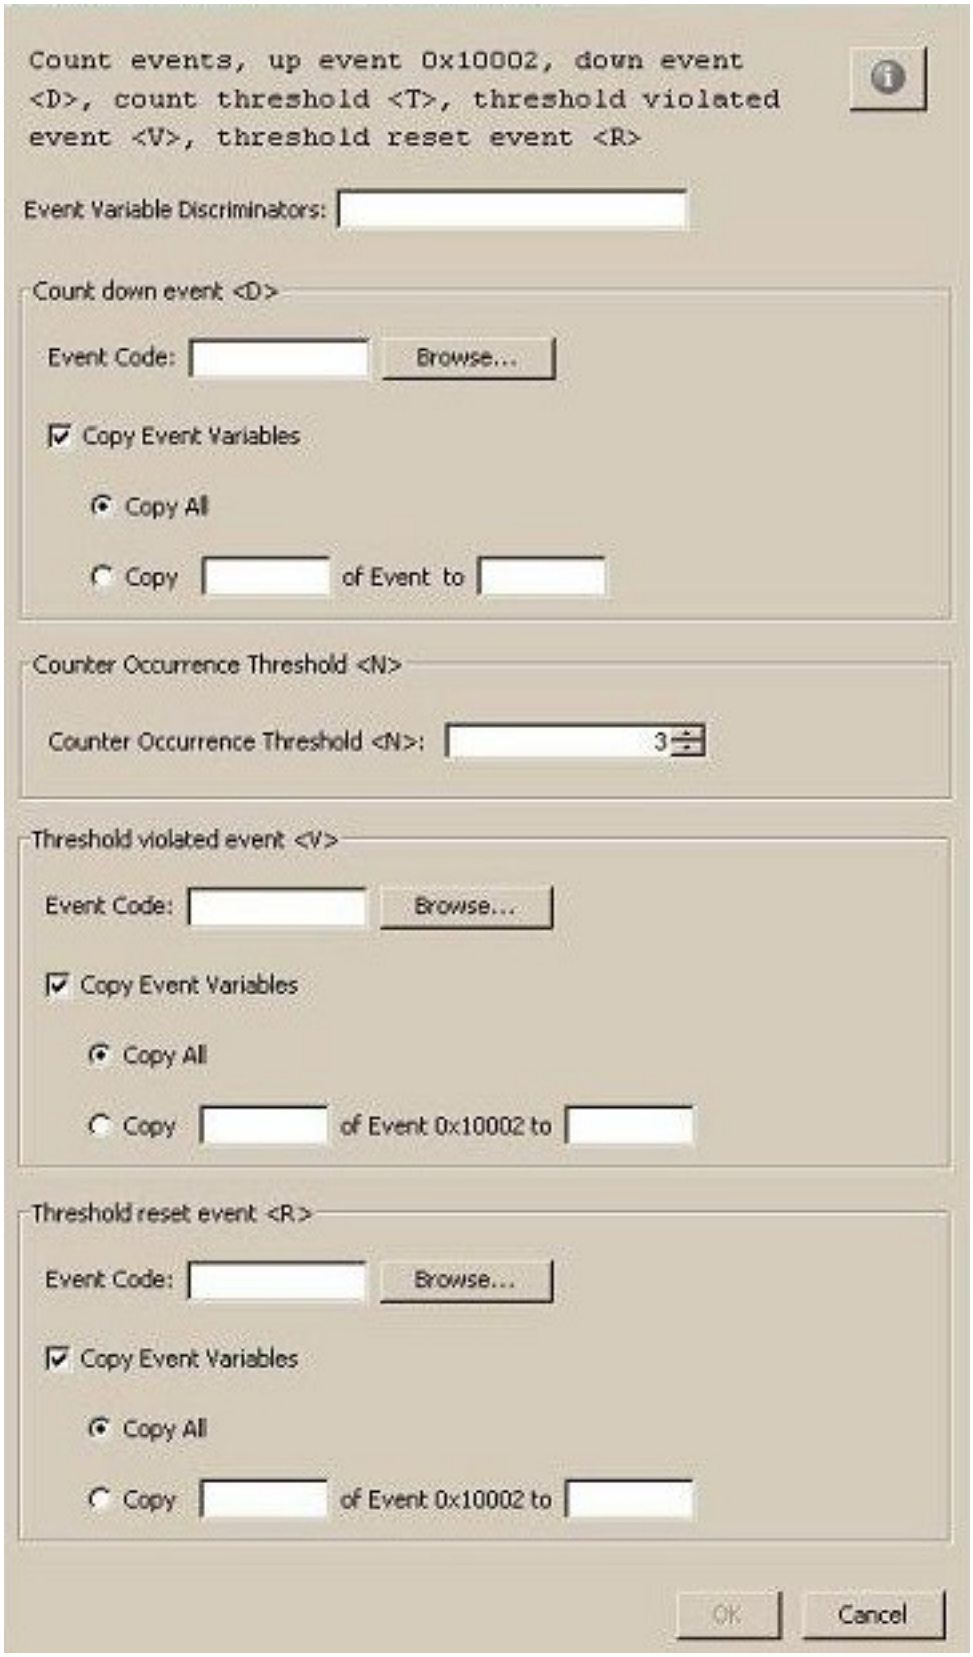
Event that triggers the rule (event to which rule is applied)	Events in the series (not ordered)	Rule output event (generated event <Z>)
0x0001002a	0x0001002b, 0x0001002c	0x0001002f

0x0001002b	0x0001002a, 0x0001002c	0x0001002f
0x0001002c	0x0001002a, 0x0001002b	0x0001002f

Using this set of rules, any combination of events 0x0001002a, 0x0001002b, and 0x0001002c occurring in any order generates event 0x0001002f.

Configuring Event Counter Rule Settings

You configure an event counter rule using the following dialog:



Count events, up event 0x10002, down event <D>, count threshold <T>, threshold violated event <V>, threshold reset event <R>
Event Variable Discriminators:
Count down event <D>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event to
Counter Occurrence Threshold <N>
Counter Occurrence Threshold <N>:
3
Threshold violated event <V>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event 0x10002 to
Threshold reset event <R>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event 0x10002 to
OK
Cancel

The settings in the dialog include the following:

The event for which the rule is defined is the one that counts up the event. The first event initiates a new rule instance and counts (count is 1).

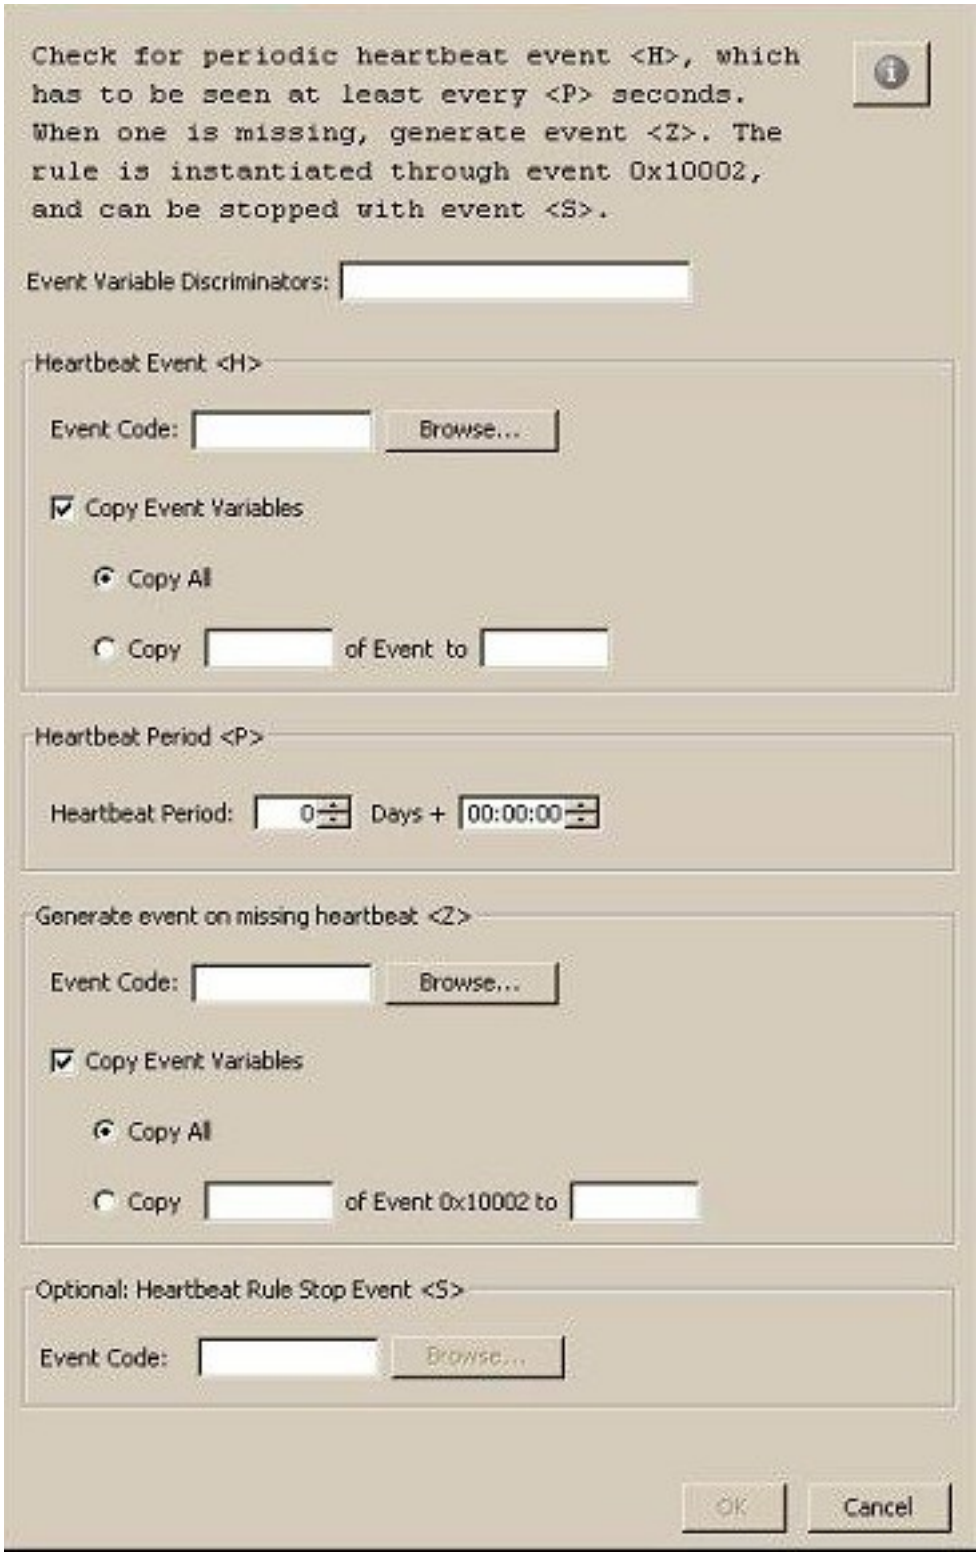
- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables in the event to evaluate as a part of the rule.

  NOTE
  Enter each ID separately; ranges of IDs are not supported. Event variable discriminators are a general feature available for all types of rules.
- **Count down event <D> - Event Code**
  Sets the event code that counts down by one. To specify the event code, click Browse, select the event in the Select Event dialog which displays all of the events that are loaded into Event Configuration, and click OK.
- **Count down event <D> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  NOTE
  For information about the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.
- **Counter Event Threshold <N>**
  Sets a certain threshold that when reached, generates a new event. The rule also generates another event when the count is lower then the threshold again.
- **Threshold violated event <V> - Event Code**
  Is generated when the count threshold is reached. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events that are loaded into Event Configuration), and click OK.
- **Threshold violated event <V> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <V>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Threshold violated event <V>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values you wish to copy. Ranges of IDs are also supported, for example, “1-4”.
- **Threshold reset event Reason: - Event Code**
  Generates when the count is below the threshold again. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events that are loaded into Event Configuration), and click OK.
- **Threshold reset event Reason: - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event Reason:, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Threshold reset event Reason:.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values you wish to copy. Ranges of IDs are also supported, for example, “1-4”.

Configuring Heartbeat Rule Settings

You can configure heartbeat rule using the following dialog.



The settings in the dialog include the following:

- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables in the event to evaluate as a part of the rule.

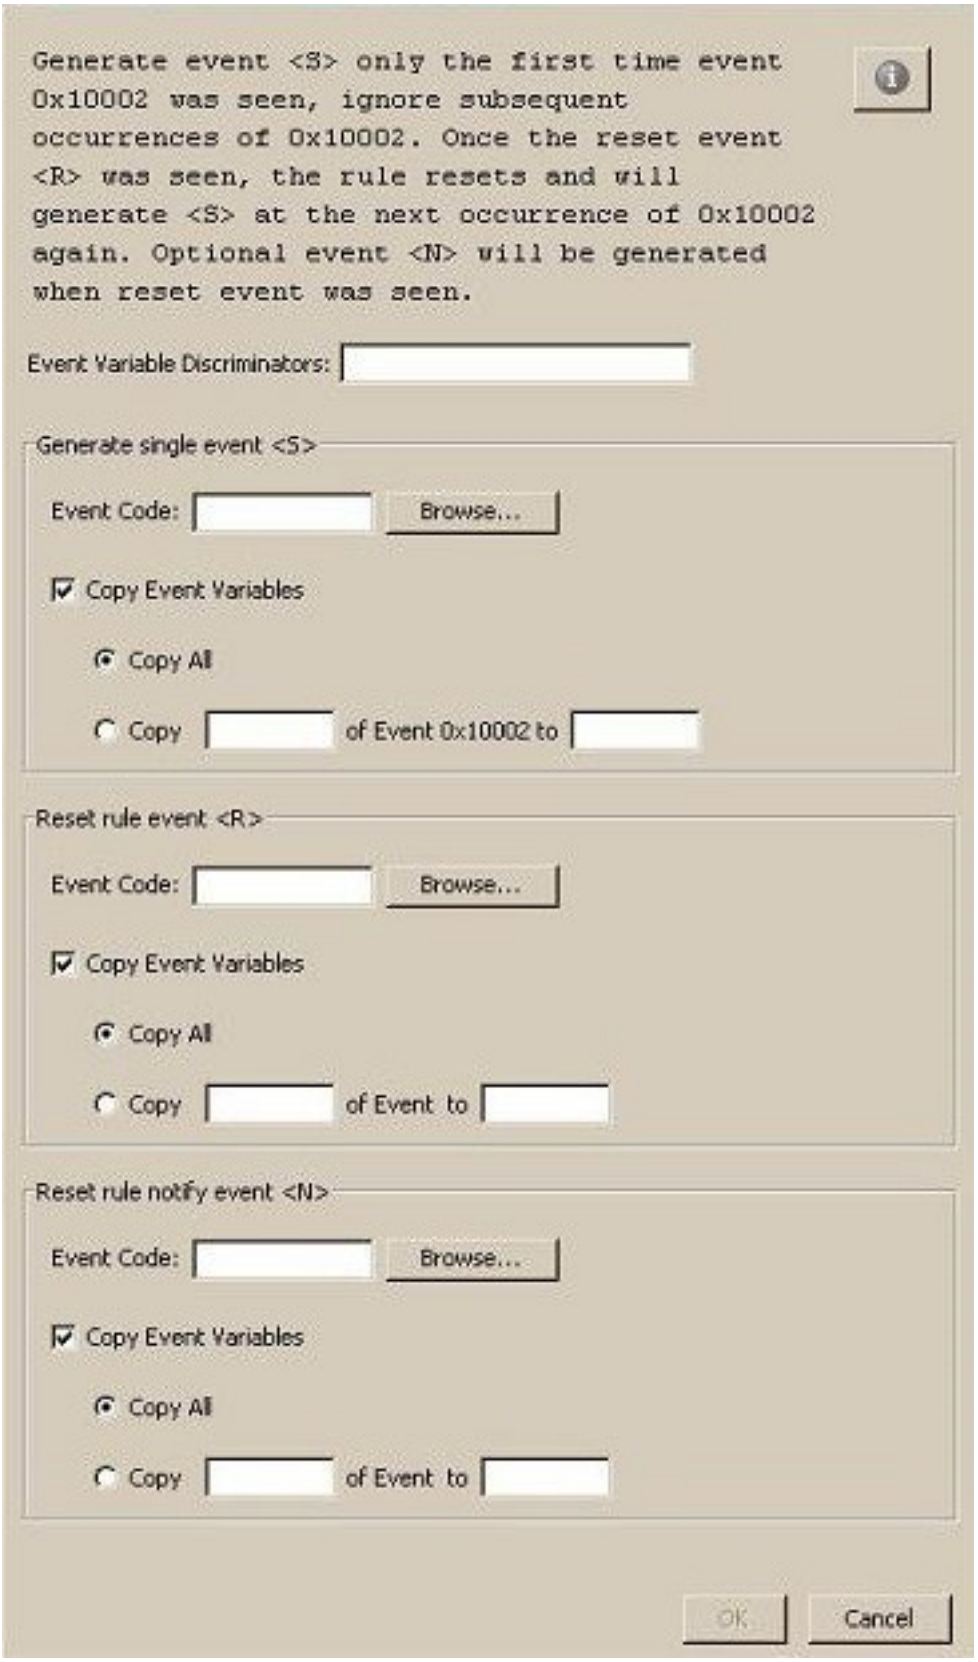
NOTE
You must enter each ID; ranges of IDs are not supported. Event variable discriminators are a general feature available for all types of rules.

- **Heartbeat Event <H> - Event Code**
  Sets the Heartbeat Event code. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Heartbeat Event <H> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <H>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Heartbeat Event <H>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  NOTE
  For information on the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.
- **Heartbeat Period <P>**
  Sets the time gap between individual heartbeats.
- **Generate event on missing heartbeat <Z> - Event Code**
  Generates an event when the heartbeat event is missed. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Generate event on missing heartbeat <Z> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <Z>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables to Generate event on missing heartbeat <Z>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.
- **(Optional) Heartbeat Rule Stop Event <S> - Event Code**
  The Heartbeat Rule Stop Event stops the Heartbeat event rule.To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.

Configuring Single Event Rule Settings

You can configure a single event rule using the following dialog.



Generate event <S> only the first time event 0x10002 was seen, ignore subsequent occurrences of 0x10002. Once the reset event <R> was seen, the rule resets and will generate <S> at the next occurrence of 0x10002 again. Optional event <N> will be generated when reset event was seen.
Event Variable Discriminators:
Generate single event <S>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event 0x10002 to
Reset rule event <R>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event to
Reset rule notify event <N>
Event Code:
Browse...
Copy Event Variables
Copy All
Copy
of Event to
OK
Cancel

The settings in the dialog include the following:

- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables in the event to evaluate as a part of the rule.

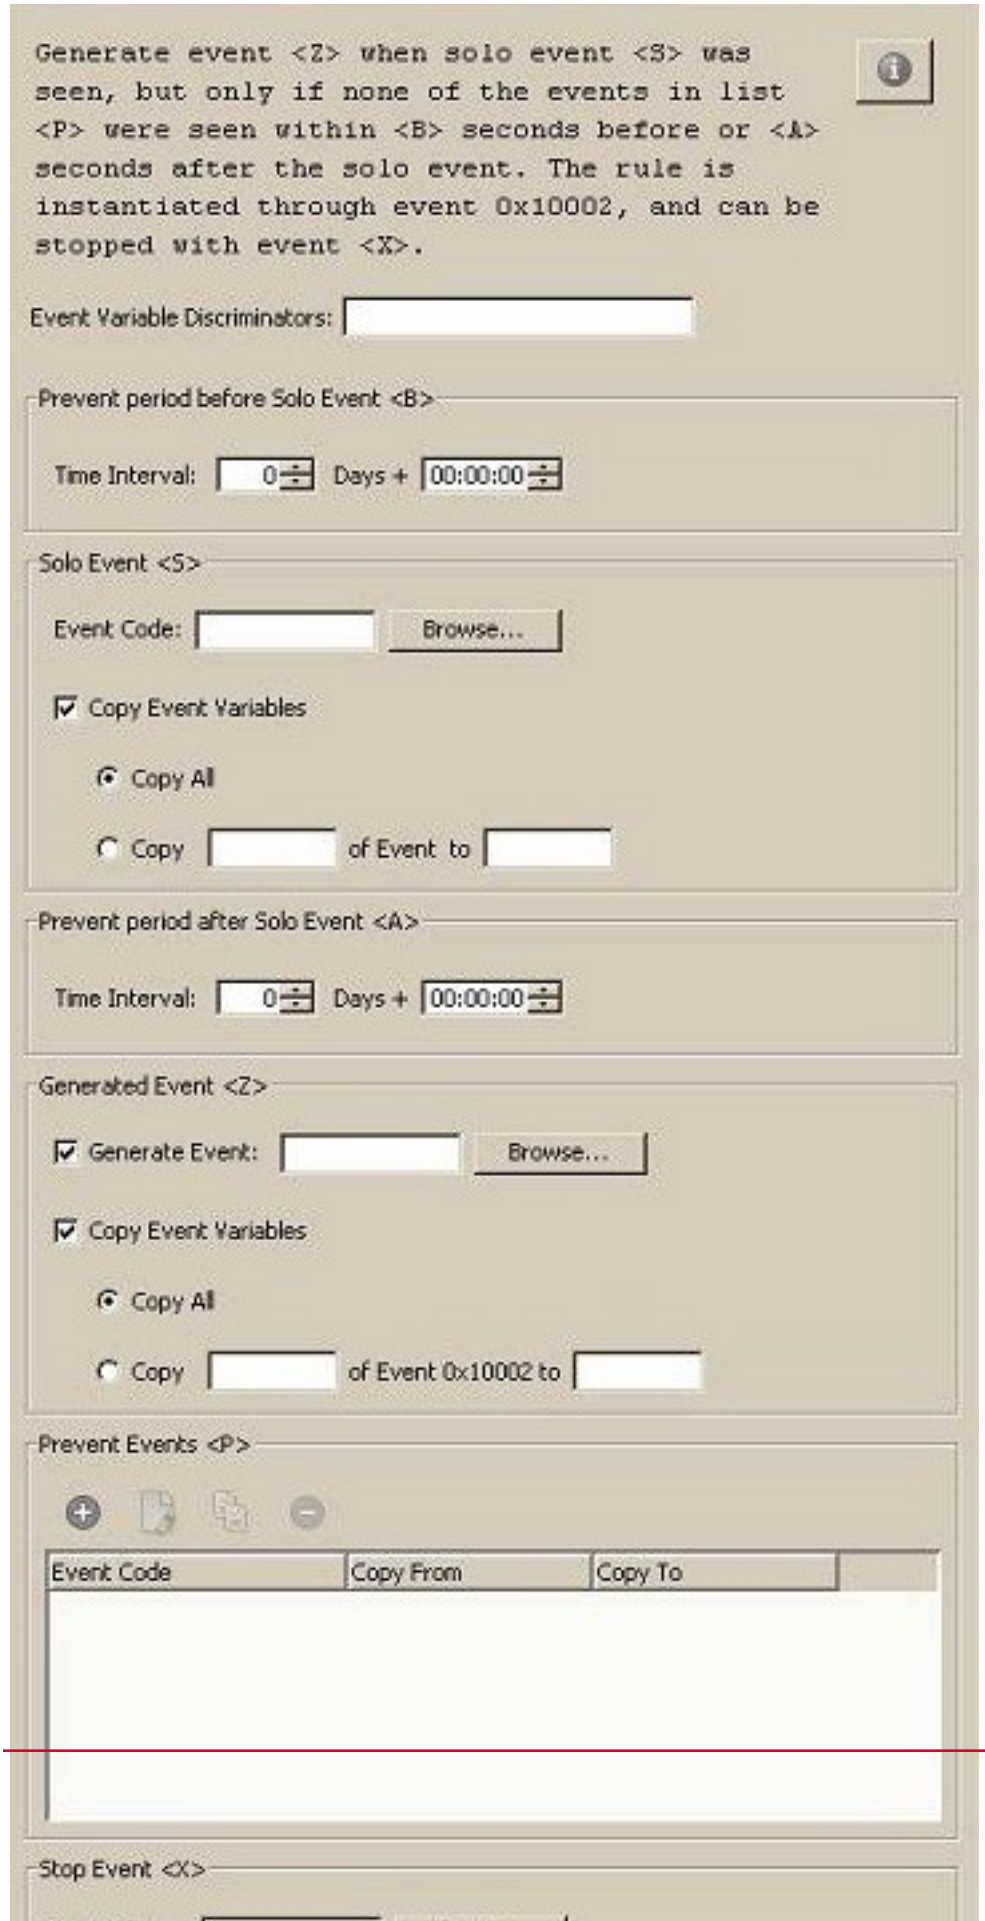
  NOTE
  You must enter each ID; ranges of IDs are not supported. Event variable discriminators are a general feature available for all types of rules.
- **Generate single event <S> - Event Code**
  It is generated the first time the trigger event is seen either when the rule is instantiated, or the first time the trigger event occurs after the reset event is seen. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Generate single event <S> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  NOTE
  For information on the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Event.
- **Reset rule event Reason: - Event Code**
  Sets the reset event. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Reset rule event Reason: - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.
- **(Optional) Reset rule notify event <N> - Event Code**
  It is generated when the reset event is seen. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Reset rule notify event <N>- Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  WARNING

Configuring Solo Event Rule Settings

You can configure a solo event rule using the following dialog.



Generate event <Z> when solo event <S> was seen, but only if none of the events in list <P> were seen within <B> seconds before or <A> seconds after the solo event. The rule is instantiated through event 0x10002, and can be stopped with event <X>.
Event Variable Discriminators:
Prevent period before Solo Event <B>
Time Interval: 0 Days + 00:00:00
Solo Event <S>
Event Code: Browse...
Copy Event Variables
Copy All
Copy of Event to
Prevent period after Solo Event <A>
Time Interval: 0 Days + 00:00:00
Generated Event <Z>
Generate Event: Browse...
Copy Event Variables
Copy All
Copy of Event 0x10002 to
Prevent Events <P>
Event Code
Copy From
Copy To
Stop Event <X>

The settings in the dialog include the following:

- **Event Variable Discriminators**
  A comma-separated list of the IDs of the event variables in the event to evaluate as a part of the rule.

  NOTE
  You must enter each ID; ranges of IDs are not supported. Event variable discriminators are a general feature available for all types of rules.
- **Prevent period before Solo Event <B>**
  Sets the time period before the solo event where none of the 'prevent' events may occur (in seconds).
- **Solo Event <S>- Event Code**
  Specifies the Solo event. To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Solo Event <S>- Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”.

  NOTE
  For information on the proper syntax to use when specifying variable IDs or ranges of IDs using Event Configuration, see Copying Variable Values from Contributing Events to the Rule Output Even
- **Prevent period after Solo Event Action:**
  Sets the period after the solo event where none of the 'prevent' events may occur.
- **Generated Event <Z> - Event Code**
  Defines the event that will be generated when the rule triggers (when just the 'solo' event is seen). To specify the event code, click Browse, select the event in the Select Event dialog (which displays all of the events loaded into Event Configuration), and click OK.
- **Generated Event <Z> - Copy Event Variables**
  If you want to copy the values of any event variables in the first event that activated the rule to generated event <D>, select Copy Event Variables, and do one of the following:
  – Select Copy All to copy the values of all of the variables into Count down event <D>.
  – Select Copy, and specify a comma-separated list of specific variable IDs whose values should be copied. Ranges of IDs are also supported, for example, “1-4”
- **Prevent Events <P>**
  Defines a list of 'prevent' events. In the dialog, use the buttons above the list of prevent events to add new events and to modify, copy, and delete a selected event.
- **Stop Event <X> - Event Code**
  The Stop Event stops the Solo Event rule. To specify the event code, click Browse, select the event in the Select Event dialog which displays all of the events loaded into Event Configuration, and click OK.

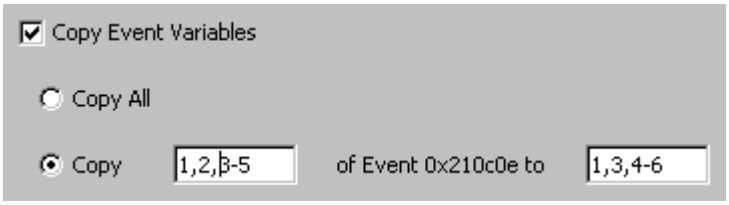
Copy Variable Values from Contributing Events to the Rule Output Event

When you use event rules, the event that is generated is sometimes generated only after multiple contributing events occur or after certain conditions are met.

By default, a rule output event has no event variables. However, you can specify optional processing. The values of the event variables in the events that contribute to the rule processing can be copied to the output event. You can then use event variable discriminators to specify event processing behaviors for the rule output event that is based on those values. And because the values of event variables in events that generate alarms are also stored in those alarms, you can use event discriminators to specify alarm processing (generation or clearing of alarms) based on the values. For an example of this usage, see Event Variable Copying and Event Discriminators.

You can specify that all of the event variables in a contributing event are copied to the rule output event, or you can specify variable IDs. Use the event variable IDs that are mapped (in the AlertMap file) to the OIDs of the variable bindings that are sent with the trap.

To copy only specific variable binding values from a contributing event to the rule output event, enter a comma-separated list of the IDs or ranges of IDs. This configuration is shown in the following image:



Use the first text box to specify the contributing event variables that you want to copy. Use the second text box to specify the event variables in the output event where the values are copied. The first ID in the “source” text box is copied into the first ID in the “target” text box, and so on.

> **NOTE**
> You can copy the value of one source variable into a target variable that has a different ID. For example, the preceding image specifies that source variable 1 is copied into target variable 1, source variable 2 is copied into target variable 3, and source variables 3, 4, and 5 are copied into target variables 4, 5, and 6, respectively.

Modifying Event Rules

You can modify event rules.

To modify event rules

1. In the Navigation panel, select the event that activates (triggers) the event rule.
2. In the Details panel, click the Event Rules tab.
   The list of event rules for the selected event appears.
3. Select the event rule to modify, and click the edit
   icon  .
4. Modify the configuration of the event rule as required.
5. Click OK.

Delete Event Rules

You can delete event rules.

To delete event rules

1. In the Navigation panel, select the event that activates (triggers) the event rule.
2. In the Details panel, click the Event Rules tab.
   The list of event rules for the selected event appears.
3. Select the event rule to delete, and click the delete
   icon  .
4. Click OK to confirm the deletion.

How to Use Procedures in Event Processing

As a DX NetOps Spectrum administrator, you are responsible for configuring DX NetOps Spectrum events. You want to configure selected event types to launch automatic actions, such as creating other events in response to selected events on selected models.
DX NetOps Spectrum includes many procedures that accomplish common tasks. The procedure files are located in *$SPECROOT*/SS/CsVendor/CA/Procedures. Each procedure XML file defines the procedure (input parameters, return value, and other options) and provides documentation about its function.
Using DX NetOps Spectrum procedures for event processing involves the following tasks:

- Understand Event Disposition Files
- Add a Procedure to an Event Map

Event Disposition Files

When DX NetOps Spectrum receives an SNMP trap and is mapped to a DX NetOps Spectrum event that is generated for the model, an *event disposition file* is used to determine how to process the event. The processing instructions in an event disposition file (an ASCII text file) can include any of the following information:

- Whether the event is logged
- The severity of the event
- Whether the event generates an alarm of a specific severity
- Whether the event clears one or more alarms
- Whether the event triggers an event rule (a series of events that are monitored and that trigger another event when they occur in a specific pattern or time frame)

DX NetOps Spectrum predefined events all have processing instructions that are defined in global and model type-specific event disposition files. In addition, whenever you create a new, custom event (either using MIB Tools, to map a trap to a new event, or later, using Event Configuration), a custom event disposition file is automatically created. Typically manual creation of the event disposition file is not required.

> **WARNING**
>
> A few types of modification, such as adding event-processing procedures to event maps, must be done in a text editor. For most other event modifications, we recommend specifying the processing instructions using Event Configuration. The Event Configuration utility can save your customizations to one or more landscapes.

If you are adding trap support for a new device, first use MIB Tools to map the traps to new DX NetOps Spectrum events and specify basic event settings. Then launch Event Configuration (it can be launched directly from MIB Tools) and can complete the event configuration. This workflow avoids most manual modifications to event disposition files. However, we have provided reference information about the proper syntax to use if manual modifications are required.

More information:
Location of Event Disposition Files
File Syntax of Event Disposition Files

File Syntax of Event Disposition Files

Each line in an event disposition (EventDisp) file is called an *event map.* Each event map can specify one or more event processing behaviors, such as whether the event is logged, or whether it generates an event. The following syntax is used for an event map:

```
eventcode E eventseverity processing parameters P procedure S sbgw processing flag
```

eventcode

Specifies the event code of the DX NetOps Spectrum event for which the processing behavior is being defined. The event code is defined in the AlertMap file that maps the trap to the event, or it is specified within the code that generates the event. The event code must be specified for DX NetOps Spectrum to process the event.

E
(Optional) Indicates that the Archive Manager logs the event data to the Distributed Data Manager (DDM) database. If the E flag is not used, the event data is temporarily logged, but it is not preserved when the SpectroSERVER is shut down and then restarted.

eventseverity
Specifies the relative severity of the event on a scale of 0 to 100, where 0 is the least severe and 100 is the most severe. If a value for event severity is not specified, DX NetOps Spectrum uses a default value of 0.

> **NOTE**
>
> The event severity parameter is not currently used by the event management system. However, if you are logging the event, you are advised to assign an event severity value. The use of this parameter can be incorporated into event processing in the future. If you are not logging the event, do not assign an event severity value.

processing_parameters
Specifies additional event processing behaviors, such as whether the event generates an alarm, clears one or more alarms, or executes one or more event rules.

P
Specifies the action code that indicates that a procedure follows.

procedure
Specifies the procedure to execute. To specify multiple procedures, use multiple instances of P *procedure*.

S *sbgw processing flag*
(Optional) Specifies whether an event should be registered for Southbound Gateway processing. It applies to modeltype specific entries only and to only those modeltypes that are derived from the southbound modeltype fragment.

An event does not require an event map in an EventDisp file, but most events have one. If an event does *not* have an event map in an EventDisp, the event is logged in the DDM database by default (which means that it is preserved when the SpectroSERVER is shut down and then restarted). However, no additional processing takes place. If an event has an event map, the event is processed according to the event map.

Note the following about EventDisp files:

- Empty lines in the EventDisp file are ignored.
- If a single event map spans multiple lines, include a backslash '\' at the end of each line so that DX NetOps Spectrum considers the next line as a part of the event map.

Location of Event Disposition Files

The name of every event disposition (EventDisp) file is always EventDisp.

> **NOTE**
>
> In the Windows environment, no file extension is used.

The EventDisp files that support the events provided with DX NetOps Spectrum are installed in the following directories:

- *$SPECROOT*/SS/CsVendor/*vendor_directory*

An EventDisp file in this location defines the processing for all events created by the developer that are *global* in scope. The *vendor_directory* variable is the name of the developer, vendor, or manufacturer for which the EventDisp file is used.

NOTE

In some instances, CA uses something other than the developer name for the developer-specific directory; for example, the IETF directory contains the EventDisp file that specifies the processing for events that result from standard RFC traps.

- *$SPECROOT*/SS/CSVendor/*vendor_directory*/*model_type_name*

An EventDisp file in this location defines the processing for all events that are created by the developer whose scope is *limited to the model type* represented by *model_type_name*. In this case, *vendor_directory* is the name of the developer, vendor, or manufacturer for which the model type was created (for example, Cisco).

NOTE

If an event map entry exists in both a global EventDisp file and a model type-specific EventDisp file, the event map entry in the model type-specific file takes precedence.

If you customize the event processing for the DX NetOps Spectrum predefined events, or if you create new custom events using MIB Tools or Event Configuration, a custom EventDisp file is created in the following directory or in one of its subdirectories:
$SPECROOT/custom/Events.

NOTE

The event map entries in a custom EventDisp file override those entries in the predefined DX NetOps Spectrum EventDisp files.

Add a Procedure to an Event Map

To specify that one or more procedures are executed when an event is processed, add the procedures to the relevant event map. The event map is included in the event disposition file. When the event is generated for a given model, the SpectroSERVER processes the event and executes the procedures.

DX NetOps Spectrum procedures can only be created using a text editor, not in the Event Configuration interface. DX NetOps Spectrum Event Configuration lets you view, but not edit, any procedures that you have associated with an event.

Associate an event procedure with an event by creating an event disposition action. Start the action with the 'P 'action code, and then contain the procedure code within double-quotation marks.

NOTE

Both the current event and the current model are required for proper procedure execution. The SpectroSERVER sets both of these parameters automatically.

Follow these steps:

1. Log in to the SpectroSERVER as an administrator.
2. Locate the event disposition files in the following directory: SS/CsVendor/*vendor_directory*
3. Find the procedure XML file that you want to use in the following directory: *$SPECROOT*/SS/CsVendor/CA/Procedures
4. Add the selected procedure to an event map using the following syntax: *event_code* E *event_severity processing_parameters* P *procedure*

***event_code* S**
Specifies the event code of the event.

E
Identifies the action code that indicates the event data is logged by the Archive Manager in the Distribute Data Manager (DDM) database.

event_severity
Specifies the relative severity of the event on a scale of 0 to 100.

processing_parameters
Specifies additional event processing behaviors, such as whether the event generates an alarm, clears one or more alarms, or executes one or more event rules.

P
Specifies the action code that indicates that a procedure follows.

procedure
Specifies the procedure to execute. To specify multiple procedures, use multiple instances of P *procedure*.
The server sets the correct environment for the procedure evaluation, with the current model and event preset.
Event disposition procedures are parsed once during server startup, producing an executable procedure object. When it receives the event for the procedure, the server evaluates the procedure object and performs the specified operations.

Example
The following event map executes a procedure that creates event 0xabcd0002 on the device model of a port, which is retrieved by reading the Device_Mdl_Handle attribute (0x10069). Event 0xabcd0002 has copies of all of the event variables in the original event.

```
0xabcd0000 E 50                                          \
    P "CreateEventWithVariables(                         \
        ReadAttribute( { C CURRENT_MODEL }, { H 0x10069 } ),  \
        { H 0xabcd0002 },                                \
        GetEventVariableList()                           \
)"
```

In the example, CURRENT_MODEL is a predefined constant that refers to the current model. The model is automatically set in the environment by the SpectroSERVER when the event is processed.
As shown in the example, a procedure must be fully enclosed in double quotes. The procedure must have a procedure name and can take parameters. Parameters follow the procedure name. Both values and constants (direct values) must be enclosed in braces and separated by commas. For example, the following syntax is valid:

```
{ U 101 } (unsigned integer with value of
 101)
{ C CURRENT_MODEL } (a constant that is defaulting to the current model handle)
```

A procedure call can be inserted by using the procedure name with its parameters. Add arguments in braces. For example:

```
ReadAttribute( { C CURRENT_MODEL }, { H 0x1006e } )
```

If a procedure spans multiple lines, use the line continuation character to indicate that each line continues a single event map.
You can use any number of procedures in an event map. No limit on the procedures that you can use from an event disposition file is enforced.

> **NOTE**
>
> The custom (user-defined) event procedures are read-only in the Event-Configuration editor.

Input Parameters

A procedure accepts the following types of input parameters:

- A value. Values are specified by type and value.
- A constant. Constants are specified by the letter C followed by the reserved word for the constant.
- Another procedure, which is evaluated when the parameter is needed and whose return value is used as the actual input parameter for the calling procedure.

Parameter Types

When you specify a direct value as a parameter, you must specify its type. Value types have a derivation hierarchy, which is shown in the following table. You can use a more specialized type for a more general type. For example, you can use a model handle in place of an unsigned integer, and you can use either of these types in place of a number.

When a parameter has a type that is not the same as or a derivative of the expected type, if the type is similar, most procedures attempt a conversion to the expected type. If a conversion fails or is not performed, an error occurs.

NOTE

You can use the ToUInteger procedure (provided with DX NetOps Spectrum) to convert a parameter value to an unsigned integer. Many times, this can help to avoid errors due to expected versus actual parameter types.

To specify a parameter type in a procedure, you specify a letter (a short symbol) for the type. For example, both of the parameters in the following procedure are handles (IDs), which are indicated by the letter 'H.' The first handle specifies the model for which to generate the event, and the second handle specifies the event to generate.
CreateEvent({ H 0x29c00003 }, { H 0xffff0000 })

The table that follows provides a short list of parameter types, their derivation hierarchy, and their associated short symbols. For the complete list of short symbols, see EventCondition Rule.

Parameter Type	Description	Short Symbol
Object	Derivation root	N/A
List	List root	N/A
AttributeList	List of attribute values	N/A
EventVariableList	List of event variables	N/A
Attribute Value	Any possible attribute value	N/A
Number	Number root	N/A
Integer	An integer value	I
Unsigned Integer	An unsigned integer value	U
DateTime	A time value	T
ModelHandle	A model handle	H
ModelType	A model type handle	H
RelationHandle	A relation handle	H
Attribute ID	An attribute ID	a
Unsigned Long	An unsigned long (64-bit) value	L
Boolean	A Boolean value	B
Double	A real value	R
String	String root	N/A
Text String	A String value	S
Octet String	An octet String value	O
Tagged Octet String	A hexadecimal tagged octet String	X
Object ID	An object ID value	o

IP Address	An IP address	A
Variable	The value of a variable	V

Constants

You specify a constant using the letter C followed by the reserved word for the constant. For example, the following procedure creates event 0xffff0000 for the current model:
CreateEvent({C CURRENT_MODEL}, { H 0xffff0000 })

You can use the following list of constants in procedures in event maps:

CURRENT_EVENT
The current event, which is set in the environment automatically by the SpectroSERVER.

CURRENT_MODEL
The current model, which is set in the environment automatically by the SpectroSERVER.

RELATION_SIDE_LEFT
The model on the left side of an association.

RELATION_SIDE_RIGHT
The model on the right side of an association.

RELATION_SIDE_EITHER
The model on either side of an association.

Return Values

Every procedure returns a value whose type depends on the function that the procedure performs, for example, a list of model handles or a Boolean value of TRUE or FALSE.

The possible types of return values are the same as the possible types of input parameters for procedures. This lets you use procedures as input parameters because they ultimately evaluate to permissible input values.

Examples of Procedures in Event Disposition Files

The following examples show how procedures can be used in event maps to implement event processing. Assume that each procedure is wrapped inside double quotes.

Add together two integer numbers (4 and 16):

```
Add( { I 16 }, { I 4 } )
```

Add together a direct value of 4 and the value in event variable 2 in the current event:

```
Add( { U 4 }, GetEventVariable( { U 2 } ) )
```

Create event 0xffff0000 for model 0x29c0003:

```
CreateEvent( { H 0x29c00003 }, { H 0xffff0000 } )
```

Create event 0xffff0000 if event variable 1 in the current event exceeds 100:

```
If( Less( { U 100 }, GetEventVariable( { U 1 } ) ),    \
 CreateEvent( { H 0x29c00003 }, { H 0xffff0000 } ), \
 Nil() )              \
)
```

Create event 0x10002 with a list of event variables. The list will be a copy of the variables in the current event. In the new event, also set event variable 2 to 1965:

```
CreateEventWithVariables( { H 0x29c00003 },       \
 { H 0x10002 },            \
 SetEventVariable( GetEventVariableList( { C CURRENT_EVENT } ),  \
 { U 2 }, \ { U 1965 }            \
 )
)
```

Create a list and add several elements. The list will contain the following elements in this order: 5,3,2,1,4,6:

```
AddTail(          \
 AddHead(         \
  AddTail(        \
   AddHead(       \
    AddHead(      \
     AddTail(     \
      CreateList(),  \
      { U 1 } ),    \
     { U 2 } ),     \
    { U 3 } ),      \
   { U 4 } ),       \
  { U 5 } ),        \
 { U 6 } )
```

Create event 0x10002 for model 0x29c00003 if the model has IP address 191.168.102.25:

```
If ( HasIPAddress( { H 0x29c00003 }, { A 192.168.102.25 } ),     \
 CreateEvent( { H 0x29c00003 }, { H 0x10002 } ),              \
Nil()                                                          \
)
```

Create event 0xffff0000 for model 0x29c00003 if attribute 0xffff0000 of the current model has the same value as event variable 1 in the current event:

```
If( Equals( ReadAttribute( { C CURRENT_MODEL }, { H 0xffff0000 }),  \
 GetEventVariable( { U 1 } )                                  \
 ),                                                            \
 CreateEvent( { H 0x29c00003 }, { H 0xffff0000 } ),              \
Nil()                                                           \
)
```

Return TRUE if the current time is 8 a.m. or later:

```
GreaterOrEqual( GetHour( GetCurrentTime() ), { U 8 } )
```

Retrieve the value of event variable 1 in the current event and write it to attribute 0xffff0001 in the current model:

```
WriteAttribute( { C CURRENT_MODEL }, { H 0xffff0001 }, GetEventVariable( { U 1 } ) )
```

Create event 0xffff0000 for model 0x29c00003 if exactly 3 event variables in the current event's event variable list have a value of 4. The procedure iterates over the list, assigning each element in the list to the loop variable 'X' in turn and checking its value. If the value of the element is 4, the return variable 'ret' is incremented. After iterating through the list, the return value is checked, and the event is generated if its value is 3:

```
If( Equals( ForEach( GetEventVariableList(),                \
  { Variable X },                                  \
```

```
   { Variable ret },                                  \
   { U 0 },                                          \
   If( Equals( { Variable X },                       \
    { U 4 } ),                                  \
    Assign( { Variable ret },                   \
     Add( { Variable ret },                \
      { U 1 } )                            \
    ),                                          \
    Nil()                                       \
   )                                                 \
  ),                                                       \
  { U 3 } ),                                               \
  CreateEvent( { H 0x29c00003 }, { H 0xffff0000 } ),       \
  Nil()                                                    \
 )
```

Parse a Single Varbind into Multiple Event Variables

In this example, a device produces a trap that contains a single varbind. That varbind contains multiple components that are required for the correct processing of the alarm. A procedure is required to extract the components and place them into event variables, where they can be used as event discriminators.
We have analyzed the trap and know that the varbind contains a string with a well-defined pattern: ERROR TEXT:SEVERITY. We also know that the ERROR TEXT could be any arbitrary string, but that the SEVERITY is limited to a set of values: Critical, Major, Minor, Clear, None, or Special.
Therefore, we must create a pattern of (.*):(Critical|Major|Minor|Clear) to match our varbind. We use the left-hand side as a discriminator, and the right side as the severity. We also want a unique alarm instance that is created for each ERROR TEXT. And we want the Clear trap to clear only matching ERROR TEXT alarms.
We want to create a single event that is capable of handling many different error code and severity combinations. Using a procedure, we instruct the event to create multiple event variables. But first, we must create an entry in the AlertMap file for the trap.
Follow these steps:

1. Log in to the SpectroSERVER as an administrator.
2. Locate the AlertMap file in the following directory: SS/CsVendor/*vendor_directory*

   NOTE

   An AlertMap file maps an alert to a DX NetOps Spectrum event. AlertMap files are automatically created when you map a trap to an event using MIB Tools.
3. Open the file in a text editor.
4. Use the following syntax for the new entry: *Alert Code Event Code OID Map*where the OID Map includes the OID, the value variable ID, and the instance variable ID.
   For example, the following syntax provides a fictional example:
   1.3.6.1.4.1.17844.1.2.6.0 0x05a91900 1.3.6.1.4.1.17844.1.1.1(1,0)
5. Create a regexp pattern to extract the error code into one variable, and the severity into another variable.
   In this example, we create a procedure that parses any number of tokens so that we can reuse it for other, similar requirements:
   Pseudo Code:

   ```
   Given a text string and a pattern
   Set the starting index
   If the text string matches the pattern then for each () in the pattern,
   extract the text enclosed and put it into an event variable at the current index; increment the index
   else throw an error message
   ```

```
When all the () are exhausted, create an event with the new event variable list
```

Example from an EventDisp File:

```
0x05a91000 P " \
SetVariable({V pattern},{S \"(.*):(Critical|Major|Minor|Clear|None|Special)\"}, \
 SetVariable({V counter},{U 500}, \
If(Regexp(GetEventVariable({U 1}),{V pattern}), \
CreateEventWithVariables({C CURRENT_MODEL},{H 0x05a91002}, \ ForEach(GetRegexpList(\
GetEventVariable({U 1}),{V pattern}),{Variable X}, \
{Variable retVal},GetEventVariableList(), \
Prog2(Assign({V retVal},SetEventVariable({V retVal},{V counter},{Variable X})), \
 Assign({V counter},Add({V counter},{U 1})))))), \
CreateEventWithVariables({C CURRENT_MODEL},{H 0x05a91001},
 GetEventVariableList())))))"
```

NOTE

Validation occurs during the processing. If the input string does not match the pattern (for example, the syntax ERROR TEXT:BadSeverity does not match), an alarm is created. The alarm details indicate that the processing did not complete because the input was not formatted correctly. Including validation is extremely helpful in troubleshooting. For a complete walkthrough of this code sample, see "Code Walkthrough," below.

6. Add the procedure to an event map using the syntax that is described in Add a Procedure to an Event Map.
   The server sets the correct environment for the procedure evaluation, with the current model and event preset.

Code Walkthrough

```
0x05a91000 P " \
SetVariable({V pattern},{S \"(.*):(Critical|Major|Minor|Clear|None|Special)\"}, \ SetVariable({V counter},{U
 500}, \
If(Regexp(GetEventVariable({U 1}),{V pattern}), \
CreateEventWithVariables({C CURRENT_MODEL},{H 0x05a91002}, \ ForEach(GetRegexpList(\
GetEventVariable({U 1}),{V pattern}),{Variable X}, \
{Variable retVal},GetEventVariableList(), \
Prog2(Assign({V retVal},SetEventVariable({V retVal},{V counter},{Variable X})), \ Assign({V counter},Add({V
 counter},{U 1})))))), \
CreateEventWithVariables({C CURRENT_MODEL},{H 0x05a91001}, GetEventVariableList())))))"
```

{V pattern} is the extraction pattern. If you wanted 3 tokens you would only have to change this pattern. The following example shows an extraction pattern:

```
(.*):(.*):(Something|Else)
The (.*) brown (fox|duck) (jumped|slid) over the lazy (.*) => {S 501}=quick {S 502}=fox
{S503}=jumped {S 504}=dog
```

{V counter} is the starting index. The GetRegexpList function determines that the entire string is contained at the counter, while the first extracted token is at counter + 1.

GetEventVariable({U 1}) returns the value of varbind 1 (you might know it as {S 1} or {I 1} in event messages). This instruction effectively means, "Get the event variable at index 1." If your variable is in varbind 100, use U 100, for example.
ForEach says, "For each item in the list returned by GetRegexpList, do something."
GetRegexpList returns a list of extracted tokens, but they cannot solely be used as event variables. They must be written to the EventVariableList.
Prog2 is like a code block that lets two independent actions execute sequentially. In this case, the code instructs, "Assign the current token to the event variable list at the current index, then increment the index counter."

Logging Errors in Event Procedures

You can log the errors that the SpectroSERVER encounters while parsing a procedure XML file or while executing a procedure in an event map to an error log file.
Errors that are found while parsing a procedure file are written to the file that is specified in the procedure_error_file parameter in the SpectroSERVER .vnmrc resource file. Errors that are found while executing a procedure that is used in an event map are written to the event disposition error file. The event disposition filename is specified in the event_disp_error_file parameter. A procedure-specific error file can also be used. Its filename is specified in the procedure_error_file parameter. A filename of "stderr" for these parameters redirects the output to the server console output.

Troubleshooting Event Procedures

Using DebugValue procedure

You can use the DebugValue procedure to assist you in troubleshooting procedures used in event processing that are not performing as you intend. The DebugValue procedure prints the value of a parameter to a log file. The error log file is specified in the event_disp_error_file parameter in the SpectroSERVER .vnmrc file.

> **NOTE**
>
> For information on how to set the event_disp_error_file parameter in the .vnmrc file in the Input Parameters section

The DebugValue procedure accepts the following input parameters:

- A text string that is printed before the value is printed. This parameter is especially helpful for differentiating values when you are using more than one DebugValue procedure in a given event procedure.
- Any value (value, constant, or another procedure).

The DebugValue procedure returns the value that is passed in as the second input parameter (which is unchanged). As a result, you can use it as an input parameter in any other procedure without affecting the execution of that procedure.
Example
The following DebugValue procedure prints a text string, followed by the value of a read operation on an attribute of the current model. It returns the value of the read operation, which is then used as the first input parameter in the Equals procedure.

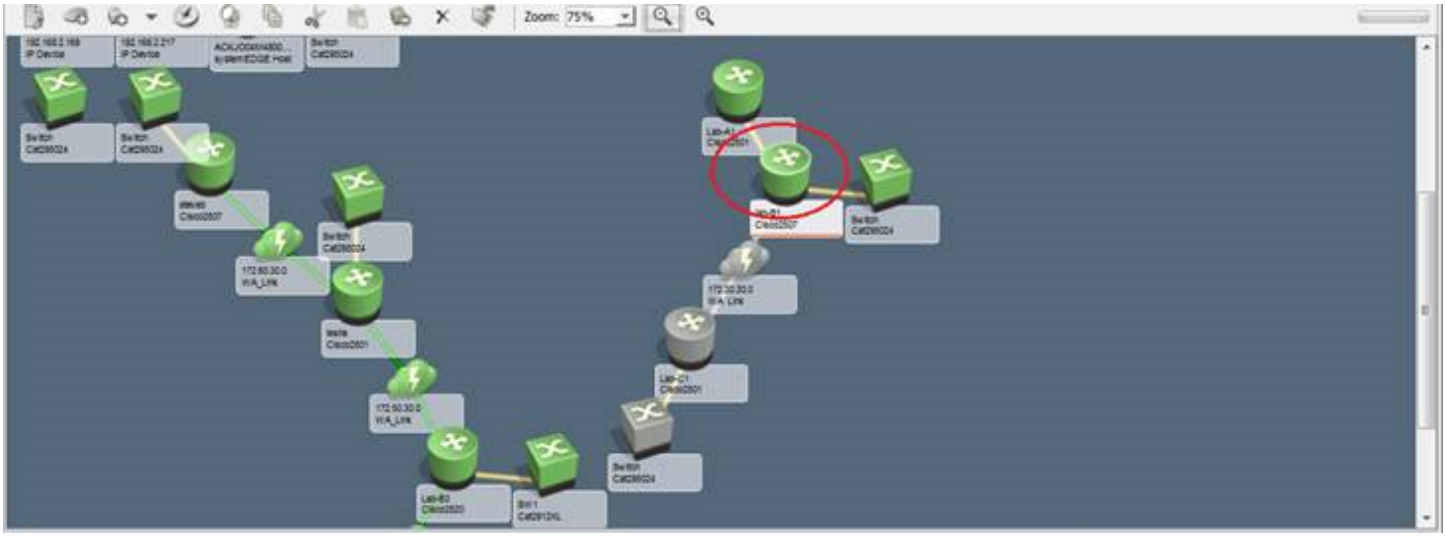
```
If( Equals( DebugValue( { S \"Attribute value is:\" },           \
  ReadAttribute( { C CURRENT_MODEL }, { H 1 } ),        \
  GetEventVariable( { U 1 } )                            \
 ),                                                     \
 CreateEvent( { H 0x29c00003 }, { H 0xffff0000 } ),           \
Nil()                                                    \
)
```

Spectrum Fault Isolation not suppressing or asserting alarms as expected

Symptom:

During a major outage, we did not receive an expected critical alarm on a model. No alarm was asserted on the model as expected. Spectrum Fault Isolation not suppressing or asserting alarms as expected.

In the following screen shot, the circled router model was down and should have alarmed Critical with the "DEVICE HAS STOPPED RESPONDING TO POLLS" alarm. However, Spectrum did not assert a Critical alarm. The model stayed green but could not be contacted by Spectrum.



Cause:

The 0x10d35 event associated with the "DEVICE HAS STOPPED RESPONDING TO POLLS" alarm was modified as follows:

0x00010d35 R CA.EventPair, 0x10d30, "0xfff0000e -:-", 600 R CA.EventCombo, "0xfff00030 -:-", 300, "0x10d30 -:-"

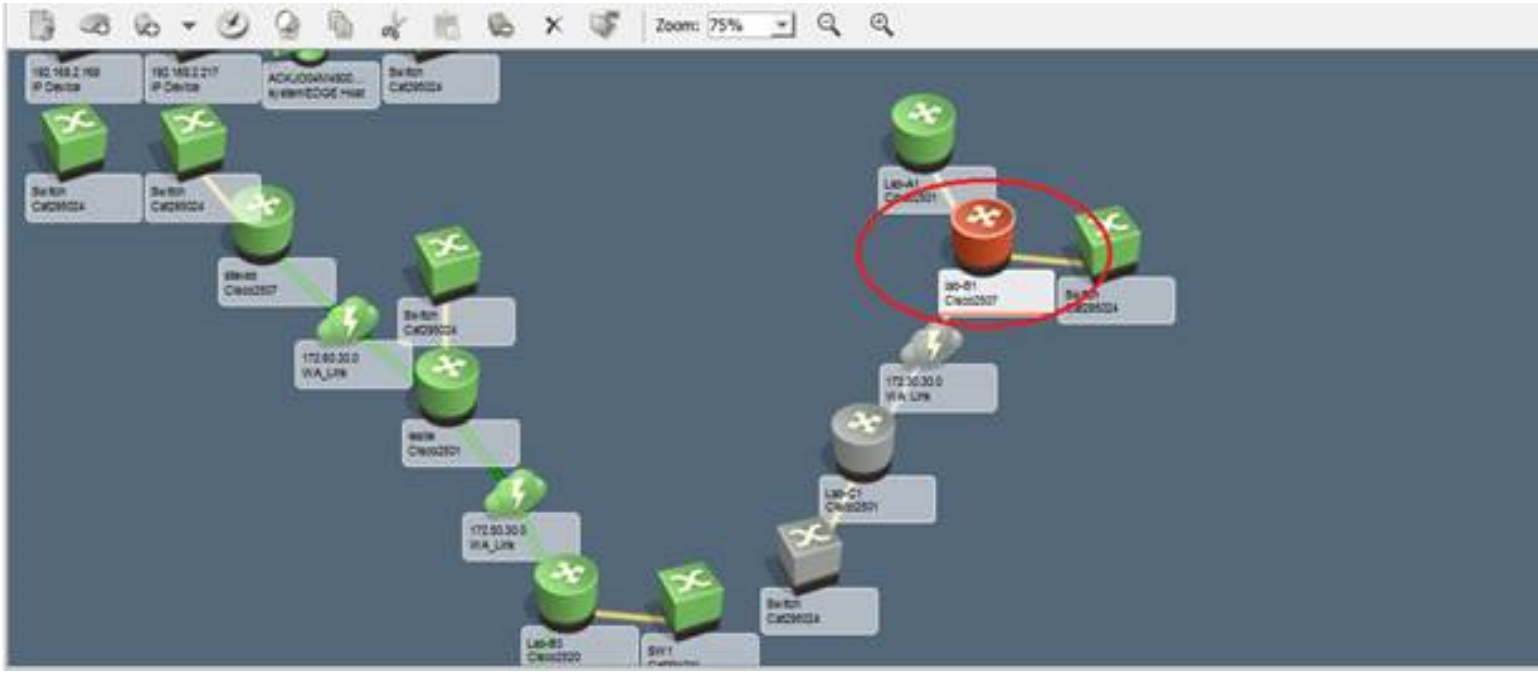
Out of the box, the 0x10d35 event is defined in the $SPECROOT/SS/CsVendor/Cabletron/EventDisp file as follows:

0x00010d35 E 75 A 3, 0x00010009,N

Resolution:

Modifying the out of the box events may have undesirable results. The underlying Fault Isolation, Impact Analysis and Fault Suppression code is looking for specific events with specific conditions and specific probable cause codes in order to function properly. Changing any one of these from the default may have undesirable results.

In the above scenario, after changing the 0x10d35 event back to the out of the box definition and replicating the outage, Spectrum alarmed as expected:



AlertMap Files

SNMP Trap Overview

An SNMP trap is sent out as a trap PDU (Protocol Data Unit). The PDU contains the following pieces of information:

- **Enterprise OID**
  Identifies the company responsible for a device sending the trap. For example, 1.3.6.1.4.1.X is an enterprise OID where X identifies the enterprise (for example, Sun). The numbers preceding the X represent a hierarchy of global bodies responsible for the management of information. The Internet Assigned Numbers Authority (IANA) allocates the enterprise level numbers that identify companies and their management MIBs on the MIB tree. For more information, see their website, http://www.iana.org.
- **Network Address**
  Specifies the network address of the managed element initiating the trap.
- **Generic Trap Identifier**
  This can be a value from 0 through 6. There are six standard industry traps within the SNMP protocol. These traps have a generic trap identifier of 0-5. The number 6 indicates that the trap is an enterprise-specific trap. Enterprise specific traps are proprietary traps that are created for developer-specific types of managed nodes. Proprietary MIBs define these traps.
- **Specific Trap**
  Specifies the specific trap number as listed in the trap definition of the trap MIB.
- **Time Stamp**
  Specifies the time at which the trap was created.
- **Variable Bindings**
  Specifies the variables and values that are defined in the trap. These variables are generally pointers to other MIB objects.

For example, when a redundant power supply fails in a Cisco router or switch, the following information is sent in the trap PDU:

- Network address of the device
- Timestamp of the trap
- Enterprise OID: 1.3.6.1.4.1.9
- Generic Trap ID: 6
- Specific Trap ID: 5
- Variable Binding(s): 1.3.6.1.4.1.9.9.13.1.5.1.2, 1.3.6.1.4.1.9.9.13.1.5.1.3

The network address and the timestamp information vary depending on the device and the time that the trap was sent.

The enterprise OID identifies the vendor company using the last two digits. In this example, 9 indicates a trap that is generated by a Cisco device.

The generic trap ID of 6 indicates that this trap is an enterprise-specific trap that is defined by a proprietary MIB. The specific trap ID of 5 is the number that is assigned to the trap in the referenced Cisco MIB. The following portion of the Cisco environment monitoring MIB (CISCO-ENVMON-MIB) defines this trap.

```
ciscoEnvMonRedundantSupplyNotification TRAP-TYPE
-- Reverse mappable trap
    ENTERPRISE ciscoEnvMonMIBNotificationPrefix
    VARIABLES {
        ciscoEnvMonSupplyStatusDescr, ciscoEnvMonSupplyState }
-- Status
-- mandatory
    DESCRIPTION
        "A ciscoEnvMonRedundantSupplyNotification is sent if the
        redundant power supply (where extant) fails. Since such a
        notification is usually generated before the shutdown state is
        reached, it can convey more data and has a better chance of being
        sent than does the ciscoEnvMonShutdownNotification."
    ::= 5
```

This trap definition has two variables (ciscoEnvMonSupplyStatusDescr and ciscoEnvMonSupplyState) that are sent as variable bindings. Such variables are actually references to other managed objects defined by the MIB. The OIDs sent in the variable bindings represent these managed objects.

The following excerpts from the MIB define ciscoEnvMonSupplyStatusDescr and ciscoEnvMonSupplyState:

```
ciscoEnvMonSupplyStatusDescr OBJECT-TYPE
    SYNTAX DisplayString(SIZE(0..32))
--         Rsyntax OCTET STRING(SIZE(0..32))
    ACCESS read-only
    STATUS mandatory
    DESCRIPTION
        "Textual description of the power supply being instrumented.
        This description is a short textual label, suitable as a human-
        sensible identification for the rest of the information in the
        entry."
    ::= { ciscoEnvMonSupplyStatusEntry 2 }
ciscoEnvMonSupplyState OBJECT-TYPE
    SYNTAX CiscoEnvMonState
--         Rsyntax INTEGER {
--             normal(1),
--             warning(2),
--             critical(3),
```

```
--             shutdown(4),
--             notPresent(5),
--             notFunctioning(6)
--             }
    ACCESS read-only
    STATUS mandatory
    DESCRIPTION
        "The current state of the power supply being instrumented."
    ::= { ciscoEnvMonSupplyStatusEntry 3 }
```

The ciscoEnvMonSupplyStatusDescr variable has a string value describing the power supply, and the ciscoEnvMonSupplyState variable can have a value of 1, 2, 3, 4, 5 or 6 depending on its status. The current value for each variable is detected using the variable bindings in the trap PDU.

