The devices and the relationships among them change frequently in virtual environments. Maintaining accurate and timely data about your virtual environment in DX NetOps Spectrum is challenging. For example, when a Huawei SingleCLOUD virtual machine is removed, DX NetOps Spectrum knows to remove the corresponding device models from Virtual Host Manager in the Navigation panel. However, should DX NetOps Spectrum keep or delete the model? You can select settings to control model deletion.

> **WARNING**
> When models are deleted, all notes or other customizations on those models are lost. You can disable this option if your models are likely to be recreated in your Huawei SingleCLOUD environment later.

Follow these steps:

1. Click the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Click the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, Huawei SingleCLOUD Discovery subview.
   Configurable Discovery options appear.
4. Click Set in the 'Allow Device Model Deletes During Huawei SingleCLOUD Discovery' field and select one of the following options:
   - **Yes**
     (Default) Deletes the Virtual Host Manager models that correspond to entities no longer managed in your Huawei SingleCLOUD environment.
   - **No**
     Places Virtual Host Manager models in the LostFound container if their corresponding entity is no longer managed by your Huawei SingleCLOUD environment, but the models are not deleted from DX NetOps Spectrum.

     > **NOTE**
     > Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

Your setting is saved, and device models are handled accordingly after the device is deleted from your Huawei SingleCLOUD environment.

Configure Model Searches Across Secure Domains (Huawei SingleCLOUD)

Rather than creating new models, Huawei SingleCLOUD Discovery attempts to locate models in the SpectroSERVER. In an environment with Secure Domain Manager deployed, Huawei SingleCLOUD Discovery searches for models within the same secure domain as your Huawei SingleCLOUD Manager. This domain is the "local" domain. However, some of your devices can exist within a different secure domain. In this case, you can configure Huawei SingleCLOUD Discovery to search all secure domains for existing models.

Follow these steps:

1. Click the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Click the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, Huawei SingleCLOUD Discovery subview.
   Configurable Discovery options appear.
4. Click Set in the 'Search for Existing Models' field and select from the following options:
   - **In Huawei SingleCLOUD Manager's Secure Domain**
     (Default) Searches for models within the same secure domain as the Huawei SingleCLOUD Manager server.
   - **In All Secure Domains**
     Searches for models within all secure domains managed by the SpectroSERVER. Select this option only in the following situations:

- All devices have unique IP addresses
- When secure domains are used for security purposes or to isolate network traffic

  NOTE
  Do not select this option for a NAT environment.

Your setting is saved, and Huawei SingleCLOUD Discovery searches for existing models in DX NetOps Spectrum according to your selection. If duplicate models (that is, models that share the same IP address) exist in multiple secure domains, Virtual Host Manager does the following:

– Selects the model in the local secure domain, if available.
– If a duplicate model does not exist in the local domain, Virtual Host Manager randomly selects a model from another secure domain.

In both cases, Virtual Host Manager generates a minor alarm for the duplicate IP addresses on the Huawei SingleCLOUD Manager model.

Manage Deletion of SNMP-Enabled Huawei SingleCLOUD Models

By default, SNMP-enabled devices are deleted from DX NetOps Spectrum when the following items are deleted:

- Huawei SingleCLOUD folder in the Explorer tab
- Huawei SingleCLOUD CAMM Presenter model
- Huawei SingleCLOUD Manager model

SNMP-enabled device models can include significant customizations that you want to retain. You can adjust your settings to avoid deleting these models. They can be placed into the LostFound container for later use.

Follow these steps:

1. Click the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Click the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, Huawei SingleCLOUD Discovery subview.
   Configurable Discovery options appear.
4. Click Set in the ‘Retain SNMP-enabled Virtual Machines During Huawei SingleCLOUD Manager Deletion' field and select one of the following options:
   – **Yes**
     Retains SNMP-enabled virtual machine models in the LostFound container when their Huawei SingleCLOUD folder, Huawei SingleCLOUD CAMM Presenter model, or Huawei SingleCLOUD Manager model is deleted.

     NOTE
     Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

   – **No**
     (Default) Deletes all Huawei SingleCLOUD models when their Huawei SingleCLOUD folder, Huawei SingleCLOUD CAMM Presenter model, or Huawei SingleCLOUD Manager model is deleted.

Your setting is saved, and SNMP-enabled device models are handled accordingly when the Huawei SingleCLOUD folder, Huawei SingleCLOUD CAMM Presenter model, or Huawei SingleCLOUD Manager model is deleted.

Configure SNMP Modeling Preferences (Huawei SingleCLOUD)

SNMP-capable devices support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. By default, Huawei SingleCLOUD Discovery creates Huawei SingleCLOUD virtual machines as VHM models. You can later upgrade them to SNMP models. However, you can also configure Huawei SingleCLOUD Discovery to model all new SNMP-capable devices as SNMP models. Although

Huawei SingleCLOUD Discovery may take longer to complete, initially modeling these as SNMP models spares you from manually upgrading these models later.

> **WARNING**
> Enable SNMP modeling *before* modeling Huawei SingleCLOUD components. If you model the Huawei SingleCLOUD components first, any child models are created as VHM models, which must be manually upgraded to SNMP models.

Follow these steps:

1. Click the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Click the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, Huawei SingleCLOUD Discovery, SNMP Discovery subview.
4. Click Set in the 'Discover SNMP-Capable Devices' field and select from the following options:
   - **Yes**
     Enables SNMP modeling during Huawei SingleCLOUD Discovery. Only devices that meet the criteria in the SNMP Discovery subview text are modeled as SNMP devices. Applies to *new* models only.
   - **No**
     (Default) Models all new devices found during Huawei SingleCLOUD Discovery as VHM models. You can manually upgrade these models to SNMP models later.

   Your setting is saved and new devices are modeled in Virtual Host Manager per your selection.

Discover and Model Your Huawei SingleCLOUD Environment

To monitor your virtual environment, you must discover and model your virtual entities -- Huawei SingleCLOUD Managers, Clouds, Hosts, and Virtual Machines. Modeling these entities in Virtual Host Manager lets you view your complete network topology in one tool, showing the relationships between your physical and virtual components.

The main steps for modeling your virtual environment are as follows:

1. Run a standard Discovery.
   The purpose of this Discovery is to model the upstream routers and switches before Huawei SingleCLOUD Discovery runs. When modeling these entities, be sure that your modeling options are set correctly to support Virtual Host Manager.
2. Define Huawei SingleCLOUD Managers.
   This step discovers and models the virtual IP addresses that CAMM uses to communicate with Huawei SingleCLOUD GalaX, the management application for the Huawei SingleCLOUD virtual platform. DX NetOps Spectrum uses these models to retrieve information about the Huawei SingleCLOUD architecture and its virtual machines.
3. Let Huawei SingleCLOUD Discovery run.
   When you model the Huawei SingleCLOUD Manager, Huawei SingleCLOUD Discovery begins automatically, discovering and modeling the virtual entities in your Huawei SingleCLOUD environment.
4. (Optional) Add SNMP Capabilities to VHM Models.
   If you modeled Huawei SingleCLOUD entities as VHM models. you can upgrade them to SNMP models.
5. (Optional) Move a Huawei SingleCLOUD Host to a Different Huawei SingleCLOUD GalaX.
   When moving a Huawei SingleCLOUD Host from management by one Huawei SingleCLOUD GalaX to another, steps should be performed in a certain order to accurately reflect the changes in the modeled DX NetOps Spectrum environment.

Each of these steps is described in detail in the following sections.

Run Discovery (Huawei SingleCLOUD)

To accurately reflect your complete Huawei SingleCLOUD environment, run standard DX NetOps Spectrum Discovery to locate any connecting devices. Upstream routers and switches are modeled so that later connections from the virtual entities can be established.

NOTE
Only an administrator performs this task.

Follow these steps:

1. Open the Discovery console.

   NOTE
   Before modeling, be sure that you know the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port.
2. In the Navigation panel. click Creates a new configuration icon  .
   The Configuration dialog opens.
3. Specify a name and location for the new configuration, and click OK.
   The Configuration dialog closes.
4. Enter individual IP addresses or the beginning and ending IP addresses in the IP/Host Name Boundary List fields and click Add.

   NOTE
   Be sure that the range of IP addresses includes all the interconnecting switches and routers.
5. Configure your Modeling Options as follows:
   a. Select the 'Discover and automatically model to CA Spectrum' option.
   b. Click the Modeling Options button.
      The Modeling Configuration dialog opens.
   c. Click the Protocol Options button.
      The Protocol Options dialog opens.
   d. Select the ARP Tables for Pingables option, and click OK.
      The Protocol Options dialog closes.
   e. Click OK to close the Modeling Configuration dialog.
6. (Optional) Click the Advanced Options button in the Advanced Options group, add your nonstandard SNMP ports (such as the CAMM port), and click OK.
7. Enter any additional values in the Discovery console, and click Discover.
   Models are created and added to your network topology in DX NetOps Spectrum for the switches and routers that connect your Huawei SingleCLOUD entities to your network.

Define Huawei SingleCLOUD Managers

After the Huawei SingleCLOUD CAMM Presenter has been defined and you have modeled your connecting devices, you can model and discover your Huawei SingleCLOUD Managers. The successful creation of the Huawei SingleCLOUD Manager model automatically triggers Huawei SingleCLOUD Discovery.

Follow these steps:

1. Select the Huawei SingleCLOUD CAMM Presenter in the Huawei SingleCLOUD folder in the Virtual Host Manager hierarchy in the Explorer tab in the Navigation panel.
   The Component Detail panel displays information for the CAMM Presenter.
2. In the Information tab in the Component Detail panel, expand the Huawei SingleCLOUD Managers subview.
   The Huawei SingleCLOUD Managers table appears.
3. Click Add.

The 'Create Model Of Type HuaweiSCManager' dialog appears.

4. Enter the information for your Huawei SingleCLOUD Manager, and click OK. Notice the following field:
   – **Network Address**
     Enter the virtual IP address used by the CAMM Presenter to communicate with Huawei SingleCLOUD GalaX.

     WARNING
     This value should not be the same as the primary IP address of the device or virtual machine where the CAMM Presenter is installed.

   A Huawei SingleCLOUD Manager model is created and appears in the table. Information about your Huawei SingleCLOUD environment comes from the Huawei SingleCLOUD Manager. When this model is created, Huawei SingleCLOUD Discovery begins.

Huawei SingleCLOUD Discovery

Huawei SingleCLOUD Discovery is a specialized discovery process that gathers detailed information about your virtual environment. The purpose of Discovery is to discover and model the virtual entities in the Huawei SingleCLOUD platform. Understanding how Huawei SingleCLOUD Discovery works reinforces the importance of installing and modeling the various components of Virtual Host Manager properly.

A key benefit of Huawei SingleCLOUD Discovery is that it runs automatically in the background, continually updating virtual environment data in DX NetOps Spectrum. Because of this automated capability, portions of Huawei SingleCLOUD Discovery have already occurred in previous steps. The following description explains the Huawei SingleCLOUD Discovery in its entirety and is provided for reference. No action is required.

The Huawei SingleCLOUD Discovery process works as follows:

1. Immediately after CAMM and the Huawei SingleCLOUD Device Pack are installed correctly, the CAMM Engine starts communicating with Huawei SingleCLOUD GalaX. Information is processed by the CAMM Presenter and is made available to DX NetOps Spectrum.

   WARNING
   CA Mediation Manager and the Huawei SingleCLOUD Device Pack must be installed and configured so that DX NetOps Spectrum, CAMM, and Huawei SingleCLOUD GalaX can communicate. If they cannot, Huawei SingleCLOUD Discovery cannot run.
2. During DX NetOps Spectrum Discovery, DX NetOps Spectrum creates models for connecting devices so that later connections from the virtual entities can be established.
3. Huawei SingleCLOUD CAMM Presenter and Huawei SingleCLOUD Manager models are created. Creation of the Huawei SingleCLOUD Manager enables DX NetOps Spectrum to handle communication between DX NetOps Spectrum and CAMM.
4. The Huawei SingleCLOUD Manager polls CAMM to gather information about the Huawei SingleCLOUD environment, which was gathered in Step 1.
5. DX NetOps Spectrum begins Huawei SingleCLOUD Discovery. DX NetOps Spectrum uses this information to update modeling in the DX NetOps Spectrum Topology tab and the Virtual Host Manager hierarchy in the Navigation panel, as follows:
   a. If you enable SNMP Discovery before Step 2, Virtual Host Manager Discovery creates SNMP models for all new SNMP-capable models that meet the SNMP Discovery criteria.

      NOTE
      By default, SNMP Discovery is disabled during Huawei SingleCLOUD Discovery.
   b. VHM models are created for the remaining non-SNMP Huawei SingleCLOUD entities.

NOTE
In a virtual environment, devices on separate Huawei SingleCLOUD Hosts can have the same IP or MAC address. In this case, DX NetOps Spectrum creates duplicate models for each occurrence of an IP address or MAC address.

6. Huawei SingleCLOUD Discovery repeats this process at each regularly scheduled Huawei SingleCLOUD Manager polling interval.

Add SNMP Capabilities to VHM Models (Huawei SingleCLOUD)

SNMP-capable devices support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. When an SNMP agent is not available or SNMP Discovery is disabled, Virtual Host Manager creates Huawei SingleCLOUD entities as VHM models.

Later, you can install an SNMP agent on any Huawei SingleCLOUD Host or virtual machine and upgrade its modeling in DX NetOps Spectrum. Options for upgrading to SNMP models are as follows:

- Upgrade only selected devices -- This method works quickly when you have a small selection of models to upgrade. The VHM models are deleted first. One drawback of this method is that after DX NetOps Spectrum deletes the models, you must wait for the next Huawei SingleCLOUD Discovery to create the new SNMP models and place them in Virtual Host Manager. Knowledge of the IP addresses for the models to upgrade is required.
- Upgrade all SNMP-capable VHM models -- This method upgrades models in batch, and this method is preferred when upgrading Virtual Host Manager to a new release. Knowledge of the IP addresses of individual models is not required. Another advantage is that after DX NetOps Spectrum deletes the VHM models, the upgraded SNMP models are immediately placed in the Virtual Host Manager hierarchy without waiting for the next polling cycle. Therefore, Virtual Host Manager manages the models more quickly.
  One drawback of this method is that it can take a long time to complete. The time required to complete this upgrade depends on how many community strings and SNMP ports Virtual Host Manager must search when locating SNMP-capable devices.

  NOTE
  Virtual Host Manager attempts to identify SNMP agents on powered-up pingable devices only.

  WARNING
  When models are deleted, all notes or other customizations on those models are lost.

Upgrade Selected VHM Models to SNMP Models (Huawei SingleCLOUD)

When an SNMP agent is not available or SNMP Discovery is disabled during Huawei SingleCLOUD Discovery, Virtual Host Manager creates Huawei SingleCLOUD Hosts and Virtual Machines as VHM models. Later, you can install an SNMP agent on these devices and upgrade their modeling in DX NetOps Spectrum. You must know the IP addresses for the device models to upgrade. Manually selecting models to upgrade works quickly, but all notes or customizations on these models are lost during the upgrade.

Follow these steps:

1. Deploy or enable an SNMP agent on the device, if required.
2. Model the device again using one of the following methods:
   – DX NetOps Spectrum Discovery
   – Model individual devices by IP address

   When the new SNMP-capable model is created, DX NetOps Spectrum removes the previous model from Virtual Host Manager and deletes it. At the next Huawei SingleCLOUD Manager polling cycle, DX NetOps Spectrum adds the SNMP-capable model to Virtual Host Manager in the Navigation panel.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Upgrade All VHM Models to SNMP Models (Huawei SingleCLOUD)

When an SNMP agent is not available or SNMP Discovery is disabled during Huawei SingleCLOUD Discovery, Virtual Host Manager creates Huawei SingleCLOUD Hosts and Virtual Machines as VHM models. Later, you can install an SNMP agent on these devices and upgrade their modeling in DX NetOps Spectrum. When upgrading in batch, DX NetOps Spectrum searches your VHM models, and locates SNMP-capable devices. Then DX NetOps Spectrum converts these to SNMP models. This method can take a long time to complete, depending on how many community strings and ports Virtual Host Manager must search.

Follow these steps:

1. Deploy or enable an SNMP agent on your devices, as required.
2. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
3. Select the Huawei SingleCLOUD Manager model in the Navigation panel that manages the models to upgrade.
4. Click the Information tab.
5. Expand the Huawei SingleCLOUD Manager, DX NetOps Spectrum Modeling Control subview.
6. Click the Upgrade ICMP-Only Devices button.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Virtual Host Manager searches for VHM models that are managed by the Huawei SingleCLOUD Manager. Virtual Host Manager upgrades the ICMP-only devices that meet the criteria for SNMP devices and places them within the Virtual Host Manager hierarchy.

Move a Huawei SingleCLOUD Host to a Different Huawei SingleCLOUD GalaX

Moving a Huawei SingleCLOUD Host from management by one Huawei SingleCLOUD GalaX to another can cause problems with DX NetOps Spectrum modeling when both Huawei SingleCLOUD Managers are modeled on the same SpectroSERVER.

Some possible symptoms of these modeling problems are as follows:

- DX NetOps Spectrum deletes the models associated with the host but does not recreate them after the move.
- False Proxy Lost alarms are created and remain, even though the new managing Huawei SingleCLOUD GalaX can contact the host and all hosted virtual machines.

To avoid these problems, perform the steps to move your host and reflect the changes in your modeled DX NetOps Spectrum environment in the correct order, as follows.

Follow these steps:

1. (Optional) Change the 'Allow Device Model Deletes During Huawei SingleCLOUD Discovery' option to No.

   NOTE
   Perform this step only if both the originating and destination Huawei SingleCLOUD Managers are modeled in the same SpectroSERVER. Setting this option to No keeps the existing Huawei SingleCLOUD Host, CNA FIP, and Virtual Machine models from being deleted when they become unmanaged by the first Huawei SingleCLOUD GalaX. Therefore, customizations or historical details for the models are preserved and available after the move.
2. Use Huawei SingleCLOUD GalaX to remove the host from management.
3. Wait for Virtual Host Manager to reflect the changes in the Navigation panel.
4. Use the destination Huawei SingleCLOUD GalaX to add management of the host.

NOTE
Virtual Host Manager is not DSS aware. Therefore, when moving the host to a Huawei SingleCLOUD GalaX managed on a different SpectroSERVER, a new set of models are created to represent the host, CNA FIP, and virtual machines.

5. (Optional) Change the 'Allow Device Model Deletes During Huawei SingleCLOUD Discovery' option back to Yes. The host is successfully moved from management by one Huawei SingleCLOUD GalaX to another and accurately reflected in the DX NetOps Spectrum modeled environment.

Viewing Your Huawei SingleCLOUD Virtual Environment

This section describes concepts for viewing your Huawei SingleCLOUD virtual environment. The basic steps are no different from the standard DX NetOps Spectrum procedures. However, this section describes conceptual differences and details that only apply to the Huawei SingleCLOUD platform.

Viewing Your Huawei SingleCLOUD Virtual Network

On the Explorer tab under the Virtual Host Manager node, the expanded Huawei SingleCLOUD folder displays a hierarchical tree structure that helps you visualize the logical organization of your managed Huawei SingleCLOUD environment.

Using this information, you can see how resources are shared across your Huawei SingleCLOUD Managers, which can help you identify opportunities to reorganize and optimize your virtual environment. This hierarchy also provides a quick way to validate the appropriate status of allocated resources in your cloud architecture, monitor performance, and troubleshoot alarms.

Because Virtual Host Manager is not aware of a DSS environment, it is located within a landscape hierarchy. The following diagram shows where Virtual Host Manager appears on the Explorer tab in the Navigation panel and illustrates the Huawei SingleCLOUD hierarchy:

```
[-] <ss> host
    [+] Universe
    [-] Virtual Host Manager
        [-] Huawei SingleCLOUD
            [+] Huawei SingleCLOUD CAMM Presenter 1
            [-] Huawei SingleCLOUD CAMM Presenter 2
                [-] Huawei SingleCLOUD Manager 1
                     [+] Huawei SingleCLOUD Cloud 1
                     [-] Huawei SingleCLOUD Cloud 2
                         [+] Huawei SingleCLOUD Host 1
                         [-] Huawei SingleCLOUD Host 2
                             . Huawei SingleCLOUD CNA FIP
                             . Huawei SingleCLOUD Virtual Machine 1
                             . Huawei SingleCLOUD Virtual Machine 2
                [+] Huawei SingleCLOUD Manager 2
                [+] Huawei SingleCLOUD Manager 3
```

Virtual Host Manager is the root node for the entire virtual environment managed by this SpectroSERVER. Selecting this node in the Navigation panel displays Virtual Host Manager details in the Contents panel. You can view details such as events and alarms related to your virtual environment as a whole.

Directly under Virtual Host Manager, virtual environments are organized within folders that represent the technology with which they are created. In the example hierarchy above, the Huawei SingleCLOUD folder contains the portion of the virtual environment that was created and managed by Huawei SingleCLOUD. In this folder, Virtual Host Manager lists

all CAMM Presenters, Huawei SingleCLOUD Managers, and clouds managed by this SpectroSERVER. Each Huawei SingleCLOUD Manager contains only the portion of the virtual environment that it manages.

The hierarchy represents the logical relationships between the following virtual entities:

- **Huawei SingleCLOUD CAMM Presenter**
  A Huawei SingleCLOUD CAMM Presenter node groups together all of the Huawei SingleCLOUD Managers that it manages. Selecting a CAMM Presenter provides access to the Huawei SingleCLOUD Managers subview, where you define the Huawei SingleCLOUD Managers managed by the Presenter by specifying the virtual IP addresses used to communicate with Huawei SingleCLOUD GalaX. Selecting the CAMM Presenter node also displays events and alarms related to the entities in its managed environment. A Physical Host Down alarm generated on the Huawei SingleCLOUD CAMM Presenter model indicates that all the Huawei SingleCLOUD Managers (virtual IP addresses) it manages have gone down.
- **Huawei SingleCLOUD Manager**
  A Huawei SingleCLOUD Manager represents the virtual IP address used by CAMM to communicate with the Huawei SingleCLOUD GalaX. DX NetOps Spectrum uses the virtual IP address to obtain information from the Huawei SingleCLOUD GalaX about the Huawei SingleCLOUD environment it manages. Selecting a Huawei SingleCLOUD Manager displays information about its managed environment, such as details about the GalaX OMMs, managed clouds, hosts, and virtual machines, including when data in the MIB was updated last. Traps received from the Huawei SingleCLOUD trap service are generated on the Huawei SingleCLOUD Manager model.
- **Huawei SingleCLOUD Cloud**
  A Huawei SingleCLOUD Cloud is the name of the managed cloud as defined in the Huawei SingleCLOUD platform. Selecting a Huawei SingleCLOUD Cloud displays details about the cloud, including:
  – Cloud type (public or private).
  – MIB-related status information, including when data for the cloud was updated last and how much time is expected between updates.

  In the hierarchy, beneath each cloud are the Huawei SingleCLOUD Hosts associated with the cloud.
- **Huawei SingleCLOUD Host**
  A Huawei SingleCLOUD Host is a CNA that hosts virtual machines. In the hierarchy, beneath each host are the CNA FIP and the virtual machines it manages. A Huawei SingleCLOUD Host can be part of a public or private cloud. Selecting the Huawei SingleCLOUD Host displays detailed host information including:
  – Cloud type (public or private) that the host is a part of.
  – Resources consumed by the CNA process, such as storage, CPU, and memory utilization.
  – Geographical information of the host for quick physical location during fault resolution.
  – MIB-related status information, including when data for the host was updated last and how much time is expected between updates.

  NOTE
  Available host information differs depending on if the host is part of a public or private cloud. The cloud type is identified in the Host Information, CNA, Properties subview.
- **Huawei SingleCLOUD CNA FIP**
  The Huawei SingleCLOUD CNA FIP is the management interface to the hosted virtual machines. The model appears as a child to its corresponding Huawei SingleCLOUD Host model and is always a leaf node on the Virtual Host Manager hierarchy tree.

  NOTE
  The Huawei SingleCLOUD CNA FIP model is the only Huawei SingleCLOUD model type that does not provide a Virtual Host Manager-specific subview on the Information tab.
- **Huawei SingleCLOUD Virtual Machine**
  A virtual machine is always a leaf node on the Virtual Host Manager hierarchy tree. Selecting a virtual machine displays details including:

- Identifying information, such as IP address and MAC address.
- Resource information, including storage, CPU, and memory utilization.
- MIB-related status information, including when data for the virtual machine was updated last and how much time is expected between updates.

Understanding the Huawei SingleCLOUD Virtual Topology

The Huawei SingleCLOUD Host, CNA FIP, and Virtual Machine models created for your virtual environment are integrated into the topology view. Huawei SingleCLOUD Host models automatically group their associated CNA FIP and Virtual Machine models. The topology shows how these elements are connected to your physical network entities.

The following example shows how these models can appear on the Explorer tab in the Navigation panel under the Universe group:

```
[-] Universe
    [-] Huawei SingleCLOUD Host
          .  Huawei SingleCLOUD CNA FIP
          .  Huawei SingleCLOUD Virtual Machine 1
          .  Huawei SingleCLOUD Virtual Machine 2
          .  Huawei SingleCLOUD Virtual Machine 3
```

Selecting one of these models displays these relationships graphically on the Topology tab in the Contents panel.

How the Huawei SingleCLOUD Data is Updated in Virtual Host Manager

During your initial Huawei SingleCLOUD Discovery, DX NetOps Spectrum populates the Virtual Host Manager hierarchy in the Navigation panel with your virtual device models. After DX NetOps Spectrum builds this initial hierarchy, your virtual network configuration can change, and Virtual Host Manager must continually work to keep this information accurate in DX NetOps Spectrum. For example, the following events can change your virtual network configuration:

- Creating or deleting clouds, hosts, or virtual machines
- Moving a virtual machine from one Huawei SingleCLOUD host to another

To keep your information accurate, Virtual Host Manager detects these changes by polling the CAMM Presenter to retrieve information about the virtual environment from the CAMM MIB. Accordingly, your virtual network configuration is updated in DX NetOps Spectrum at each polling cycle. Because of the communication with Huawei SingleCLOUD GalaX, DX NetOps Spectrum is aware of spontaneous network configuration changes (such as migrations and host outages), which are quickly reflected in OneClick and factored into the root cause analysis.

When DX NetOps Spectrum detects a change in your virtual network configuration, DX NetOps Spectrum performs the following tasks:

- Updates the placement of your virtual device models in the Virtual Host Manager hierarchy of the Navigation panel
- *Automatically* rediscovers connections to the affected models and associates them with the correct Huawei SingleCLOUD Host in the Universe topology

  WARNING
  To reestablish connections to your virtual models correctly, all interconnecting routers and switches in your physical network must be modeled. If these models do not exist before connections to your virtual devices are rediscovered, DX NetOps Spectrum cannot resolve those connections and display the information correctly in the Universe topology view.

In addition to polling-based events, DX NetOps Spectrum also supports traps from the Huawei SingleCLOUD trap service and generates corresponding events. By reviewing the event log, you can find out when configuration changes occur, such as when a virtual machine is created or migrated.

CAMM MIB Updates

DX NetOps Spectrum retrieves information about the Huawei SingleCLOUD environment from the CAMM MIB. To keep the modeling in DX NetOps Spectrum accurate, the data in the MIB must be up-to-date.