About Mapping a Trap to a DX NetOps Spectrum Event

When DX NetOps Spectrum receives a trap, it must be associated with a specific DX NetOps Spectrum event for DX NetOps Spectrum to use the trap information. This association is made in an AlertMap file.

NOTE
DX NetOps Spectrum can receive SNMP traps from devices that have been modeled using the Pingable model type. To enable this association, you must set the enable_traps_for_pingables variable in the DX NetOps Spectrum .vnmrc file to TRUE. For information about how to do this, see the Distributed SprectroSERVER Administration section. The AlertMap file for the Pingable model type is located in the <*$SPECROOT*>\SS\CsVendor\Cabletron\Pingable directory.

About Processing Alerts with AlertMap Files

The IP address of the managed element issuing the trap is sent as a part of the trap information. DX NetOps Spectrum uses the IP address to identify the model that represents the managed element issuing the trap. From this information, DX NetOps Spectrum is able to identify the model type that is associated with the managed element.

To process the trap correctly, DX NetOps Spectrum refers to the AlertMap file. Depending on where they reside, AlertMap files can be applied globally (that is, to all DX NetOps Spectrum model types) or only to models of a specific model type.

Thus, if you want to change the trap mapping for a particular model type only, you must modify the AlertMap file for that model type. If an AlertMap file at the model type level does not exist, you must create one and must make your changes there.

If you want to change how an alert is mapped globally (that is, for all model types), you need to find all AlertMap files that specify a mapping for that trap, and make your changes to each one of these files.

NOTE
Global AlertMap files apply to all vendor model types, not just those models types created by the vendor who created the file.

AlertMap File Location

NOTE
Default trap mappings are located in the <*$SPECROOT*>/SS/CsVendor directory while MIB Tools customized trap mappings are located in the <*$SPECROOT*>/custom/Events/AlertMap directory. MIB Tools' customized trap mappings are preserved when you upgrade DX NetOps Spectrum, and they take precedence over any existing default trap mappings. For more information about working with custom trap mappings and default trap mappings, see Map Tab.

Global AlertMap files are located in <*$SPECROOT*>/SS/CsVendor/<*developername*>/AlertMap, where <*developername*> is usually the name of the vendor, manufacturer, or developer that is associated with the model type.

In some instances, CA uses something other than the developer name for the directory. For example, the IETF directory contains the AlertMap file that maps standard RFC traps.

If the AlertMap file is specific to the model type, it is located in <*$SPECROOT*>*/SS/CSVendor/* <*developername*>/ <*model_type_name*>AlertMap, where:

<*developername*> is the name of the vendor, manufacturer, or developer that is associated with the model type (for example, Compaq). If you are developing your own management module, your developer name is used here.

<*model_type_name*> is the name of the model type.

If a mapping for a trap exists in both a model type AlertMap file and a global AlertMap file, the model type AlertMap file takes precedence for that particular model type.

When you map traps using MIB Tools, entries are generated in the following file on all SpectroSERVERs in your DSS environment:

<*$SPECROOT*>/custom/Events/AlertMap

The mapping information for a trap in these files overrides any mapping information that previously existed for that same trap in other files or directories on the SpectroSERVER.

NOTE
The name of every AlertMap file is always “AlertMap.” No file extension is used in the Windows environment.

NOTE

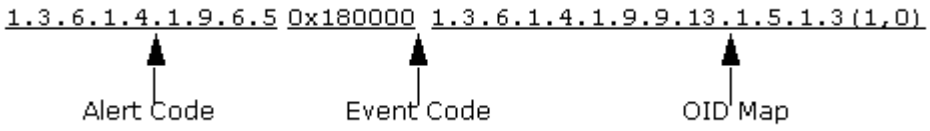
For more information about managing MIBs and traps, see the Certifications section.

NOTE

Trap mappings for the two traps, jnxVpnIfUp and jnxVpnIfDown are removed from the AlertMap file located at <$SPECROOT>/SS/CSVendor/junpr_rtr/ directory. The VPN Manager Explorer view does not list the Device models under VPN Site models. So, the JnxVPN traps assert alarms on VPN Manager model instead on the device model.

AlertMap File Syntax

If the appropriate AlertMap file is found, DX NetOps Spectrum looks for an entry matching the trap. Each entry in the Alert Map file has three components: the alert code, the event code, and the OID map.



Alert Code

The alert code consists of three pieces of information from the trap: the Enterprise OID string, the generic trap identifier, and the specific trap identifier.

1.3.6.1.4.1.9: Enterprise OID (in this case indicating a Cisco device).

6: The Generic Trap Identifier (in this case the 6 indicates an Enterprise specific trap).

5: Specific Trap Identifier (in this case 5).

Event Code

The event code is a 4-byte integer that is expressed in hexadecimal format. Each event code has two parts: the first 2 bytes contain the developer ID of the developer who created the file, and the last 2 bytes identify the event with a unique number relative to all other event codes for that particular developer.

If the event code is zero, an event is not generated for that particular alert.

If the event code is non-zero, DX NetOps Spectrum maps the alert variables to event variables using the OID map.

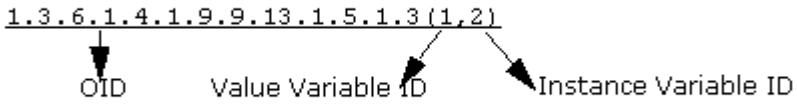
OID Map

The trap that you are mapping can include one or more pieces of variable information, which is known as variable bindings. Each of these variable bindings provides information about the trap. You can select to map these bindings to event variables so that the information is used by DX NetOps Spectrum.

Variable bindings and the information about how DX NetOps Spectrum maps them are specified in the OID map section of the alert map entry. A single alert map entry can have multiple OID maps that are associated with it indicating that there were many variable bindings that are sent with the SNMP trap. These OID maps are separated by the backslash (\) character and a new line as in the following example.

```
1.3.6.1.4.1.9.6.5 0x180000 1.3.6.1.4.1.9.9.13.1.5.1.3(1,2)\
1.3.6.1.4.1.9.9.13.1.5.1.2(4,0)
```

As shown in the following example, the OID map can be broken down into three parts: the OID, the value variable ID, and the instance variable ID.



The OID identifies the specific variable being sent with the trap. The previous OID references the ciscoEnvMonSupplyState variable in the Cisco Environment monitoring MIB (CISCO-ENVMON_MIB).

The value variable ID stores the value of the variable that is sent in the variable binding. Any integer value can be used here; however, it must be different from the integer that is used for the instance variable ID. A value of zero indicates that you do not want to store the value of the variable binding.

The instance variable ID stores the instance portion of the OID. If your variable binding identifies a particular object from a table variable within the trap MIB, it is likely to include an instance ID. Any integer value can be used here; however, it must be different from the integer that is used for the value variable ID. A value of zero indicates that you do not want to store the value of the instance variable.

> **WARNING**
> Do not use spaces between the OID, the value variable ID, and the instance variable ID.

Comments

There are two comment identifiers that allow you to add comments to the AlertMap file: # or //. Text that is entered after one of these identifiers and before the start of the next line is ignored when processing the AlertMap file.

For example:

```
#Comment
0.0 0x10306 #Comment
1.0 0x10307 //Comment
```

```
2.0 0x220001  1.3.6.1.2.1.2.2.1.1(1,2)
3.0 0x220002  1.3.6.1.2.1.2.2.1.1(1,2)\
              1.3.6.1.2.1.2.2.1.3(4,0)
//Comment
//Comment
4.0 0x1030a
5.0 0x1030b
1.3.6.1.4.1.45.6.271 0x1060f 1.3.6.1.4.1.45.1.2.1.9.2.1.2(3,4) #Comment
```

As shown in OID Map, the backslash (\) character is used as a line continuation character. You can also use comments when using the line continuation character.

For example:

```
3.0 0x220002  1.3.6.1.2.1.2.2.1.1(1,2)\ #Comment
              1.3.6.1.2.1.2.2.1.2(3,0)\
                //Comment
              1.3.6.1.2.1.2.2.1.3(4,0)
```

NOTE
Inline and multiline comments are not supported.

How DX NetOps Spectrum Maps Alert Variables to Event Variables

DX NetOps Spectrum maps alert variables to event variables as follows:

1. DX NetOps Spectrum scans the AlertMap file entry to find an OID Map whose OID either exactly matches the trap variable's OID, or is a prefix of the trap variable's OID.
2. If more than one OID map has an OID that is a prefix of the trap variable's OID, DX NetOps Spectrum chooses the OID with the longest prefix (best match).
3. If an OID map is found, DX NetOps Spectrum examines its value variable ID to decide whether to translate the trap variable's value into an event variable. If an OID map is not found, DX NetOps Spectrum ignores the alert variable.
4. If the value variable ID is zero, DX NetOps Spectrum ignores the trap variable's value. Otherwise, the type, length, and value of the event variable are obtained from the trap variable, and an event variable is constructed. The value variable ID can then be used to represent the value of the variable binding in an Event Format file.
5. DX NetOps Spectrum examines the OID Map to decide whether to translate the trap variable's instance ID into an event variable. If the OID in the OID Map exactly matches the trap variable's OID, there is no instance ID to translate. If the instance variable ID in the parameter is zero, the instance OID is ignored. If the instance ID exists and the instance variable ID is non-zero, an event variable is constructed. The instance variable ID can then be used to represent the value of the OID instance in an Event Format file.

Error Messages

If DX NetOps Spectrum is unable to identify the model for a given IP address, an event is generated on behalf of the VNM model indicating that a trap was received from an unknown SNMP device (event 0x00010802). Contained within this event are details about the trap, including the agent IP address, enterprise OID, trap code, community name, and variable binding data.

If DX NetOps Spectrum can properly identify the model for the trap source, but it cannot find an entry for the specific trap code in the AlertMap file, an event indicating that an unknown alert was received (event 0x00010801) is generated on behalf of that model. Contained within the event are details about the trap, including the agent IP address, device type, device time, trap type, and variable binding data.

SNMPv2 Support

DX NetOps Spectrum supports the receipt and processing of SNMPv2 format InformRequests and traps as defined by RFC 2576, “Coexistence between Version 1, Version 2, and Version 3 of the Internet-Standard Network Management Framework.”

InformRequest Support

When DX NetOps Spectrum receives an SNMPv2 InformRequest, it is decoded and converted to SNMPv1 format as specified in RFC 2576. A response to the InformRequest is generated and sent back to the inform originator.

How an SNMPv2 Trap is Mapped to a DX NetOps Spectrum Event

If you are mapping SNMPv2 traps to DX NetOps Spectrum events, you need to reference the translated trap in the AlertMap file.

The following is an overview of how an SNMPv2 trap is translated. For complete information about this process, see RFC 2576. Section 3.2 of the RFC explains how an SNMPv2 trap is translated into an SNMPv1 trap so that it can be used in an SNMPv1 environment.

1. The SNMPv1 enterprise OID for the trap is determined as follows:
   a. If the SNMPv2 snmpTrapOID parameter is one of the standard traps (defined in RFC 1907), then set the value of the SNMPv1 enterprise parameter to the value of the snmpTrapEnterprise.0 variable binding if it exists. If it does not exist, set the value to snmpTraps.
   b. If the SNMPv2 snmpTrapOID parameter is not a standard trap, the following criteria is used:
      If the next-to-last sub-identifier of the snmpTrapOID is 0, then find the enterprise number by removing the last two sub-identifiers.
      snmpTrapOID = 1.3.6.1.4.1.1916.4.1.0.1
      Enterprise number = 1.3.6.1.4.1.1916.4.1
      If the next-to-last number is not 0, then find the enterprise number by removing the last sub-identifier.
      snmpTrapOID = 1.3.6.1.4.1.5486.1.3.8
      Enterprise number = 1.3.6.1.4.1.5486.1.3
2. The SNMPv1 generic trap identifier for the trap is determined as follows:
   a. If the SNMPv2 snmpTrapOID parameter is a standard trap as defined in RFC 1907, use the standard generic trap parameter for that trap (0-5).
      standard trap = 1.3.6.1.6.3.1.1.5.1 (cold start)
      generic trap identifier = 0
   b. If the SNMPv2 snmpTrapOID parameter is not a standard trap, set the generic-trap parameter to 6.
      snmpTrapOID = 1.3.6.1.4.1.5486.1.3.8
      generic trap identifier = 6
3. The SNMPv1 specific trap parameter is determined as follows:
   a. If the SNMPv2 snmpTrapOID parameter is a standard trap as defined in RFC 1907, set the specific-trap parameter to 0.
      standard trap = 1.3.6.1.6.3.1.1.5.1 (cold start)
      specific trap parameter = 0
   b. If the SNMPv2 snmpTrapOID parameter is not a standard trap, set the specific-trap parameter to the last sub-identifier of the SNMPv2 snmpTrapOID parameter.
      snmpTrapOID = 1.3.6.1.4.1.5486.1.3.8
      specific trap parameter = 8
4. The SNMPv2 variable bindings are converted directly to SNMPv1 bindings. As noted in RFC 2576, variable bindings of type Counter64 cannot be translated.

Example:

If you are sending the following SNMPv2 snmpTrapOID to the SpectroSERVER: 1.3.6.1.4.1.5486.1.3.8

Use the following OID as the alert code in the AlertMap file: 1.3.6.1.4.1.5486.1.3.6.8.

Enterprise OID: 1.3.6.1.4.1.5486.1.3

Generic Trap Number: 6

Specific Trap Number: 8

About Event Disposition Files

When DX NetOps Spectrum receives an SNMP trap and is mapped to a DX NetOps Spectrum event that is generated for the model, an *event disposition file* is used to determine how to process the event. The processing instructions in an event disposition file (an ASCII text file) can include any of the following information:

- Whether the event is logged
- The severity of the event
- Whether the event generates an alarm of a specific severity
- Whether the event clears one or more alarms
- Whether the event triggers an event rule (a series of events that are monitored and that trigger another event when they occur in a specific pattern or time frame)

DX NetOps Spectrum predefined events all have processing instructions that are defined in global and model type-specific event disposition files. In addition, whenever you create a new, custom event (either using MIB Tools, to map a trap to a new event, or later, using Event Configuration), a custom event disposition file is automatically created. Typically manual creation of the event disposition file is not required.

> **WARNING**
> A few types of modification, such as adding event-processing procedures to event maps, must be done in a text editor. For most other event modifications, we recommend specifying the processing instructions using Event Configuration. The Event Configuration utility can save your customizations to one or more landscapes.

If you are adding trap support for a new device, first use MIB Tools to map the traps to new DX NetOps Spectrum events and specify basic event settings. Then launch Event Configuration (it can be launched directly from MIB Tools) and can complete the event configuration. This workflow avoids most manual modifications to event disposition files. However, we have provided reference information about the proper syntax to use if manual modifications are required.

Location of Event Disposition Files

The name of every event disposition (EventDisp) file is always EventDisp.

> **NOTE**
> In the Windows environment, no file extension is used.

The EventDisp files that support the events provided with DX NetOps Spectrum are installed in the following directories:

- *$SPECROOT*/SS/CsVendor/*vendor_directory*
  An EventDisp file in this location defines the processing for all events created by the developer that are *global* in scope. The *vendor_directory* variable is the name of the developer, vendor, or manufacturer for which the EventDisp file is used.

  > **NOTE**
  > In some instances, CA uses something other than the developer name for the developer-specific directory; for example, the IETF directory contains the EventDisp file that specifies the processing for events that result from standard RFC traps.
- *$SPECROOT*/SS/CSVendor/*vendor_directory*/*model_type_name*
  An EventDisp file in this location defines the processing for all events that are created by the developer whose scope is *limited to the model type* represented by *model_type_name*. In this case, *vendor_directory* is the name of the developer, vendor, or manufacturer for which the model type was created (for example, Cisco).

NOTE
If an event map entry exists in both a global EventDisp file and a model type-specific EventDisp file, the event map entry in the model type-specific file takes precedence.

If you customize the event processing for the DX NetOps Spectrum predefined events, or if you create new custom events using MIB Tools or Event Configuration, a custom EventDisp file is created in the following directory or in one of its subdirectories:

$SPECROOT/custom/Events

NOTE
The event map entries in a custom EventDisp file override those entries in the predefined DX NetOps Spectrum EventDisp files.

File Syntax of Event Disposition Files

Each line in an event disposition (EventDisp) file is called an *event map*, and each event map can specify one or more event processing behaviors, such as whether the event should be logged or whether it should generate an event. The following syntax is used for an event map:

```
<eventcode> E <eventseverity> <processing parameters> S <sbgw processing flag>
```

- **<eventcode>**
  Specifies the event code of the DX NetOps Spectrum event for which the processing behavior is being defined. The event code is defined in the AlertMap file that maps the trap to the event, or it is specified within the code that generates the event. The event code must be specified for DX NetOps Spectrum to process the event.
- **E**
  (Optional) Indicates that the event data should be logged by the Archive Manager to the Distributed Data Manager (DDM) database. If the E flag is not used, the event data is temporarily logged, but it is not preserved when the SpectroSERVER is shut down and then restarted.
- **<eventseverity>**
  Specifies the relative severity of the event on a scale of 0 to 100, where 0 is the least severe and 100 is the most severe. If a value for event severity is not specified, DX NetOps Spectrum uses a default value of 0.

  NOTE
  The event severity parameter is not currently used by the event management system. However, if you are logging the event, you are advised to assign an event severity value since use of this parameter may be incorporated into event processing in the future. If you are not logging the event, an event severity value should not be assigned.
- **<processing parameters>**
  Specifies additional event processing behaviors, such as whether the event generates an alarm or clears one or more alarms. The topics in this section provide detailed information on the proper syntax for various event processing behaviors.
- **S <sbgw processing flag>**
  (Optional) Specifies whether an event should be registered for Southbound Gateway processing or not. It applies to modeltype specific entries only and only those modeltypes derived from the southbound modeltype fragment. The S is followed by either of the following sbgw processing flags:
  - + (process for Southbound Gateway: S+)
  - - (do not process for Southbound Gateway: S-)

Because the default sbgw processing flag setting is '+', an entry without the 'S' flag present will always be processed by the Southbound Gateway. Setting any entry to 'S-' adds a modeltype specific EventDisp action without it being processed by the Southbound Gateway.

While an event does not require an event map in an EventDisp file, most events have one. If an event does *not* have an event map in an EventDisp, the event is logged in the DDM database by default (which means it is preserved when the SpectroSERVER is shut down and then restarted), but no additional processing takes place. If an event *does* have an event map, the event is processed according to the event map.

Note the following about EventDisp files:

- Empty lines in the EventDisp file are ignored.
- If a single event map spans more than one line, a backslash '\' at the end of each line must be used to help ensure that DX NetOps Spectrum considers the next line as a part of the event map.

Generating Alarms

The following syntax is used to generate an alarm:

```
<eventcode> E <eventseverity> A <alarmseverity>,<alarmcause>
```

- **A**
  Indicates that an alarm is generated when the specified event occurs.
- **<alarmseverity>**
  Specifies a number between 0 and 6 that identifies the severity of the alarm:
  – 0 (Normal)
  – 1 (Minor)
  – 2 (Major)
  – 3 (Critical)
  – 4 (Maintenance)
  – 5 (Suppressed)
  – 6 (Initial)
  Each severity in the preceding list is associated with a color-coded condition. When an alarm is asserted on a model, the associated condition color is displayed on the model's icon to reflect the alarm status.
  You can also specify an alarm severity of Variable or Conditional, each of which evaluates to one of the numeric severity levels. The following syntax is used to indicate a severity level of Variable:
  ```
  { v <event_variable_ID> }
  ```
  – **<event_variable_ID>**
    Specifies the ID of the event variable in the event to evaluate to determine the alarm severity level.
  Similarly, the following syntax is used to indicate a severity level of Conditional:
  ```
  { v <event_variable_ID> <folder_name>.<file_name> }
  ```
  – **<event_variable_ID>**
    Specifies the ID of the event variable in the event to evaluate.
  – **<folder_name>**
    Specifies the severity mapping file to use to determine the alarm severity level.
  – **<file_name>**
    Specifies the severity mapping file to use to determine the alarm severity level.

    NOTE
    If a severity is not specified in the event map, DX NetOps Spectrum uses a default value of 0 (Normal).
- **<alarmcause>**
  Specifies a number that is used to identify the probable cause file that contains the messages associated with the alarm.

Example:

The following event map serves as an example:

```
0x3e00002 E  50  A  2,0x3e00003
```

The example specifies the following about an event with an event code of 0x3e00002:

- It is logged in the Distributed Data Manager (DDM) database by the Archive Manager for historical and reporting purposes.

  NOTE
  Events for a model that are not logged in the DDM database are displayed on the Events tab in OneClick only if they are generated while the Events tab for that model is displayed.
- It has a severity level of 50.
- It generates a major (orange) alarm whose alarm cause code is 0xe00003.

Generating Alarms for Events Based on the Values of Event Variables

Event discriminators are references to event variables that let you to generate alarms for events based on the values of the variables.

The following syntax is used to generate an alarm using event discriminators:

```
<eventcode> E <eventseverity> A <alarmseverity>,<alarmcause>,<eventdiscriminators>
```

where <eventdiscriminators> is a comma-separated list of one or more event variable IDs that indicate the event variables to examine to determine whether to generate an alarm. These are the event variable IDs that are mapped (in the AlertMap file) to the OIDs of the variable bindings sent with the trap.

The following event map serves as an example:

```
0x3b10011 E 70 A 1,0x3b10011,1,3
```

This example specifies that when an event with an event code of 0x3b10011 is generated, if an existing alarm with an alarm cause code of 0x3b10011 already exists on the model, another alarm for the same event is generated only if the values for *both* event variables 1 and 3 are *different* in the new event when compared to current alarms on the model generated from the same event.

NOTE
The values of event variables are also stored in the alarms that are generated based on events. This means you can also use event discriminators to differentiate multiple occurrences of an alarm and clear alarms based on the values of the variables.

Generating Alarms Unconditionally for Each Event

By default, if an alarm exists on a model for a given event, DX NetOps Spectrum does not generate a new alarm each time the same event occurs. However, the U flag can be used to change the default behavior and generate a new alarm unconditionally each time the same event occurs. The syntax is as follows:

```
<eventcode> E <eventseverity> A <alarmseverity>,<alarmcause>,U
```

This following event map serves as an example:

```
0x3dc0000 E 50 A 1,0x3dc0000,U
```

Generating Alarms That Users Cannot Clear

By default, users can clear alarms. However, the N flag can be used to change the default behavior so that users cannot clear an alarm. The syntax is as follows:

```
<eventcode> E <eventseverity> A <alarmseverity>,<alarmcause>,N
```

The following event map serves as an example:

```
0x3dc0000 E 50 A 1,0x3dc0000,N
```

Generating Alarms That Are Not Persistent

By default, alarms are persistent, that is, they are retained in memory if the SpectroSERVER is shut down and restarted. However, the T flag can be used to change the default behavior so that an alarm is not persistent. The syntax is as follows:

```
<eventcode> E <eventseverity> A <alarmseverity>,<alarmcause>,T
```

The following event map serves as an example:

```
0x3dc0000 E  50  A  1,0x3dc0000,T
```

Combining the U, N, and T Flags

Any combination of the U, N, and T flags can be used within an event map.

As an example, the following event map generates a unique alarm for each event that has an event code of 0x3dc0000. The alarm cannot be cleared by users, and it is not persistent.

```
0x3dc0000 E 50 A 1,0x3dc0000,U,N,T
```

The N flag and the T flag can be used with event discriminators as shown in the following example, which is a variation of the event map described in Generating Alarms for Events Based on the Values of Event Variables.

```
0x3b10011 E 70 A 1,0x3b10011,1,3,N,T
```

Specify an Event Frequency

The F flag can be used to detect if an event is occurring with abnormal frequency within a specified period of time. Use event rate rules to generate events for this purpose. The syntax described in this section is supported only to preserve compatibility with EventDisp files created for versions prior to version 6.5.

The syntax for using the F flag in an event map is as follows:

```
<EventCode> E <EventSeverity> F <OccurenceLimit> <Duration> <FrequencyEventCode>
```

- **F**
  Indicates how frequently the event is evaluated.
- **<OccurenceLimit>**
  Specifies the number of times that the event must occur.
- **<Duration>**
  Specifies the amount of time in seconds in which the number of events specified in <OccurenceLimit> must occur to generate an event.
- **<FrequencyEventCode>**
  Specifies the event code of the event to generate if the specified number of events occurs within the specified period of time.

Specify an Event Duration

You can use the D flag to detect that a second event in what was expected to be a pair of events did not occur within a specified period of time.

> **NOTE**
> Use event pair rules to generate events for this purpose. The syntax described in this section is supported only to preserve compatibility with EventDisp files created for versions prior to version 6.5.

The syntax for using the D flag in an event map is as follows:

```
<FirstEventCode> E <EventSeverity> D <SecondEventCode> <Duration> <DurationEventCode>
```

- **D**
  Indicates that the duration of the time between events is evaluated.
- **<SecondEventCode>**
  Specifies the event code of the second event that should occur.
- **<Duration>**
  Specifies the amount of time in seconds to wait for the second event to occur.
- **<DurationEventCode>**
  Specifies the event code of the event to generate if the second event does not occur within the specified period of time.

Clearing Alarms

You can specify that an event can clear any of the following types of alarms:

- An alarm with a specific alarm cause code that was created without event discriminators.
- All alarms with a specific alarm cause code that were created based on event discriminators if their variable values *match* the variables in the alarm-clearing event.
- All alarms with a specific alarm cause code that were created based on event discriminators *regardless* of whether their variable values match those in the alarm-clearing event.

Clear Alarms Created Without Event Discriminators

The following syntax is used to clear an alarm that was not created with event discriminators (which means there is only one instance of the alarm, and it does not contain copies of the event variables):

```
<eventcode> E <eventseverity> C <alarmtobecleared>
```

- **<eventcode>**
  Specifies the event code of the event.
- **E**
  Indicates the Archive Manager logs the event data to the Distributed Data Manager (DDM) database.
- **<eventseverity>**
  Specifies the relative severity of the event on a scale of 0 to 100, where 0 is the least severe and 100 is the most severe.
- **C**
  Indicates that an alarm be cleared when the specified event occurs.
- **<alarmtobecleared>**
  Specifies the alarm cause code of the alarm to clear.

Example:

```
0xfffff0000 A 1, 0xffff0000
0xfffff0001 C 0xffff0000
```

The first event map generates alarm 0xffff0000 when event 0xfffff0000 occurs. The second event map clears alarm 0xffff0000 when event 0xfffff0001 occurs.

Clear Alarms Based on Event Discriminator Values

In the context of clearing alarms, event discriminators are the IDs of the event variables to examine in the alarm-clearing event and an alarm to determine whether to clear the alarm as a result of the event.

Recall that the event variable IDs are mapped (in the AlertMap file) to the OIDs of the variable bindings that are sent with the trap, and their values are copied from the alarm-generating event to the alarm if the alarm is generated as a result of examination of their values.

Because the values of event variables are also stored in the alarms that are generated based on events, you can use event discriminators to differentiate multiple occurrences of an alarm and clear alarms that are based on the values of the variables. More specifically, the alarm can be cleared if the values in the alarm-clearing event *match* the values that are stored in the alarm.

The following syntax is used to clear an alarm that is based on event discriminator values:

```
<eventcode> E <eventseverity> C <alarmtobecleared>,<eventdiscriminators>
```

- **<eventcode>**
  Specifies the event code of the event.
- **E**
  Indicates that the Archive Manager logs the event data to the Distributed Data Manager (DDM) database.
- **<eventseverity>**
  Specifies the relative severity of the event on a scale of 0 to 100, where 0 is the least severe and 100 is the most severe.
- **C**
  Indicates that an alarm is cleared when the specified event occurs.
- **<alarmtobecleared>**
  Specifies the alarm cause code of the alarm to clear.
- **<eventdiscriminators>**
  Specifies a comma-separated list of one or more event variable IDs that indicate the variables to examine to determine whether to clear the alarm.

Example:

```
0xfffff0000 A 1, 0xffff0000, 1, 2
0xfffff0001 C 0xffff0000, 1, 2
```

Alarm 0xffff0000 is cleared only if the values of event variables 1 and 2 in the alarm-clearing event (0xffff0001) have the same values as those stored in the alarm, which are copied from the alarm-generating event (0xffff0000) when the alarm is generated. If the alarm-clearing event does *not* contain these event variables, the alarm is not cleared.

You can also use the following syntax to specify that a single event clears multiple types of alarms:

```
<eventcode> C <alarmtobecleared>,<eventdiscriminators> C <alarmtobecleared>,<eventdiscriminators>,...
```

Examples of Event Maps That Clear Alarms

In the following example, the first event map specifies that event 0x3dc0004 generates alarm 0x3dc0001. The second event map specifies that event 0x3dc0002 clears alarm 0x3dc0001.

```
0x3dc0004  E  50  A  2,0x3dc0001
0x3dc0002  C  0x3dc0001
```

The following two event maps are the same as those above except both use event discriminators. The first event map specifies that a new alarm is generated for each 0x3dc0004 event that has unique values for *both* event variables 1 and 3. The second event map clears all alarms with the alarm cause code of 0x3dc0001 if the values in the alarm for variables 1 and 3 *match* the values for the same variables in event 0x3dc0002.

```
0x3dc0004  E  50  A  1,0x3dc0001,1,3
0x3dc0002  C  0x3dc0001,1,3
```

NOTE
If the event map that creates the alarm uses event discriminators, but the event map that clears the alarm does not, the event discriminators are still considered when clearing the alarm.

The following event maps use the same logic as the example above even though the event discriminators are not explicitly stated in the event map that clears the alarm. Collectively, the event maps specify that all alarms with an alarm cause code of 0x3dc0001 should be cleared if the values in the alarm for variables 1 and 3 *match* the values for the same variables in event 0x3dc0002.

```
0x3dc0004  E  50  A  1,0x3dc0001,1,3
0x3dc0002  C  0x3dc0001
```

The following event map uses the U flag to generate a unique alarm each time that event 0x3dc0004 occurs. The event that clears the alarm, event 0x3dc0002, clears all alarms that have an alarm cause code of 0x3dc0001.

```
0x3dc0004  E  50  A  1,0x3dc0001,U
0x3dc0002  C  0x3dc0001
```

In the following example, the first two event maps generate alarms. The third event map uses event 0x3dc0009 to clear alarms with different alarm cause codes. All alarms with an alarm cause code of 0x3dc00010 are cleared, and all alarms with an alarm cause code of 0x3dc00011 are cleared if their values for variables 1 and 3 match the values for the same variables in event 0x3dc0009.

```
0x3dc0006 E 50 A 2,0x3dc00010
0x3dc0007 E 50 A 1,0x3dc00011,1,3
0x3dc0009 C 0x3dc00010 C 0x3dc00011,1,3
```

Clearing Alarms Regardless of Event Discriminator Values

Use the following syntax to clear all instances of an alarm that were generated based on event discriminators regardless of whether the values in the alarm-clearing event match the values that are stored in the alarm instances:

```
<eventcode> E <eventseverity> C <alarmtobecleared>,A
```

- **<eventcode>**
  Specifies the event code of the event.
- **E**
  Indicates that the Archive Manager logs the event data to the Distributed Data Manager (DDM) database.
- **<eventseverity>**
  Specifies the relative severity of the event on a scale of 0 to 100, where 0 is the least severe and 100 is the most severe.
- **C**
  Indicates that an alarm be cleared when the specified event occurs.
- **<alarmtobecleared>**
  Specifies the alarm cause code of the alarm to clear.
- **A**
  Specifies that all alarm instances be cleared regardless of the values of the variables that are stored in the events.

Example:

```
0xffff0000 E 50 A 1,0xffff0000,1,2,3
0xffff0002 E 50 C 0xffff0000,A
```

In this example, all instances of alarm 0xffff0000 are cleared when event 0xffff0002 occurs regardless of whether event 0xffff0002 contains event variables 1, 2, and 3, and, even if it does, regardless of whether their values match those stored in the alarms.

About Defining Event Rules

Event rules let you specify a complex decision-making system to indicate how an event is processed. An event rule looks for a series of events to occur on a model in a certain pattern or time frame. If the events occur as the rule specifies, another event is generated for the given model, and that new event must be defined in the EventDisp file so that DX NetOps Spectrum processes them appropriately.

> **WARNING**
> While you can create event rules manually, we recommend that you use the Event Configuration application to do so. This section is provided merely as a reference of the underlying syntax that is used to define rules in EventDisp files.

Event Rule Syntax

Event rules are implemented via event maps using the following syntax:

```
<EventCode> E <EventSeverity> R {<event_discriminators>} <event_rule_name>,
 <event_rule_parameter1>, ...<event_rule_parameterN>
```

- **R**
  Indicates that an event rule is used.
- **{<event_discriminators>}**
  (Optional) Comma-separated list of one or more event variable IDs that indicate the variables to examine to determine whether to generate the rule output event. These are the event variable IDs that are mapped (in the AlertMap file) to the OIDs of the variable bindings sent with the trap.

  > **NOTE**
  > Event discriminators apply to each contributing event in the event rule. For examples of using event discriminators with event rules, see EventRateCounter Rule and EventCombo Rule.
- **<event_rule_name>**

Is expressed using the following syntax:

CA.<RuleName>

<RuleName> specifies one of the following types of rules:

- EventPair
- EventRateWindow
- EventRateCounter
- EventSequence
- EventCombo
- EventCondition
- EventCounter
- Heartbeat
- SingleEvent
- SoloEvent

<eventruleparameter>

Varies depending on which type of rule is being used.

EventPair Rule

The syntax of an event pair rule is as follows:

```
<FirstEventCode> R CA.EventPair, <SecondEventCode>, <GeneratedEventCode>, <time>
```

For example, the following event pair rule generates event 0x0001002f when event 0x0001002a occurs but is not followed by event 0x0001002b within 60 seconds:

```
0x0001002a  R CA.Eventpair, 0x0001002b, 0x0001002f, 60
```

To also log event 0x0001002a and assign it a severity level of 50, the following syntax is used:

```
0x0001002a E 50 R CA.Eventpair, 0x0001002b, 0x0001002f, 60
```

EventPairTimeAttr Rule

The EventPairTimeAttr Rule is similar to EventPair Rule. The difference is that it the Attribute ID is the third parameter instead of the Time window.

The syntax of an event pair rule is as follows:

```
<FirstEventCode> R CA.EventPairTimeAttr, <SecondEventCode>, <GeneratedEventCode>, <Attribute ID>
```

- **Attribute ID**
  Specifies an attribute on the current model (the one where the event was generated one), which holds the time value for the pair rule. It can be used to set individual, model-specific time values for the rule instead of globally defined hardcoded ones.

EventRateWindow Rule

> **NOTE**
> An EventRateWindow rule is an event rate rule that uses a sliding window of time.

The syntax of an EventRateWindow rule is as follows:

```
<TriggerEventCode> R CA.EventRateWindow, <NumberofOccurrences>, <time>, <GeneratedHighRateEventCode>,
 <GeneratedLowRateEventCode>
```

where <GeneratedHighRateEventCode> is the event to generate if the trigger event occurs at the specified frequency in the specified time frame. If you also specify an event for <GeneratedLowRateEventCode>, which is an *optional* parameter, if the frequency drops below the threshold, the rule generates the low rate event. The rule generates the high rate event again only when the frequency threshold is crossed again.

As an example, the following EventRateWindow rule generates event 0x0001002f if five events of type 0x0001002a occur within 60 seconds:

```
0x0001002a R CA.EventRateWindow, 5, 60, 0x0001002f, 0x000100030
```

Once the frequency threshold is crossed and the high rate event (0x001002f) is generated, another rule output event is not generated until the frequency drops below 5 events within 60 seconds. At this point, the low rate event (0x000100030) is generated. The high rate event is not generated again until the frequency threshold is crossed again.

EventRateWindowAttrParams Rule

> **NOTE**
> An EventRateWindowAttrParams rule is an event rate rule that uses a sliding window of time.

The syntax of an EventRateWindowAttrParams rule is as follows:

```
<TriggerEventCode> R CA.EventRateWindow, <Attribute containing NumberofOccurrences>, <Attribute containing
 time window>, <GeneratedHighRateEventCode>, <GeneratedLowRateEventCode>, <GeneratedStopEventCode>
```

where <GeneratedStopEventCode> is the event that is generated to stop the rule. Update the attributes for the model and then generate this stop event to stop the rule instance on that model. The next rate window event starts a new rule instance, which reads and uses the new attribute values.

The EventRateWindowAttrParams rule is similar to the EventRateWindow rule. However, this rule accepts attribute ids instead of direct values for the event occurrence parameter and the time window parameter. These attributes must be present on the model where the event is generated and should contain integer values.

The EventRateWindowAttrParams rule is most useful for detecting an event that is not significant if it happens occasionally, but is significant if it happens frequently. If the event occurs above a certain rate, this rule generates another event. No additional events are generated as long as the rate stays at or above the threshold. But if the rate drops below the threshold and then subsequently exceeds the threshold, another event is generated.

An event can also be generated when the rate drops below the threshold.

> **NOTE**
> See EventRateWindow Rule for descriptions of the <GeneratedHighRateEventCode> and <GeneratedLowRateEventCode> events.

EventRateCounter Rule

> **NOTE**
> An EventRateCounter rule is an event rate rule that uses a sequential window of time.

The syntax of an EventRateCounter rule is as follows:

```
<TriggerEventCode> R CA.EventRateCounter, <NumberofOccurrences>, <time>, <GeneratedEventCode>
```

As an example, the following EventRateCounter rule generates event 0x0001002f if 5 events of type 0x0001002a occur within 60 seconds:

```
0x0001002a R CA.EventRateCounter, 5, 60, 0x0001002f
```

To also log event 0x0001002a and assign it a severity level of 50, the following syntax is used:

```
0x0001002a E 50 R CA.EventRateCounter, 5, 60, 0x0001002f
```

Example: Using Event Discriminators with an EventRateCounter Rule

The following example shows two event discriminators used in an EventRateCounter rule:

```
0x10001 E 50 R {1,2} CA.EventRateCounter, 3, 60, 0xffff0000
```

The event discriminator list, {1,2}, contains variable IDs 1 and 2. Therefore, in order for event 0xffff000 to be generated, event 0x10001 must occur 3 times within 60 seconds, and all 3 instances must contain the same values for variable IDs 1 and 2.

For example, if event 0x10001 occurred 3 times in 60 seconds, and each time variable ID 1 had a value of 10.253.40.57 and variable ID 2 had a value of 65, then event 0xffff0000 would be generated. However, if event 0x10001 occurred 3 times in 60 seconds but the first 2 times variable ID 1 had a value of 10.253.30.57 and the third time it had a value of 10.253.89.60, then 0xffff0000 would not be generated.

EventSequence Rule

An EventSequence rule is an event series rule that requires the series of events to occur in a specific sequence.

The syntax for the EventSequence rule is as follows:

```
<FirstEventCode> R CA.EventSequence, <GeneratedEventCode>, <time>, <SecondEventCode>,
 <ThirdEventCode>,...<NthEventCode>
```

As an example, the following EventSequence rule generates event 0x0001002f when events 0x00010002a, 0x0001002b and 0x0001002c occur, in that order, within 60 seconds.

```
0x0001002a R CA.EventSequence, 0x0001002f, 60, 0x0001002b, 0x0001002c
```

To also log event 0x0001002a and assign it a severity level of 50, the following syntax is used:

```
0x0001002a E 50 R CA.EventSequence, 0x0001002f, 60, 0x0001002b, 0x0001002c
```

EventCombo Rule

NOTE
An EventCombo rule is an event series rule that requires the series of events to occur but the order of occurrence does not matter.

The syntax of an EventCombo rule is as follows:

```
<FirstEventCode> R CA.EventCombo, <GeneratedEventCode>, <time>, <EventCodeA>, <EventCodeB>, ...<EventCodeN>
```

As an example, the following EventCombo rule generates event 0x0001002f if event 0x0001002a occurs, and it is followed by at least one instance each of event 0x0001002b and event 0x0001002c within 60 seconds and in any order.

```
0x0001002a R CA.EventCombo, 0x0001002f, 60, 0x0001002b, 0x0001002c
```

To specify that the new event should be generated but one of several events can first trigger the rule, create a series of n rules where n is the number of events in the combination, and where each rule uses a different event for the trigger. For example, consider the following three rules:

```
0x0001002a R CA.EventCombo, 0x0001002f, 60, 0x0001002b, 0x0001002c
0x0001002b R CA.EventCombo, 0x0001002f, 60, 0x0001002a, 0x0001002c
0x0001002c R CA.EventCombo, 0x0001002f, 60, 0x0001002a, 0x0001002b
```

Using this set of rules, any combination of events 0x0001002a, 0x0001002b, and 0x0001002c occurring at least once within 60 seconds and in any order would generate event 0x0001002f.

To also log event 0x0001002a and assign it a severity level of 50, the following syntax can be used:

```
0x0001002a E 50 R CA.EventCombo, 0x0001002f, 60, 0x0001002b, 0x0001002c
```

Example: Using Event Discriminators with the EventCombo Rule

The following example shows two event discriminators used in an EventCombo rule:

```
0x10001 E 50 R {1} CA.EventCombo, 0xffff0000, 60, 0x10002
```

The event discriminator list, {1}, contains variable ID 1. Therefore, event 0x10001 must occur, and then event 0x10002 must occur within 60 seconds, and each must contain the same values for variable ID 1 in order for event 0xffff000 to be generated.

For example, if event 0x10001 occurred and had 10.253.40.57 as a value for variable ID 1, and event 0x10002 occurred 45 seconds later and had a value of 10.253.40.57 for variable ID 1, then event 0xffff0000 would be generated. However, if event 0x10001 occurred and had 10.253.40.50 as a value for variable ID 1, and event 0x10002 occurred 45 seconds later and had a value of 10.253.40.57 for variable ID 1, then event 0xffff0000 would not be generated.

EventComboInclusive Rule

The EventComboInclusive rule is similar to the EventCombo rule. The difference is that it registers all the combo events, and not just the one which the rule is defined for.

The syntax of an EventComboInclusive rule is as follows:

```
<FirstEventCode> R CA.EventComboInclusive, <GeneratedEventCode>, <time>, <EventCodeA>,
 <EventCodeB>, ...<EventCodeN>
```

As an example, the following EventComboInclusive rule generates event 0x0001002f if either of event 0x0001002a, 00x0001002b or event 0x0001002c occurs:

```
0x0001002a R CA.EventComboInclusive, 0x0001002f, 60, 0x0001002b, 0x0001002c
```

EventCondition Rule

The conditional expressions in an EventCondition rule can compare a variable binding value or a DX NetOps Spectrum attribute value to a user-specified value using standard comparison operators as follows:

```
<FirstEventCode> R CA.EventCondition, "<conditional expression 1>", <event to generate when 1 is
 TRUE>,"<conditional expression n>", <event to generate when n is TRUE>, "default", <default event>
```

- **“<conditional expression x>”**
  Consists of one or more expressions comparing a variable binding value or a DX NetOps Spectrum attribute value to a user-defined value (x represents any value from 1 to n).
- **<event to generate when x is TRUE>**
  Specifies the event that is generated if the conditional expression evaluates to TRUE.
- **“default”, <default event>**
  (Optional) Specifies a default event that is generated if none of the conditions are met. For example, if the following syntax was included at the end of the rule, event 0xffff1234 would be generated if none of the other conditions expressed in the rule were met:
  ```
  "default", 0xffff1234
  ```

  NOTE
  Default can be expressed as “DEFAULT”, “default”, or “Default”.

Conditional expressions are evaluated from left to right and, with some simplification, follow C programming-style evaluations. If the whole condition evaluates to TRUE, then the event is generated.

Condition Syntax

The conditional text is always enclosed in quotation marks as follows:

“condition”

A simple condition is made up of data or objects and comparison operators or methods.

Data or Objects

Each data element or object to be compared in the condition must be contained within curly brackets and must have both a type and a value:

```
{ TYPE VALUE }
```

For example, a comparison that involves an integer value of 2 is expressed as { I 2 }.

The following lists the supported types and their meanings:

Short Symbol	Alternate Names	Meaning	Type Values	Examples
A	Addr ADDR address IP Addr IP Address IP_ADDRESS	Contains an IP address	XXX.XXX.XXX.XXX where each XXX subterm is a number from 0 to 255, and the whole term forms a valid IP address	{ Addr 192.168.1.1 }

a	attr ATTR attribute ATTRIBUTE	References a model attribute of the model for which the event rule is being processed. When evaluated, the attribute's current value is read. The attribute's type is used to determine if comparison is valid.	An attribute ID, specified as a hex number. The leading 0x is optional. The letters a-f may be lower- or uppercase. The reading of table attributes using an object ID or variable data as an index is also supported (see examples).	{ attr 0x11564 } { Attribute A00044 } { attr 0xffff0001 obj 1.1.6.8.0.1 } would read table attribute 0xffff0001, with "1.1.6.8.0.1" as the OID suffix (index). { attr 0xffff0001 VARDATA 2 } would read table attribute 0xffff0001 using the object id contained in the second variable binding as the OID suffix (index).
B	BOOL Bool Boolean boolean	A boolean value	False, true This value is not case-sensitive	{ B True } { boolean false }
H	HEX Hex Hex_ID HEX Id	A hex attribute ID value (this is just a value, not an attribute reference, use 'a' for that purpose)	An attribute ID, specified as hex number. The leading 0x is optional. The letters a-f may be lowercase or uppercase.	{ Hexid 0xffff0123 } { H ABCD } { HEX 0X91 }
I	Int integer INTEGER INT	An integer value	Any number within the range of -214783648 to 214783647	{ Int 10 } { I 98765 } { integer -300 }
L	Unsigned long int LONG long UNSIGNED_LONG_INTEGER LongInt	An unsigned long 64 bit integer	Any number within the range of 0 to 18446744073709551615	{ L 0 } { LongInt 123456789098}
o	Object ID obj obj_id OBJECT	An object ID	X X.X X.X.X and so on where X is an unsigned integer (>= 0)	{ o 1.2.3.4.5.6 } { object_id 1.3.6.1.2.1 } { OBJ 100000.4.5 }
O	Octet Octet String Decimal Octet String DEC Oct_Str Dec_OCTET_str	A tagged octet string comprised of decimal values	#.#.#.... where # is any number between 0 and 255	{ Oct Str 1.2.3.4 } { OCTET_STR 255.0.1.20 } { OCTSTR 10.20.30.40.50 }
R	REAL real Real	A real number (double)	Any number containing a '.' , and possibly followed by an exponent: E|e +|- EXP EXP any number	{ R 1. } { Real 3.1415 } { REAL -2.843E-17 } { R .00001e+20 }

S	String str Str STRING	A string	Any characters enclosed in double quotes	{ S \" a string \" } { String \"another string\" } { str \"12345a@b?c*\" } { S \"\" }
U	unsigned unsigned long unsigned long int ULONG U INT U_long_integer	An unsigned long integer	Any number in the range from 0 to 4294967295	{ uint 1234567890 } { UNSIGNED INT 0 }
v	variable data VARDATA Var_DATA EventAttr event_attr	References an event attribute (variable data) from the current event. Like a model attribute reference, this is evaluated when needed, and the event attribute type is used to check if the comparison is valid	A unsigned integer (> 0)	{v 1 } { VARDATA 2 } { event attr 3 }
X	Hex octet string HEXOCT_STR Hex_Octet HEXOctet	A tagged hexadecimal octet string	XX.XX.XX..... Where XX is a hex number from 0 to FF	{ X 12.01.AB.EF } { HEXOCT AB.CD.EF.01 } { Hex octet string 2.3 } { X a.b.c }

Using the Escape Character

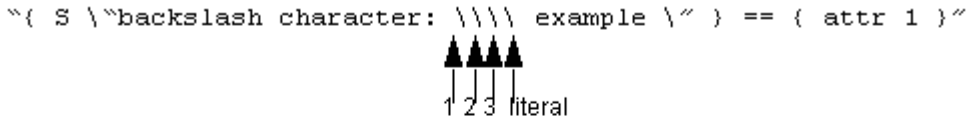
In addition to enclosing the entire condition within quotation marks, you must also enclose a string in quotations marks. Also, to help ensure that the entire condition is parsed properly, the opening and closing quotation marks enclosing the string both must be preceded by a backslash. The following condition, which includes string xyz, serves as an example:

```
"{ S \"xyz\" } == { v 1 }"
```

If you want to include a backslash '\' or a double quote in the string itself, you need 3 backslashes before each of these characters, as shown in the following example where:

- Backslash 3 represents the escape for the literal backslash or quote
- Backslash 2 represents the escape character needed to escape backslash 3 within the string
- Backslash 1 represents the escape character needed to escape backslash 2

This same logic holds true for a double quote example.



Regular expressions also use the backslash ‘ \’ as an escape character. Because the regular expression can be used in a condition, the backslash used within the regular expression as the escape character must be preceded by several backslashes.

Comparing Strings

The strcmp method is used to compare characters in a string (for example, in strings, octet strings, IP Addresses, and so on). Note that the implementation of this method differs slightly from the standard C implementation of strcmp. This method returns TRUE if the two strings are equal, and it returns FALSE if the strings are not equal.

To make use of this method, use the following format:

```
"strcmp({ TYPE <string> }, { TYPE <string> })"
```

For example, the following condition compares an IP Address with a DX NetOps Spectrum attribute whose value is an IP Address. If the two strings are the same, the condition returns TRUE.

```
"strcmp({ A 179.82.253.01 }, { attr 0x00011aec })"
```

Note the following in the example:

- Each type/string pair to be compared is enclosed in curly brackets
- The two type/string pairs are separated by a comma and enclosed in parenthesis
- The name of the method, strcmp, is placed on the left hand side of the parenthesis
- The entire condition is enclosed in quotes

Regular Expressions

The regexp or REGEXP method is used to compare a string to an input pattern. To do this, regular expressions use a series of meta-characters that let you express the pattern of characters that you are looking for. The method returns TRUE if the regular expression input pattern matches the input string; otherwise, it returns FALSE.

To make use of this method, use the following format:

```
"regexp({ TYPE <string> }, { TYPE <input pattern> })"
```

The EventCondition rule supports the syntax of the Perl Compatible Regular Expression (PCRE) package. The following are some of the basic meta-characters supported by the PCRE package and examples of their usage:

Meta-character	Meaning	Example
^	Indicates the beginning of a line.	The following example searches for the string “CA” occurring at the beginning of a line in event variable 1: “regexp({ VARDATA 1 }, { S \“^CA\” })”
$	Indicates the end of a line.	The following example searches for lines ending with the string “CA” in event variable 1: “regexp({ VARDATA 1 }, { S \“CA$\” })”
[]	Encloses a character class. A character class shows some literal text that you would like to let at a certain point within the string.	This example searches for the string “port” followed by a value of 1, 2 or 3 in event variable 1: “regexp({ VARDATA 1 }, { S \“port [1-3] \” })”
*	Indicates zero or more of the specified preceding characters.	This example searches for zero or more occurrences of 172 in the value of the attribute 0x00011aec: “regexp({ attr 0x00011aec }, { S \“(172)*\” })”

+	Indicates one or more of the specified preceding characters.	This example searches for one or more occurrences of 172 in the value of the attribute 0x00011aec: “regexp({ attr 0x00011aec }, { S \“(172)+ \” })”
.	Represents any single character except for a new line character.	This example searches for an occurrence of the word “port” followed by a space and then any single character within event variable 1: “regexp({ VARDATA 1 }, { S \“port . \” })”
|	Separates alternative patterns.	“regexp({ VARDATA 1 }, { S\“interface|port \” })” This example searches for either the word interface or the word port within the event variable 1.
\	Used as a general escape character letting you to use the literal meaning of a meta-character. When you use the escape character within the regular expression, you must be sure to also consider the necessary escape characters to be used within the context of the string and the condition..	This example searches for the string “172.55” within event variable 1: “regexp({ VARDATA 1 }, { S\“172\\\\.55\” })” Because the . character is usually treated as a meta-character within a regular expression, it is necessary to use the escape character (a backslash) to indicate that you would like the . to be treated literally. At the regular expression level, this yields the following syntax: 172\.55. However, since you are using this regular expression within a string, you must precede the backslash with an additional backslash. Reading the expression from left to right, the first backslash represents the escape character needed to escape the second backslash within the string. This yields the following syntax: 172\\.55. Additionally, you are using the string within the context of the condition, therefore each existing \ must have a corresponding backslash to be used as an escape. This yields the following syntax: 172\\\\.55.

Comparison Operators

The following comparison operators are supported for numeric or boolean values:

- **==**
  equal to
- **!=**
  not equal to
- **>**
  greater than
- **<**
  less than
- **<=**
  less than or equal to
- **>=**

greater than or equal to

Most numeric values can be compared with each other even if they are not of the same type. For example, the following condition compares the integer 2 to the value of a DX NetOps Spectrum attribute:

```
"{ I 2 } = = { attr 0x000117dc }"
```

Exists Operator

You can use the exists operator to check for the existence of a variable binding value or other value:

```
exists( <expression> )
```

This can be useful, for example, when you want to evaluate a value if it exists, and exit the event condition rule if it does not. The following spelling variants are supported:

exists

Exists

EXISTS

An exists conditional expression returns TRUE when the expression is valid and contains a value. For example, “exists({ v 1 })” returns TRUE when event variable 1 exists and contains any value.

To terminate an event condition rule without action when an exists conditional expression returns FALSE, you can use the “no action” action (which sends the 0x00010000 null event). The following spelling variants are supported in either all lower case, all upper case, or initial capital letters:

no action

no-action

no_action

As an example, the following event condition rule checks whether event variable 1 exists in event 0xffff0000. If it does not exist, no action is taken. If it does exist, event 0xffff0001 is generated.

```
0xffff0000 E 50 R CA.EventCondition,           \
     " ! Exists( { v 1 } )", "No-Action",      \
     " { v 1 } == { I 1 } ", 0xffff0001
```

The Logical NOT (!)

You can use the logical NOT (!) operator to reverse the logical value of an expression. Apply the logical NOT (!) in the same way as you would when writing C++ code. For example, the following condition compares variable binding 1 and variable binding 2. The logical NOT (!) is applied to the outcome of the comparison. Thus, if variable binding 1 is equal to variable binding 2, the entire expression evaluates to false.

```
"! ({ v 1 } = = { v 2 })"
```

Complex Conditions

More complex conditions can be created which use logical operators and parenthesis to combine simple conditions. Valid logical operators are the following:

&&, which represents AND

||, which represents OR

The following condition includes several subconditions enclosed in braces and linked together using logical operators.

```
"({ I 2 } = = { I 2 }) &&  ({ I 2 } != { I 3 })"
```

For this condition to evaluate to TRUE, both of the subconditions on either side of the && must evaluate to TRUE. Since an integer value of 2 is equal to an integer value of 2, the left side of the condition is TRUE. Since an integer value of 2 is not equal to an integer value of 3, the right side of the condition also evaluates to TRUE. This means that the whole condition evaluates to TRUE.

```
"({ I 3 } = = { I 4 } ) || ({ I 4 } > { I 2 })"
```

For this condition to evaluate to TRUE, the subcondition on the left hand side of the || or the subcondition on the right hand side of the || must evaluate to TRUE. Since 3 is not equal to 4, but 4 is greater than 2, the entire expression evaluates to TRUE.

Multiple subconditions can be used to create the necessary expression. For example, the following condition evaluates to TRUE since 4 is greater than 2, and 3 is less than 8.

```
"({ I 3 } = = { I 2 } || { I 4 } > { I 2 }) && ({ I 3 } < { I 8 } || { I 2 } = = { I 4 })"
```

Nested Conditions

Although simple conditions can be combined together using logical operators to create complex conditions, you cannot use simple conditions as a part of other expressions. A simple condition can have only one comparison operator in it.

For example, the following syntax is not supported. The result of a strcmp() cannot be used as the argument for an equals (==) operator:

```
"strcmp ( { S \"a\" }, {S \"a" } ) = = { B TRUE }"
```

Example: Basic EventCondition Rule

The following example shows a basic EventCondition rule that uses some of the condition syntax described in the previous sections. The first condition that evaluates to TRUE is used, and the event code immediately following that condition is generated.

```
0x00045678 R CA.EventCondition,                                    \
    "regexp({ VARDATA 1 }, { S \"port [1-3] \" })",                        \
    0x00012345,"{ VARDATA 2 } == { attr0x000117dc }",                      \
    0x00012344, "strcmp({ A 179.82.253.01 }, \{ attr 0x00011aec }    \
            )",                     \
0x00122334
```

Example: (Complex EventCondition Rule) Generating an Event Based on a Variable Binding Value

The following example shows an EventCondition rule that generates an alarm based on the value of one of the variable bindings sent with the trap. The event condition rule generates a second event, 0xffff0000, if the value of variable binding 1 is equal to any of the following values: DAT0005, DAT0006, DAT0007, DAT0008, DAT0011, DAT0012, DAT0013, DAT0014, DAT0021, DAT0022, or DAT0023.

```
0x1030f E 50 R CA.EventCondition,                    \
  "regexp( { v 1 },                                      \
           { S \"DAT00(05|06|07|08|11|12|13|14|21|22|23) \" } \
         )",                                             \
  "0xffff0000 -:-"
```

> **NOTE**
> There is a space at the end of the regular expression, which indicates that each pattern must end with a space.

The regular expression first looks for a match between variable binding 1 and DAT00 combined with any of the choices in the brackets (05 , 06 , 07 , etc.).

There is a -:- at the end of the event condition. This symbol specifies that all of the variable binding values from the originating event (0x1030f) should be copied to the new event (0xffff0000).

To generate an alarm when the event condition evaluates to true, an event map for the new event (0xffff0000) that specifies to generate an alarm is needed in the EventDisp file.

EventCounter Rule

The EventCounter rule implements a counter, counting up for 'up' and down for 'down' events. The rule creates an event if a certain threshold is reached.

The syntax of EventCounter rule is as follows:

```
<CountUpEventCode> R CA.EventCounter, <CountDownEventCode>, <threshold>, <ThresholdBreachedEventCode>,
 <ThresholdResetEventCode>
```

- **CountUpEventCode**
  Counts up by one. The first one also initiates the counter rule.
- **CountDownEventCode**
  Counts down by one.
- **threshold**
  The counter threshold (integer number). Once the count reaches (equals) that threshold, the target event is generated
- **ThreaholdBreachedEventCode**
  Generates when the count threshold is reached
- **ThresholdResetEventCode**
  Generates when the count is below the threshold again

Example: EventCounter rule

```
0x0f420001 E 50 R CA.EventCounter, 0x0f420002, 3, 0x0f420003, 0x0f420004
```

Use events 0x0f420001 to count up, and events 0x0f420002 to count down. When the counter is greater or equal to 3, event 0x0f420003 will be generated. Once the count falls below 3 again, event 0x0f420004 will be generated.

Heartbeat Rule

The Heartbeat rule is set to watch a 'heartbeat' event. The event is seen at a regular interval. In case any instance of the heartbeat is found missing, the rule creates an event.

```
<TriggerEventCode> R CA.Heartbeat, <HeartbeatEventCode>, <MissingHeartbeatEventCode>, <timeout>,
 <StopEventCode>
```

- **TriggerEventCode**
  Instantiates the heartbeat event rule
- **HeartbeatEventCode**
  The heartbeat event code
- **MissingHeartbeatEventCode**
  The event generated in case a heartbeat is missing
- **timeout**
  The time gap between individual heartbeats (in seconds)
- **StopEventCode**
  (Optional) The event code that stops the rule. The rule instance is running forever, looking for a heartbeat until stopped

Example: Heartbeat Rule

```
0x0f440001 E 50 R CA.Heartbeat, 0x0f440002, 0x0f440003, 10, 0x0f440004
```

Event 0x0f440001 instantiates the heartbeat rule. Next, it will look for event 0x0f440002 to occur at least once every 10 seconds. If a heartbeat event is found missing, the rule creates event 0x0f440003. Use event 0x0f440004 to stop the heartbeat rule instance.

SoloEvent Rule

The SoloEvent rule finds an instance of the target event that is not followed by or preceded by any other event in a defined time window. The events that are in the prevent list may not occur. Other events will not affect the Solo event.

As an example, you may want to have a rule triggered when event A occurred, but only none of events B, C or D (the 'prevent' events) occurred within five minutes before or 10 minutes after it.

The syntax of the SoloEvent Rule is as follows:

```
<TriggerEventCode> R CA.SoloEvent, <StopEventCode>, <SoloEventCode>, <prePreventPeriod>, <postPreventPeriod>,
 <TargetEventCode>, <PreventCode 1>, <PreventCode 2 (optional), ... , <PreventCode N (optional)>
```

- **TriggerEventCode**
  Initiates the 'solo' event rule.
- **StopEventCode**
  Stops the rule. The rule will run endlessly, unless you set the stop event.
- **SoloEventCode**
  Sets the solo event.
- **prePreventPeriod**
  Sets the time period before the solo event where none of the 'prevent' events may occur (in seconds).
- **postPreventPeriod**
  Sets the time period after the solo event where none of the 'prevent' events may occur.
- **TargetEventCode**
  Defines the event that will generate when the rule triggers (when just the 'solo' event was seen).
- **PreventCode 1 to PreventCode N**
  Defines a list of 'prevent' events.

Example: SoloEvent Rule

The following example will create event code 0x0f400005 if the solo event 0x0f400003 was seen, and none of the events 0x0f400006, 0x0f400007, 0x0f400008 or 0x0f400009 were seen within 20 seconds before or after it. The first event 0x0f400001 will have to be generated to instantiate the rule. Event 0x0f400002 is available to stop the rule.

```
0x0f400001 E 40 R CA.SoloEvent, 0x0f400002, 0x0f400003, 20, 20, 0x0f400005, 0x0f400006, 0x0f400007,
 0x0f400008, 0x0f400009
```

SingleEvent Rule

The SingleEvent rule reduces an event stream where one event ('up' event) may occur multiple times, before a reset ('down') event is seen. Instead of the multiple 'up' events, a single event is set that can be reused in other rules, denoting the condition ('up' or 'down').

The syntax of SingleEvent rule is as follows:

```
<TriggerEventCode> R CA.SingleEvent, <ResetEventCode>, <SingleTargetEventCode>, <SingleResetTargetEventCode>
```

- **TriggerEventCode**
  Occurs multiple times and should be converted into a 'single' occurrence. This will also trigger the rule to be instantiated when it occurs the first time.
- **ResetEventCode**
  Sets the reset event. When this event is seen, the rule is ready to create another single event again.
- **SingleTargetEvent**
  Generates the first time the trigger event is seen either when the rule is instantiated, or the first time the trigger event occurs after reset event is seen.
- **SingleResetTargetEvent**
  (Optional) Generates when the reset event is seen.

Example: SingleEvent Rule

```
0x0f430001 E 50 R CA.SingleEvent, 0x0f430002, 0x0f430003, 0x0f430004
```

Generates event 0x0f40003 every time event 0x0f430001 is seen for the first time. The SingleEvent is instantiated either at initial rule creation, each time after the trigger is seen the first time or after the reset event 0x0f430002 was seen. Event 0x0f430004 will also be generated when the reset event has been seen.

Using Multiple Event Rules in a Single EventDisp Entry

You can specify that a single event be processed using multiple event rules. For example, the following event disposition entry specifies that event 0x0001002a be processed using both the EventSequence rule and the EventPair rule:

```
0x0001002a R CA.EventSequence, 0x0001002c, 60, 0x0001002d,0x0001002e \
    R CA.EventPair, 0x0001002b, 0x0001002f, 60
```

This entry specifies that event 0x0001002c will be generated when events 0x0001002a, 0x0001002d, and 0x0001002e occur in that order within 60 seconds, and event 0x0001002f will be generated if event 0x0001002a occurs, but is not followed by event 0x0001002b within 60 seconds.