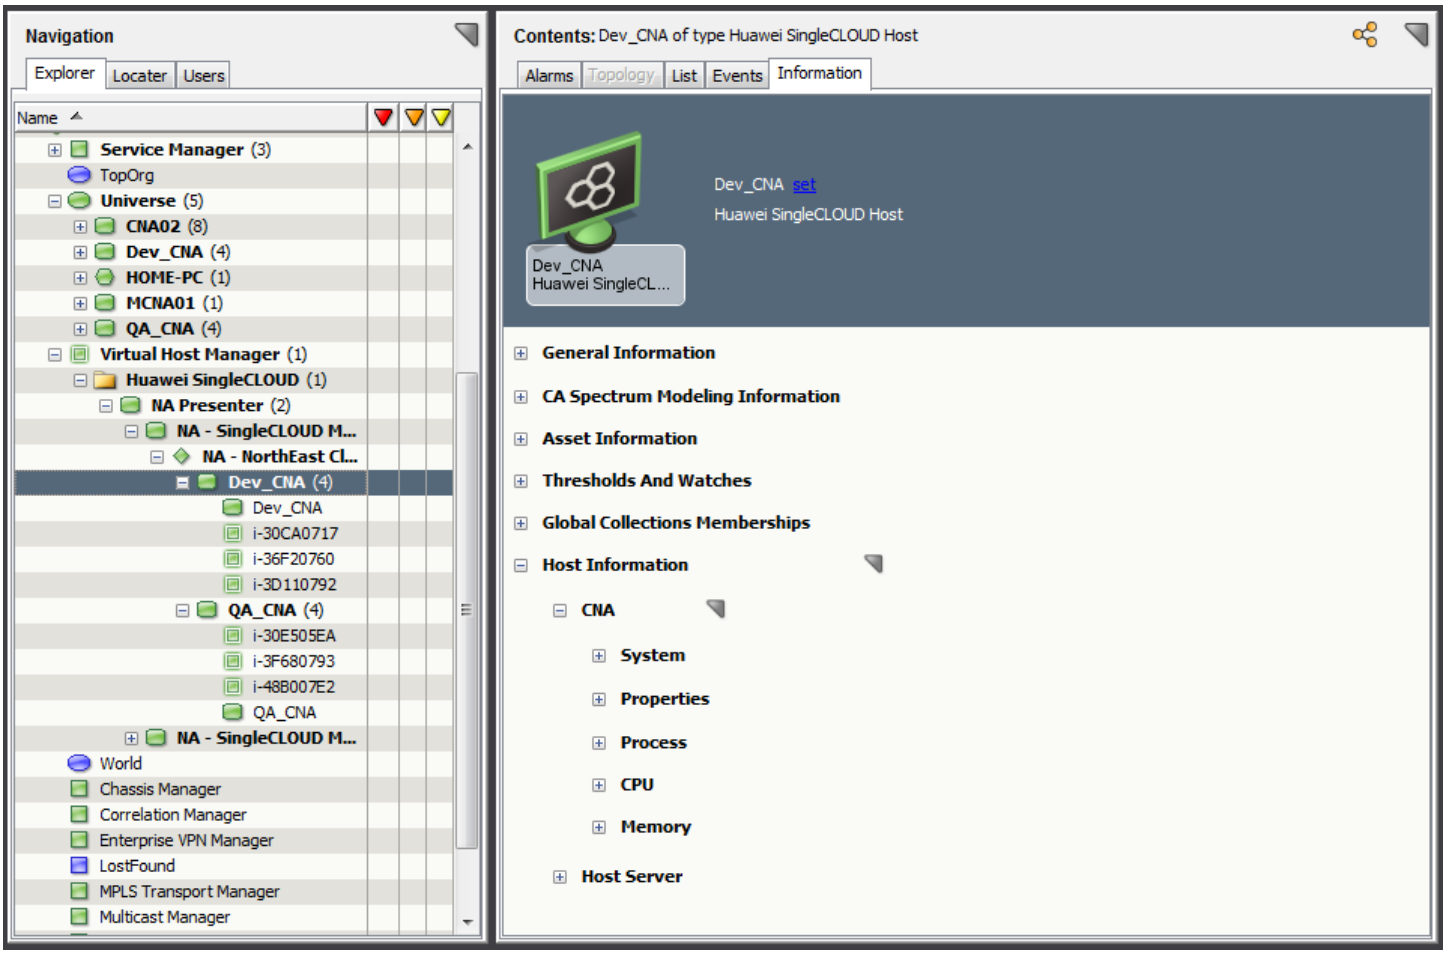
CAMM obtains data from Huawei SingleCLOUD GalaX and updates the MIB according to a configured poll rate in the CAMM Engine. DX NetOps Spectrum uses SNMP to retrieve data from the MIB according to the poll interval specified on the Huawei SingleCLOUD Manager model.

You can determine when CAMM last updated the MIB and when it is expected to be updated again by using the custom subviews for various Huawei SingleCLOUD entity models, where the following MIB-related status information fields are provided:

- **Last Updated**
  Displays when the MIB was last updated. This timestamp value is updated by CAMM when information about the respective entity is obtained from Huawei SingleCLOUD GalaX. You can use this value to determine how current the MIB information for the entity is.
- **Expected Update Delta (s)**
  Displays the expected amount of time between MIB updates, in seconds. If a host or virtual machine has not been updated within the expected amount of time, a Proxy Lost alarm is generated to indicate that updated information cannot be obtained for the entity.

Custom Subviews

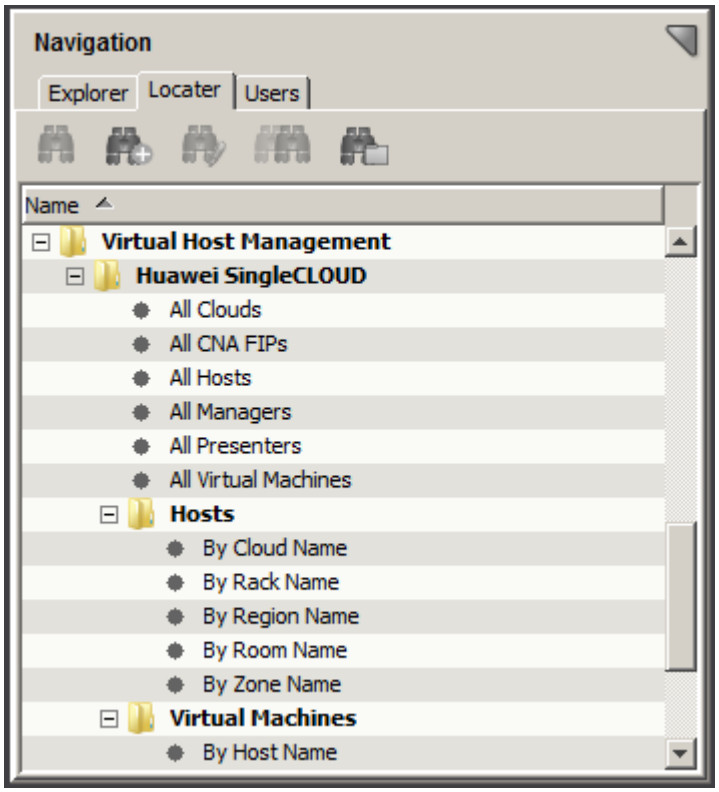
Your Virtual Host Manager models collectively provide information about your virtual environment. Individually, each model provides unique information or configuration settings, depending on the virtual entity type it represents. Custom subviews appear on the Information tab in the Contents panel. These subviews can contain real-time data, such as CPU status or memory utilization. For example, the custom subview for a Huawei SingleCLOUD Host model is the Host Information subview, which provides details specific to a host, as shown:



NOTE
The Huawei SingleCLOUD Manager model provides combined information for all virtual devices managed by the Huawei SingleCLOUD Manager. Selecting the Huawei SingleCLOUD Manager model in the Navigation panel displays unique information, such as about the Huawei SingleCLOUD GalaX OMMs, as well as combined information about all Huawei SingleCLOUD clouds, hosts, and virtual machines it manages. This information contains some of the same data that is displayed on the Information tab for each individual entity model. The combined view in the Huawei SingleCLOUD Manager model can provide a good overview about all of the virtual entities it manages.

Locater Tab for Huawei SingleCLOUD Searches

In addition to viewing details about your virtual environment on the Explorer tab, you can also use the Locater tab to run preconfigured searches. The search options are grouped under the Virtual Host Management, Huawei SingleCLOUD folder on the Locater tab, as shown:



These detailed searches can help you investigate information related to Huawei SingleCLOUD entities that have been modeled in the DX NetOps Spectrum database.

NOTE
Although Virtual Host Manager is not DSS aware, these preconfigured searches let you select multiple landscapes to search in the search parameters.

NOTE
The following types of searches are provided for Huawei SingleCLOUD:

- **Huawei SingleCLOUD**
  Locates Huawei SingleCLOUD entities that have been modeled in the DX NetOps Spectrum database by model type. These include:
  - All Clouds
  - All CNA FIPs
  - All Hosts
  - All Managers
  - All Presenters
  - All Virtual Machines
- **Hosts**
  Locates Huawei SingleCLOUD Hosts by cloud name or geographic location (rack, region, room, and zone).
- **Virtual Machines**
  Locates all virtual machines that reside on a particular Huawei SingleCLOUD Host.

Deleting Virtual Host Manager Models (Huawei SingleCLOUD)

Models can be deleted from OneClick at any time for various reasons. However, Virtual Host Manager restricts your ability to delete models from the Virtual Host Manager hierarchy in the Navigation panel. To delete models manually, you have the following options:

- Delete the Huawei SingleCLOUD folder, a Huawei SingleCLOUD Presenter model, or a Huawei SingleCLOUD Manager model in Virtual Host Manager
- Remove a virtual entity using Huawei SingleCLOUD GalaX

In Virtual Host Manager, models are sometimes deleted automatically. The following circumstances cause DX NetOps Spectrum to automatically delete Virtual Host Manager models:

- **The Huawei SingleCLOUD folder, a Huawei SingleCLOUD CAMM Presenter model, or a Huawei SingleCLOUD Manager model is deleted**
  If you delete the Huawei SingleCLOUD folder, a Huawei SingleCLOUD CAMM Presenter model, or a Huawei SingleCLOUD Manager model from the Navigation panel, DX NetOps Spectrum deletes all related child models. For the CAMM Presenter model, this includes all virtual IP addresses.
- **An entity is removed from a Huawei SingleCLOUD virtual environment**
  As you delete Huawei SingleCLOUD hosts and virtual machines using Huawei SingleCLOUD GalaX, DX NetOps Spectrum also deletes those models and their child models from Virtual Host Manager.
- **Upgraded models exist.**
  In some cases, a virtual machine is first modeled for Virtual Host Manager without SNMP capabilities. If SNMP capabilities are later added to a VHM model, the previous model is deleted and replaced with the new SNMP-capable model.

  NOTE
  Although the default setting is to delete the models, you can configure Virtual Host Manager to place the Huawei SingleCLOUD Host and Huawei SingleCLOUD Virtual Machine models in the LostFound container when they are removed from Virtual Host Manager. This configuration setting applies only when you remove an entity using Huawei SingleCLOUD GalaX. However, this setting does not apply when you delete the Huawei SingleCLOUD folder, delete a Huawei SingleCLOUD Manager model, or upgrade a VHM model.

Alarms and Fault Isolation for Huawei SingleCLOUD

To alert you to problems within your virtual network, DX NetOps Spectrum generates alarms. Quickly identifying any device faults helps you to maximize system up-time and the reliability of your cloud architecture. Alarms are created by:

- Traps sent from Huawei SingleCLOUD.
- Polling. Alarms are generated for the following conditions:
  - A Huawei SingleCLOUD Manager (proxy) is down or communication is lost.
  - A Huawei SingleCLOUD virtual machine is not running.
  - CAMM has not been updated within the defined poll rate.
  - A virtual machine has moved to a new Huawei SingleCLOUD Host.
  - An unsupported Virtual Host Manager configuration has been encountered.

  Alarms that are generated from polling are described in Fault Management for Huawei SingleCLOUD.

Traps for Huawei SingleCLOUD

Traps are generated by the Huawei SingleCLOUD trap service and identify events related to configuration changes, process status, disk or memory usage, and power supply or fan status, as well as others. Traps are generated on the Huawei SingleCLOUD Manager model and can generate alarms in DX NetOps Spectrum.

This section includes the following topics:

Traps and Alarm Severity for Huawei SingleCLOUD

If a trap is received and generates an alarm, DX NetOps Spectrum uses the value of the “state” varbind passed with the trap to determine the alarm severity. DX NetOps Spectrum maps these Huawei SingleCLOUD states to DX NetOps Spectrum alarm severity, as shown:

Huawei SingleCLOUD State	DX NetOps Spectrum Alarm Severity
0: Warning	Minor (Yellow)
1: Minor	Minor (Yellow)
2: Major	Major (Orange)
3: Critical	Critical (Red)

Supported Traps for Huawei SingleCLOUD

The following tables provide the supported Huawei SingleCLOUD traps and their respective trap types. The value of the OID suffix (the lowest node in the trap OID) indicates the trap type.

OID Suffix	Trap Type
.1	Set
.2	Update
.3	Clear

Trap Name	Trap OID
Config Management Agent Process Abnormal	1.3.6.1.4.1.60001.10.1.10.1000001.6.1 1.3.6.1.4.1.60001.10.1.10.1000001.6.2 1.3.6.1.4.1.60001.10.1.10.1000001.6.3
Occupied Space in the Directory Too High	1.3.6.1.4.1.60001.10.1.15.1000203.6.1 1.3.6.1.4.1.60001.10.1.15.1000203.6.2 1.3.6.1.4.1.60001.10.1.15.1000203.6.3
CNA Node Disk Usage Above the Threshold	1.3.6.1.4.1.60001.10.1.15.1000036.6.1 1.3.6.1.4.1.60001.10.1.15.1000036.6.2 1.3.6.1.4.1.60001.10.1.15.1000036.6.3
Hard Disk Lost	1.3.6.1.4.1.60001.10.1.15.1000202.6.1 1.3.6.1.4.1.60001.10.1.15.1000202.6.2 1.3.6.1.4.1.60001.10.1.15.1000202.6.3
VM MEM Usage Over the Threshold	1.3.6.1.4.1.60001.10.1.15.1000102.6.1 1.3.6.1.4.1.60001.10.1.15.1000102.6.2 1.3.6.1.4.1.60001.10.1.15.1000102.6.3

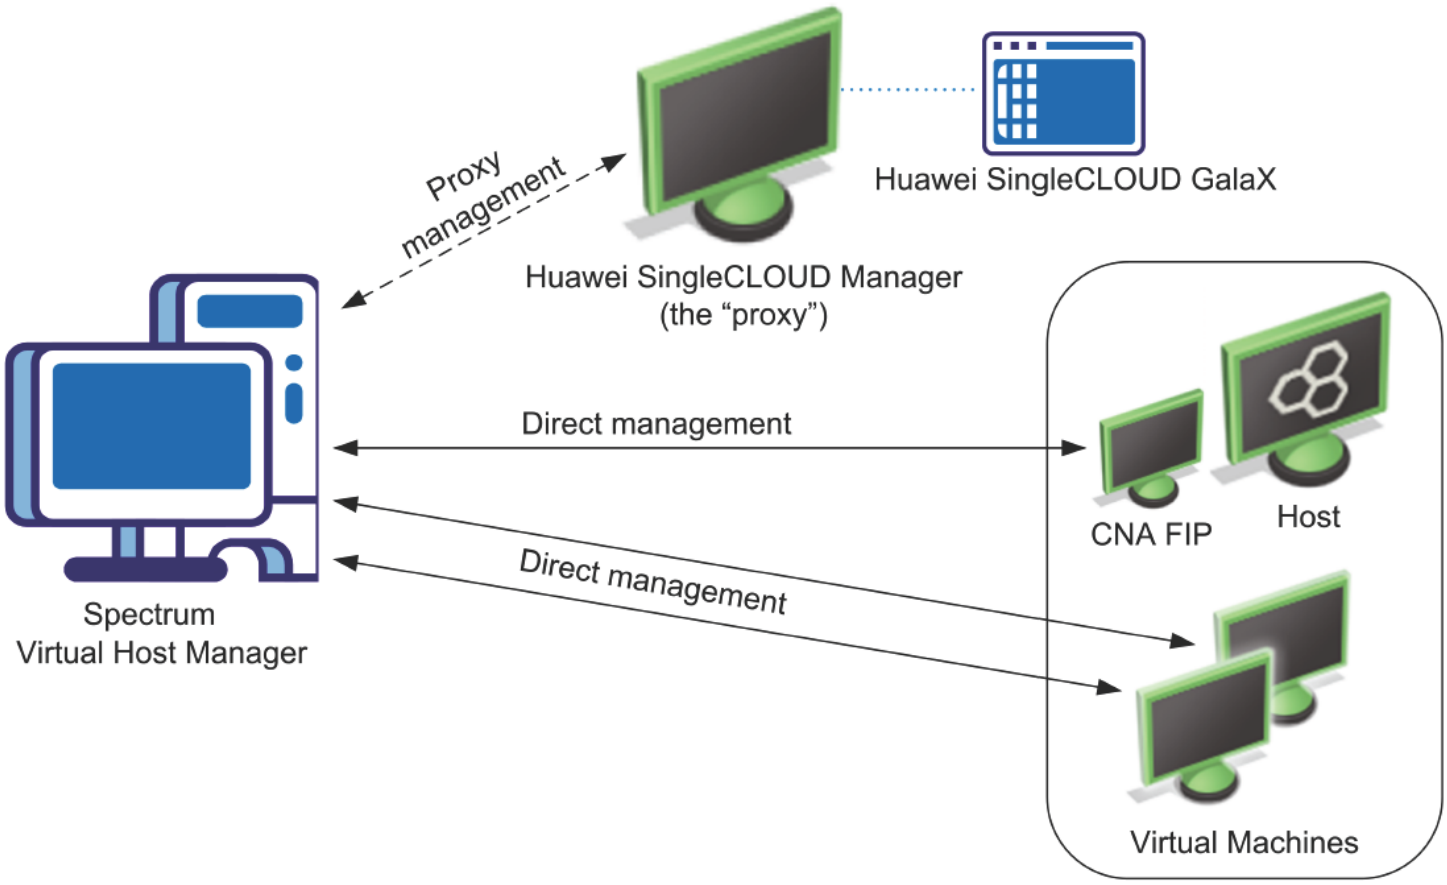
Fan Status Abnormal	1.3.6.1.4.1.60001.10.1.15.1000017.6.1 1.3.6.1.4.1.60001.10.1.15.1000017.6.2 1.3.6.1.4.1.60001.10.1.15.1000017.6.3
Controller Node Hard Disk Usage Above the Threshold	1.3.6.1.4.1.60001.10.1.15.1000015.6.1 1.3.6.1.4.1.60001.10.1.15.1000015.6.2 1.3.6.1.4.1.60001.10.1.15.1000015.6.3
Power Supply Status Abnormal	1.3.6.1.4.1.60001.10.1.15.1000016.6.1 1.3.6.1.4.1.60001.10.1.15.1000016.6.2 1.3.6.1.4.1.60001.10.1.15.1000016.6.3

Fault Management for Huawei SingleCLOUD

The goal of fault isolation is to narrow down the root cause of a networking problem. Finding the root cause can help you to troubleshoot and quickly correct the problem or to correct the problem programmatically with automated scripts. Deciding which device is the root cause of an alarm can be difficult, because problems with a single device can cause several devices in your network to generate events.

For example, losing contact with a Huawei SingleCLOUD Host often means that you have also lost contact with the virtual machines it manages. Therefore, the Huawei SingleCLOUD Host model and all affected virtual machines generate alarms. Using fault isolation techniques, Virtual Host Manager correlates these alarms in an attempt to identify a single root cause.

Virtual networks provide a unique management opportunity because they provide DX NetOps Spectrum an alternate management perspective. That is, DX NetOps Spectrum can gather information through direct contact with your virtual devices or through CAMM, which communicates with Huawei SingleCLOUD GalaX.



This alternate management perspective enhances standard DX NetOps Spectrum fault management in two ways:

- **Enhanced Contact Lost alarms** -- Two sources of information about a device means Virtual Host Manager can pinpoint the cause and more easily correlate events to a single root cause.
- **Proxy Failure alarms** -- Proxy management is the act of managing network devices using an alternate management source in place of or in addition to the primary manager. For example, DX NetOps Spectrum can manage Huawei SingleCLOUD virtual machines by contacting them directly or through CAMM, which obtains data from Huawei SingleCLOUD GalaX. When the Huawei SingleCLOUD Manager loses contact with Huawei SingleCLOUD GalaX or when Huawei SingleCLOUD GalaX loses contact with a virtual device, Virtual Host Manager generates one of the proxy management alarms for each device. These alarms alert you to the fact that *management* of the device through the *proxy* is affected, not the state of the device or direct (SNMP) management.

How Fault Isolation Works when Device Contact is Lost (Huawei SingleCLOUD)

To help you troubleshoot networking problems with your devices, DX NetOps Spectrum uses fault isolation to narrow down the root cause of an alarm. For virtual networks, Virtual Host Manager uses information from direct contact with the device plus information provided by Huawei SingleCLOUD GalaX through CAMM. In many cases, standard DX NetOps Spectrum fault management can pinpoint the root cause. But in special circumstances, the approach for isolating problems in a virtual network goes beyond the standard methods.

The type of fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe fault management situations and how DX NetOps Spectrum isolates the networking error in your virtual network.

Scenario 1: Huawei SingleCLOUD Virtual Machine is not running

In a virtual environment, the virtual management application can provide more details than DX NetOps Spectrum can discover through standard device monitoring. For example, Huawei SingleCLOUD GalaX is aware when a virtual machine changes from the running state to another state.

If a virtual machine is no longer running and DX NetOps Spectrum loses contact with it, but proxy management of the virtual machine is uninterrupted, DX NetOps Spectrum determines the root cause as follows:

1. When DX NetOps Spectrum loses contact with a virtual machine, it generates a Contact Lost alarm.
2. During its next polling cycle, the Huawei SingleCLOUD Manager model polls CAMM, which communicates with Huawei SingleCLOUD GalaX, to gather information about the virtual machine. Because Huawei SingleCLOUD GalaX manages the virtual machines, it can provide a unique view into the possible cause of alarms generated by the virtual machine.
3. If Huawei SingleCLOUD GalaX indicates that the virtual machine is in the not-running mode, it generates a Huawei SingleCLOUD Not Running alarm.

   NOTE
   This alarm is cleared during the poll cycle after which CAMM determines the virtual machine is running again.
4. Virtual Host Manager correlates the Contact Lost alarm to the corresponding Huawei SingleCLOUD Not Running alarm created by DX NetOps Spectrum. Virtual Host Manager makes the Contact Lost alarm appear as a symptom of the Huawei SingleCLOUD Not Running alarm.

Scenario 2: Huawei SingleCLOUD Host is down

If DX NetOps Spectrum loses contact with all virtual machines running on a Huawei SingleCLOUD Host, DX NetOps Spectrum checks the status of the upstream routers and switches. Depending on their status, DX NetOps Spectrum determines the root cause as follows:

- **When all upstream devices for one or more Huawei SingleCLOUD Virtual Machines are unavailable**
  Standard DX NetOps Spectrum fault isolation techniques are used to determine the root cause:
  – A Gateway Unreachable alarm is generated on the Huawei SingleCLOUD Host when *all* upstream connected devices are down.
- **When at least one upstream device is available for every virtual machine connected to the Huawei SingleCLOUD Host**
  DX NetOps Spectrum infers that the Huawei SingleCLOUD Host is the root cause and responds as follows:
  a. All Huawei SingleCLOUD virtual machines, ports, and fanouts that are directly connected to the Huawei SingleCLOUD Host models generate the standard fault isolation alarms.
  b. Virtual Host Manager creates a Physical Host Down alarm for the Huawei SingleCLOUD Host model.
  c. All fault isolation-related alarms that are created for the impacted devices (such as virtual machines, ports, and fanouts) are correlated to the Physical Host Down alarm, making them symptoms of the Physical Host Down alarm. These symptom alarms appear in the Symptoms table on the Impact tab for the Physical Host Down alarm.

     NOTE
     For each Huawei SingleCLOUD Host model, Virtual Host Manager creates a "virtual fault domain." This domain includes the Huawei SingleCLOUD Host, CNA FIP, and Virtual Machines, plus all ports and fanouts directly connected to the Huawei SingleCLOUD Hosts. When the Huawei SingleCLOUD Host generates the Physical Host Down alarm, all standard fault isolation alarms within the domain are correlated to it. Correlating these alarms as symptoms indicates that the Physical Host Down alarm on the Huawei SingleCLOUD Host is the root cause.
  d. All impacted devices are listed in the Management Lost Impact table on the Impact tab for the Physical Host Down alarm.

     NOTE
     Devices that are suppressed do not have a corresponding alarm in the Symptoms table.

For more information about using the Impact tab for alarm information, see Determining Virtual Machines Affected by Host Outages.

e. If all upstream devices for one or more virtual machines go down, DX NetOps Spectrum can no longer reliably state that the fault lies with the Huawei SingleCLOUD Host. DX NetOps Spectrum clears the Physical Host Down alarm and applies the standard DX NetOps Spectrum fault isolation techniques.

How Fault Isolation Works when Proxy Management is Lost (Huawei SingleCLOUD)

Huawei SingleCLOUD GalaX, which is used to create your virtual network, provides DX NetOps Spectrum a unique management opportunity. DX NetOps Spectrum can use the standard methods to contact your virtual devices directly, plus DX NetOps Spectrum can simultaneously gather virtual device information from CAMM with the Huawei SingleCLOUD Device Pack, which communicates with Huawei SingleCLOUD GalaX. In this sense, CAMM is a "proxy" from which DX NetOps Spectrum gathers virtual device information. If DX NetOps Spectrum loses direct contact with a device, it generates alarms. Likewise, if CAMM loses contact with a virtual device (by way of Huawei SingleCLOUD GalaX) or if Virtual Host Manager loses contact with CAMM, Virtual Host Manager generates alarms -- proxy management alarms.

In response, DX NetOps Spectrum attempts to isolate the cause of the proxy management failure. Proxy fault isolation is similar to the standard DX NetOps Spectrum fault isolation, except that these alarms alert you to the fact that *proxy* management of a virtual device is affected. Proxy management fault isolation cannot tell you whether a virtual device is up or down. However, it is important to know when contact through the proxy is lost, because you could be missing important virtual information about a device.

The type of proxy fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe proxy fault management situations and how Virtual Host Manager isolates the networking error in your virtual network.

Scenario 1: Contact between DX NetOps Spectrum and CAMM (Huawei SingleCLOUD Manager) is lost

If DX NetOps Spectrum loses contact with or stops polling the Huawei SingleCLOUD Manager model, DX NetOps Spectrum cannot obtain updated Huawei SingleCLOUD GalaX data about all virtual models managed by that Huawei SingleCLOUD Manager. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. DX NetOps Spectrum generates Proxy Lost alarms for all virtual models managed by that Huawei SingleCLOUD Manager, including Huawei SingleCLOUD Clouds, Hosts, CNA FIPs, and Virtual Machines. DX NetOps Spectrum also generates a separate Manager Unavailable alarm on the Huawei SingleCLOUD Manager model.
2. The Huawei SingleCLOUD alarms are correlated to their corresponding Huawei SingleCLOUD Host model alarm.
3. The Huawei SingleCLOUD Cloud and Host model alarms are correlated to a Proxy Unavailable alarm for the Huawei SingleCLOUD Manager model.
4. This Proxy Unavailable alarm is then correlated to the root cause of the Huawei SingleCLOUD Manager being down. The root cause is typically an alarm generated by standard DX NetOps Spectrum fault management, such as the alarms created for the following situations:
   - Lost management of Huawei SingleCLOUD Manager (that is, a problem occurred with CAMM)
   - Machine contact is lost
   - Huawei SingleCLOUD Manager model is in maintenance mode

Scenario 2: Contact between CAMM and Huawei SingleCLOUD GalaX is lost

If CAMM is not updated within a certain amount of time, the Huawei SingleCLOUD platform data reported by CAMM may not be current. Using a heartbeat indicator and the configured poll rate, DX NetOps Spectrum can identify when a managed Huawei SingleCLOUD entity was last updated.

When a Huawei SingleCLOUD Host or Virtual Machine has not been updated within the configured amount of time, Virtual Host Manager determines that the CAMM is unable to contact Huawei SingleCLOUD GalaX. Proxy Lost alarms are generated on the Huawei SingleCLOUD Host, CNA FIP and Virtual Machine models managed by this Huawei SingleCLOUD Manager. When multiple elements have not been updated, DX NetOps Spectrum correlates these alarms

to the appropriate root cause (for example, multiple virtual machine alarms correlated to a host). In addition, when none of the virtual IPs associated with the CAMM Presenter can be contacted, a Physical Host Down alarm is generated on the Huawei SingleCLOUD CAMM Presenter model. Identifying information for the faulting CAMM Engines and the time since the last successful communication is provided in the alarm text.