The backslash character is used at the end of the line to show that the event disposition entry continues onto the next line.

> **NOTE**
> Multiple rules must be specified within a single event disposition entry. If you were to create two separate event disposition entries for an event, only the first event disposition entry would be processed.

Copy Event Variables from One Event to Another

You can trigger events using event rules. However, sometimes the event is generated only after multiple contributing events occur or certain complex conditions are met.

By default, a rule output event does not have any event variables. You can however specify that, the values of the event variables in the events that contribute to the processing of the rule, be copied to the rule output event. Copying the event variables lets you specify event processing behaviors for the rule output event based those values, which you can do using event variable discriminators. Moreover, because the values of event variables in events that generate alarms are also stored in those alarms, you can also use event discriminators to specify alarm processing (generation or clearing of alarms) based on the values of the copied variables.

This section provides reference information about event variable copying syntax.

Event Variable Copying Syntax

Consider the following EventCombo rule which generates event 0xa000f, when events 0x10002, 0x10003, and 0x10004 are all received within 10 seconds of event 0x10001:

```
0x10001 R CA.EventCombo, 0xa000f, 10, 0x10002, 0x10003, 0x10004
```

Now assume that the contributing events have variable bindings that have values, some of which you want to copy to event 0xa000f as follows:

Contributing Event	Event Variables to Copy	Event Variables in 0xa000f to Receive the Copies
0x10001	2, 3	1, 2
0x10002	1, 5	3, 4
0x10003	none	none
0x10004	2, 3, 4, and 5	5, 6, 7, and 8

NOTE
An event generated by an event rule does not have any event variables unless they are copied from contributing events.

To copy the event variables as specified in the preceding table, the following event variable copying syntax is used:

```
0x10001 R CA.EventCombo, "0xa000f 2-3:1-2",    \
            10,                  \
            "0x10002 1:3, 5:4",   \
            0x10003,             \
            "0x10004 2-5:5-8"
```

This syntax copies event variables 2 and 3 in 0x10001 to event variables in 0xa000f, copies event variables 1 and 5 in 0x10002 to event variables 3 and 4 in 0xa000f, and copies event variables 2, 3, 4, and 5 in 0x10004, respectively, to event variables 5, 6, 7, and 8 in 0xa000f.

Event Parameters and Variable IDs

Event parameters specify the event variables to copy from a contributing event to the event generated by the rule. This information is associated with the contributing event, and it is entered after the event ID. To specify that the event copy information is part of the event parameter and not the next rule parameter, the event ID and the copy information need to be enclosed in double quotes, as shown:

```
"0x10002  1:3"
```

Event Variable Copy Information

The event variable copy information section of an event parameter can consist of several parts, each separated by a comma. Each part specifies a source variable ID or range of IDs. followed by a target variable ID or range of IDs. A colon separates the source IDs from the target IDs, as shown:

```
"0x10001  1:1, 2:3"
```

NOTE
If the source IDs and the target IDs are the same, either can be left empty.

Variable IDs

A single event variable is identified by its ID, which typically is a small number.

To copy a specific source event variable, enter its ID in the source position (left of the colon) in the copy information section. Similarly, to copy to a specific event variable, enter its ID in the target position (right of the colon).

For example, the following syntax copies variable 1 in event 0x10001 to variable 1 in the rule-generated event:

```
"0x10001  1:1"
```

Similarly, the following syntax copies variables 1 through 5 in event 0x10003 to variables with the same IDs in the rule-generated event:

```
"0x10003 1:1, 2:2, 3:3, 4:4, 5:5"
```

Variable IDs Using Ranges

Ranges of source and target variable IDs can be specified using a start ID followed by the dash ('-') character and then a stop ID. The start and stop IDs are included in the range.

The start ID, the stop ID, or both IDs can be left out. An entry with no start ID copies all of the IDs in the range from 1 to the stop ID, inclusive. An entry with no stop ID copies all of the variables with IDs equal to or greater than the start ID. An entry without either the start ID or the stop ID copies all of the variables (the dash can be left out too).

The number of variables in the source and target ranges need to be the same. If the numbers do not match, the number of IDs in the smaller range is used to copy variables, and a warning is generated.

As examples, the following 3 rule fragments are all equivalent. Each copies variables 1 through 73 in event 0x10004 to variables with the same IDs in the rule-generated event:

```
"0x10004  1 - 73 : 1 - 73"
"0x10004  1-73 :"
"0x10004 :1-73"
```

To copy variables 1 through 3 in event 0x10005 to the rule-generated event using new IDs 6 through 8:

```
"0x10005 1-3:6-8"
```

To copy all variables up to and including variable 5 to the rule-generated event using new IDs beginning with 1:

```
"0x10006 -5:1-"
```

To copy variables 2 through 5 to new IDs 1 through 4, and to also copy all remaining variables beginning with ID 7 using the same target IDs in the rule-generated event:

```
"0x10007 2-5:1-4, 7-:7-"
```

To copy all of the variables in event 0x10008 to the rule-generated event, use any of the following:

```
"0x10008 -:-"
"0x10008 -:"
"0x10008 :-"
"0x10008 :"
"0x10008 1-:1-"
```

The following example copies variables 3 to 5 from event 0x10009 to the rule-generated event where the source event has fewer variable entries then the target event. This example will succeed, but a warning will be generated:

```
"0x10009 3-5:3-"
```

Copying Variables from the Initial Event

Copying variables from the initial event (the event that the event disposition entry is for) is a special case. In this case, the copy information for the initial event is attached to the event to be generated rather than the source event.

As an example, consider the following EventCombo rule and EventRate rule, both of which watch for event 0x10001. If event 0x10001 occurs in combination with event 0x10002, its event variable 1 is important; if it occurs frequently, its event variable 3 is of interest:

```
0x10001        R CA.EventCombo, "0xa000f 1:1", 10, 0x10002 \
        R CA.EventRateCounter, 10, 3600, "0xa000e 3:1"
```

NOTE
Different types of rules specify the event to generate in different parameter positions. In the preceding example, the EventCombo rule uses the first variable position, and the EventRateCounter rule uses the third variable position.

Multiple Event Occurrence

When two event rules watch for multiple occurrences of an event (for example, an EventRateWindow rule and an EventRateCounter rule), the final occurrence of the event is used to copy the event variables, since they are the most current.

As an example, assume that event 0x10001 is a security alert from an intrusion detection system that holds information about the severity of a potential intrusion. Also assume that the following event rate rule exists, which generates event 0xa000f when event 0x10001 is received at least 5 times during a 100 second interval:

```
0x10001 R CA.EventRateCounter, 5, 100, "0xa000f  1:1"
```

A possible sequence of contributing events might be as follows:

NOTE
For readability, the severity event variable is shown as a text string.

0x10001 Warning

0x10001 High

0x10001 Warning

0x10001 Critical

0x10001 Critical

where the fifth 0x10001 event received triggers the generation of the rule output event, creating event 0xa000f with its variable 1 set to “Critical.”

As an alternative and more specific approach, the following EventCondition rule could be used so that the rule output event is only generated in response to five critical 0x10001 events (instead of in response to five 0x10001 events of any severity):

```
0x10001 R CA.EventCondition, \
    "regexp ( { variable 1 } , { S \"Critical\" } )", "0xa0001 1:1"
0xa0001 R CA.EventRateCounter, 5, 100, "0xa000f"
```

Event Variable Copy Example

Having reviewed Event Variable Copying Syntax for information about how to copy event variables from contributing events to rule-generated events, examine again the following event variable copy example:

```
0x10001 R CA.EventCombo, "0xa000f 2-3:1-2",    \
            10,                  \
            "0x10002 1:3, 5:4",  \
            0x10003,             \
            "0x10004 2-5:5-8"
```

When this EventCombo rule generates event 0xa000f, the event variables in the contributing events are copied as shown in the following table:

Source Event	SourceVariable ID	0xa000f (Target)Variable ID
0x10001	2	1
0x10001	3	2
0x10002	1	3
0x10002	5	4
0x10004	2	5
0x10004	3	6
0x10004	4	7
0x10004	5	8

Event Variable Copying and Event Discriminators

The event copying syntax can be used in conjunction with event discriminators to differentiate events that generate alarms. For example, assume alarm 0xffff0000 should be generated when event 0x10001 is received, and event variable 1 contains the index of the board that failed. Event variable 1 can be used as the alarm discriminator. Also assume that the device sometimes falsely reports errors, and the alarm should be cleared if supporting event 0x10002 is not received within 10 seconds. The following event maps satisfy these requirements:

```
0x10001 E 50 \
    A 2, 0xffff0000, 1 \
    R CA.EventPair, 0x10002, "0xa000f 1:1", 10
0xa000f C 0xffff0000, 1
```

The EventPair rule is used to watch for the second event and issue the clearing event containing the correct variable needed to clear the alarm. Note the use of the event discriminator to determine whether to generate and to clear the alarm, as well as the copy information contained in the rule.

Syntax Errors in EventDisp Files

All of an event's processing syntax must exist as a single event map. An EventDisp file that lists the same event code twice as the first entry on a line is considered to be improperly formatted. In this situation, the first line that applies to a particular event code is processed, and any additional entries are discarded.

The following example illustrates *incorrect* syntax:

```
0x3e00002  E  50
0x3e00002  A  2,0x3e00002
```

The following example illustrates *correct* syntax:

```
0x3e00003  E  50  A  2,0x3e00003
```

In the incorrect example, only the first event map is processed. Thus, when event 0x3e00002 is received, it is logged with an event severity of 50. However, no alarm is generated.

The correct example shows how to specify that DX NetOps Spectrum should log an event, assign an event severity to it, and generate an alarm as a result of the event.

Add Comments in EventDisp Files

You can add comments to an EventDisp file using the # identifier. Any text that follows this identifier on a line is ignored when the EventDisp file is processed.

You must enter the # identifier as the first character on the line. Do not enter a space and then #, as this produces an error when the EventDisp file is processed. If the comment must span multiple lines, enter the # identifier as the first character on each line.

The following example shows proper usage:

```
# This is a valid comment.
# This is a valid comment.
0x3dc0004  E  50  A  2,0x3dc0001
0x3dc0002  C  0x3dc0001
```

Event Format Files

About Event Format Files

An *event format file* contains the message about the event that is displayed to users on the Events tab in OneClick when the event occurs. The message can contain references to the event variables that hold data retrieved from the variable bindings of the trap. There exists an event format file for each event generated by DX NetOps Spectrum.

The events provided with DX NetOps Spectrum all have event format files that define appropriate event messages. In addition, whenever you create a new, custom event (either using MIB Tools when you are mapping a trap to the new event or later using Event Configuration) the associated event format file is automatically created. This means that typically you should not need to manually create an event format file.

> **WARNING**
> It is recommended that you create and modify all event messages using Event Configuration, which updates the appropriate event format files on (only) the OneClick web server to which you are connected when you save the changes to a landscape. However, this appendix provides reference information on event format files if manual modifications are ever required.

Location of Event Format Files

The event format files that support the events provided with DX NetOps Spectrum are installed in the following folder:

<$SPECROOT>/SG-Support/CsEvFormat

Custom event format files that are created by MIB Tools or Event Configuration are installed in the following folder:

<$SPECROOT>/custom/Events/CsEvFormat

Each event format file is named Event<event_code>, where <event_code> is the 4-byte, hexadecimal event code assigned to the event. For example, an event with an event code of 0x12345678 has an event format file named Event12345678.

Contents of an Event Format File

If you modify an event format file manually, note the following:

- As you compose the event message, keep in mind that most of the information that a OneClick user receives about an event is via the message text that is associated with the event. For this reason, provide as much information about the event as possible in the message.
- An event message can consist of plain text and variables that reference specifics about the instance of the individual event. For information on the correct syntax for including variables, see Variable Descriptions and Syntax.
- If there exists an event format file for an event, but no event map for the event exists in an event disposition file, the contents of the event format file are still displayed on the Events tab in OneClick when the event occurs.
- If no event format file exists for an event, a default message indicating this is displayed on the Events tab in OneClick.

About Event Table Files

An *event table file* does the following:

- Enumerates the possible values of a variable binding that is sent with a trap. The values can be attribute values in MIB tables, OID values, and integer bit values.
- Provides corresponding text values for the enumerated values.

When a trap is mapped to a DX NetOps Spectrum event, the variable bindings sent with the trap are mapped to event variables. This means that by referencing an event variable and the event table file for the appropriate variable binding you can define event messages that include the text values for the variable binding values. In turn, this means that the event message that is displayed to users in OneClick contains data that is specific to the trap that is sent.

You do not need to manually create event table files. All of the events provided with DX NetOps Spectrum that are mapped to traps that contain variable bindings with enumerated definitions in the MIB have supporting event table files. In addition, whenever you add trap support for a device that is not supported by default in DX NetOps Spectrum, and you map the traps to new, custom events using MIB Tools, an event table file is automatically created for each variable binding that meets this same criterion.

> **NOTE**
> This appendix provides reference information on the proper syntax for an event table file. However, typically you should not need to modify these files.

Location of Event Table Files

The event table files that support the events provided with DX NetOps Spectrum are installed in the following folder:

<$SPECROOT>/SG-Support/CsEvFormat/EventTables

Custom event table files created by MIB Tools are installed in the following folder:

<$SPECROOT>/custom/Events/CsEvFormat/EventTable

Each event table file is named based on the associated device and variable binding.

Contents of an Event Table File

Event table files are used to enumerate the possible attribute values, OID values, or integer bit values in a variable binding sent with a trap, and to associate those values with corresponding text values that can be used in event messages.

Associate the Attribute Values in a MIB Table with Text Values

To associate an attribute value in a MIB table with a text value, the file must iterate each possible value in hexadecimal format and its associated text value, as shown in the following example:

```
0x00000001 Reconfiguration
0x00000002 Signal-Loss
0x00000003 Bit-Streaming
0x00000004 Contention-Streaming
0x000000ff None
```

Associate OID Values with Text Values

To associate an OID value with a text value, the file must iterate each possible OID value and its associated text value, as shown in the following example:

```
1.3.6.1.4.1.1563.1.2.1.1.3.2.36.2.6 dot6
1.3.6.1.4.1.1563.1.2.1.1.3.2.36.2.5 dot15
1.3.6.1.4.1.1563.1.2.1.1.3.2 dot7
```

Associate Integer Bit Values with Text Values

To associate an integer bit value with a text value, the file must iterate each possible integer bit value and its associated text value, as shown in the following example:

```
1 dsx1NoAlarm
2 dsx1RcvFarEndLOF
3 dsx1XmtFarEndLOF
4 dsx1RcvAIS
```

This example works only with OneClick. Change the integer values to its equivalent 8 byte HEX values to make the event table file work with AlarmNotifier, as shown in the following example:

```
0x00000001 dsx1NoAlarm
```

```
0x00000002 dsx1RcvFarEndLOF
0x00000003 dsx1XmtFarEndLOF
0x00000004 dsx1RcvAIS
```

Probable Cause Files

About Probable Cause Files

A *probable cause file* is an ASCII text file that defines the symptoms, probable causes, and recommended corrective actions for an alarm. When an alarm is generated as a result of an event, the text in the associated probable cause file is displayed on the Alarm Details tab in OneClick. In this way, OneClick users are provided with information that can assist in resolving the abnormal condition. There exists a probable cause file for each alarm generated due to a DX NetOps Spectrum event.

The events provided with DX NetOps Spectrum that generate alarms all have probable cause files that define appropriate alarm-related messages. In addition, whenever you create a new, custom event that generates an alarm (either using MIB Tools when you are mapping a trap to the new event or later using Event Configuration) the associated probable cause file for the alarm is automatically created. This means that typically you should not need to manually create a probable cause file.

> **WARNING**
> It is recommended that you create and modify all alarm-related messages using Event Configuration, which updates the appropriate probable cause files on (only) the OneClick web server to which you are connected when you save the changes to a landscape. However, this appendix provides reference information on the proper syntax to use if manual modifications are ever required.

Location of Probable Cause Files

The probable cause files that support the events and alarms provided with DX NetOps Spectrum are installed in the following folder:

<$SPECROOT>/SG-Support/CsPCause

Custom probable cause files that are created by MIB Tools or Event Configuration are installed in the following folder:

<$SPECROOT>/custom/Events/CsPCause

Each probable cause file is named Prob<alarm_cause_code>, where <alarm_cause_code> is an 8-digit (including leading zeros), hexadecimal code that identifies the probable cause of the alarm.

> **NOTE**
> As a convention, events that generate alarms typically use their event codes as alarm cause codes.

Contents of a Probable Cause File

The contents of a probable cause file should include text only. On the first line, specify the cause of the alarm in all capital letters; this information is displayed as the alarm type (or title) on the Alarm Details tab. Also provide one section each on the following:

- The symptoms of the alarm
- The probable causes
- Recommended corrective actions

If there are multiple items under a category, enter the information in numbered list format.

Example: Probable Cause File Using Appropriate Syntax

```
UNKNOWN USER
SYMPTOMS:
The user's SMTP mail transaction failed with error code 550 - unknown user.
PROBABLE CAUSES:
1) The user may have entered an invalid SMTP mail login.
2) The SMTP server login account information may be incorrect.
RECOMMENDED ACTIONS:
1) Have the user check their username and try again.
2) If the username is correct, check the SMTP server login account information.
```

Host System Resources Management

Introducing the Host System Resources Manager

Host resources monitoring is a DX NetOps Spectrum mechanism that defines host resource conditions and thresholds that, when met or violated, generate events and alarms. The goal of resource monitoring is to alert network administrators about significant resource events that could affect host performance and Service Level Agreements.

To help you monitor resources, DX NetOps Spectrum provides management support for the following resource monitoring agents:

- **CA SystemEDGE Agent**
- **CA Unicenter NSM System Agent**
- **Dell OpenManage**
- **Fujitsu ServerView Agent (for PRIMERGY servers)**
- **HP Systems Insight Manager**
- **iAgent**
- **IBM Director**
- **Net-SNMP (UC Davis)**
- **Sun Management Center**

This support for the monitoring agents lets you view and evaluate relevant, up-to-date information about the status of resources on host systems in the network.

Host System Resources Management Concepts

Host System Resources Management Concepts

The following terms and concepts are key to understanding and working with <sp> host system resources management.

Alarm Condition
An alarm condition refers to process thresholds that you specify in an RFC 2790 monitoring rule.

Configuration Threshold
A configuration threshold refers to process thresholds that you specify in an NSM Agent monitoring rule.

File System
A file system is any data storage system on a host.

Host
A host is any computer system that communicates with other systems in the network. In this section, a host refers to any device that is modeled in <sp> and that supports the RFC 2790 host resources MIB, NSM Agent proprietary MIBs, or log file monitoring.

Host Resources
Host resources are the processes, file systems, processors, memory, and other host elements that can be monitored.

Log File
A log file is any file that includes status information about a host or a host application.

Monitor Rule
A monitor rule in <oc> lets you associate <sp> alarms with resource state changes and resource activity thresholds.

Process
A process is any application that runs on a host.

Monitoring Tasks Overview

Monitoring Tasks Overview

This section provides instructions for completing the following tasks in OneClick:

- Create and manage process monitoring rules
- Create and manage the file system monitoring rules
- Create the file system monitoring rule sets that are applied to DX NetOps Spectrum Global Collection containers to automate the creation of monitoring rules
- Create a log file monitor

Creating Process and File System Monitoring Rules

When you create a process or file system monitoring rule for a host model, you specify conditions that cause DX NetOps Spectrum to generate alarms. You can specify multiple available conditions when you create a monitoring rule. You can also specify whether DX NetOps Spectrum generates alarms for the monitoring rule model or the host model.

RFC 2790 Host Resources MIB Monitoring Rule Alarm Conditions and Thresholds

A process monitoring rule for a host that supports the RFC 2790 host resources MIB includes the following alarm conditions:

- Process start
- Process stop
- Process instance count exceeds a certain number
- Process instance count falls below a certain number

A file system monitoring rule includes the following alarm conditions:

- File system utilization threshold is met
- File system goes offline

For more information about RFC 2790 host resources monitoring rules, see Configure RFC 2790 Process Monitoring Rule Parameters.

NSM Agent Monitoring Rule Thresholds

The following table shows the configuration thresholds that you can specify for an NSM Agent process monitoring rule. The available thresholds depend on both the host type (UNIX or Windows) and the version (3.1 or r11) of the agent on the host.

For more information, see NSM Agent Process Monitoring Rule Parameters.

	Platforms and NSM Agent Versions	Platforms and NSM Agent Versions	Platforms and NSM Agent Versions	Platforms and NSM Agent Versions
Configuration Thresholds	**Win r11**	**UNIX r11**	**Win 3.1**	**UNIX 3.1**
Children	X	X	X	X
CPU Usage	X	X	X	X
CPU Usage Long-term		X		
Handles	X			
Instances	X	X	X	X
Restart	X	X		
Runtime	X			
Size	X	X	X	X
Threads	X	X	X	

Using Rule Sets to Automate Monitoring Rule Creation

A rule set is a collection of monitoring rules. You can apply one or more rule sets to a Global Collections container to automate monitoring rule creation for models in the container. When a model that supports the RFC 2790 MIB or the NSM Agent is added to the collection, monitoring rules are automatically configured on the model. Rules are configured for any of the processes or file systems to which rules in the rule set apply.

For example, a rule set that includes a monitoring rule for the svchost.exe process is applied to a Global Collection. The collection is configured to add Windows hosts as the hosts are modeled in DX NetOps Spectrum. The monitoring rule for svchost.exe is configured on all host models that are added to the collection. Conversely, when the hosts are removed from the collection the monitoring rule is removed from the hosts.

Modifications that you make to a rule in a rule set that is associated with a Global Collection apply to all instances of that rule. This type of rule has an indicator that it belongs to (or is "owned" by) a rule set. You can check rule set ownership in the rule set name. The name appears in the Rule Owner field in all monitored process tables and monitored file system tables in OneClick.

Suppose you want to change an alarm condition for svchost.exe monitoring. In the svchost.exe rule, change the maximum process count threshold from 10 to 12. The change then applies to all svchost.exe monitoring rule instances in the collection.

For more information, see Create a Rule Set.

About Creating a Log File Monitor

Agents that support log file monitoring use regular expressions to find the log file text. Typically, you monitor log files to find information about system or application error conditions. Discovery of a text match results in DX NetOps Spectrum generating an alarm on the device where the log file entry originated.

For more information, see Log File Monitoring.

Host Resources Monitoring and Service Level Agreements

Host resource monitoring lets you monitor host resources that can affect the network services that are defined in a Service Level Agreement (SLA). For example, a process monitoring rule can determine whether a virus protection process has

stopped unexpectedly, or whether a malicious process has started on a host. A file system monitoring rule can determine whether a disk drive or physical RAM on a host has reached or is nearing capacity. The viability of a business service can depend on whether processes are running on a host, or whether the host provides adequate data storage capacity.

NOTE
For more information about setting up a service management system and SLAs, see the Service Manager section.

Host Resource Events and Alarms Reporting

The DX NetOps Spectrum Report Manager application lets you generate reports on events and alarms for host models. Alarms and reports are generated for threshold violations for monitored processes and the file systems. Alarms are also generated from error messages that are parsed from log files.

NOTE
For more information, see the Report Manager section.

Getting Started with Managing Host System Resources in OneClick

This section describes how to invoke workspaces where you configure monitoring rules, rule sets, and views of monitored host resource information.

NOTE
For more information about the OneClick Console interface elements, see the Using OneClick section.

Access the Workspace for Creating and Managing Monitoring Rules

Create and manage monitoring rules from the context of a host model that supports a monitoring agent.

Follow these steps:

1. Select the host for which you want to create a monitoring rule from the Contents panel.
2. Expand the System Resources option under the Information tab in the Component Detail panel.
   The Running and Monitored Processes section lets you create and manage process monitoring rules. For more information, see Process Monitoring.
   The Monitored Logs and Process Logs section lets you create log file monitoring rules. For more information, see Log File Monitoring.
   The File Systems section lets you create file system monitoring rules. For more information, see File System Monitoring.

Access the Workspace for Creating and Managing Rule Sets

Unlike monitoring rules that you create for a particular host, DX NetOps Spectrum creates different rules for Global Collections. For any host that is included in a Global Collection to which the rule set has been applied, DX NetOps Spectrum creates rules that you specify in a rule set. This feature automates the process of creating monitoring rules for multiple, different host types.

Manage rule sets in the Contents panel.

Follow these steps:

- Select Locater, System & Application Monitoring, All Monitoring Rules.
  The Contents panel lists any rule sets that have been created.
  Default rules are not set. See Working with Monitoring Rule Sets for details about creating and managing rule sets and applying them to Global Collections.

View Monitoring Rule Information

OneClick lets you view comprehensive information about monitored processes and file systems in the Component Detail panel.

To view information about a process monitoring rule:

- Select Locater, System & Application Monitoring, All Monitored Processes.

> **NOTE**
> Because process models are not created for rules for SystemEDGE hosts, monitoring rules for SystemEDGE hosts do not appear in this view.

To view information about a file system monitoring rule:

- Select Locater, System & Application Monitoring, All Monitored File Systems.

The view provides information about the selected host and the monitoring configuration on the host. The monitoring agent that is associated with the rule determines the information that the view provides.

Process Monitoring

A process monitoring rule specifies the criteria that, when met, cause DX NetOps Spectrum to generate alarms. This section describes how to set up process monitoring rules for host models with process monitoring agents. See Working with Monitoring Rule Sets for information about setting up an automated method for creating process monitoring rules for models included in Global Collection containers.

Create a Process Monitoring Rule

You can create a process monitoring rule for a host model regardless of whether the process is running on the host.

> **NOTE**
> Only the users with the appropriate privileges can create process monitoring rules. For more information, see System and Application Monitoring Privileges.

Follow these steps:

1. In the Contents panel, select the host model for which you want to create a monitoring rule.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, on the Information tab, expand System Resources, Running, and Monitored Processes.
   The available process options for this host type appear.

   > **NOTE**
   > RFC 2790 indicates a host that supports the RFC 2790 host resources MIB.
3. Expand both Running Processes and Monitored Processes.
   The Running Processes table lists running processes for the selected host model.
   The Monitored Processes table lists process monitoring rules that have been created for the selected host model.
4. To create a process monitoring rule for the selected host model, use *one* of the following methods:
   - If the process is running, right-click the process in the Running Processes table and select 'Monitor this process.'
   - If the process is not running, it is excluded from the Running Processes table. Click Add above the Monitored Processes table. You can then specify process monitoring rules for processes that run periodically but are not currently running that you want to know about when they start. For example, you want to know when virus scan and system maintenance processes run.

NOTE
For NSM Agent monitoring, use this method when you want to create a monitoring rule that watches multiple, different processes that the match criteria specify. For more information, see NSM Agent Process Monitoring Rule Parameters.

A dialog opens, depending on the host type. If you selected a process from the Running Processes table, the dialog includes the process name and other information. If you invoked the dialog using the Add option, you are prompted to provide all process information.

5. Configure process monitoring rule settings:
   – For agents that support the RFC 2790 host resources MIB, see RFC 2790 Process Monitoring Rule Parameters.
   – For agents that support NSM Agent versions 3.1 or r11, see NSM Agent Process Monitoring Rule Parameters.
   – For SystemEDGE host agents, see SystemEDGE Host Process Monitoring Rule Parameters.
6. Click OK.
   The following events occur:
   – The process monitoring rule is added to the Monitored Processes table. The table columns represent predefined process identifier information specific to the monitoring agent type on the selected host. The rule applies to all identical instances of the process that satisfy the process match selection criteria.
   – A process model is created for RFC 2790 and NSM Agent rules.

     NOTE
     Local ownership in a monitoring rule indicates that the rule has been created explicitly for a particular host. As a result,it is not part of a rule set. For more information about rule sets, see Working with Monitoring Rule Sets.
7. Specify the alarm generation and agent polling options, which are located above the Monitored Processes table, depending on host type:
   – **Watch For New Processes Every (seconds)**
     Specify the frequency with which DX NetOps Spectrum inspects the Running Processes table for new instances of processes that a monitoring rule is watching. DX NetOps Spectrum updates the 'Number Running' value in the Monitored Processes table for a monitored process when it detects that a new instance of the process is running.
   – **Generate Alarm On**
     Select a destination for alarms resulting from rule violations. You can specify that DX NetOps Spectrum create alarms on the process monitoring rule model or the host model.
   – **Agent Poll Interval (seconds)**
     Specify the frequency with which the agent collects process information from the host device. The minimum value is 30 seconds.
   – **Agent Poll Method**
     Specify how and when the agent collects process data:
     - **disabled**
       The agent does not retrieve process information (by polling or by get request), and it sets all status indications for alarm conditions to passive or ok.
     - **poll-interval-and-query**
       The agent retrieves process information both by polling and by the get request.
     - **poll-interval-only**
       The agent retrieves process information by polling only.
     - **query-only**
       The agent retrieves process information by get request only.

Differentiating Processes

At any time, a host can run multiple instances of a particular process. The svchost.exe process on Windows hosts and the nfsd process on Linux and UNIX hosts are typical examples. You can create a process monitoring rule that applies to all process instances, to some process instances, or to a single process instance. For example, if you decide to monitor all instances of svchost.exe, do not differentiate them by parameters or names.

For DX NetOps Spectrum, the alarm conditions and thresholds that are specified in the svchost.exe process monitoring rule apply to all instances of the process. Assuming that the rule specifies an alarm for process starts and stops, DX NetOps Spectrum generates an alarm for each start and stop, for each instance. In other words, DX NetOps Spectrum applies the rule to each entry in the Running Processes table that matches an entry (by process name) in the Monitored Processes table.

You can create a rule for an instance or a group of identical instances of a process. In this case, you must differentiate the instance or group of instances from the instances that you do not want to monitor. You can use a unique name, parameters, or both to distinguish them. The differentiation options let you make many different types of distinctions between process instances.

Process Monitoring Rule Parameters

The section describes the process monitoring rule parameters for the following host types:

- RFC 2790
- NSM Agent
- SystemEDGE Host

RFC 2790 Process Monitoring Rule Parameters

You can specify the following parameters when you create process monitoring rules for hosts that support RFC 2790 monitoring:

- Process identifiers, including a process name and process differentiator
- Process start/stop and process count alarm conditions
- Polling of the Running Processes table for new instances of processes with associated monitoring rules

Monitor Information

You can selectively monitor all instances of a process or specific instances of a process. Use the following parameters in the monitoring rule:

- **Process Name**
  Identifies the process on the host model. You can differentiate a process instance with this setting , or you can also use the Match Parameters field to provide more precise differentiation.
  For hosts that support RFC 2790 monitoring, the value that is entered in this field is case-insensitive. It converts to lowercase, as displayed in the Monitored Processes (RFC 2790) table. Also, duplicate entries are not allowed. If a new entry is created with the same Process Name (and Match Parameters value, if specified), the new entry replaces the existing entry. Any configuration settings that were changed are updated.
- **Match Parameters**
  Specifies one or more process parameters that differentiate identically named instances of the same process. You can add parameters or can modify the parameters that are included with a process before you save the configuration. This setting is used along with the Process Name to differentiate a process instance.
- **Descriptive Name**
  Identifies a nickname for the process. We recommend supplying a descriptive name that more clearly conveys the purpose or function of a process than its proper name (for example, "java runtime" for the javaw.exe process). This setting does not serve as a process differentiator.

Alarm Configuration for RFC 2790

You can specify the following alarm conditions in an RFC 2790 monitoring rule:

- **Process Count Less Than**
  Specifies whether DX NetOps Spectrum generates an alarm when a process instance count is less than a particular value. DX NetOps Spectrum clears the alarm when the process count is equal to or greater than the value.
- **Process Count Greater Than**
  Specifies whether DX NetOps Spectrum generates an alarm when a process instance count is greater than a particular value. DX NetOps Spectrum clears the alarm when the process count is equal to or less than the value.
- **Process Start**
  Specifies whether DX NetOps Spectrum generates an alarm whenever the process is started. DX NetOps Spectrum clears the process-start alarm when the process stops.
- **Process Stop**
  Specifies whether DX NetOps Spectrum generates an alarm whenever the process is stopped. DX NetOps Spectrum clears the process-stop alarm when the process starts.

NSM Agent Process Monitoring Rule Parameters

Process monitoring rules are defined in the Add Monitored Process dialog, as described in Create a Process Monitoring Rule. When you create a process monitoring rule for a host that supports NSM Agent monitoring, you can specify the following parameters:

- Process monitoring rule identifiers
- Process match criteria
- Configuration threshold monitoring options
- Configuration threshold values
- Advanced options, such as aggregate status evaluation policy, resource cluster group, and aggregate violation threshold

> **NOTE**
> Your NSM Agent version and agent host platform determine your access to all of these settings and to the options that are described in this section.

You can specify the agent polling interval and method for all NSM Agent versions on all platforms. For more information, see Create a Process Monitoring Rule.

Monitor Information

The Add Monitored Process dialog includes the following process monitoring rule identifiers. Available identifiers depend on the NSM Agent version and agent host platform:

- **Monitor Name**
  Identifies the name of the monitoring rule. DX NetOps Spectrum distinguishes identical monitoring rule configurations by the monitor name. This name must be unique.
- **Descriptive Name**
  Identifies a monitoring rule nickname or brief descriptive term.

The following table describes the attributes, or fields, that uniquely identify the process monitor for each agent type:

Version	Monitor Identification Fields
Win r11	Monitor Name* Descriptive Name (optional)
UNIX r11	Monitor Name* Descriptive Name (optional)

Win 3.1	Descriptive Name (optional) Process Name* Path* User*
UNIX 3.1	Process Name* Parameters * Path * User *

* Uniquely identifies the process monitor.

Process Match Criteria

Before you implement a process monitoring rule on an NSM agent, identify the processes that you want DX NetOps Spectrum to evaluate according to the threshold criteria. You can use regular expressions and string comparisons to identify processes.

WARNING
The r11 agent supports regex for match criteria, but the 3.1 agent supports wildcard (*) use only.

The following table describes the attributes, or fields, that are used as process matching criteria for each type of NSM agent.

NOTE
For r11 NSM Agents, Match Type applies to the combination of all the other match criteria attributes. It defines how the combinations of the other process match fields are evaluated.

Version	Monitor Identification Fields
Win r11	Process Name Match Type Path User
UNIX r11	Process Name Match Type Parameters Path User
Win 3.1	Process Name Path User
UNIX 3.1	Process Name Parameters Path User

The Add Monitored Process dialog includes the following fields and options, depending on the NSM Agent version and agent host platform you are working with:

- **Process Name**
  Identifies the process or processes text pattern to match. You can use literal string identifiers or regular expressions to specify a text search pattern.

NOTE
If no other process match criteria is specified, all processes matching the name in the Process Name field are monitored.

- **Match Type**
  Lets you specify the process or processes that match or do not match the process match criteria.

  NOTE
  Process Name match criteria are case-insensitive.

  Options include:
  - **positive-regular-expression**
    The agent searches for processes that match the process name as a regular expression.
  - **negative-regular-expression**
    The agent searches for processes that do not match the process name as a regular expression.
  - **positive-string-compare**
    The agent searches for processes that match the process name as a string comparison.
  - **negative-string-compare**
    The agent searches for processes that do not match the process name as a string comparison.
- **Parameters**
  Identifies the process arguments to match. You can specify parameters as a literal string or a regular expression depending on the version of NSM and the platform you are using.
- **Path**
  Identifies the path name of the process or processes to match. You can specify paths as a literal string or a regular expression.
- **User**
  Identifies the user name of the process account to match. You can specify user names as a literal string or a regular expression depending on the version of NSM and the platform you are using.

Threshold Configuration for NSM Agent

Threshold configuration defines what is watched by the monitor. You can specify multiple thresholds when you create a monitoring rule. For example, you can instruct the monitor to watch only the amount of CPU time that a process consumes. Or you can instruct the monitor to watch CPU usage and process children, threads, and handles, and also how often a process restarts.

DX NetOps Spectrum generates Major (Orange) alarms for violations of warning thresholds and Critical (Red) alarms for violations of critical thresholds. Alarm generation depends on the overall status of the monitoring rule.

The thresholds that you can specify depend on the host platform (Windows or UNIX) and the NSM Agent version (3.1 or r11) running on the host.

The following table describes the threshold and monitoring options that are available for each NSM agent:

Threshold	Monitoring Options (Platform and Agent Version)	Monitoring Options (Platform and Agent Version)	Monitoring Options (Platform and Agent Version)	Monitoring Options (Platform and Agent Version)
	Win r11	**UNIX r11**	**Win 3.1**	**UNIX 3.1**
Children	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	do-not-monitor monitor

CPU Usage	do-not-monitor warning-only critical-only minimum-only maximum-only all	do-not-monitor warning-only critical-only minimum-only maximum-only all	do-not-monitor warning-only critical-only both	do-not-monitor warning-only critical-only both
CPU Usage Long-Term	N/A	do-not-monitor warning-only critical-only minimum-only maximum-only all	N/A	N/A
Handles	do-not-monitor down-warning down-critical	N/A	N/A	N/A
Instances	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	do-not-monitor monitor
Restart	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	N/A	N/A
Runtime	do-not-monitor down-warning down-critical	N/A	N/A	N/A
Size	do-not-monitor warning-only critical-only minimum-only maximum-only all	do-not-monitor down-warning down-critical	do-not-monitor warning-only critical-only both	do-not-monitor monitor
Threads	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	do-not-monitor down-warning down-critical	N/A

NOTE
Specify the value '-1' for a particular minimum or maximum value threshold to disable the threshold. You can selectively specify that the monitor watches, for example, a minimum threshold but not a maximum threshold, or the reverse.

- **Children**
  Specifies whether the monitor watches the process children count.

  NOTE
  For version r11 on Windows, this option is in the Resources, Type drop-down list.
- **CPU Usage/CPU Shortterm Usage/CPU Longterm Usage**
  Specifies whether the monitor watches the amount of CPU time that a process uses.
  Some of the available options include the following:
  - **Warning Threshold**
    This value can be between one (1) and ninety-nine (99) percent, but it must fall below the critical threshold percent value. For multiple process instances, the maximum of all instances is compared with this value.
  - **Critical Threshold**

This value can be between two (2) and one hundred (100) percent, but it must exceed the warning threshold percent value. For multiple process instances, the maximum of all instances is compared with this value.

CPU Interval

This value defines the total value in seconds to use as the base to calculate the CPU value. Specifically, the CPU usage of a process, in seconds, refers to this interval. You can set the value to any value greater than zero (0) or -1.

- If set to -1, the CPU value is calculated as the CPU usage, in seconds, used up to the current time since the start of the agent or the creation of the process monitoring rule.
- If the CPU interval is set to a value greater than the current agent polling interval and this time has not elapsed for the first time, the CPU value is extrapolated.
- If the CPU interval is set to a value smaller than the current agent polling interval, the CPU value is calculated as the appropriate fraction of the value for the last agent polling interval.
- If the CPU interval is set to a value greater than the current agent polling interval and this time has already elapsed, the CPU value is calculated as the sliding sum (the sum of the value for the current poll interval and the value calculated at the last poll) weighted according to its fraction of the CPU interval.
- If the interval is set to -1, any overloading (%) used for the thresholds are ignored.

- **Min/Max Units**
  The unit of measure, in seconds or as a percentage, used for CPU usage thresholds.
- **Instances**
  Specifies whether the monitor watches the process instance count.
- **Resources**
  Specifies whether the monitor watches one of the following resource types:
  - **threads**
    Specifies the process thread count.
  - **handles**
    Specifies the total number of handles currently opened by each thread in the process.
  - **children**
    Specifies the process children count.
  - **runtime**
    Specifies the time, in seconds, that the process has been running since it was created.
- **Restart**
  Specifies whether the monitor watches the process restart count. Determines the policy that the agent uses to determine when to set the status of the restart alarm condition to down for a threshold violation.
  - **none-should-stop-or-start**
    Sets the status to down if any process stops or starts.
  - **none-should-stop**
    Sets the status to down if any process stops.
  - **none-should-start**
    Sets the status to down if any process starts.
  - **some-should-continue**
    Sets the status to down if all processes stop.
- **Size**
  Specifies whether the monitor watches the amount of memory (in kilobytes) that a process consumes.
- **Threads**
  Specifies whether the monitor watches the process thread count.

NOTE
For version r11 on Windows, this option is in the Resources, Type drop-down list.

Monitoring Options

A monitoring option specifies whether the NSM Agent watches a particular configuration threshold and which threshold types (warning or critical, minimum, or maximum values) to watch.

Monitor drop-down lists in the Add Monitored Process dialog contain the following options depending on the host platform (Windows or UNIX), the NSM Agent version (3.1 or r11), and the particular alarm condition you are configuring:

- **do-not-monitor**
  No alarm. The agent disregards threshold settings.
- **monitor**
  Critical alarm. The agent monitors minimum and maximum values for all thresholds.
- **warning-only**
  Major alarm. The agent evaluates only the warning thresholds (both minimum and maximum) to determine the status of the process.
- **critical-only**
  Critical alarm. The agent evaluates only the critical thresholds (both minimum and maximum) to determine the status of the process.
- **minimum-only**
  Major (warning) and Critical (critical) alarms. The agent evaluates only the minimum thresholds (both warning and critical) to determine the status of the process.
- **maximum-only**
  Major (warning) and Critical (critical) alarms. The agent evaluates only the maximum thresholds (both warning and critical) to determine the status of the process.
- **all**
  Major (warning) and Critical (critical) alarms. The agent evaluates all thresholds.
- **down-warning**
  Major alarm. When the resource is in a bad condition the agent uses a warning severity. This lets you designate a threshold violation as less crucial than a down-critical violation.
- **down-critical**
  Critical alarm. When the resource is in bad condition the agent uses a critical severity. This lets you designate a threshold violation as more crucial than a down-critical violation.
- **both**
  Major (warning) and Critical (critical) alarms. The agent evaluates both warning and critical thresholds to determine the status of the process.

Advanced Options

Advanced options let you specify an evaluation policy for configuration threshold violations when the monitor watches two or more processes, a process resource cluster group, and an aggregate alarm condition violation threshold that when met degrades the status of a process and triggers DX NetOps Spectrum alarm generation.

> **NOTE**
> The advanced options available depend on which host platform (Windows or UNIX) and NSM Agent version (3.1 or r11) you are configuring.

- **Evaluation Policy (r11 only)**
  Specifies how the agent calculates values that it compares to alarm condition thresholds for a monitor that watches multiple, different processes. It also specifies which other processes are included in the threshold violation culprits list.

  > **NOTE**
  > NSM Agent version 3.1 compares the worst values (the individual policy) from all watched process instances to alarm condition thresholds to determine threshold compliance.

  Evaluation Policy options include:

  - **individual (default)**
    Specifies that the agent compares the worst values (lowest and/or highest) of all process instances to alarm condition threshold values. If a value violates a threshold condition, the culprits list includes all instances individually violating the most severe threshold.
  - **min**
    Specifies that the agent compares the lowest values (minimum) of all process instances to alarm condition threshold values. If a value violates a threshold condition, the culprits list includes all instances with the same minimum value.
  - **max**
    Specifies that the agent compares the highest values (maximum) of all process instances to alarm condition threshold values. If a value violates a threshold condition, the culprits list includes all instances with the same maximum value.
  - **sum**
    Specifies that the agent compares the cumulative values (sum) of all process instances to alarm condition threshold values. If a value violates a threshold condition, the culprits list includes all instances.
  - **avg**
    Specifies that the agent compares the average values of all process instances to alarm condition threshold values. If a value violates the threshold condition, the culprits list includes all instances individually violating the most severe threshold.
- **Cluster Resource Group (r11 only)**
  Identifies the cluster resource group.
- **Aggregate Violation Threshold**
  This option specifies the consecutive number of agent polling cycles for which any threshold is required to be in a less-than-ok state before the aggregate status for the monitor changes. This value must be greater than 0. The Aggregate Violation Threshold field is not available for UNIX 3.1.
  The Status field in the Monitored Processes table for the selected host model indicates the aggregate status condition.

If the NSM Agent Fails to Retrieve Process Information

If the NSM Agent subagent that is responsible for retrieving process monitoring information goes down, DX NetOps Spectrum responds as follows:

- Generates an NSM PROCESS MONITORING AGENT LOST alarm on the host model
- Asserts a suppressed APPLICATION_LOST alarm condition on the process models

When the process monitoring subagent restarts, DX NetOps Spectrum clears the NSM PROCESS MONITORING AGENT LOST alarm on the host model and clears the APPLICATION_LOST alarms on the associated process models.

Status Indications for NSM Agent Process Monitoring Rules

The Status field in the Monitored Processes table for the selected host model indicates the aggregate status condition of the monitor. The status field represents the worst-case aggregate for the status values of each threshold that is defined on the monitor.

The aggregate status enters a suboptimal state when any threshold is in a violated state over a particular number of consecutive agent polling cycles. The Aggregate Violation Threshold field defines the number of consecutive times that any threshold is in a violated state before the aggregate status value changes. DX NetOps Spectrum does not generate alarms for violated thresholds until the aggregate status is in a suboptimal state.

SystemEDGE Host Process Monitoring Rule Parameters

Process monitoring rules are defined in the Add Process Monitor Table Entry dialog. For more information, see Create a Process Monitoring Rule.

When you create a process monitoring rule for a SystemEDGE host, you can specify the following parameters:

- Process monitoring rule identifiers
- Configuration threshold monitoring options
- Configuration threshold values
- Advanced options, such as sending traps and monitoring a parent process or Windows service

NOTE
When a rule is created for a SystemEDGE host, a process model is not created. As a result, when you search for and view rules in the Locater tab, the monitoring rule does not appear.

Monitor Information

The Add Process Monitor Table Entry dialog includes the following process monitoring rule identifiers:

- **Index**
  Specifies an integer value that uniquely identifies the process monitor entry. If this field is left blank or set to 0 when creating an entry, an unused index is automatically selected.
- **Process Name**
  Identifies the process text pattern to match. You can use literal string identifiers or regular expressions to specify a text search pattern.
- **Match Parameters**
  Indicates whether to match both the process name and the parameters or simply the process name.
- **Description**
  Identifies a monitoring rule nickname or brief descriptive term.

Threshold Configuration

Threshold configuration defines the attributes and metrics that the monitor watches. Depending on the SystemEDGE host version, you can specify applicable thresholds when you create a monitoring rule.

The following parameters are available:

- **Attribute**
  Is the process attribute to monitor.
- **Operator**
  Is the Boolean operator that is used to compare the current value to the threshold value. 'No Operation' only tracks the current value; it does not compare against the threshold value.
- **Threshold Value**
  Is the threshold value against which the agent compares the current value. This parameter works with the Operator parameter.
- **Interval**
  Is the time (in seconds) between successive samples by the agent. Values range from 30 to MAXINT and must be a multiple of 30.
- **Sample Type**
  Is the type of sampling to perform on the monitored object.
  - **absolute**
    Measures the actual value (for example, a gauge).
  - **delta**
    Measures a change in value (for example, a counter).
- **Severity**
  Is the severity to use for the object state model.

  NOTE
  This threshold value is not available for all SystemEDGE host versions.
- **Object Class**

Is the object class to use for the object state model.

NOTE
This threshold value is not available for all SystemEDGE host versions.

- **Object Attribute**
  Is the object attribute to use for the object state model.

  NOTE
  This threshold value is not available for all SystemEDGE host versions.
- **Object Instance**
  Is the object instance to use for the object state model.
  Note: This threshold value is not available for all SystemEDGE host versions.
- **Execute Action**
  Specifies the command that is executed if a threshold is crossed (a string, up to 4096 characters). The action script must be present on the host.
- **Send Arguments**
  Indicates whether to send default arguments to action scripts or programs (for example, trap type or a description field).

Advanced Options

Advanced options let you specify actions to perform during the monitoring process.

- **Send SNMP Traps**
  Indicates whether to send SNMP traps.
- **Send Process Start Traps**
  Indicates whether to send process start traps.
- **Handle Process Start Traps**
  Indicates whether to execute actions, log events, and send SNMP traps when a process start trap occurs. Acts as a convenience flag for setting the three individual flags at the same time.
- **Send Not-Ready Trap**
  Indicates whether to send not-ready traps.
  - **Single**
    A single not-ready trap is sent.
  - **Continuous**
    A continuous not-ready trap is sent.
- **Send Process Clear Traps**
  Indicates whether to send process clear traps.
- **Monitor Parent Process**
  Indicates whether to monitor the parent process.
- **Monitor Windows Service**
  Indicates whether to monitor the Windows service.
- **Reinitialize Entry**
  Indicates whether to reinitialize the entry.
- **Log Events**
  Indicates whether to log events.
- **Monitor For *x* Processes**
  Indicates whether to monitor for the specified number of processes.
- **Breach After *x* Consecutive Events**
  Indicates whether to send a trap after the specified number of consecutive events.
- **Allow For *x* Consecutive Breach Traps**
  Indicates whether to allow for the specified number of consecutive breach traps.

Creation of SystemEDGE Process Models

For granular monitoring of services and processes running on SystemEDGE host, you can enable the creation of process models of all the monitored processes.

This functionality is enabled by adding the "enable_sysedge_process_modeling_support=true" configuration to the ".vnmrc" file. When this functionality is enabled, you can see the list of process models in the "Locater, System and Application Monitoring, All Monitored Processes".

When you configure the alarms to be generated on these process models, the alarms are mapped to the process models, and not to the SystemEDGE. As a result, only the service monitoring a process which is down is shown effected.

Edit a Process Monitoring Rule

You can edit local process monitoring rules. You can also edit rules that are owned by rule sets in the context of a host model. In the latter case, the modification transforms the ownership of the rule from the rule set to the model (Rule Owner value converts to Local).

> **NOTE**
> To edit a rule, you must have a user model in all landscapes where the rule was created.

Follow these steps:

1. In the Contents panel, select the model with the process monitoring rule that you want to edit.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, in the Information tab, expand System Resources, Running, and Monitored Processes, Monitored Processes.
   The Monitored Processes table lists process monitoring rules for the selected model.
3. Select the process monitoring rule that you want to edit, and click Edit.
   The Edit Process Monitor Table Entry dialog opens.
4. Modify the settings as required, and click OK.
   Changes to the process monitoring rule for the selected model take effect immediately.

Delete a Process Monitoring Rule

You can delete local process monitoring rules and rules that are owned by rule sets for a host model. In the former case, monitoring stops for the process. In the latter case, the deletion also stops monitoring for the particular model by the rule from the rule set. However, the deletion of a rule set rule is temporary. Process monitoring that is specified by the rule is reestablished the next time the rule set is updated. See Deleting a Rule Outside of a Rule Set for more information.

When you delete a process monitoring rule, DX NetOps Spectrum and the process monitoring agent stop monitoring all identical (non-differentiated) instances of the process that is specified in the rule. In addition, the rule is removed from the agent MIB.

Follow these steps:

1. In the Contents panel, select the model with the process monitoring rule that you want to delete.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, Running, and Monitored Processes, Monitored Processes.
   The Monitored Processes table lists process monitoring rules for the selected model.
3. Select the process monitoring rule that you want to delete, and click Delete.
   You are prompted to confirm the deletion.
4. Confirm the deletion.
   The process monitoring rule is deleted.
   Process monitoring that is specified by the rule for the selected model stops immediately.

Maintenance Mode

When a process monitor is in maintenance mode, the process is not monitored. Any events or alarms that are related to monitoring of that process are not generated.

Placing a process monitor into maintenance mode can be useful when a single application on a host where several critical applications are running is upgraded. You can place only the process that is associated with that particular application into maintenance mode while the upgrade is taking place. Monitoring of the other applications can continue.

Maintenance mode can also be scheduled, which allows you the ability to specify what time of day to alarm on processes.

Maintenance mode is only supported for RFC 2790 and NSM Agent process monitoring.

NOTE
When a host device is in maintenance, process monitoring for that device is automatically suspended.

Place Process Monitor in Maintenance Mode

A process monitor can be placed into maintenance mode at any time. This procedure describes how to place a process monitor into maintenance mode immediately.

Follow these steps:

1. In the Contents panel, select the host model for which you want to place a process monitor into maintenance mode.

   NOTE
   Maintenance mode is only supported for RFC 2790 and NSM Agent process monitoring.
2. In the Component Detail panel, in the Information tab, expand System Resources, Running and Monitored Processes, and RFC 2790, if applicable.
3. Perform *one* of the following steps from the Monitored Processes or Monitored Processes (RFC 2790) table to place a process monitor into maintenance mode:
   - Select the process monitor to place into maintenance mode, and click the Maintenance button above the table.
   - Right-click the process monitor to place into maintenance mode, and select 'Toggle Maintenance Mode.'

   The process monitor is now in maintenance mode, and its icon changes to brown. The mode is reflected in the Condition column of the Monitored Processes table. If the icon does not change immediately, click Refresh.

   NOTE
   You can use this same procedure to take a process monitor out of maintenance mode.

Schedule Maintenance Mode for Process Monitor

You can schedule the times when a process monitor is in maintenance mode by applying a maintenance schedule. You can apply an existing schedule, or you can create a new one. You can apply multiple schedules to a process monitor.

Follow these steps:

1. On the Locater tab, select System & Application Monitoring, All Monitored Processes.
2. Select the process monitor in the Contents panel to which you want to apply a maintenance schedule.

   NOTE
   Maintenance mode is only supported for RFC 2790 and NSM Agent process monitoring.
3. In the Component Detail panel, expand the Process Monitor Details subview, locate 'In Maintenance,' and click Schedule.
   The Add/Remove Schedules dialog opens. Any maintenance schedules that are applied to the process monitor appear in the Current Schedules column.
4. (Optional) Apply an existing schedule. Select a schedule from the Available Schedules column, and click the left arrow to move it to the Current Schedules column.
5. Click Create.

The Create Schedule dialog opens.

6. Select a Start Date, a Start Time, and either an End Time or Duration for the schedule.
7. Select a Recurrence factor.

   NOTE
   Leave the Recurrence set to None to create a one-time maintenance mode window.
8. Supply a Description to identify the schedule.
9. Click OK.
   The Create Schedule dialog closes. The new schedule appears in the Current Schedules column in the Add/Remove Schedules dialog.
10. Click OK.
    The Add/Remove Schedules dialog closes. The maintenance mode scheduling changes are applied to the process monitor. The changes appear in the Assigned Maintenance Schedules list.

Roll Down Maintenance Alarms from the Device Model

When a device is placed in maintenance mode, the maintenance alarms that are generated on the device can be rolled down to the associated process models. Enable this propagation by setting the rollMMAlarmToApp attribute to true. When this option is enabled, the alarms also roll down to the application models that are associated with the device.

NOTE
For information about placing a device into maintenance mode, see the Using OneClick section. For information about modifying model attributes, see the Modeling and Managing Your IT Infrastructure Administration section.

Process Model Internal Condition

DX NetOps Spectrum can maintain the condition of process models without having the process monitoring events generate alarms. This functionality can be useful when incorporating multiple monitored process models within a service or resource monitor. Rather than having alarms generated on the device or process models each time a process monitoring rule is violated, you can have a single alarm on the service model when the service policy is violated.

The functionality is disabled by default. Enable it by using the Attribute Editor to set the value of the EnableInternalCondition attribute to Yes. This attribute is on the device model for NSM Process Monitoring and on the rfc2790App application model for RFC 2790 Process Monitoring. When the functionality is either enabled or disabled, any existing process monitoring alarms are cleared on the associated process models, and their InternalCondition attribute is set to Normal.

While the functionality is enabled and the 'Generate Alarm On' option is set to 'Process Model', process monitoring events do not generate alarms. Instead, the InternalCondition attribute of the process model is set to reflect the condition of the process model. The value of this attribute is displayed on the Internal Condition column of the System & Application Monitoring, All Monitored Processes table on the Locater tab. The value can also be found on the Attributes tab of the process model.

While the Internal Condition functionality is enabled, do not map log-file monitors to any process models. The log-file monitoring events continue to generate alarms.

For hosts that support RFC 2790 monitoring:

- When the functionality is enabled or disabled:
  - Manually clear any process monitoring alarms that exist on the affected device model.
  - Process count conditions are reasserted; however, the process start and process stop conditions are not reasserted.
- If a SpectroSERVER is restarted while the Internal Condition functionality is enabled on a device in its landscape, you must disable the functionality and then reenable it on the device. These steps ensure that the Internal Condition of the process models accurately synchronizes with the actual condition of the process monitor.

File System Monitoring

A file system monitoring rule (RFC 2790) specifies file system alarm conditions that cause DX NetOps Spectrum to generate alarms. Alarms are generated when the conditions occur on a host model for which the rule is created:

- File system utilization
- File system goes offline

This section describes how to set up file system monitoring for particular host models. See Working with Monitoring Rule Sets for information about automating the creation of file system monitoring rules for models in Global Collection containers.

Create a File System Monitoring Rule

When you create a file system monitoring rule, you can specify any file system, online or offline. DX NetOps Spectrum creates a model for the rule.

During file system monitoring rule configuration, you define the alarm conditions that cause DX NetOps Spectrum to generate alarms. Examples of such alarm conditions include system utilization thresholds or a file system that goes offline.

Note: Only users with the appropriate privileges can create file system monitoring rules. For more information, see System and Application Monitoring Privileges.

Follow these steps:

1. In the Contents panel, select the model with the file system that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, File Systems.
   The available file system monitoring options for this host type appear.
3. Expand File Systems (RFC 2790) and Monitored File Systems (RFC 2790).
   The File Systems (RFC 2790) table lists file systems for the selected model. The Monitored File Systems (RFC 2790) table lists file system monitoring rules that have been created for the selected model.
4. Use *one* of the following methods to create a file system monitoring rule for the selected model:
   - If the file system you want to monitor is available, right-click the file system in the File Systems (RFC 2790) table and select Monitor this File System.
   - If the file system is not available and therefore not included in the File Systems (RFC 2790) table, click Add on the Monitored File Systems (RFC 2790) table. This lets you specify, for example, a file system that is offline that you want to know about and monitor when it does come online.

   The Add File System Monitor dialog opens. If you selected a file system from the File Systems (RFC 2790) table, the box includes the file system name.
5. Configure the settings. The available settings include the following:
   - **File System Name**
     Specifies the file system. If you added a file system to monitor that is not currently available, type the name. If you added an available file system, the name is entered automatically.
     For hosts that support RFC 2790 monitoring, the value that you enter in this field is case-insensitive. This field converts to lowercase, as displayed in the Monitored File Systems (RFC 2790) table. Duplicate entries are not allowed. If a new entry is created with the same File System Name, the new entry replaces the previous one, updating any configuration settings that were changed.
   - **Description**
     Specifies a nickname, or alias, for the file system.
   - **Threshold Value Type**

Specifies whether to monitor file system utilization thresholds in terms of capacity percentage or unit of storage (Bytes, Kbytes, Mbytes, Gbytes, Tbytes).

- **Utilization Thresholds**
  Specifies thresholds for events, minor alarms, major alarms, and critical alarms. DX NetOps Spectrum clears threshold alarms when metrics no longer exceed thresholds.
- **Alarm if Offline**
  Specifies whether DX NetOps Spectrum generates an alarm when the file system goes offline. DX NetOps Spectrum clears the alarm when the file system comes back online.

6. Click OK.
   The file system monitoring rule is added to the Monitored File Systems (RFC 2790) table. DX NetOps Spectrum generates alarms in response to the alarm condition threshold violations specified in the rule.

   NOTE
   A value of "Local" in the Rule Owner field of a monitoring rule indicates that the rule has been created explicitly for a particular host and is therefore not part of a rule set. For more information about rule sets, see Working with Monitoring Rule Sets.
7. Select a destination for alarms resulting from rule violations from the Generate Alarm On drop-down list. You can specify that DX NetOps Spectrum create alarms on the monitoring rule model or the host model.

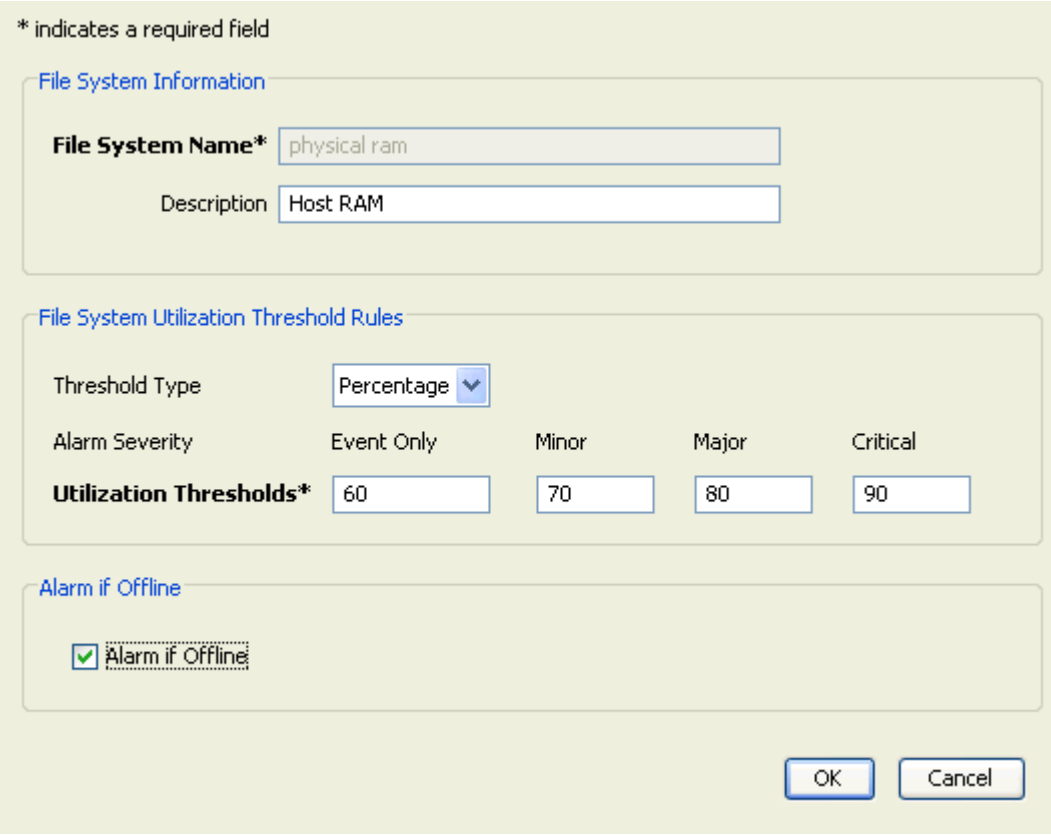
Edit a File System Monitoring Rule

You can edit local file system monitoring rules and rules that are owned by rule sets for a host model. In the latter case, the modification transforms the ownership of the rule from the rule set to the model (Rule Owner value converts to Local). However, the changes and the ownership conversion are temporary because the original rule specifications and ownership are reestablished the next time the rule set is updated. See Editing a Rule Outside of a Rule Set for more information.

NOTE
To edit a rule, you must have a user model in all landscapes where the rule was created.

Follow these steps:

1. In the Contents panel, select the model with the file system monitoring rule that you want to edit.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, File Systems, Monitored File Systems (RFC 2790).
   The Monitored File Systems (RFC 2790) table lists file system monitoring rules.
3. Select the file system rule that you want to edit, and then click Edit.
   The Edit File System Monitor dialog opens. Read-only settings are grayed out.



4. Modify settings as required, and click OK.
   Changes to the file system monitoring rule for the selected model take effect immediately.

Delete a File System Monitoring Rule

You can delete local file system monitoring rules and rules that are owned by rule sets for a host model. In the former case, monitoring stops for the file system. In the latter case, the deletion also stops monitoring for the particular model by the rule from the rule set. However, deletion of a rule set rule is temporary because file system monitoring specified by the rule is reestablished the next time the rule set is updated. See Deleting a Rule Outside of a Rule Set for more information.

Follow these steps:

1. In the Contents panel, select the model with the file system monitoring rule you want to delete.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, File Systems, Monitored File Systems (RFC 2790).
   The Monitored File Systems (RFC 2790) table lists file system monitoring rules.
3. Select the file system monitoring rule that you want to delete, and then click Delete.
   You are prompted to confirm the deletion.
4. Confirm the deletion.
   File system monitoring that is specified by the rule for the selected model stops immediately.

Working with Monitoring Rule Sets

A rule set is a collection of monitoring rules for processes and file systems you can apply to a Global Collection. Rule set automates the process of setting up and managing monitoring for hosts modeled in DX NetOps Spectrum. When

you create a process or file system monitoring rule for a particular host model, that rule applies only to that host model. If you want to apply the same rule to other host models, create the same rule again and again for each host model. If you want to edit the rule for all models, modify each instance of the rule for each host model. This task is obviously a tedious and inefficient way to manage host monitoring for numerous host models. By applying rule sets to Global Collections, you leverage a more efficient method of managing IT infrastructure resources. When host models are added to a collection, DX NetOps Spectrum creates monitoring rules that reference the processes or file systems for those models. Furthermore, when monitoring rules in rule sets are modified, the modifications apply to all host models in the collection. When host models are removed from a collection, all monitoring rules for the models are removed too.

Create a Rule Set

You can create rule sets that contain multiple monitoring rules for both host processes and file systems, or you can create rule sets that include one or the other. You can apply as many rule sets as you want to a Global Collection. You can also apply the same rule set to multiple collections.

> **WARNING**
> Plan your rule set implementation carefully to avoid duplicating rules or implementing conflicting rules. Duplicate or conflicting rules can cause unexpected results and make troubleshooting difficult. Also verify that the Global Collections to which you apply rule sets include host models that are appropriate for the monitoring rules in those rule sets.

As you create rule sets, keep the following points in mind:

- Rule sets must have unique names.
- Rules that are included in rule sets do not override identically named local monitoring rules for host models included in Global Collections. If a local monitoring rule has been created for a particular host model and the model is included in a Global Collection that has a rule set applied to it that contains an identically named rule, the local rule is preserved and remains in effect for the model.

> **NOTE**
> Only users with the appropriate privileges can create monitoring rule sets. For more information, see System and Application Monitoring Privileges.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists any rule sets that have been created.
   Default rule sets are not present.
2. Click Create a New Rule Set by
   Type 
3. Select one of the following options, depending on the agent you are working with:
   - RFC2790
   - NSM Agent:
     - r11 Windows
     - r11 UNIX
     - 3.1 Windows
     - 3.1 UNIX

   The 'New Rule Set' dialog appears.
4. Type a name for the rule set in the Rule Set Name field, and then click OK.
   The new rule set appears in the list. You can now add process monitoring and file system monitoring configuration rules to the rule set. And you can apply the rule set to a Global Collection container.

Add a Monitoring Rule to a Rule Set

You can add monitoring rules to a rule set before or after you apply the rule set to a Global Collection.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists rule sets.

   NOTE
   If no rule sets are listed, create a rule set for the rule, as described in Create a Rule Set.
2. Select the rule set to which you want to add the monitoring rule.
   The Component Detail panel displays information about the rule set.
3. On the Information tab, specify the type of rule to add to the rule set:
   – To add a process monitoring rule, expand Process Monitoring Rules.
   – To add a file system monitoring rule, expand File System Monitoring Rules.

   NOTE
   The NSM rule sets do not support file system monitoring rules.

   Each rules table lists rules that have been added to the rule set.
4. Click Add for the type of rule to add to the rule set.
   Either the Add Monitored Process dialog or the Add File System Monitor dialog opens.
5. Configure settings.
   – See Process Monitoring Rule Parameters for information about configuring a process monitoring rule.
   – See Create a File System Monitoring Rule for information about creating a file system monitoring rule.
6. Click OK.
   The rule is added to the rule set.

Apply a Rule Set to a Global Collection

Applying a rule set to a Global Collection automates the process of creating monitoring rules. DX NetOps Spectrum automatically creates monitoring rules for all models in the Global Collection.

As you apply rule sets to Global Collections, consider the following facts:

- If you remove models from the Global Collection, all monitoring rules that are specified by the rule set are removed from the models.
- If you edit a rule from a rule set for a particular model that is included in a Global Collection, the ownership of a rule changes to local ownership. The rule is no longer associated with the rule in the rule set and applies only to that particular model.
- If you delete a rule set that is associated with a Global Collection or vice versa, the rules that are specified by the rule set are removed from the models in the collection.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists rule sets.

   NOTE
   If no rule sets are listed, create a rule set as described in Create a Rule Set.
2. Right-click the rule set or sets that you want to apply to a Global Collection, and select Apply/Remove Global Collection(s).
   The 'Apply and Remove Collection(s) to/from the Rule Set' dialog appears.
   All Global Collections that are listed in the left side of the dialog are currently applied to the selected rule set. Global Collections that are listed on the right side have not been applied.
3. In the Not Applied To list, double-click the Global Collection to which you want to apply the rule set.

The selected Global Collection moves to the Applied To list.

NOTE
You cannot apply Global Collections to multiple rule sets simultaneously.

4. (Optional) Select the Reapply check box to reapply the Global Collection or Collections that are already applied to the rule set when you click OK in the dialog.
5. Click OK to apply your changes.

NOTE
Only the changes that you made in the dialog are applied. A Global Collection that already appears in the Applied To list is not reapplied unless you have selected the Reapply check box.

The Applied Global Collections List in the Information tab of the selected rule set shows the Global Collections to which it is applied.

Remove a Rule Set from a Global Collection

When you remove a rule set from a Global Collection, DX NetOps Spectrum removes monitoring rules in the rule set from all models in the Global Collection.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists rule sets.
2. Right-click the rule set or sets from which you want to remove a Global Collection and select Apply/Remove Global Collection(s).
   The 'Apply and Remove Collection(s) to/from the Rule Set' dialog appears.

NOTE
You can also click the icon in the Results tab toolbar to launch this dialog.

All Global Collections that are listed in the left side of the dialog are currently applied to the selected rule set. Global Collections that are listed on the right side have not been applied.

3. In the Applied To list, double-click the Global Collection that you want to remove from the rule set.
   The selected Global Collection is moved to the Not Applied To list.

NOTE
You cannot remove Global Collections from multiple rule sets simultaneously.

4. (Optional) Select the Reapply check box to reapply the Global Collection or Collections that are already applied to the rule set when you click OK in the dialog.
5. Click OK to apply your changes.

NOTE
Only the changes you made in the dialog are applied. A Global Collection that already appears in the Applied To list is not reapplied unless you have selected the Reapply check box.

The Applied Global Collections List in the selected Information tab of the rule set is updated. The Global Collection or Collections that you removed are no longer displayed.

Edit a Rule in a Rule Set

When you edit a rule in a rule set that is applied to a Global Collection, the revised rule settings extend to all models in the Global Collection.

NOTE
To edit a rule, you must have a user model in all landscapes where the rule was created.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists rule sets.
2. Select the rule set with the rule that you want to edit.
   The Component Detail panel displays information about the rule set.
3. In the Component Detail panel, specify the type of rule to edit, either a process monitoring rule or a file system monitoring rule.
   Each rule type table lists rules that have been included in the rule set.
4. Select a rule, and click Edit.
   The Edit dialog opens.

   NOTE
   Some settings are unavailable for edit.
5. Edit settings, and then click OK.
   The modified settings take effect immediately.

Editing a Rule Outside of a Rule Set

Under some circumstances, you may want to modify a monitoring rule for a particular model in a Global Collection even though the rule belongs to a rule set that has been applied to a Global Collection. You might not want the modification to apply to the rule in the rule set because the modification would then apply to all models in the Global Collection. But you still want to keep the model in the collection.

In this case, convert the rule to a local version for the model. You can modify this rule from the context of the particular model outside of the rule set to achieve this result.

Delete a Rule from a Rule Set

When you delete a rule from a rule set that is applied to a Global Collection, the rule is removed from all models in the Global Collection.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists rule sets.
2. Select the rule set with the rule that you want to delete.
   The Component Detail panel displays information about the rule set.
3. In the Component Detail panel, specify the type of rule to delete from the rule set, either a process monitoring rule or a file system monitoring rule.
   Each rule table lists rules that have been included in the rule set.
4. Select the rule, and click Delete.
   The rule is removed from the rule set and from its rule table.

Deleting a Rule Outside of a Rule Set

Under some circumstances, you may want to delete a rule for a particular model in a Global Collection even though that rule belongs to a rule set that is applied to a Global Collection. You might not want to delete the rule in the rule set and thus delete it for all models in the Global Collection. But you still want to keep the model in the collection.

In this case, delete this rule from the context of the particular model outside of the rule set. When the association between the rule set and the Global Collection is updated, however, the deleted rule is recreated for the model.

Delete a Rule Set

When you delete a rule set that is applied to a Global Collection, all rules in the rule set are removed from the models in the collection.

Follow these steps:

1. Select Locater, System & Application Monitoring, All Monitoring Rules.
   The Contents panel lists all available rule sets.
2. Select the rule set to delete, and click Delete.

Log File Monitoring

This chapter describes how to set up log file monitoring in OneClick for the following agents:

- iAgent
- CA SystemEDGE Agent
- CA Unicenter NSM Agent

This chapter also describes how to configure iAgent syslog server monitoring and trap forwarding to DX NetOps Spectrum.

Setting up log file monitoring entails the following tasks:

- Specifying the criteria that initiate the trap and the event generation. The traps and events are generated when the type of information that you specify is detected in a log file.
- (Optional) Specifying an association between a log file and a monitored process model. Events are then generated in response to a log file entry for the process model. The events are generated on the process model rather than on the process host model.

About the Log File Monitoring Process

Various devices on your network can be configured to send data to log files on an iAgent, SystemEDGE agent, or NSM server. Or the applications on one of these servers can send data to a log file. In either case, these agents can be configured to monitor these log files and generate SNMP traps based on the content in log file entries.

Log file monitoring involves setting up a text pattern matching system that detects and parses log files for the type of information that you specify. The monitoring agent then sends a trap to DX NetOps Spectrum that contains data about the parsed text. This data is then mapped to a DX NetOps Spectrum event and an alarm is asserted on the agent model or the device or process to which it pertains. You can also use an event condition rule to configure DX NetOps Spectrum to create a more granular event, and optionally an alarm, from the "text match in log file" event. As a result, you receive notifications of events that have occurred in your infrastructure and that indicate potential or actual problems. For more information, see Event Configuration .

The syntax of the log file that you are monitoring depends on the type of log file and the data that is sent to it. Because application log files are matched directly to the applications that you are monitoring, no special log file syntax is required. However, DX NetOps Spectrum processes other log files that gather data from other devices differently. Therefore, these log file entries must conform to certain syntax criteria.

Regardless of the type of log file that you want to monitor, whether an application log file or a syslog file containing entries for multiple applications from multiple devices, you must define a regular expression (regex) that identifies, or parses, the type of information that you want to monitor. The regex syntax must be compatible with the type of agent. When matching text is found, the monitoring agent sends a trap to DX NetOps Spectrum that contains the matching text. DX NetOps Spectrum associates the trap to an event that is asserted on the host model.

NOTE
For more information about defining regular expressions, see Event Configuration .

Configuring DX NetOps Spectrum to Process Syslog File Matches explains how to configure an agent to monitor log files for strings of information that generate a trap.

NOTE
iAgent can only monitor log files that exist on the iAgent server. It cannot monitor log files on a mapped network drive.

Log File Syntax

You can monitor application logs or log files that receive data from other devices, such as Syslog files. No special syntax is required for log files that monitor application logs. However, for DX NetOps Spectrum to assert the trap information about the appropriate device model, log files that receive information from devices on the network must have the following format, which is based on the BSD Syslog and Cisco IOS format:

```
<MessagePrefix>%<MessageHeader><Additional_Information>
```

- ***<MessagePrefix>***
  Contains the date and time of the message and the IP address or the host name of the source of the information contained in the entry. There can be other information that is interspersed within the prefix, but it must contain these two pieces of information.

  NOTE
  If a host name is used to identify the source, it can be of the form myhost.ca.com or myhost.
- ***<MessageHeader>***
  Must have the format < *A*>-< *B*>-
  - ***< A>***
    Contains any number of uppercase alpha characters, underscores, or the string "Aprisma."
  - ***< B>***
    Contains any number of uppercase alpha characters, numeric characters, or underscores.
  - ***< C>***
    Contains any number of uppercase alpha characters, underscores, or dashes.
- ***<Additional_Information>***
  Can contain any data.

In general, this syntax can be found in the following types of log files:

- Kiwi syslog file entries from a Cisco or Riverstone device.
- Kiwi syslog file entries from another type of device that uses the *<MessageHeader>* format described previously.
- CA log files.

NOTE
For information about configuring DX NetOps Spectrum to process iAgent traps, see Configuring DX NetOps Spectrum to Process Syslog File Matches.

Create Log File Monitors for iAgent Hosts

The following procedure describes how to set up log file monitoring for iAgent host agents.

Follow these steps:

1. In the Contents panel, select the model with the log file you want to monitor.
   Information for this host device appears in the Component Detail panel.

2. In the Component Detail panel, in the Information tab, expand System Resources, Monitored Logs and Process Logs, Monitored Logs.
   The Monitored Logs list is displayed.

   NOTE
   Some list fields are agent-specific.
3. Click Add in the Monitored Logs list.
   The Add Log File Monitor dialog for the agent opens.
4. Configure log file monitor settings as needed. Pay particular attention to the following mandatory and optional settings:
   - **Log File Name**
     Identifies the monitored log file.
   - **Regular Expression**
     Identifies the text patterns to parse in the log file.

     NOTE
     For more information about defining regular expressions, see the Event Configuration section.
   - **Description**
     Indicates the purpose of the monitor to other users.
   - **Send Trap on Match/Send Trap**
     Specifies whether the agent sends a trap to DX NetOps Spectrum when the regular expression detects a matching text pattern.
5. Click OK.
   The monitoring configuration is added to the Monitored Logs list, and monitoring begins immediately.

Log File Monitors for NSM Agents

You can set up log file monitoring and file monitoring for NSM Agents in OneClick. The following definitions describe how these two monitors differ:

- **NSM Log File Monitor**
  An NSM Log File Monitor watches contents of a file for specific patterns.
- **NSM File Monitor**
  An NSM File Monitor simply watches for the existence or absence of a file.

NSM Agent log file monitoring lets you perform the following tasks.

- Edit and view file monitors for NSM Agents
- Edit and view log monitors for NSM Agents
- View status changes for file and log monitors for NSM Agents

Set Up a Log File Monitor for NSM Agents Using OneClick

You can use OneClick to set up log file monitoring for NSM host agents.

Follow these steps:

1. In the Contents panel, select the model with the log file that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, in the Information tab, expand System Resources, Monitored Logs and Files, Monitored Logs.
   The Monitored Logs list appears.
3. Click Add in the Monitored Logs list.
   The Add Log File Monitor dialog opens.
4. Configure log file monitor settings as needed. The following options are available:

- **Monitor Name**
  Identifies the name of this log file monitor.
- **File Name**
  Identifies the full path and file name (or wildcarded file name) of the log file to monitor.
- **Positive Pattern**
  Places the monitor in a DOWN state if the specified regular expression is found in the file.
- **Negative Pattern**
  Places the monitor in a DOWN state if the specified regular expression is *not* found in the file.
- **Toggle Positive Pattern**
  Places the monitor in an UP state if the specified regular expression is found in the file. This field is only available when the Status Policy is toggled or toggledEOF.
- **Toggle Negative Pattern**
  Places the monitor in an UP state if the specified regular expression is *not* found in the file. This field is only available when the Status Policy is toggled or toggledEOF.
- **Start**
  Is the starting character position.
- **End**
  Is the ending character position.
- **Status Policy**

Defines how the monitor handles files. The following options are available:

- **poll**
  a. Sets monitor status to UP at the beginning of each poll. If a match is made, the state changes to DOWN. The file is scanned from the last read location unless it is a new monitor, in which case the entire file is read.
- **historical**
  a. Sets monitor status to DOWN when a match occurs, and status remains DOWN for the life of the log file. Therefore, the log file is recreated. The file is scanned from the last read location unless it is a new monitor, in which case the entire file is read.
- **startFromPreviousRead**
  a. Sets monitor status to DOWN when a match occurs, and status remains DOWN until you reset it. The file is scanned from the last read location.
- **toggled**
  a. Lets you specify a DOWN pattern, as with the historical attribute, and also an UP pattern (formed with the toggle positive and negative pattern attributes), which is compared for changing the state back to UP. The file is scanned from the last read location.
- **firstLineOnly**
  a. Reads only the first line of a file. The monitor status is set to UP at the beginning of each poll. If a match is found, the state changes to DOWN.
- **pollEOF**
  a. Sets the monitor status to UP at the beginning of each poll. If a match is found, the state changes to DOWN. The file is scanned from the last read location unless it is a new monitor, in which case reading starts at the end of the file.
- **startFromPreviousReadEOF**
  a. Sets the monitor status to DOWN when a match occurs, and status remains DOWN until you reset it. The file is scanned from the last read location unless it is a new monitor, in which case reading starts at the end of the file.
- **toggledEOF**
  a. Lets you specify a down pattern, as with the historical attribute, and also an up pattern (formed with the toggle positive and negative pattern attributes) which is compared for changing the state back to UP. The file is scanned from the last read location unless it is a new monitor, in which case reading starts at the end of the file.
- **rescan**
  a. Rescans the file from the beginning if the file length has increased. If the file exceeds 10 KB, sets the monitor to UNKNOWN.
- **Monitor Status**
- Lets you disable the status side of the monitor without matching trap sending. The following options are available:
- **downCritical**
  a. Indicates that the state change works as configured and a critical alert is raised.
- **doNotMonitor**
  a. Indicates that the log file is monitored, but the state is always UP.
- **downWarning**
  a. Indicates that the state change works as configured and a warning alert is raised.
- **Trap Send Policy**

Defines the policy that is applied to the monitor status traps. The following options are available:

- **never**
  a. Indicates that the state change never causes traps to be sent.
- **once**
  a. Indicates that the state change trap is sent only when the monitor state changes.
- **perPoll**
  a. Indicates that the state change trap is sent every poll, even if the state does not change but a match condition occurred since the last poll.
- **each**
  a. Indicates that the state change trap is sent for each match that the agent finds. For toggle attributes, when the monitor goes down, the toggle pattern is the next match that is looked for. As a result, subsequent down patterns are not matched.
- **Match Trap Policy**
  Defines the policy that is applied to the match traps. The following options are available:
- **send**
  a. Sends a trap for each match that is found. For toggle attributes, when the monitor goes down, the toggle pattern is the next match that is looked for. As a result, subsequent down patterns are not matched unless status monitoring is switched off.
- **doNotSend**
  a. Does not send a trap for each match found.
- **History Policy**
  Defines whether trap details are stored in the history table. The following options are available:
- **generateHistory**
  a. Indicates that status traps are recorded in the history table.
- **noGenerateHistory**
  a. Indicates that status traps are not recorded in the history table.

5. Click OK.
   The monitoring configuration is added to the Monitored Logs list. Monitoring begins immediately.

Set Up a File Monitor for NSM Agents Using OneClick

You can use OneClick to set up log file monitoring for NSM host agents.

Follow these steps:

1. In the Contents panel, select the model with the file that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, in the Information tab, expand System Resources, Monitored Logs and Files, Monitored Files.
   The Monitored Files list is displayed.
3. Click Add in the Monitored Files list.
   The Add File Monitor dialog opens.
4. Configure file monitor settings. Pay particular attention to the following mandatory and optional settings:
   - **Monitor Name**
     Identifies the name of the file monitor.
   - **File Name**
     Identifies the name of the file that this monitor watches.
   - **File Exists**
     Indicates whether the file exists.
   - **Trap Send Policy**

Specifies the frequency with which the NSM Agent sends traps. The following settings are available:

- **never**
  a. Never sends a trap.
- **once**
  a. Sends a trap only when the state has changed.
- **perPoll**
  a. Sends a status trap at each poll if the state is DOWN.
- **History Policy**
  For details about History Policy settings, see Set Up a Log File Monitor for NSM Agents Using OneClick.

5. Click OK.
   The monitoring configuration is added to the Monitored Files list, and monitoring begins immediately.

Create Log File Monitors for SystemEDGE Hosts

You can use OneClick to set up log file monitoring for a SystemEDGE host agent.

Follow these steps:

1. In the Contents panel, select the model with the log file that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, in the Information tab, expand System Resources, Monitored Logs and Process Logs, Monitored Logs.
   The Monitored Logs list appears.
3. Click Add in the Monitored Logs list.
   The Add Log File Monitor dialog for the agent opens.
4. Configure the log file monitor settings as needed:
   - **Log File Name or Directory Name**
     Identifies the monitored log file or directory, depending on the Monitor Type.
   - **Monitor Type**
     Identifies whether to monitor a log file or a directory.
     - **File**
       Indicates that a log file is monitored.
     - **Directory**
       Indicates that a directory is monitored. You can also specify whether to Monitor Recursively and whether to Follow Symbolic Links.
   - **Description**
     (Optional) Is a brief description to indicate the purpose of the monitor, for example.
   - **Interval**
     Is the interval, in minutes, between successive scans of the log file.
   - **Severity**
     Is the severity to use for this monitor entry.
   - **Parse File**
     Is a regular expression to match in the log file (up to 256 characters). The value must be a valid string, as defined in ed(1).
   - **Does Not Match**
     Indicates whether to apply a logical NOT operator when parsing the log file.
   - **Execute Action**
     Is a string that specifies the command that is executed after finding a match (up to 4096 characters). The action script must be present on the host.
   - **Send Arguments**

Indicates whether to send default arguments to action scripts or programs (for example, trap type, a description field).

- **Send SNMP Traps**
  Specifies whether the agent sends a trap to DX NetOps Spectrum when the regular expression detects a matching text pattern.
- **Send Not-Ready Trap**
  Indicates whether to send not-ready traps.
  - **Single**
    A single not-ready trap is sent.
  - **Continuous**
    A continuous not-ready trap is sent.
- **Reinitialize Entry**
  Indicates whether to reinitialize the entry.
- **Breach After *x* Consecutive Matches**
  Indicates whether to send a trap after the specified number of consecutive matches have occurred.
- **Log Events**
  Specifies whether to log events.

5. Click OK.
   The monitoring configuration is added to the Monitored Logs list, and monitoring begins immediately.

Log-to-Process Mapping

DX NetOps Spectrum can generate an event on the process that a parsed log file entry references rather than on the host model. To configure such events, verify that the process monitoring rule for the host model references the process. And associate the process with the log file that includes the entry that is related to the process. See Process Monitoring for more information about process monitoring rules.

Specify a Mapping for RFC 2790 Agents and SystemEDGE Hosts

You can use OneClick to specify a mapping of log to process for RFC 2790 Agents.

Follow these steps:

1. In the Contents panel, select the model with the log files that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, Monitored Logs and Process Logs, Monitored Process Log File Mappings.
   The Monitored Process Log File Mappings list appears.
3. Click Add in the Monitored Process Log File Mappings list.
   The Add Log to Process Mapping dialog appears.
4. Enter the following data:
   - **Log File Name**
     Is the log file to monitor.
   - **Process Name**
     Is the process that is specified in the process monitoring rule.
5. Click OK.
   The mapping is added to the Monitored Process Log File Mappings list. DX NetOps Spectrum generates events on the monitored process model whenever text about the process is parsed from a log file.

Mapping for NSM r11 Agents

You can use OneClick to specify a mapping of log to process for NSM r11 Agents.

NOTE
You cannot create mappings for NSM 3.1 Agents.

Follow these steps:

1. In the Contents panel, select the model with the log files that you want to monitor.
   Information for this host device appears in the Component Detail panel.
2. In the Component Detail panel, expand System Resources, Monitored Logs and Files, Monitored Process Log File Mappings.
   The Monitored Process Log File Mappings list appears.
3. Click Add in the Monitored Process Log File Mappings list.
   The Add Log to Process Mapping dialog opens.
4. Enter the following data:
   – **Log File Name**
     Name of the log file.
   – **Monitor Name**
     Name of the process monitor. This value likely differs from the name that is specified for the process in the process monitoring rule.
5. Click OK.
   The mapping is added to the Monitored Process Log File Mappings list. DX NetOps Spectrum generates events on the monitored process model whenever text about the process is parsed from a log file.

Managing Monitored Log and Process Log Mapping Settings

You can use OneClick to edit and delete monitored log and process log file mapping settings.

- To edit monitored log and process log file mapping settings, select a configuration entry that you want to modify, click Edit on the configuration entry list, edit the entry, and then click OK.

  NOTE
  You cannot edit an active monitor entry. To edit a monitor entry that is in an active state, change the status of the entry to notInService(2) or notReady(3). You can perform this task in MIB Tools, using the SET command.
- To delete monitored log and process log file mapping settings, select a configuration entry that you want to remove, click Delete on the configuration entry list, and then click OK.

Configuring the Product to Process Syslog File Matches

You can configure DX NetOps Spectrum to process a Syslog file matches from iAgent, SystemEDGE, and NSM Agents.

Trap Processing Overview

Each trap that an agent generates based on the content of a log file entry has an OID. This OID generates the DX NetOps Spectrum event 0x3e00009 based on the trap mapping in the AlertMap file of the agent. This event is asserted on the model.

The matched line of each log file entry (up to 255 characters) and the log file name that generated the trap is sent as part of the trap information. DX NetOps Spectrum parses the trap data to determine the original source of the log file entry. The source can be an IP Address, hostname, DX NetOps Spectrum model handle, or application log file name.

Processing Traps That Contain an IP Address, Host Name, or Model Handle

If an IP address, hostname, or a model handle has been extracted as the source of the log file entry, DX NetOps Spectrum can find the device model that matches the IP address, hostname or model handle and can assert the event

on this model. If the log file entry conforms to the syntax described in Log File Syntax, to make the event asserted on the device model meaningful, you can create a ParseMap file to customize the event and its contents.

NOTE
DX NetOps Spectrum contains many ParseMap files. You do not always have to create one.

If no ParseMap file is created, the event that is routed to the device model is the same event asserted on the mode of the agent.

Disable DNS Lookup for Syslog Traps

If a hostname is received as part of the Syslog trap, DX NetOps Spectrum (until 10.2.3) uses DNS Lookup to resolve the hostname to an IP address and locates the associated model. Or, DX NetOps Spectrum checks for the host entry in the /etc/host file.

In your environment, if the DNS Server is not accessible or you do not want to contact DNS Server or /etc/hosts file to resolve hostnames, you can use the ‘preventDNSlookup’ attribute (introduced in 10.3) to stop DNS Lookup.

From 10.4.2.2, when the 'preventDNSlookup' attribute is enabled, instead of resolving the hostname to IP address, DX NetOps Spectrum fetches the model handles of the models from DX NetOps Spectrum Database that has the model name same as hostname received in the Syslog message and asserting Syslog trap on those models. If there are multiple models whose model name matches the hostname from the Syslog message, the trap is asserted on all the matched models.

To enable the ‘preventDNSlookup’ attribute follow these steps:

1. Select the VNM model of a landscape in the Topology tab
2. Go to Component details->Attributes tab
3. Search for ‘preventDNSlookup’ attribute and double click it to edit
4. Change the value to Yes. The 'preventDNSlookup’ attribute is enabled for the selected VNM of the landscape. If you want to enable “preventDNSlookup” attribute on VNM models of other landscapes, repeat all the above steps.

NOTE

The default value for ‘preventDNSlookup’ attribute is ‘No’. When the value is ‘No’ DX NetOps Spectrum uses ‘DNSlookup’ to resolve the hostnames.

Create ParseMap Files

ParseMap files specify the event that is associated with the information in the incoming trap. In addition, ParseMap files allow you to specify that portions of the log file entry text be used as event variables. You can use these variables in conjunction with an Event Rule to process the event.

NOTE
For information about event processing and Event Rules, see theEvent Configuration *section*.

As described in Log File Syntax, a log file entry contains the following components:

```
<MessagePrefix>%<MessageHeader><Additional_Information>
```

DX NetOps Spectrum identifies the ParseMap file that processes the trap by finding the ParseMap file whose name matches the text of the *<MessageHeader>* from the log file entry. The following log is an example of a log file entry:

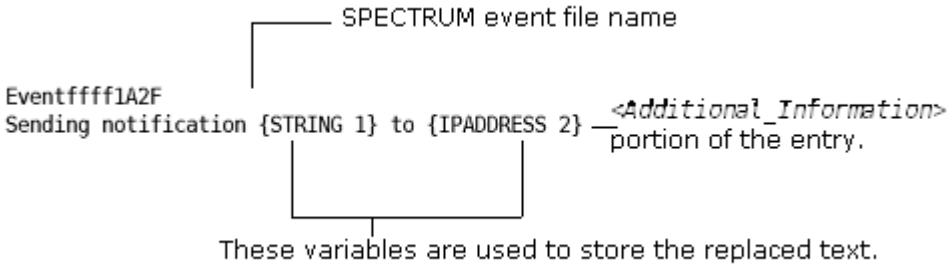
```
2004-2-19 11:19:14 Local7.Info 172.19.38.36 Feb 19 09:14:50
%SNMP-I-SENT_TRAP, Sending notification linkUp to 192.168.32.44
```

The *<MessageHeader>* portion of the entry is SNMP-I-SENT_TRAP. As a result, DX NetOps Spectrum looks for a ParseMap file named SNMP-I-SENT_TRAP. Create a ParseMap file for each log entry with a unique *<MessageHeader>* that you configure to generate a trap.

NOTE
Many ParseMap files are available for use in DX NetOps Spectrum. You can find them in the following directory: *<$SPECROOT>*/SS/CsVendor/ParseMaps.

Follow these steps:

1. Create new text file using any text editor.
   A text file is ready for editing.
2. In the first line of the text file, type the new event file name for the event that you want to generate. The event file name must begin with Eventfffff and end with xxxx where x is any valid hexadecimal number.
   For example, Eventfffff1A2F and Eventfffff1234 are the valid event file names; Event012za8b is not.
3. Add a new line in the text file (press the Enter key).
4. Use this line as the *<Additional_Information>* portion of the log file entry. You can specify portions of this text as event variables, which can be used to process the event with an Event Rule.
   Specify variables using a data type and an integer. Valid data types are STRING, STRINGNOWS, INTEGER, and IPADDRESS. See STRING Data Type Usage Guidelines for important information.
   The following image shows a valid ParseMap file for the log entry shown in the previous section. The variable 1 stores Uplink as a String. The Variable 2 stores 192.168.32.44 as an IP Address.



5. Save the text file in the *<$SPECROOT>*/SS/CsVendor/ParseMaps directory. The name of this text file must match the *<MessageHeader>* portion of the log file entry. In this example, the filename would be SNMP-I-SENT_TRAP.

   NOTE
   Do not include a file extension in the filename.

   Only the first two lines of the ParseMap file are processed. The information that you include on subsequent lines is not processed but can be included for informational purposes.

ParseMap File Example

The following sequence of lines is an example of a ParseMap file that is provided with DX NetOps Spectrum named SYS-0-MOD_TEMPMAJORFAIL. The ParseMap file can be found in the following directory: *<$SPECROOT>*/SS/CsVendor/ParseMaps.

```
Event04bd1522
Module {STRING 1} major temperature threshold exceeded
%SYS-0-MOD_TEMPMAJORFAIL: Module {STRING} major temperature threshold exceeded
```

This instructs a matched syslog file:

```
Jul 28 10:56:42 [10.253.9.11.2.45] 7931: *Jul 28 10:50:47.271:
%SYS-0-MOD_TEMPMAJORFAIL: Module 100 major temperature threshold exceeded
```

This causes the event Event04bd1522 to be generated on the model with the IP address 10.253.9.11, even though the agent generated the trap.

STRING Data Type Usage Guidelines

This section provides important information about using STRING data types in your ParseMap files.

Valid STRING Data Types

As mentioned in "To create a ParseMap file," the following data types are valid for use in variables.

- **STRING**
  Matches all string characters up to the next literal, data type, or to the end of a string.
- **STRINGNOWS**
  Matches all string characters up to the next space, literal, data type, or the end of a string.
- **INTEGER**
  Matches any positive integer value.
- **IPADDRESS**
  Matches any valid IPv4 address.

Whitespace in STRING Variables

Because whitespace is a valid character in the definition of the STRING variable, always separate multiple STRING tokens with recognizable patterns.

For example, The following ParseMap are *valid* entries:

```
{STRING 1}, {STRING 2}
{STRING 1} {IPADDRESS 2} {STRING 3}
{STRING 1} literal text {STRING 2}
{STRINGNOWS 1} {STRING 2}
```

However, do not have these entries because the resulting regular expression becomes ambiguous:

```
{STRING 1}{STRING 2}
{STRING 2} {STRING 2}
```

Create an Event Format File

Each event code that you specify in a ParseMap file must have a separate Event Format file. When an event is asserted, the text of the Event Format file appears in the Event Log. When creating the Event Format file, keep in mind that most of the information the troubleshooter receives about an event comes from the event message text.

Create the Event Format file using a text editor and place the file in the following directory: *<$SPECROOT>*/SG-Support/CsEvFormat. The Event Format file must be named Event*<xxxxxxxx>* where *<xxxxxxxx>* is the event code that is given to the event in ParseMap file. For example, if you have an event with an event code of 0xffff1A2F, DX NetOps Spectrum uses the Event Format file named Eventffff1A2F.

To make the text of the event message meaningful, you can use the variables assigned in the ParseMap file of the event and the built-in variable available for all Event Format files.

> **NOTE**
> For complete instructions on creating an Event Format file, including the built-in variables that are available, see the Event Configuration section.

Example: Event Format File

Use the following Event format file for the event generated by the ParseMap file.

The IP Address variable is inserted using the data type O (octet) and the variable that is assigned from the ParseMap file, 1. The device name variable is inserted using the data type s (string) and the variable assigned from the ParseMap file, 2. The built-in variables {d "%w- %d %m-, %Y - %T"}, {m}, {t}, and {e} show the date of the event, model name, model type name, and event ID.

```
{d "%w- %d %m-, %Y - %T"} A device {m} of type {t} has reported a problem.
Its ip address is {S 1} and the device name is {S 2}. - (event [{e}])
```

Generating an Alarm Based on the Event

You can specify further processing on the event created in the ParseMap file. You can generate an alarm based on the event, or can use the event as part of an Event Rule. To do this, determine all of the model types that this event could be asserted on and could specify the appropriate event processing in each model type's EventDisp file. If you want the event to be processed the same way for each model type, you can specify the event processing in a global EventDisp file.

If you have specified that an alarm is created based on an event, create a probable cause file that are displayed in the OneClick Console when the alarm is asserted.

> **NOTE**
> For more information about EventDisp and probable cause files, see the Event Configuration section.

Apply the Changes to the SpectroSERVER

To activate the new or updated Event Format and ParseMap files, apply the changes to the SpectroSERVER. This can be done using the Update command found in the Event Configuration Editor, using the command line interface, or by stopping and restarting the SpectroSERVER. See the Event Configuration *section* for more information about each of these methods.

Enable Event Forwarding for Agent Models

You can configure the model of an agent to forward events to models on remote landscapes. Set the SBG_AlertForwardingEnabled (0x3dc000c) attribute for the model to TRUE.

SystemEDGE Application Insight Modules (AIMs)

The SystemEDGE agent provides a plug-in architecture through which it can load Application Insight Modules (AIMs) when it initializes. These AIMs provide an extensible and flexible approach to supporting application-specific semantic knowledge.

DX NetOps Spectrum supports the following AIMs:

- Apache Web Server
- Microsoft IIS
- CA Insight DPM for DB2, Oracle, SQL Server, and Sybase

> **NOTE**
> The SystemEDGE AIMs are available from the Information tab in the Component Detail panel for a selected SystemEDGE agent.

In addition, DX NetOps Spectrum reports alarms which are sent through traps by the Insight AIMs. Each Insight AIM sends out a trap unique to its type, which lets you differentiate between the Insight AIM agent types. Detailed per-alarm information also includes the database name, the alarm type, and the alarm description.

The Insight AIM alarm types vary between agent types and cover a wide range of notifiable conditions. These AIM alarms are no different from other alarms in DX NetOps Spectrum and appear in the same tables and offer the same functionality.

Apache Web Server

The AIM for Apache lets you monitor the health and availability of the Apache web server.

This module works with the SystemEDGE agent to provide the following information:

- The number of "hits" that your web server is receiving. You can track daily volume and set monitor points to watch for unusual traffic levels or denial of service attacks.
- The amount of space that your web log file and web server file are consuming.
- Idle services and active processes. You can gauge how effectively the Apache web server processes monitor idle services, see a warning when the number of idle services is too low, and can monitor the number of active processes.
- The percentage of system resources (CPU and memory) that the Apache web server is using.
- Whether bottlenecks on your web server are related to the CPU, memory, disk, or network.

Microsoft IIS

The AIM for Microsoft IIS provides you with the information you required to monitor the Microsoft IIS application and its use of your system resources.

This module works with the SystemEDGE agent to let you do the following tasks:

- Monitor the availability of Microsoft IIS and its services (Web, FTP, SMTP, and NNTP).
- Automatically restart any service that fails.
- Determine if Microsoft IIS starts to consume significant levels of system resources, including central processing unit (CPU) usage, disk space, and memory.
- Monitor logs for security, system, and application events across the Web, FTP, SMTP, and NNTP services.
- Detect error statistics across the Active Server Pages (ASP), Common Gateway Interface (CGI), and Internet Server Application Program Interface (ISAPI) application extension pages, including Web 404 (page-not-found) errors and ASP script errors.

CA Insight DPM

The Insight AIM provides important information about performance, configuration, availability, and health of DBMS type, for real-time management and long term trending and capacity planning.

The Insight AIM implements a management information base (MIB) that includes variables that are specific to each supported DBMS type. The following DBMS types are supported:

- DB2
- Oracle
- SQL Server
- Sybase

View NSM Agent Information

DX NetOps Spectrum OneClick provides visibility into information that the NSM System agents gather. You can configure process, log file, and file monitoring in the System Resource subview section. Other views provide read-only information that is available from the proprietary MIB values.

You can access NSM agent information in OneClick. This procedure assumes that you have already modeled the NSM agents in your network, either by Discovery or by modeling them manually.

Follow these steps:

1. Select a modeled NSM agent device icon in the Topology tab.
   The Component Detail panel displays the Information tab for the selected NSM agent model.
2. Expand the System Resources subview.
   NSM agent-specific information is displayed.

Trap-to-Alarm Mapping

The CA Unicenter NSM agent management module integrates NSM agent traps into the DX NetOps Spectrum event and alarm processing.

DX NetOps Spectrum processes traps that are sent by NSM agents including System and Performance agents. For each NSM System or Performance agent trap with a state of Warning or Critical received, DX NetOps Spectrum generates an alarm as shown in the following table. When DX NetOps Spectrum receives the related OK trap, DX NetOps Spectrum clears the corresponding alarm.

NSM Trap Received by DX NetOps Spectrum	DX NetOps Spectrum Alarm Generated
Warning Trap	Minor alarm
Critical Trap	Major alarm

Trap processing is based on the NSM agent model types. Each model type processes traps for several agents as outlined in the following table.

Model Type	Processes Traps on Behalf of These Agents
Host_NSMSysUnix	caiUxsA2 caiLogA2 hpxAgent
Host_NSMSysWin	caiWinA3 caiLogA2 caiAdsA2 hpxAgent
Host_NSMv3SysUnix	caiUxOs caiLogA2 hpxAgent
Host_NSMv3SysWin	caiW2kOs caiLogA2 caiAdsA2 hpxAgent

Event Code and Probable Cause File ID Ranges

The following table lists event codes and probable cause file IDs for NSM Agent MIBs.

NSM Agent MIBs	Range of Associated DX NetOps Spectrum Event Codes and Probable Cause Files
caiUxsA2	Event04ef0000 - Event04ef00e9 Prob04ef0002 - Prob04ef00e3
caiWinA3	Event04ef1000 - Event04ef10c7 Prob04ef1002 - Event04ef10c1
caiLogA2	Event04ef2000 - Event04ef2010 Prob04ef2002 - Prob04ef200e
caiAdsA2	Event04ef3000 - Event04ef3042 Prob04ef3002 - Prob04ef303e

hpxAgent	Event04ef4000 - Event04ef4008 Prob04ef4002 - Prob04ef4006
caiUxOs	Event04ef5000 - Event04ef5069 Prob04ef5002 - Prob04ef5067
caiW2kOs	Event04ef6000 - Event04ef6099 Prob04ef6002 - Prob04ef6095

System and Application Monitoring Privileges

This section lists privileges that are related to system and application monitoring for OneClick users.

NOTE
For more information about configuring privileges, see OneClick Administration .

- **System & Application Monitoring**
  Controls access to the System & Application Monitoring privileges. Deselecting this privilege automatically deselects the following privileges:
  - **Manage Rule Sets**
    Allows the user to create a monitoring rule set.
  - **Monitor File Systems**
    Allows the user to create a file system monitoring rule.
  - **Monitor Processes**
    Allows the user to create a process monitoring rule.

IP Routing Manager

The information about the IP Routing Manager is classified down into the following sections.

Introducing IP Routing Manager

Introducing IP Routing Manager

Provides an overview of IPRM Features, Concepts and Architecture, as well as the Route Explorer overview.

IP Routing Manager and Features

DX NetOps Spectrum IP Routing Manager (IPRM) was created as a tool to proactively monitor the state of IP routing protocols. IPRM also assists with troubleshooting failures and performance degradation impacting service delivery. The status of IP routing protocols is critical to the overall health of any environment's network. Additionally, IP Routing Manager helps you monitor and visualize the IP routed path(s) between critical endpoints in the network to ensure data flows over the most desirable and high-performing paths. Understanding the path that data takes is necessary to correlate service assurance alarms to their root cause.

DX NetOps Spectrum IP Routing Manager allows you to discover and view a network's topology by integrating with Route Explorer (REX). Route Explorer (REX) is an appliance-based route analytics solution developed and marketed by Packet Design.

DX NetOps Spectrum IP Routing Manager features include:

- Discovering and visualization of the Layer 3 network
- Providing visualization of Autonomous System (AS) and OSPF-specific hierarchies

  NOTE

  Visualization of BGP devices in IPRM hierarchies is not supported.
- Discovering real-time Layer 3 paths through the network
- Providing dynamic updates to Layer 3 topology and paths
- Performing dynamic path monitoring:
  - Path hop details
  - Forward and reverse path support
  - ECMP support
  - Path change events/alarms
- Monitoring REX trap events/alarms
- Providing visualization of IP Subnets
- Providing bulk modeling of unmanaged devices
- Performing visualization of Layer 3 link information and custom icons
- Integrating Layer 3 topology view with other DX NetOps Spectrum's topology views (for example Universe)

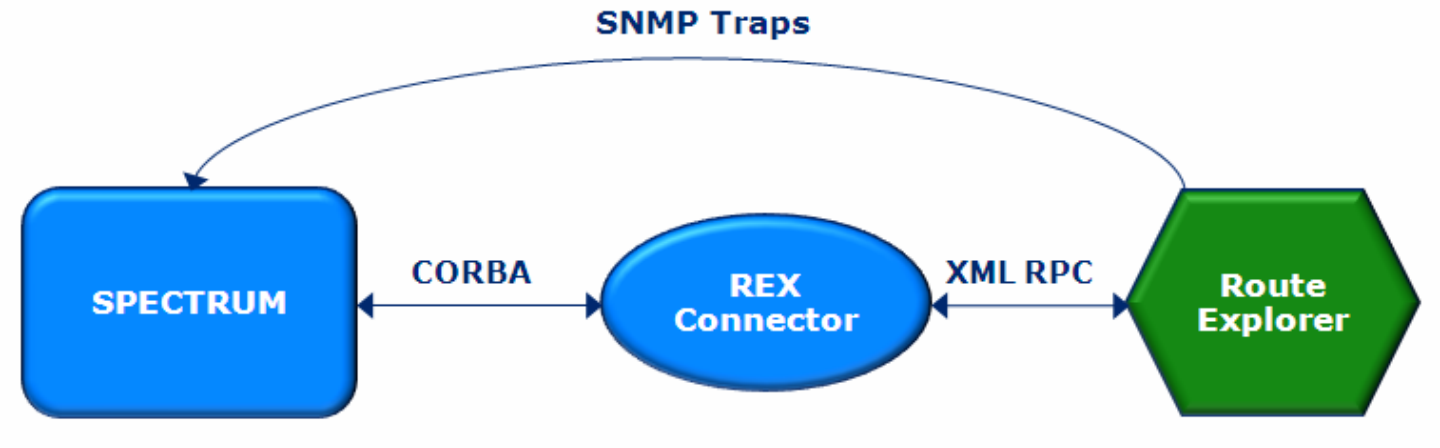
The product supports both fault tolerant and distributed DX NetOps Spectrum deployments, with all user configuration and interaction being performed on the main location server (MLS) system.

In addition to REX appliance, IP Routing Manager will also work with IPRM Route Recorder and OEMed versions of REX - RAMS from Hewlett Packard and Route Insight Manager from Juniper. IPRM Route Recorder (IPRM-RR) is a special version of REX that does not expose its GUI, but acts as instrumentation for IPRM delivering real-time routing information via an XML API. Packet Design will make this product available to DX NetOps Spectrum customers wishing to take advantage of IPRM.

IP Routing Manager Architecture and Concepts

IP Routing Manager utilizes the following architecture. The REX Connector is a separate process, and is the connection between DX NetOps Spectrum and Route Explorer. REX Connector utilizes the REX API to communicate with Route Explorer.

The Route Explorer software can be configured to notify clients of routing events via SNMP traps. Each one indicates some sort of Layer 3 topology change or information. These traps sent from Route Explorer will be translated into DX NetOps Spectrum events (and alarms when appropriate) and will be generated on the corresponding device model.

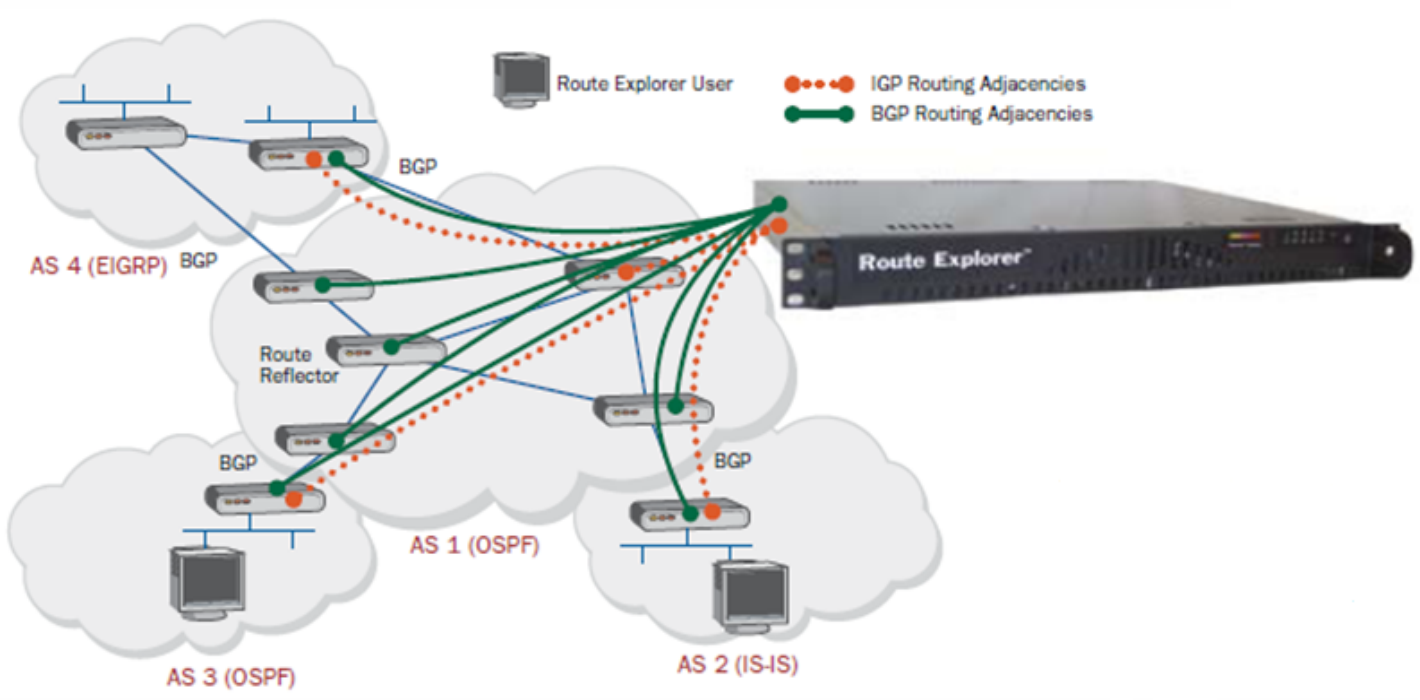


Some important concepts to understand to utilize IPRM fully:

- **IP Subnet** - An IP Subnet (REX refers to them as prefixes). IPRM distinguishes between two logical types of subnets:
  - **User Subnet** - IP Subnet attached to at least one router (also known as a gateway) and typically serving a number of hosts and devices. IPRM defaults to hiding these icons from the topology view.
  - **Infrastructure Subnet** - IP Subnet interconnecting two or more routers (REX shows them in its topology GUI as pseudo-nodes). In cases when only two routers are attached to such a subnet, IPRM can be configured to represent these as links in topology view, otherwise these are represented as IP Subnet icons.
- **PointToPoint Link** - IPRM's representation of Layer 3 Point-to-Point Links between two routers.
- **Managed Path** - End-to-end Layer 3 path across managed infrastructure configured for proactive assurance monitoring.
- **Autonomous System (AS)** - Part of the Layer 3 topology (a collection of routers and IP subnets), organized by REX into an Administrative Domain. IPRM also arranges OSPF protocol models within corresponding AS models.

Route Explorer Overview

A single Route Explorer can concurrently monitor and analyze complex IP networks which may have multiple routing protocols (OSPF, IS-IS, EIGRP, and BGP) and span multiple autonomous systems. A distributed architecture involving multiple appliances may be employed to enhance management continuity in the event of a network failure while supporting multi-tiered or regionalized management domains.



The routing analytics appliance is developed and marketed by CA's Technology Partner - Packet Design. This appliance operates by passively monitoring the routing protocols exchanges between routers. It 'announces' itself as if it was a router, but does not advertise any prefixes, so no traffic flows to/through it. Therefore, it's neither a bottleneck nor a failure point.

IP addresses are assigned and adjacencies are set up with a small number of routers:

- REX requires an adjacency with one router in each OSPF area or IS-IS level. Once adjacencies are up, REX begins monitoring the protocols and is able to present a complete, network-wide map within minutes.
- Each adjacency may be over a physical connection (local) or GRE tunnel/VLAN (remote)

The only messages Route Explorer sends out to its neighbors are periodic 'Hello' messages to maintain adjacencies. Therefore, virtually zero load is placed on the real routers or the network, both during discovery and ongoing monitoring. REX can scale to manage the largest networks in the world (7,000 routers/8 million routes with a single box). In 99%+ of cases a single appliance is adequate.

REX has two interfaces, a web-based user interface for REX administration purposes and a graphical user interface for the end-user. IPRM-RR will have have the REX GUI disabled, to allow for easy DX NetOps Spectrum OneClick utilization.

Route Explorer Administration

The following guidelines are helpful to Route Explorer Administration:

- For DX NetOps Spectrum and REX firmware version compatibility, see the Integration Compatibility section.

  NOTE
  Additional future versions of REX firmware may be supported by IP Routing Manager v10.1 or higher, based upon API compatibility.
- In a distributed REX installation, for example, a modeling engine and one or more pure route recorder(s); you should configure IP Routing Manager's REX integration settings to connect to the modeling engine.
- Only one REX connection is supported.

REX Connector Process

IP Routing Manager communicates with REX via a process called the REX Connector. This process is managed by process daemon and started up when the SpectroSERVER is started. Because this process can use large amounts of CPU processing when Layer 3 topology discoveries are done, it is ideal to run DX NetOps Spectrum on a multi-CPU system.

- Integrates DX NetOps Spectrum with Route Explorer
- External Java-based application
- Implements a new CORBA interface allowing DX NetOps Spectrum to request Layer 3 topology and path information
- Translates DX NetOps Spectrum's CORBA-based requests into Java/XML-Remote Procedure Calls to access REX API
- Performs topology and path polling for change detection, notifies clients of changes via callbacks
- Supports configuration of Route Explorer alerts in the OneClick client
- Utilizes ports 14002 and 14006 to communicate with the SpectroSERVER and Naming Service
- Utilizes port 2000 to communicate with Route Explorer

  NOTE
  The REX Connector should run on separate CPU from SpectroSERVER if possible.

  WARNING
  IP Routing Manager communicates with the REX API via XML-RPC over a TCP connection. This TCP connection is not encrypted. This should be realized for data passing over the tunnel. However, the REX API password is encrypted in DX NetOps Spectrum.

Autonomous Systems

Router Explorer organizes protocol instances (for example BGP and OSPF) into groups called 'Administrative Domains'. You can create a hierarchical structure of Administrative Domains to arrange the protocol instances in a way that is coherent with your IT infrastructure. The IP Routing Manager data model provides the Autonomous System model as a

logical container for protocol models. To provide continuity, as well as synchronization between the two data models, IP Routing Manager uses the Administrative Domain path as the name of the corresponding Autonomous System model.

For example, the following text is a sample topology name as provided by the REX API:

```
CA.MySubDomain.OSPF/Backbone
```

IP Routing Manager takes the text that precedes the protocol name, in this case OSPF, and uses it as the name of the Autonomous System model: 'CA.MySubDomain'.

You can set the model name on the Autonomous System model according to your needs.

Using the REX Administration Features

Refer to Route Explorer Administration section for instructions on how to utilize the REX Administration web-based user interface.

Installing and Configuring IP Routing Manager

Installing IP Routing Manager

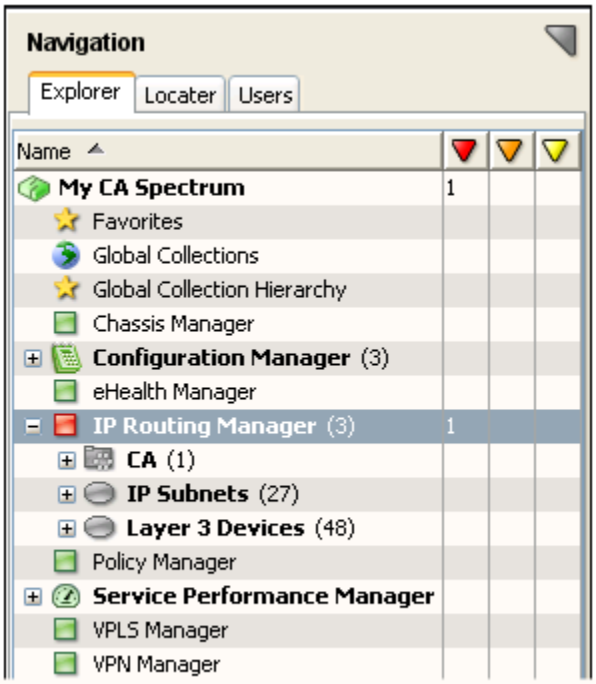
To install IP Routing Manager

1. Run the DX NetOps Spectrum installation program to install DX NetOps Spectrum and OneClick. See Install DX NetOps Spectrum for details.
2. Bring up the DX NetOps Spectrum Control Panel, click the Start SpectroSERVER button.

After installing this product, you will see an IP Routing Manager entry at the 'global' level in the Navigation Panel of the OneClick Console; the IP Routing Manager model of the Main Location Server (MLS) will be shown. This IP Routing Manager view is the central point for all Layer 3 topology-related activities: viewing Layer 3 topology and paths, configuration tasks, and general information gathering.

When you have discovered the Layer 3 topology, all Layer 3 topology and path data models representing the logical protocol hierarchy will be listed underneath the IP Routing Manager icon in the Navigation Panel. All Layer 3 paths you have created will be listed underneath the IP Routing Manager icon in the corresponding folder icon.

This panel also displays the entire Layer 3 topology across *all* DX NetOps Spectrum landscapes. It will also display all critical paths across DX NetOps Spectrum landscapes.



NOTE
IP Routing Manager *can* generate events and alarms even before it is setup or configured. This may happen because you previously configured Route Explorer to send traps to DX NetOps Spectrum; when DX NetOps Spectrum receives these traps, IP Routing Manager will generate the appropriate events/alarms regardless of whether or not it is setup and connected to Route Explorer.

Connecting to Route Explorer

To connect to Route Explorer

1. Navigate to the Component Details Panel of the IP Routing Manager model.
2. Select the Information Tab, and open the Route Explorer Integration sub-view.
3. Enter the Route Explorer machine's host name, the query password, and the Administrative Domain name you'd like to use.
   You can also choose to enter a new heartbeat value. The heartbeat value determines how often IP Routing Manager pings Route Explorer to make sure it's still up and functioning.
4. Once these values are configured, press the Connect button.
   IP Routing Manager will then attempt to connect to Route Explorer, and you will be notified of the success/failure of the operation.

   NOTE
   You will not be able to connect unless you authorize the SpectroSERVER to be able to connect with the REX machine through the 'Queries' Admin Page in the REX Web UI.

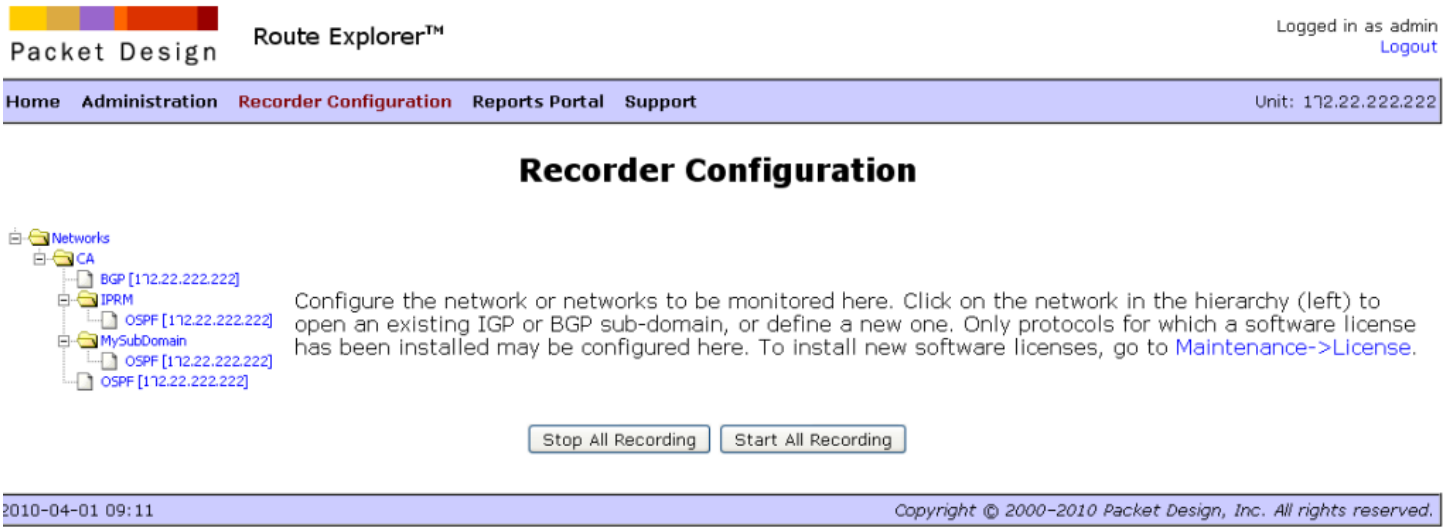
   The Connection Status field displays the status of IP Routing Manager's connection to Route Explorer. Once connected, the Connect button will become a Disconnect button, which you can use to disconnect from Route Explorer when desired.

   NOTE
   To change any of these REX configuration settings, first disconnect from REX, make the required changes, and then re-connect for the changes to take effect.

WARNING
If Route Explorer stops recording information on particular protocols, IP Routing Manager will notify you through an event and alarm.

Route Explorer Configuration Considerations

When configuring the 'Administrative Domain' setting in the REX Configuration subview; you should refer to the 'Recorder Configuration' in the Route Explorer web interface. The 'Recorder Configuration' is accessed by logging into the web interface and clicking on the 'Recorder Configuration' in the menu at the top. In the case of a distributed REX deployment (where there are multiple Route Explorer units all replicating their data to a single Modeling Engine unit), refer to the 'Recorder Configuration' on the Modeling Engine's web interface.



The 'Recorder Configuration' page displays a hierarchy containing the Administrative Domains (represented as folders) and the protocol instances (represented as sheets of paper). The 'Networks' folder at the top of the hierarchy is the root folder and cannot be used when configuring IPRM. The next folder down is the top-level administrative domain. Enter the name of the top-level administrative domain into the Route Explorer Configuration sub-view in IPRM.

Upgrading IP Routing Manager

For sites who have configured/used IP Routing Manager in Spectrum 9.4 and are upgrading to a newer release (such as Spectrum 9.4.1), you will need to perform the following steps after the upgrade has finished installing.

To upgrade IP Routing Manager:

1. From the OneClick, Explorer option, select 'IP Routing Manager'.
2. Select the Contents, Information tab.
3. Expand the 'Route Explorer Integration' option and select Configuration.
4. For the 'Query Password' field, select the 'set' link and set the appropriate password value; and select Save when finished.

   WARNING
   This step needs to be performed even if the ‘Query Password' has not changed. This will encrypt the password value and is *required* in order for IP Routing Manager to be able to connect to the Packet Design appliance.

1. If a fault tolerant SpectroSERVER is being used, then an Online Backup should be performed after re-setting the query password so that the attribute change is propagated to the backup SpectroSERVER.

2. After setting the Query Password, you can verify a connection from IP Routing Manager to Route Explorer by selecting Connect.
3. After successfully connecting to Route Explorer, perform a layer 3 topology discovery by selecting the 'Discover' option in the IP Routing Manager configuration subview. You do not need to clear the layer 3 topology first. (This step ensures that certain attributes are updated to support some of the new features introduced in IPRM 9.2.1.)

Alarm and Event Configuration

DX NetOps Spectrum has the ability to manage the alert configurations on the Packet Design appliance via a subview in OneClick. Expanding the Route Explorer Integration, Alerts subview reveals the alert configuration settings. Modifying the alert configuration settings in this view will automatically create the appropriate corresponding alert configurations on the Packet Design appliance to which IP Routing Manager is connected.

> **NOTE**
> In order to configure alerts, IP Routing Manager must be connected to an appliance and 'Topology and Managed Path Monitoring' must be set to either 'Initiated by Traps Only' or 'Traps and Scheduled Polling'.

Traps Sent to MLS

Since the IP Routing Manager product will span all SpectroSERVERs in a DSS environment, and Route Explorer will only be communicating with the MLS landscape, the MLS will forward traps sent from Route Explorer to the correct SS in a DSS environment so events and alarms are generated on the correct device models.

In DX NetOps Spectrum, you must use the Route Explorer GUI in order to configure alerts. Using the IPRM you can configure four types of alerts (adjacency state, router state, peering state and prefix state) through OneClick.

Note: See the Route Explorer Administration for assistance in configuring the traps.

Topology Change Trap Details

IP Routing Manager supports the following *Router State Change Traps*:

- **Router Connected**
  This trap is sent when a router begins participating in the routing protocol. The router may have just come up. This is a notification that a full adjacency has been established between the router and one of its neighbors.
- **Router Isolated**
  This trap is sent when a router becomes isolated from the network. The router may not actually be down, but isolated because of another outage.
- **Router State Flap**
  This trap is sent when the router's connected/isolated flap count exceeds a threshold over a given duration. DX NetOps Spectrum will include the threshold values in the event generated.

IP Routing Manager supports the following *Adjacency State Change Traps*:

- **Adjacency State Up**
  This trap is sent when a IP Subnet protocol adjacency comes up. This adjacency can be between two routers (and each one's interfaces), or between a router and a pseudo-node (this is how REX refers to a IP Subnet LAN).
- **Adjacency State Down**
  Same information as above, but the adjacency goes down.
- **Adjacency State Flap**
  This trap is sent to indicate adjacency flapping. DX NetOps Spectrum will include the threshold values in the event generated.