Scenario 3: Contact between Huawei SingleCLOUD GalaX and Huawei SingleCLOUD Host is lost

If Huawei SingleCLOUD GalaX loses contact with one of the Huawei SingleCLOUD Hosts it is managing, the proxy data about the host and all hosted virtual devices is lost. To isolate the problem, Virtual Host Manager determines the root cause as follows:

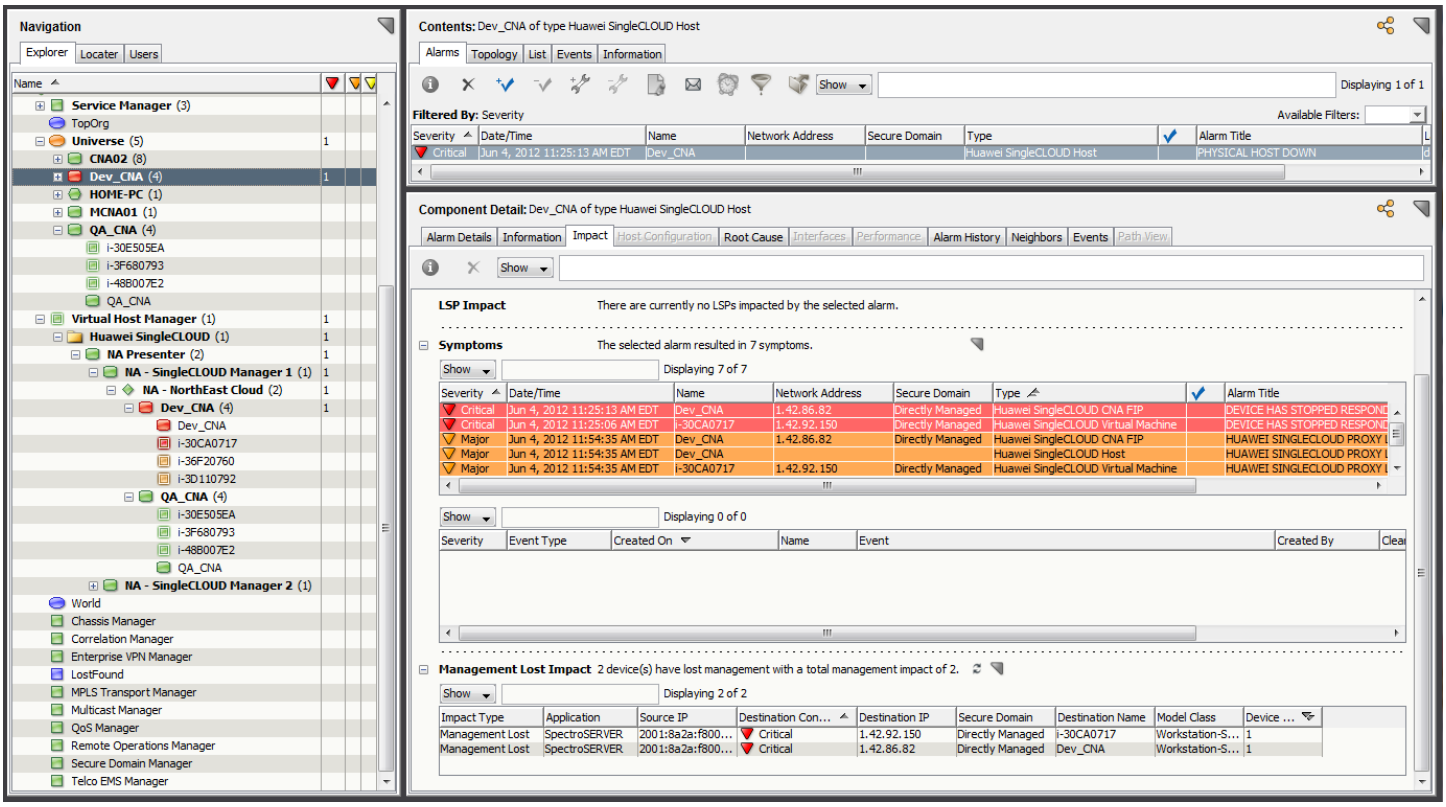
1. A Proxy Lost alarm is generated on the Huawei SingleCLOUD Host, CNA FIP, and all hosted virtual machines.
2. The CNA FIP and virtual machine alarms are correlated to the Proxy Lost alarm for the Huawei SingleCLOUD Host, making these alarms symptoms of the Huawei SingleCLOUD Host alarm. Correlating these alarms as symptoms indicates that the Huawei SingleCLOUD Host alarm is the root cause.
3. If DX NetOps Spectrum also loses contact with the Huawei SingleCLOUD Host and generates a Physical Host Down alarm, the Proxy Lost alarm generated for the Huawei SingleCLOUD Host is correlated to the Physical Host Down alarm. In this case, the Proxy Lost alarm becomes a symptom of the Physical Host Down alarm. Correlating this alarm as a symptom indicates that the Physical Host Down alarm on the Huawei SingleCLOUD Host is the root cause.

Determining Virtual Machines Affected by Host Outages

When contact with a Huawei SingleCLOUD Host is interrupted or the Huawei SingleCLOUD Host goes down, all virtual machines hosted by the Huawei SingleCLOUD Host are affected. Because the Huawei SingleCLOUD Manager cannot communicate with the Huawei SingleCLOUD Host to get usage information, you might not receive alarms for a critical virtual machine hosted on that Huawei SingleCLOUD Host.

To find out if a critical virtual machine is impacted, you can view a list of affected virtual machines on the Impact tab of the alarm, as follows:

- Symptoms subview -- displays all symptom alarms generated by the affected virtual machines
- Management Lost Impact subview -- lists the virtual machines impacted by the alarm



Troubleshooting

This section describes common symptoms or issues that can occur when using Virtual Host Manager and our recommended solution.

Duplicate Models Created After SNMP and vCenter Discovery

Symptom:

After I run the standard DX NetOps Spectrum Discovery on my virtual network and then let Virtual Host Manager run a vCenter Discovery, I get a Duplicate Models alarm for some of my virtual machines. Which model should I delete, and how do I prevent it from happening again?

Solution:

When modeling a virtual environment, a duplicate model can be created when a virtual machine does not have either VMware tools or an SNMP agent installed. The duplicate model is created as follows:

1. DX NetOps Spectrum Discovery models the virtual machine using a pingable model type, because the virtual machine does not have an SNMP agent installed. This model contains an IP address, but it does not contain a MAC address. The upstream router that usually looks up the MAC address for a device is not yet modeled, so the MAC address for the virtual machine cannot be resolved.
2. Virtual Host Manager runs a vCenter Discovery and finds the same virtual machine. Because the virtual machine does not have VMware tools installed, Discovery can identify a MAC address but cannot determine the IP address. Therefore, vCenter Discovery does not recognize it as the existing model created in step 1, so it creates a second model for the virtual machine. This model contains a MAC address but no IP address.

3. When DX NetOps Spectrum finds a model with no IP address, it performs an OS call using the model name to get the IP address. If the virtual machine name in vCenter matches the name returned from the OS, the OS passes the IP address of the virtual machine device to DX NetOps Spectrum. DX NetOps Spectrum sets the IP address in the model created by the vCenter Discovery -- this model now contains both the MAC address and IP address.
4. The Duplicate Model alarm is triggered for each model, because they both have the same IP address.

To correct the problem, delete the virtual machine device model created by the DX NetOps Spectrum Discovery (that is, the model that contains the IP address only) -- *keep the model that has both an IP and MAC address*. Otherwise, the same problem repeats the next vCenter poll cycle. If the delete affects the Virtual Host Manager hierarchy, wait one polling cycle of the vCenter server host, and the modeling is restored.

To avoid this problem when modeling your virtual environment using DX NetOps Spectrum Discovery, verify that the upstream routers for all virtual machines without VMware tools meet one of the following criteria:

- Routers have already been modeled with an SNMP-capable model type
- Routers are included in your Discovery range along with the proper SNMP credentials

By including the upstream routers, DX NetOps Spectrum attempts to resolve the physical address belonging to each host that does not have an SNMP agent.

If you model your virtual environment by modeling your VMware vCenter server by IP address and Discovery creates models without IP addresses, you must manually specify the IP for those devices before running DX NetOps Spectrum Discovery.

Customizing

This section contains information about customizing the product.

Modeling Gateway Toolkit

The DX NetOps Spectrum Modeling Gateway toolkit lets integrators import and export network topology data into and out of DX NetOps Spectrum. The toolkit includes a Document Type Definition (DTD) that defines XML elements and attributes. The toolkit also includes a resource file that defines DX NetOps Spectrum syntax and what information to import or export.

For a topology import, using the DTD elements, you can create an XML file that describes devices, ports, and connections on your network. This XML file can create new topology data in DX NetOps Spectrum, update existing data, or can destroy data that is no longer correct. Additionally, the elements and attributes that are used in the XML syntax can be expanded and customized to suit the needs of most integrations.

The toolkit also lets you use comma-delimited ASCII text files to import Frame Relay or ATM connections. You can also import this connection information using the XML functionality that was mentioned previously.

Once the network topology data exists in DX NetOps Spectrum, you can manage these devices like any other models that are created manually or by Discovery. You can view the results of the import, as well as any diagnostic information about each import.

The Modeling Gateway toolkit also lets you export topology information and configuration settings from DX NetOps Spectrum using an XML file. The information can then be imported into a specified SpectroSERVER through the Modeling Gateway.

Populating DX NetOps Spectrum with dynamic network topology information on an ongoing basis was previously a difficult task. Discovery and manual modeling are not suited to the constant updates necessary in a changing environment. Modeling connectivity using Discovery can also be a challenge with various physical infrastructures, such as those found in these environments:

- Cable MSO (Multi-Service Operator)
- ATM (Asynchronous Transfer Mode)
- Frame Relay
- Wireless Devices

NOTE

When you use the Modeling Gateway with devices located in a Secure Domain, you need to add the attribute details of the secure domain to the import to allow the Modeling Gateway to find models in question and discover the secure domain. Normally, devices can be found with just the device IP.

Example: (Device ip_dnsname="x.x.x.x" secdomain_ipname="y.y.y.y")"

WARNING
When 10.2.1 Modeling Gateway files (containing SNMPv3 profiles) get imported into 10.4.1, then SpectroSERVER crashes and stops responding. As a workaround, users must first upgrade to the 10.2.3 (or later) release to support this scenario.

Modeling Gateway Export and Import Support for World and TopOrg Views

10.3 supports an out of the box approach to export and import xml files via Modeling Gateway for **World** and **Top_Org** models. This support is beneficial for customers moving from 10.3 to any higher version.

NOTE

By default the 'RootContainderToExport' value is '**Universe**'.

To export models under **World** View:

1. In the $SPECROOT/SS-Tools\modelinggatewayresource.xml file, change the RootContainerToExport value to '**World**'.

To export models under **TopOrg** View:

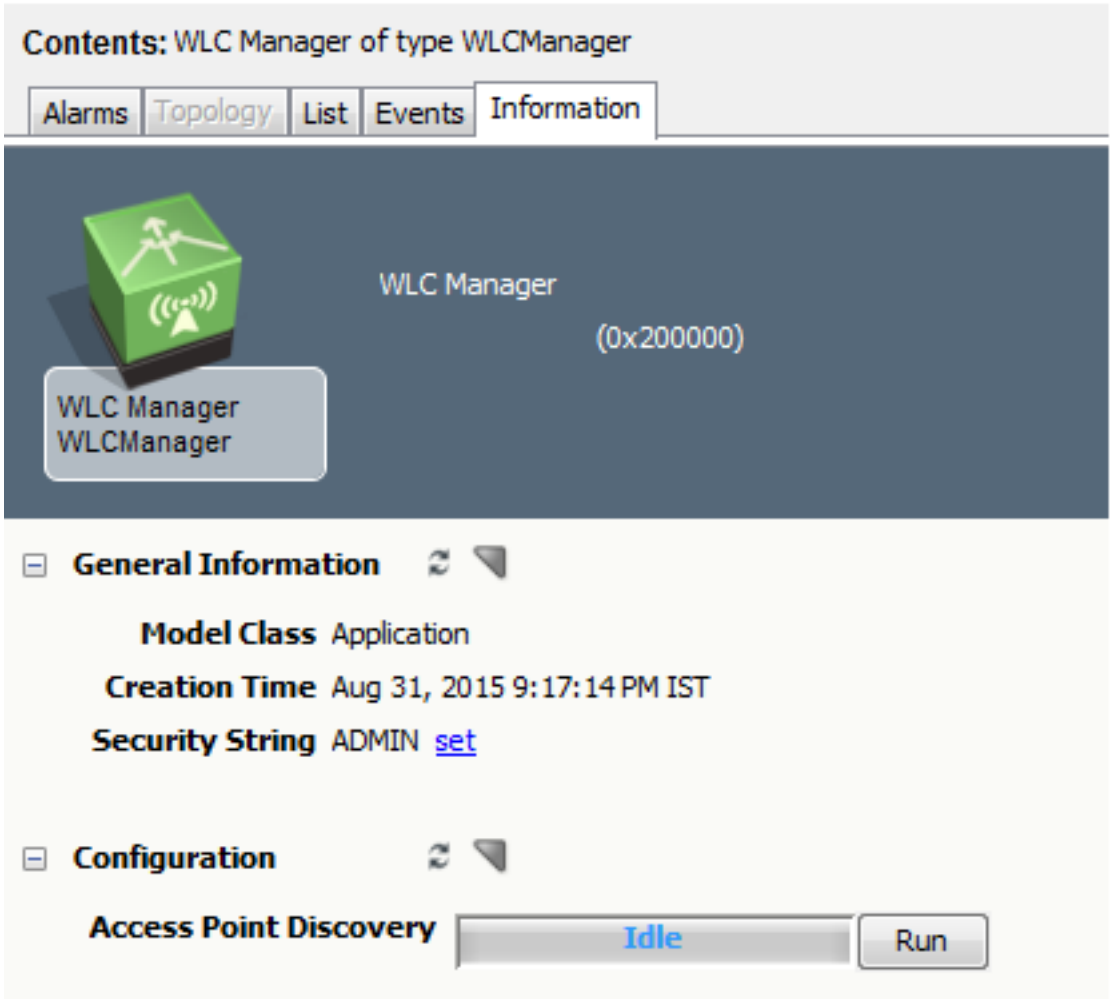
1. In the $SPECROOT/SS-Tools\modelinggatewayresource.xml file, change the RootContainerToExport value to '**Top_Org**'.

Modeling Gateway Support for Wireless Devices

From 10.1, you can import and export topology data and configuration settings for wireless devices from and to DX NetOps Spectrum. However, AccessPoint devices are not supported by the Modeling Gateway Toolkit.

To discover and model AccessPoint devices, follow these steps:

1. Import the relevant comma-delimited ASCII text/ XML file, using the **Modeling Gateway Toolkit**.
2. Navigate to **Explorer View > WLC Manager > Information Tab > Configuration** sub-view **> Access Point Discovery:** and then click **Run.**



All existing access points **(APs)** will be created under their corresponding **WLC Device**(s).

DX NetOps Spectrum Modeling Gateway is an effective solution for these problems.

Modeling Gateway Prerequisites

Before you use the DX NetOps Spectrum Modeling Gateway toolkit, make sure that you:

- Have had significant exposure to DX NetOps Spectrum.
- Read SpectroSERVER and DX NetOps Spectrum Databases Overview .
- Have a working knowledge of XML.
- Understand the concept of a Document Type Definition (DTD).
- Have a detailed understanding of the network topology you are importing.
- Can use UNIX or Windows to navigate through the file system, copy and delete files, as well as, create and edit text files.

Import and Export Architecture

Import Architecture

For an import, during the import integration process you take data from the third-party database and create an input file. Depending on the content, this input file can be an XML file or a comma-delimited ASCII file. The XML input file gives you the widest range of import options and is the main focus of this section. The comma-delimited file lets you create connections for Frame Relay and ATM circuits.

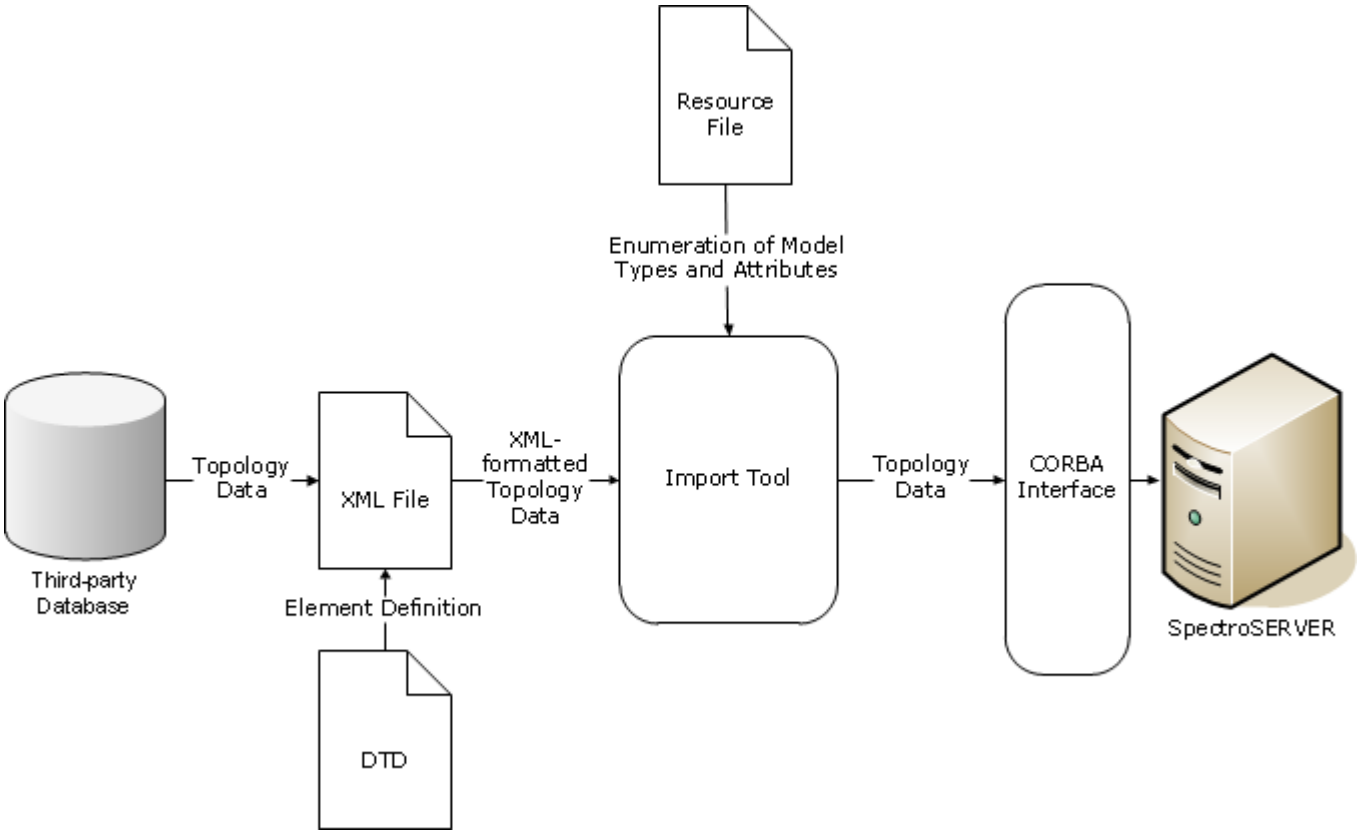
When creating an XML input file, work with the provided Document Type Definition (DTD) file and the .modelinggatewayresource.xml file. The DTD defines the XML elements, attributes, and their associated syntax rules. The .modelinggatewayresource.xml file shows which DX NetOps Spectrum model types and attributes are available for use. This file relates the DX NetOps Spectrum model type names and attribute names with the unique hexadecimal identifier that DX NetOps Spectrum uses for that model type or attribute. The .modelinggatewayresource.xml file can be customized to suit the needs of your specific integration.

Once you create the first input file, it can act as a template for multiple data sets representing the same type of input. For example, you can create an XML file for importing devices and can use this file repeatedly by substituting the device-specific topology data.

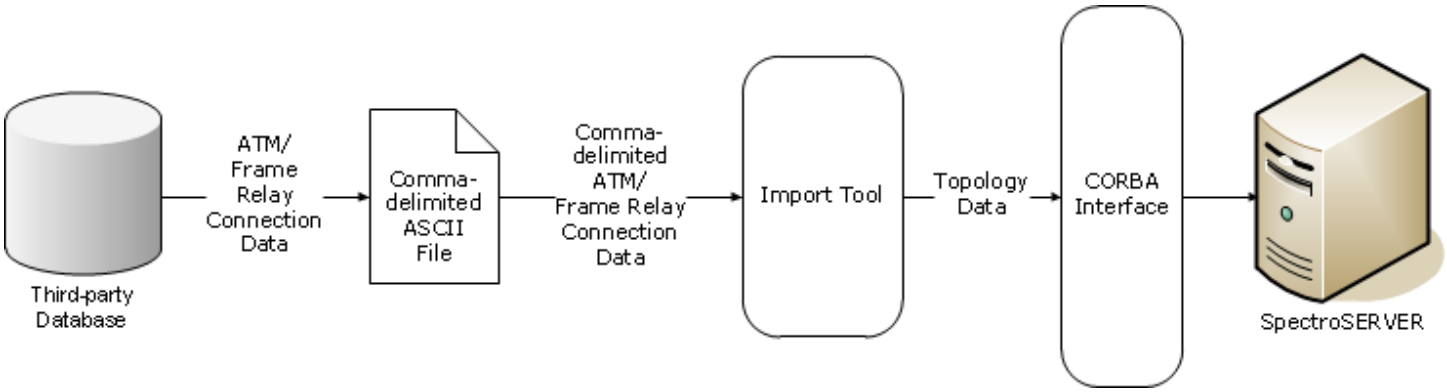
The modelinggateway tool is a command-line utility that reads the network topology information from the input file and sends the data to the SpectroSERVER database. With the data from the XML file, the import tool can create, destroy, and update connections, devices, and container models. The tool can also be used to export data from DX NetOps Spectrum.

The DX NetOps Spectrum Modeling Gateway also provides mechanisms to verify the safety and accuracy of each database import. For example, it can maintain an audit trail that includes a record of each creation, deletion, association, and update made. You can view information about the import within OneClick. DX NetOps Spectrum reports the error by generating an event when any type of critical failure occurs during the import process. All errors and their possible causes are logged in an error log file. You can also turn on a debug log which can help you locate the source of problems or inaccuracies.

The following illustration shows how the Modeling Gateway uses an XML file for importing data. The data flows from the third-party database and is formatted in the XML file using the DTD and .modelinggatewayresource.xml for syntax purposes. The import tool then interprets the XML file and sends data into DX NetOps Spectrum through the DX NetOps Spectrum CORBA interface.



The following illustration shows how the Modeling Gateway uses a comma-delimited ASCII text file to import Frame Relay and ATM connection information.



Export Architecture

For export, using the SpectroSERVER as a resource, Modeling Gateway can export topology and configuration data into an XML file. This XML file can then be integrated with a third-party tool or reimported into another SpectroSERVER. For example, the file can be reimported for a DX NetOps Spectrum partition or landscape handle change.

Spectrum modelling gateway can export Global Collections and Services without any errors even if they have any duplicate names, as the modelling gateway uses model handle to uniquely identify them.

Import Topology Data into the Product

You can import the third-party topology data into DX NetOps Spectrum using Modeling Gateway. Initially, extract the topology data from the third-party database and format the data in an input file.

To import third-party topology data into DX NetOps Spectrum using Modeling Gateway, perform these tasks:

1. Extract Topology Data.
   Extract the network topology data from the third-party database. Since each database system is different, see the documentation for the database you are working with to complete this step.
2. Format the Data in an Input File.
   To format the data for the import tool, create an XML or a comma-delimited input file.
3. (Optional) Move the modelinggateway Tool.

   NOTE
   To run the modelinggateway tool on another server, move the modelinggateway tool and all of its support files to that server. For more information, see Distributed SpectroSERVER Administration .
4. Run the modelinggateway Tool.
   Once the input file is created, use the import tool to send the data into DX NetOps Spectrum.
5. (Optional) Import Comma-delimited Files.
   You can import Frame Relay and ATM connection data from the OneClick interface without the import tool.
6. View Import Information
   Verify the progress and results of the import in OneClick.

   NOTE
   Do not use Modeling Gateway to migrate models from one version of DX NetOps Spectrum to another. The methodology that is used to identify and model an entity can differ between DX NetOps Spectrum versions. Therefore, do not use Modeling Gateway to import any XML files that are exported from a different version of DX NetOps Spectrum.

Format the Data in an Input File

Two types of input files are used to import data using the Modeling Gateway: XML files and comma-delimited files. XML input files can be used to create or destroy models and connections, and update attribute values and connectivity information. The syntax in the DTD provided with the Modeling Gateway defines the elements to be used in the XML input file. Comma-delimited files can only be used to create ATM and Frame Relay connections. The following sections outline how to create each of the types of input files.

XML Input Files

To understand the elements that create an XML input file, be familiar with the process DX NetOps Spectrum uses to model a network infrastructure. The following section provides an overview of this process and discusses how it applies to the XML elements used in an XML input file. If you are comfortable with these concepts, you can skip this section and can go to XML Input File Syntax:

Hierarchical Views

A view in DX NetOps Spectrum is a way to organize data so it can be displayed or manipulated. The hierarchical views represent ways to structure your network data. When structuring your network data in the XML file, you choose from elements that represent each of the hierarchical views. The two types of hierarchical views are Topology and Location.

Topology View

The Topology view is really an abstraction of networking components. When working with this view, you represent the physical or logical components of your network and group these components with logical connectivity in mind. You can also choose to represent connections graphically using pipes that show how devices are connected at the port or device level. In OneClick, this view appears as the Universe topology.

Location View

The Location view organizes your network data by physical location. Using this view, you can depict your network in terms of geography. You can start with your global offices. Then, go right to the wiring closet on each floor of each building in each region where your offices are located. In OneClick, this view appears as the World topology.

NOTE
For more information about the topology views available in OneClick, see the Modeling and Managing Your IT Infrastructure .

Models and Model Types

Numerous model types are predefined in DX NetOps Spectrum. When model types are instantiated in the DX NetOps Spectrum interface to represent a specific network entity, they are referred to as models. The two major categories of model types are:

- Intelligent model types
- Container model types

Intelligent model types can be instantiated to represent actual devices that operate on the network. They have IP and MAC addresses, and DX NetOps Spectrum can communicate directly with these devices using SNMP. Container model types are instantiated into models that are primarily used to group models together.

Models can be grouped based on the type of hierarchical view being used. For example, you can use the Topology view to create a LAN model that groups certain devices on a segment of your network. Or, you can use the Location view to create a Room model that groups the devices together in one room of your building.

A container model can contain other container models, intelligent models, or both, depending on the specific model type. For example, a network container model could contain an intelligent model to represent a router. The network container model could also contain a LAN container model to represent a range of IP addresses. On the other hand, a Building model can only contain container models; for example, a Floor, a Section, or a Room.

The elements in the DTD let you depict your network topology using any of the hierarchical views and their respective container model types. You can also use any of the instantiable intelligent model types. Intelligent model types are not dependent on the type of hierarchical view used.

NOTE

You can specify the model handle rather than the model type to identify a model, if desired. When specifying a model handle, Modeling Gateway ignores any other model identifiers, and it uses only the model handle to identify the model.

Not all model types that are defined in the DX NetOps Spectrum knowledge base can actually be used to create a model in OneClick. Some are used as base model types from which other model types are derived.

For more information, see SpectroSERVER and DX NetOps Spectrum Databases Overview .

Modeling Methods

Two methods are used to model devices in DX NetOps Spectrum. The first method is to use the IP address or the DNS name of the device. With this information, DX NetOps Spectrum contacts the device and creates a model using the model type that best represents the functionality of the device.

The second method is to provide a model type for the device model creation. You still must provide an IP address or a DNS name so DX NetOps Spectrum can communicate with the device. However, your chosen model type or model handle is instantiated regardless of the DX NetOps Spectrum assessment of the device functionality.

NOTE
To create a nondevice model, like a container model, a model type and model name must be provided for the import.

DX NetOps Spectrum Attributes

Each model type has a set of associated attributes. Each attribute describes the model type in some way. The attributes in an instantiated model take on values that reflect the device that the model represents and describe the current state of the model. For example, the model type Host_Sun has the attribute IPAddress. If a model of the type Host_Sun is instantiated, the value of this attribute reflects the IP address of the device that the model represents.

XML syntax also uses the term attribute. The XML attributes describe more information about an element. In DX NetOps Spectrum Modeling Gateway XML syntax, some XML attributes are used to give value to DX NetOps Spectrum attributes.

NOTE
Attributes that DX NetOps Spectrum defines are referred to as DX NetOps Spectrum attributes; the generic XML attributes are referred to simply as attributes.

XML Input File Syntax

Use the syntax rules that are defined in the DTD file when you generate the XML file. The following section provides an overview of the functionality of each of the DTD elements.

NOTE
The following explanations and examples do not cover all the attributes of each element. For a complete reference on each element and its attributes, see Document Type Definition Elements.

Root Element

The elements that are defined in the DTD exist in a hierarchical structure that parallels the network representation within DX NetOps Spectrum. The root element that must be used with each XML import file is the Import element. XML syntax rules specify that the root element is the outermost element and denotes the beginning and end of the XML file. Therefore, the Import element surrounds the rest of the XML elements that are used in your document.

Model-Oriented Elements

The model-oriented elements define physical or logical components of your network. They are container-type elements that are used to create models which define logical ways of grouping network elements. Grouping is based on the type of DX NetOps Spectrum hierarchical view they are in. Each of these container-type elements can exist in one of the specific hierarchical views.

- Topology_Container
- Location_Container
- Device
- Schedule
- Port
- Connection
- GenericView_Container
- **Topology_Container**

The Topology_Container element creates a model that groups other models according to physical or logical topology. The Topology_Container element creates container models, so use the model_type attribute or a model handle to identify the specific container you want to use. An enumeration of possible model_type values is in the DTD. A LAN is an example of a Topology_Container model_type value. You specify the name of the Topology_Container using the name attribute. The name and model_type attribute uniquely identify the created model. If you specify a model handle, the name and model_type attributes are ignored. Topology_Containers can contain other Topology_Container elements, devices, or connections. The Topology_Container models are always placed in the OneClick Topology view.

NOTE
By default, the name and model_type attributes give values to the DX NetOps Spectrum attributes Model_Name and Modeltype_Name. However, you can change which DX NetOps Spectrum attribute the name attribute gives value to by editing the .modelinggatewayresource.xml file. Whatever new DX NetOps Spectrum attribute is chosen (along with the model type) is used to identify uniquely the container. This change lets two containers have the same model name.

- **Location_Container**
  The Location_Container element groups other models according to physical or geographical location. A Building and a Room are both examples of Location_Container element model type values. The Location_Container element creates container models, so use the model_type attribute or a model handle to identify the specific container you want to use. An enumeration of possible model_type values is in the DTD. You specify the name of the Location_Container using the name attribute. The name and model_type attributes uniquely identify the created model. If you specify a model handle, the name and model_type attributes are ignored.

  NOTE
  By default, the name and model_type attributes give values to the DX NetOps Spectrum attributes Model_Name and Modeltype_Name. However, you can change which DX NetOps Spectrum attribute the name attribute gives value to by editing the .modelinggatewayresource.xml file. Whatever new DX NetOps Spectrum attribute is chosen (along with the model type) is used to identify uniquely the container. This change lets two containers have the same model name.

- **Device**
  The Device element defines a device on the network. This element is used with other elements to create, update, or destroy an instance of a device model in DX NetOps Spectrum. When working with an SNMP device, provide a valid and unique IP address or DNS name to identify uniquely the device using the ip_dnsname attribute. This unique identification lets DX NetOps Spectrum communicate with the device and select the most appropriate model type, which is based on the device functionality. Set the ip_dnsname to a valid string. If ip_dnsname is invalid or not contactable, the device model creation can fail. If model_type is provided with an invalid or noncontactable ip_dnsname, a device model is still created with the specified model type. However, the device model is not activated to provide any valid network information or status. Possible model_type values for devices are enumerated in the .modelinggatewayresource.xml file.
- **Schedule**
  The Schedule element defines when a device model is put into maintenance mode. When a device model is in maintenance mode, management traffic to the device and its components is suspended. Suspending traffic prevents DX NetOps Spectrum from generating any events or alarms on the device model while you are performing maintenance on the device.
- **Port**
  Ports are automatically created for a device when you create the device model. The Port element lets you modify some DX NetOps Spectrum port attribute values, or specify a port-level connection. You can specify different kinds of ports, including a Frame Relay or ATM circuit. To identify the port on the device, provide the values for the identifier_name and identifier_value attributes. The possible values for identifier_name are enumerated in the DTD. The identifier_value is the value of the identifier that the identifier_name attribute chooses. A Port element must always be specified as a child of a Device element.
- **Connection**

The Connection element defines a physical or logical connection between two devices, including WAN link connections, and therefore must contain two Device child elements. If a Port element is specified in the Device element, the connection is resolved on the specified port for that device. If the Device element does not specify a Port element, DX NetOps Spectrum Discovery tries to determine the ports in the connection to be resolved.

- **GenericView_Container**
  To create a container model in a Generic view, use the GenericView_Container element. Both the GenericView and GenericView_Container elements are used to create a customized view. Therefore, as the integrator, you decide when or how to use this container.

Task-Oriented Elements

The rest of the elements that are defined in the DTD are task-oriented elements. These elements and their attributes help define the type of action the input file generates. Using them, you can create new topology information, update, overwrite, or delete existing topology information. An individual input file can use zero or one of each of these elements, except for the Connection element. You can use as many Connection elements as necessary.

- Topology
- Location
- GenericView
- Connection
- Update
- Destroy

New Topology Data

The task-oriented elements define what action you would like to take with your XML file. Use the Topology and Location elements when you would like to create new network topology data in DX NetOps Spectrum. These elements define the hierarchical view where you would like to create the data. You can then use the corresponding model elements as child elements to create models for the network entities. To customize a view for your specific integration needs, use the GenericView element.

Create a Location View

You can create your topology information in the Location view for viewing in the World topology in OneClick. To create this information in the Location view, construct your XML file using the Location element inside the Import root element. The Location element can contain Location_Container elements to create a specific container model, or Device elements to create device models.

Example: Site Container in Location View

The following example creates a Site container in the Location view and a device within that container.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
    <Location>
        <Location_Container  model_type = "Site" name = "My_Town" >
            <Device ip_dnsname= "10.253.9.18"
                community_string="public"/>
        </Location_Container>
    </Location>
</Import>
```

The Import element is the root element and is always contained in the input file.

The Location element indicates that you are creating models in the Location view.

The Location_Container element creates a container model. This model is a logical component rather than a physical component of the network. Therefore, DX NetOps Spectrum cannot contact it and cannot define the model type using an IP address or a DNS name. To indicate the type of container model to create, provide a value for the model_type attribute and name attribute. Possible model_type attribute values are listed in the DTD and in the following section: Location_Container. The name attribute is required and must specify a unique name for the model.

> **NOTE**
> When you specify a model handle, the model handle is used to identify the container model. Therefore the name and model_type attributes are ignored if provided.

The Device element creates a model inside the Site Location_Container model. The ip_dnsname attribute is a required attribute for the Device element. If a device can be contacted, DX NetOps Spectrum uses the IP Address or the DNS name to find the device.

For a complete reference of these elements and their possible attributes, see Document Type Definition Elements.

Create a Topology View

You can import your network data into the Topology view for viewing in the Universe topology in OneClick. To import into the Topology view, construct your XML file using the Topology element inside the Import root element. The Topology element can contain:

- Topology_Container elements to create a specific type of container model.
- Device elements to create a specific type of device model.
- Connection elements to create connections between two devices.

Using the hierarchy and syntax rules that are outlined in the DTD, you can accurately express the physical and logical connectivity of your network.

Example: LAN Container in Topology View

This example creates a LAN container in the Topology view and a device within that container.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
    <Topology>
        <Topology_Container  model_type = "Lan"
            name = "Sample_LAN" Security_String = "public"
            subnet_address= "10.253.9.0" subnet_mask = "255.255.255.0">
            <Device ip_dnsname= "10.253.9.18"
                community_string="public"/>
        </Topology_Container>
    </Topology>
</Import>
```

The Import element is the root element and is always contained in the input file.

The Topology element indicates that you are going to create models in the Topology view.

The Topology_Container element creates a container model. This model is a logical component rather than a physical component of the network. Therefore, DX NetOps Spectrum cannot contact it and cannot define the model type using an IP address or a DNS name. To indicate the type of container model to create, provide a value for the model_type attribute and name attribute. The possible model_type attribute values are listed in the DTD and in the following section: Topology_Container. The name attribute is required and must specify a unique name for the model. The other attributes that are specified are optional.

NOTE

When you specify a model handle, the model handle is used to identify the container model. Therefore the name and model_type attributes is ignored, if provided.

The Device element creates a model inside the LAN Topology_Container model. The ip_dnsname attribute is a required attribute for the Device element. If DX NetOps Spectrum can contact the device, the IP Address or the DNS name is used to find the device. When DX NetOps Spectrum locates the device, it determines the appropriate model type to use to create the model.

Represent the Same Device in Multiple Views

You can create an XML file that represents a device in multiple views. To create this file, we recommended that each Device element you use to create a model of this device has identical attributes and attribute values. If they are not identical, the import tool attempts to merge the attributes and values of these Device elements to create a set of consistent attributes and values. Sometimes an attribute is specified in each of these Device elements, but different values are used. In this case, the value for the last Device element that is listed in the XML file overrides all previous values for that attribute in the other Device elements that are used to create a model of that device.

Remember that some attributes have default values. For example, the default value of the attribute community_string is public. Therefore, when you specify a Device element attribute and value to represent device A, we recommended that you specify it in any other Device element that represents device A. Doing so _helps ensure that a default value for that attribute is not used to override the previously specified value.

Example: Create a Device in Both the Topology and Location Views

In the following example, device 10.253.9.16 is created in the Topology and Location views. You can see that the attributes and values that are used to describe the device is the same for both views.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
<!-- Topology View import -->
 <Topology discover_connections="false" complete_topology="false">
  <Device ip_dnsname="10.253.9.16" community_string="zippo" />
 </Topology>
<!-- Location View import -->
 <Location complete_topology="true">
  <Location_Container model_type="Site" name="Durham">
   <Device ip_dnsname="10.253.9.16" community_string="zippo"/>
  </Location_Container>
 </Location>
</Import>
```

Create Connections Using Discovery

A DX NetOps Spectrum connection represents a physical or logical link between two devices. You can create connections two different ways in the XML input file. The first method employs DX NetOps Spectrum Discovery, using the discover_connections attribute of the Topology element. Discovery runs on the newly created device models when the discover_connections attribute is set to true. Then, Discovery establishes connectivity for these devices.

NOTE

For more information about Discovery, see the Modeling and Managing Your IT Infrastructure .

Example: Using Discovery to Create Connections

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
    <Topology >
        <Topology_Container  model_type = "Lan" name = "Sample_LAN" discover_connections= "true"
            Security_String = "public" subnet_address= "10.253.9.0"
            subnet_mask = "255.255.255.0" >
            <Device ip_dnsname= "10.253.9.18"
                community_string="public"/>
            <Device ip_dnsname= "10.253.9.20"
                community string="public"/>
        </Topology_Container>
    </Topology>
</Import>
```

Create Connections Using the Connection Element

The second way to create connections is to use the Connection element, which connects devices that are already created. Connections can be specified between two ports, between a device and a port, or between two devices.

Specifying the connectivity between devices lets DX NetOps Spectrum isolate faults to the device, but specifying port-level connections is preferred. The port-level connections are a finer grade of connectivity, allowing DX NetOps Spectrum to resolve the connections and analyze faults at the port level. DX NetOps Spectrum automatically attempts to determine the ports when you specify a connection between two devices but you do not specify one or both ports that are used in the connection. If this process is successful, DX NetOps Spectrum resolves the connection to the port level.

DX NetOps Spectrum generates an error indicating a connection failure when both of these conditions apply:

- DX NetOps Spectrum is unable to determine both ports that are used in the connection.
- At least one of these devices is a manageable device.

The error is written to the error log file.

If DX NetOps Spectrum can determine only one of the ports, then the connection is resolved only to the port level on one side of the connection. The other side remains resolved to the device level.

If both devices are unmanageable devices, DX NetOps Spectrum establishes the connection at the device level.

NOTE

When you use the Modeling Gateway with devices located in a Secure Domain, you need to add the attribute details of the secure domain to the import to allow the Modeling Gateway to find models in question and discover the secure domain. Normally, devices can be found with just the device IP.

Example: (Device ip_dnsname="x.x.x.x" secdomain_ipname="y.y.y.y")"

Example: Create a Connection between Existing Ports

The following example creates a connection between two existing ports, each port belonging to a different device. The Connection element identifies both the Port and Device elements to be linked. The connection is resolved at the port level for both devices because a Port element is specified within each Device element.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
    <Connection>
        <Device ip_dnsname= "172.19.57.93">
            <Port identifier_name = "frCircuitTableInstance"
                identifier_value="4.161"/>
```

```
        </Device>
        <Device ip_dnsname = "192.168.125.161">
            <Port identifier_name= "frCircuitTableInstance"
                identifier_value= "2.861"/>
        </Device>
    </Connection>
</Import>
```

The previous example specifies a connection between the DLCI ports. Because the value of the identifier_name attribute is frCircuitTableInstance, the port is identified using the OID instance value from the frCircuitTable object in the MIB. The OID instance value is specified using the identifier_value attribute.

The Connection element is contained within a Topology element or a Topology_Container element to indicate the hierarchical placement of the devices. This case does not change the results of the input file.

WARNING
Modeling Gateway does not report an error when you attempt to import an XML file that contains multiple Connection elements using the same Port element. A single port cannot have multiple connections. If the same port is specified in multiple Connection elements, the last Connection element in the XML file overrides all the previous Connection elements specifying that port.

Create WA_Link Connections

To create WA_Link connections, use the following syntax:

```
<Connection>
    <Device ip_dnsname=10.253.9.18/>
    <Device ip_dnsmame=10.253.9.100 model_type="WA_Link">
</Connection>
```

Modeling Gateway automatically creates a WA_Segment. The link is created between the segment and the device or devices. To specify a connection between a second device and the link, add a second connection tag to the import file.

Synchronize Information Between the Product and the Third-Party Database

The Topology, Location, Topology_Container, and Location_Container elements have an attribute named complete_topology. Setting the value of this attribute to true indicates that the XML file defines all the models and connections that DX NetOps Spectrum must know about. When the XML file is imported into DX NetOps Spectrum, any models in that DX NetOps Spectrum view that are not represented in the XML file are sent to the Lost and Found. If there are subcontainers in the view, DX NetOps Spectrum refers to the value of the complete_topology attribute that is set in the element specifying the subcontainer. If the complete_topology attribute value is not specified in the subcontainer element, the value is inherited from the parent element. Thus, if the parent element has a complete_topology setting of true and the subcontainer element does not specify a setting for complete_topology, the complete_topology value for the subcontainer is also true.

When DX NetOps Spectrum imports the XML file, models are sent to the Lost and Found under these conditions:

- The models exist either directly in the view you are importing into or in the subcontainer of that view.
- The models *do not* exist in the XML file.

This behavior is useful when synchronizing the data in your third-party database with the data in DX NetOps Spectrum.

Example: Complete_Topology Set to True

In the following example, complete_topology is set to true within the Topology element. Except for models that are specified in this input file, all existing models in the Topology view would be sent to the Lost and Found. With this sample input file, only two models are specified:

- The LAN Topology_Container
- The device at IP address 10.253.9.18

If these models did not exist, they would be created. If they existed, DX NetOps Spectrum would update their DX NetOps Spectrum attribute values using the attribute values in the input file. Any other model existing in the Topology view (except for the VNM) would be sent to the Lost and Found.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
    <Topology complete_topology="true">
        <Topology_Container  model_type = "Lan" name ="Sample_LAN"
            Security_String = "public" subnet_address= "10.253.9.0"
            subnet_mask = "255.255.255.0">
            <Device ip_dnsname= "10.253.9.18"
                community_string="public"/>
        </Topology_Container>
    </Topology>
</Import>
```

If the complete_topology attribute was used in the Topology_Container element instead of the Topology element, DX NetOps Spectrum would remove only unspecified models from that Topology_Container down through the hierarchy.

Update Information

To update DX NetOps Spectrum attribute and association information for existing models, use the Update element. The Update element can enclose Container elements, Device elements, and Association elements. The value of Port attributes is updated using the appropriate Device element.

Example: Update Attributes for Two Different Models and Create an Association

The following example shows an Update input file. In this case, two attributes for two separate models are updated and an association is created between the two models.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
  <Update>
    <Topology_Container model_type="Lan" name="Sample"
                        model_name = "newLAN"/>
    <Device ip_dnsname= "Test1" poll_interval= "1108"/>
    <Association relation="0x10002">
       <Left_Model> <Topology_Container name="Net"
                                        model_type="Network" /></Left_Model>
       <Right_Model> <Device ip_dnsname="172.24.94.94" /></Right_Model>
    </Association>
  </Update>
</Import>
```

The first updated attribute is the model_name attribute of the LAN container model. The model name is changed from Sample to newLAN. Note the use of the following attributes: name and model_name. Both of these attributes exist to change the DX NetOps Spectrum attribute Model_Name. To identify the container model and then specify the new name of the container model using the model_name attribute, use the name attribute with the current name as the value.

Next, the example changes the value of the poll interval for the device from Test1 to 1108. Assigning a new value to the poll_interval attribute overwrites the old value.

This example also creates an association of relation 0x10002 between container model "Net" of the Network model type and device model 172.24.94.94, as long as both models exist on the SpectroSERVER.

Destroy Information

Use the Destroy element to delete container models, device models, connections, and associations. When you destroy a device, all port and application models that are associated with the device are also destroyed.

Example: Destroy a LAN Container, a Connection, and an Association

In the following example, the LAN topology container named newLAN is destroyed. All models within this container are sent to the Lost and Found, unless they are specified to be destroyed. This example also destroys a connection between two devices, Test1 and Test2, which is specified at the port level. If a Collects association exists between the container model "Net" of model type Network and device 172.24.94.94, it is destroyed.

```
<?xml version = "1.0" standalone = "no" ?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
   <Destroy>
    <Topology_Container model_type="Lan" name="newLAN"/>
    <Connection>
      <Device ip_dnsname= "Test1">
       <Port identifier_name= "ifIndex" identifier_value= "1"/>
      </Device>
      <Device ip_dnsname= "Test2">
       <Port identifier_name="ipAddress"
              identifier_value = "10.253.8.18"/>
      </Device>
    </Connection>
    <Association relation="Collects">
       <Left_Model> <Topology_Container name="Net"
                                    model_type="Network" /></Left_Model>
       <Right_Model> <Device ip_dnsname="172.24.94.94" /></Right_Model>
    </Association>
   </Destroy>
</Import>
```

> **WARNING**
> To destroy a model representing a device that has already been removed from the network, use the IP address of the device rather than the DNS name when specifying the ip_dnsname attribute of the Device in the Destroy element of an XML file. Once the device has been removed from the network, the DNS entry for that device no longer exists. And, the Modeling Gateway cannot identify the appropriate model to delete.

The .modelinggatewayresource.xml File

The Topology_Container, Location_Container, and Device elements have a model_type attribute that must have a value equal to a valid DX NetOps Spectrum model type. DX NetOps Spectrum uniquely identifies model types using a hexadecimal number. These hexadecimal values have been enumerated in the resource file .modelinggatewayresource.xml. This file pairs a text value for the model type with the unique hexadecimal identifier. The text values are then displayed in the DTD.

Many of the attributes that are defined in the DTD correspond to DX NetOps Spectrum attributes. DX NetOps Spectrum attributes are uniquely identified in DX NetOps Spectrum using a hexadecimal number. The .modelinggatewayresource.xml file does not use these hexadecimal values in the DTD or in the XML file. Instead, the file pairs the hexadecimal identifiers of the DX NetOps Spectrum attributes with more intuitive text-based names.

Both the ModelType element and the Attribute element of the .modelinggatewayresource.xml file can be customized.

NOTE
The .modelinggatewayresource.xml file is also used for exporting topology data from DX NetOps Spectrum. For more information, see Export Topology Data from DX NetOps Spectrum.

Define Character Set Encoding

The DX NetOps Spectrum XML input file is encoded with UTF-8 by default. To import special characters or foreign languages, specify the appropriate character set encoding in the XML file header, as shown in the following example.

Example: Set the Input File Character Encoding to Greek

The following example shows how you would modify the XML file to set the character encoding to Greek:

```
<?xml version="1.0" encoding="ISO-8859-7" standalone="no"?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
```

View Character Set Encoding Information

Determine the character set encoding that DX NetOps Spectrum uses from the OneClick Administration Pages.

Follow these steps:

1. Click Administration in the OneClick home page.
   The Administration Pages open.
2. Click Character Set in the panel on the left.
   The Character Set Encoding page opens, displaying a list of encodings and their applicable languages.

Comma-Delimited Input Files

The Modeling Gateway can specify ATM and Frame Relay connectivity in an XML input file. The toolkit can also accept ATM and Frame Relay connectivity information from a comma-delimited ASCII text file. This file can be used to import information about connections between:

- Two ATM circuits
- Two Frame Relay circuits
- An ATM and a Frame Relay circuit

You can specify that a live pipe is created in OneClick to represent the connection. Multiple connections can be specified in the same input file.

NOTE
The device models that are involved in these connections must previously exist in DX NetOps Spectrum.

Comma-Delimited Input File Syntax

The following example shows the format that is used in the comma-delimited input file:

```
<Device_IP>, <OID>, <Device_IP>, <OID>, <CircuitName>, <CircuitID>, <Pipe>
```

- **Device_IP**
  Specifies the IP address of each device that is involved in the connection. Required.
- **OID**
  Specifies the OID instance of frCircuitTable, atmVclTable, or atmVplTable to specify the circuit link on the device.
- **CircuitName**
  (Optional) Specifies the name of the circuit involved.
- **CircuitID**

(Optional) Specifies the ID of the circuit involved.

- **Pipe**
  (Optional) Has two possible values: CREATE_PIPE or NO_CREATE_PIPE. If the value is set to CREATE_PIPE, live pipes are created between the connections specified. If the value is set to NO_CREATE_PIPE, live pipes are not created between the connections specified. If no value is specified for this parameter, a default value of CREATE_PIPE is assumed.

Example: Specified Connection between Frame Relay Circuits

The following example shows an input file that specifies the connection between two Frame Relay circuits. A live pipe is created between these two ports.

```
172.19.57.93, 4.161, 192.168.125.161, 2.161, FR_Circuit_Name, Circuit_Id_123, CREATE_PIPE
```

Run the modelinggateway Tool for Import

Import a Single File

To run the modelinggateway tool for importing a single file, use the following syntax.

Windows

```
modelinggateway.bat -vnm vnm_name -i import_file [-o outputfile] [-debug debugfile]
```

Linux

```
modelinggateway -vnm vnm_name -i import_file [-o outputfile] [-debug debugfile]
```

- **-vnm *vnm_name***
  Specifies the SpectroSERVER host name.
- **- i *import_file***

Specifies the XML file name which contains the necessary input information (that is compiled with .modelinggateway.dtd.)

> **NOTE**
>
> If you are importing from multiple files, specify the files names that are enclosed in comma-separated {} brackets. For example, refer to the syntax sample for importing multiple files.

- **-o *outputfile***

(Optional) Logs the error information to the file named in the *outputfile* parameter.

> **NOTE**
>
> If you don't specify the debug/output file names, the error information is logged to a file named *import_file*.log;where, *Import_file* is the name of the XML file.In case of multiple imports, the debug/output files are appended and you can see consolidated logs.

- **-debug *debugfile***

(Optional) Indicates that you would like to create a debugging output file during the import process. When using the -debug option, you can provide your own debug file name for output. If you do not supply a value for *debugfile*, the debug file name defaults to the *import_file* name suffixed with ".debug."

NOTE
The -debug option requires disk space on the machine where Modeling Gateway is run. For example, a large debugging output file can result when the number of models in the *import_file* is large or when the device models have large interface densities.

Import Multiple Files

The modelinggateway tool now supports import from multiple XML files. You can now specify any number of import files.

To run the modelinggateway tool for importing multiple files, use the following syntax:

```
modelinggateway -vnm vnm_name [-user SS user][-i importfile1,importfile2,..]|[-o outputfile] [-debug
 debugfile]
```

For Example :
./modelinggateway.bat -vnm <vnm name> -i test1.xml, test2.xml

When you execute the above syntax, you see the following result message:
Multiple import XML files specified
Import will be done sequentially one after the other

ImportConfiguration Element

To control certain aspects of how Modeling Gateway imports data, use the ImportConfiguration element.

The ImportConfiguration element has the following syntax:

```
<ImportConfiguration
   do_not_process_pre_existing_devices_under_container_node = "false"
   import_to_primary_ss_only = "false"
   max_device_creation_threads = "50"
/>
```

- **do_not_process_pre_existing_devices_under_container_node**
  Specifies whether DX NetOps Spectrum processes devices that are found under a container element which previously exist in DX NetOps Spectrum.
  Default: false
- **import_to_primary_ss_only**
  Specifies whether Modeling Gateway connects to the secondary SpectroSERVER when the primary SpectroSERVER is down.
  Default: false
- **max_device_creation_threads**
  Specifies how many device models can be created and activated simultaneously.

  NOTE
  Setting this value to an amount higher than 50 can result in too much SNMP traffic.

  Default: 50

Import Comma-Delimited Files

The previous section described how to import input files using the modelinggateway import tool. You can also import Frame Relay and ATM connection data from the OneClick interface.

Follow these steps:

1. Click the applicable VNM model in the OneClick Console.

2. Click the Information tab in the Component Detail panel.
3. Click Logical Connection Import to expand the section.
4. Click Import, locate the comma-delimited file containing the data that you want to import into DX NetOps Spectrum, and then click Open.
   OneClick imports the data. The Import Results dialog appears, providing you with information about the success of the import.

View Import Information

The DX NetOps Spectrum Modeling Gateway provides mechanisms to help ensure the safety and accuracy of each database import. DX NetOps Spectrum Modeling Gateway maintains an audit trail that includes a record of each creation, deletion, association, and update made. You can view data about the import within OneClick and you can also track information about import problems in the error and debug logs.

View Modeling Gateway Results in OneClick

You can verify the results of the Modeling Gateway import from the VNM model, Information tab in the OneClick Console.

Follow these steps:

1. Click the applicable VNM model in the OneClick Console.
2. Click the Information tab in the Component Detail panel.
3. Click Modeling Gateway to expand the section.
4. Review the table in the Modeling Gateway section for information about recent imports. The table contains the following information:
   - **Import File**
     Displays the name of the import file.
   - **Log File**
     Displays the name of the log file.
   - **Start Time**
     Indicates when the topology import process began.
   - **End Time**
     Indicates when the topology import process completed.
   - **Progress**
     The progress field shows the status of a topology import that has not yet finished. The possible values for this field are:
     - Initializing
     - Identifying Models
     - Creating Models
     - Activating Models
     - Mapping Connectivity
     - Placing Models
     - Creating Connections
     - Updating Models
     - Destroying Models
     - Complete
     - Disconnected
   - **Errors**

Displays the number of errors that are generated during the import process.
- **Models Created**
  Displays the number of models that are created during the import process.
- **Models Destroyed**
  Displays the number of models that are eliminated during the import process.
- **Models Updated**
  Displays the number of models that are updated during the import process.
- **Connections Created**
  Displays the number of connections that are created during the import process.
- **Connections Removed**
  Displays the number of connections that are removed during the import process.

5. Click the Max Records set link to modify the number of import files that are listed in the table.
6. Click any of the table column headers to sort the data as needed.
7. Enter text in the Filter field to restrict the import data to specific criteria.
8. Click Update to check the status of an import as it is processing.
   The screen refreshes and displays the most recent import information available.

Error Log

All errors and their possible causes are logged in an error log file. By default, the import tool creates an error log named <*nameofimportfile*>.log where <*nameofimportfile*> is the name of your import file. You can also specify a particular name for your log file using the syntax that is specified in the section on the import tool. When the import is complete, the log file appears in the SS-Tools directory. The log file records the number of successful creations, deletions, and updates of models and connections. The log file also records each single failure that occurred during the importing process.

Export Topology Data

Modeling Gateway supports exporting topology information and configuration settings from a SpectroSERVER. The information is exported into an XML-formatted file, which can then be imported into a specified SpectroSERVER using the Modeling Gateway.

The following types of information are exported by default:

- Device elements, with configuration attributes.
- Port elements, with configuration attributes.
- Container elements, with configuration attributes.
- Connections (resolved and unresolved, WA_Link connections).
- Universe topology hierarchy.
- Layout for each view in the Universe topology, including annotations and zoom information but excluding background images.
- User models and the entire user scheme such as user-related relations, attributes, and models like LicenseRole, AccessGroup, PrivilegeRole, and UserGroup.
- Discovery configurations.
- Service Management schemes and attributes.
- Static and dynamic global collections including all the models in each global collection, all dynamic collection criteria, zoomed list, grouped list, and topology layout.

WARNING
Modeling Gateway partitions a SpectroSERVER database across two or more SpectroSERVERs, or to change the landscape handle of a single SpectroSERVER database. To configure behaviors and set up modeling for data that is not currently supported in the export capabilities, some manual work is required after the exported

data is imported. Examples of types of data which are not exported includes, but are not limited to, Service Performance Manager (SPM) tests, NCM configurations, and Events.

Configure Export Settings

You can control what is exported by modifying the ExportConfiguration element in the .modelinggatewayresource.xml file. By default, all topology and modeling information under the Universe container is exported. You can modify the RootContainerToExport element to specify a different root container from which to export. All the contents of the root container and each of its subcontainers are exported.

NOTE

You do not need to use the DTD for exporting data; the DTD is used only for importing data.

The attributes that are exported for devices, containers, and ports are defined in the following elements respectively: DeviceExportAttributes, ContainerExportAttributes, and PortExportAttributes. Add and subtract attributes from these elements as needed.

The SpectrumConfigurationExport element controls what types of DX NetOps Spectrum configuration data are exported when the export_spectrum_settings flag in the ExportConfiguration element is set to true.

For example, the following element controls the attributes that are exported for the LostFound model:

```
<SpectrumConfigurationExport model_type="LostFound" >
    <Automatic_Model_Destruction attribute_id="0x11de1" />
    <Model_Destruction_Interval_Hours attribute_id="0x11de3" />
    <Model_Destruction_Interval_Minutes attribute_id="0x11de4" />
</SpectrumConfigurationExport>
```

NOTE

The modeling information of the devices which are in the "LostFound" folder is not exported.

ExportConfiguration Element

To control export behavior, use the ExportConfiguration element in the .modelinggatewayresource.xml file.

The ExportConfiguration element has the following syntax:

```
<ExportConfiguration
   export_devices           = "true"
   export_containers        = "true"
   export_port_attributes   = "true"
   export_links             = "true"
   export_topology_layout   = "true"
   export_annotation        = "true"
   export_WA_Link_models    = "true"
   export_spectrum_settings = "true"
   export_user_models       = "true"
   export_service_modeling  = "true"
   export_schedules         = "true"
   export_global_collections = "true"
   export_discovery_configs = "true"
```

```
    export_from_primary_ss_only = "false"
    export_policy_manager = "true"
 />
```

- **export_devices**
  Exports device models.
- **export_containers**
  Exports container models.
- **export_port_attributes**
  Exports port attributes.
- **export_links**
  Exports device links.
- **export_topology_layout**
  Exports device and container models' x,y coordinates in the topology.
- **export_annotation**
  Exports the annotations and model group information.
- **export_WA_Link_models**
  Exports WA_Link models. If you decide not to export WA_Link models, they are treated as transparent. Wide area links between two device models are exported as a direct link.
- **export_spectrum_settings**
  Exports DX NetOps Spectrum settings such as the settings for fault isolation, Discovery, and VNM control.
- **export_user_models**
  Exports user models, user licenses, user privileges, user preferences, and all other user-related relations attributes and models.
- **export_servicemodeling**
  Exports the service management schemes and attributes.

  NOTE
  For more information about Service Manager, see Service Manager .
- **export_schedules**
  Exports the schedules.
- **export_global_collections**
  Exports static and dynamic global collections including all the models in each global collection, all dynamic collection criteria, zoomed list, grouped list, and topology layout.
- **export_discovery_configs**
  Exports the Discovery configurations.
- **export_from_primary_ss_only**
  Specifies whether Modeling Gateway connects to the secondary SpectroSERVER when the primary SpectroSERVER is down.
- **export_policy_manager**
  Exports the Policy Manager policies. All related models, policies, rules, permissions, and templates are included.

Example:

The following example exports everything except for port attribute information. This example also tells Modeling Gateway *not* to connect to the secondary SpectroSERVER when the primary is down.

```
<ExportConfiguration
   export_devices           = "true"
   export_containers        = "true"
   export_port_attributes   = "false"
   export_links             = "true"
   export_topology_layout   = "true"
```

```
    export_annotation        = "true"
    export_WA_Link_models    = "true"
    export_spectrum_settings = "true"
    export_user_models       = "true"
    export_service_modeling  = "true"
    export_schedules         = "true"
    export_global_collections = "true"
    export_discovery_configs = "true"
    export_from_primary_ss_only = "true"
    export_policy_manager = "true"

/>
```

The modelinggateway Tool for Export

The Modeling Gateway command-line tool, 'modelinggateway,' (modelinggateway.bat on Windows) is located in the SS-Tools directory. Its syntax for export is:

Windows

```
modelinggateway.bat -vnm vnm_name [-cmdb] -e export_file [-o outputfile] [-debug debugfile]
```

Linux

```
modelinggateway -vnm vnm_name [-cmdb] -e export_file [-o outputfile] [-debug debugfile]
```

- **-vnm *vnm_name***
  Specifies the name of the SpectroSERVER host.
- **-cmdb**
  (Optional) Exports the contents of your SpectroSERVER in a format that can be used when integrating DX NetOps Spectrum with CA CMDB. For more information on implementing this integration, contact CA Support.
- **-e *export_file***
  Exports DX NetOps Spectrum topology data.
- **-o *outputfile***
  (Optional) Logs the error information to the file named in the *outputfile* parameter. If this option is not used, the error information is logged to a file named *export_file*.log. *Export_file* is the name of the XML file.
- **-debug *debugfile***
  (Optional) Indicates that you would like to create a debugging output file during the export process. When using the -debug option, you can provide your own debug file name for output. If you do not supply a value for *debugfile*, the debug file name defaults to the *export_file* name suffixed with .debug.
  Note: The -debug option requires disk space on the machine where Modeling Gateway is run. The number of models in the *export_file* affects the size of the debugging output file: the greater the number of models in the database, the larger the debug file produced.

  NOTE
  To run the modelinggateway tool on another server, move the modelinggateway tool and all of its support files to that server. For more information, see the Distributed SpectroSERVER Administration .

Export DX NetOps Spectrum Topology Data

Export DX NetOps Spectrum topology data using the modelinggateway tool.

Follow these steps:

To export DX NetOps Spectrum topology data, use the -e flag. For example, running the following command exports the data from the SpectroSERVER on NOC1_Spectrum into a Modeling Gateway formatted xml file named NOC1_data.xml:

```
modelinggateway -vnm NOC1_Spectrum -e NOC1_data.xml
```

Import Modeling Gateway XML file

You can import the data from a Modeling Gateway formatted XML file into DX NetOps Spectrum.

Follow these steps:

To import from a Modeling Gateway formatted XML file, use the -i flag. For example, running the following command imports the data from NOC1_data.xml into the SpectroSERVER at NOC2_Spectrum.

```
modelinggateway -vnm -user SS user NOC2_Spectrum -i NOC1_data.xml
```

Appendix A. Document Type Definition Elements

This section describes the functionality of each element that is defined in the Document Type Definition (DTD). This section also provides context for each one. This section *does not* describe the XML syntax that is used in the DTD. For syntax information, see an XML reference.

Association

Syntax

Parent Elements:

- Update
- Destroy

Child Elements:

- Left_Model
- Right_Model

Rules: The Association element must contain one Left_Model element and one Right_Model element.

Usage

The Association element creates or destroys associations between models.

If the Association element is used as a child of the Destroy element, the association that is specified is destroyed. If the Association element is used as a child of the Update element, the association that is specified is created.

Attributes

- **relation**
  Specifies the name or handle of the DX NetOps Spectrum relation between the Left_Model and Right_Model in this association.

Connection

Syntax

Parent Elements:

- Topology
- Topology_Container
- Update
- Destroy

Child Elements: Device

Rules: The Connection element must contain two device elements.

Usage

The Connection element specifies a connection between two devices. The Connection element must always contain two device elements and each of these Device elements can contain zero or one Port element. If a port or ports are specified, the connection is resolved at the port level. If a port or ports are not specified, Discovery is triggered to find the port or ports for the connection.

If the Connection element is used as a child of the Destroy element, the connection that is specified is destroyed. If the connection is used in any other context, the connection is created.

Attributes

- **create_pipe**
  Indicates whether a graphical representation of the specified connection is shown in OneClick.
  Default: True

Correlation

Syntax

Parent Element: Import

Child Element: Correlation_Domain

Rule: The Correlation element can contain any number of child elements.

Usage

The Correlation element represents a Correlation Manager model and is used with the DX NetOps Spectrum Service Manager. See Service Manager for usage details.

Attributes

None.

Correlation_Domain

Syntax

Parent Element: Correlation

Child Elements:

- Device
- Port
- Model_Attr
- GenericView_Container

Rule: The Correlation_Domain element can contain any number of child elements.

Usage

The Correlation_Domain element is used with the DX NetOps Spectrum Service Manager. See Service Manager for usage details.

Attributes

See Service Manager for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A

CustomerManager

Syntax

Parent Element: SM_Service_Mgt

Child Elements:

- SM_Customer
- SM_CustomerGroup

Rule: The CustomerManager element can contain any number of these child elements.

Usage

The CustomerManager element is used with the DX NetOps Spectrum Service Manager. See Service Manager for usage details.

Attributes

NOTE
See Service Manager for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	Groups_Customers	N/A
model_type	Character	CustomerManager	N/A

Destroy

Syntax

Parent Element: Import

Child Elements:

- Topology_Container
- Location_Container
- GenericView_Container
- Device
- Model
- Connection
- EventModel
- SM_Service
- SM_AttrMonitor
- SM_LatencyMon
- SM_ConnectMon
- SM_SLA
- SM_Guarantee
- SM_Customer
- Association

Rule: The Destroy element can contain as many of each of these child elements as necessary.

Usage

Use the Destroy element to remove container models, device models, connections, and associations. You cannot nest elements in the Destroy element to express hierarchies or destroy hierarchies. The only hierarchy that is allowed in the Destroy element is the Connection-Device-Port hierarchy, which specifies at the port level the connection to destroy. You could destroy a container model without destroying the device models or other container models that are contained inside it. In this case, the remaining models are placed in the DX NetOps Spectrum Lost and Found.

Attributes

The Destroy element does not have any attributes.

Device

Syntax

Parent Elements:

- Topology
- Location
- Topology_Container
- Left_Model
- Right_Model
- Location_Container
- GenericView
- GenericView_Container
- Connection
- Update
- Destroy
- SM_Service
- SM_AttrMonitor

Child Elements:

- Port
- Schedule

Rules:

- **Port:** If a Device element is contained within a Connection element, only one port element is allowed. If a Device element in contained within an Update element to update ports, more than one port element is allowed. The ports are ignored when a Device element is contained in a View, a Container, or a Destroy element.
- **Schedule:** The Device element can contain one Schedule element.

Usage

To create, destroy, or update a device model, use the Device element. The Device element lets you define the device model using either an IP address or a DNS name.

> **NOTE**
> If community_string and agent_port attributes are not provided during the device creation, DX NetOps Spectrum creates the device using the predefined SNMP credentials. These credentials are configured in the Modeling and Protocol Options section of the AutoDiscovery Control subview in the VNM model Information tab in OneClick.

Attributes

- **ip_dnsname**
  Specifies the IP address or DNS name of the device. If the device does not support SNMP communication, you can use a unique string here with model_type specified.
- **secdomain_ipname**
  (Optional) Specifies the IP address of a host running an SDConnector in the secure domain where the device is located.
  Default: 0.0.0.0
- **model_handle**
  (Optional) Specifies the model_handle to identify an existing device model.

  > **NOTE**
  > If you provide a model_handle, the value of ip_dnsname is ignored.
- **model_type**
  (Optional) The DX NetOps Spectrum model type that is used to model your device. This device model can be any intelligent model type that is defined in the .modelinggatewayresource.xml file.

  > **NOTE**
  > If you have provided a valid IP address or DNS name, you do not need to specify a value here.
- **community_string**
  (Optional) The community string of the device.

  > **NOTE**
  > If community_string is not included, DX NetOps Spectrum uses the first SNMP Community Strings value to create the device. These values are specified in the VNM model Information tab, AutoDiscovery Control subview, Modeling and Protocol Options subview in OneClick.
- **agent_port**
  (Optional) Controls the port number that is used when communicating with the SNMP agent of a device.

  > **NOTE**
  > If agent_port is not included, DX NetOps Spectrum uses the first SNMP Ports value to create the device. These values are specified in the VNM model Information tab, AutoDiscovery Control subview, Modeling and Protocol Options subview in OneClick.
- **is_managed**
  (Optional) Puts the device model in maintenance mode, when set to true.

Default: True

- **poll_interval**
  (Optional) Specifies the time interval, in seconds, that the SpectroSERVER reads all attributes of the device model that are flagged as POLLED.
- **log_ration**
  (Optional) Specifies the number of SpectroSERVER polls of a device that occur before logging the poll results in the database.
- **poll_status**
  (Optional) Lets you disable the SpectroSERVER polls of a device by setting the polling status to false.
- **model_name**
  (Optional) Specifies the name of the model.
- **DeviceType**
  (Optional) Specifies the device type of the model.

  NOTE
  See the Certifications for more information about device types.
- **reconfig**

  NOTE
  (Optional) Specifies whether Modeling Gateway sends an action to the SpectroSERVER to reconfigure the device model.
- **discover_connections**
  (Optional) Runs Discovery on any newly created device models to map automatically the model connectivity, when set to true.

EventModel

Syntax

Parent Element:

- Topology_Container
- Left_Model
- Right_Model

Child Element: None

Rule: N/A

Usage

To import the EventModel models for use with a Southbound Gateway integration, use the EventModel element. For more information about Southbound Gateway, see the Southbound Gateway Toolkit .

Attributes

- **model_name**
  Specifies the unique name of the model that is instantiated or identified.
- **unique_id**
  Specifies the identifier that is used to define uniquely the event source that this EventModel model represents. For more information, see the Southbound Gateway Toolkit .
- **model_handle**
  (Optional) Specifies the model_handle to identify an existing device model.
- **Security_String**
  (Optional) Specifies the security string for the EventModel.

Default: public

- **manager_name**
  (Optional) Specifies the name of the third-party application that is using the Southbound Gateway.
  Note: Use the default value for any application that is not listed here.
  Default: 0
  - **1**
    NetMentor
  - **2**
    SSM
  - **3**
    Omni2000

GenericView

Syntax

Parent Element: Import

Child Elements:

- GenericView_Container
- Device

Rule: The GenericView element can contain any number of these child elements.

Usage

To create a customized hierarchical view other than the Topology view and Location view, use the GenericView element. You can modify this element to meet the needs of your integration.

Attributes

- **containment_relation**
  Specifies a relation handle that defines which DX NetOps Spectrum relation defines the containment relationship within this view.
  Limits: Must be a DX NetOps Spectrum containment relation.
- **model_type**
  Specifies a model type that represents the top container model that is defined for this view. This model_type must be specified with its model handle in the .modelinggatewayresource.xml file.
- **name**
  Specifies the unique name of the instantiated container model highest in the GenericView hierarchy.
- **complete_topology**
  (Optional) Destroys any unspecified, existing container and device model in the GenericView view when set to true. Also, destroys these models in the sub-containers of that view.

GenericView_Container

Syntax

Parent Element: GenericView

Child Elements:

- GenericView_Container
- Device

Rule: The GenericView_Container element can contain any number of child elements.

Usage

To create a container model in the Generic view, use the GenericView_Container element. Both the GenericView and GenericView_Container elements are used to create a customized view. Therefore, as the integrator, you decide when or how to use this container.

Attributes

- **name**
  Specifies the name of the model that is instantiated or identified. The model_type and the name attribute are required to identify uniquely the GenericView_Container. By default, this attribute is used to set the value of the DX NetOps Spectrum model name attribute (attr id 0x1006e). However, this attribute can be changed to any other attribute in the .modelinggatewayresource.xml file. You can change the .modelinggatewayresource.xml so that the name maps to a different attribute. In this case, that new attribute (along with the model type) is used to identify the container. This behavior lets two containers have the same model name.
- **model_type**
  Specifies the DX NetOps Spectrum model type that is used to create the model. This model_type must be specified with its model handle in the .modelinggatewayresource.xml file. The model_type and the name attribute are required to identify uniquely the GenericView_Container.
- **containment_relation**
  (Optional) The name of the DX NetOps Spectrum relation that exists between the Generic_Container and the models within the container. If no value for this attribute is specified, the containment relationship of the parent model is inherited.

GlobalCollection

Syntax

Parent Element: Import

Child Elements:

- Device
- Topology_Container
- Location_Container

Usage

Represents a GlobalCollection model.

Attributes

- **name**
  Specifies a name for this global collection.
- **containment_relation**
  Specifies a relation handle that defines which DX NetOps Spectrum relation defines the containment relationship within this view.
  Default: "GlobalCollect"
- **collectionDescription**
  (Optional) Describes the global collection.
- **Security_String**
  (Optional) Specifies the security string for the global collection.

Import

Syntax

Parent Element: None

Child Elements:

- Topology
- Location
- GenericView
- Update
- Destroy
- SM_Service_Mgt
- Correlation
- GlobalCollection

Rule: The Import element can contain one of each of these child elements.

Usage

The Import element is the root element, and it must be included in each input file.

Attributes

- **model_activation_time**
  Specifies the maximum number of minutes that are allowed for each device model activation.
  Data Type: Character
  Default: 5 minutes

Left_Model

Syntax

Parent Element: Association

Child Elements:

- Device
- Port
- Topology_Container
- Location_Container
- EventModel
- Model

Rules: The Left_Model element can contain only one child element.

Usage

The Left_Model element defines the left side model in an association.

Attributes

None.

List_Value

Syntax

Parent Element: Model_Attr

Child Element: None

Rule: N/A

Usage

To specify a DX NetOps Spectrum list attribute value, use the List_Value element.

Attributes

None.

Location

Syntax

Parent Element: Import

Child Elements:

- Location_Container
- Device

Rule: The Location element can contain any number of child elements.

Usage

To specify that you would like to create models in the Location view (World topology) of OneClick, use the Location element.

Attributes

- **complete_topology**
  (Optional) When set to true, any unspecified, existing containers and device models in the Location view, or any subcontainers, are destroyed during the import.
  Default: False
  Data Type: Boolean

Location_Container

Syntax

Parent Elements:

- Location
- Location_Container
- Left_Model
- Right_Model
- GlobalCollection

Child Elements:

- Location_Container
- Device

Rule: The Location_Container element can contain any number of child elements.

Usage

To create or specify a Location_Container model that is used to group models and other location containers in the Location view, use the Location_Container element.

Attributes

- **name**
  The name of the model that is instantiated or identified. The model_type and the name attribute are required to identify uniquely the Location_Container.
  By default, this attribute is used to set the value of the DX NetOps Spectrum model name attribute (attr id 0x1006e). However, this attribute can be changed to any other attribute in the .modelinggatewayresource.xml file. You can change the .modelinggatewayresource.xml so that the name maps to a different attribute. In this case, that new attribute (along with the model type) is used to identify the container. This behavior lets two containers have the same model name.
- **model_type**
  Indicates the type of model you want to create. The model_type and the name attribute are required to identify uniquely the Location_Container. Possible values include:
  – Country
  – Region
  – Site
  – Building
  – Floor
  – Section
  – Room
- **model_handle**
  (Optional) Can be used to identify models. If you provide a model_handle, the values of name and model_type are ignored.
- **Security_String**
  (Optional) Defines the requirements for access to a model by DX NetOps Spectrum users. Each security string consists of one or more Security Community entries and is assigned to models.
- **model_name**
  (Optional) To change the name of the model, use the name and the model_name attributes. The name attribute specifies the old name and the model_name attribute specifies the new name.
- **model_modify_author**
  (Optional) Writes data to the DX NetOps Spectrum attribute mdl_modfy_athr.
- **complete_topology**
  (Optional) When set to true, any unspecified, existing containers and device models in the Location view, or any subcontainers, are destroyed during the import.
  Default: False

Model_Attr

Syntax

Parent Element: Correlation_Domain

Child Element: List_Value

Rule: The Model_Attr element can contain any number of child elements.

Usage

To specify DX NetOps Spectrum attributes whose values contain multiple lines of text or a list of values, use the Model_Attr element.

Attributes

- **attr_id**
  Indicates the DX NetOps Spectrum attribute ID of the attribute you are specifying.
  Data Type: Character

Model element

Syntax

Parent Elements:

- Left_Model
- Right_Model

Child Elements: None

Usage

To represent any DX NetOps Spectrum model, use the Model element.

Attributes

- **name**
  Specifies a name for this model.
- **model_type**
  Specifies the model type of this model.
- **model_handle**
  (Optional) Specifies a model_handle for this model. If a model_handle value is specified, the name and model_type values are ignored.

MonitorPolicy_Attr

Syntax

Parent Element:

- SM_Service
- SM_AttrMonitor

Child Element: None

Rule: N/A

Usage

The MonitorPolicy_Attr element is used with the DX NetOps Spectrum Service Manager. See Service Manager for usage details.

Attributes

None.

Port

Syntax

Parent Elements:

- Device
- Left_Model
- Right_Model
- Correlation_Domain
- SM_Service
- SM_AttrMonitor

Child Element: None

Rule: N/A

Usage

The Port element is used to specify connections at the port level or to update port attributes. When updating, the parent Device element is contained within an Update element. When specifying a connection, the parent device element is contained within a Connection element.

Attributes

- **identifier_name**
  Works with the identifier_value attribute to identify uniquely the port. The identifier_name can be any one of the MIB OID names that are listed in the Possible Values column. The portID value can be used to identify a port by its Component_OID attribute (0x1006a). If the Port element represents a Frame Relay virtual circuit, use frCircuitTableInstance. If the Port element represents an ATM virtual channel or path link, use atmVclTableInstance. The portID value can be used to identify a port by its Component_OID attribute (0x1006a). If the Port element represents a Frame Relay virtual circuit, use frCircuitTableInstance.If the Port element represents an ATM virtual channel or path link, use atmVclTableInstance. Possible values include:
  - ifIndex
  - ipAddress
  - ifPhysAddress
  - ifName
  - ifAlias
  - model_name
  - portDescription
  - portID
  - frCircuitTableInstance
  - atmVclTableInstance
  - atmVplTableInstance
- **identifier_value**
  Specifies the value of the identifier_name selection.
- **model_handle**
  (Optional) Specifies the model_handle to identify an existing model.
  Note: If you provide a model_handle, the values for identifier_name and identifier_value are ignored.
- **ip_dnsname**
  (Optional) Specifies the IP address or DNS name of the port model. If the port model does not support SNMP communication, you can use a unique string here with model_type specified.
- **model_name**
  (Optional) Specifies the name of the model you are updating.
- **circuit_id**
  (Optional) Identifies the circuit that is involved in an ATM or Frame Relay connection by ID.
- **circuit_name**
  (Optional) Identifies the circuit that is involved in an ATM or Frame Relay connection by name.
- **log_ratio**
  (Optional) Specifies the number of port model polls that occur before logging the poll results in the database.
- **poll_interval**
  (Optional) Specifies the time interval, in seconds, that the SpectroSERVER reads all attributes of the port model that is flagged as POLLED.
- **poll_status**
  (Optional) Lets an administrator disable port model polls by setting polling status to False.

Right_Model

Syntax

Parent Element: Association

Child Elements:

- Device
- Port
- Topology_Container
- Location_Container
- EventModel
- Model

Rules: The Right_Model element can contain only one child element.

Usage

The Right_Model element defines the right side model in an association.

Attributes

None.

RTM_Test

Syntax

Parent Elements:

- SM_Service
- SM_AttrMonitor

Child Element: None

Rule: N/A

Usage

The RTM_Test element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
model_type	Character	RTM_Test	N/A

Schedule

Syntax

Parent Elements: Device

Child Element: None

Usage

To create a maintenance mode schedule for a particular device model, use the Schedule element.

Attributes

- **name**
  Specifies the name of the schedule.
- **SCHED_Recurrence**
  Specifies how often the device model is put into maintenance mode.
  - **1**
    Always (24x7)
  - **2**
    Daily
  - **3**
    Weekly
  - **4**
    Monthly
  - **5**
    Yearly

  Default: 1
- **SCHED_Start_Hour**
  (Optional) Specifies the hour that the device goes into maintenance mode.
  Limits: 0-23
- **SCHED_Start_Minute**
  (Optional) Specifies the minute the device goes into maintenance mode.
  Limits: 0-59
- **SCHED_Start_DoW**
  (Optional) Specifies the day of the week the device goes into maintenance mode.
  - **0**
    Sunday
  - **1**
    Monday
  - **2**
    Tuesday
  - **3**
    Wednesday
  - **4**
    Thursday
  - **5**
    Friday
  - **6**
    Saturday
- **SCHED_Start_DoM**
  (Optional) Specifies the day of the month the device goes into maintenance mode.
  Limits: 1-31
- **SCHED_Start_Month**
  (Optional) Specifies the month that the device goes into maintenance mode.
  - **0**
    January
  - **1**

February
  - **2**
    March
  - **3**
    April
  - **4**
    May
  - **5**
    June
  - **6**
    July
  - **7**
    August
  - **8**
    September
  - **9**
    October
  - **10**
    November
  - **11**
    December
- **SCHED_Duration**
  (Optional) Specifies the length of time the device is in maintenance mode, which is defined in seconds.
  Default: 0
- **SCHED_Recurrence_Multiplier**
  (Optional) Specifies the number of recurrence units (days, weeks, months, years) that determine the length of time between the start of each scheduled maintenance mode.
  Default: 1
- **SCHED_Daily_Repeat_Limit**
  (Optional) Specifies the number of consecutive days to repeat the scheduled maintenance (specified by SCHED_Start_Hour and SCHED_Start_Minute) during each recurrence period. This attribute is only applicable to a weekly, monthly, or yearly recurrence.

SM_AttrMonitor

Syntax

Parent Element: SM_Service

Child Element: None

Rules: N/A

Usage

The SM_AttrMonitor element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	N/A	SLMMonitors SLMWatchesContainer
AttrToWatch	Character	N/A	N/A
MonitorPolicy_ID	Character	N/A	N/A
is_managed	Boolean	N/A	True False
Generate_Service_Alarms	Boolean	N/A	True False
model_type	Character	SM_AttrMonitor	N/A

SM_Customer

Syntax

Parent Elements:

- SM_CustomerGroup
- CustomerManager

Child Element: None

Rule: N/A

Usage

The SM_Customer element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	N/A	SlmAgreesTo SlmUses
Security_String	Character	N/A	N/A
CustomerID	Character	N/A	N/A
Criticality	Character	N/A	N/A
CustomerField4	Character	N/A	N/A
CustomerField5	Character	N/A	N/A
CustomerField6	Character	N/A	N/A
CustomerField7	Character	N/A	N/A
Contact_Name	Character	N/A	N/A

Contact_Title	Character	N/A	N/A
Contact_Location	Character	N/A	N/A
Email_Address	Character	N/A	N/A
Phone_Number	Character	N/A	N/A
Mobile_Phone_Number	Character	N/A	N/A
Pager_Number	Character	N/A	N/A
Fax_Number	Character	N/A	N/A

Secondary_Contact_Location	Character	N/A	N/A
Secondary_Email_Address	Character	N/A	N/A
Secondary_Phone_Number	Character	N/A	N/A
Secondary_Mobile_Phone_ Number	Character	N/A	N/A
Secondary_Pager_Number	Character	N/A	N/A
Secondary_Fax_Number	Character	N/A	N/A
Secondary_User_Defined_1	Character	N/A	N/A
Secondary_User_Defined_2	Character	N/A	N/A
Secondary_User_Defined_3	Character	N/A	N/A
Secondary_User_Defined_4	Character	N/A	N/A
model_type	Character	SM_Customer	N/A

SM_CustomerGroup

Syntax

Parent Elements:

- CustomerManager
- SM_CustomerGroup

Child Elements:

- SM_CustomerGroup
- SM_Customer

Rule: The SM_CustomerGroup element can contain any number of these child elements.

Usage

The SM_CustomerGroup element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	NA	N/A
containment_relation	Character	Groups_Customer	N/A
model_type	Character	SM_CustomerGroup	N/A

SM_Guarantee

Syntax

Parent Element: SM_SLA

Child Element: None

Rule: N/A

Usage

The SM_Guarantee element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	SlmIsMeasuredBy	N/A
is_managed	Boolean	N/A	True False
DegradedTimeViolationLevel	Character	N/A	N/A
DegradedTimeWarningLevel	Character	N/A	N/A
DownTimeViolationLevel	Character	N/A	N/A
DownTimeWarningLevel	Character	N/A	N/A
LorTimeViolationLevel	Character	N/A	N/A
LorTimeWarningLevel	Character	N/A	N/A
model_type	Character	SM_Guarantee	N/A

SM_LatencyMon

Syntax

Parent Elements:

- SM_Guarantee
- SM_AttrMonitor
- SM_Service

Child Elements:

- Topology_Container
- MonitorPolicy_Attr

Rule: The SM_LatencyMon element can contain any number of these child elements.

Usage

The SM_LatencyMon element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Managersection for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	N/A	SlmMonitors SlmWatchesContainer
is_managed	Boolean	N/A	True False
DefaultMaxRTT	Character	N/A	N/A
DefaultMeasureInterval	Character	N/A	N/A
mode_type	Character	SM_LatencyMon	N/A

SM_Service

Syntax

Parent Elements:

- SM_Service
- SM_ServiceMgr

Child Elements:

- SM_Service
- SM_AttrMonitor

Rule: The SM_Service element can contain any number of these child elements.

Usage

The SM_Service element is used with the DX NetOps Spectrum Service Manager. See the Service Managersection for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
Criticality	Character	N/A	N/A
containment_relation	Character	N/A	SlmMonitors SlmWatchesContainer

AttrToWatch	Character	N/A	N/A
MonitorPolicy_ID	Character	N/A	N/A
is_managed	Boolean	N/A	True False
Generate_Service_Alarms	Boolean	N/A	True False
Security_String	Character	N/A	N/A
model_type	Character	SM_Service	N/A

SM_Service_Mgt

Syntax

Parent Element: Import

Child Elements:

- SM_ServiceMgr
- CustomerManager
- SM_SLA_Mgr

Rule: Only a single instance of each of these child elements can exist in SM_Service_Mgt.

Usage

The SM_Service_Mgt element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	Service Management	N/A
containment_relation	Character		N/A
model_type	Character		N/A

SM_ServiceMgr

Syntax

Parent Element: SM_Service_Mgt

Child Element: SM_Service

Rule: The SM_ServiceMgr element can contain any number of this child element.

Usage

The SM_ServiceMgr element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name	Character	N/A	N/A
containment_relation	Character	SImContains	N/A
model_type	Character	SM_ServiceMgr	N/A

SM_SLA

Syntax

Parent Element: SM_SLA_Mgr

Child Element: SM_Guarantee

Rule: The SM_SLA element can contain any number of this child element.

Usage

The SM_SLA element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name *(required)*	Character	N/A	N/A
containment_relation	Character	SImContains	N/A
is_managed	Boolean	N/A	True False
Security_String	Character	N/A	N/A
model_type	Character	SM_SLA	N/A

SM_SLA_Mgr

Syntax

Parent Element: SM_Service_Mgt

Child Element: SM_SLA

Rule: The SM_SLA_Mgr element can contain any number of this child element.

Usage

The SM_SLA_Mgr element is used with the DX NetOps Spectrum Service Manager. See the Service Manager section for usage details.

Attributes

See the Service Manager section for attribute definitions.

Attribute	Data Type	Default Value	Possible Values
name	Character		N/A
containment_relation	Character	SlmContains	N/A
model_type	Character	SM_ServiceMgr	N/A

Topology

Syntax

Parent Element: Import

Child Elements:

- Topology_Container
- Device
- Connection

Rule: The Topology element can contain any number of these child elements.

Usage

To create models in the OneClick Topology view (Universe topology), use the Topology element.

Attributes

- **complete_topology**
  Destroys any unspecified, existing container and device model in the Topology view during the import when set to true. Also, destroys any subcontainers of that view.
  Default: False
- **discover_connections**
  When set to true, Discovery runs on any newly created device models to map automatically the connectivity of the model.
  Default: False

Topology_Container

Syntax

Parent Elements:

- Topology
- Topology_Container
- SM_Service
- SM_AttrMonitor

Child Elements:

- Topology_Container
- Device
- EventModel
- Connection

Rule: The Topology_Container element can contain any number of these child elements.

Usage

To create or specify a Topology_Container model that is used to group models and other topology containers in the Topology view, use the Topology_Container element. Possible model types are listed in the following table in the model_type section.

Attributes

- **model_type**
  Indicates the type of model you want to create. The model_type and the name attribute are required to identify uniquely the Topology_Container.
  - Network
  - LAN
  - IPClassA
  - IPClassB
  - IPClassC
  - LAN_802_3
  - LAN_803_5
  - EventAdmin
  - ATM_Network
- **model_handle**

  NOTE
  (Optional) Can be used to identify existing models. If you provide a model_handle, the values of model_type and model_name are ignored.
- **Security_String**
  (Optional) Specifies the assigned DX NetOps Spectrum security level for the model.
- **subnet_address**
  (Optional) Specifies the subnet address of the device.
- **subnet_mask**
  (Optional) Specifies the mask that determines what subnet the device IP address belongs to.
- **model_name**
  (Optional) Specifies a model name for the container model.
- **trapIPAddress**
  (Optional) For the EventAdmin models only.
- **x_coordinate**
  (Optional) Specifies the x coordinate of the model in the topology.
- **y_coordinate**
  (Optional) Specifies the y coordinate of the model in the topology.
- **complete_topology**
  (Optional) When set to True, any unspecified, existing container and device model in this Topology_Container and, any subcontainers, are destroyed during the import.
  Default: False
- **discover_connections**
  (Optional) Specifies whether DX NetOps Spectrum discovers and models devices that are connected to this model.

Update

Syntax

Parent Element: Import

Child Elements:

- Topology_Container
- Location_Container
- GenericView_Container
- Connection
- Device
- Model
- EventModel
- SM_Service
- SM_AttrMonitor
- SM_LatencyMon
- SM_ConnectMon
- SM_SLA
- SM_Guarantee
- SM_Customer
- Association

Rule: The Update element can contain any number of these child elements.

Usage

To update attributes for any device, container, or port subelements, use the Update element.

> **NOTE**
> The hierarchical specifications are not allowed when using this element, except for using the Port element within the Device element.

Attributes

None.

Appendix B. Document Type Definition File

This section contains the Document Type Definition (DTD), which defines XML elements and attributes for import.

> **WARNING**
>
> Note that the following DTD file is not meant for editing, but to be used as a reference, when editing the XML file. For example, there is an attribute for model activation timeout, referenced in the DTD, that can be used to extend the model activation time, for large imports.
> This should be added to the Import tag of the XML import file, at root node as below, in order to increase the timeout to 50 mins:
> landscape_handle="0xXXX00000" model_activation_time="50">
>
> **NOTE**
> The following code might not be the latest version of this file. For the latest version of the DTD, use the actual file that shipped with your Modeling Gateway toolkit. The file is located in the SS-Tools directory and is named .modelinggateway.dtd.

Sample Document Type Definition File