IP Routing Manager supports the following *Path Change Traps*:

- **Path Change**
  This trap is sent when REX detects any change in the IP Subnet path(s) between the given end points, including number of hops, path cost (metric), intermediate hops, etc. This trap does not directly result in an event or alarm being generated. DX NetOps Spectrum uses this trap as a way to detect topology/path changes, and the needed event or alarm will be generated when the topology/path changes are modeled.

IP Routing Manager supports the following *Prefix State Change Traps*:

- **Prefix State Up**
  This trap is sent when a router interface is turned on (enabled). This trap announces that the interface's prefix has come online. This trap is also sent for routes that are redistributed from another routing protocol via a router.
- **Prefix State Down**
  This trap is sent when a router goes away, and all of its prefixes are removed. A router may also remove a prefix that it is advertising (premature withdrawal).
- **Prefix State Flap**
  Same handling as for other 'flap' traps.

Path Change

You can configure each monitored path to generate an event or an alarm of a specified severity when the path changes. Changes detected include: path cost, number of ECMPs, and actual path hops traversed.

To accomplish this, select a specific Layer 3 Path model's Information Tab, and configure the relevant settings.

WARNING
Once a path change alarm is created for a given managed path, any subsequent changes will not result in new alarms but will instead be appended as events to the existing outstanding alarm.

NOTE
You can utilize the Layer 3 Path History feature to help debug why the path may have changed or been lost.

Path Loss

You can configure each monitored path to generate an event or an alarm of a specified severity when the path is lost. A path is determined to be 'lost' if there does not exist at least one complete forward and return path, if applicable, where both the source and destination nodes are matched with the requested source and destinations.

To accomplish this, select a specific Layer 3 Task model's Information Tab, and configure the relevant settings.

Self Monitoring

If IP Routing Manager loses the connection to REX, or there is a configuration problem with the integration, a red alarm is asserted on the IP Routing Manager model notifying the user of the situation.

Fault Tolerance Support

IP Routing Manager fully supports fault-tolerant SpectroSERVER setup. The REX Connector runs on primary and secondary landscapes, both connected to REX. Secondary landscapes periodically poll Route Explorer to verify that it is still available, but they do not detect any topology or path changes. On failover, secondary SpectroSERVER resumes normal REX communication and polling.

In order for REX traps to be handled correctly, you need to configure REX to send traps to both the primary and secondary SpectroSERVERs. Optionally, a tool like TrapExploder could be used which allows you to configure REX to send traps to a single IP address, and the TrapExploder can be configured to replicate the traps it receives to multiple recipients.

When a secondary SpectroSERVER becomes active it automatically configures alerts on the Route Explorer appliance so that the desired traps are sent to the secondary SpectroSERVER. In order for this to function properly, you must perform an OnlineBackup after you have configured the alerts on the primary SpectroSERVER.

NOTE
If the secondary SpectroSERVER is in 'warm' or 'cold' standby mode it will not process any traps; if it is in 'hot' standby mode it will process traps.

Using IP Routing Manager

Here are some of the ways of using the IP Routing Manager:

- Initiating Layer 3 Topology Discovery
- Additional Discovery Explanation
- Layer 3 Topology Navigation
- Using the Layer 3 Path Discovery Feature

Initiating Layer 3 Topology Discovery

A topological model of your Layer 3 topology will be built and maintained inside the SpectroSERVER. The Layer 3 topology, including Autonomous System and OSPF protocol details, will be graphically displayed to you using traditional DX NetOps Spectrum device icons, new LAN icons, and pipes. All routers from all landscapes in the DSS will be displayed in this single view.

The entire Layer 3 routing hierarchy will be displayed in the OneClick Navigation Panel under the IP Routing Manager entry. Sub-hierarchies will include an entry for each Autonomous System (AS) that is being managed. Each AS will be further broken down into OSPF protocol details (if applicable). You will be able to expand the hierarchy to drill down and get detailed information about the IP Subnet topology.

WARNING
IP Routing Manager prevents creating duplicate Layer 3 paths. Duplicates are determined by source IPs, destination IPs, and path names.

To initiate Layer 3 topology discovery

1. Navigate to the Component Details Panel of the IP Routing Manager model.
2. Select the Information Tab, and open the Configuration sub-view.
   The Layer 3 Topology view contains buttons to discover and model the Layer 3 topology.
   Use the Topology and Managed Path Monitoring field to configure how IP Routing Manager should monitor the Layer 3 topology and paths. The various values supported include:
   - Traps and Scheduled Polling - REX Connector polls for changes, and SS responds to REX change traps
   - Initiated by Traps Only - No REX Connector polling, but SS does respond to REX change traps
   - Off - No changes are detected. No REX Connector polling and no trap handling. You must manually initiate re-discovery.

   If the Traps and Scheduled Polling option is used, you should set the value of Scheduled Polling Interval (s) to the desired value. When changes are detected, IP Routing Manager will dynamically update the Layer 3 topology with new and removed routers and links.
   See the '*Without GUI component, how will I be able to configure IPRM-RR traps?*' question within the Frequently Asked Questions section for additional information.
3. Click the Discover button to begin the Layer 3 topology discovery and modeling process.

Depending on the size of the Route Explorer database you've connected to, this process could take many minutes to complete. Once finished, the complete and current Layer 3 topology will be saved in the DX NetOps Spectrum database.

NOTE
The Last Topology Update field will also contain the date and time of the discovery. The Last Topology Update field is updated every time DX NetOps Spectrum models a topology change.

NOTE
You can click the Discover button at any time to have IP Routing Manager update (or re-discover) the complete Layer 3 topology, and thus stay in sync with Route Explorer. You can also press the Clear button to completely remove all Layer 3 topology modeling (including Layer 3 paths that may have been discovered).

User subnets are discovered and modeled when you invoke a Layer 3 discovery or on dynamic updates. They are differentiated from Infrastructure subnets by a new attribute field in the models' Information Tab. You can choose whether or not User subnets are displayed in the Layer 3 topology view by setting the 'Display User IP Subnets' value in the IP Routing Manager Configuration sub-view.

Additional Discovery Explanation

The following items are important to consider in OneClick Integration:

- IP Routing Manager gathers data from all the distributed landscapes that you have configured and runs at a global level, above any landscape, in the Navigation Panel.
- When you deploy DX NetOps Spectrum in a distributed environment, you have multiple landscapes. You must assign one as a main location server. This is where all Layer 3 modeling is stored and then displayed at a global level. All the other landscapes communicate with this main landscape location.

Security Impact

The user privileges can be found in the Component Details panel of the selected user model in the Users tab. IP Routing Manager's privilege group contains the following values:

- **IPRM hierarchy**
  Allows a user to see the IPRM hierarchy.
- **Manage IP Subnet Paths**
  Enables/disables the path creation menu items and the Layer 3 Path configuration sub-view.
- **Configure IPRM**
  Shows/hides the Configuration sub-view on the IPRM model.
- **Configure Route Explorer Integrations**
  Shows/hides Route Explorer Integrations sub-view on the IPRM model.

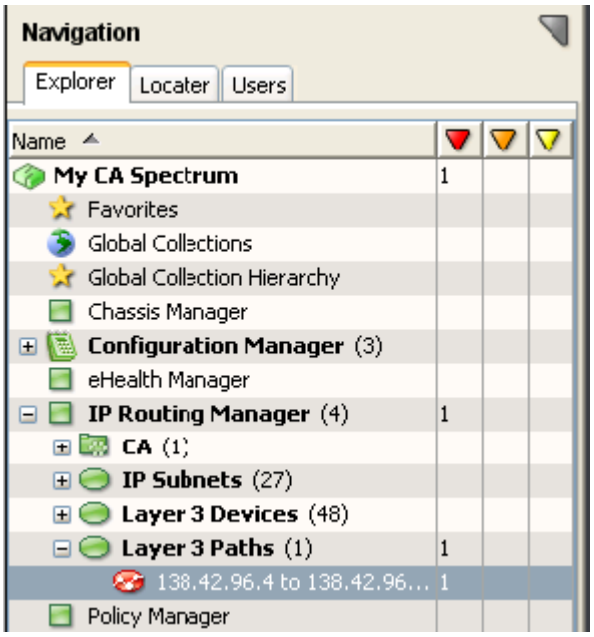
Layer 3 Topology Navigation

The following areas are important when utilizing Layer 3 Topology Navigation.

Navigation Panel

The entire Layer 3 routing hierarchy is displayed in the OneClick Navigation Panel under the IP Routing Manager entry. Sub-hierarchies include an entry for each Autonomous System that is being managed. Each Autonomous System is further broken down into OSPF protocol details (if applicable). You are able to expand the hierarchy to drill down and get detailed information about the Layer 3 topology.

A Layer 3 Devices container and an IP Subnets container exist in the Navigation Panel, allowing you to quickly find and spotlight any IP Subnet device or LAN currently shown in the topology (e.g. user LANs and LANs connected to only two routers are hidden by default, and are not listed in the IP Subnet container).



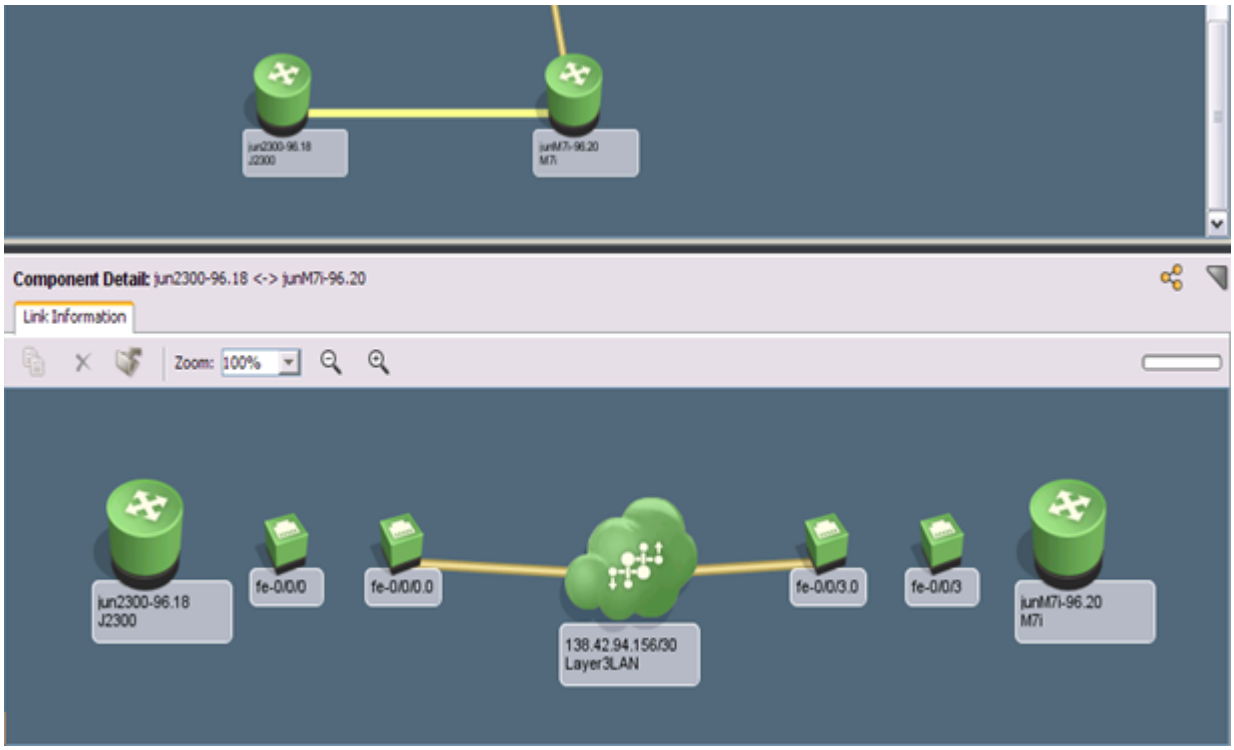
Topology Tab

A topological model of your environment's Layer 3 topology is built and maintained inside the SpectroSERVER. When the Topology Tab is selected, the Layer 3 topology, including Autonomous System and OSPF protocol details, is graphically displayed using traditional DX NetOps Spectrum device icons, new IP Subnet icons, and pipes. All routers from all landscapes in the DSS are displayed in a single topology view. A standard information view is provided for IP Subnets.

Additionally, a Link Information view is provided to show the port-level connectivity between routers and subnets, as well as show the hidden IPSubnet or PointToPointLink model for a given connection.

The Link Information tab has been enhanced with the concept of a middle model. If you select a link between two routers (a link which represents a IPSubnet or a PointToPointLink) in the Layer 3 topology, the Link Information view will show the port-level connections (if available) between the two routers, as well as the (hidden) IPSubnet or PointToPointLink model between the two routers. If you select a link between a router/UnmanagedDevice and a IPSubnet, the Link Information view will show the port-level connections between the router and that LAN.

WARNING
Interface connectivity will not be available if the connected router is currently modeled as an 'UnmanagedDevice'.



By default, the Layer 3 topology view will only show an actual icon for the IPSubnet when there are more than two routers connected to it. IP Routing Manager compresses the LAN icons connected to only two routers into a simple pipe. You could optionally turn on display of all IPSubnet icons (via the 'Display IP Subnet Between Two Routers' configuration option on the IP Routing Manager model). The ability to display IPSubnet icons allows you to refine the Layer 3 topology view to best suit your needs. PointToPointLink models are always represented as a simple pipe between two routers.

Mouse-over pop-ups are supported. Any time the mouse hovers over an IP Subnet icon, or any pipe connected to an IP Subnet, simple information about the IP Subnets and connected interfaces will be displayed.

List Tab

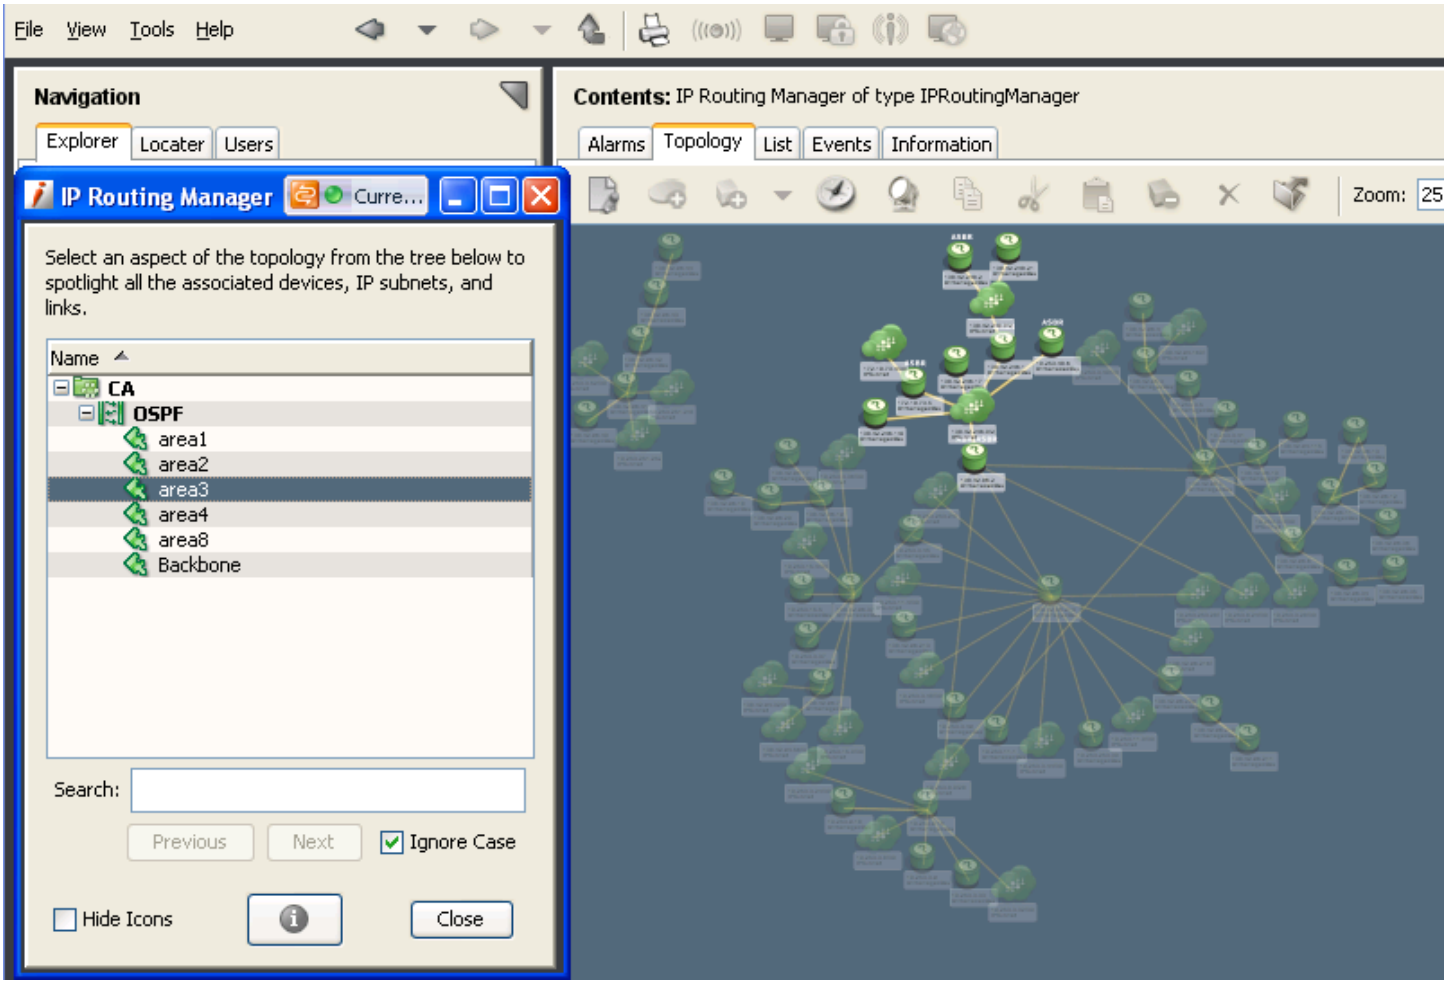
The List Tab of the IP Routing Manager model contains information about all routers and subnets that exist in the IP Subnet topology. The contents of the List Tab will be filtered based on what is selected in the Navigation Panel. Let's say you select an OSPF area. In the Topology Tab, all routers, subnets, and pipes involved in the OSPF area are spotlighted, and the rest are grayed out. The List Tab will then only display the models that are spotlighted. The List Tab contains a new Layer 3 Node Type column which displays the role each router is playing in the Layer 3 topology. Highlighting each model in the List Tab allows you to explore the Component Details of each model. IPSubnet and PointToPointLink models display AS and OSPF-specific data, as well as the designated router IP.

Spotlighting

A new navigation-based spotlighting capability has been introduced. Selecting (highlighting) a Layer 3 path model in the Navigation Panel will cause that particular path to be spotlighted in the IP Routing Manager's topology view. This Navigation Panel feature can be thought of as a built-in spotlighting feature that you can access *without* clicking the spotlight icon in the top menu and opening a separate dialog box. It's built right in.

This product also supports the traditional toolbar-based spotlighting dialog box, similar to VRRP and VLANs, so that you can un-dock the topology view and still use the spotlighting feature. When opened, the dialog box will contain a Layer 3 hierarchy exactly like the one displayed in the Navigation Panel. Toolbar-based spotlighting takes precedence over Navigation-based spotlighting.

For example, when you select an OSPF area in the Navigation Panel, all routers, subnets, and links which are members of the selected OSPF area will be spotlighted. The rest of the topology view will be grayed out. Spotlighted router icons will display protocol-specific annotations such as ABR and ASBR and the like.



Unmanaged Devices

All routers that Route Explorer knows about may not be modeled in the DX NetOps Spectrum DSS environment. When this happens, an UnmanagedDevice model is created, and its NetworkAddress attribute is filled in with the IP address of the router. UnmanagedDevice models are displayed in the Layer 3 topology just like 'full' DX NetOps Spectrum router models.

To model an UnmanagedDevice as a 'full' DX NetOps Spectrum router model, you have two options:

1. Right-click the icon and select 'Manage selected device…'. The Create by IP dialog opens, which lets you discover the device and replace the new model in all DX NetOps Spectrum views where the current UnmanagedDevice model exists.
2. Select multiple UnmanagedDevice models in the IP Routing Manager List Tab. Right-click and select 'Manage selected devices ...' to launch an AutoDiscovery. Auto discovery automatically populates the IP range list with the IP addresses of all selected models.

Both methods of discovery allow you to select which landscape (if in a DSS) to place the newly discovered device models.

In addition to the Model Unmanaged Device menu option, you can use the Discovery application to model your unmanaged devices. Every time AutoDiscovery is run, it will always attempt to replace any UnmanagedDevice models with a newly discovered device in its results set.

The existing context-launch functionality of Discovery is leveraged to allow users to select one or more UnmanagedDevice models in the topology tab and the list tab, and then launch Discovery from the toolbar or right-click menu. Discovery uses the IP information from the selected UnmanagedDevice models to create a new Discovery configuration. The Discovery configuration can then be used to discover the unmanaged devices and create device-specific models to replace the UnmanagedDevice models.

During the final stages of a modeling process (within the Discovery app), the DX NetOps Spectrum searches all landscapes for UnmanagedDevice models. It then compares the IP addresses of the newly modeled devices with the IP addresses of the UnmangedDevice models. If an address from a new model matches the address from the UnmanagedDevice model, the UnmanagedDevice model is replaced with the new device-specific model (even if the new model is a Pingable). In the IPRM topology view, the UnmanagedDevice icon is replaced with the icon of the new model.

Jump to Feature

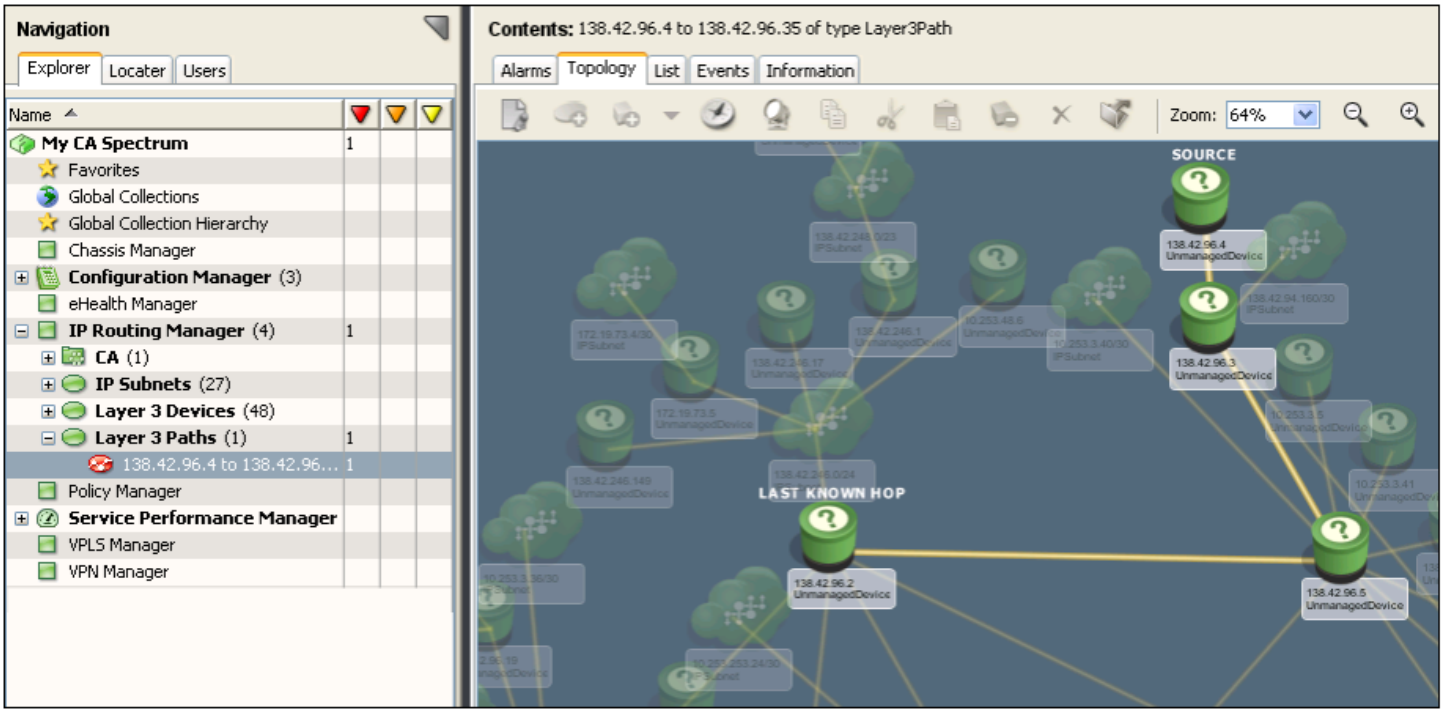
You are able to right-click on any router in the Layer 3 topology and select Location, Universe. This enables you to view the traditional DX NetOps Spectrum topology/universe view of the container model in which the router model exists. If the router model exists in a remote landscape in a DSS environment, it supports this as well. The router model is highlighted in the view. This feature is the key to integrating the new Layer 3 topology with the traditional DX NetOps Spectrum modeling and viewing hierarchy (Layer 2).

You are also able to right-click on any router in a traditional DX NetOps Spectrum topology or any other OneClick view and select Location, IP Routing Manager. This enables you to jump to the new Layer 3 topology view of the MLS and highlights the router in the view.

> **WARNING**
> The most efficient way to search when you have a long list of models in the Explorer is to find the model using a Locater search, select the found model, right click and select Location, IP Routing Manager.

Providing End to End Layer 3 Path Visualization

IP Routing Manager provides end-to-end Layer 3 path visualization. This provides you with hop-by-hop paths and alerting on critical paths.



Using the Layer 3 Path Discovery Feature

You have the ability to view and monitor the current Layer 3 path(s) between any two IP-based endpoints within REX's visibility on demand using OneClick.

Using the Layer 3 Path Discovery Feature

1. Select the start point in the IP Routing Manager Topology View; right-click on the node and select 'Utilities, Select As Layer 3 Path Source'.
2. Select the end point in the IP Routing Manager Topology View; right-click on the node and select 'Utilities, Create Layer 3 Path'.
   This will bring up up a new dialog for you to enter additional information.
   A name for the Layer 3 path is automatically created by DX NetOps Spectrum, but you can assign any name in the dialog box. When manually entering path destination IP address information, you may choose a single device/port IP address, or a subnet IP/mask pair. The path source must be a single IP address of a router. When entering an IP subnet for the path destination, dotted-decimal or CIDR suffix notation may be used for the mask.

   NOTE
   Duplicate Layer 3 paths cannot be created. Duplicates are determined by source/destination IPs, as well as path names.

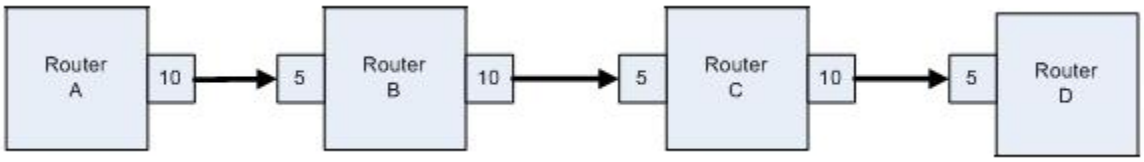
   You also have the option to discover only forward paths between the source and destination, or both forward and return paths. Discovering return paths will help you discover asymmetric paths, as well as add to IP Routing Manager's ability to detect when a path is down.
3. Click the OK button in the Create Layer 3 Path dialog to initiate path discovery and modeling.
   When finished, the new Layer 3 path model is displayed in the Navigation Panel under a new Layer 3 Paths container in the IP Routing Manager hierarchy.

Important Considerations

There is no separate monitoring mode for paths. All paths will be monitored for changes according to the global Topology and Managed Path Monitoring value.

When you trace a path to a loopback IP on a router, there's a good chance that REX will include the last internal hop in its cost calculation and hops returned. Since IP Routing Manager has no way to graphically display this internal hop in the topology view, the REX Connector prunes it from the data returned, and IP Routing Manager doesn't show it in the topology view or the path hop details table. The cost of the internal hop is included in the overall path cost, however.

The cost of a path is determined by adding the routing metrics assigned to each of the egress interfaces of each hop in the path. See the attached picture for an example. The path is from the loopback IP address of router A to the loopback IP address of router D. The path data REX sends will contain a path cost of 31. This is the sum of all egress interface metrics, plus the internal hop of router D. Since IPRM cannot visualize the internal hop in router D, it doesn't include that hop in the Path Hop Details table.



NOTE
IP Routing Manager currently only supports creation of Layer 3 paths whose endpoints are within REX's visibility. If you enter an IP/subnet that is outside this visibility, then the path may not be complete, and a path lost alarm could be generated.

Layer 3 Path Viewing

Selecting a Layer 3 path model in the Navigation Panel allows you to view data about the path. The Component Detail panel contains source and destination IP information, the cost of the path, the number of hops, and the date/time it was discovered or last updated.

If the path has more than one equal-cost multi-path (ECMP), then DX NetOps Spectrum creates separate Layer 3 ECMP models, and displays them as children of the Layer3Path model in the Navigation Panel. When you highlight a Layer 3 Path in the Navigation panel, the Layer 3 topology will spotlight all of the routers, subnets and connections which are included by all of the associated ECMP's. When you highlight a specific Layer 3 ECMP in the hierarchy, the topology will spotlight only the routers, subnets and connections which represent that particular ECMP.

NOTE
Alarms are never generated on ECMP models, only the Layer 3 Path model. Thus, an ECMP model will always be green.

Select a Layer 3 Path or ECMP to view the Path Hop Details table, which contains dynamic, comprehensive information for each hop in the path. Details include source/destination routers, ingress/egress interfaces, link type and prefix, hop cost, and protocol.

NOTE
Path Hop Details are dynamic only when 'Topology and Managed Path Monitoring' is set to 'Traps and Scheduled Polling' or 'Initiated by Traps Only'. For more information, see Initiating Layer 3 Topology Discovery.

You can destroy Layer 3 Path models by simply right-clicking on them in the OneClick Navigation Panel and selecting Delete.

In REX, pseudonodes represent IP Subnet IP subnets/LANs. The REX GUI displays them as nodes in the topology with routers connected to them. REX considers pseudonodes as distinct hops in a Layer 3 path. For example, for a path between 3 routers (A, B, and C), there will be two IP subnets (X and Y) with one between each router. REX would consider this path to have 4 hops: A -> X, X -> B, B -> Y, Y -> C.

IPRM uses pseudonodes to create IPSubnet models, and displays them similarly to how REX displays them. But in Layer 3 Paths, IPRM treats pseudonodes (IPSubnets) as something that a hop transitions through. So, for the path above, IPRM says the path has 2 hops: A -> X -> B, B -> Y -> C. A subnet is not really a hop endpoint, but a portion of the network that the data travels through to get to the next hop.

> **NOTE**
> In Route Explorer version 9.3.16, pseudonodes are no longer recognized as distinct hops in a path. Instead, pseudonodes are now treated similarly to how IP Routing Manager recognizes them.

Layer 3 Path History

The Layer 3 Path history feature allows the user to view changes in the Layer 3 path between two end points over a specified period of time.

Using the Layer 3 Path History Feature

1. Select the start point in the IP Routing Manager Topology View; right-click on the node and select 'Utilities, Select As Layer 3 Path Source'.
2. Select the end point in the IP Routing Manager Topology View; right-click on the node and select 'Utilities, View Layer 3 Path Change History'.
   This will bring up a new dialog.
3. In the dialog, enter the time range for historical data you want to view.
4. Click the View History button.
   The Path Change History table appears.

> **NOTE**
> The content of the Path Change History table is static. For dynamically updated information on the path, use the Path Hop Details table as described in Layer 3 Path Viewing.

Viewing the Path History of a Monitored Path

For any Layer 3 Path model you have created you have the ability to see the path change history for that monitored path.

- Right click on an existing Layer 3 Path model in the explorer view and select 'Utilities, View Layer 3 Path History' top launch the path history view.
  This automatically fills in the Source and Destination IPs for the dialog.

Viewing the Path History from an Alarm

If you receive a Layer 3 Path Lost or a Layer 3 Path Change alarm you can view the path change history.

- Right click on the alarm in the Contents Panel and selecting 'Utilities, View Layer 3 Path History'.

Important Considerations

> **NOTE**
> If IP Routing Manager is connected to a Packet Design appliance that is running the Packet Design/Route Explorer software, the Path Change History's 'Link Prefix' column may contain missing values.

The path change history functionality works by taking samples of the Layer 3 topology at specified times. By default IPRM take 100 samples over the time range. This is the maximum allowed; the minimum is 5. If you experience performance problems or the path history takes a long time to render you can reduce this value by setting a parameter in the $SPECROOT/IPRM/REX/config.xml file:

```
<path_history_sample_count>10</path_history_sample_count>
```

> **NOTE**
> DX NetOps Spectrum recommends setting this value to 30 for 2x series Packet Design appliances running REX software below version 8.0. For 3x series appliances running REX software 8.0 or higher, you can experiment setting the value as high as 100 (which is the default) depending on the size of your Layer 3 topology.

Frequently Asked Questions and Useful Tips

Frequently Asked Questions

Integration Overview

- **Question: Does the REX appliance perform the layer 3 topology discovery and DX NetOps Spectrum IPRM imports that information from REX? Or does DX NetOps Spectrum perform its own native layer 3 topology discovery?**
  Answer: REX performs the layer 3 topology discovery and passes this information to IPRM.
- **Question: Does IPRM keep track of routing changes in real-time?**
  Answer: IPRM Topology is updated in real time and spotlighting can be used to view up to date hop-by-hop path composition. Also, IPRM supports related alarm conditions based on the updates from the REX appliance.
- **Question: How long does it take to remove the disconnected router icon from the topology view?**
  Answer: Disconnected routers age-out of REX database slowly. The time for the disconnected routers to age out of the REX database is based on the routing protocol being used. In the case of OSPF, it is approximately one hour.
- **Question: Why would IPv4 prefix count shown in REX GUI differ from IP Subnet count shown by IPRM?**
  Answer: There could be several reasons for this:
  - By default (user configurable) IPRM hides the icons representing User Subnets - IP subnets with one (gateway) or more routers and a number of end hosts and devices served. In this case these models are completely hidden in OneClick UI (including Topology Tab, List Tab and in the Navigation Tree).
  - By default (user configurable) IPRM hides the icons representing IP Subnets used solely to connect two routers. In this case the corresponding IP Subnet models are hidden in OneClick UI.
  - REX's count of prefixes is really count of routes. For example, if the same prefix is announced by two routers it counts it twice. IPRM does not create multiple IP Subnet models for the same subnet.
  - In the case of distributed Route Explorer configuration, it's important to make sure IPRM is connected to the REX appliance acting as the 'Modeling Engine' and the replication is turned on to ensure it can have the complete topology picture.
- **Question: Does IPRM connect to REX via the REX API or directly with the database?**
  Answer: IPRM uses REX's XML RPC API.
- **Question: How secure is data transmitted between REX and IPRM?**
  Answer: The API password (Query Password) is transmitted encrypted.
- **Question: Which ports are used between the REX, IPRM Connector and SpectroSERVER?**
  Answer: Communication between SpectroSERVER and REX Connector uses ports 14002 and 14006 for CORBA, as well as a few dynamically-chosen ports as connection sources from the REX Connector to the Naming Service and to the SpectroSERVER.
  REX Connector expects open TCP connection to port 2000 on the Route Explorer appliance.
- **Question: How secure is REX appliance's communication with the routers?**
  Answer: REX only uses read-only access and supports both RADIUS and TACACS secure access methods. It also supports MD5 authentication for OSPF and BGP peerings.

User Interface

- **Question: What kind of UI does REX offer?**
  Answer: REX UI has two components: Administration & Configuration is available via the Web and all the product features are available via X-GUI. Any standard browser (Mozilla, IE) can be used to access the Web UI while the X-GUI can be accessed either via a X-Manager or a VNC client.
  X-GUI is disabled in IPRM-RR, since it is expected you use DX NetOps Spectrum's OneClick GUI.
- **Question: Without GUI component, how will I be able to configure IPRM-RR traps?**
  Answer: IPRM provides configuration of path change, router state, adjacency state, prefix state, and peering state alerts via OneClick GUI.
- **Question: Is there a context sensitive integration between IPRM and REX GUI?**

Answer: No, DX NetOps Spectrum OneClick is the only GUI part of the solution (with the exception of web-based REX administration console used during the installation).

Routing Protocols

- **Question: What routing protocols does IPRM support?**
  Answer: REX appliance supports all routing protocols, including the following standard protocols as defined by the IETF RFCs: IS-IS, OSPF, BGP and MP-BGP as well as EIGRP (Cisco proprietary) and static routes.
  IPRM shows the full routed topology as discovered by REX appliance. Initial version of IPRM in 9.2.0 offered navigation-based spotlighting and icon labeling for OSPF protocol and AS groups. As a result of customer feedback, in Spectrum r9.2.1 navigation-based spotlighting was replaced by individually customizable topology maps. Users can still leverage the spotlighting dialog to highlight different routing protocol aspects in their Layer 3 topology view.
  Other visualization techniques under consideration for future IPRM releases include display of EIGRP session establishment status, spotlighting for IS-IS levels, display of attributes from BGP packet headers as observed by REX, etc.
  In addition to visualization techniques, protocol support includes display of routing protocol attributes. Here DX NetOps Spectrum already offers support for BGPv4 (RFC 1269), RIPv2 (RFC 1724) and OSPF (RFC 1253) SNMP MIBs.
- **Question: Is monitoring of BGP prefixes supported?**

For example, I have configured BGP and are able to see BGP UP/DOWN alarms of most of the devices monitored by DX NetOps Spectrum. In case BGP is up on one router, but the number of BGP prefixes received from its peer is 0 (zero), the device will not have complete routing table and as result it will not route the traffic. I would like to know if DX NetOps Spectrum can generate an alarm in such case.

Answer: REX appliance can generate necessary alert and forward to IPRM which will then be able to create an alarm from this.

For loss of Peering, between REX and a router, the 'Peering State' alert can be used. For loss of prefixes, the 'BGP Prefix Flood/Drought' alert can be used.

The BGP Prefix Flood/Drought alarms rely on the baseline of BGP prefixes, which is done automatically by the IPRM Route Recorder (no user intervention necessary).

Let the recording go on for 24 hours; IPRM RR would have then established a baseline (containing prefixes expected from each BGP peer). Configure BGP prefix Flood and Drought alert with the following parameters:

1. A watch list (via a router group) containing the peers that need to be watched.
2. Configure prefix drought alert with a threshold of 100%. This will issue an alert when all baselined prefixes being heard from this peer are withdrawn.

For a greater sensitivity (i.e., cause alerts to be fired when some number of prefixes, less than 100%, are withdrawn), change the threshold parameter as required (say 90%).

- **Question: How can modifying my IPRM Alert Configuration Defaults affect DX NetOps Spectrum's performance?**
  Answer: IPRM Alert Settings *can* be used to tailor the amount of events/alarms you see in IPRM.
  For example, if you are monitoring adjacencies, and a link was flapping constantly (coming up and going down), you would see 5 events for that link from each router (both ends of the adjacency) in 60 seconds. For prefix alert, you would see 5 events for that prefix being pulled in 60 seconds. Therefore, with a constantly flapping interface, you would probably see 15 events for that 60 second period, and then 15 more for the next 60 second period. With IPRM's current default settings, users could see up to 15 events/minute for a flapping link. If 'x' links are flapping, then you'd get 'x' times 15 events/minute. This may raise the concern that with a high rate of events was that these events would trigger excessive device polling. However, that is not a problem because IPRM does not poll devices as a result of these events; instead, these events trigger IPRM to re-discover the layer-3 topology so that it can determine what has changed in the topology. Additionally, IPRM leverages a 'rolling timer' to prevent topology re-discovery from happening too frequently. IPRM doesn't re-discover for every event that occurs, it will only re-discover at most once every minute

as long as these events are occurring. Since the alerts are all disabled by default in IPRM, it's not until a client site makes changes to the alert configuration that they can expect to start seeing events/alarms in IPRM.

- **Question: Is multi-protocol BGP supported?**
  Answer: No, multi-protocol BGP is used for VPN services over Layer 3 and as such is outside the scope of this product.
- **Question: Does IPRM support route summarization boundaries for EIGRP?**
  Answer: To correctly model EIGRP networks, REX needs to establish an adjacency behind the summarization boundaries. So knowledge of where the summarization boundaries exist is important for the correct and complete REX configuration.
- **Question: Are static routes supported?**
  Answer: REX appliance normally doesn't poll devices, but it can optionally collect static route information (along with other data not distributed in the routing protocols such as interface names, router models, etc) via SNMP polling. This is completely configurable by the customer. The static nature of such data requires very low frequency polling (e.g. once a day or week at most). Note also that REX only polls (potentially only those selected by customers) routers, not every network device.
- **Question: Protocols that support some form of adjacency setup, such as OSPF or IS-IS, may be used to bootstrap a BFD session. These protocols may then use BFD (Bidirectional Forwarding Detection) to receive faster notification of failing links than would normally be possible using the protocol's own 'KeepAlive' mechanism. Does IPRM support BFD events?**
  Answer: BFD protocols are not supported.
- **Question: Is policy based routing supported?**
  Answer: No, the information about policy based routing is not advertised in routing protocols, the primary source of information for REX.
- **Question: How are routing loops supported?**
  Answer: Unfortunately, REX does not track routing loops. Routing loops are transient issues in the network. Most routing loops occur as protocols converge and hence are short-lived (milliseconds to seconds). For example, a routing loop may occur because of reordering of the protocol packets received by a router. REX does not (in most cases cannot) track such transient issues. REX assumes that all protocols have converged and accordingly compute the Routing Information Bases at different routers.
  There could be some long lived routing loops that can be analyzed in REX. If you try to find a path and a routing loop exists along the way, REX will show that depending on the root-cause of the routing loop. However, it is virtually impossible for REX to dynamically track and alert on this condition as this would require REX to track all possible paths in the network (even for a medium size network this could mean tens of thousands of paths).
- **Question: Does IPRM support IPv6 addressing?**
  Answer: No, the first release of IPRM doesn't support IPv6 addressing. REX appliance does support this and IPRM will be extended to support this as well in one of the upcoming upgrade releases.

Managed Path

- **Question: Can I create managed path between routers from different OSPF areas?**
  Answer: Yes, you can monitor paths from one OSPF area to another. It supports paths from one AS to another.
- **Question: Can I create managed path between user IP subnets?**
  Answer: The source of the managed path has to be a router; the destination can be IP Subnet. Currently, REX restricts managed path source to routers only, however this restriction may be lifted in the future and IPRM updated accordingly.
- **Question: Can IPRM display path change history between any two end points?**
  Answer: Yes, IPRM can display path change history between any two end points.
- **Question: Why does the hop count for managed path differ between IPRM and REX? (This question is ONLY applicable for 9.2 and REX 8.5.x.)**
  Answer: In REX, pseudo-nodes represent IP Subnets, in line with IS-IS and OSPF protocols modeling.
  The REX GUI distinctly displays pseudo-nodes in its topology view and IPRM follows the suit representing them as IP Subnet models in its own topology view

When it comes to Layer 3 path modeling, REX continues treating pseudo-nodes as distinct hops. For example, for a path between 3 routers (A, B, and C), there will be two IP Subnets (X and Y) with one between each router. REX would consider this path to have 4 hops:
1. A -> X
2. X -> B
3. B -> Y
4. Y -> C

IPRM takes a different approach and treats pseudo-nodes as something that data simply travels through to get to the next hop. So, for the path above, IPRM shows the path having only 2 hops:
1. A -> X -> B
2. B -> Y -> C

- **Question: Does IPRM support routing changes simulation?**
  Answer: No. This capability is supported by Route Explorer's GUI which is not directly leveraged by IPRM. If you already have a full REX appliance, you will continue to be able to benefit from this capability.
- **Question: Does IPRM expose any other Packet Design add-on capabilities such as MPLS LDP LSPs and traffic monitoring?**
  Answer: No, IPRM integrates DX NetOps Spectrum with REX only at this stage.
- **Question: Why is the path cost value different from the sum of the metrics in the Path Hop Details table?**
  Answer: The path may traverse an internal router hop, for which the metric value will not be displayed in the Path Hop Details table (or the Path View tab).

IPRM Deployment

- **Question: What versions of REX appliance are supported?**
  Answer: CA Spectrum r10.0 IPRM supports REX firmware version 11.0.47.1.
- **Question: How many REX appliances will I need?**
  Answer: One REX appliance is sufficient (2600 unit with 8 GB of RAM). If you have multiple REX appliances, IPRM connects to the master modeling engine that aggregates all of the data from multiple REX appliances.
- **Question: I already have HP RAMS deployed. Can I use it with IPRM?**
  Answer: Yes, if you are considering moving from HP NNM to DX NetOps Spectrum, you can take advantage of any investment they have made in HP RAMS. IPRM is compatible with HP RAMS 8.11 and newer.
- **Question: I have a distributed Route Explorer installation, i.e. a modeling engine and one or more route recorders. The route recorder is responsible for collecting routing information, and the modeling engine provides GUI and a central database. How is DX NetOps Spectrum IPRM integrated in this case?**
  Answer: In this case, you should configure IPRM's REX integration settings to connect to the Modeling Engine and enable replication so that all data is copied to the Modeling Engine.
- **Question: What's the performance impact from adding IPRM to the SpectroSERVER?**
  Answer: There is no precise measurement available. A lot will depend on the amount of IPRM polling configured by the operator (for example, none vs. every 60 seconds).
- **Question: What is the performance impact on the network devices when REX performs discovery and monitoring?**
  Answer: Route Explorer operates by passively monitoring the routing protocols exchanges between routers. To do this, Route Explorer 'announces' itself as if it were a router, but doesn't advertise any prefixes, so no traffic flows to/through it (its neither a bottleneck nor a failure point).
  When Route Explorer is installed, it is given an IP address and adjacencies are set up with a small number of routers (e.g. REX requires an adjacency with one router in each OSPF area or IS-IS level). If the router is local, this can be a physical connection. Otherwise, REX can connect to remote routers either via GRE tunnels or VLANs. Once these adjacencies are up, REX begins monitoring the protocols and is able to present a complete, network-wide map within minutes.
  The only messages Route Explorer sends out to its neighbors are periodic 'KeepAlive' messages to maintain these adjacencies. Thus, there is virtually zero load placed on the real routers or the network, both during discovery and ongoing monitoring.
- **Question: How does REX establish routing adjacency with remote autonomous systems?**

Answer: In these cases GRE tunnels or VLANs can be configured to establish secure links to remotely located routers. In cases where the network policy, architecture or devices don’t allow or support this, you can deploy multiple REX appliances (Route Recorders) at the appropriate places in the network to establish direct adjacencies/peerings with the routers. In this distributed architecture, routing information collected by multiple Route Recorders is combined into a single topology view at the 'master' REX appliance (Modeling Engine). IPRM accesses the Modeling Engine to get the complete topology view of the network.

- **Question: Does REX appliance always work in passive mode?**
  Answer: In the majority of cases routing topology and management information is obtained from listening to routing protocol exchanges. However one routing protocol works in a different way from others - Cisco EIGRP. In this case only the change in distance to a given subnet can be determined. Based on this information alone REX uses its sophisticated algorithms to work out the routing topology and path state changes, and then uses some non-privileged CLI commands (and screen scraping) to validate its calculations.
  Optionally, REX also uses SNMP or CLI commands to collect information about Static routes; since static routes don’t change frequently, SNMP polling is done at very low frequency (typically, once a day; this is configurable).
- **Question: How does REX achieve scalability?**
  Answer: Packet Design have done quite a bit of scalability testing, both in-house and based on real world usage by their customers, and they can provide more details. That said, in 99%+ of the cases, a single appliance will be more than adequate. The reason Packet Design is so confident is due to the fact that under recommended deployment conditions REX will not have any users (i.e. GUI sessions).
  The limitation for scalability has to do with memory since REX requires a separate copy of the topology model for each user session (as well as another copy for monitoring/alerting). Large networks (# of routes and routers) can require very large models, and therefore take up a significant amount of memory. But without the need to support any direct users, Packet Design believes they have not seen a network that would not easily fit within a single appliance. And they have production deployments at some of the largest routed networks in the world. To put some parameters around that, Packet Design is already supporting networks comprised of over 7,000 routers and more than 8 million routes with a single box.

  NOTE
  Only routers are counted as nodes, whereas the number of devices monitored by a large DX NetOps Spectrum deployment includes many non-routing devices.
- **Question: Does REX support NAT'ed environment?**
  Answer: No, REX does not support this environment type.
- **Question: Does IPRM support subnets configured with overlapping IP addresses?**
  Answer: Route Explorer and DX NetOps Spectrum take different approaches to supporting this network configuration, and as such the initial release of IPRM does not support it. However, in future IPRM may be extended to support this deployment scenario.
- **Question: Does IPRM support fault tolerant DX NetOps Spectrum deployment?**
  Answer: Yes, secondary SpectroSERVER takes over communication with REX in case of failover, and pass control back to primary when it goes back online.
- **Question: Does REX support fault tolerant deployment?**
  Answer: Yes, primary REX appliance can be configured with secondary 'warm' standby REX appliance. In case of primary REX failure the switchover is to be done manually, but the secondary REX will have complete routing history from prior to the switchover event.
- **Question: Does IPRM support distributed DX NetOps Spectrum deployment?**
  Answer: Yes, all user configuration and interaction is performed on the main location server (MLS).

Useful Tips

Useful tips for IP Routing Manager:

- REX Connector should run on separate CPU from SpectroSERVER if possible to reduce impact on SpectroSERVER. This is because when Layer 3 discovery is performed, the REX Connector causes additional CPU usage. This is

primarily applicable to Windows, which can be adjusted by using Task Manager's 'Set Affinity' option. UNIX/Linux applications handle the load balancing better.
- You must disconnect from REX to change REX configuration settings (for example, REX administrative domain), and then re-connect for the changes to take effect.
- When using Monitoring Mode = 'Off', you must manually configure topology and path-related change notifications (traps) within REX GUI beforehand.
- Disconnected routers age-out of REX database slowly. The time for the disconnected routers to age out of the REX database is based on the routing protocol being used. In the case of OSPF, it is approximately one hour.
- Use 'Clear Layer 3 Topology' button to start over. This deletes all IPRM modeling in MLS, including subnets, paths, and Unmanaged Device models.
- An Autonomous System in IPRM is equivalent to an 'Administrative Domain' in REX.
- Source and destination of Layer 3 paths must be within REX's visibility.
- When tracing a path to a router loopback IP, the last internal hop is used in cost calculation and number of hops, but not included in path hop details nor topology view. This last internal hop is not represented visually in topology view.
- In OneClick, the 'View Layer 3 Path Change History', 'Create Layer 3 Path' and 'Select as Layer 3 Path Source' menu items may be disabled in the Tools, Utilities menu. These items are enabled/disabled based on what is currently selected in the Explorer tab.
  For example, if you select a router model under the 'Layer 3 Devices' container in the Explorer tab, all three of these menu items will be enabled under Tools, Utilities.

IP Routing Manager Troubleshooting

Known Anomalies

DX NetOps Spectrum's IP Routing Manager contains the following known anomalies:

- Modeling your Packet Design appliance in DX NetOps Spectrum will prevent IPRM-related traps and alarms from working properly.
- LANs/subnets cannot be used as the source for IP Subnet paths. This is a limitation of Route Explorer. In some cases, multiple routers route to the same subnet so REX is unable to determine the source router for the path.
  Therefore, IPRM cannot discover forward-and-return paths when a LAN/subnet is used as the path destination.
- Some interface information may appear 'missing' from the Path Hop Details table. In some cases, particularly with IS-IS, REX cannot determine the interface IP address for a hop in the path.
- Paths that have an internal router as the final path hop do not show this hop in the Path Hop Details table or in the path topology view. An internal router hop cannot be visualized in the topology and is therefore omitted from the topology view and the Path Hop Details table, but the cost of the internal hop is included in the path's total cost calculation.
- IPv6 is not supported.
- Overlapping IP address and AS ranges are not supported.
- If IP Routing Manager is connected to a Packet Design appliance that is running version 9.2 or greater of the Packet Design/Route Explorer software, the Path Change History's 'Link Prefix' column may be missing values.
- **Problem:**
  If a particular IP address is configured on the interface of more than one router and these routers are modeled in DX NetOps Spectrum, but at least one of the routers is modeled as a Pingable; IP Routing Manager may create links to the wrong model. In particular, there may be a link connecting one router model to another when that link should instead be connecting the Pingable model (which represents a different router) to another router model. A side-effect of this issue is a broken Layer 3 path view, where the path through the network is contiguous from source to destination, but the IP Routing Manager topology view displays a disjointed view of the path.
  Solution:
  Replacing the Pingable model with a model of a more appropriate, SNMP-managed model type (for example, Rtr_Cisco) and then re-discovering the Layer 3 topology in IP Routing Manager can resolve the issue.

IP Routing Manager Traceability Events

IP Routing Manager creates DX NetOps Spectrum events when any of the following occurs in IPRM so that users have visibility into what led to the current state of the IPRM. All events will be generated on the IP Routing Manager model.

- **DISCOVER_BUTTON_PRESSED_EVENT (0x564001e)**
  This event will be generated whenever the user presses the Discover button in OneClick. The name of the user will be included in the event.
- **CLEAR_BUTTON_PRESSED_EVENT (0x564001f)**
  This event will be generated whenever the user presses the Clear button in OneClick. The name of the user will be included in the event.
- **CONNECT_TO_REX_BUTTON_PRESSED_EVENT (0x5640020)**
  This event will be generated whenever the user presses the Connect button in OneClick. The name of the user will be included in the event.
- **DISCONNECT_FROM_REX_BUTTON_PRESSED_EVENT (0x5640021)**
  This event will be generated whenever the user presses the Disconnect button in OneClick. The name of the user will be included in the event.
- **REX_HOSTNAME_CHANGED_EVENT (0x5640022)**
- **REX_QUERY_PASSWORD_CHANGED_EVENT (0x5640023)**
- **REX_ADMINISTRATIVE_DOMAIN_NAME_CHANGED_EVENT (0x5640024)**
- **REX_HEARTBEAT_INTERVAL_CHANGED_EVENT (0x5640025)**
  The above events will be generated whenever the user changes one of the corresponding REX Configuration values OneClick. The name of the user will be included in the event.
- **TRAP_BASED_TOPOLOGY_POLL_EVENT (0x5640026)**
  This event will be generated whenever IPRM performs a Layer 3 topology poll based on receiving a trap from REX.
- **STARTUP_BASED_TOPOLOGY_UPDATE_EVENT (0x5640027)**
  This event will be generated whenever IPRM performs a Layer 3 topology update when the SpectroSERVER is restarted, or when regaining contact with REX after a communication problem.
- **MON_MODE_CHANGE_BASED_TOPO_UPDATE_EVENT (0x5640028)**
  This event will be generated whenever IPRM performs a Layer 3 topology update based on changes to the Topology Monitoring Mode in OneClick.
- **IF_RECONFIG_BASED_TOPOLOGY_UPDATE_EVENT (0x5640029)**
  This event will be generated whenever IPRM performs a Layer 3 topology update based on DX NetOps Spectrum router model interface reconfigurations. This is done to keep the Layer 3 topology in sync with DX NetOps Spectrum device modeling.
- **TOPOLOGY_UPDATED_EVENT (0x564002a)**
  This event will be generated whenever a Layer 3 topology update has been completed. Situations in which this is done outside of other events include topology changes detected by the REX Connector in Active mode.
- **TOPOLOGY_MONITORING_MODE_CHANGE_EVENT (0x564002b)**
  This event will be generated whenever the user changes the Topology Monitoring Mode in OneClick. The name of the user will be included in the event.
- **TOPOLOGY_POLLING_INTERVAL_CHANGE_EVENT (0x564002c)**
  This event will be generated whenever the user changes the Topology Polling Interval in OneClick. The name of the user will be included in the event.

IP Routing Manager Debugging

You have the ability to turn on debugging output for IPRM intelligence running inside the SpectroSERVER. An attribute called DebugLogEnabled exists on the IP Routing Manager model which controls the generation of log files. You can access it via the Attribute Tab of the IP Routing Manager model's Component Details panel.

Upon SpectroSERVER startup, it checks to see if DebugLogEnabled is TRUE. If so, then it opens a new log file in the IPRM/logs/debug directory and begins outputting data when necessary. When you set DebugLogEnabled to

FALSE, the log file is closed. When you set DebugLogEnabled back to TRUE, a new log file is created. After that, every night at midnight, the current log file is closed and a new one is opened. The log file names are of the form 'Layer3ModelingDebugLog.<datetime>'.

All Layer 3 topology and path modeling functionality will output modeling details to the debug log. This includes manually-triggered discoveries, discoveries triggered by changes detected, path creation requests, etc. The modeling details we output include data on each router and subnet that exists in the Layer 3 topology, links that were created or removed, UnmanagedDevice models created, attribute value updates, path creation details including hop details, path change information, and so on.

All debug output is time-stamped so the user can easily cross-reference it with debug output generated by the REX Connector.

Steps to Take if the REX Connector is Not Running

Steps to Take if the REX Connector Is Not Running

1. Check the following files for errors:
   ```
   $SPECROOT/IPRM/REX/REXCON.OUT
   $SPECROOT/lib/SDPM/processd_log for errors
   ```
2. Use DX NetOps Spectrum CLI to manually start the REX Connector:
   ```
   update  action=0x5640002 mh=<mh_of_IPRM>
   ```

Steps to Take if Unable to Connect to Route Explorer

Steps to Take if Unable to Connect to Route Explorer

- The password encryption for API requests may be broken if the Query Password had been set and then a Route Explorer software update had been performed. To alleviate this problem, set the Query Password on each of the Packet Design appliances (via the REX web interface) to a temporary value, save the changes, and then set the Query Password back to the original password and save the changes.
- Verify that 'Queries' are enabled in REX.
- Login to REX web interface and go to Application, 'Administration -> Application -> Queries'.
- Ensure the following are enabled 'XML-RPC Query Server' and 'Enable remote access'.
- Set the password to the same value entered in the IPRM configuration.
- Ensure REX Connector is able to access tcp port 2000 on Route Explorer system.

Layer 3 Topology Discovery Fails

Error: Unable to retrieve Layer 3 topology

Symptom:

When the DX NetOps Spectrum is integrated with Route Explorer (REX), the discovery of layer 3 topology fails.

Description:

When you initiate the Discovery to retrieve layer 3 topology from REX, if the response is huge the discovery fails with the following heap memory error:

```
Java.lang.OutOfMemoryError.Java heap space
```

Solution:

Starting from the 10.1 release, the DX NetOps Spectrum retrieves Layer 3 topology in chunks. The default chunk size is configured as 5000. So, DX NetOps Spectrum retrieves 5000 entries per chunk. You can configure the default chunk size in the config.xml file, which is at $SPECROOT\IPRM\REX. The changes are reflected in the REXCON.OUT file after 30 seconds.

Set the chuck size to a less number to receive the Layer 3 topology data.

Example: <chunk_size>2000</chunk_size>

REX Connector Debug Logging

To Set REX Connector Debug Logging

1. Edit IPRM/REX/config.xml file.

   NOTE
   The REX Connector checks config.xml for changes every 30 seconds, there is no need to restart the connector.
2. Set the <debugging> tag to one or more of these values (comma-separated, case insensitive):
   - **Off**
     No output at all.
   - **Trace**
     Minimal REX Connector startup, shutdown, administrative tasks.
   - **Comm**
     Includes basic information about communication with REX.
   - **Debug**
     Includes useful, human-readable topology and path data that REX provides. Technical Support can use this to cross-reference with modeling debug provided by the SpectroSERVER.
   - **Max**
     Includes raw XML from REX API requests and responses.

   Output is written to:

   ```
   IPRM/REX/logs/debug/debug.log.<timestamp>
   ```

REX Connector Debug Client

A command line utility 'rexcli' simulates SpectroSERVER-based requests to the REX Connector. The 'rexcli' utility provides a picture of the topology or a path at a specified date/time.

To Edit the 'rexcli' Utility

1. Navigate to IPRM/REX and edit 'rexcli' utility.
2. Specify the following supported parameters (if needed):
   - **-topo <date>**
     Retrieves the topology at the given time.
   - **-path <srcIP> <dstPrefix> [forward_and_return] <date>**
     Retrieves the path at the given time.
   - The 'dstPrefix' is specified in 'slash notation'
     (for example, 10.253.5.2/32 for a router destination).
   - The 'forward_and_return' (optional) retrieves both the forward and return paths
     (when possible).
   - The 'date' is the date/time for which you want to retrieve the IP Subnet topology or path, and is specified as: 2011/07/31T14:56:42; which represents: July 31, 2011 2:56:42 pm.

   The output is written to the shell; you can redirect to a file.

By enabling debugging in the REX Connector's config.xml file, you can correlate the output from 'rexcli' utility with the debug output from the REX Connector.

Initiating Layer 3 Topology Discovery Using an Offline Database

The REX Connector can also use 'offline' Route Explorer databases. 'Offline' Route Explorer databases are generally historical databases which have been archived on the Route Explorer unit. This feature allows IPRM to discover the Layer 3 topology stored in an offline database; this is useful for testing different types of networks and for customer support.

You can add an additional XML configuration option to the REX Connector's `config.xml` file. This additional option is a boolean named 'allow_offline_dbs'. When this option is set to 'true', users can configure the REX integration (via OneClick) to use an offline database.

Follow these steps:

1. Navigate to the Component Details Panel of the IP Routing Manager model, and then open the Configuration sub-view.
2. Clear any existing Layer 3 topology data by clicking **Clear**.
3. Set REX Connector options in `IPRM/REX/config.xml` .
4. Add <use_offline_dbs>TRUE</use_offline_dbs> to the file to access offline databases.
5. Click **Discover** in the IP Routing Manager model's Configuration sub-view.

Modeling and Managing Your IT Infrastructure Administrator

Network Modeling in DX NetOps Spectrum

Network modeling in DX NetOps Spectrum is the act of graphically representing network entities and their connections. Icons that are created, placed, and connected within the OneClick topology views represent various aspects of a modeled network.

Using the modeling features of the OneClick client, you can easily create and maintain accurate software models of your network. These intelligent network models enable DX NetOps Spectrum to determine actual points of failure and to suppress superfluous alarms.

DX NetOps Spectrum network representation is based on logical relationships and rules and appears different from your network diagrams. Discovery uses address tables and ICMP ping tests to identify subnet address ranges and devices within those ranges. Once discovered, DX NetOps Spectrum models those devices and subnets.

OneClick Topologies

You can use four core topologies to model your IT infrastructure in DX NetOps Spectrum:

- Universe Topology
- Global Collections Topology
- World Topology
- TopOrg Topology

All four of these topologies are available from the Navigation panel.

> **NOTE**
> We recommend that you begin modeling with the Universe topology. After you have established one or more modeled elements in the Universe topology, you can reuse these modeled elements to define the other topologies.

To navigate through the model views of any topology, click the view control icons in the toolbar. In some cases, you can click an aggregate icon container to view its content.