```
<!-- ********************************************************** -->
<!-- The root Import element contains 0 or 1 of the Topology,     -->
<!-- Location, GenericView, Update, Destroy elements,             -->
<!-- SM_Service_Mgt, Correlation, and Global Collection.          -->
<!--                                                              -->
<!-- This element has one attribute model_activation_time which   -->
<!-- is the maximum waiting time in minutes, for each device model-->
```

```
<!-- activation. It defaults to 5 minutes.                        -->
<!-- ********************************************************** -->
<!ELEMENT Import ( ( Topology       |
            Location       |

Appendix C. XML Examples

This section contains the following XML examples to help you work with the DTD:

> **NOTE**
> The element names in each example are highlighted in bold. Making the names bold makes the examples easier to read; it is not intended to imply formatting necessary for the XML input file.

Example 1 Importing into the Topology View

This example shows a basic input file that imports information into the DX NetOps Spectrum Topology view. This file creates a Network container model in the Topology view. In the Network container, a LAN container model is created. Within the LAN container two devices are created. The DNS name deadlock identifies one device, and the IP address identifies the other device.

The complete_topology attribute of the Topology element is set to False. In this case, DX NetOps Spectrum respects other models that previously exist in the Topology view. Consequently, this file only looks to create models for entries that are listed in the XML file that are not already modeled. The models that are created are placed in the Topology hierarchy as specified in the file. Models that previously exist in the Topology hierarchy are not rediscovered but are moved to the container specified in the file.

> **NOTE**
> When complete_topology is set to false, existing models that are in the container but not listed in the import file are *not* sent to the Lost and Found. These models *are* sent to Lost and Found when complete_topology is set to true.

            Security_String="public" subnet_address="10.253.9.0"
            subnet_mask="255.255.255.0">
            <Device ip_dnsname="deadlock" />
            <Device ip_dnsname="10.253.9.18" poll_interval="333" />
```

```
        </Topology_Container>
    </Topology_Container>
</Topology>
</Import>
```

Example 2 Creating Connections

The following example shows the creation of a connection between two ATM circuits and the creation of a connection between two Frame Relay circuits. The example also shows a connection between a FrameRelay DLCI port and an ATM VCL port.

```
<?xml version="1.0" standalone="no"?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
<Topology complete_topology="false">
 <Connection create_pipe="false">
  <Device ip_dnsname="10.253.32.225">
   <Port identifier_name="atmVclTableInstance"
    identifier_value="5.0.5"
    circuit_name="ATM Link1"
    circuit_id = "ATM 5017" />
  </Device>
  <Device ip_dnsname="192.168.52.25">
   <Port identifier_name="atmVclTableInstance"
    identifier_value="3.0.12"
    circuit_name="ATM Link1"
    circuit_id = "ATM 5017" />
  </Device>
 </Connection>
 <Connection>
  <Device ip_dnsname="10.253.9.18">
   <Port identifier_name="frCircuitTableInstance"
    identifier_value="2.27"/>
  </Device>
  <Device ip_dnsname="nmcss52-5">
   <Port identifier_name="frCircuitTableInstance
    identifier_value="4.161"/>
  </Device>
 </Connection>
 <!-- ****************************************** -->
 <!-- Connection between a FrameRelay DLCI port and -->
 <!-- an ATM VCL port.                           -->
 <!-- ****************************************** -->
 <Connection>
  <Device ip_dnsname="10.253.9.18">
   <Port identifier_name="frCircuitTableInstance"
    identifier_value="2.27"/>
  </Device>
  <Device ip_dnsname="10.253.32.225">
   <Port identifier_name="atmVclTableInstance"
    identifier_value="5.0.17"/>
  </Device>
 </Connection>
```

```
 <Connection>
  <Device ip_dnsname="nmcss52-5">
   <Port identifier_name="ifIndex" identifier_value="3"/>
  </Device>
  <Device ip_dnsname="10.253.9.17">
   <Port identifier_name="ifPhysAddress"
    identifier_value="0:4:27:C:91:C0"/>
  </Device>
 </Connection>
<Topology>
</Import>
```

Example 3 Updating and Destroying

This example illustrates the use of the Update and the Destroy elements.

The Update element contains a Location_Container element. This example updates the model name by using the name and model_name attributes of the Location_Container element. The name attribute is set equal to the current name and identifies the model to be updated. The model_name attribute updates the value of the name attribute to Peace2.

The Update element also contains a Device element and Port element. The attributes identifer_name and identifier_value are used to identify the port to be updated. The other attributes that are specified are those attributes whose values are updated. The port model name is changed to port 2 and the poll_status is changed to False.

The Destroy element eliminates the device model deadlock. Any connections or ports that are associated with deadlock are automatically destroyed. The Building container model Durham is also eliminated. Any models that are contained within the Durham building container are sent to the Lost and Found.

The Destroy element also removes the connection between the specified port on device nmcss52-5 and the specified port on nmcss52-3.

```
<?xml version="1.0" standalone="no"?>
<!DOCTYPE Import SYSTEM ".modelinggateway.dtd">
<Import>
<!-- ********************************************** -->
<!-- Model update.....................................-->
<!-- ********************************************** -->
 <Update>
<!-- ********************************************** -->
<!-- Change container Peace's model name from Peace to-->
<!-- Peace2 ..................................... ....-->
<!-- ********************************************** -->
  <Location_Container model_type="Building" name="Peace"
   model_name="Peace2"/>
<!-- ************************************** -->
<!-- Update port ifIndex=2 on device nmcss52-5  -->
<!-- ************************************** -->
  <Device ip_dnsname="nmcss52-5">
   <Port identifier_name="ifIndex" identifier_value="2"
    model_name="port 2" poll_status="false" />
  </Device>
 </Update>
  <!-- ***************************** -->
  <!-- Destroy models and connections. -->
  <!-- ***************************** -->
```