Universe Topology

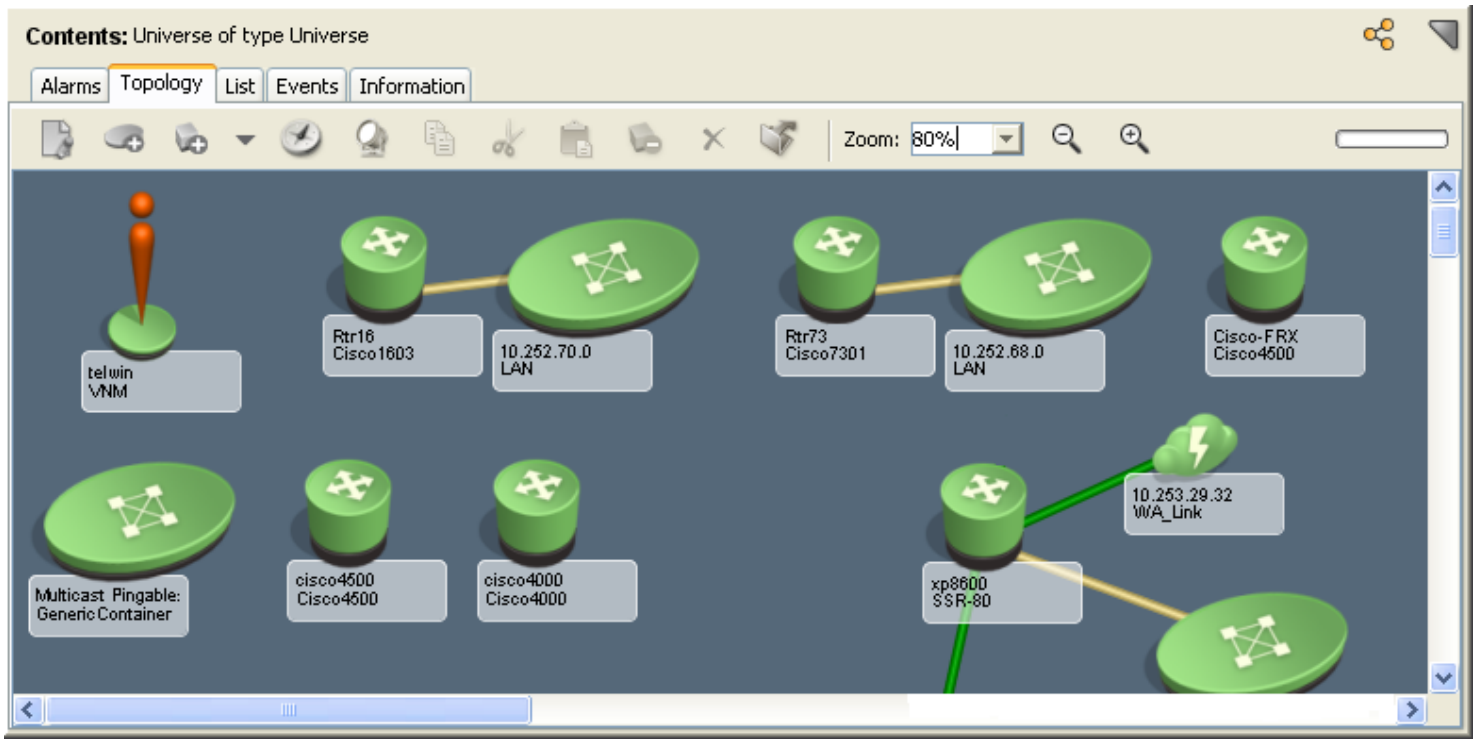
The Universe topology helps you organize an enterprise network view of your infrastructure. Most often, it provides a view of:

- A top-level topology view of OSI Layer 3 devices and their connections
- A drill-down topology view of OSI Layer 2 devices and their connections
- A Component Detail view, showing the attributes that are associated with a modeled entity

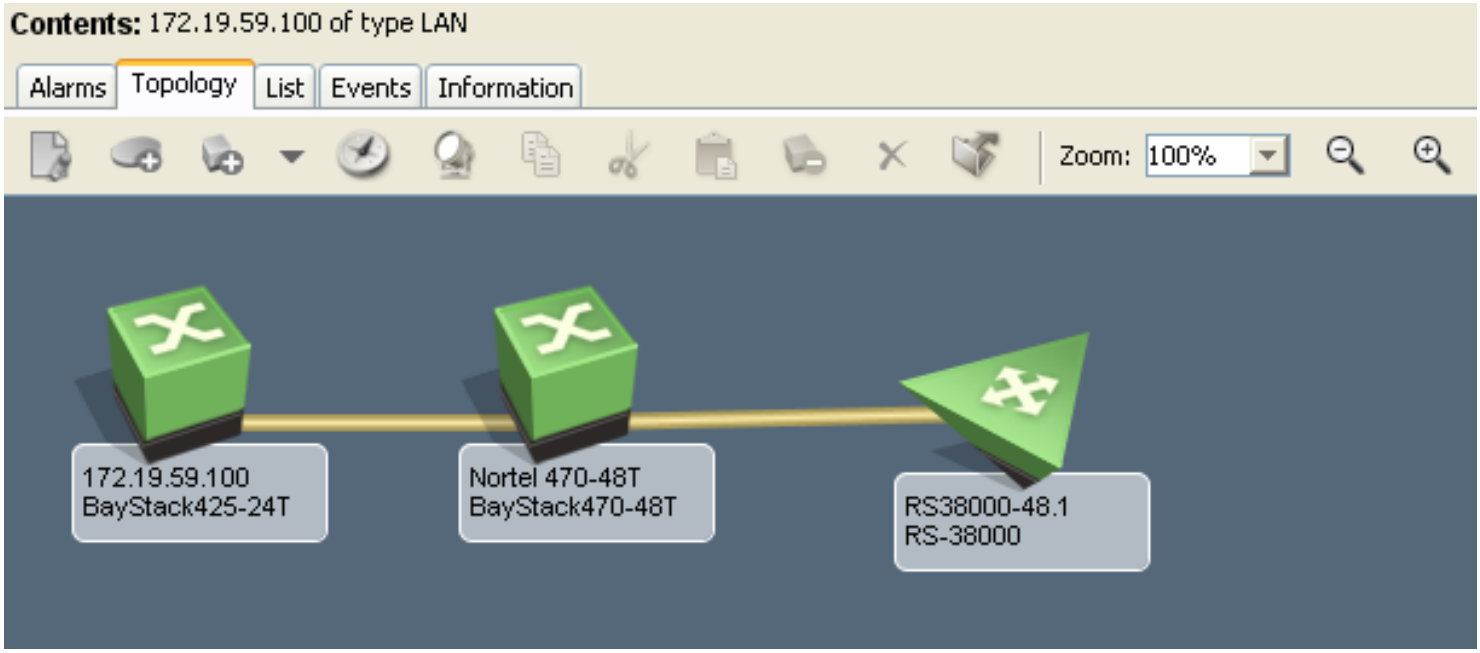
The top view in the Universe topology typically includes:

- The DX NetOps Spectrum Virtual Network Machine (VNM)
- Network groupings
- Network segments
- OSI Layer 3 devices and their connections

The following illustration shows a typical top view:

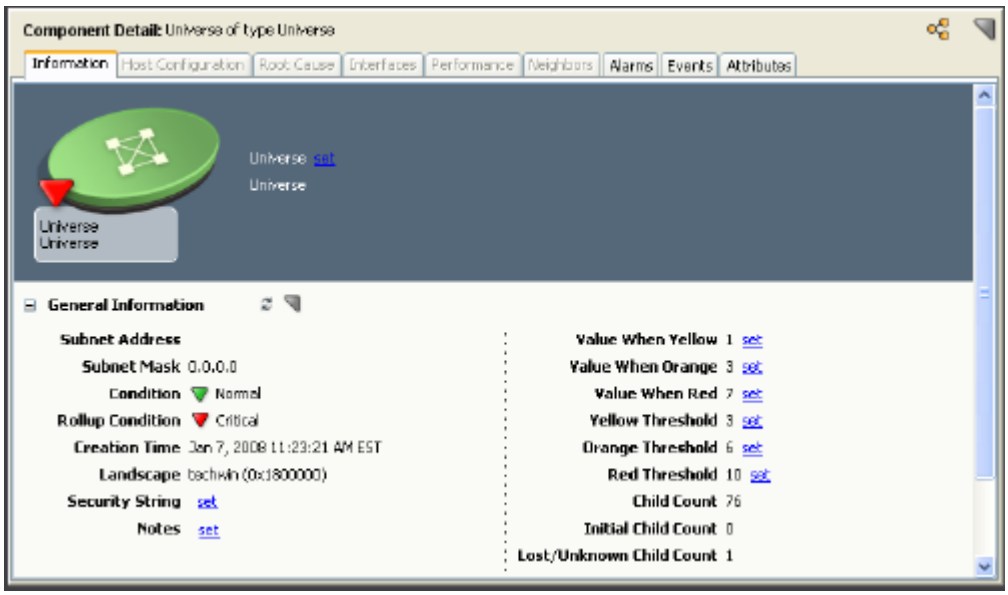


The following illustration shows a drill-down view of a LAN container that is selected from the top view. A drill-down view in the Universe topology most often includes all OSI Layer 2 devices and their connections. The drill-down view also shows off-page references to devices modeled in other views, as shown in the following illustration:



Component Detail Panel

The Component Detail panel within the Universe topology identifies the attributes that are associated with a modeled network entity. Attributes can include the device interfaces, alarms and events, and other pertinent device information.



You can view the device attributes and possibly change their settings by clicking the Component Detail panel tabs. Depending on the context of the Contents panel, you can use the Component Detail panel to:

- View current alarms in the Alarm Details tab.
- View and modify general device settings in the Information tab. For example, grant or deny access to a modeled device by providing or possibly removing a security string.
- View root cause analysis data in the Root Cause tab.
- View CPU and memory utilization information in the Performance tab.
- View device interface information in the Interfaces tab.
- View neighboring routers in the Neighbors tab.
- View historical events in the Events tab.
- View attribute information from the Attributes tab. This information appears only under these conditions:
  - You select an entity from the Explorer tab.
  - You are in either the Topology, List, or Events tab in the Contents panel.

Define Models in the Universe Topology

You can define models in the Universe topology using the OneClick Discovery feature, which automates the modeling process for you. You can also manually define new models or edit existing models in the Universe topology by using the modeling tools that are provided with OneClick.

The Universe topology view represents a true connectivity view of your infrastructure. Therefore, we strongly recommend that you reuse modeled elements from this view when creating other views. Therefore, as a best practice, copy model elements from the Universe topology view to create Global Collections, World, or TopOrg views. This approach helps to ensure accurate fault isolation of your network within the OneClick environment.

Global Collections Topology

A *landscape* is the network domain that is managed by a single SpectroSERVER. In OneClick, a landscape is the network view of one SpectroSERVER. To organize entity-based network views that span one or more landscapes, use Global Collections. Global collections enable you to monitor all aspects of your IT infrastructure from any perspective.

As an administrator, you can use Global Collections to create and track collections of network entities, organizations, or services that make up your infrastructure. For example, you can create and maintain collections that identify and track:

- Response teams within an organization responsible for maintaining equipment
- Devices supporting various services in your organization
- Customers receiving services from your organization

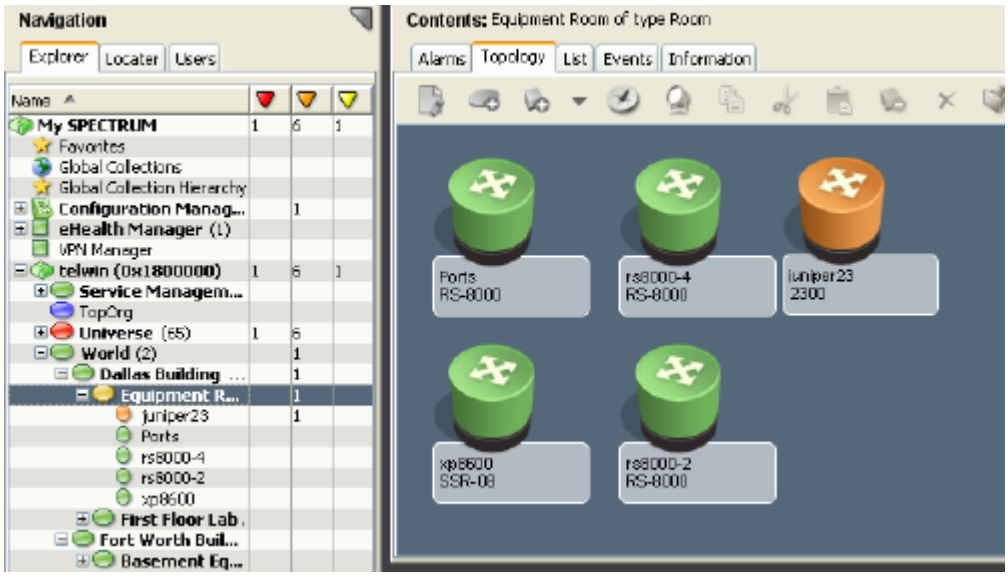
View or Modify Modeled Devices

You can view and change modeled device attributes or settings in the Component Detail panel within a Global Collections topology. Click the tabs in this panel for general information about a device, its interfaces, alarms, events, and other pertinent information.

World Topology

The World topology helps organize your network geographically in OneClick. In this topology, you can represent device models of network locations from a national or regional level all the way down to a wiring closet.

The following example illustrates a drill-down view of an equipment room that is at a fictitious North Dallas location.



In the World topology, you can create several layers of views that represent locations of your network devices. For example, you can have views for Texas regional offices, Dallas office, and Dallas Equipment room. Additionally, the Component Detail panel lets you view and sometimes change the attributes that are associated with a modeled device in any World topology view. For instance, clicking the Component Detail tabs for a modeled device lets you view device information, interfaces, alarms, events, and other pertinent device information.

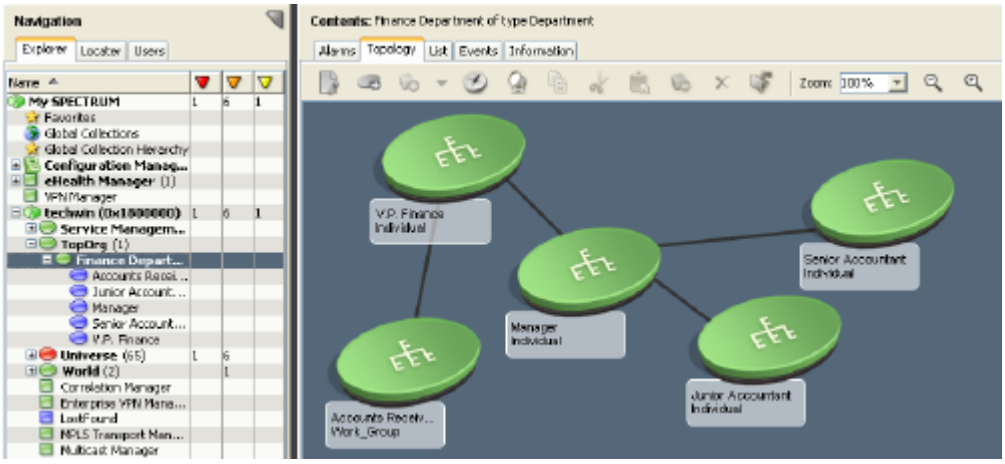
NOTE

- When populating the World topology views with modeled devices, we highly recommend that you **copy and paste modeled elements from Universe topology views**. Universe topology views represent the true connectivity views of your infrastructure, helping to ensure accurate fault isolation of your network within the OneClick environment.
- The Cut, Copy, Paste and Delete functionality for VHM models is disabled by default. If required, you can enable the option by following the steps explained in the 'Cut, Copy, Paste and Delete Functionality for VHM Models' section.

TopOrg Topology

The TopOrg topology allows you to represent your network organizationally. In this topology, you can group subnets and device models by services, responsibilities, departments, or by other organizational considerations.

The following illustration displays an organizational view that identifies individuals and groups within a fictitious Finance Department. This type of view is useful when identifying how a network failure or a reconfiguration affects an organizational unit.



NOTE
If you purchased the Service Manager module, you can use this module with the TopOrg topology to model business services and applications. Further, the Service Manager module also tracks the performance of the service against a contract or Service Level Agreement (SLA).

NOTE
For more information about using the Service Manager module, see Service Manager .

In the TopOrg topology, you can create several layers of views that represent various levels of your network devices. For example, you can have views for Enterprise ownership, Department ownership, supporting devices, and supporting services. Additionally, the Component Detail panel lets you view and possibly change the attributes that are associated with a modeled device in any TopOrg topology view.

NOTE
When populating the TopOrg topology views with modeled devices, we recommend that you copy and paste modeled elements from Universe topology views. Universe topology views represent the true connectivity views of your infrastructure. Therefore, using them as your base for all other views helps ensure more accurate fault isolation of your network within the OneClick environment.

Topology Toolbar

The following table describes some of the buttons available in the Topology tab toolbar for working with topologies.

Icon	Description
	**Edit mode:** Click to put the current topology view into Edit mode.
	**Create new model by type:** Click to create a new model by type and add it to the topology view.
	**Create new model by IP:** Click to create a new model by IP address or Host Name. Click the down arrow and select one of the following options: Create By IP Create By Host Name
	**Discovery:** Click to create a new discovery based on the selected model or models.

	**Spotlight View:** Click to highlight all models related to a VPN, a VLAN, or router redundancy in the Topology view. Spotlighting allows you to easily determine relationships between these items and your network, and between these items and other models on your network. When you click the Spotlight view button, a menu appears containing the following options: Router Redundancy VLAN List VPN List
	**Remove Model:** Click to remove the selected model from the Topology view.

Icons in Topology Views

Icons that appear in OneClick topology views are graphical representations of network entities. Some network entities include:

- Individual devices
- Groups of devices
- Geographic locations
- Physical connections

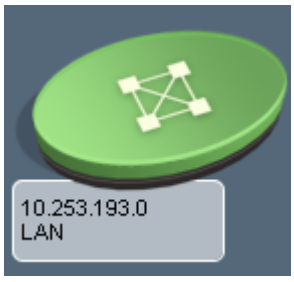
An icon is simply the image with which you interact when you manipulate and configure a modeled element. When monitoring the condition of your network, an icon represents the current status of a device, network group, device location, or a physical link.

DX NetOps Spectrum offers both aggregate and individual icons for representing entities in your infrastructure.

Aggregate Icons

An IP or physical address does not manage an aggregate icon. However, you can configure aggregate icons to display the device IP address that a container represents. Or, you can configure them to display the subnet address of the devices that the container represents. Aggregate icons primarily act as containers, or placeholders, in a topology view.

An aggregate icon often represents a network group. Some examples of network groups are LAN, LAN_802.x, FDDI, ATM_Network, WA_Link, and Dialup_Link. The following image is an example of an aggregate icon:

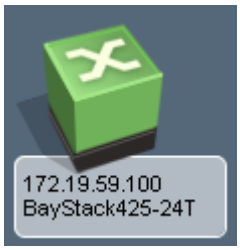


DX NetOps Spectrum offers many types of aggregate icons. The appearance of an aggregate icon is always based on the entity it represents in your network.

Individual Icons

Individual icons are typically associated with an IP address or a physical address. DX NetOps Spectrum can communicate directly with the devices the individual icons represent, so long as the entities they represent are SNMP and ICMP entities.

Individual icons often represent network devices. Some examples of individual icons are those icons that represent a router, switch, or host. The following image is an example of an individual icon:



DX NetOps Spectrum offers many types of individual icons. The appearance of an individual icon is always based on the entity it represents in your network.

Icon Types by Device model category

You model devices in your network through Discovery or manual modeling. During modeling, DX NetOps Spectrum automatically determines the functionality of each device and selects the appropriate icon shape and symbol for that device.

Icons come in various shapes and sizes. Icon symbols vary by the model class that is represented and by the topology in which the icon is located.

Icon types include:

- VNM icon
- Network group icon
- Device icon
- Off-page reference icon
- Segment icon
- Live pipes (links)

VNM

The Virtual Network Machine (VNM) icon typically appears in the top-level view above the network group icons. The background color of the VNM icon changes to indicate the current condition of the SpectroSERVER. For example, the VNM icon turns red when SpectroSERVER disk space reaches 90 percent capacity.

Network Group Icon

The network group icons represent network groupings, for example, cable groups, LANs, and IP Class A, B, C networks. The following icon shows an example of a LAN network group icon:

Device Icon

A device icon represents an individual device. The device icon color changes to indicate the current condition of the modeled device. For example, the device icon changes to red whenever DX NetOps Spectrum detects a serious condition requiring attention. The following icon shows an example of a device icon:

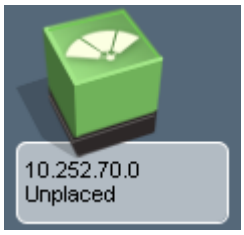
Off-Page Reference Icon

The off-page reference icon is a special purpose topology icon. The off-page reference icon represents a device that is directly connected to a device in the current view but which is modeled in another layer. The following icon shows an example of an off-page reference icon:

NOTE
You can globally suppress off-page references in topology views. For more information about suppressing off-page references, see Using OneClick .

Segment Icon

Segment icons represent conceptual elements of a network. Examples of segment icons can include a coax segment, a wa_segment, a fanout, an unplaced icon, and a pingable. The following icon shows an example of a segment icon:



Live Pipes (Links)

Live pipes represent the connection status between network devices. The links change color to indicate the current condition. A gold pipe represents a resolved connection or indicates that live pipes have not been enabled for the connection. A silver pipe represents an unresolved connection.

Live pipes are not enabled by default. To monitor the connection status between devices, enable a live pipe. The following image shows an example of a live pipe which has been enabled:

Icon Color and Condition

All icons change color to indicate the condition of the device or devices they represent. For instance, a device icon changes color when an alarm condition for that device occurs. A rollup triangle on a device icon or container icon changes color when an alarm condition occurs on one or more of its components. The components include devices or interfaces.

Rollup Condition Colors

The rollup triangle that is associated with the network container icon indicates that one or more components of the container has an alarm condition. In this example, a device within the network container has a critical alarm.

The rollup triangle that is associated with the device icon indicates that a component of that device has an alarm condition. In this example, an interface on a Cisco router has a minor alarm.

Icon Condition Colors

Logical links (or pipes) change color to indicate the condition of the connection:

- Disabled or maintenance conditions = brown
- Good conditions = green
- Initial conditions = blue
- Suppressed or unknown conditions = silver
- Poor conditions = red

Proxy Models

To easily identify proxy models in a topology view you will see a PROXY text watermark show up overlaid over the model icon. You can see various types of highlighted Proxy Models below:

Do the following to enable or disable this view:

- You need to select the relevant model and set the **"Is a Proxy Model"** attribute to **Yes**, to enable the view.
- You can also set the **"Is a Proxy Model"** attribute to **No**, to disable the view.

> **NOTE**
>
> You can use **Attribute Editor** to set the **"Is a Proxy Model"** attribute by editing the **isEventCreationEnabled (0x129f8)** attribute.
> The **isEventCreationEnabled (0x129f8)** attribute= **false** only indicates that the model is a proxy model and nothing more.

Wireless Network Devices

Wireless Devices models in the Topology View has the Wireless sign on the icon to distinguish them from non-wireless device models.
The icon colors of wireless device models will depend on the state or Icon condition as explained in the Icon Condition Colors above.

Wireless Controller Device icons

Wireless Access Points icons

Topology View using new Accessibility Icon theme

To provide a better user experience and in adherence to VPAT/508 standards, we have enabled an Accessibility theme for the OneClick topology view.
This theme provides new indicators denoting model severity/icon conditions on top of our existing topology view. This will enable model severity view, which is currently color coded, for users who are unable to distinguish between colors.
The accessibility icons will have additional indicators so that users can easily identify the difference in the icon model's severity.

The OneClick Console has two icon themes, Accessibility and OneClick. By default, the OneClick icon theme is selected.

To enable the Accessibility theme, follow these steps:

1. Click **Start Console** from the OneClick Administration page.
   The OneClick Console user interface is launched.
2. Navigate to the menu options, **View** > **Icons Theme**, and then select **Accessibility**.
   The OneClick Console automatically refreshes and the Accessibility indicators are displayed in the topology view.

The Icons theme selection is persistent across sessions. Once you have selected an icon theme for your topology, you will view the same theme in the OneClick console every time you logon.

Mapping the Accessibility Icons/ indicators with model severity status:

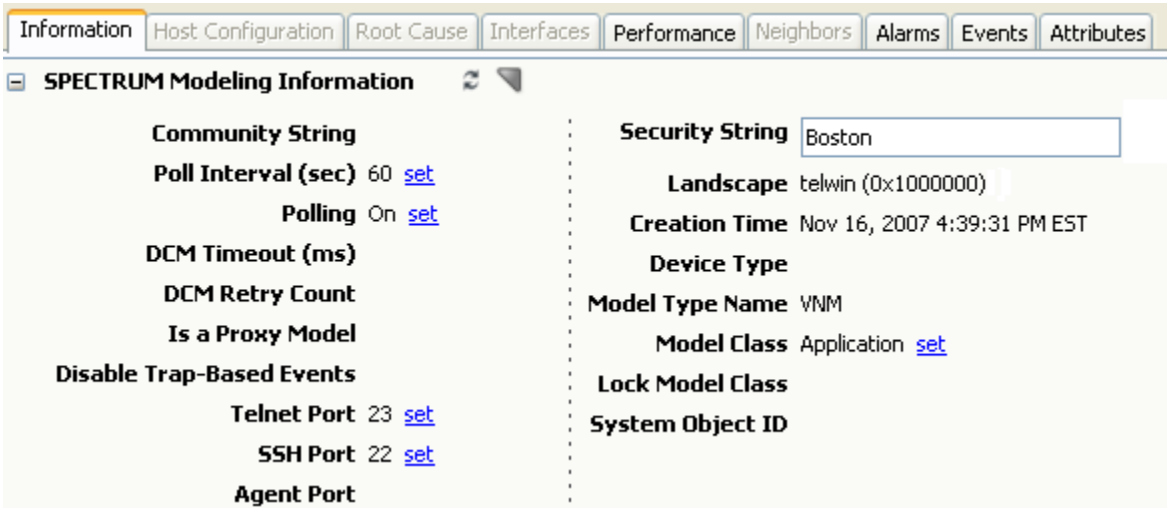
To revert to the (default) OneClick icon theme, follow these steps:

1. Navigate to the **OneClick Console** menu options, **View** > **Icons Theme**, and then select **OneClick.** The OneClick Console automatically refreshes and the default theme is displayed in the topology view.

Provision Access to Modeled Elements

As an administrator you can secure access to models by applying a security string. A security string establishes permission to various modeled elements in a OneClick topology view such as a modeled device.

After a security string is applied to a modeled device, all subcomponent models (or views) of that device inherit the security string. The security string field for implementing this model security appears in the Component Detail panel, as shown in the following example:



As shown, the security string ‘Boston’ prevents any user that does not have an Access Group of ‘Boston’ from accessing this modeled element.

NOTE
Any user with an Access Group of ‘Admin’ overrides model security; such users can access all model elements regardless of the security string implemented.

NOTE
For more information about creating or renaming Access Groups that are associated with individual users or user groups, see OneClick Administration .

Discovering and Modeling Your Network

This section details how you can discover devices and model your network topology by the following means:

Discovery

Discovery is a utility that you can run to find devices in your network and to model them automatically in the Universe topology. Discovery uses a set of configuration parameters that you can modify to determine which network entities to discover and model. You can reuse any set of previously saved configuration parameters and you can also rename, duplicate, or delete configurations.

A configuration determines the focus and scope of a Discovery or modeling session. You define the configuration by selecting parameters on the Discovery Console Configuration tab. After you create a configuration, you can choose when to activate it:

- You can activate the configuration immediately.
- You can schedule the activation, including scheduling it to recur.
- You can save the configuration and activate it later.

Depending on your user privileges, you can use the automated Discovery and modeling features together or you can use them separately. For example, here are some ways you can use Discovery:

- **To perform network inventories:** With read/write privileges to the Discovery parameters, you can use Discovery to identify assets within your network. And, you can export, as needed, the results describing those assets to a desired file format for further review and distribution.
- **To model network entities that you want to manage:** With read/write privileges to both Discovery and modeling parameters, you can use Discovery to:
  a. Determine which elements in your network you want to model.
  b. Identify how you would like DX NetOps Spectrum to model these elements for you automatically.

  Specifying modeling parameters with the Discovery parameters lets you easily create accurate software models of your infrastructure with less time and effort than modeling manually.

Separate Configurations

Creating separate Discovery and modeling configurations offers you more flexibility for customizing the Discovery and modeling process. By providing separate configurations, you can:

- Discover limited portions of your network by performing several smaller Discovery operations instead of performing one large Discovery operation.
- Model the results of a Discovery operation using different modeling options.
- Filter and export the results of a Discovery session in different ways.
- Filter and export the results of a modeling session in different ways.

Discovery Console

The Discovery Console consists of two panels: the **Navigation** panel on the left, and the **Contents** panel on the right.

Navigation Panel

The **Discovery Navigation** panel contains the **Landscape** drop-down list, a toolbar, and a list of configurations and folders available on the selected landscape. From the toolbar you can create, copy, delete, import, or export configurations and create new folders for the configurations. In the **Name** column, you can select a configuration to open it and view its details in the **Contents** panel.

Contents Panel

The Discovery Console groups the parameters you use to define **Discovery** and modeling configurations into four tabs in the **Discovery Contents** panel:

- Configuration Tab
- Discovery Tab
- Modeling Tab
- History Tab

Configuration Tab

The Discovery Configuration tab lists all the required and optional parameters you can set to create a configuration.

This tab contains the following settings:

- **Seed Routers**
  Specifies the IP addresses or hostnames of your network seed routers that act as an initial communication point for discovering the network topology. For a hostname, DX NetOps Spectrum attempts to resolve the host name to an IP address when you start Discovery. If DX NetOps Spectrum cannot resolve the host name to an IP address, an error message occurs. The error message displays in the Discovery status panel in the lower section of the Discovery tab. If you start Discovery in the context of a network element, the device IP address is populated in the Seed Router field. You can add more seed router IP addresses as needed.
- **IP/Host Name Boundary List**
  Specifies IP ranges, IP addresses, host names, or any combination of this information that DX NetOps Spectrum can use to define the boundaries for the configuration. For a host name, DX NetOps Spectrum attempts to resolve the host name to an IP address when you start Discovery. If DX NetOps Spectrum cannot resolve the host name to an IP address, an error message occurs. The error message displays in the Discovery status panel in the lower section of the Discovery tab. You can start Discovery in the context of a container in the Topology tab or the Explorer tab. In this situation, DX NetOps Spectrum populates the IP/Host Name Boundary List with an address range. The address range is determined using the IP address and network mask of the selected device. You can specify more IP addresses, IP address ranges, or host names.

  NOTE
  The IP/Host Name Boundary List also accepts single IPv6 addresses; however, IPv6 ranges are not supported.
- **SNMP Information**
  Specifies SNMP community strings and profiles for SNMPv1, SNMPv2c, and SNMPv3 communication.
- **Modeling Options**
  Specifies whether to perform a Discover only operation or a combined Discover and model operation. To review and accept the modeling defaults or to edit them, click the Modeling Options button.
- **Advanced Options**
  Contains the Advanced Options button which opens the Advanced Options dialog. In the Advanced Options dialog you can review, accept, or redefine the following options:
  - **SNMP Ports**
    Specifies the default SNMP port and any additional ports. This feature is most often used for managed node environments that use port numbers other than the default port number of 161.
  - **IP Exclusion List**
    Create, delete, modify, or import an IP exclusion list. This list instructs the Discovery session to exclude the devices in a defined IP address range.
  - **Discovery Options**
    Specifies whether the Discovery process uses ICMP and Route Tables. For the Route Tables option, you can set a Throttle level to control how often the server sends SNMP requests.
  - **Auto Export**

Specifies whether to export the Discovery session results automatically and the preferred format for exporting them: comma-delimited, tab-delimited, or web page.

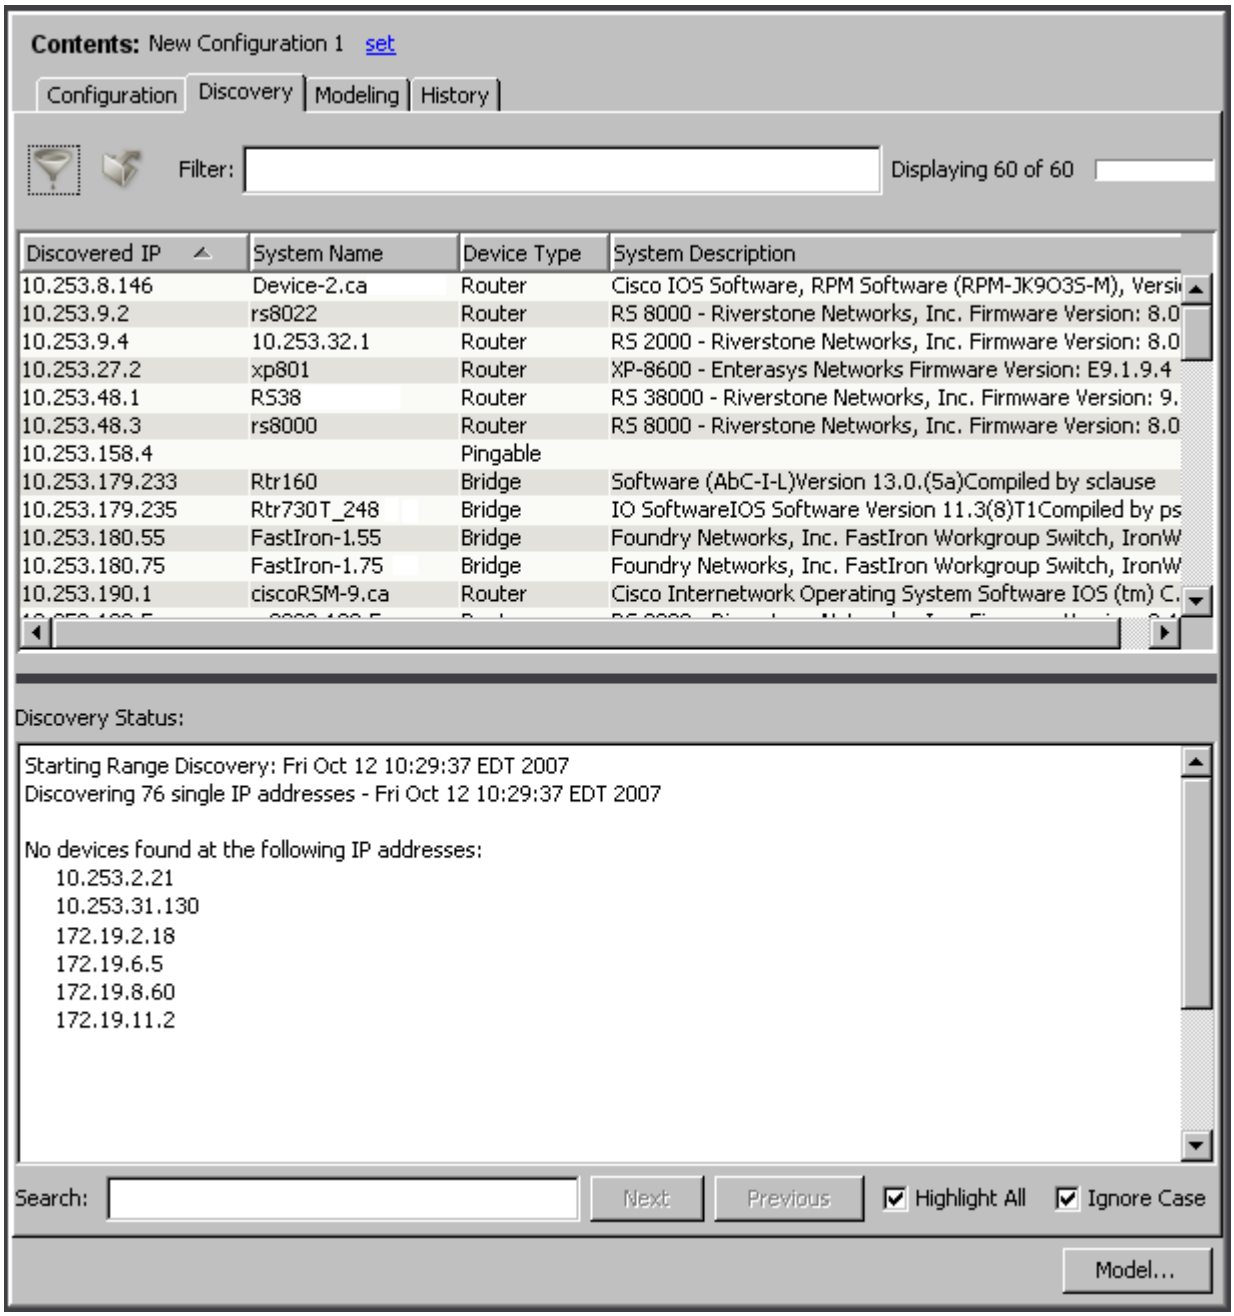
- **Scheduling Options**
  Specifies whether to activate certain configurations regularly using a schedule.

  NOTE
  In a DSS environment that spans multiple time zones, the local time of each SpectroSERVER is used for scheduling. For more information about OneClick schedules, see OneClick Schedules in a DSS environment .
- **Save options as default**
  Specifies whether to save the current configuration settings as the default configuration. For example, by default the ‘Discover only’ option is enabled on the Configuration tab. To change the default setting to the ‘Discover and automatically model to DX NetOps Spectrum’ option, select that option. Then, select the ‘Save options as default’ check box, and select File, Save.
- **Discover**
  Activates the Discovery session as it is defined in the Configuration tab.

Discovery Tab

The Discovery tab displays the results and status of the most recent Discovery session for the configuration that is selected in the Navigation panel. The discovered devices appear at the top of the Discovery tab. In the lower section of the Discovery tab, the status and error messages that are generated display in the Discovery Status panel. All users with Discovery privileges can access this tab. The Discovery tab initially appears disabled for new Discovery configurations and becomes enabled after an initial Discovery session is generated from the Configuration tab.

The Discovery results table includes the following columns by default: Discovered IP, System Name, Device Type, and System Description. To display the Table Preferences dialog, right-click one of the column headers. From this dialog, you can select more columns to display. The Model State column tells you whether the device is modeled in OneClick. This information is useful when identifying devices that are discovered on your network that require modeling in OneClick.



Filter, Sort, Export, Search, and Model Discovery Results

The Discovery tab provides the following options to help you review, filter, export, and model Discovery results:

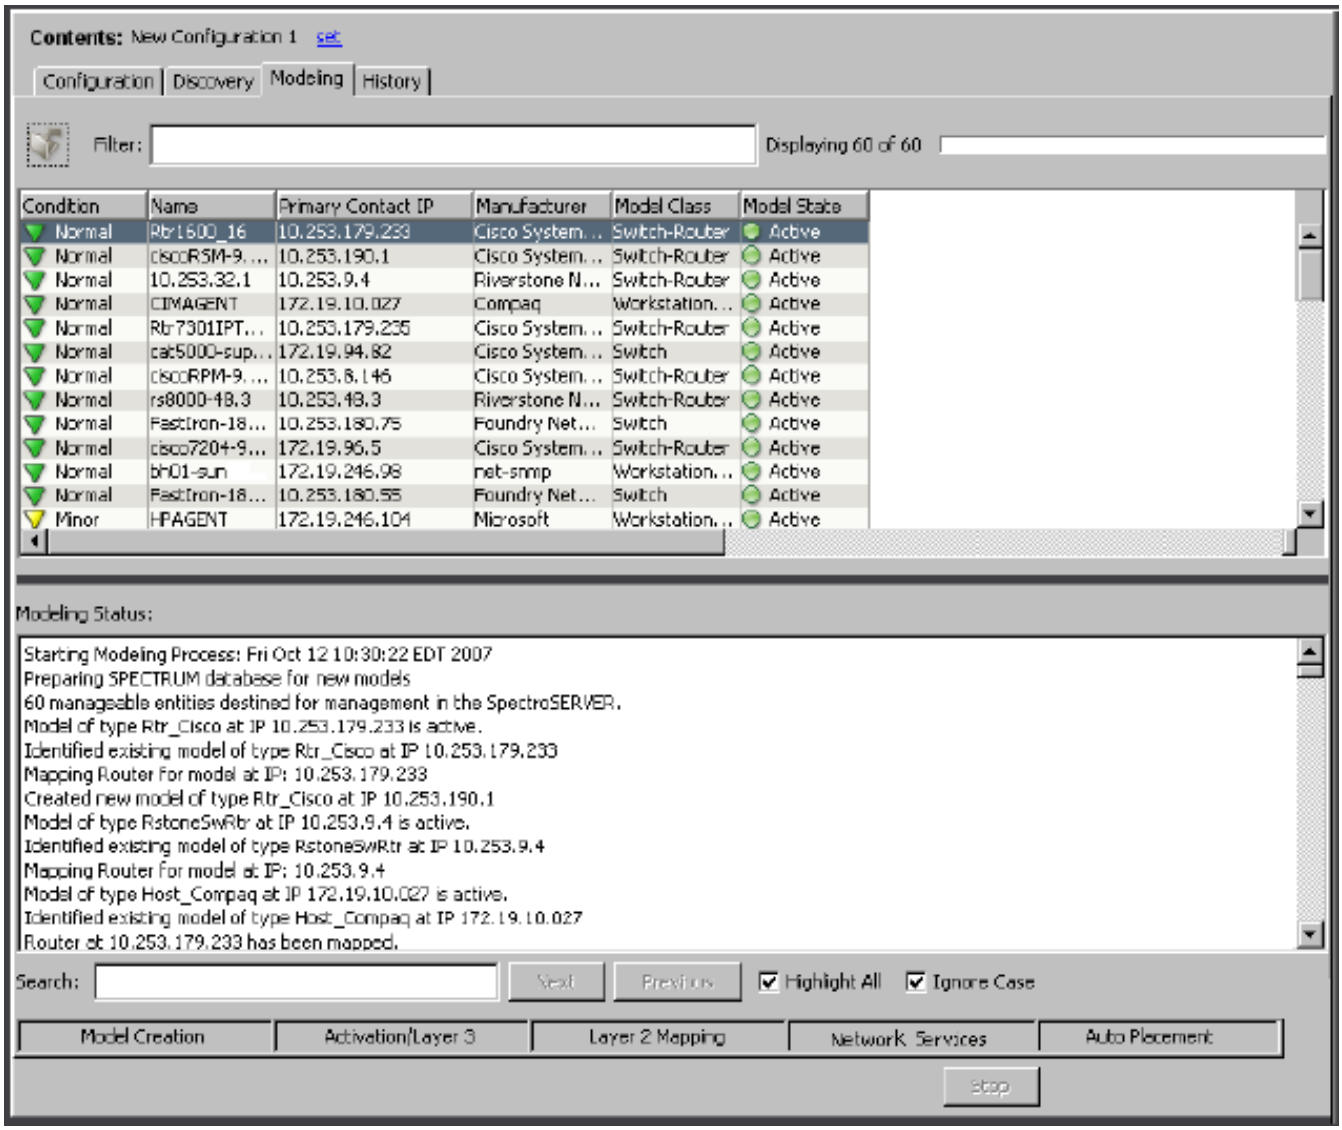
- **Filter:** The Filter text box lets you quickly filter the devices in the results list. For example, to develop, model, and export a list of Cisco devices from your results list, complete the following procedure:
  a. Type **Cisco** in the Filter text box.
     This filters the results list by Cisco devices.
  b. Click Model.
     This models only the Cisco devices.
  c. Click Export.

This exports the Cisco device results list.

- **Advanced Filter:** To apply more filter criteria, click the Advanced Filter button and creating one or more expressions. These expressions let you set more filters on the Discovery results list.
- **Exclude:** You can exclude one or multiple entries in the Discovery results list by right-clicking the entries that you want to exclude and selecting Exclude. You can also exclude these devices from the Discovery configuration. Select 'Save options as default' in the Configuration tab. Exclude one or more devices, then save the configuration. Discovery excludes those devices when it runs.
- **Export:** Click Export to open the Export table data to file dialog. In this dialog, you can specify a file format and location to export the Discovery results.
- **Status Search:** Enter character strings that you want to search for in the Discovery or the Model Status sections into the Search text box. To see all search matches in the Status panel, select the ‘Highlight All’ check box. To make the search case-insensitive, select the ‘Ignore Case’ checkbox. Use Next and Previous to navigate through the search matches in the Discovery Status panel.
- **Model:** Click to open the Modeling Configuration dialog. In this dialog, you can review or modify the default modeling options provided. When you click OK, DX NetOps Spectrum models only the devices appearing in the Discovery results list.

Modeling Tab

The Modeling tab displays the results and status of the last modeling session. The top portion of the tab shows the modeled devices. The Modeling Status section at the bottom displays the status and error messages that are generated during the last modeling session.



All users with modeling privileges can view the Modeling tab. This tab initially appears disabled for new Discovery configurations and becomes enabled only after an initial modeling session is activated from the Discovery tab.

NOTE
The Modeling tab provides the same options that the Discovery tab does to help you review, filter, export, and search modeling results.

Modeling Session Status Bar

The Modeling Status section displays a status bar at the bottom. The status activates immediately after clicking the Model button on the Discovery tab. This status bar divides the modeling process into four operation phases:

- **Model Creation**
  Phase 1 -- The label for this phase turns green while the SpectroSERVER processes the data to model.
- **Activation/Layer 3**
  Phase 2 -- The label for this phase turns green while the SpectroSERVER maps Layer 3 devices.
- **Layer 2 Mapping**

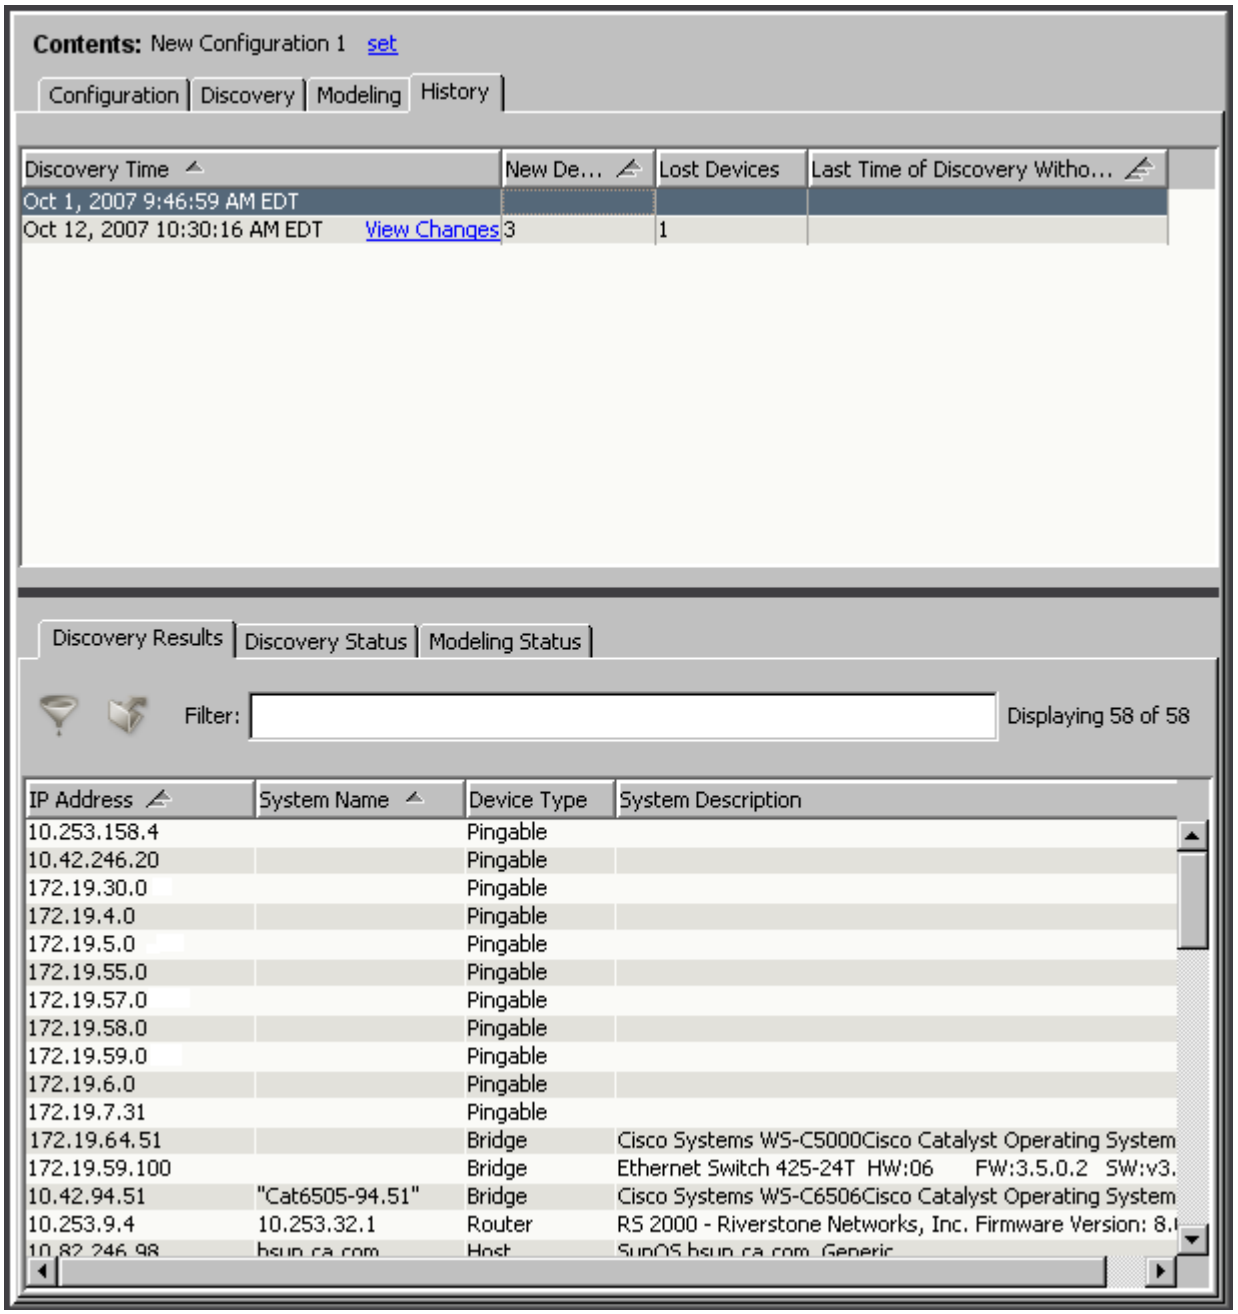
Phase 3 -- The label for this phase turns green while the SpectroSERVER waits for model activation and maps Layer 2 devices.

- **Network Services**
  Phase 4 -- The label for this phase turns green while the SpectroSERVER processes the running status for each network service.
- **Autoplacement**
  Phase 5 -- The label for this phase turns green while the SpectroSERVER places the models appearing in the modeling result list.

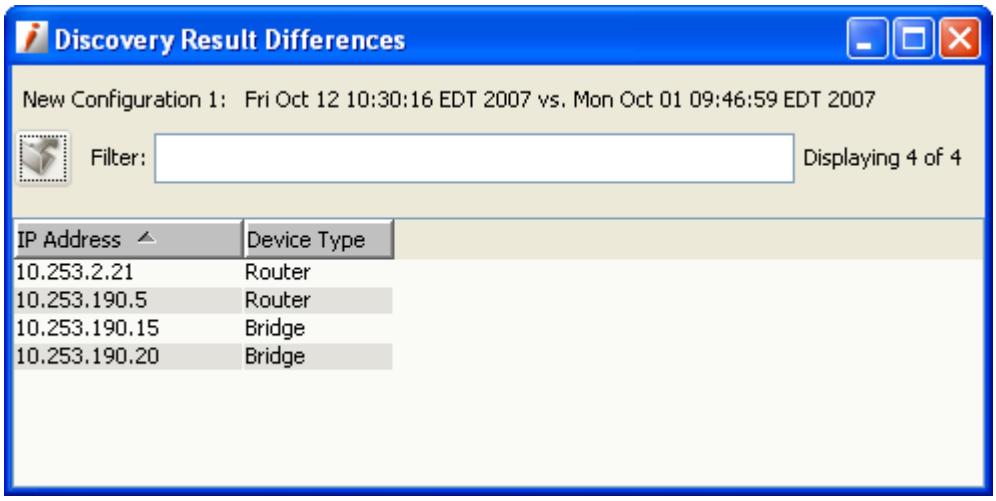
  NOTE
  On the Discovery Console, the Status box at the bottom displays the status and error messages that are related to each of these phases.

History Tab

The History tab displays information about the configuration that is selected in the Discovery Navigation tab. The following image shows an example of the History tab.



- **Discovery Time**
  Displays the time and date that a Discovery session occurred.
- **View Changes**
  Opens the Discovery Result Differences dialog. The dialog lists all devices that were either found or lost during the selected Discovery session when compared to the previous Discovery session. You can filter the information and can export it to a file.



- **New Devices**
  Displays the number of new devices that are found since the previous Discovery session for the selected configuration.
- **Lost Devices**
  Displays the number of devices that are lost between a previous Discovery session and the next Discovery session for the selected configuration.
- **Last Time of Discovery Without Changes**
  Displays the time and date information for when the selected configuration last ran without any changes. No time and date information are displayed when changes have occurred each time that the configuration has run.

The History tab also displays the Discovery Results, Discovery Status, and the Modeling Status tabs in the lower panel.

Discovery Connection Status

To display the Discovery Connection Status dialog, click the Connection status icon
( ).
In the Discovery Console, this icon is located in the Status bar.

When displayed from the Discovery Console, the Connection Status dialog shows:

- SNMP Service (SpectroSERVER) connection status
- Web server connection status
- Landscape (SpectroSERVER) connection status

NOTE
For more information about the Connection Status dialog and the Status bar, see Connection Status Indicator.

Open the Discovery Console

When creating a Discovery configuration, you can open the Discovery Console from the context of a selected model. You can also open the Discovery Console without this context.

To open the Discovery Console without specific model context, do *one* of the following steps:

- Click Tools, Utilities, Discovery Console. The Discovery Console opens.
- Click

  (Discovery) in the Topology tab toolbar without selecting a device in the Navigation panel or Topology tab. The Discovery Console opens.
- Click

  (Discovery) in the List tab toolbar without selecting a device in the Navigation panel or Topology tab. The Discovery Console opens.

Discovery can also be launched with context. Launching in context automatically generates a Discovery configuration that is based on the models that are selected in the OneClick Console. Discovery retrieves IP/subnet mask information from the selected routers, switch-routers, and LAN models and automatically creates a Discovery configuration that is based on this information.

To open the Discovery Console with context, do *one* of the following steps:

- Right-click a selected model in the Universe Navigation panel and select Utilities, Discovery Console.
- Right-click a selected model in the Contents panel, Topology tab. Select Utilities, Discovery Console.
- Select a model in the Topology tab and click

  (Discovery) in the toolbar.
- Right-click a selected model in the Contents panel, List tab. Select Utilities, Discovery Console.
- Select a model in the List tab and click

  (Discovery) in the toolbar.

The Discovery Console opens. If you select certain types of containers, a router, or a switch-router, the Configuration dialog also opens from the context of the selected model.

Discovery derives the context differently, based on how you create the Discovery configuration, as follows:

- From the Discovery button (Topology or List tab) - Discovery derives the context using your selection in the Contents panel.
- From the Tools menu - Discovery gets its context from your most recent selection in the Navigation panel.

Define a Discovery Configuration

A Discovery configuration determines which network devices to discover. When creating a Discovery configuration, you can open the Discovery Console from the context of a network element or container. You can also open the Discovery Console without this context.

Without context: Follow these steps:

1. Open the Discovery Console.
2. Specify the Discovery configuration settings.

NOTE
The IP/Host Name Boundary List and SNMP Information sections are mandatory for a successful Discovery configuration.

3. Do *one* of the following steps:
   – Click Discover to activate a Discovery session for the configuration you created.
   The results of the Discovery session appear on the Discovery Console, Discovery tab.
   – Click File, Save.
   The configuration that you created is saved.

Note: To apply the most recent changes that are made to any Discovery configuration, select the 'Save options as default' check box.

You can create a Discovery configuration with seed router context. As expected, Discovery discovers the selected router model. Plus, depending on other configuration parameters, Discovery discovers the LANs and routers that are connected to the seed router.

A Discovery configuration with container model context finds all of the network devices that reside within that container IP range.

With context: Follow these steps:

1. Open the Discovery Console.
2. Do *one* of the following steps:
   – If the Configuration dialog opens, enter a name for the configuration and click OK.

   NOTE
   The Configuration dialog opens when Discovery cannot find an existing Discovery configuration for the selected device.

   – If the Use Existing dialog opens, do *one* of the following steps:
   • Select an existing configuration that you want to use and click OK.
   • Click Create, enter a name for the new configuration, and click OK.
   If no existing configurations include the IP address of the selected device, the Configuration dialog opens. Use the provided name for the new configuration (which is based on the device type), or enter another name.
   – If the Configuration dialog does not open,
   click Discovery 
   Then, do *one* of the following steps:
   • Select an existing configuration that you want to use and click OK.
   • Enter a name for the new configuration and click OK.
   The Configuration dialog closes and the Discovery Console is now fully visible. The Seed Router section of the Configuration tab contains an IP address entry for the selected device. If you select 'LAN containers' in the OneClick Console before launching Discovery, the IP/Host Name Boundary List section can contain one or more IP ranges.
3. Specify the Discovery configuration fields in the Configuration tab.
   The Discovery configuration is defined.

How to Set Discovery Configuration Parameters

To set the parameters in the Discovery Configuration tab, do the following steps:

- Populate the Seed Routers List
- Specify Host Names and IP Addresses
- Specify SNMP Information
- Specify Modeling Options
- Configure Advanced Options

Seed Routers

The Seed Routers section is optional, but recommended for large Discovery operations. Seed routers are a core list of routers that Discovery uses as a starting point when determining the routed subnets. All routers that are discovered within the IP/Host Name Boundary List are treated as seed routers.

If you start Discovery in the context of a selected device, the IP address for the device appears in the Seed Routers field.

Populate the Seed Routers List

You can populate the Seed Routers list to have Discovery determine the routed subnets from this list.

Follow these steps:

1. In the Seed Routers field, enter addresses or host names to build a list of one or more seed routers and click Add.
2. From the Discovery Type drop-down list, choose *one*:
   - **Routers only**
     Discovers only the routing devices within the IP range or host name.
   - **Routers and only local LANs in IP/Host Name Boundary List**
     Discovers only the routed subnets within the IP range or host name.
   - **Routers and all local LANs**
     Discovers all subnets that are routed by the routers that are discovered in the IP range or host name.
3. Depending on how you want DX NetOps Spectrum to discover subnets, choose *one* of the following options:
   - Select the 'Scan Subnets Using ICMP/SNMP Sweep' option and then select the maximum subnet size that you want to discover.
   - Select the 'Discover Subnets Using:' option and then select either 'ARP tables,' 'Cisco CDP tables,' or both.
   - Continue setting configuration parameters in the other view sections, as needed.

   Seed Routers information has now been added to the Discovery configuration.

IP/Host Name Boundary

The IP/Host Name Boundary List section is required for all Discovery configurations. The IP/Host Name Boundary List field populates with an IP range when you start Discovery with a container selected from the Topology tab. The IP range is determined using the network address and network address mask for the container. However, you can specify more IP ranges, individual IPs, or one or more host names, as needed.

- For IPv4, the boundary list accepts single IPs, IP ranges, and host names. Wildcards can also be applied.
- For IPv6, the boundary list accepts single addresses and host names. IPv6 ranges are not valid input. Also, wildcards cannot be applied to IPv6 addresses.
- If an IPv6 address is entered into the first IP address field, the second IP address field is automatically disabled. In this case, you cannot enter an IPv6 range.

Specify Host Names and IP Addresses

You can specify which host names, IP addresses, or IP address ranges you want DX NetOps Spectrum to discover using these three methods:

- Manual entry
- Import statically
- Import dynamically from a specified file location

Manual: Follow these steps:

1. Enter in the IP/Host Name Boundary List section (first text box) any *one* of the following values:

- A host name
- A single address
- The lowest address in the IP range

NOTE
You can use a wildcard character to input individual IP addresses. For example, entering 10.10.*.1 could discover: 10.10.0.1; 10.10.16.1; 10.10.32.1; and so on.

2. Enter in the second text box the same single host name or address, or the highest address in the IP range. Click Add.

WARNING
Attempting to process a large range of IP addresses or several sparsely populated subnets can lead to unwanted results.

3. Repeat Step 1 and Step 2 for each host name, IP address, or IP range of addresses that you want Discovery to contact.
You can also import a list of host names, IP addresses, or IP address ranges for DX NetOps Spectrum to discover.

Import statically: Follow these steps:

1. Click Import in the Configuration tab.
2. Select Local Host from the 'Import file location' drop-down list.
3. Select the text file containing the host names or IP addresses. Click Open.
OneClick Discovery reads the host names or IP addresses information from the selected file.

Import dynamically: Follow these steps:

1. Click Import in the Configuration tab.
2. Select ‘One Click web server host’ from the 'Import file location' drop-down list.
3. Enter the path to the text file containing the host names or IP addresses.
The file must be on the OneClick web server host. The file path must use the native format of the OneClick web server operating system (OS):
   - If the web server is running a Microsoft Windows OS, the format of the path must be:
     C:\Program Files\Spectrum\IP_Files\core_network_ips
   - If the web server is running a Linux OS, the format of the path must be:
     /usr/Spectrum/IP_Files/core_network_ips

NOTE
By default, the installation path for the OneClick web server appears in the Import file path field.

4. Click Open.
OneClick reads the file and imports the host names or IP addresses during each configuration activation. The host names or IP addresses in the text file can be updated regularly, and the updates are reflected in each activation. Importing dynamically lets you maintain current host names or IP addresses automatically when activating a configuration on a scheduled basis.

IP Address Considerations

When specifying IP addresses in the IP/Host Name Boundary List fields, consider the following situations, which can lead to unwanted results:

- Attempting to process a large range of IP addresses. Consider the inclusive range when entering IP address boundaries, and be as specific as possible. You get better results by entering multiple smaller and more pertinent ranges than a single large range. For example, do *not* attempt to run a Discovery with a single IP range of 0.0.0.1 to 255.255.255.255.
- Attempting to discover several sparsely populated subnets. This situation takes significant time because of the timeouts and retries for each unused address. Although many threads are involved in this process, a sparsely

populated subnet can quickly exhaust all the available threads. This situation causes the discovery process to take a long time. In this case, seed router discovery can be a better choice.

SNMP Information

The SNMP Information section is mandatory for Discovery configurations. Here you can review, edit, or remove SNMPv1 and v2c SNMP community strings and v3 security parameters that are currently applied to the configuration. You can also add new strings and profiles manually or you can import them from a text file.

> **NOTE**
> You cannot create a profile name using Import. Instead, first create any desired profile names using the Edit SNMP v3 Profiles dialog before importing the text file. When importing a text file, DX NetOps Spectrum compares the SNMPv3 profile names to the existing profiles. These existing profiles were created manually using the Edit SNMP v3 Profiles dialog. If a profile name included in the text file being imported does not exist in DX NetOps Spectrum, an error message displays, and the import action fails.

Specify SNMP Information

The SNMP Information section is mandatory for all Discovery configurations. You can manually specify an ordered list of SNMP community strings and profiles for SNMPv1, v2c, and v3. Or, you can import a list of strings. By default, Discovery uses ‘public’ if no other SNMP community strings are specified.

> **NOTE**
> For SNMPv3 communication, use profiles.

Manual: Follow these steps:

1. Select either the SNMP v1 option or the SNMP v2c option in the SNMP Information section.
2. Type the SNMP community string name for the devices you want discovered in the SNMP Community String field and click Add.
   The SNMP community string is inserted into the available SNMP community strings and profile names list.

Import: Follow these steps:

1. Create and save a text file containing the SNMP community strings that you want to use for SNMP. Be sure to use the correct syntax.
2. Click Import in the SNMP Information section.
3. Select the text file that contains the SNMP community strings you want to import.
   Valid SNMP community strings and profile names that are imported are added to the available SNMP community strings and profile names list.

Syntax for Imported SNMP Communities and Profiles

You can use this syntax to create a text file that contains SNMP community strings for importing into Discovery configurations.