```
 <Destroy>
  <Device ip_dnsname="deadlock"/>
  <Location_Container  model_type="Building" name="Durham" />
  <Connection>
   <Device ip_dnsname="nmcss52-5">
    <Port identifier_name="ifIndex"
     identifier_value="1"/>
   </Device>
   <Device ip_dnsname="10.253.9.17">
    <Port identifier_name="ipAddress"
     identifier_value="10.253.8.18"/>
   </Device>
  </Connection>
 </Destroy>
</Import>
```

Example 4 Creating, Updating, and Destroying

The following XML file illustrates most of the functionality of the elements that are contained within the DTD. This file creates data in both the Topology and Location views, creates connections, updates attributes, and destroys models and connections.

The first section of the XML file creates models and connections between these models in the Topology view. The section begins with the Topology element, <Topology...>. The container and device models are created first and then connections are established. This section ends when the Topology element closes, </Topology>.

After the Topology element is closed, there is a section where another connection is created. This section illustrates that you can create connections without nesting the Connection element within the Topology element.

The next section of the file begins with the Location element, <Location...>. This section demonstrates creating a container and device models in the Location view. This section ends when the Location element closes, </Location>.

The next section begins with the Update element, <Update>. In this section, attribute values of a container, a device, and a port are modified. You cannot know the current attribute values of each of the elements that are represented by looking at the XML file. Therefore, it is not easy to discern which elements are being updated. In general, each element contains an attribute that uniquely identifies the model or port to be updated. The rest of the attributes are specified to update their values. For example, the first element is the Location_Container element. The name attribute uniquely identifies the model. The model_type attribute is specified to update its value, perhaps from Region to Building. The only hierarchy that can be defined in the Update element is the Device/Port hierarchy that specifies the port you would like to update. This section ends when the Update element closes, </Update>.

The last section of this file uses the Destroy element. The Destroy element eliminates:

- The device at 10.253.9.19
- The container model Durham
- The connection between the specified ports on device nmcss52-5 and the device at 10.253.9.17

Model Type Editor

Introducing the Model Type Editor

This section introduces the Model Type Editor application and the database objects that you can create using it, namely, model types, attributes, relations, and meta-rules.

The section also discusses model type inheritance, which is an important concept to understand before creating and modifying model types.

> **WARNING**
> Before using the Model Type Editor, read Certifications . The *Certification space* provides information on the GnSNMPDev management module. You can use GnSNMPDev to represent a SNMP-compliant network device that lacks a corresponding DX NetOps Spectrum management module. You can also use GnSNMPDev as a toolkit to create new management modules that include new, supporting device model types and application model types.

Modeling Concepts

DX NetOps Spectrum and Model Type Editor

DX NetOps Spectrum is an integrated management system that runs on the Linux and Windows platforms. The DX NetOps Spectrum design is based on a client/server model. The server, called the SpectroSERVER, includes the DX NetOps Spectrum knowledge base, which gets and stores all network information. The client is the DX NetOps Spectrum user interface, called OneClick, which provides a graphical representation of the network environment.

The SpectroSERVER provides intelligence and contains models of the actual network devices and their relationships -- models that continuously collect data about the entities they represent and collectively provide a comprehensive management perspective of the network. Through polling, the DX NetOps Spectrum database gains extensive information about network devices, their relationships, and their performance.

The OneClick client application provides a multi-dimensional picture of the SpectroSERVER database. Users can retrieve and view the information maintained in the SpectroSERVER database, and they can invoke the SpectroSERVER to control objects on the network. Network information can be presented from various perspectives, including topological or geographical views.

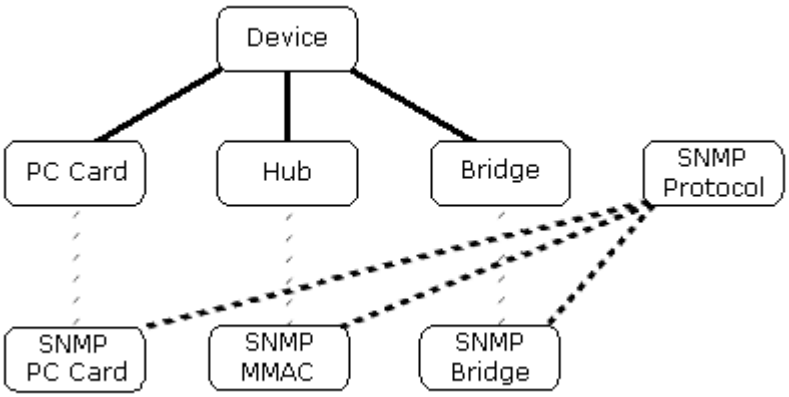
DX NetOps Spectrum deploys model types, models, attributes, relations, and meta-rules to monitor network infrastructure. *Model types* are the templates used to create models, and *models* are specific instances of a model type. (The terms "model type" and "template" are used interchangeably in DX NetOps Spectrum documentation.) *Attributes* are the characteristics of a specific model type, and *relations* and *meta-rules* define how model types interact with each other. While models and associations are defined using OneClick, the Model Type Editor lets you define model types, rules, relations, and attributes.

The Model Type Editor is the Java-based application that you use to create, modify, and delete modeling catalog objects. Because it is a thick-client application that accesses the SpectroSERVER database, you must run it from the SpectroSERVER platform.

Model Types and Attributes

A *model type* is a template that is used to create models, and it is defined by a specific set of attributes. In turn, *attributes* are the database variables that collectively characterize the real-world object represented by the model type. Model types range from simple with few attributes and relationships to very complex with many attributes and relationships.

Complex model types are often derived by inheriting attributes from several, simpler model types. The resulting combination constitutes a hierarchy of model types. Parent model types (model types from which one or more other model types have been derived) are called *base model types*. Child model types (model types that have been derived from one or more other types) are called *derived model types*. The following illustration shows a sample model type hierarchy that illustrates model type derivation.

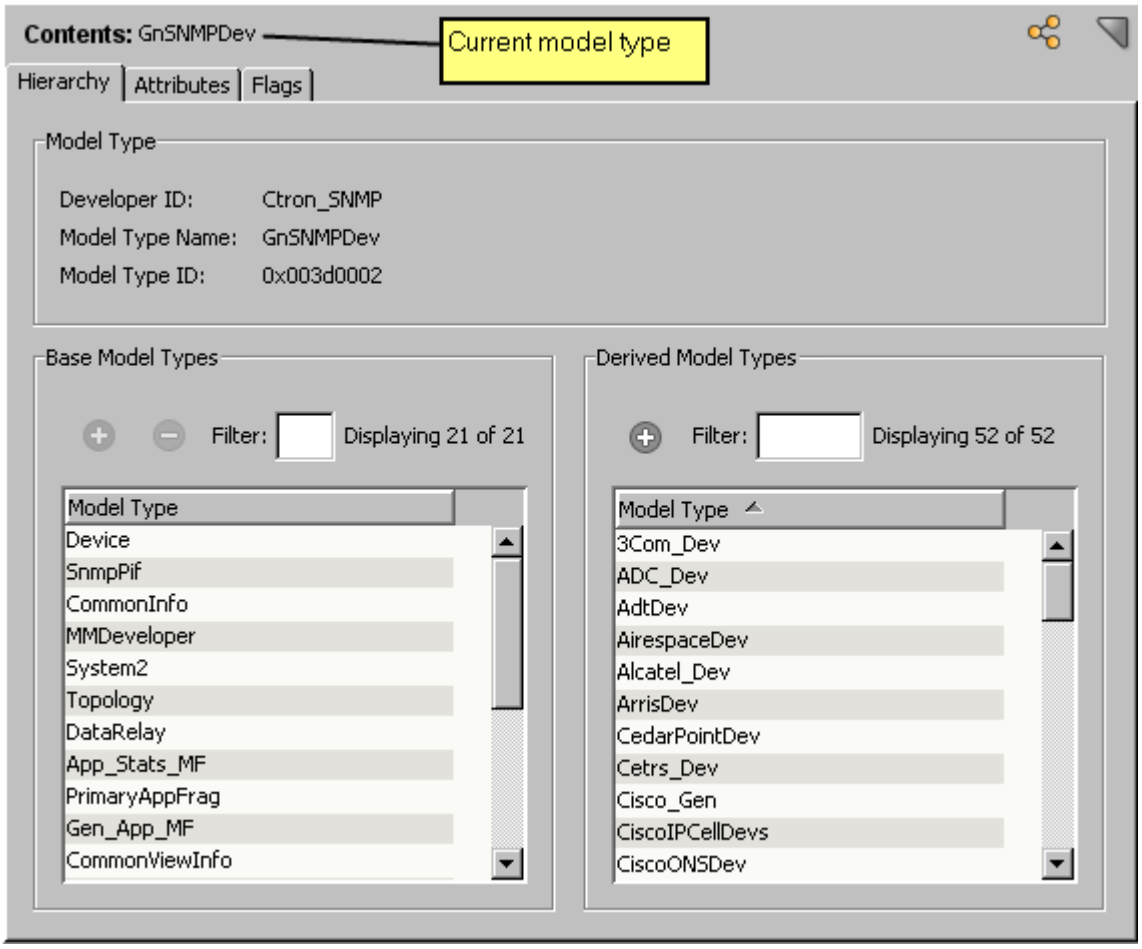


In the illustration, Device is a base model type for three model types: PC Card, Hub, and Bridge. As such, all three derived model types inherit the attributes of Device.

In turn, PC Card, Hub, and Bridge are each used as a base model type for another model type, respectively, SNMP PC Card, SNMP MMAC, and SNMP Bridge. All of these derived model types inherit the attributes of their immediate parent model type, and by extension, the attributes of the Device model type. In addition, they also inherit the attributes of a model type named SNMP Protocol.

In the Model Type Editor, you can identify a model type's position in the model type hierarchy using the Hierarchy tab. The tab shows the following for the current model type:

- The base (parent) model types from which the current model type is derived
- The derived (child) model types that are derived from the current model type



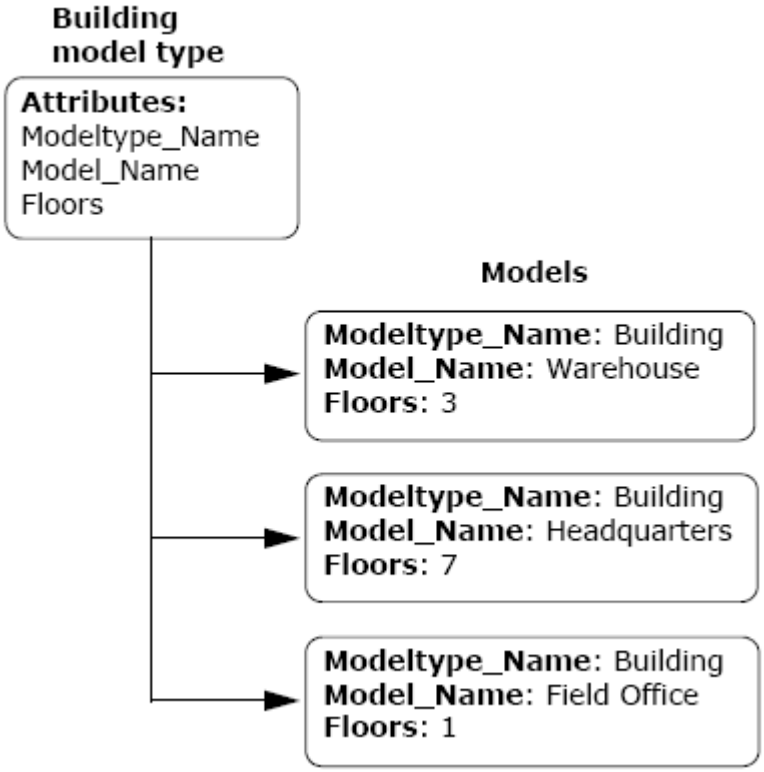
The Model Type Editor also provides an Attribute tab that shows the attributes of a model type and their default values.

There are various rationales for attributes. Certain attributes, such as the name of a router or its IP address, are necessary in order to uniquely identify a resulting model within the DX NetOps Spectrum database. Other attributes relate a model to the SNMP object identifiers (OIDs) supported by the model. Still others support DX NetOps Spectrum functionality. For example, Discovery_Precedence is used by the Discovery program; Value_When_Red is used for alarm roll-up, and Polling_Interval is used to determine how often DX NetOps Spectrum polls the given device for information.

Models

A *model* is an instantiation of a model type by the SpectroSERVER. All models instantiated from the same model type have the same set of attributes and DX NetOps Spectrum intelligence. However, the values for the attributes are unique to each model except in the case of Shared attributes (that is, attributes for which the Shared flag is set).

As a simple example, the following illustration shows three models derived from a model type named Building, which has three attributes: Modeltype_Name, Model_Name, and Floors. Because each model is instantiated from the same model type, each model has the same value for Modeltype_Name (a Shared attribute). However, the values for Model_Name and Floors vary.



NOTE
A network administrator can add, edit, and delete models using OneClick. For more information, see Modeling and Managing Your IT Infrastructure.

Relations and Meta-Rules

A *relation* is a database construct that defines a specific type of relationship between model types. The following are examples of relations:

- Contains
- Collects
- Executes
- HASPART
- Is_Adjacent_to
- Monitors
- Pings_Through
- Schedules

Each relation is defined by one or, more typically, several rules called meta-rules. The *meta-rules* for a relation apply the relation to specific model types, thereby defining how the model types can interact with one another. As an example, the following are several of the meta-rules defined for the Contains relation:

- Building Contains Floor
- Building Contains Room
- Building Contains Section
- Country Contains Building
- Country Contains Region
- Country Contains Site

Each meta-rule must have exactly one antecedent model type (the left-hand entry) and exactly one predicate model type (the right-hand entry). Any model type can be an antecedent or a predicate for any number of meta-rules.

OneClick uses the meta-rules for model types to establish the rules for interaction between specific models instantiated from the model types. In DX NetOps Spectrum terms, instantiation of a meta-rule between two models produces an *association* between the models, and each model can react to the knowledge that it is associated with the other model. For example, consider the following meta-rule:

Country Contains Building

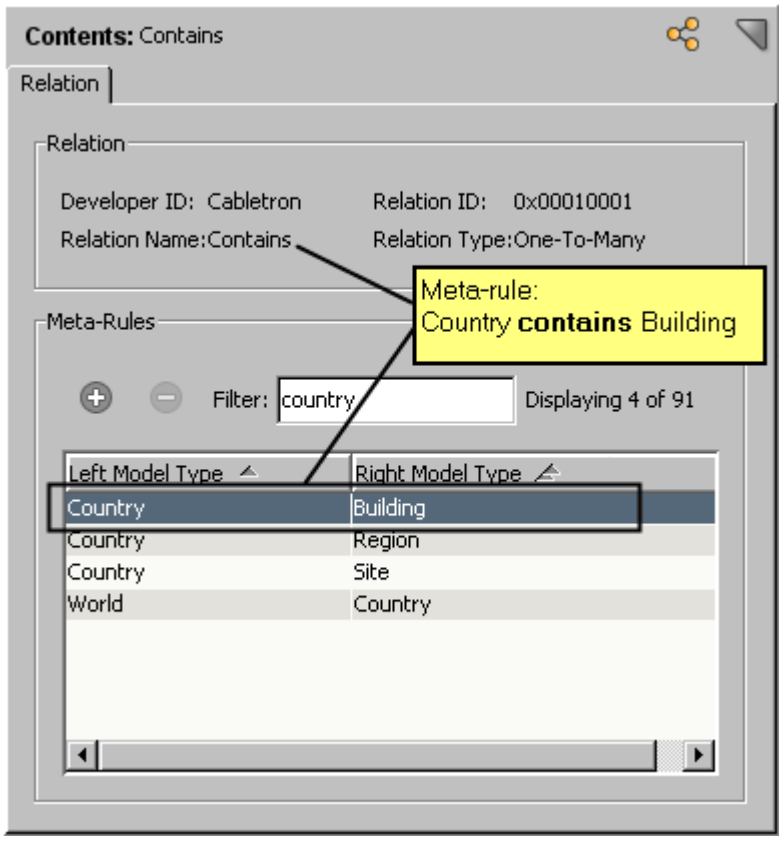
This might result in the following association between two specific models:

France contains Corporation001

There are two types of relations:

- **One-To-Many**
  A relation of this type defines how a single model of one model type relates to multiple models of another model type. For example, Contains is a one-to-many type of relation. As such, it can have one or more meta-rules that define one-to-many relationships between models. For example, it includes a "Country contains Building" meta-rule, which specifies that a *single* model of the Country model type can contain *multiple* models of the Building model type.
- **Many-To-Many**
  A relation of this type defines how multiple models of one model type relate to multiple models of another model type. For example, Is_Adjacent_to is a many-to-many type of relation. As such, it can have one or more meta-rules that define many-to-many relationships between models. For example, it includes a "Device Is_Adjacent_to Device" meta-rule, which specifies that *multiple* models of the Device model type can be adjacent to *multiple* models of the Device model type.

The Model Type Editor provides a Relation tab that shows the meta-rules defined for a specific relation.



Most relations in the modeling catalog that comes with the basic DX NetOps Spectrum package have meta-rules that specify the model types to which the relations can be applied.

Model Type Inheritance

When you derive new model types from existing model types, the specifics of model type and attribute inheritance are important to understand because the functionality of each model type depends on its inheritance.

This section provides information on important concepts related to inheritance, namely, attribute descriptors, standard versus specialized hierarchies, model type precedence, and attribute collapsing.

Attribute Descriptors

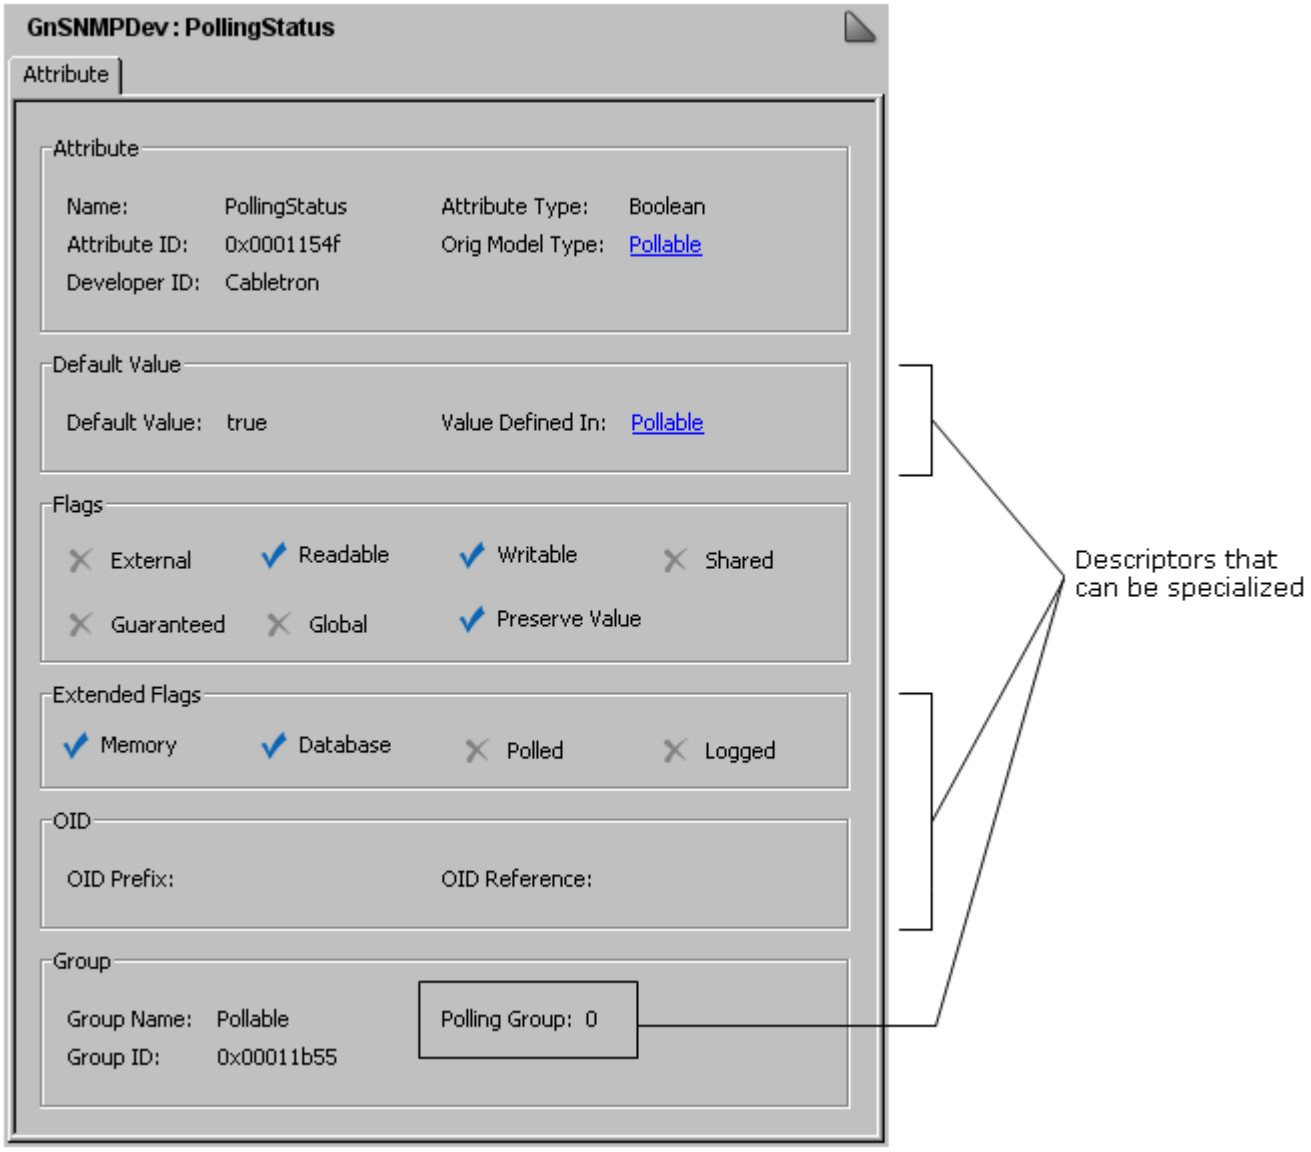
Attribute descriptors are the characteristics that define the attribute, for example, its type (boolean, integer, text string, and so on) and default value.

An attribute has two types of descriptors:

- **Standard descriptors**: The values of these attribute descriptors are inherited by all model types derived directly or indirectly from the base model type in which the attribute was first created (referred to as the *originating model type*). You can only modify the values of standard descriptors in the originating model type; you cannot modify their values in derived model types.
  Name, Attribute ID, and the Shared flag are three examples of standard descriptors.
- **Descriptors that can be specialized**: Like standard attribute descriptors, the values of these descriptors are inherited by all model types derived directly or indirectly from the base model type in which the attribute was first created. However, unlike standard descriptors, you can modify the values of these descriptors at any level in the model type hierarchy. This process is called *specialization*.

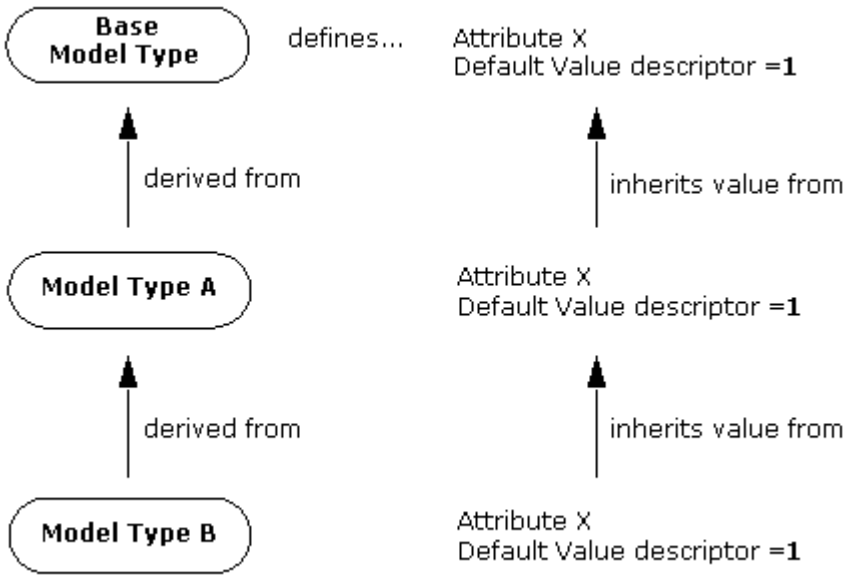
When you modify a descriptor value in a derived model type, the new value overrides the inherited value for that derived model type and any of its own derived (child) model types. Other model types that are derived from the same base model type -- and that are unspecialized with respect to the same attribute descriptor -- continue to inherit their descriptor values; this is also the case for any of their derived (child) model types.

WARNING
The complete list of descriptors that you can specialize includes -- notably, Default Value -- as well as the Extended Flags (Memory, Database, Polled, and Logged), OID Prefix, OID Reference, and Polling Group, as identified in the following image.



Standard Hierarchy

The following illustration shows a model type hierarchy whose attributes and their default values are inherited through a standard hierarchical sequence.



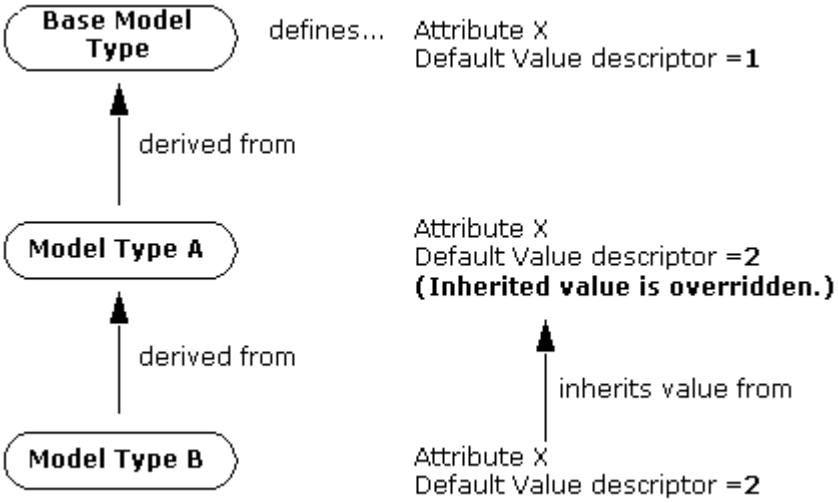
In the illustration, Model Type A is derived from Base Model Type, and, as a result, Model Type A inherits attribute X and its default value of 1 from Base Model Type. In a similar manner, Model Type B is derived from Model Type A, and, as a result, Model Type B inherits attribute X and its default value of 1 from Model Type A.

This hierarchical relationship of inheritance is applied to all other model types derived from Model Type A, Model Type B, or any of their descendants. Moreover, the relationship is maintained by the database so that any change made to the value of the Default Value attribute descriptor in the originating model type is immediately applied to all derived model types that inherit the descriptor value.

As a simple example, assume you add a Technical_Assistance text string attribute to Base Model Type with a telephone number as the default value. Model Type A, Model Type B, and all other model types that derive from them would all inherit the Technical_Assistance attribute and, therefore, the value of the Default Value attribute descriptor (the telephone number). If you then changed the telephone number, all of the model types derived directly or indirectly from Base Model Type would immediately inherit the new telephone number.

Specialized Hierarchy

In contrast to the standard hierarchy, the following illustration shows a model type hierarchy where one derived model type inherits its default value but another does not.

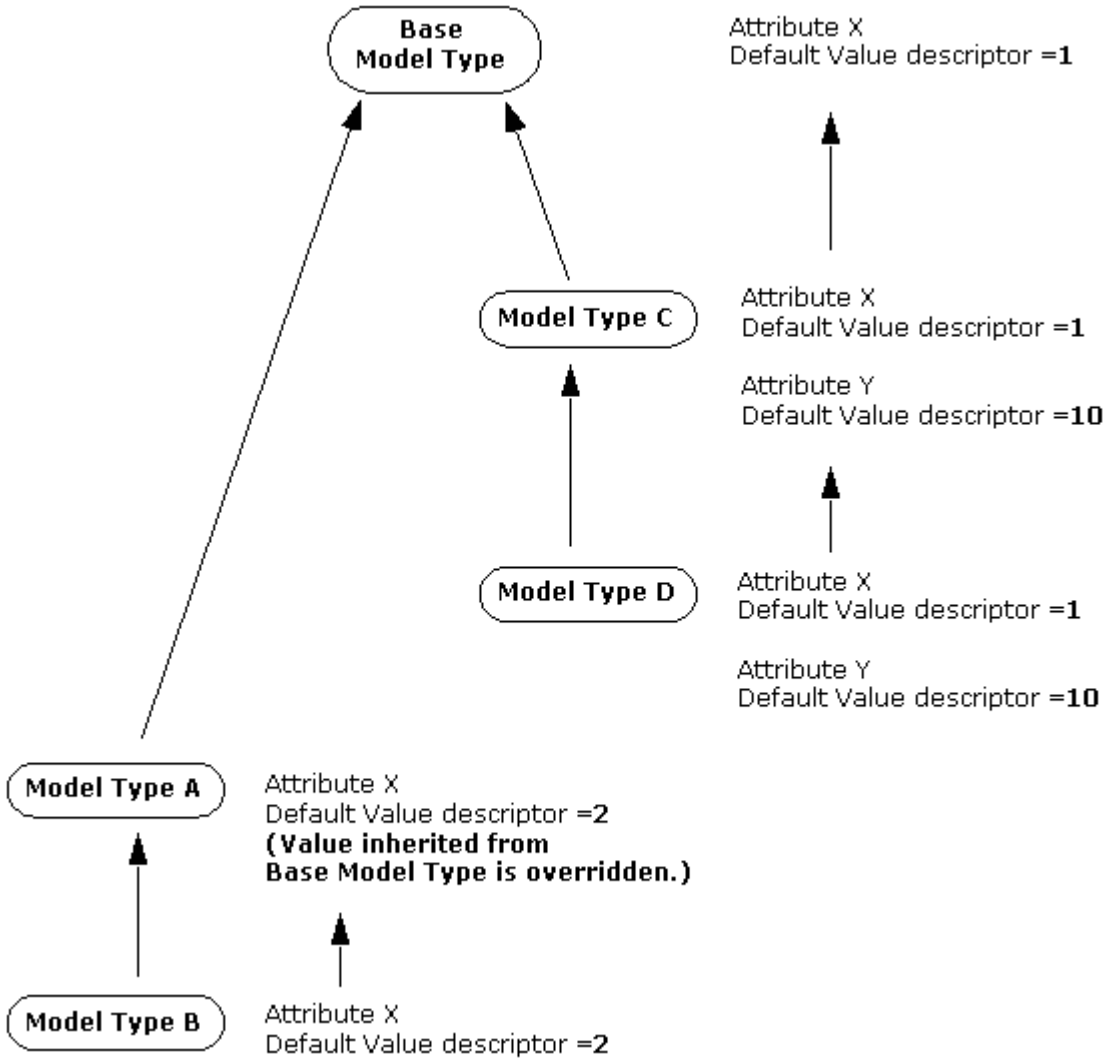


In this illustration, the default value for attribute X (or, more specifically, the value of the Default Value attribute descriptor for attribute X) in Model Type A is specified, not inherited. In other words, the value inherited from Base Model Type is overridden and no longer used. As mentioned previously in this section, this process is called *specialization*.

When you override a descriptor value that is inherited, you break the relationship to the base (parent) model type *for that attribute descriptor only*. The inheritance relationship with respect to the values of all other attribute descriptors is not affected. Furthermore, model types that are derived from specialized model types behave exactly as if they were derived from unspecialized model types. In the illustration, Model Type B inherits its default value for attribute X from Model Type A just as it would if Model Type A were not specialized. If you were to change the default value of attribute x in Model Type A, the default value of the same attribute in Model Type B would immediately change as well. Because the inheritance relationship is in effect, this would be the case even if you derived Model Type B before you made the change.

In reality, the attribute hierarchy often consists of a combination of inherited and specialized values, particularly when multiple model types are derived from a common base model type. Moreover, while specialization is most typical with respect to the Default Value attribute descriptor, it is possible for any other descriptor that can be specialized. The

following diagram illustrates a model type hierarchy that uses both inheritance and specialization for an attribute (attribute



X).

Note that, in the figure that Model Type C is specialized by introducing new attribute Y. Therefore, this attribute is inherited by derived Model Type D.

Model Type Precedence

The process of inheriting attributes from base model types means that a derived model type can inherit the same attribute from two or more inheritance paths that have a common originating model type. To avoid ambiguity in this situation, the base model types are ranked according to the order in which they are added as base model types for a derived model type, and this model type ranking determines the inheritance path to use when a derived model type can inherit an attribute from multiple paths. More specifically, the derived model type inherits the attribute from the base model type with the *lowest* ranking.

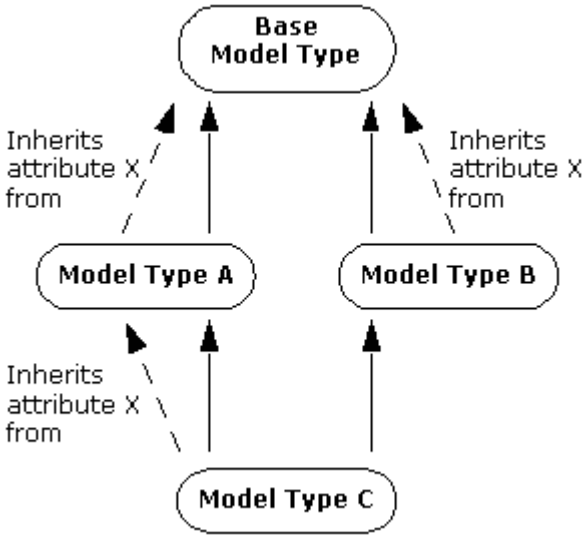
When you first derive a model type from a base model type, that base model type is given a ranking of 1. If you then add a second base model type to the derived model type, that second base model type is given a ranking of 2. Subsequent base model types are assigned rankings in a similar manner.

As an example, consider the following model type derivation workflow:

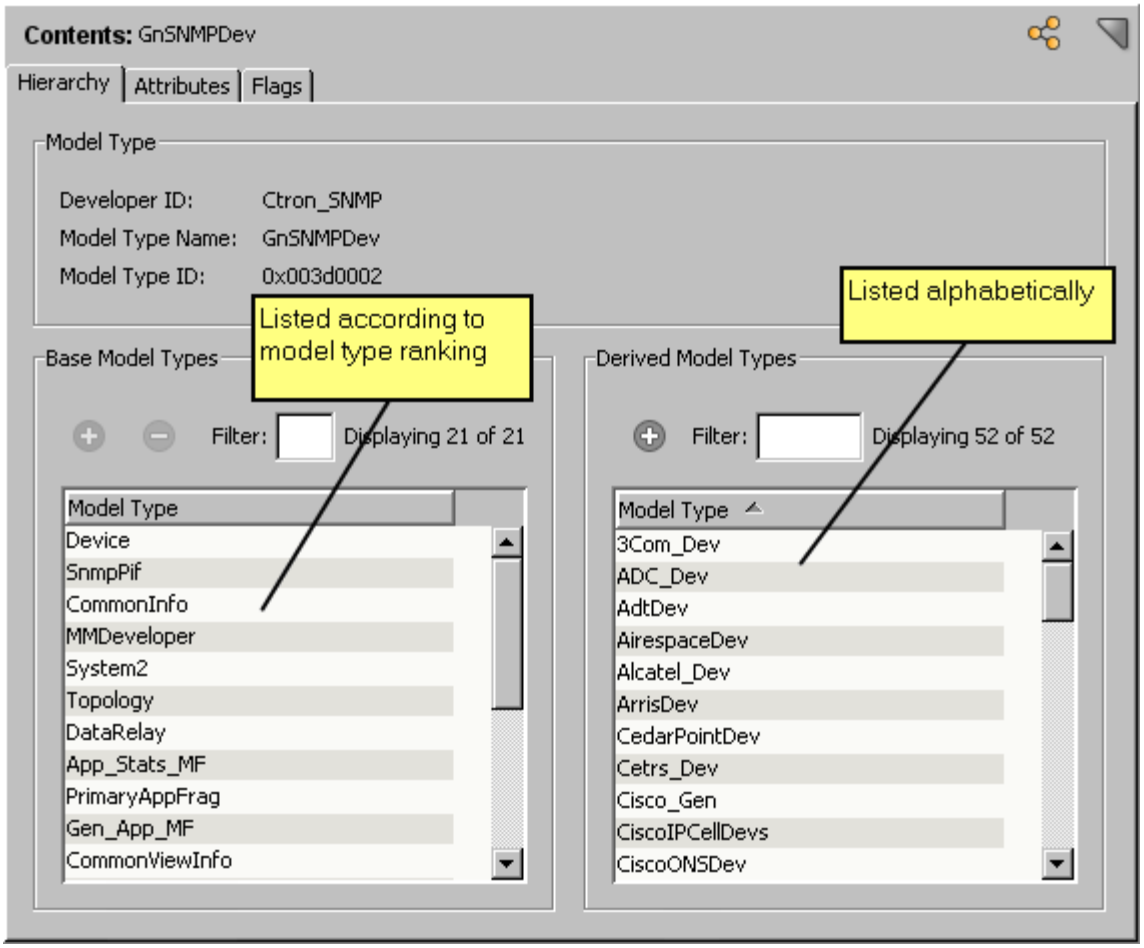
1. You derive model type A and model type B from a common base model type.

   The base model type defines attribute X, which is inherited by both derived model types. The base model type is assigned a ranking of 1 with respect to both derived model types.
2. You derive model type C from model type A.

   Model type C inherits attribute X from model type A, which, in turn, inherits the attribute from the base model type. Because model type C was created based on model type A, model type A is assigned a base model type ranking of 1 with respect to derived model type C.
3. You add model type B as a base model type of model type C.



Model type B is assigned a base model type ranking of 2 with respect to derived model type C. Because model type A has a lower ranking as a base model type, model type C inherits attribute X from model type A, not from model type B. In the Model Type Editor, the base model types for a given model type are listed in ranked order, so you can identify the order of precedence for attribute inheritance.



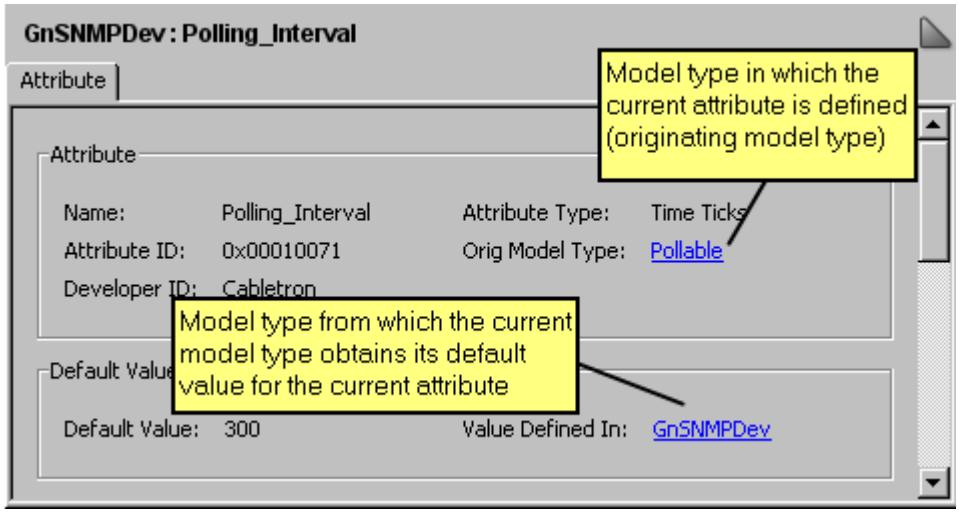
NOTE
You can change a base model type's ranking by removing it and then re-adding it as a base model type in a specific location in the list.

Attribute Collapsing

To maintain an attribute hierarchy that is as simple as possible, the Model Type Editor includes a feature that eliminates unnecessary specialization. That is, if you modify the Default Value descriptor (or any other descriptor that can be specialized) in a derived model type so that its value *matches* the value in the corresponding descriptor in the base model type from which it immediately inherits the attribute (that is, from an immediate parent model type), the database discards the modification and instead inherits the descriptor value from the base model type. This process is called "attribute collapsing;" its goal is to simplify a specialized hierarchy as much as possible by removing unnecessary customizations.

Once the descriptor value reverts to the inherited value, if you subsequently change the descriptor value in the base model type, the derived model type also receives the change (which is normal inheritance behavior).

You can identify the model type from which the current model type obtains its default value in the Value Defined In field in the Component Detail panel, as shown in the following image.



NOTE
Attribute collapsing does not take place for default values if the attribute is Shared (that is, the Shared flag is set).

Getting Started with the Model Type Editor

Before using the Model Type Editor, we recommend that you also read Certification . The section provides information about the GnSNMPDev management module provided with DX NetOps Spectrum. You can use GnSNMPDev to represent an SNMP-compliant network device that does not have a corresponding DX NetOps Spectrum management module. You can also customize GnSNMPDev to extend its support, or you can use it as a toolkit to create new management modules that include new, supporting device model types and application model types.

Using a Developer ID

DX NetOps Spectrum uses developer IDs to help ensure that objects such as model types that are created by users and application integrators have unique identifiers and, therefore, can be distributed to other users without conflict.

There are two types of developer IDs:

- **Registered developer IDs**
  This is a unique, CA-assigned developer ID that protects a developer's model types, attributes, relations, and meta-rules from being edited by other users.
- **The default developer ID**
  This is the developer ID applied when the current user is not registered with CA as a DX NetOps Spectrum developer; the code designation is DF, with a Developer ID value of 0xffff.

Whenever you create a model type, attribute, or relation, the Model Type Editor uses the developer ID that is currently active (loaded in the database) to create the ID or handle for the new object. This ID is either your unique, registered developer ID or the default ID.

The Model Type Editor also uses developer IDs to determine the access privileges of users with respect to creating, modifying, and destroying modeling catalog objects (model types, attributes, relations, and meta-rules).

- Any developer can use the Model Type Editor as the default developer. However, the modeling catalog objects created using the default developer ID are not protected.
- To obtain a developer ID from CA, contact Support.
- To be issued a developer ID, you must have purchased the Level 1 toolkit.

> **NOTE**
> For more information about the toolkit, see Spectrum Integrator .

You can activate your developer ID by loading the developer information file that contains the ID into the SpectroSERVER database. This is a *one-time* operation after you have initialized the database. However, if you reinitialize the database, you must reload the information.

> **NOTE**