This syntax has the following format:

```
<name>,v<SNMP_version>
```

> **NOTE**
> The text file must list each SNMP community string and profile on a separate line.

- ***<name>***
  Defines the SNMP community string.
- ***<SNMP_version>***
  Defines the applicable SNMP version, either 1, 2, or 3.

NOTE
The version number for SNMPv1 community strings is optional.

Examples: SNMPv1

```
public
public,v1
```

Example: SNMPv2

```
public,v2
```

Example: SNMPv3

```
public,v3
```

Modeling Options

Modeling configuration settings determine how Discovery models discovered devices. By default, OneClick provides modeling configuration parameters that you can use and modify. Access these settings by clicking the Modeling Options button on the Discovery Configuration tab. Or click the Model button on the Discovery tab.

This Modeling Configuration dialog contains the following settings for configuring discovered models:

- **Destination Container**
  Specifies the topology view container where Discovery places discovered device models. You can select a container, such as a LAN container or the New Devices container.
  Default: Universe container
- **Modeling Layout**
  Specifies how Discovery places and arranges models in the Universe topology view.
  - **Placement**
    Specifies where models appear in the topology:
    - **Flat:** Discovery places all devices, including Layer 1 and Layer 2 in the Destination Container; no LAN containers are created.
    - **Hierarchical:** (Default) Discovery places all Layer 3 devices, LAN containers, and Wide Area Links in the Destination Container. Layer 1 and Layer 2 devices are placed in the proper LAN container (based on IP address) under the Destination Container. If Discovery cannot find the appropriate LAN container for Layer 1 or Layer 2 devices, these devices are placed in the Destination Container.
  - **Arrangement**
    Specifies how models are arranged in the topology:
    - Grid
    - Radial (Default)
    - Tree
- **Modeling Options**
  Specifies how Discovery models discovered devices:
  - **Create Wide Area Link Models**
    Determines whether Discovery creates a WA_Link model between the wide area linked interfaces of two routers. When this option is disabled, Discovery directly connects the linked interfaces.
    Default: Enabled
  - **Create LANs (IP Subnets)**
    Determines whether Discovery uses a LAN container when representing an IP Subnet. Discovery creates the LAN container during the Layer 3 mapping process for any router interface that routes to a local LAN.
    Default: Enabled
  - **Remove Empty LANs**

Determines whether Discovery destroys any empty LAN containers that the Create LANs (IP Subnets) option created.
Default: Disabled

– **Create “802.3” (Fanout)**
Determines whether Discovery models an 802.3 Fanout segment when DX NetOps Spectrum cannot make an accurate connection among three or more interfaces. This model represents the ambiguous connections among these interfaces. However, DX NetOps Spectrum uses network traffic data (IfInOctet and ifOutOctect statistics) when the Traffic Resolution protocol option is enabled. This protocol determines connections between interfaces and, in many cases, eliminates the need to model a Fanout.
Default: Disabled

Note: If you have 50 or more connections to a single Fanout model, consider changing this model to a Shared Media Link. The Shared Media Links must be modeled manually. These models can provide more control over fault management behavior when multiple connections are monitored. Unlike a Fanout model, Shared Media Links provide configurable thresholds for handling downstream connections that report problems. For example, a Fanout model reports a problem only when *all* downstream connections are down. However, a Shared Media Link can report the problem sooner, as when 60 percent of the downstream connections are down.

Create Physical Addresses

Determines whether to create a physical address model for a MAC address that is heard by a switch but not associated with any modeled device. The layer 2 mapper attempts to find a connection for each address found. If a connection is found, a Fanout is created and the physical address is associated to it through Connects_To. If no connection is found, the model is placed in Lost and Found. This option is not recommended.

Default: Disabled

- **New Devices in Maintenance Mode**
  Determines whether DX NetOps Spectrum places the newly discovered devices directly into maintenance mode.
  Default: Disabled
- **Activation Timeout (in minutes)**
  Determines the number of minutes that Discovery waits for new models to activate before mapping their connectivity. When the timeout expires without any new devices activating, connectivity is established to the extent possible. Connectivity occurs regardless of whether all connections to discovered devices have activated. The minimum activation time is 5 minutes and the maximum time is 15 minutes.

Protocol Options

Lets you configure options for mapping the connectivity between models. By default, Discovery enables several protocol options that are based on best practices. You can disable the default settings or can enable other protocol settings.

NOTE
IPv6 MIB data is not used for connection mapping.

Network Services Options

Let you specify the network services to run during the modeling process. The supported options include VPN, Enterprise VPN, QoS, Multicast, VPLS, and MPLS Transport. Options are available depending on the components that you have installed.

Filter

Opens the Advanced Filter dialog, where you can exclude selected discovered devices from modeling. You can also click Show Advanced to create a complex filter criterion that includes a combination of AND/OR clauses. The ‘Hints’ link on the Advanced Filter dialog provides more information.

Auto Export

Specifies whether and how you want to export modeling results automatically. Also lets you select the format for exporting them: comma-delimited, tab-delimited, or web page.

Reset Defaults

Instructs Discovery to use the default modeling settings that are provided with DX NetOps Spectrum.

Define Modeling Options

The modeling configuration settings determine how Discovery models the devices it discovers. By default, OneClick provides modeling configuration parameters that you can use or modify. At any time, you can review or change the modeling configuration. Change the configuration using one of these methods:

- Click the Modeling Options button on the Discovery Configuration tab.
- Click the Model button on the Discovery tab.

NOTE
Before you can define a modeling configuration, define a Discovery configuration.

Follow these steps:

1. In the Discovery Console, with the current Discovery configuration selected in the Navigation panel, do *one* of the following steps:
   – Define a combined Discovery and modeling session by selecting 'Discover and automatically model to DX NetOps Spectrum.' To review or modify the modeling configuration, click the Modeling Options button in the Configuration tab.
   – Define a Modeling session after activating a Discovery session by clicking the Model button in the Discovery tab.

   The Modeling Configuration dialog opens.
2. In the Modeling Configuration dialog, review or modify any of the fields as needed.
3. How you accessed the Modeling Configuration dialog in Step 1 determines which of these Discovery options you can select:
   – If you clicked Modeling Options on the Discovery Configuration tab to access the Modeling Configuration dialog, click OK. All of your changes are saved, and the Modeling Configuration dialog closes.
   Upon activating the next modeling session, Discovery uses the last saved modeling parameters.
   – If you clicked Model on the Discovery tab to access the Modeling Configuration dialog, click OK. The currently specified modeling configuration parameters are saved, modeling session is activated, and the Modeling Configuration dialog closes.

   Discovery starts a modeling session that is based on the parameters you have specified.

Advanced Options

Configure Advanced Options if you want to perform any of these Discovery configuration procedures:

- Define the SNMP ports in addition to the default port (161).
- Exclude certain IP addresses from the Discovery.
- Modify the default settings for ICMP, route tables, throttle, time-out, and retries.
- Enable or disable the automatic export of Discovery results.

Follow these steps:

1. Click Advanced Options.
   The Advanced Options dialog opens.
2. (Optional) Enter a new port number in the SNMP Ports text box and click Add.
   The new SNMP port appears in the list of ports Discovery uses for this configuration.
3. (Optional) Enter an IP address or range to the IP Exclusion List text box.
   The IP addresses you enter are excluded from this Discovery.
4. Modify the default Discovery Options settings as needed. These options are as follows:
   – **Use ICMP first, then SNMP**

When this option is enabled, Discovery uses ICMP when discovering devices. If ICMP is enabled, Discovery pings the devices in the ranges/subnets first. The devices that responded to ICMP are then queried using SNMP. This option can help reduce the number of SNMP requests, especially when multiple SNMP community strings are being used.
Default: Enabled

- **Use Route Tables**
  Use this option only if seed routers are specified in the Discovery configuration. When this option is enabled, Discovery finds neighbor routers and the routed subnets from the IP route tables.
  Default: Enabled
- **Require discovered IP entry in device's IP Address Table**
  When this option is enabled, Discovery includes only those devices which have the discovered IP address present in their IP address table.
  To discover devices that do not have their discovered IP address in the IP address table (e.g. devices using NAT addresses) this option must be disabled. Disabling this option ignores IP address table checking for range discovery.
  Default: Enabled
- **Throttle**
  Most often this option applies to networks with routing tables containing more than 1,000 entries. If you have networks with routing tables containing over 1,000 entries, you can specify a throttle value (Low, Medium, or High) to stagger the processing workload by having DX NetOps Spectrum pause for one second after reading every 50 entries (High), 100 entries (Medium), or 250 entries (Low).
  Default: None
- **Timeout (in seconds)**
  Specifies the number of seconds that Discovery waits for a device response.
  Default: 3
- **Retries**
  Specifies the number of attempts that Discovery makes after the first attempt times out before establishing contact.
  Default: 3
- **ICMP Payload Size**
  Specifies the payload size in bytes. This option is only available if you have selected 'Use ICMP, then SNMP.'
  Default: 8
- **Secure Domain**
  This option is only available if you have the Secure Domain Manager installed.

  NOTE
  For information about the Secure Domain option, see Secure Domain Manager.

5. Do *one* of the following steps in the Auto Export section:
   - To disable Auto Export, select 'Do not export results' from the Auto Export drop-down list.
     Auto Export is not enabled for this Discovery and results are not exported automatically.
   - To enable Auto Export, select *one* of the following options from the Auto Export drop-down list:
     - Export results as CSV (Comma delimited)
     - Export results as text (Tab delimited)
     - Export results as a web page

     Auto Export is enabled for this Discovery. The Discovery results are sent to the location identified on the dialog and in the format that you selected.
6. Click Close.
   The Advanced Options dialog closes and your settings are saved to this Discovery configuration.

Scheduling Options

The scheduling options are as follows:

- Select an existing schedule to run the configuration (click the Select button in the Scheduling Options section).
- Create a schedule.

If the configuration is scheduled, the schedule name displays next in the Scheduling Options section.

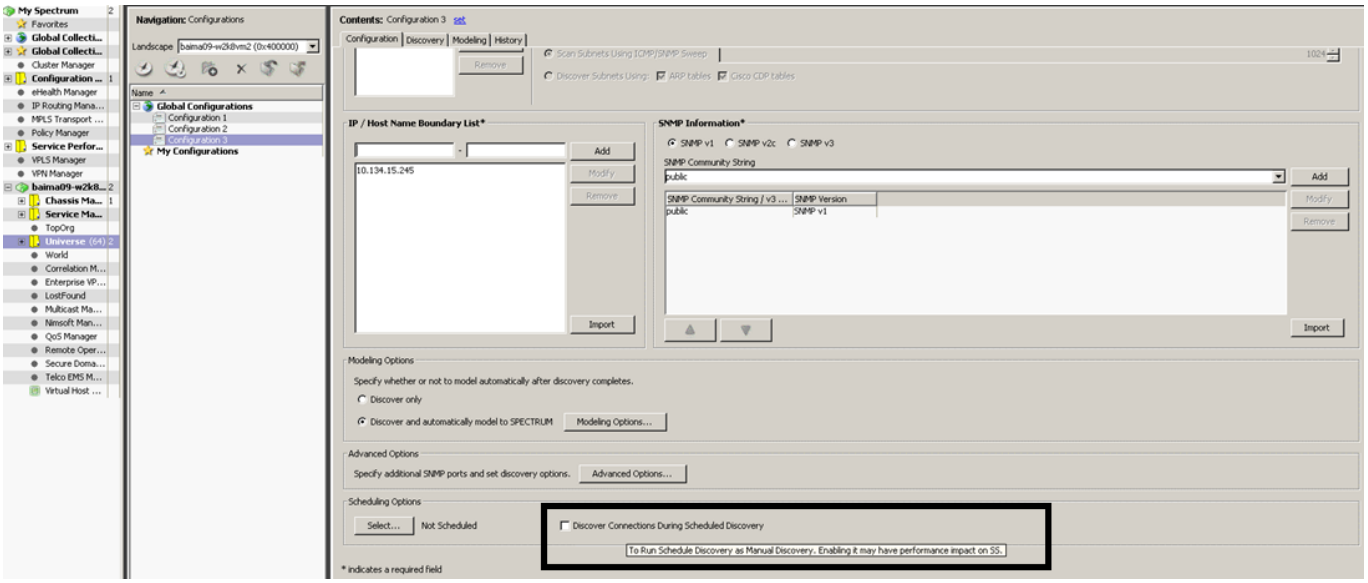
NOTE
For more information about setting schedules, see Using OneClick .

Discover Connections During Scheduled Discovery

Use the Discover Connections During Scheduled Discovery option to run the scheduled discovery as a manual discovery. Unlike normal schedule discovery, this option discovers and models all the devices (with their connections) that are specified in the respective configuration IP range, irrespective of the existing discovered devices. You can access this option from the OneClick Discovery Console.

NOTE
By default, the Discover Connections During Scheduled Discovery option is not selected. If you want to run the schedule discovery as manual discovery, select this option. You may experience a performance impact on SpectroSERVER.

The following image displays the Discover Connections During Scheduled Discovery option that is available in the Discovery Console:



Activate a Discovery Session

Activating a Discovery Session

If you have Discovery operations privileges, you can activate a Discovery session by clicking Discover in the Configuration tab. In addition, if you have privileges to modeling operations, you can click Model to activate a Discovery session from the Modeling tab. The following procedure provides instructions for activating a Discovery session for an existing Discovery configuration using the Discovery Console.

NOTE
If you do not have a Discovery configuration that is ready to activate, Define a Discovery Configuration before activating a Discovery session. We recommend that you also review and make any necessary changes to the Discovery configuration before using this procedure to activate a Discovery session.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.
2. Click the name of the Discovery configuration for which you want to activate a Discovery session in the Discovery Navigation panel.
3. In the Discovery Configuration tab, click Discover to do either one of the following tasks:
   – To activate a Discovery session and/or combined Discovery and Modeling session.
   Discovery activates a Discovery session or a combined Discovery and modeling session that is based on the parameters that are specified in the Configuration tab. The results of the Discovery session appear in the Discovery tab. The results of the modeling session appear in the Modeling tab.
   – To rediscover an existing discovered or modeled configuration.
   All newly discovered results appear in the results list on the Discovery tab.

   NOTE
   Results from this new Discovery session overwrite the results of the previous Discovery session.

How to Discover Devices in Your Network

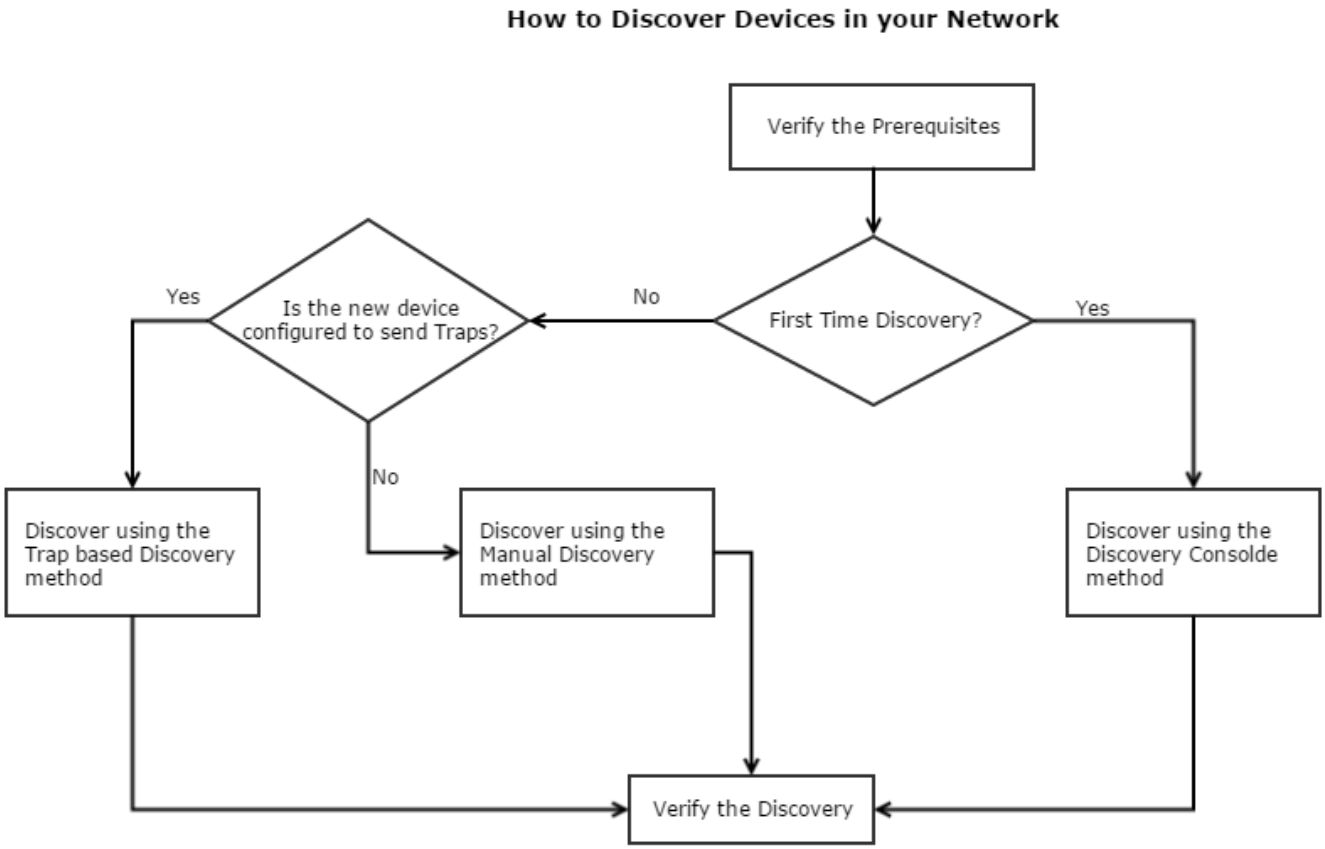
As a DX NetOps Spectrum administrator, you are responsible for discovering all of the devices in a network. Your goal is to create a DX NetOps Spectrum landscape. A landscape is all the data that is specific to any one virtual network machine (VNM) in a single network. The term also identifies the network domain that is managed by a single SpectroSERVER. In the OneClick console, a landscape is the network view of one SpectroSERVER. DX NetOps Spectrum gathers the MAC address, IP address, and other important information about the devices in your landscape when you discover them. Discovery helps you perform the following tasks:

- Update device configurations
- Detect the root cause of a network breakdown
- Troubleshoot faulty devices

After devices are discovered in a network, DX NetOps Spectrum models them in real-time on the OneClick console, a web client application to view and manage network devices. The real-time modeling of devices gives you a full view of a network, and lets you track conditions within the computing infrastructure.

The following diagram shows how to discover devices in your network so that you can monitor and manage them:

Figure 75: Discover devices in network



Running discovery the devices involves the following tasks:

- Verify the Prerequisites.
- Determine the Discovery Method.
- Discover Using the Full Discovery Method.
- Discover Using the Automatic Discovery Method.
- Discover Using the Manual Discovery Method.
- Verify the Discovery.

Verify the Prerequisites

Before you discover devices in your network, verify the following prerequisites:

- DX NetOps Spectrum is installed on your host.
- You are logged in to the OneClick console with discovery privileges.
- The OneClick console displays your DX NetOps Spectrum landscape with your host name on the Navigation panel.
- The Universe container exists in your landscape.
  The Universe container helps you organize an enterprise network view of your infrastructure.
- You know how to configure your network devices to send traps to DX NetOps Spectrum.

Determine the Discovery Method

Your goal is to discover and model devices in your network. Select one of the following discovery methods depending on whether you are discovering devices for the first time, or you are discovering new devices in your network:

Discovery Console Method
Select this method when you want to discover a new network and all of its existing devices for the first time. Use the Discovery Console method after installing DX NetOps Spectrum. This method takes a long time to discover all the existing devices depending on the size of the network.

Trap Based Discovery Method
Select this method when new devices are configured to send traps to DX NetOps Spectrum. As soon as you add the device to the network, the device sends a trap and DX NetOps Spectrum automatically discovers the device.

Manual Discovery Method
Select this method when you want to manually discover existing devices in a network that are not configured to send traps. Use the manual discovery method when you know the IP address or the model type of the new device. This method is best for discovering a new device quickly.

Discover Using the Discovery Console Method

Use the Discovery Console method to discover a network and its existing devices for the first time. In this method, you specify the discovery parameters (for example, IP Address range, SNMP version) in a configuration file to discover the network and its devices.

> **NOTE**
>
> The devices that are configured with SNMP v3 profiles are discovered as unknown device types. To discover devices for which SNMP v3 profiles are configured, select the SNMP v3 option. Create an SNMP v3 profile with parameters or select an existing profile. The devices that are configured with SNMP v3 profiles are discovered only when the DX NetOps Spectrum and the device SNMP v3 profiles match.

Follow these steps:

1. Log in to the OneClick console.
2. Select Explorer from the Navigation pane, and perform the following actions:
   a. Expand your landscape.
   b. Click Universe.
3. Select Topology, and click Discovery on the toolbar.
   The Discovery Console opens.
4. Click Create a new folder.
5. Perform the following actions to create and save a configuration file in this folder:
   a. Expand Global Configurations.
   b. Right-click the new folder, and select Create.
   c. Enter the configuration file name.
      Retain the default value of the Landscape field, and click OK.
   The configuration file is created, and the Configuration tab on the Contents pane of the Discovery Console is activated.
6. Perform the following actions to configure the discovery parameters:
   a. Enter the IP address ranges of all the subnets in the IP/Host name boundary List pane.
   b. Select the SNMP Communication option from the SNMP Information pane.
   c. Add all the SNMP Community Strings in the SNMP Information pane.
   d. Select the required Discovery Type from the Seed Routers pane.
   e. Select 'Discover and automatically model to Spectrum' as the Modeling Option.
7. To discover SNMP v3 configured devices, perform the following actions:
   a. Select SNMP v3 and click Profiles.

The Edit SNMP v3 Profiles dialog opens.
   b. Choose an existing profile from the list or create a profile.
   c. To create a profile, enter the Profile Name, User ID, Authentication Type, and click Add.
8. Click Discover.

DX NetOps Spectrum discovers and models the complete network and its existing devices in the OneClick console.

Discover Using the Trap-Based Discovery Method

After you perform a full discovery using the full discovery method, you can discover new devices that are added to the network using the automatic discovery method. With this method, you enable DX NetOps Spectrum to process unmanaged traps coming from the devices and the traps are used to discover the devices automatically.

Follow these steps:

1. Log in to the OneClick console.
2. Select Explorer from the Navigation pane and perform the following actions:
   a. Expand your landscape.
   b. Click Universe.
3. Select Topology, and click the VNM model type.
   The VNM model on the OneClick console represents the host computer running DX NetOps Spectrum.
4. Perform the following actions in the Component Detail pane:
   a. Select Information.
   b. Expand AutoDiscovery Control.
   c. Expand Trap Based Continuous Discovery.
   d. Enable Unmanaged Trap Discovery.

The new devices are discovered and modeled. You can view them in the OneClick console.

NOTE

Traps from the already discovered and modeled devices are not considered for discovery.

Discover Using the Manual Discovery Method

When a new device is not configured to send a trap to DX NetOps Spectrum, you can discover the device using the manual discovery method. In this method, you specify the IP address, model type, or the host name to discover the device.

NOTE

To discover devices on which SNMP v3 profiles are configured, select the SNMP v3 option. The devices that are configured with SNMP v3 profiles do not respond to the ordinary discovery. Create an SNMP v3 profile with parameters or select an existing profile. The devices that are configured with SNMP v3 profiles are discovered only when the DX NetOps Spectrum and the device SNMP v3 profiles match.

Follow these steps:

1. Log in to the OneClick console.
2. Select Explorer from the Navigation pane and perform the following actions:
   a. Expand your landscape.
   b. Click Universe.
3. Select Topology from the Contents pane.
4. On the toolbar, click Create new model by type, Create new model by IP, or Create By Host Name.
   The Select Model Type or the Create Model By IP Address dialog opens.

5. Perform the following actions to configure the discovery parameters:
   a. Enter the name, IP address, and SNMP Community String.
   b. Set the values for the Poll Interval (sec), Agent Port, and Secure Domain.
   c. Select the SNMP Communication Option.
6. To discover SNMP v3 configured devices, perform the following actions:
   a. Select SNMP v3 and click Profiles.
      The Edit SNMP v3 Profiles dialog opens.
   b. Choose an existing profile from the list or create a profile.
   c. To create a profile, enter the Profile Name, User ID, Authentication Type, and click Add.
7. Click OK.

DX NetOps Spectrum discovers and models the device. You can view them in the OneClick console.

Verify the Discovery

You verify the discovery process by checking the model and MAC address of the discovered devices using the OneClick console.

Follow these steps:

1. Log in to the OneClick console.
2. From the Contents pane, click Topology.
3. Verify that the discovered devices are modeled in real time.
4. Click a device model
5. From the Component Detail pane, select Information.
6. Expand General Information.
7. Verify that the MAC address is present for the device model.
8. Click all the device models that are created in order, and verify their MAC addresses.

You have discovered devices in your network and verified the discovery. You can now manage and monitor your network and its devices.

Activate a Modeling Session

You can model your Discovery results during the Discovery session, or you can save the configuration and model the results later. You can specify how DX NetOps Spectrum models discovered devices that appear in the Discovery tab results list. In the Modeling Configuration dialog, you can accept the default modeling options, or you can change them to meet your requirements.

You can activate a modeling session in the following two ways:

- Select the ‘Discover and automatically model to DX NetOps Spectrum’ option in the Configuration tab before Discovery runs. A modeling session runs automatically with this option selected.
- Click Model in the Discovery tab after a ‘Discover only’ session has run for that configuration.

Prerequisites to Activating a Modeling Session

- Activate at least one Discovery session of an existing Discovery configuration.
- Review and make any necessary changes to the modeling configuration.
- (Optional) Exclude certain devices from being modeled.
- Ensure that you have sufficient privileges for activating a modeling session.

Follow these steps:

1. In the Discovery Console, click the name of the Discovery configuration for which you want to activate a modeling session in the Navigation panel.
2. Do *one* of the following tasks:
   – In the Configuration tab, select the 'Discover and automatically model to DX NetOps Spectrum' option, and click Discover.
   Discovery activates a Discovery session and then automatically models the discovered devices appearing in the Results tab of the Discovery tab.
   – In the Discovery tab, click Model to activate a modeling session and model the last set of discovered devices. The last set of discovered devices appear in the Results list of the Discovery tab.

Run a Network Services Discovery

You can discover devices for the following network services: VPN, Enterprise VPN, QoS, Multicast, VPLS, and MPLS Transport. Options are available depending upon the products you have installed.

> **NOTE**
> You can only run one Network Services Discovery at a time.

Follow these steps:

1. Select the models that you want to run a Network Services Discovery for:
   a. Expand any subnet, folder, and so on, in the Explorer tab or in the List tab, that contains the models you want to select.
   b. Click the List tab in the Contents panel and select the models by using CTRL+click.
2. Click Tools, Utilities, Network Services Discoveries, and then select the Network Services Discovery that you want to run.
   The Discovery executes for the selected models. A pop-up window appears, indicating success or failure of starting the Discovery. The Network Services Discovery fails only when a Discovery is already running for the selected product.
   The Discovery process can run for some time. You can check the status of the Discovery process:
   a. Select the product in the Navigation panel.
   b. Click the Information tab in the Contents panel.
   c. Expand the Configuration subview.
   d. Expand the Discovery subview.

> **NOTE**
> For more information about running a specific Network Services Discovery, see VPN Manager , Enterprise VPN Manager , QoS Manager , Multicast Manager or MPLS Transport Manager . For more information about VPLS, see Enterprise VPN Manager .

Create Discovery Configuration Folders

Discovery configurations are stored in folders. You can create a folder for a new configuration or a copy of an existing configuration.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.

2. Click
   
   (Creates a new folder).
   The New Folder dialog opens.
3. Type a name for this Discovery configuration.
   The new folder is displayed in the Navigation panel.

Reorganize Discovery Configurations

You can move configurations and folders to different folders using the drag-and-drop method.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.
2. Select the configuration or folder you want to move and drag and drop it to the desired location.
   The configuration or folder is moved to the desired location.

Rename Discovery Configurations or Folders

You can change the original name of a Discovery configuration after a Discovery session has ended and you can rename Discovery configuration folders.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.
2. Right-click the configuration or folder you want to rename and select the Rename node option.
3. Type the new name and click OK.
   The configuration or folder you selected displays its new name.

> **NOTE**
> You can also rename configurations by clicking ‘set’ beside the current configuration name in the Contents panel. However, you cannot rename folders from the Contents panel.

VLAN Discovery

Discovering Virtual Local Area Network

To discover Virtual Local Area Networks (VLANs) successfully, create a root container for each VLAN domain (in a VLAN domain, each VLAN ID is unique). All the devices in a VLAN domain must be placed in a unique root container.

If the devices from different VLAN domains are placed in the same container, VLAN Discovery on that container might not work properly. Also, the VLAN spotlighting might not be able to distinguish the VLANs and devices from the different VLAN domains.

View, Filter, and Export Results Lists

Each time that you activate a Discovery or modeling session, Discovery automatically places the results in the Discovery tab or the Modeling tab. You can use these results to select the devices you want to model or export. For more information, see the following sections:

- Filter, Sort, Export, Search, and Model Discovery Results
- Export a Results List
- Set a Modeling Results List to Export Automatically
- Filter Results Using Advanced Filter

Export a Results List

You can export a results list by clicking the Export button that appears on the Discovery or Modeling tab. The Export feature accesses the Export table data to file dialog where you can identify:

- Location to save the exported data file
- Name for the exported data file
- Type of file to use to export the data
- Type of file format to save the file

Follow these steps:

1. In the Discovery Console, click the Discovery tab or the Modeling tab.
2. Click the Export button.
   The 'Export table data to file' dialog opens.
3. Complete the following information:
   - **Save in**
     Specifies the location to save the exported data file.
   - **Save as type**
     Specifies the file type that you want to use when saving the exported data.
   - **File name**
     Defines the name for the exported data file.
   - **Files of type**
     Specifies the type of file format to use.
4. Click Save.
   The data is exported to the specified location, file name, and file format.

Set a Modeling Results List to Export Automatically

You can automatically export your Discovery or modeling results and status to a web server location.

Follow these steps:

1. In the Discovery Console, select the Discovery configuration for which you want to automate exporting of modeling results.
2. In the Configuration tab, select the 'Discover and automatically model to DX NetOps Spectrum' option.
3. Click the Modeling Options button.
   The Modeling Configuration dialog opens.
4. In the Auto Export section, do these steps:
   a. To export modeling results tables, select the 'results table' check box.
   b. Choose the exported files format from the results tables drop-down list: CSV (Comma delimited), text (Tab delimited), and web page.
   c. To export status data, select the 'status information (plain text only)' check box.
5. Click OK.

Filter Results Using Advanced Filter

Using the Advanced Filter dialog, you can create filters with compound clauses to exclude certain entries from appearing in the Discovery or modeling results list. If you have privileges to both Discovery and modeling operations, you can access

the Advanced Filter dialog before activating a combined Discovery and modeling session. If you have privileges to the Discovery operations only, you can access the Advanced Filter dialog after initiating a Discovery session.

NOTE
Discovery uses the results list on the Discovery tab to determine which devices to model or export.

Follow these steps:

1. Before you perform a Discovery, do these steps:
   a. In the Discovery Console, in the Configuration tab, select the Discover and automatically model to DX NetOps Spectrum option, and then click Modeling Options.
   The Modeling Configuration dialog opens.
   b. Click the Filter Options button.
   The Advanced Filter dialog opens.
   c. Go to Step 3.
2. After a Discovery session, do these steps:
   a. In the Discovery Console, click the Discovery tab.
   b. In the Discovery tab, click the Advanced Filter button.
   The Advanced Filter dialog opens.
   c. Go to Step 3.
3. In the Advanced Filter dialog, complete the fields as follows to create a single expression filter.
   – **Attribute/Ignore Case**
   Select a device attribute to filter.

   NOTE
   If you choose an alphabetic attribute value, you can either clear (ignore) or select (include) the Ignore Case check box.
   – **Comparison Type**
   Select the type of comparison to make against the value that is specified in the Attribute field.
   – **Attribute Value**
   Enter or select the desired attribute value to filter.
4. To filter a single expression, click OK.
   The Advanced Filter option excludes entities in the results list using the filter parameters that you specified.
   Build a compound clause:
5. Click Show Advanced.
   The compound expression box and logical operator buttons appear.
6. Click Add to move the single expression (created in Step 2) to the compound expression box.
7. Click *one* of the following logical operator buttons to build a compound expression: New AND; New OR; or AND/OR.
   – The compound expression is represented in a tree structure that is grouped by logical operators (AND/OR). Each logical operator in the tree can include any number of attribute criteria nodes and logical operator nodes. For more information, click Hints.
   – Alternatively, you can create advanced search expressions using prefix notation.
8. Repeat Step 5 and Step 6 for each compound expression you want to build.
9. Click OK after building the expressions.
   The Advanced Filter mechanism excludes the entities in the results list using the compound filter expressions applied.

Importing and Exporting Discovery Configurations

Import Discovery Configurations

You can import multiple Discovery configurations from your computer, in XML format, into DX NetOps Spectrum.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.
2. Click
   
   (Import).
   The Open dialog opens.
3. Browse for the Discovery configuration you want to import from your local computer and click Open.
   The Discovery configuration is imported.

Export Discovery Configurations

You can export multiple Discovery configurations, in XML format, to your computer.

Follow these steps:

1. Click Tools, Utilities, Discovery Console.
   The Discovery Console opens.
2. Expand the folder where the configuration you want to export is located in the Navigation panel and select the configuration.
3. The configuration information appears in the Contents panel.

   NOTE
   You can select multiple configurations. If you select a folder with multiple configurations, all of those configurations are exported. However, the folder hierarchy is not exported.
4. Click
   
   (Export).
   The Export to file dialog opens.
5. Select the export location on your local computer, enter a configuration name in the File name field, and click Save.
   The Export Results from Export dialog opens.
6. Click OK.
   The Discovery configuration is exported.

After Discovering and Modeling

DX NetOps Spectrum does not support all possible network devices with model types and management modules. To get the DX NetOps Spectrum environment you need for managing your network, you can modify the Discovery and Modeling results.

After you successfully discovered and modeled your network, you can examine and enhance the results, for example:

- Modify the device type names to reflect the devices on your network accurately.

  NOTE
  For more information about device types, see Certifications.
- Modify the attributes for device models and model types using the Attribute Editor or the Attributes tab.
- Create model types for devices that the DX NetOps Spectrum model types and management modules do not directly support.

NOTE
For more information, see Certifications.

- Import MIBs using the OneClick MIB Tools utility to get updated MIBs for devices, and for features that the provided DX NetOps Spectrum MIBs do not support.

  NOTE
  For more information about using MIB Tools, see Certifications.
- Modify the names of the existing Discovery configurations.

VNM AutoDiscovery Control Settings

AutoDiscovery control settings available on the VNM Information tab affect some of the actions that occur during Discovery and Modeling sessions.

If you have a Distributed SpectroSERVER (DSS) environment with multiple SpectroSERVERs, apply all settings changes to *all* of your SpectroSERVERs.

Access VNM AutoDiscovery Control

To access the VNM AutoDiscovery Control subview, select the VNM in the Explorer tab or in a Universe topology view.

Then select the Information tab in the Component Detail panel.

Loopback Interfaces and Discovery

You can set DX NetOps Spectrum to use a loopback interface as a primary agent address.

You can also specify which loopback interface to use when modeling devices.

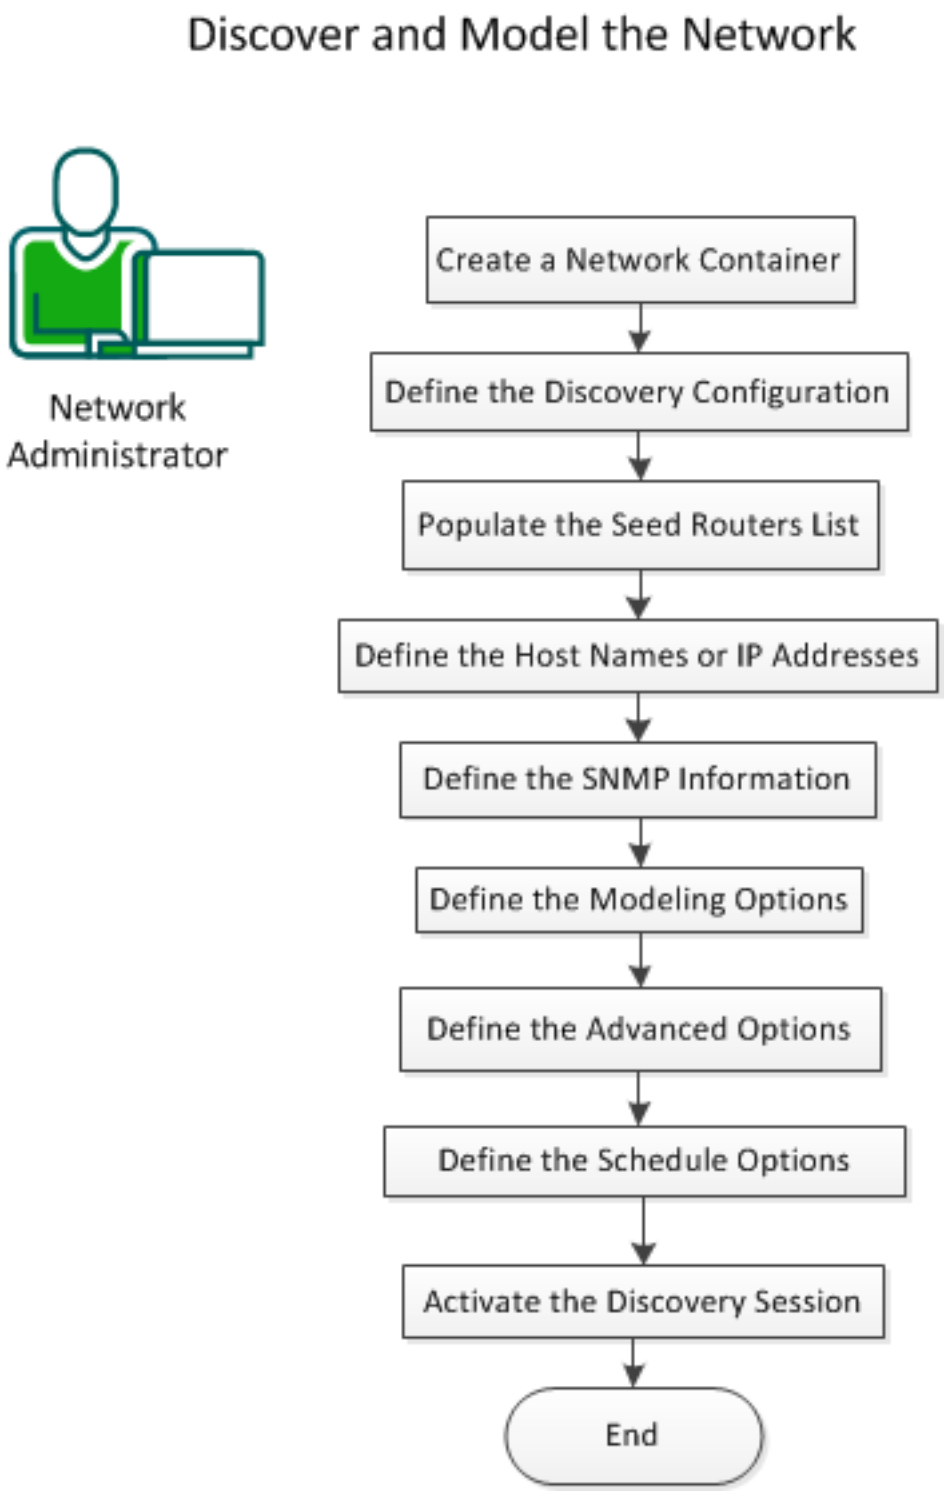
How to Discover and Model the Network

DX NetOps Spectrum is a services and infrastructure management system that monitors the state of managed elements including devices, applications, host systems, and connections. DX NetOps Spectrum includes some client applications. OneClick is the client application that provides the graphical user interface to monitor the network and launch other client applications. You can create and maintain the software models of a network by using the modeling features of OneClick.

This scenario describes how a network administrator uses the Discovery utility of OneClick to define and discover models that represent entities in the IT infrastructure.

The OneClick client application provides the graphical user interface to monitor the network and launch other client applications. Run the Discovery utility of OneClick to define and discover models that represent entities in the IT infrastructure.

The following diagram describes how to use Discovery:



Create a Network Container

A container represents the group of devices that you want to model. Containers help you monitor and manage the health of the devices that they represent. Create a container in the Universe topology.

Follow these steps:

1. Expand <*usxxyyzz*> on the **Explorer** tab in the **OneClick Navigation** pane and select **Universe.**
   The <*usxxyyzz*> hierarchy identifies the local **SpectroSERVER** landscape.
2. Select **Topology** in the **Contents** pane.
3. Select the **Model by Type** icon, select **Network,** and select **OK.**
4. Complete the following fields in the **Create Model of Type Network** dialog:
   Name - Defines the unique host name for the device that you are modeling.(Optional)
   Network Address - Specifies the IPv4 or IPv6 address for the device that lets DX NetOps Spectrum communicate with the device.
   (**Optional) Security String** - Specifies the security for the device. Adding a security string prevents certain users from viewing the model.
   (**Optional) Subnet Mask** - Specifies the device subnet address that the container represents. When specified, the subnet address label appears whenever a user points the mouse to a container icon in a topology view.
5. Select **OK.**

Define the Discovery Configuration

Discovery uses a set of configuration parameters that you can define to determine the network entities to discover and model.

Follow these steps:

1. Select the network container on the Topology tab.
2. Right-click on the selected container and select Utilities, Discovery Console.
3. Type a name for the configuration.
4. Select a landscape.
5. Specify the folder in which the new configuration must be created.
6. Select OK.
   The procedures that follow let you configure the parameters.

Populate the Seed Routers List

> **NOTE**
> The Seed Routers section is optional. We recommend that you populate the seed routers list for large Discovery operations.

Seed routers are a list of core routers that Discovery uses as a starting point when determining the routed subnets. All routers that are discovered within the IP / Host Name Boundary List are treated as seed routers. Add the seed routers list to let Discovery determine the routed subnets from the list.

Follow these steps:

1. Type an IP address or host name in the **Seed Routers** section and select **Add.**
2. (Optional) To create a range of IP addresses or host names, repeat Step 1.
3. Select one of the following options from **Discovery Type**:
   Routers only - Discovers the routing devices within the IP address range or host names. Routers and only local LANs in IP/Host Name Boundary ListDiscovers the routed subnets within the IP range or host name.
   Routers and all local LANs - Discovers the subnets that are routed by the routers that are discovered within the IP range or host name.
4. If you selected '**Routers and only local LANs in IP/Host Name Boundary List**' or '**Routers and all local LANs**', select one of the following options:

- – **Scan Subnets Using ICMP/SNMP Sweep** - Scans the subnets that use ICMP or SNMP sweep. If you select this option, set the maximum subnet size in the counter.

- – **Discover Subnets Using** - Discovers the subnets that use the following tables:
- – • **ARP tables** - Specifies that the subnet uses the Address Resolution Protocol (ARP) tables.
  • **Cisco CDP tables** - Specifies that the subnet uses the Cisco Discovery Protocol (CDP) tables.

Define the Host Names and IP Addresses

The IP / Host Name Boundary List field populates with an IP range when you start Discovery with a container that is selected from the Topology tab. Import the host names, IP addresses, or IP address ranges from a file on the OneClick web server.

Follow these steps:

1. Select **Import** in the **IP / Host Name Boundary List** section.
2. Select **'One Click web server host'** from **'Import file location'**.
3. Type the path to the text file containing the host names or IP addresses in one of the following formats:
   Microsoft Windows: C:\Program Files\Spectrum\IP_Files\core_network_ips
   Linux: /usr/Spectrum/IP_Files/core_network_ips
4. Select **OK.**

Define the SNMP Information

Import an ordered list of SNMP community strings for SNMP v1, SNMP v2c, or profiles for SNMPv3.

Follow these steps:

1. Create a text file that lists each SNMP community string and profile in the following format:
   `<name>v<SNMP_version>`
   Defines the SNMP community string. Defines the applicable SNMP version.
   Note: The version number for SNMPv1 community strings is optional.
   Examples: SNMPv1publicpublic, v1Example: SNMPv2public, v2Example: SNMPv3public, v3
2. Select Import in the SNMP Information section.
3. Select the text file that you created in Step 1.
4. Select Open.

Define the Modeling Options

Define the modeling configuration settings to combine the Discovery and modeling sessions.

Follow these steps:

1. Select '**Discover and automatically model to SPECTRUM**'.
2. Select **Modeling Options**.
3. Specify the destination container by performing the following steps:
   a. Select **Destination Container**.
   b. Select the topology view container to place the discovered models.
   c. Select **OK.**
4. Configure the modeling layout by performing the following steps:
   a. Select one of the following options from Placement to specify where models appear in the topology:
      Flat Discovery places all devices, including Layer 1 and Layer 2 in the Destination Container; no LAN containers are created.
      Hierarchical Discovery places all Layer 3 devices, LAN containers, and Wide Area Links in the Destination Container. Layer 1 and Layer 2 devices are placed in the proper LAN container (based on IP address) under the

Destination Container. If Discovery cannot find the appropriate LAN container for Layer 1 or Layer 2 devices, these devices are placed in the Destination Container.

b. Select one of the following options from Arrangement to specify the arrangement of models in the topology:
Grid arranges the models in a grid pattern.
Radial arranges the models in a radial pattern.
Tree arranges the models in a tree structure.

5. Configure the modeling options by selecting the required options in the **Modeling Options** section:

- **Create Wide Area Link Models**

Determines whether Discovery creates a WA_Link model between the wide area linked interfaces of two routers. When this option is disabled, Discovery directly connects the linked interfaces.

- **Create LANs (IP Subnets)**

Determines whether Discovery uses a LAN container when representing an IP Subnet. Discovery creates the LAN container during the Layer 3 mapping process to connect a router to a local LAN.

- **Remove Empty LANs**

Determines whether Discovery removes any empty LAN containers that the Create LANs (IP Subnets) option creates.

- **Create “802.3” (Fanout)**

Determines whether Discovery models an 802.3 Fanout segment when DX NetOps Spectrum cannot make an accurate connection among three or more interfaces. This model represents the ambiguous connections among these interfaces. However, DX NetOps Spectrum uses network traffic data **(IfInOctet** and **ifOutOctect** statistics) when the Traffic Resolution protocol option is enabled. This protocol determines connections between interfaces and, often, eliminates the need to model a Fanout.

NOTE

- Because DX NetOps Spectrum cannot identify the actual traffic flown path link between a device and fanout, when you try to delete one of the links, Spectrum deletes all the links that are connected to fanout.
- If you have 50 or more connections to a single Fanout model, consider changing the model to a Shared Media Link. The Shared Media Links must be modeled manually. These models can provide more control over fault management behavior when multiple connections are monitored. Unlike a Fanout model, Shared Media Links provide configurable thresholds for handling downstream connections that report problems. For example, a Fanout model reports a problem only when all downstream connections are down. However, a Shared Media Link can report the problem sooner, as when 60 percent of the downstream connections are down.

- **Create Physical Addresses**

Determines whether to create a physical address model for a MAC address that a switch hears but not associates with any modeled device. The layer 2 mapper attempts to find a connection for each address found. If a connection is found, a Fanout is created and the physical address is associated to it through Connects_To. If no connection is found, the model is placed in Lost and Found.

WARNING
Important! We recommend that you do not enable this option to avoid performance issues.

- **New Devices in Maintenance Mode**

Determines whether DX NetOps Spectrum places the newly discovered devices directly into maintenance mode.

- **Create Wireless Access Points**

Determines whether the Discovery creates models of Wireless Access Points (**WAP**s) to a particular controller given in the Discovery list. SNMP disabled APs and APs which are not mentioned in the discovery list are modeled as **AccessPoint** models (**AccessPoint models**).

- **Reconfigure Interfaces**

Determines whether the Discovery/Schedule Discovery re-configures the interfaces of the devices which are already modeled in the network for the given IP range. Select this check box to reconfigure the interfaces of the existing devices with the discovery of new devices.

- **Activation Timeout (in minutes)**

Determines the number of minutes that Discovery waits for new models to activate before mapping their connectivity. When the timeout expires without any new devices activating, connectivity is established to the possible extent. Connectivity occurs regardless of whether all connections to discovered devices have activated.Limits: 5-15 minutes.

1. Specify the protocol that is used in connectivity-mapping process by performing the following steps:
   a. Select **Protocol Options**.
   b. Select the required options:
      IP Address Tables - Determines whether to use IP address tables when mapping. When disabled, Discovery disables Layer 3 mapping and maps only the Layer 2 connections. Additionally, Discovery disables the following options:
      - IP Route Tables Protocol
      - Create Wide Area Link Model
      - Create LANs (IPSubnets)
      - Remove Empty LANs.

      IP Route Tables - determines whether to use the IP Address Table when mapping routers. By default, this option is not selected because these tables can be large and can take time to read. When this option is enabled, DX NetOps Spectrum cannot map unnumbered IP interfaces (0.0.0.0).
      Source Address Tables - Determines whether Discovery uses the device Source Address table when mapping layer 2 connectivity.
      Discovery Protocol Tables - Determines whether Discovery uses the Discovery Protocol tables when mapping device connectivity. Supported discovery protocols include Cisco, Nortel, Cabletron Switch, Extreme, Alcatel, Foundry, and Link Layer.
      ARP Tables for Pingables - Determines whether Discovery uses the ARP table when determining MAC addresses that can be used for the connectivity mapping.
      Spanning Tree - Determines whether Discovery uses the device Spanning Tree Address table (SAT) when mapping Layer 2 connectivity information about the device.
      Traffic Resolution - Determines whether Discovery uses network traffic data when determining connections between interfaces. Often, letting Discovery to use the traffic data eliminates the need to model Fanout segments.
      ATM Protocols - Determines whether the ATM Discovery runs against all ATM switches in the SpectroSERVER database.
      Note: For more information about ATM Protocols, see ATM Circuit Manager .
   c. Select OK in the **Protocol Options** dialog.
2. Configure the **Network Services Options** by performing the following actions:
   a. Select **Network Services Options**.
   b. Select the options to specify the network services to run during the modeling process.
      Note: OneClick displays the options that are based on the installed components.
   c. Select OK.
3. Configure the filtering options by performing the following actions:
   a. Click **Filter Options**.
   b. Specify the parameters to exclude selected discovered devices from modeling.

c. (Optional) select **Show Advanced** and create a complex filter criterion that includes a combination of the AND/OR clauses.
d. (Optional) select the ‘Hints’ link for more information.
e. Select OK in the **Advanced Filter** dialog.

4. (Optional) select 'results table' in the Auto Export section and specify the file format in the drop-down to export modeling results automatically.
5. (Optional) select 'status information (plain text only)' in the Auto Export section to automatically export the status information of the discovered devices.
6. Select OK in the **Modeling Configuration** dialog.

(Optional) Define the Advanced Options

Define Advanced Options to perform *one* of the following Discovery configuration procedures:

- Define the SNMP ports in addition to the default port (161).
- Exclude a specific IP address from Discovery.
- Modify the default settings for ICMP, route tables, throttle, time-out, and retries.
- Manage the export of Discovery results.

Follow these steps:

1. Select **Advanced Options**.
2. Type a new port number in the **SNMP Ports** section and select **Add.**
3. Type an IP address or range in the **IP Exclusion List** section and select **Add.**
4. Modify the following settings in the **Discovery Options** section:
   Use ICMP first, then SNMPUses ICMP when discovering devices. If ICMP is enabled, Discovery pings the devices in the ranges or subnets first. The devices that responded to ICMP are then queried using SNMP. This option reduces the number of SNMP requests, especially when multiple SNMP community strings are being used. Use Route Tables identifies the neighbor routers and the routed subnets from the IP route tables. Use this option only if seed routers are specified in the Discovery configuration.ThrottleStaggers the processing workload of Discovery by pausing for one second after reading the routing table entries, if there are more than 1000 entries. Select High, Medium, or Low to pause after reading 50, 100, or 250 entries, respectively. Timeout (in seconds) Specifies the number of seconds that Discovery waits for the response from a device.RetriesSpecifies the number of attempts that Discovery makes after the first attempt times out before establishing contact.ICMP Payload Size Specifies the payload size in bytes. This option is only available if you have selected ‘Use ICMP, then SNMP.’Secure Domain specifies the secured domain.

   NOTE
   This option is available only if you have the Secure Domain Manager installed. For more information, see the Secure Domain Manager section.
5. Do one of the following steps in the **Auto Export** section:
   – To disable auto export, select ‘**Do not export results’**.
   – To enable auto export, select the file format that you want to export in, followed by the type of results you want to export.
6. Select **OK.**

(Optional) Define the Schedule Options

Configure the scheduling options to run the configuration. If the configuration is scheduled, the schedule name is displayed in the Scheduling Options section.

Follow these steps:

1. Click Select in the **Scheduling Options** section.
2. Create a schedule.

Activate the Discovery Session

Activate the Discovery session after defining all parameters.

Follow these steps:

1. (Optional) select '**Save options as default**' to save the current configuration settings as the default configuration.
2. Select **Discover** to activate the Discovery session.
3. Select **File, Close** when the modeling process is complete.
   The network is discovered and modeled.

The network entities and their connections are represented graphically in the Topology tab. Icons that are created, placed, and connected within the OneClick topology views represent various aspects of a modeled network.

Modeling Your Network Manually

This section contains information about how to monitor your network manually.

When to Model Manually in OneClick

When to Model Manually in OneClick

You most often perform manual modeling tasks when you want to represent one or more previously modeled Universe topology devices in other OneClick topologies. For example, OneClick topologies such as Global Collections, World, or TopOrg.

You can also model a network device in DX NetOps Spectrum manually after using Discovery in the Universe topology. For example, the Discovery feature is unable to discover new devices in your network that are temporarily offline or blocking management communication. To resolve this situation, you could rediscover these new devices later using Discovery, or you could manually add them to the Universe topology.

In the Universe topology, you can also manually:

- Add devices and annotations to existing models.
- Change device configuration information.
- Improve the readability of models by keeping the layers within the Universe topology simple.

DX NetOps Spectrum can model Fanouts automatically, but consider manually changing these Fanouts to a Shared Media Link model when the Fanout has more than 50 connections. The Shared Media Link models use configurable thresholds that can provide more control over fault management behavior.

To keep the layers within the Universe topology simple, consider placing routers near the top and grouping devices logically by IP domains.

Additionally, you can manually model one or more network connections between modeled devices appearing in a Universe or Global Collections view. Finally, manually model all container icons within a World or TopOrg topology view.

How to Model Manually in the Universe Topology

This section describes the steps to manually model in the OneClick Universe topology.

Create Model Dialog

The Create Model dialog includes the Create Model by Type, Create Model by IP, and Create Model by Host Name dialogs. These dialogs contain settings that depend on the model:

- **Name**
  Specifies the unique host name for the device that you are modeling.

  NOTE
  Model by Host Name supports host names that resolve to either an IPv4 or an IPv6 address.
- **Network Address**
  Specifies the IPv4 or IPv6 address for this device to let DX NetOps Spectrum communicate with it.
- **SNMP Community String**
  Specifies the SNMP community string for this device to let DX NetOps Spectrum communicate with it.
  Note: You can create a model using Create Model by IP or Create Model by Host Name. If you do not specify a value for SNMP Community String or Agent Port, DX NetOps Spectrum uses the predefined SNMP credentials. You configure these SNMP credentials in the VNM model's Information tab in OneClick. Navigate to the Modeling and Protocol Options section of the AutoDiscovery Control subview. If the device cannot be contacted using each of the SNMP credentials but it can be contacted using ICMP, a Pingable model is created.
- **Serial Number**
  Specifies the serial number for the device that you are modeling.
- **Security String**
  Specifies the security for the device. Adding a security string prevents selected users from viewing this model.
- **Subnet Mask**
  Specifies the device subnet address that this container represents. The subnet address label then appears when a user points to a container icon in a topology view.
- **Poll Interval (sec)**
  Specifies the frequency with which this device is polled. By default, DX NetOps Spectrum polls modeled devices for status updates every 60 seconds (or for some model types every 300 seconds).
  Longer polling intervals use less bandwidth for management traffic, but you receive fewer device status updates. Consider whether to use the default polling interval (60 seconds) for critical devices and to use 600 seconds for less important devices.
- **Log Ratio**
  Defines how often DX NetOps Spectrum polls devices for updates before logging the results.
  Default: 10
- **Creation Author**
  Specifies the name of the user who is modeling this managed device.
- **Manufacturer**
  Specifies the manufacturer name of the managed device that you are modeling.
- **Southbound Gateway-specific**
  For more information about the Southbound Gateway settings, see the Southbound Gateway Toolkit section.
- **Unique ID**
  The Unique Identifier is a composite of up to six variable data items (1-6). The final unique identified string is composed as follows:
  <1>_<2>_<3>_<4>_<5>_<6>
  If one of the unique identifier components is not provided, it is not included within the composite unique identifier.
- **Manager Name**
  If the name of the third-party application does not apply in the list, choose Default. When this attribute is set on the EventAdmin, all EventModels contained with this EventAdmin inherit this attribute.
- **Event Model Prefix**

This field is prepended to the EventModel name for the Event Models that this EventAdmin contains. This behavior provides consistent naming prefixes for all EventModels that are associated with a particular EventAdmin. This prefix is useful when sorting or filtering various DX NetOps Spectrum applications.

- **Dialup Link Type**
  Specifies the functional type of the Dialup_Link. Possible types are Dial Backup Link, Primary on Demand Link, and Bandwidth on Demand Link.

  NOTE
  For more information about the Dialup_Link settings, see the Non-Persistent Connections Manager User *section*.
- **Dialup Protocol Type**
  Specifies the protocol type to use on the Dialup_Link. Possible protocol types include Analog, Switch-56, ISDN, and Frame_Relay.
- **Activation Grace Period (Min)**
  Specifies the time (in minutes) for the secondary link to become active after a primary link failure. If this grace period expires before the secondary link is active, a red alarm is generated. Only the Dialup_Link models use this field.
  Default: 3 minutes
- **Deactivation Grace Period (Min)**
  Specifies the time (in minutes) for an active secondary link to deactivate after the failed primary link reactivates. If the secondary link is still active after this grace period expires, then a yellow alarm is generated. Only the Dialup_Link models use this field.
  Default: 3 minutes
- **Active Time Until Yellow (Hours)**
  Specifies the number of hours that a backup link can be active before a yellow alarm is generated.
- **Active Time Until Orange (Hours)**
  Specifies the number of hours that a backup link can be active before an orange alarm is generated.
- **Active Time Until Red (Hours)**
  Specifies the number of hours that a backup link can be active before a red alarm is generated.
- **Device Symbol**
  Specifies the type of icon to use for this device in the Topology view.
- **DCM Timeout (ms)**
  Specifies how long the SpectroSERVER waits for a device response.
  Default: 3000 milliseconds
- **DCM Retry Count**
  Specifies the number of times that the SpectroSERVER tries to establish device communication after the DCM timeout value expires.
  Default: 3
- **Agent Port**
  Specifies the SNMP agent port.
  Default: 161

  NOTE
  You can create a model using Create Model by IP or Create Model by Host Name. If you do not specify a value for SNMP Community String or Agent Port, DX NetOps Spectrum uses the predefined SNMP credentials. Configure these SNMP credentials in the OneClick Information tab for the VNM model. Navigate to the Modeling and Protocol Options section of the AutoDiscovery Control subview. If the device cannot be contacted using each of the SNMP credentials but can be contacted using ICMP, a Pingable model is created.
- **Secure Domain**
  Specifies a secure domain for this device. Select the applicable domain from the drop-down list.
- **SNMP Communications Options**

Specifies that SNMP protocol that this device supports: SNMP v1, SNMP v2c, or SNMP v3. DX NetOps Spectrum uses the protocol that you specify here to discover and map this device.

  - **Profiles**
    Opens the Edit SNMP v3 Profiles dialog, where you can create profiles for SNMP communication.

- **Discover Connections**
  Specifies DX NetOps Spectrum Discovery behavior. When enabled, DX NetOps Spectrum discovers the linked connections (pipes) between this device and other devices.

Add Containers to Universe Topology Views

You can create a container or can use an existing container to represent the group of devices you want to model. You can create containers at any topology level to help reduce the complexity of your topology views. Containers can effectively help you monitor and manage the health of the devices they represent.

You can manually add a container to a Universe topology view by using the Select Model Type dialog. Some examples of containers you can add include LAN, FDDI, Network, or WAN.

Follow these steps:

1. Select the Universe topology view where you want to add a container.
   The selected topology view appears in the Topology tab, Contents panel.
2. Click
   
   (Creates a new model by type) in the Topology tab toolbar.
   The Select Model Type dialog opens.
3. Click the Containers tab, select the type of container you want to add, and click OK.

   NOTE
   You can use the Filter text box to filter the containers list in the Containers tab. For example, enter **LAN** in the Filter text box to filter the container list to show the LAN container types only.

   The Create Model of Type dialog opens.
4. Complete the fields in the dialog.
5. Click OK.
   The Create Model of Type dialog closes, and OneClick places the newly created network container in the selected Universe topology view.

Add Existing Devices to a Container

To add modeled network devices to a container, double-click the container icon and copy and paste modeled devices into the selected container. These modeled devices can come from other Universe topology views, list views, or the Explorer tab. Or, model new devices in this container by using these topology toolbar functions:

- Create a model by model type.
- Create a model by IP address.
- Create a model by host name.

Add Network Devices to Universe Topology Views

You can manually add network devices to a Universe topology view using the Topology toolbar ‘Create model by’ functions. You can add one or more devices to a container using these buttons.

The best practice for manually adding a device to the OneClick environment is to use one of these functions:

- Create a model by IP address.
- Create a model by host name.

Add a Device Using Create Model by Model Type

Creating Model by Model Type

The ‘Create model by model type’ function is considered an advanced function. This function requires that you have an understanding of how network devices are categorized in the SpectroSERVER modeling catalog.

Follow these steps:

1. Select the Universe topology view where you want the new device to appear.
   The selected Universe topology view appears in the Topology tab, Contents panel.
2. If you want to place the new device inside a container, double-click the container icon to display the topology view for that container.
3. Click
   
   (Creates a new model by type) in the Topology tab toolbar.
   The Select Model Type dialog opens.
4. Click the All Model Types tab.
   A list of model types appears.
5. (Optional) Enter text in the Filter field to filter the list.
   As you type characters in the Filter field, only the model type names that contain the same string of characters are shown in the list.
6. Select the model type of the device you are adding and click OK.
7. The Create Model Of Type dialog opens.
8. Complete the fields in the dialog.
9. Click OK.
   The Create Model of Type dialog closes and OneClick places the newly created device icon in the selected Universe topology view.

Add a Device Using Create Model by IP Address or Create Model by Host Name

You can add a device using the ‘Create Model by IP’ or ‘Create Model by Host Name’ function.

Follow these steps:

1. Select the Universe topology view where you want the new device to appear.
   The selected Universe topology view appears in the Topology tab, Contents panel.
2. To place the new device inside a network group container, double-click the container icon to display its topology view.
3. Click the Create Model by IP down arrow
   ()
   and select one of these options in the Topology tab toolbar:
   – Create by IP
   – Create by Host Name
   The Create Model dialog opens.
4. Complete the fields in the dialog.
5. Click OK.

The Create Model dialog closes, the Creating Model dialog indicates that the request is processing. When it closes, the newly created device icon is placed into the selected Universe topology view.

Manual Modeling Tips

To move or enhance the appearance of the recently modeled device icon, click **Edit mode** in the Topology tab toolbar.

To cut/copy/paste the modeled device icon to another Universe topology view, list view, or the Explorer tab, use one of the following cut/copy/paste functions:

- The Topology tab toolbar
- The List tab toolbar
- The right-click menu in the Explorer tab

To change configuration parameters of a modeled device, select the modeled device and change the appropriate settings in the Component Detail panel, Information tab. For example, configuration parameters can include the SNMP community string, polling interval, logging interval, and security string.

Model By Type Preference

Specify which model types are available when users manually create models by model type in the Topology tab using the Model By Type preference. When users click **Creates a new model by type** () in the Topology tab toolbar, the Select Model Type dialog opens. The Select Model Type dialog contains the **All Model Types** tab. This tab lists all the model types available for them when they create a model. You can prevent model types from appearing in this list by modifying the Model By Type preference.

Configure Availability of Model Types for Manual Modeling

As an administrator, you can configure the Model By Type preference to exclude or include certain model types. This feature controls which model types that users can see when they manually add models in the Topology tab.

> **NOTE**
> For general information about setting preferences and using the Set Preferences dialog, see the *Operator section*. For advanced information about setting user preferences, locking preferences, and administrating preferences, see the Administrator *section.*

Follow these steps:

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Topology Tab folder in the Name column and click Model By Type.
   The Set Preferences dialog displays the Include Model Types list on the left and the Exclude Model Types list on the right.

   > **NOTE**
   > By default, the Include Model Types list includes all the available model types when you first access the Model By Type preference. You have not yet excluded any model types.
3. (Optional) Enter text in the appropriate Filter field to filter the desired list.
   As you type characters in the Filter field, only the model type names that contain the same string of characters are shown in the list.
4. Do *one*:
   – From the Include Model Types list, select the model type that you want to *exclude*. Click the right arrow button to move it to the Exclude Model Types list.

NOTE
To select several model types at once, press the CTRL key and click each model type.

After you click Apply, the selected model type is moved to the Exclude Model Types list. This model type no longer appears in the Select Model Type dialog.

– From the Exclude Model Types list, select the model type that you want to *include*. Click the left arrow button to move it to the Include Model Types list.
After you click Apply, the selected model type is moved to the Include Model Types list.This model type now appears in the Select Model Type dialog.

5. Click Apply.
The model type changes you made are applied.
6. Click OK.
The Set Preferences dialog closes.

Polling Interval Changes

You can change the polling interval for any device. To change the interval, enter a new value in the Poll Interval (sec) field in the DX NetOps Spectrum Modeling Information subview for the device model. You can also use the Attribute Editor.

NOTE
Polling intervals also apply to application models, many of which have an initial setting of zero, which in effect disables polling. However, the preferred method for disabling polling for any model is to set the Polling Status attribute to Off.

Disable Polling for a Model or a Model Type

To conserve bandwidth, you can increase the default polling intervals for selected models. Additionally, you may decide that the status of certain devices is not worth any polling bandwidth, even at longer intervals. For example, some network administrators choose to disable modeling endpoint devices such as workstations. The reason is that they do not need to receive the alarms that occur each time that these devices are powered down. Therefore, to model the endpoints but conserve bandwidth from network polling traffic, you can disable polling to these models (or to any models). You disable polling by changing the value of the Polling Status attribute to FALSE.

Polling Status Changes

You can change the polling status for any model by turning on or off polling. To change polling status, use the Polling setting in the DX NetOps Spectrum Modeling Information subview for the selected model. You can also use the Attribute Editor.

NOTE
The Polling Status value takes precedence over the Polling Interval value in terms of enabling/disabling various periodic external requests to a model. Setting the Polling Interval to zero automatically changes the Polling Status to Off. If you reset the Polling Status to On, the DX NetOps Spectrum inference handlers could still generate requests, even though the Polling Interval is set to zero. However, to enable normal DX NetOps Spectrum polling for fault isolation purposes, the Polling Interval would have to be manually reset to a non-zero value.

Poll Devices That Are Down

When contact with a device has been lost, DX NetOps Spectrum uses two methods to continue polling the device for a status change. First, DX NetOps Spectrum pings the device once every 60 seconds. Second, DX NetOps Spectrum sends SNMP requests every third polling interval by default. For example, if the device polling interval is set to 60 seconds, DX NetOps Spectrum polls the down device once every 180 seconds.

To change the default interval at which DX NetOps Spectrum polls a down device, insert the following syntax into the **<$SPECROOT>/SS/.vnmrc** file:

```
down_device_poll_interval_multiplier=<user_defined_multiplier>
```

For example, if the **<user_defined_multiplier>=2** and the device polling interval is 60 seconds, then DX NetOps Spectrum polls the down device once every 120 seconds (2*60=120).

Connections (Pipes) Between Modeled Devices

You can depict the physical connections (pipes) between the modeled devices using the **Start** and the **End Connection** options in the Topology right-click menu. In OneClick, you can manually create three types of connections between modeled devices:

- **Resolved connection:** (For a fully resolved connection.) A resolved connection occurs when two devices are connected at the port level. For example, Port-A of device one is connected to Port-B of device two.
- **Partially resolved connection:** A partially resolved connection occurs when only one port is known between two devices. You typically create this type of connection when you know only the port of one modeled device. For example, device-one is connected to Port-A of device-two.
  When you manually model a partially resolved connection, DX NetOps Spectrum attempts to resolve the port connection of the other device. If DX NetOps Spectrum succeeds, it represents the connection as a fully resolved connection. You can later determine whether the connection is fully resolved. To check for a resolved connection, click the link within that view and view the Link Information tab in the **Component Detail** panel.
- **Unresolved connection:** An unresolved connection occurs when two modeled devices (or containers) are not connected in any way at the port level. For example, container-A is connected to container-B.

Make sure that the Live Pipes attribute for each VNM is set to **Enable** when these conditions exist:

- You have a DSS (distributed SpectroSERVER) environment.
- Any of the connections or pipes that you are creating span between two or more devices that different SpectroSERVERs manage.

Dynamic Link Status Partial or Fully Resolved Connections

After you create a partial or fully resolved connection between two modeled elements, you can monitor the status of that connection. You monitor the status by enabling the connection as a Live Pipe. The color of live pipes in the Universe topology views indicates status information about the connection. For example, good connection conditions are green, bad connection conditions are red, and disabled live-pipe connections are gold.

A live pipe shows a combined status condition for fully resolved connections (two ports). The connection having the most severe condition determines the color of the pipe. A live pipe can generate an alarm when one or both the links it represents goes down.

> **NOTE**
> Initially after modeling a connection, the color of the connection is gold or silver. Gold appears for resolved or partially resolved connections; silver appears for all unresolved connections.

DX NetOps Spectrum monitors the Border Gateway Protocol (BGP) peer session under these circumstances:

- Live pipes are enabled on a connection between two routers, or on a connection between a router and a provider cloud.
- The ports that are involved with the connection are participating in a BGP peer session.

Remove Connections from a Universe Topology View

You can delete a connection between two modeled elements in the Universe topology view by right-clicking the pipe and selecting Delete. When a pipe is deleted, DX NetOps Spectrum removes all of its associations. If the pipe represents more than a single port connection, DX NetOps Spectrum prompts you to confirm the deletion.

Automatic Recreation of Pipes

DX NetOps Spectrum automatically recreates pipes when you copy and paste a set of previously connected modeled icons to another Universe topology view or list view. Also, pipes are automatically recreated when you copy and paste the models in the Explorer tab. If you delete one of the connected modeled icons for a view, the pipe is erased. Later, you could copy that device from the Lost and Found view to the original topology view or list view. In this case, OneClick automatically recreates the connection between the two modeled devices.

Create an Unresolved Connection Between Modeled Elements

When you do not know the port connections between two modeled elements that you want to connect, you can create an unresolved connection. When you create an unresolved connection between two modeled elements in the Universe topology view, the pipe representing the connection is silver. You are prevented from enabling that connection as a Live Pipe. However, after you create an unresolved connection between two modeled elements in a Universe topology view, DX NetOps Spectrum automatically attempts to resolve the connection between them. If DX NetOps Spectrum succeeds in resolving the connection, the pipe representing the connection is gold and it behaves as a resolved connection. You can then proactively monitor the status of that resolved connection by right-clicking the pipe and selecting Live Pipe.

If DX NetOps Spectrum is unable to detect at least one port-level connection between two devices, the pipe in the topology view remains as an unresolved connection (silver). You cannot enable Live Pipe on an unresolved connection.

Follow these steps:

1. In a Universe topology view, right-click any modeled element (device or container) and select Start Connection to designate the starting point of a connection.
2. In a Universe topology view, right-click the modeled element (device or element) and select Connect with <*starting point address*> to designate the endpoint of the connection.
   DX NetOps Spectrum models an unresolved silver-colored pipe between the two modeled devices that are specified. If the connection between the modeled elements spans two separate views, an off-page reference icon appears in the view.

Create a Resolved Connection

When you know the ports of both modeled devices, you can create a port-to-port resolved connection.

Follow these steps:

1. Designate the starting point of a connection in a Universe topology as follows:
   a. Select a modeled device (such as a switch or router) that contains port interfaces.
   b. Click the Interfaces tab in the Component Detail panel.
   c. Right-click a port row in the Interfaces tab and select Start Connection.
2. Designate the endpoint of the connection in a Universe topology as follows:
   a. Select a modeled device (such as a switch or router) that contains port interfaces.
   b. Click the Interfaces tab in the Component Detail panel.
   c. Right-click a port description in the Interfaces tab and select Connect with <*starting point port address*>.
   DX NetOps Spectrum creates a resolved (gold-colored) pipe between the two modeled icons. If the modeled devices are in separate views, an off-page reference icon appears in the view.
3. To monitor the link status of this connection, right-click the connection and select Enable/Disable Live Links.

Create a Partially Resolved Connection

Sometimes, you know only the device port of one of the two modeled devices that you want to connect. In this case, you can create a partially resolved connection.

Follow these steps:

1. Designate the starting point of a connection by following these steps:
   a. In a **Universe** topology view, select a modeled device (such as a switch or router) that contains port interfaces.
   b. In the **Component Detail** panel, click the **Interfaces** tab.
   c. In the **Interfaces** tab, right-click a port row and select **Start Connection**.
2. Designate the endpoint of the connection. In a **Universe** topology view, right-click any modeled element (device or container) with an unknown port address and select **Connect with** *<starting point modeled port address>*.
   DX NetOps Spectrum models a partially resolved (gold) pipe between these two modeled devices. If the connection between the modeled devices spans two separate views, an off-page reference icon appears in the view.
3. (Optional) Monitor the link status of this connection.

> **NOTE**
> OneClick automatically attempts to locate the unknown device port. You can verify whether DX NetOps Spectrum locates this device port by clicking the link and viewing the Information tab in the **Component Detail** panel.

Resolve Unresolved Connections

You can resolve unresolved and partially resolved connections from the Interfaces tab.

Follow these steps:

1. Select the device model for which you want to resolve a connection.
2. Click the Interfaces tab in the Component Detail panel.
   A warning appears in the Interfaces tab toolbar specifying how many unresolved connections this device has.
3. Right-click an unused interface and select Resolve Connection To, *<model at other end of connection>*.
   The warning in the Interfaces toolbar changes to show the revised number of unresolved connections. For example, if you had only one unresolved connection, the warning now disappears. If you had two unresolved connections, the warning now indicates that you have only one unresolved connection.

Lock and Unlock Resolved Connections

In OneClick, you can preserve a resolved connection between two modeled devices by locking that connection. When you lock a connection, Discovery does not delete the connection.

Follow these steps:

1. In a Universe topology view, right-click the resolved connection that you want to lock/unlock and select Lock/Unlock Connection.
   The Lock/Unlock Connection dialog opens.
2. Select the connections that you want to lock/unlock and click OK.
   The resolved connection is locked/unlocked according to your selection.

Enable/Disable Modeling of a Connection Between Two Ports

10.4.2 allows you to enable or disable modeling of a connection between two ports. It provides a new attribute (LockPort) on the port model type. This attribute helps you decide whether you want to create connections between two ports. By default, the value of the attribute is set to *No*. This implies that there is no change in the existing behavior while performing the discovery or establishing a connection between two ports. However, if you set the value to *Yes* and again perform the discovery, then no connection is established on the port for which LockPort is set to Yes. The LockPort value acts only when there is no connection between ports. If a connection already exists and you change the port's LockPort value to Yes and again perform the discovery, then no change happens to the existing connection.

Understand the Working

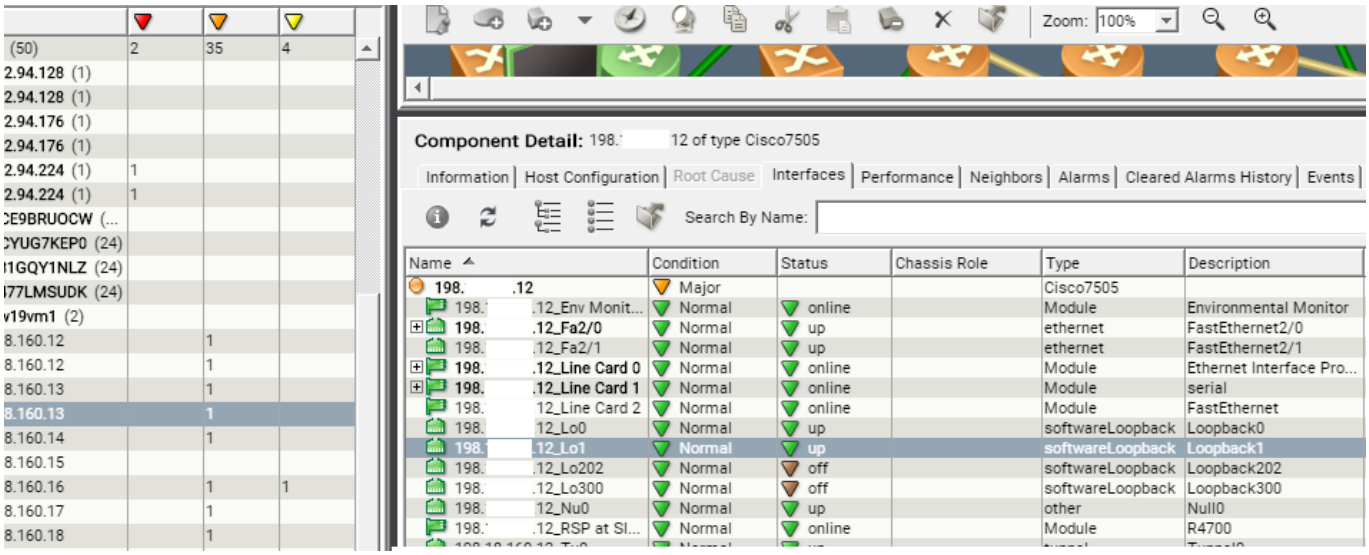
During the initial or new discovery, all the devices and the connections between them are created in the usual manner. At a later stage, if you do not want to create a connection between any ports, select the required port, locate the LockPort attribute, and change the value to Yes. Now, you can remove the unwanted connections for that port. From this point onward, for all kinds of discoveries, no connection is made on this port. If that is device is removed, the LockPort attribute value is reset to No.

Configure the Value

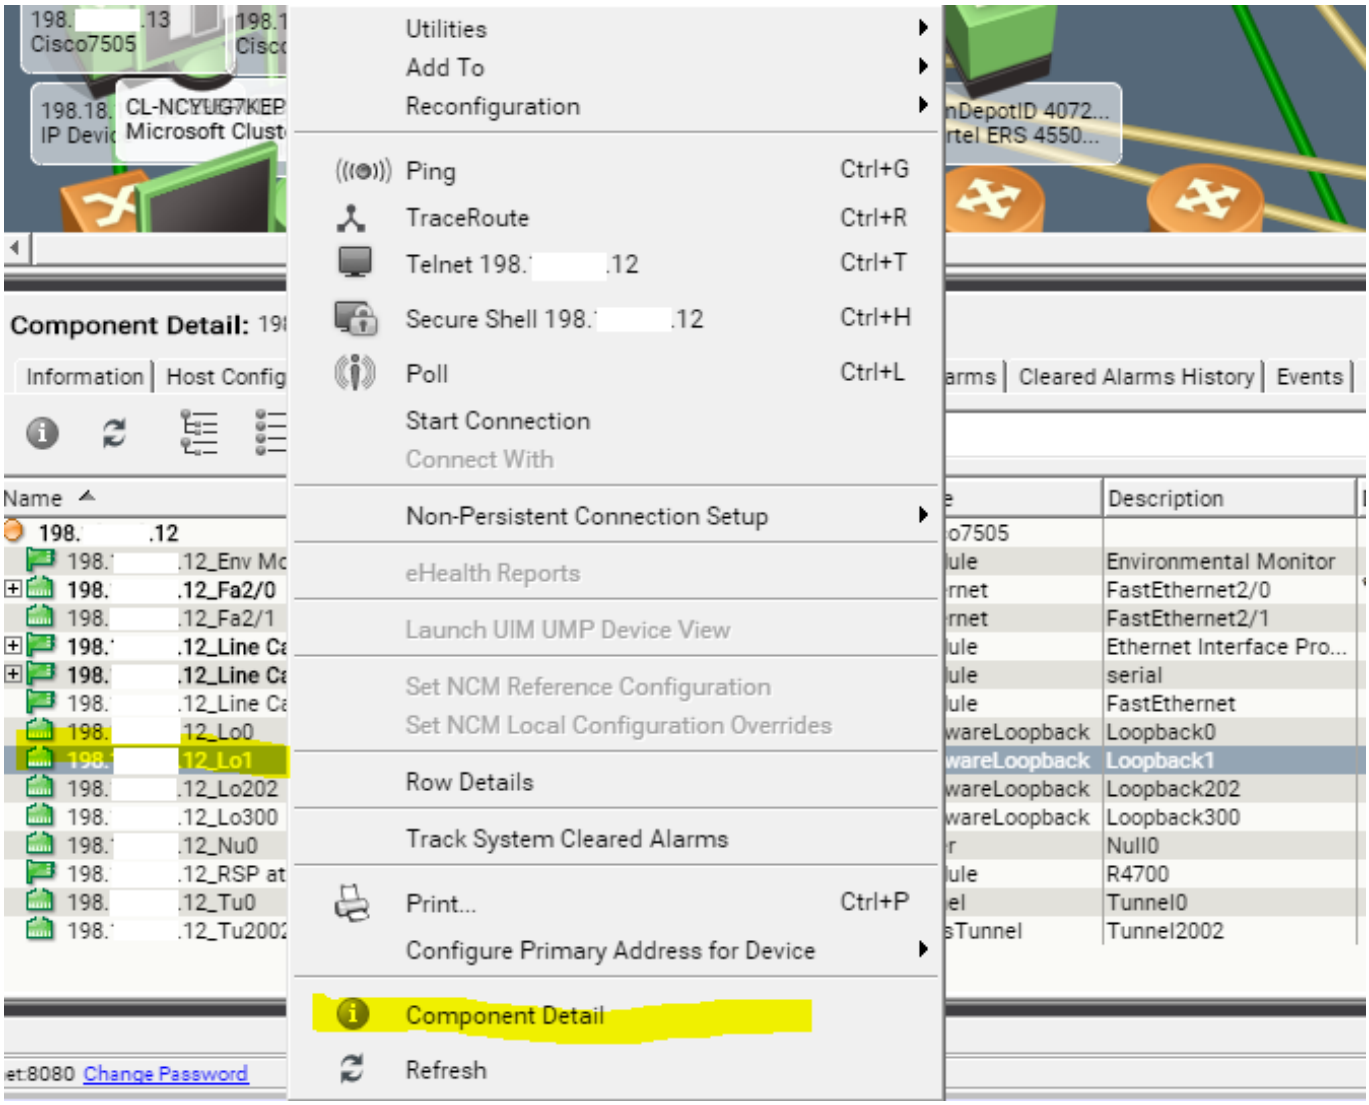
You can configure the value of the LockPort attribute.

Follow these steps:

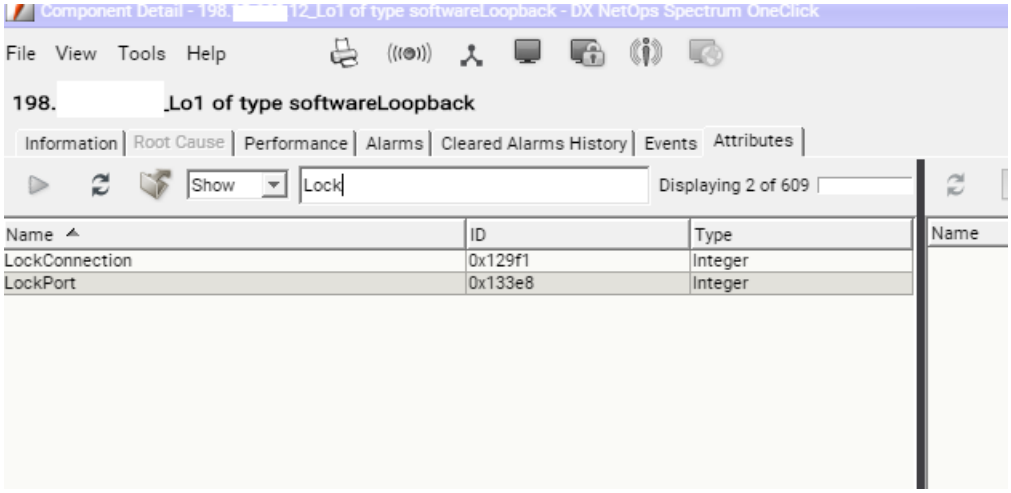
1. Access the OneClick UI.
2. Select any device that has interfaces and then select the **Interfaces** tab under the **Component Detail** pane.



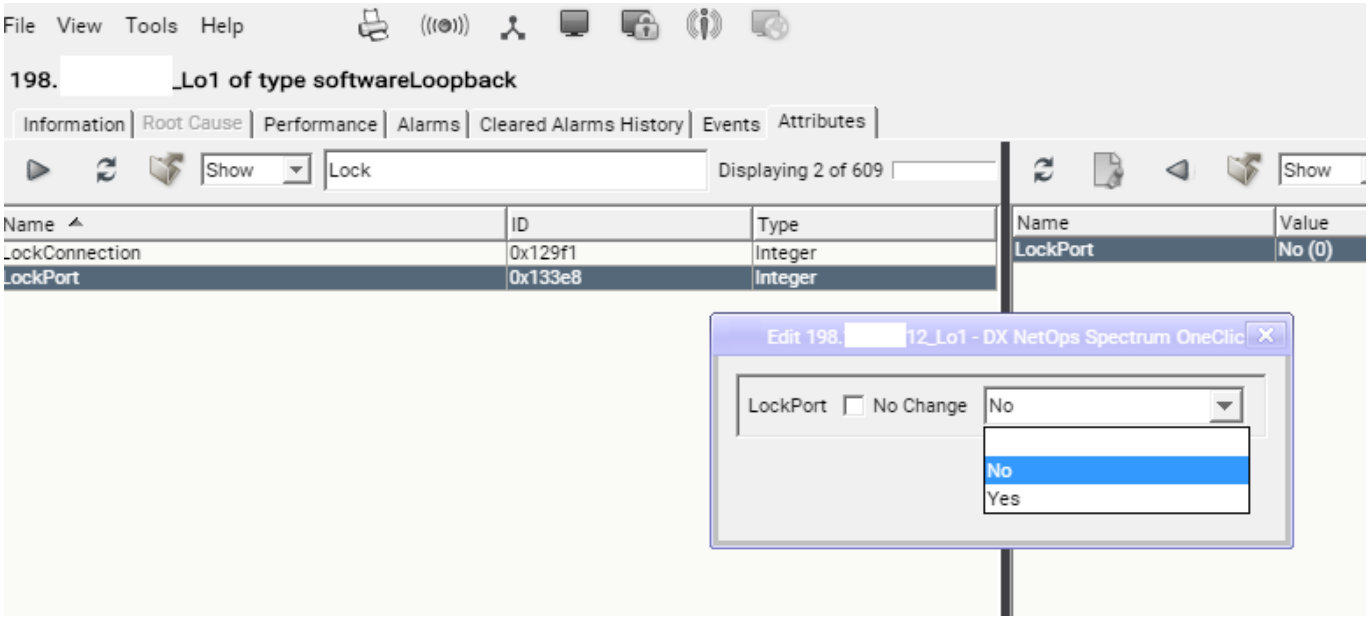
3. Select any interface (for example, Loopback, Ethernet, or Tunnel Interface).
4. Right-click and select the **Component Detail** option.



5. Select the **Attributes** tab and search for the LockPort parameter.



6. Change the value of the parameter as required.



You have successfully changed the value of the attribute.

> **NOTE**
> This functionality is not applicable for DMVPN discovery and Manual connection.

Enable or Disable a Live Link

You can monitor the link status of any resolved connection that is depicted in the Universe topology views by enabling Live Links. For live links on a partial or fully resolved connection, you can monitor the port connections at either end of the modeled devices.

The status of a live link displays through colors (red for critical, green for good, and so on). In addition, if a port connection within a live link goes down, you can view alarm information about that connection in the Alarms tab of the Contents panel.

You can enable and disable a live link for a partial or fully resolved connection.

> **NOTE**
> You cannot enable live links on a silver (unresolved) connection.

Follow these steps:

1. Right-click the connection that you want to enable/disable as a live link and select Enable/Disable Live Link.
2. Select the connections that you want to change and click OK.
   If you enable a connection, the color changes to green (good condition) or red (bad condition). The color of a disabled connection is gold.

Enable All Live Links

To enable all live links at once you need to:

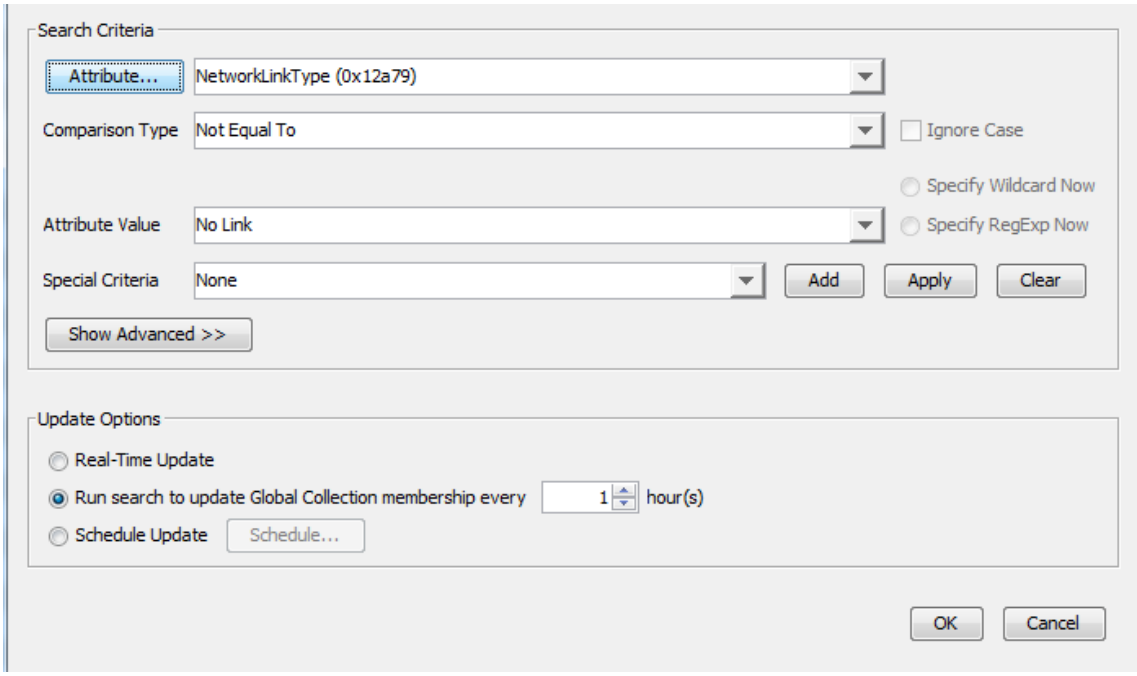
- Create a **Global Collection** for all live links in the Navigation pane.
- Apply the **ok_to_poll** attribute on that Global Collection using Attribute Editor.

Follow these steps to create the Global Collection:

1. Right-click **Global Collections** and select **Create Global Collection**.

The **Create Global Collection** dialog appears.

2. Enter the **Name**, **Owner**, **Description**, **Security String** for the new Global Collection.
3. Click **Landscapes** to select the required landscapes, and click OK.
4. Click **Search options** to create a Global Collection for all connected port models (live links).
   The **Search Options** dialog appears.
5. Configure the Search Options dialog as shown in the following image:



6. Click OK.

The Global Collection for all connected port models is created.

Follow these steps to enable all the live links using ok_to_poll attribute:

1. Select the new Global Collection of all connected port models (live links) in the **Navigation** pane.
2. Click List, and select all the port models in the **Contents** pane.
3. Right-click, and Select **Utilities**, **Attribute Editor.**
   The **Attribute Editor** dialog appears.
4. Click **add** in the left pane to add a user defined attribute.
   The Attribute Selector dialog appears.
5. Select **Port** in the left pane, and then select the **ok_to_poll** attribute in the right pane and Click OK.
   You are back to **Attribute Editor** dialog.
6. Set this attribute to Yes, and then Click Apply.
   Now this Attribute value is loaded on all the live links of the global Collection. After loading, click Close.
7. Click OK to close the **Attribute Editor**.

All the live links are enabled in the **Universe**, you can see that all enabled healthy live links in green. The color changes based on the condition of the links.

To disable all the live links at once, set the **ok_to_poll** attribute to "No" on the Global Collection, or delete the Global Collection.

BGP Peer Session Monitoring

Border Gateway Protocol (BGP) peer session monitoring polls the status of the peer session between two BGP devices.

From 10.4.2, DX NetOps Spectrum uses the Cisco BGP MIB to monitor the ipv4 and ipv6 BGP peer sessions for cisco devices. If the device does not support Cisco BGP MIB, then DX NetOps Spectrum uses the BGP standard MIB.

NOTE
When you upgrade DX NetOps Spectrum to 10.4.2, reconfigure the devices to monitor the peer session using the Cisco BGP MIB.

DX NetOps Spectrum monitors the BGP port peer session status at the polling interval of the port model's Polling_Interval attribute value under these conditions:

- The BGP peer session monitoring is enabled.
- The live pipe on a BGP peer session port is turned on.

When a monitored BGP peer session is no longer found in the bgpPeerTable MIB table, the result is:

- A "BGP peer session removed" event is generated.
- The session is no longer monitored.

Consider the following information about alarms and BGP peer sessions:

- Set the Polling_Interval attribute from 0 to 120 (or some other positive value). For more information, see Not Receiving BGP Alerts After Enabling BGP Peer Session Monitoring in the VNM Model.
- When WA_Link is connected to the ports in a BGP peer session, a BGP peer session down alarm is generated on one of the port models. The session is not generated on WA_Link.
- If the loss of a BGP peer session is the root cause of a downstream outage, a critical BGP alarm is generated. This alarm hides the lost contact alarm of the downstream device.
- If a monitored BGP peer session goes down, a single alarm is generated on the BGP peer session port model. If the monitored BGP peer session is between two directly connected routers, the alarm is asserted on the port model on which the outage is first detected.
- If a BGP peer session port is administratively disabled or operationally down, the BGP peer session alarm on the port model becomes symptomatic alarm of the link condition alarm.
- When a backward transition trap is received, the BGP MIB is polled to verify that the peer session is established. If the peer session is not established, an alarm is generated on the peer session port model.

NOTE
For more information about using MIB Tools, see the Certifications section.

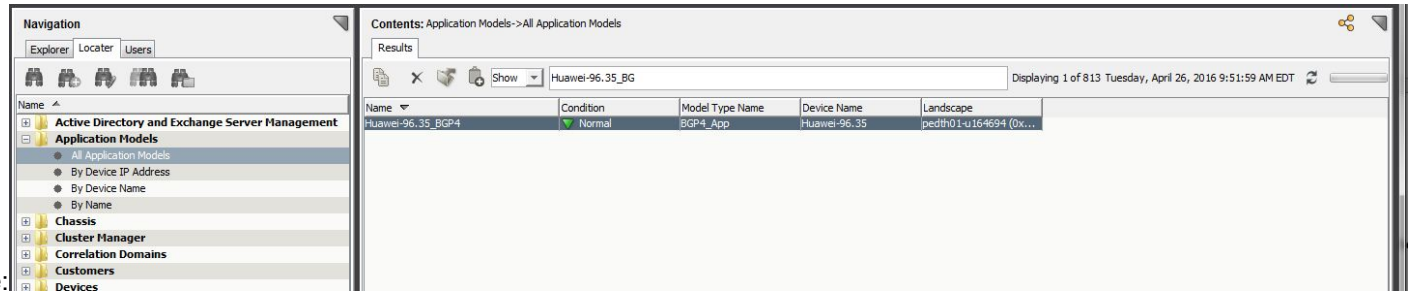
Troubleshooting BGP Peer Monitoring

This section discusses the common errors that occur while configuring BGP Peer Monitoring and their solution.

Not Receiving BGP Alerts After Enabling BGP Peer Session Monitoring in the VNM Model

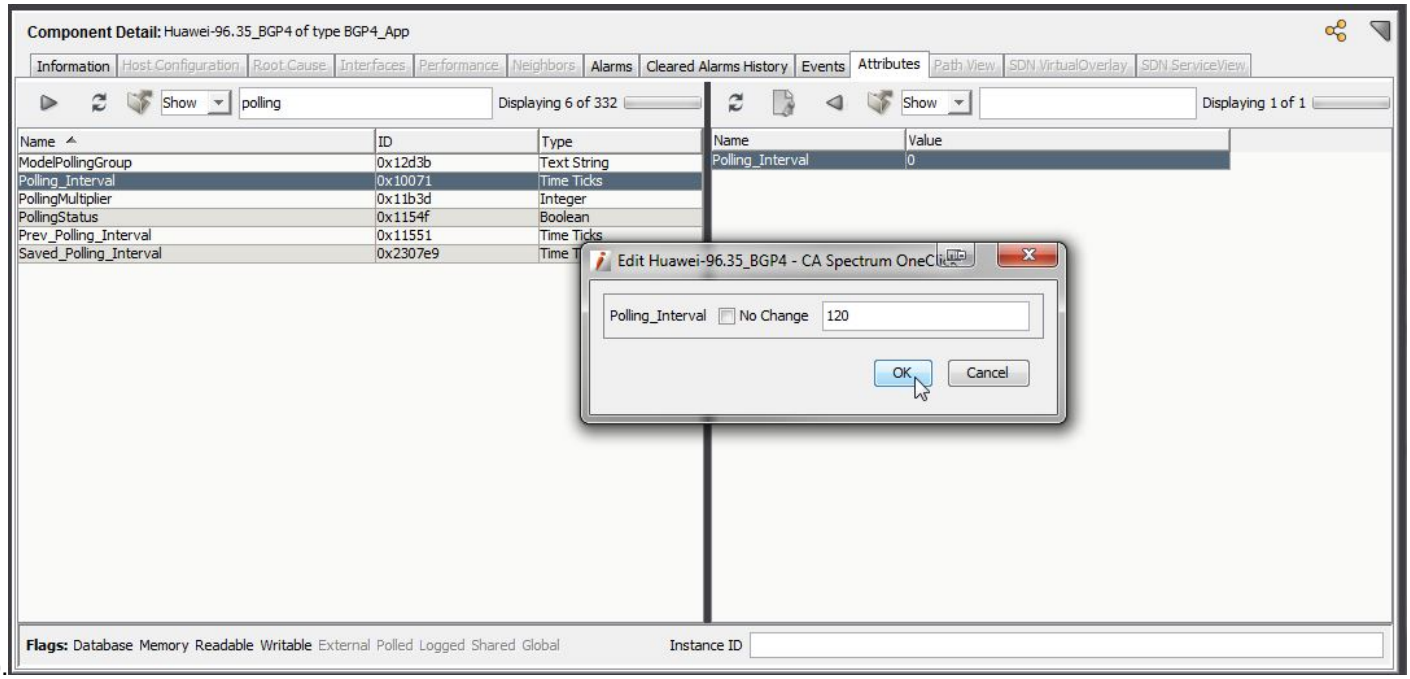
You may not receive BGP alerts if the polling interval is not set on the BGP Application Model.

1. Run a **Locater** search for **Application Models,** filtering on the BGP4_App for the device:



2. Under **Component Detail** for the BG4_App, click on the **Attributes** tab.

3. Search for the **Polling_Interval**.
4. Set the **Polling_Interval** from 0 to 120 (or some other positive value).



5. Save the changes.
   After this change, you should start seeing expected BGP alerts.

Remove Modeled Elements from the Universe Topology View

The Universe Topology and Explorer view allows you to remove modeled elements.

> **WARNING**
>
> Due to high possibility of models getting corrupted in the process, it is recommended that you do not use this option, unless the model exists in a static Global Collection or in the World view.

To remove modeled elements from the Universe Topology/ Explorer View,

Follow these steps:

1. In the **Universe** topology/explorer view, right-click the modeled element, and select **Remove.**
   The **Confirm Removal** dialog opens.
2. Click **Yes.**
   The element is removed from the topology/explorer view.
   Models are placed in the Lost and Found (**LostFound**) subview.

Delete Modeled Elements from the Universe Topology View

You can delete modeled elements from the Universe topology view.

Follow these steps:

1. In the Universe topology view, right-click the modeled element, and select Delete.
   The Confirm Delete dialog opens.
2. Click Yes.

The model is deleted permanently from the system. When deleting containers, models within the containers are placed in the Lost and Found. If those models exist in other topologies like World View and Global Collection, they continue to exist there. In this case, they are not moved to Lost and Found.

Cut Modeled Elements from the Topology View or List View

You can cut a modeled element from a topology view, list view, or using the right-click menu in the Explorer tab. In this case, OneClick removes the model from the view and places it into the Lost and Found. If desired, you can remove the modeled element from the Lost and Found view as well.

To cut a modeled element from a view, right-click the modeled element and select Cut.

The cut modeled element moves to the Lost and Found view.

Follow these steps:

1. Select **LostFound** in the Explorer tab in the OneClick Navigation panel.
2. Click the List tab in the Contents panel.
3. Select the elements that you want to remove in the List tab.
4. Right-click and select Delete.

Enhance Topology Views

You can put the current Topology view in Edit mode. Then, you can enhance the Topology view using the tools that are provided in the Edit mode toolbar.

Export a Topology View

You can export any topology view to a PNG file format.

Follow these steps:

1. Navigate to the topology view that you want to export.
2. Click the Export button in the Topology tab toolbar.
   The Save As dialog opens.
3. Specify a name and location for the file and click OK.
   The topology view is saved as a PNG file.

> **NOTE**
> For more information about exporting views and table data, see the Using OneClick section.

Modeling Manually in a Global Collections Topology

If you have the Manage Global Collections privilege, you can create a collection in the Global Collections topology. Create a collection from any modeled elements that were previously modeled in one or more Universe topology views.

When you create a collection within the Global Collections topology, provide a name and an owner for that collection and define its members. The owner field is used to indicate who is responsible for the Global Collection. This field is initially set to the OneClick user who created the collection. Select members for a collection either by specifying search criteria or by using the copy and paste feature.

Dynamic Membership

When you use search criteria to define the members of a Global Collection, the members of that Global Collection are considered *dynamic*. They remain in the Global Collection only as long as they meet the specified search criteria.

DX NetOps Spectrum automatically removes a modeled element from the Global Collection that no longer meets the original search criteria, using the method that you choose:

- The next time the Global Collection is manually updated
- Periodically, at the next scheduled interval
- Dynamically, as soon as the model no longer meets the Global Collection search criteria
- Scheduled, according to the assigned schedule

The default period for automatic scheduled collection updates is 24 hours. At any time, you can redefine the dynamic members in a Global Collection by editing the specified search criteria.

> **NOTE**
> Schedules can be assigned only after the initial creation of a Global Collection. Schedules are intended for Global Collections with search criteria that have the capacity to result in degraded product performance.

Static Membership

When you use copy/paste or add functions to define members of a collection, the members of that collection are considered static. The static members always remain in a collection until you decide to remove them manually.

Connections Between Modeled Elements (Members)

The connections between modeled elements in a Global Collection topology view and in a Universe topology view are similar. In both views, connections exhibit the same behavior and functionality. In the Global Collections view, you can create partial and fully resolved connections, or unresolved connections (links, pipes). You can monitor the status of any resolved connection using Live Links.

Updating Modeled Elements in Global Collections

DX NetOps Spectrum updates all modeled elements in a Global Collection view, using the method that you choose:

- The next time the Global Collection is manually updated

  > **NOTE**
  > You must have the Update Global Collection Membership privilege to update a Global Collection manually.
- Periodically, at the next scheduled interval
  The default period for automatic scheduled Global Collection updates is 24 hours. At any time, you can redefine the dynamic members in a Global Collection by editing the specified search criteria.
- Dynamically, as soon as the model changes to meet or no longer meet the Global Collection search criteria
- Scheduled, according to the assigned schedule

Note: Scheduled updates can only be applied if you have the Schedule Global Collection Updates privilege. Scheduled updates are intended for Global Collections with search criteria that have the capacity to result in degraded product performance. Scheduled updates are not available during the initial creation of a Global Collection. Without the Schedule Global Collection Updates privilege, you cannot change the Global Collection Update Options when a schedule is applied to a Global Collection.

Generate Reports on Collections

You can generate reports on global collections using the Report Manager module. By using the Report Manager module with the OneClick Global Collections topology, you can at any time generate a single report about any one collection. For more information about running reports, see the Report Manager section.

NOTE
The Report Manager module is not included in the DX NetOps Spectrum core product line. This module must be purchased separately.

How to Define and Manage Global Collections

Defining and Managing Global Collections

When defining a collection of modeled elements in the Global Collection topology, consider following this process:

1. Create a Global Collection.

   NOTE
   A new global collection remains empty until you define its members.
2. Define Dynamic members or, when necessary, Define static members.
3. Edit the members in a global collection as needed. For dynamic members in a global collection, you can redefine the search criteria. For static members in a global collection, you can delete, or copy/paste members in a global collection, or can add members to a global collection.
4. Create a Global Collection Hierarchy if you want to organize global collections using folders and subfolders.
5. Delete global collections as needed. The modeled elements within a global collection represent copies of modeled elements from the Universe topology. Therefore, Delete removes only the specified global collection and the copies of the modeled elements that global collection represents.

Create an Empty Global Collection

You can create an empty global collection when you are unsure of the type of global collection you want to create. To create an empty global collection, provide only the name of the global collection. Save your empty global collection until you are ready to add static members, dynamic members, or both.

Follow these steps:

1. In the Explorer tab of the Navigation panel, right-click Global Collections and select Create Global Collection. The Create Global Collection dialog opens.
2. Complete the following fields and click OK:

- **Name**
  Specifies the name for the global collection.

  NOTE
  If your global collection name matches an existing global collection name, a warning appears. Click Yes to continue naming the global collection, or click No to enter another name for the global collection.

- **Owner**

Specifies the user who is responsible for the global collection.

- **Description**
  (Optional) Specifies a description for the global collection.
- **Security String**

(Optional) Specifies a security string expression to prevent certain users from viewing the contents of this global collection.

NOTE
For information about security string expressions, see the Administration section.

The global collection is created and appears in the Navigation panel under Global Collections.

Create a Global Collection of Dynamic Members

You can create a dynamic collection of dynamic members.

Follow these steps:

1. In the Explorer tab of the Navigation panel, right-click Global Collections and select Create Global Collection.
   The Create Global Collection dialog opens.
2. Enter relevant values for the following fields.
   - **Name**
     Specifies the name for the global collection.

     NOTE
     If your global collection name matches an existing global collection name, a warning appears. Click Yes to continue naming the global collection, or click No to enter another name for the global collection.
   - **Owner** Specifies the user who is responsible for the global collection.
   - **Description**
     (Optional) Specifies a description for the global collection.
   - **Security String**
     (Optional) Specifies a security string expression to prevent certain users from viewing the contents of this global collection.

     NOTE
     For information about security string expressions, see the Administrating section.

3. Click Search Options to provide the search settings for the global collection.
   Complete any of the following fields to create a single search expression:
   - **Attribute**
     Specifies the attribute of a device to filter. From the drop-down list of commonly used attributes, select the attribute that you want to use. The predefined list might not include the attribute that you want. In this case, click Attribute to specify the model type (device, port, or other) and its associated attribute that you want to find.

     NOTE
     If you choose an alphabetic attribute value, you can either clear (ignore) or select (include) the Ignore Case checkbox.
   - **Comparison Type** Specifies the type of comparison to be made against the value that is specified in the Attribute field. Only the comparison types appropriate to the attribute data type are available.
   - **Ignore Case** Determines whether the comparison is case-sensitive. If you do not select this checkbox, the comparison is case-sensitive. This selection is only enabled when it is appropriate for the data type of the attribute you selected.
   - **Attribute Value** Enter the desired attribute value to search.
   - **Devices Only** Specifies that the search results list includes only devices.
4. (Optional) To use a wildcard character or regular expression in the Attribute Value field, select a valid attribute in the Attribute field.
5. Select Matches Pattern in the Comparison Type field. Then, select one of the following options:
   - **Specify Wildcard Now**

Lets you search for a value using a wildcard. The following wildcards are available:

- *****
  Matches *any number* of characters.
  For example, 'switc*' returns 'switch' and 'switch-router.'
- **?**
  Matches any *single* character.
  For example, 'switc?' returns 'switch' but it does not return 'switch-router.'
  Both wildcards can be used anywhere and in any combination for a wildcard match.

  NOTE
  'Matches Pattern' is not a valid comparison type for all attributes.
- **Specify RegExp Now**
  Specifies that you want to create a search using Perl Compatible Regular Expression (PCRE) matching on attributes of the type 'text string'. Text string searches are available only for Matches Pattern comparison types. PCRE matching helps you to find and group models using specific pattern searches that are more advanced than existing searches or wildcard searches can provide.

  NOTE

  By default, all users have the privilege to enter regular expressions. Administrators can disable this privilege on a per-user basis.

6. (Optional) To conduct a compound search clause or a single search clause, do *one* of the following steps:
   - To conduct a search that is based on a single expression, click OK.
   - To conduct a search that is based on a compound clause, complete the following steps to build a compound search clause:

   a. a. Click Show Advanced. The compound expression box and logical operator buttons appear.
      b. Click Add to move the single expression you created in Step 4 to the compound expression box.
      c. Click one of the following logical operator buttons to build a compound expression: New AND; New OR; or AND/OR.

         NOTE
         The compound expression is represented in a tree structure that is grouped by logical operators (AND/OR). Each logical operator in the tree can include any number of attribute criteria nodes and logical operator nodes. For more information, click Hints in the Advanced section.
      d. (Optional) Click the Add Existing button to create a global collection from an existing attributebased search, actionbased search, or relationbased search.
      e. Repeat Steps 4 through 5 for each compound search expression you want to build.
7. Click OK.
   The Advanced Search mechanism locates and places a copy of all matching modeled elements (previously defined in the Universe topology) into the global collection.

   NOTE
   For more information about searches, see the Administration section.
8. (Optional) Select the Real-Time Update checkbox.
   This option disables the update interval.
   Also, it adds or removes models to and from the global collection when the models meet or no longer meet the search criteria.
9. (Optional) Specify a value in the **Run search to update Global Collection membership every <> hours** field.
   This field determines how often you want OneClick to conduct a search to update the dynamic members that are defined in the global collection.

   NOTE

   The option to associate a schedule with a global collection is not available during the initial creation of a collection.

10. Click OK.
    The Search Options dialog closes and the Create Global Collection dialog opens.
11. Click Landscapes to identify which landscapes you want Search to include when searching models to populate the global collection.
12. Click OK.

The global collection of dynamic members is created.

Global Collection Search Recommendations

The following information provides search criteria recommendations when defining global collections with dynamic members. The order of the criteria can affect the search performance.

The order of attribute criteria is based on two categories: *storage of information* and *data type.*

- **Storage of information**
  Order the attributes from least CPU (quickest access) to most CPU (slowest access), as follows:
  - **Memory flag** (least CPU/quickest access)
  - **Database flag**
  - **Calculated**
  - **External flag** (most CPU/slowest access)
- **Data type**
  Order the attributes from quickest comparison to slowest comparison, as follows:
  - Integer, counter, enumeration, model type handle (quickest comparison)
  - IP address, octet string
  - Text string (slowest comparison)

Combining the two categories of criteria, the overall attribute placement for complex searches of AND/OR order from top to bottom is as follows:

1. **Memory flag**
   a. Integer, counter, enumeration, model type handle
   b. IP address, octet string
   c. Text string
2. **Database flag**
   a. Integer, counter, enumeration, model type handle
   b. IP address, octet string
   c. Text string
3. **Calculated**
   a. Integer, counter, enumeration, model type handle
   b. IP address, octet string
   c. Text string
4. **External Flag**
   a. Integer, counter, enumeration, model type handle
   b. IP address, octet string
   c. Text string

Example

You would like to define a global collection containing dynamic members that are based on the following search criteria (in no particular order):

- **ifDesc**
- Topology model name string
- Network address
- Model type handle

Using the recommended ordering logic, we recommended the following order:

1. Model type handle (memory flag : model type handle)
2. Network address (memory flag/database flag : IP address)
3. Topology model name string (calculated flag : text string)
4. **ifDesc** (external flag : text string)

Create a Global Collection of Dynamic Members from an Existing Search

You can create a global collection of dynamic members from an existing attribute-based search, action-based search, or relation-based search. The existing searches can be found in the **Locater** tab.

> **WARNING**
> You can create a global collection that is based on an existing search. However, the association between the global collection and the existing search is not maintained. After the global collection has been created, any modifications to the search criteria for the global collection must be made in the global collection itself. Any changes to the existing search (in the **Locater** tab) on which the global collection was originally based are not propagated to the global collection.

Follow these steps:

1. In the **Locater** tab, locate the existing search that you want to base your global collection on.
2. Right-click the existing search and select Create Global Collection From.
   The Create Global Collection dialog opens.
3. Do the following, as necessary. The type of search you choose determines which options appear:
   - Enter a value for the search criteria. Options can include Matches Pattern, Equal To, Contains, and Starts With.
   - Select the Ignore Case check box to make the search case-insensitive.
   - Click Landscapes to identify which landscapes you want the Search to include when searching models to populate the global collection.
   - Click the List button and either enter a list of values to include in the search, or click Import to import a list of values. Click OK, and then click OK again.

   The Create Global Collection dialog reopens.
4. Complete the following fields:
   - **Name**
     Specifies the name for the global collection.

     > **NOTE**
     > If your global collection name matches an existing global collection name, a warning appears. Click Yes to continue naming the global collection, or click No to enter another name for the global collection.

Owner

Specifies the user who is responsible for the global collection.

- **Description**
  (Optional) Specifies a description for the global collection.
- **Security String**
  (Optional) Specifies a security string expression to prevent certain users from viewing the contents of this global collection.

NOTE
For information about security string expressions, see the Administrating *section.*

(Optional) Do the following steps to add another existing attribute-based, action-based, or relation-based search:

1. Click Search Options, click Show Advanced, and then click the Add Existing button.
   The Add Existing Search dialog opens.
   Note: Adding an existing search to your custom search copies the existing search and embeds it, as it is now, into your custom search. If you modify the existing search later, your custom search does not change. Your custom search contains only a *copy* of that existing search, as it was when you first copied it.
2. Select the existing search that contains the criteria you want to add to the current search and click OK.
   The Search dialog opens.
3. Do the following steps:
   – Enter a value in the provided field or select a value from the drop-down menu, if the drop-down menu is available.
   – Click Landscapes to identify which landscapes you want to include when searching models to populate the global collection.

   Click OK.
   The criteria that you selected is added to the compound expression.

   NOTE
   For more information about searches, see the Administrating *section.*

Click OK.

The Create Global Collection dialog closes and the global collection is created. The global collection appears in the Navigation panel under the Global Collections folder.

Create a Global Collection of Static Members

You can create a global collection of static members on the fly from a topology view.

Follow these steps:

1. In a topology view, do one of the following steps to designate the modeled devices that you want to add to a global collection:
   – To select a single modeled device, right-click a modeled device in the Navigation panel and select **Add To**, **Global Collection(s)**.

     NOTE
     You can right-click a single modeled device in *any* topology view to add the modeled device to a static global collection.
   – To select multiple modeled devices in any topology view, do the following steps:
     a. Press and hold the SHIFT key and individually select the modeled devices.
     b. While the SHIFT key is pressed, right-click the last selected modeled element and select **Add To**, **Global Collection(s)**.

     NOTE
     You can also select one or more modeled elements in the List tab and add them to a global collection.

   The Select Global Collections dialog opens.
2. Click Create.
   The Create Global Collection dialog opens.
3. Complete the following fields as needed:
   – **Name**
   Specifies the name for the global collection.

NOTE
If your global collection name matches an existing global collection name, a warning appears. Click Yes to continue naming the global collection, or click No to enter another name for the global collection.

Owner

Specifies the user who is responsible for the global collection.

- **Description**
  (Optional) Specifies a description for the global collection.
- **Security String**
  (Optional) Specifies a security string expression to prevent certain users from viewing the contents of this global collection.

  NOTE
  For information about security string expressions, see the Administration section.

Click OK.

The global collection of static members is created and appears in the Navigation panel under Global Collections.

Add Static Members to a Global Collection

You can add static members to an existing global collection.

Follow these steps:

1. In any topology, do *one* of the following steps to designate the modeled elements that you want to add to a global collection:
   – **Single modeled element selection:** In the Navigation panel, right-click a modeled element and select **Add To**, **Global Collection(s)**.
   The Select Global Collections dialog opens.

   NOTE
   Alternatively, you can right-click a single modeled element in a topology view and can select **Add To**, **Global Collection(s)**.
   – **Multiple modeled element selection:** To multiselect modeled elements in a topology view, take the following steps:
   a. Press and hold the SHIFT key and individually select the modeled elements.
   b. While the SHIFT key is pressed, right-click the last selected modeled element and select **Add To**, **Global Collection(s)**.
   The Select Global Collections dialog opens.

   NOTE
   Or you can multiselect one or more modeled elements in the List tab and can add them to an existing global collection.
2. Select the name of the global collection where you want to add the modeled elements, and click OK.
   The static members are added to the global collection.

Remove Static Members from a Global Collection

You can remove static members from an existing collection.

Follow these steps:

1. In the Global Collections navigation tree, right-click the static member that you want to remove from the collection and click Remove.
   A dialog prompts you to confirm the deletion.

2. Click Yes.
   The static member is removed from the collection.
   The Remove operation removes the element from the collection, but it does not destroy the modeled element. If the modeled element exists in other topologies, it continues to exist in those topologies. If the modeled element does not exist in any other topology, it is placed in the Lost and Found and later destroyed.

   NOTE
   If you attempt to remove a *dynamic* member from a collection, an error message appears. The error message informs you that the selected member was added through a search criterion. In this case, redefine the search criteria to remove the dynamic member.

Edit Dynamic Members in Existing Global Collections

You can edit dynamic members in existing global collections.

Follow these steps:

1. In the Explorer tab of the OneClick Navigation panel, navigate to the Global Collections node.
2. Right-click the collection and select Edit Global Collection.
   The Edit Global Collection dialog opens.
3. Edit the following fields as needed:
   - **Name**
     Specifies the name for the global collection.

     NOTE
     If your global collection name matches an existing global collection name, a warning appears. Click Yes to continue naming the global collection, or click No to enter another name for the global collection.
   - **Owner**Specifies the user who is responsible for the global collection.
   - **Description**
     (Optional) Specifies a description for the global collection.
   - **Security String**
     (Optional) Specifies a security string expression to prevent certain users from viewing the contents of this global collection.

     NOTE
     For information about security string expressions, see the Administration section.
4. Click Search Options to modify the search settings for this global collection.

   NOTE
   If the search criteria of a global collection has been identified as having the capacity to result in degraded performance, make an audit.

   Sometimes you cannot mitigate the potential performance impact by changing the search criteria. In this case, change the global collection Update Options to only update the collection members at a scheduled time.
   To schedule the membership update:
   Select the Schedule button.

   NOTE

   - Avoid scheduling multiple updates at the same time, because it increases the potential to affect DX NetOps Spectrum performance.
   - In a DSS environment that encompasses multiple time zones, the scheduled update times are local to each of the SpectroSERVERs. Consider this behavior when scheduling updates for any global collection that spans multiple landscapes.

WARNING
If a schedule is applied at the same time that the search criteria are changed, some landscapes could be updated when the changes are committed. This behavior is a known anomaly. To avoid this behavior, apply a schedule and commit the change before you change the search criteria.

5. Click Landscapes to modify the landscapes for this global collection.
6. Click OK

Your changes are saved and the dialog closes.

Auditing Global Collections

Several reasons could prompt you to audit a global collection, for example:

- Performing general housekeeping (identifying which collections are no longer needed).
- Determining who changed attributes of a collection, such as the update interval, search criteria, or name.
  The following events can be used to gain information about changes that were made to global collections:
  - **Event 0x1a100**
    Generated when the name of a global collection is changed.
  - **Event 0x1a110**
    Generated when the owner of a global collection is modified and indicates the OneClick user that has modified the attribute.
  - **Event 0x1a101**
    Generated when the search criteria is modified. This event indicates when the search criteria was changed and what it was changed to.
  - **Event 0x1a111**
    Generated when the update method of a global collection is changed. You can use this event to determine when the method was changed and what it was changed to.

    NOTE
    If the changes are made to the update method for the global collection using CLI, the 0x1a111 and 0x1a110 events are not generated.
- Determining the mitigation of performance impacting collections.
  When the search criteria of a global collection has the capacity to result in degraded DX NetOps Spectrum performance, make an audit. Using the audit findings, determine how to mitigate best the impact on the performance. Some indications that search criteria for a dynamic global collection could be resulting in degraded DX NetOps Spectrum performance include:
  - A SpectroSERVER performance event of type 0x10f20 or 0x10f21 has been generated on the global collection model.
  - OneClick becomes unresponsive or disconnects from the Tomcat server during the dynamic update for the global collection.

  For either symptom, we recommend that you examine the global collection to determine whether it is necessary. If the collection is still needed, the next step is to look at the search criteria to determine if it can be made more efficient.

Copy Annotations from One Global Collection to Another

You can copy annotations (text) from one global collection and paste them into another global collection.

Note: You must have administrative privileges to copy annotations.

Follow these steps:

1. Expand Global Collections in the Explorer tab and select the global collection from which you want to copy annotations.
2. Click the Topology tab in the Contents panel.

Topology information for the global collection appears.

3. Click  (Edit) in the Topology tab toolbar.

   NOTE
   You must have administrative privileges to put a topology in Edit mode.
4. Select all of the annotations you want to copy and click Copy in the Topology tab toolbar. To select several annotations at once, press the CTRL key and click each annotation.

   NOTE
   If you select all of the annotations, the relative placement of the annotations is preserved.
5. Select the global collection that you want to copy the annotations to from Global Collections, in the Explorer tab.
6. Click the Topology tab in the Contents panel.
7. Click  (Edit) in the Topology tab toolbar and then click Paste.
   The annotations are copied to the global collection you selected.

Copy Models from One Global Collection to Another

You can copy models from one global collection and paste them into another global collection.

NOTE
You must have administrative privileges to copy models.

Follow these steps:

1. Expand Global Collections in the Explorer tab and select the global collection from which you want to copy models.
2. Click the List tab in the Contents panel.
   A list of all of the models in the global collection appears.
3. Select all of the models you want to copy and click Copy in the List tab toolbar. To select several models at once, press the CTRL key and select each model. To select a group of models at once, press the Shift key and select one model in the list. Then, select another model in the list. All of the models between the two selected models are also selected.
4. Select the global collection that you want to copy the models to from Global Collections in the Explorer tab.
5. Click the List tab in the Contents panel and then click Paste in the List tab toolbar.
   The models are copied to the global collection you selected.

Find the Global Collections for a Model

You can determine whether a model belongs to a global collection of dynamic members, static members, or both.

Follow these steps:

1. Select the model for which you want to view global collection information.
2. Click the Information tab in the Component Details panel and scroll down to the Global Collections Memberships subview.
3. Expand the Global Collections Memberships subview.
   The Static Global Collection Memberships subview and the Dynamic Global Collection Memberships subview appear.
4. Expand either subview to review the global collections that the model belongs to. If the model does not belong to any global collections, the tables within these subviews are empty.

Create a Global Collection Hierarchy

If you intend to organize your global collections using folders, set up the OneClick Navigation panel with a Global Collection Hierarchy. In this Global Collection Hierarchy, you can create multiple levels of folders to represent previously defined global collections.

Follow these steps:

1. In the Explorer tab of the Navigation panel, right-click the Global Collections Hierarchy node and select New Folder.
2. Type a descriptive folder name in the New Folder dialog and click OK.
   The folder appears in the Global Collection Hierarchy tree.
3. In the Global Collection Hierarchy tree, perform any of the following tasks:
   - **Build more top-level folders:** Repeat Steps 1 and 2.
   - **Build one or more subfolders:** To create a subfolder, right-click a top-level folder and select New Folder.
   - **Populate a folder at any level:** To populate a folder with one or more collections, follow these steps:
     a. Right-click the folder and select Add Global Collections.
     b. In the Select Global Collections dialog, select the name of the collection you want to add and click OK.

NOTE
The Select Global Collections dialog represents the list of collections that are previously created in the Global Collection topology.

Modeling Manually in the World Topology View

You can represent your network geographically by creating a World topology view. In a World topology view, you can model several layers of container views to depict your network locations. For example, you can create container views of network infrastructure from a national or regional level all the way down to an individual room that contains network equipment.

How to Model Locations

When modeling multiple containers representing locations within your network infrastructure, it is recommended that you use this process:

Step 1: Create top-level location views: From the World topology node, you can begin depicting the top-level view of any network location by modeling one of the following top-level containers:

- Building
- Site
- Region
- Country

Step 2: Create one or more sublevel location views: Depending on the top-level container that is modeled, you can then depict one or more sublevel containers.

For this top-level container:	You can model any of these sub-containers:
Building	Floor, Room, or Section
Site	Building
Region	Building or Site
Country	Region, Building, or Site

Step 3: Populate a room container view with modeled devices: After you have created a room container view, you can populate that view with modeled devices.

NOTE
The best practice is to model devices in the Universe topology view and then copy and paste these devices to the World topology view. You can use the **Create Model by IP** or the **Create Model by Type** option to manually model devices in a World topology view. However, this alternative approach is not recommended, because the Universe topology views represent the connectivity views of your network.

Define a Top-Level or Sub-Level Location View

You can create a top-level and sublevel location view, as well as populate a room container view with modeled devices.

Follow these steps:

1. In the Explorer tab of the OneClick Navigation panel, do one of the following steps:
   - **To define a top-level location view:** Click the World topology node to display the World topology view in the Topology tab of the Contents panel.
   - **To define a sublevel location view:** Click one of the top-level view folders appearing under the World topology node. The World topology view for that folder appears in the Topology tab of the Contents panel.
2. Click
   
   (**Creates a new model by type**) in the Topology tab toolbar.
   The Select Model Type dialog opens.
3. In the Container tab of the Select Model Type dialog, select a container type that best describes the network location you are depicting. Click OK.
   The Create Model of Type dialog opens.
4. Specify a name that best describes the network location in the Name field.
5. Specify a security string in the Security String field if you want to secure this view from certain users.

   NOTE
   For more information about securing views, see Provision Access to Modeled Elements.
6. Click OK.
   The named icon container appears in the top-level (or sublevel) view of the World topology. The named folder representing the container appears in the Navigation panel under the World topology node.
7. (Optional) Click the Edit mode button in the World topology view to move the container icon or annotate this view further.

To populate a Room container view with modeled devices:

1. Go to the Universe topology view and copy the modeled devices that you want to display in a World topology view.
2. In the World topology view, navigate to a room container-type view.
3. In the room container-type view, paste the modeled devices.
4. Move the modeled devices to the desired location within this view.

   NOTE
   You cannot paste the same model into two different room containers. For example, you try to paste these same models into a different room container. You are asked whether you want to move them to the new room container or to keep them in the original room container.