> Activate your developer ID using SSdbload with the -d option. For more information, see the discussion about loading developer information in Administrating

Access Privileges With Developer ID

Your developer ID determines your access privileges with respect to model types, attributes, relations, and meta-rules.

If you work in the Model Type Editor using the default developer ID, you can:

- View, create, modify, delete, and export model types and attributes that were created with the default developer ID. This includes modifying the derivation of model types by adding and removing base model types.
- View model types that were created by other registered developers.
- Create, modify and delete relations and meta-rules that were created with the default developer ID.
- Export model types, attributes, relations, and meta-rules that were created with the default developer ID.
- Import model types, attributes, relations, and meta-rules from another compatible database.
- Import a Management Information Base (MIB) text file.

If you work in the Model Type Editor using a registered developer ID, you can:

- View, create, modify, or delete model types and attributes that were created with your registered developer ID. This includes modifying the derivation of model types by adding and removing base model types.
- Create, modify, and delete relations and meta-rules that were created with your registered developer ID.
- Export model types, attributes, relations, and meta-rules that were created with your registered developer ID.
- Import model types, attributes, relations, and meta-rules from another compatible database.
- Import a MIB text file.

> **WARNING**
> We recommend all users register with CA as a DX NetOps Spectrum developer to obtain a registered developer ID.

A registered developer can export model types, attributes, relations, and meta-rules that were created using a registered developer ID. This not only removes ID conflicts, but also protects the objects from accidental or deliberate modification. As indicated previously, if you use the default developer ID, you can export only the model types, attributes, relations, and meta-rules that were created with the default developer ID. It is probable that the IDs (handles) of these objects will conflict with those on another system to which you might want to export the objects. In addition, the exchange of such objects between systems using the default developer ID means that the objects are susceptible to modification or corruption on the receiving system.

SpectroSERVER Database Protection

When a program or process such as the Model Type Editor accesses the SpectroSERVER database, a soft lock file named .VNMDB.LOCK is created. The lock file is a safety feature that protects the database by restricting access to one CA-developed application or process at a time. Because non-CA applications or tools may not check for this lock, exercise care when using these applications to prevent concurrent access to the SpectroSERVER database; this can result in the corruption of the database.

While lock files are removed automatically during normal shutdown of a DX NetOps Spectrum application, an abnormal shutdown can leave behind a lock file erroneously. In rare situations like this, you can manually remove the database lock. For information about how to do this, see Database Management .

Use of the Model Type Editor involves several risks to the SpectroSERVER database, such as the accidental destruction of necessary model types, the inappropriate setting of attribute flags, and the creation of more than one database with different model type derivations. For this reason, it is recommended that you adopt the following strategies to help preserve the database:

- Avoid editing the database that you use to model your network until absolutely necessary. First test your model type changes using a test database.
- Restrict the use of the Model Type Editor to individuals who are familiar with the long-term plans for your model type derivation scheme. This can help to prevent unnecessary modifications to the database.
- Do not permit editing across multiple databases by more than one user using the same developer ID. This practice creates conflicts between the IDs of modeling catalog objects, which can only be corrected by manually recreating the affected objects. If two separate databases are being used, verify that the database files are being modified with different developer IDs.
- Use the database management utilities provided with DX NetOps Spectrum namely SSdbload and SSdbsave to initialize and copy the database. You may get unpredictable results if you use another method.

  NOTE
  For information about using these utilities, see *Database Management* .

Considerations on Database Migration

It is recommended that you record all changes that you make with the Model Type Editor because some changes are not migrated when the database is updated to a later version of DX NetOps Spectrum. Specifically, if you change attributes (for example, flag settings), the model type hierarchy, or relations and associated meta-rules in the model types supplied by CA or another developer (vendor), most likely the changes will not be migrated when the database is upgraded, and you will need to reapply them manually.

To preserve the *default values* of attributes, you can enable the Preserve Value attribute descriptor flag on the relevant attributes. This flag prevents changed default values from being overwritten by subsequent database updates. However, be aware that enabling this flag may prevent you from receiving intended changes pertaining to the same attributes.

About Starting the Model Type Editor

To start the Model Type Editor for the first time, obtain a registered developer ID. You can activate the ID by loading the information into the SpectroSERVER database.

NOTE
For more information, see Database Management .

WARNING
Only one application or process can access the SpectroSERVER database at a time. As a result, after you start the Model Type Editor, all other DX NetOps Spectrum applications, including the SpectroSERVER, are denied access. While CA-developed applications automatically deny access to other CA applications as needed, be aware that some third-party applications do not. Database corruption can result.

In rare situations, the SpectroSERVER database is not closed properly by a process, for example, during a power failure. In these situations, the database lock erroneously remains in effect and prevents you from starting the Model Type Editor. To use the Model Type Editor, you must have read and write permissions to the files in the <*$SPECROOT*>\SS directory.

NOTE
For information about removing a database lock, see the Database Management .

Start Model Type Editor from the Control Panel

You can start the Model Type Editor from the Control Panel.

Follow these steps:

1. Stop the SpectroSERVER if it is running.
2. Verify that no other programs that can access the SpectroSERVER database are running.
3. Open the DX NetOps Spectrum Control Panel and click Configure, Model Type Editor.
   The Model Type Editor opens. The Root model type is set as the current model type. The Root model type is the model type at the highest point in the model type hierarchy.

Start Model Type Editor from the Command Line

You can also start the Model Type Editor from the command line.

Follow these steps:

1. Stop the SpectroSERVER if it is running.
2. Verify that no other programs that can access the SpectroSERVER database are running.
3. Log in to a shell environment if you are running on Unix or Linux, or open a command prompt if you are running on Windows.
4. Change to the directory that contains the SpectroSERVER database that you want to modify using the Model Type Editor.

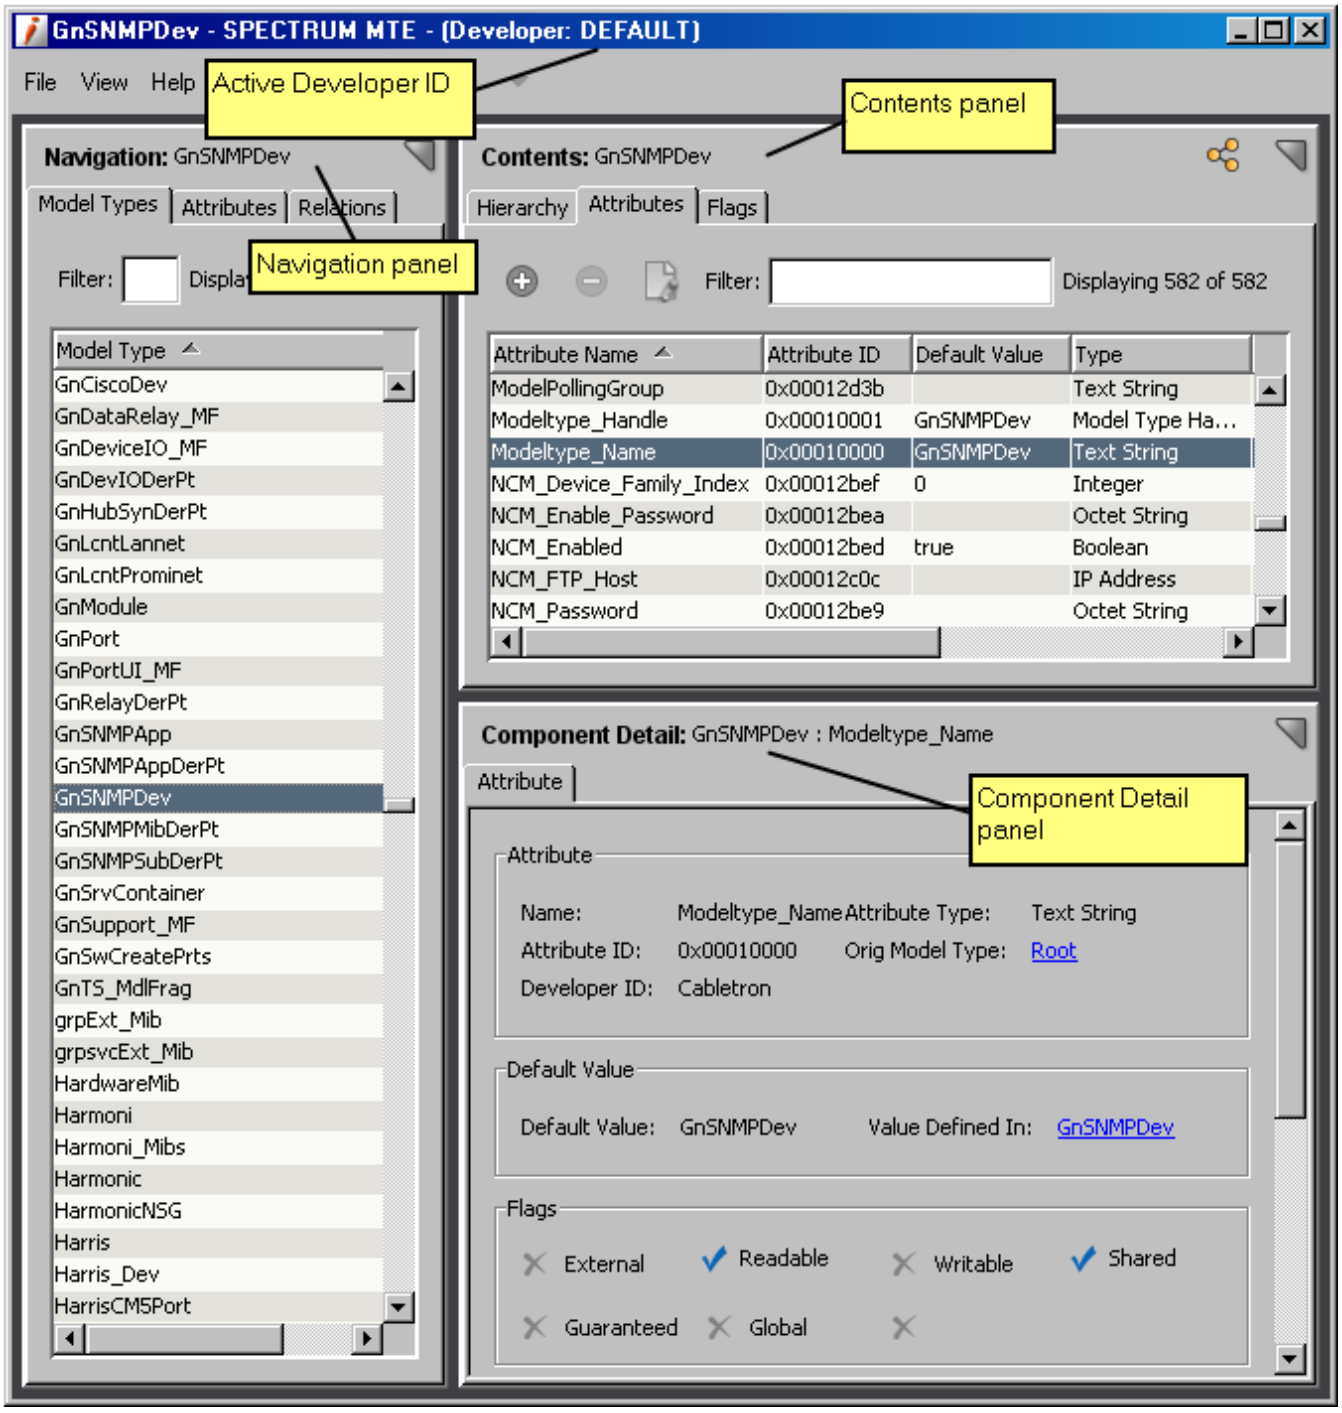
   NOTE
   The executable file for the Model Type Editor is installed in <*$SPECROOT*>/SS-Tools, but it must be called from the directory that contains the SpectroSERVER database that you want to modify. Typically, this directory is DX NetOps Spectrum/SS. The directory should contain the database files, which consist of paired *.db and *.ix files, miscellaneous files, and supporting subdirectories.
5. Enter the following command:

   ```
   ../SS-Tools/mte
   ```

   The Model Type Editor opens. The Root model type is set as the current model type. The Root model type is the model type at the highest point in the model type hierarchy.

Overview of the User Interface

The following image identifies the main work areas, or panels, in the Model Type Editor user interface.



Use the Navigation panel on the left to search for and select a model type, attribute, or relation. Information about a selected object appears in the Contents panel on the right. Use the Contents panel to modify the object, delete the object, or create related objects (for example, to derive a new model type from the current model type).

When you work with attributes, a Component Detail panel lets you view and modify the descriptor values of the current attribute.

Commit Changes to the SpectroSERVER Database

While you work in the Model Type Editor, you work with a temporary cache of database objects called the *working catalog*. The Model Type Editor adds only the database objects that are required for your activities to the working catalog.

The Model Type Editor automatically saves any changes that you make to model types, attributes, relations, and meta-rules to the working catalog. You can add them to the permanent catalog in the SpectroSERVER database on demand, or you can add them when you exit the application. You are prompted to add them when you exit the application to avoid losing your work.

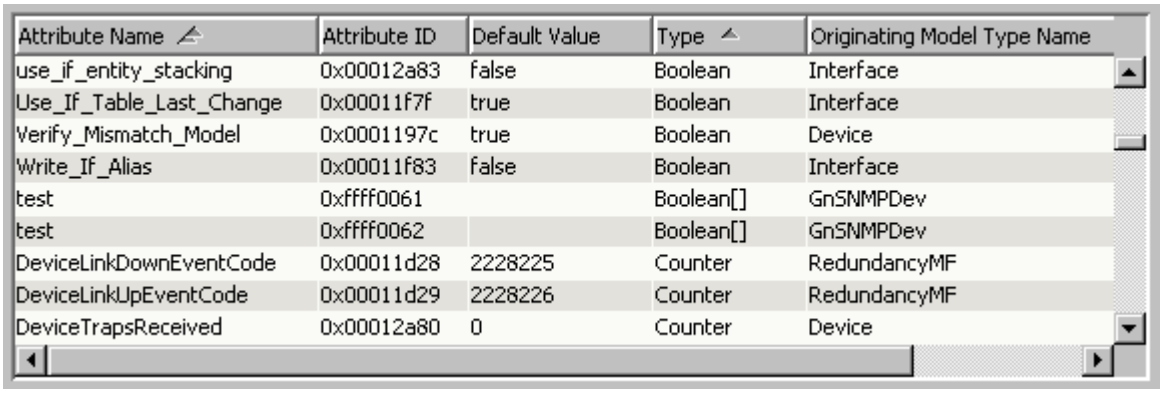
You can commit changes to the SpectroSERVER database on demand.

Follow these steps:

1. Click File, Commit to Database.
   A confirmation dialog opens.
2. Click OK.
   Your changes are saved in the permanent catalog in the SpectroSERVER database. As a result, subsequent calls to the database for the affected objects retrieve the updated versions of those objects.

Sorting and Filtering Lists

To make it easier to work with large lists of modeling catalog objects (for example, model types or attributes), you can sort the lists in tables in ascending or descending order by clicking any column header. You can also sort lists using multiple column headers. For example, the following image shows a list of attributes first sorted in ascending order by Type and then sorted in ascending order by Attribute Name, as indicated by the icons in the column headers.



Attribute Name	Attribute ID	Default Value	Type	Originating Model Type Name
use_if_entity_stacking	0x00012a83	false	Boolean	Interface
Use_If_Table_Last_Change	0x00011f7f	true	Boolean	Interface
Verify_Mismatch_Model	0x0001197c	true	Boolean	Device
Write_If_Alias	0x00011f83	false	Boolean	Interface
test	0xffff0061		Boolean[]	GnSNMPDev
test	0xffff0062		Boolean[]	GnSNMPDev
DeviceLinkDownEventCode	0x00011d28	2228225	Counter	RedundancyMF
DeviceLinkUpEventCode	0x00011d29	2228226	Counter	RedundancyMF
DeviceTrapsReceived	0x00012a80	0	Counter	Device

You can also use the Filter and Search text boxes provided on the various tabs in the Model Type Editor to display only the catalog objects whose names or IDs include a specific character string regardless of case (uppercase or lowercase). In the Filter text boxes, this limits the list of already displayed names. In the Search text box for attributes, this narrows the search criteria applied against the working catalog.

Keep in mind the following as you filter and search for modeling catalog objects:

- To filter lists by ID (for example, model type ID), the ID column must be displayed in the table.
- The Search text box for attributes always searches using both the attribute name and attribute ID as criteria.
- In most cases, a filter or search criterion remains in effect until you clear it by deleting the character string. There are a few actions that automatically clear a filter, for example, when you add a new attribute to a model type.

Add and Remove Columns from Tables

You can modify the information that is displayed in any table in the Model Type Editor by adding and removing columns from the table.

Follow these steps:

1. Right-click the table heading.
   The Table Preferences dialog opens.
2. Click the Columns tab, and select the columns you want to display.
3. (Optional) Change the table sorting and font using the controls on the Sort and Font tabs.
4. Click OK.

Exit the Model Type Editor

When you close the Model Type Editor, you are prompted to save any changes that you have made to the working catalog. Saving them propagates the changes to the SpectroSERVER database.

> **NOTE**
> For information about the difference between the working catalog and the permanent catalog, see Commit Changes to the SpectroSERVER Database.

Follow these steps:

1. Click File, Exit.
   A confirmation dialog opens.
2. Click OK.
   If you have made changes to the working catalog that is stored in cache, you are prompted to save the changes to the permanent catalog in the SpectroSERVER database.
3. Do *one* of the following:
   – To save the changes to the permanent catalog, click Yes.
   – To discard the changes, click No.

   The changes are saved, if appropriate, and the Model Type Editor is closed.

Creating and Modifying Model Types

Creating and Modifying Model Types

This section provides information about how to do the following:

- Extend and customize the default modeling catalog provided with DX NetOps Spectrum by creating and modifying model types.
- Import MIBs.
- Create and manage attribute groups.
  Attribute groups make it easier to work with logically related attributes in the Model Type Editor.

Attributes of Model Types

A model type is defined by the following attributes and classes of attributes:

- Developer ID
- Model type name
- Model type ID (handle)
- Base model types
- Derived model types
- Flags
- Custom attributes

Developer ID

The developer ID that was active when the attribute was created. This can be a registered ID obtained from CA or the default ID. Once a developer ID is assigned to an attribute, it cannot be changed.

After you create an attribute, the access privileges of users for modifying, deleting, and exporting it are determined based on whether the active developer ID matches the developer ID associated with the attribute.

Model Type Name

A descriptive identifier that typically describes the model type's function. Model type names should be a maximum of 128 characters and should only consist of letters, numbers, underscore (_) characters, and dashes (-). Spaces, punctuation, or other symbols should not be used.

> **NOTE**
> A model type name does not need to be unique across the modeling catalog, but you should help ensure it is unique across the model types created under a given developer ID. DX NetOps Spectrum differentiates model types using both the model type name and the developer ID component in the model type ID.

While you can rename a model type, be aware that this affects the AlertMap file that is specific to the model type because the file is located in the following directory:

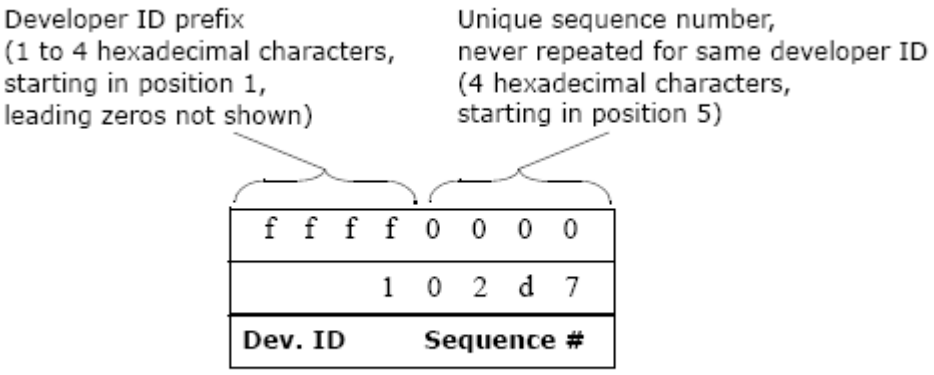
```
SS/CsVendor/<developer name>/<model type name>
```

If you rename a model type, you will need to manually create a new directory based on the new model type name and then move the AlertMap file.

Also be aware that it is possible -- although unusual and discouraged -- that an inference handler depends on the name of a model type rather than its model type ID (handle).

Model Type ID (Handle)

A unique ID that is assigned to the model type when the model type is created. The ID is generated by ORing together the value of the active developer ID and a counter value in the range from 0x0001 and 0xFFFF, as shown in the following illustration.



Structural Makeup of the Model Type ID

Once a model type ID is assigned to a model type, it cannot be modified. Additionally, if the model type is deleted, the ID is not reused.

Base Model Types

A ranked list of parent model types from which the current model type directly inherits attributes and SpectroSERVER intelligence.

Because a model type can inherit the same attribute from two or more inheritance paths that have a common originating model type, the ranking of the base model types is used to determine the inheritance path.

You cannot remove attributes inherited from a base model type, and you have limited capabilities to edit them. To remove an inherited attribute, or to have full editing capabilities, you must use the same developer ID that was active when the model type was created, and you must make the change in the originating model type. The originating model type is the model type in which the attribute was created.

Derived Model Types

An alphabetically sorted list of child model types that are directly derived from the current model type. That is, the derived model types inherit attributes and SpectroSERVER intelligence from the current model type -- and by extension -- from the base model types of the current model type.

Model Type Flags

There are several model type flags that control basic characteristics of a model type.

> **NOTE**
> You can only modify flag settings for a model type if you are using the developer ID that was active when the model type was created.

The following describes each model type flag:

- **Visible**
  If enabled (checked), the model type is exposed in the output when you run a report on the modeling catalog using the reports database utility provided with DX NetOps Spectrum. If disabled (not checked), the model type is only exposed in the output if the model type was creating using the developer ID that is currently loaded in the database. The default value is enabled.

  > **NOTE**
  > The Visible flag does not affect what a user can view in the Model Type Editor or in OneClick, nor does it affect the operation of the SpectroSERVER. However, future releases of DX NetOps Spectrum may respect

the flag and stops access to model types and models when the flag is disabled. For more information about the reports utility, see Database Management .

- **Instantiable**
  If enabled (checked), models of the model type can be created in the SpectroSERVER database by users and inference handlers. If disabled (not checked), models of the model type cannot be created, and the model type is not available in OneClick when creating a model by model type. The default value is disabled.
  Changing the condition of the Instantiable flag for a model type does not affect existing models of that type. For example, if you were to disable the flag after creating models A and B, models A and B would be unaffected. However, you could not create additional models after disabling the flag.
- **Derivable**
  If enabled (checked), the model type can be used as a base model type from which other model types can be derived. If disabled (not checked), the model type cannot be used as a base model type. The default value is enabled.
  DX NetOps Spectrum checks the Derivable flag only as new model types are being created. In other words, if you derive several model types from model type A and then disable the Derivable flag for model type A, the newly derived model types are unaffected, but you are no longer able to derive additional model types from model type A.
- **No Destroy**
  If enabled (checked), models of the model type *cannot* be deleted from the SpectroSERVER database by users and inference handlers. If disabled (not checked), models of the model type can be deleted. The default value is disabled.

  NOTE
  You can only enable this flag if you also enable the Instantiable flag.

- **Unique**
  If enabled (checked), only one model of the model type can exist in the SpectroSERVER database. If disabled (not checked), additional models of the model type can exist. The default value is disabled.
  DX NetOps Spectrum checks the Unique flag only as models are being created. If you create several models of a model type and then disable the Unique flag, the previously created models are unaffected, but you are no longer able to create additional models of the model type.

  NOTE
  You can only enable this flag if you also enable the Instantiable flag.

- **Required**
  If enabled (checked), the SpectroSERVER creates a model of the model type at server startup if a model does not already exist. If disabled (not checked), a model of the model type is created only if requested by a user, inference handler, or application. The default value is disabled.

  NOTE
  You can only enable this flag if you also enable the Instantiable flag.

Custom Attributes

In addition to the model type attributes described earlier in this section (such as model type ID), a model type has many other attributes that are inherited from base (parent) model types or that originate in the model type itself. You can view this list of attributes on the Attributes tab in the Contents panel, as shown in the following image.

You can click the Attribute Name column header to sort the attribute list alphabetically in ascending or descending order.

The Originating Model Type column displays the model type in which each attribute was created.

You can click the Originating Model Type column header to sort the list alphabetically in ascending or descending order. This lets you group together and, therefore, identify all of the attributes in the current model type that originate in the model type itself or in a base (parent) model type.

The values for the attribute descriptors of the selected attribute are displayed in the Component Detail panel.

Standard Attribute Descriptors

Standard Attribute Descriptors

As discussed earlier in this section, every attribute is described by a set of characteristics called *attribute descriptors*. The following are attribute descriptors that you can only modify in the originating model type (the model type in which the attribute was defined):

Developer ID

The developer ID that was active when the attribute was created. This can be a registered ID obtained from CA or the default ID. Once a developer ID is assigned to an attribute, it cannot be changed.

After you create an attribute, the access privileges of users for modifying, deleting, and exporting it are determined based on whether the active developer ID matches the developer ID associated with the attribute.

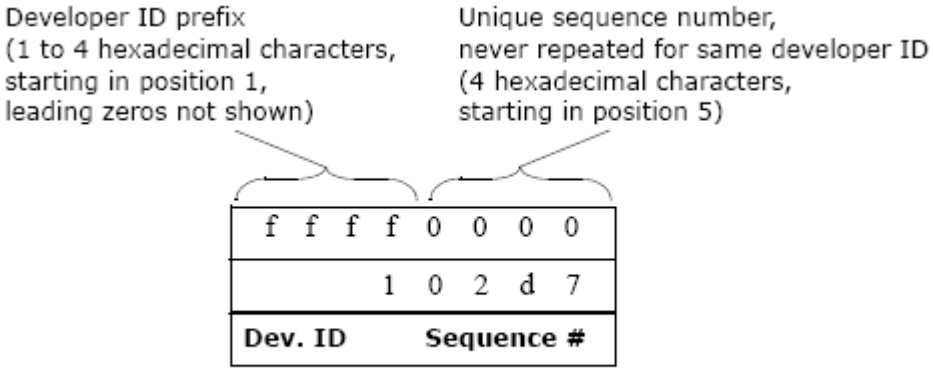
Attribute Name

An attribute name is a descriptive identifier. Attribute names should be a maximum of 128 characters and should only consist of letters, numbers, underscore (_) characters, and dashes (-). Spaces, punctuation, or other symbols should not be used.

> **NOTE**
> An attribute name does not need to be unique across the modeling catalog, but it should be unique across the attributes in the model type that were created using the same developer ID. In other words, within a single model type, two attributes can have the same name if they were created using different developer IDs.

Attribute ID (Handle)

A unique ID that is assigned to the attribute when the attribute is created. The ID is generated by ORing together the value of the active developer ID and a unique sequence number (counter value), as shown in the following illustration.



Structural Makeup of the Attribute ID

Once an attribute ID is assigned to an attribute, it cannot be modified. Additionally, if the attribute is deleted, the ID is not reused.

Type

The attribute type defines the kind of data that the value of the attribute can hold. If the attribute represents a managed object that is defined in the MIB, you should set the type to correspond to the type defined in the MIB.

If an attribute requires a list of values, you must select the List check box.

> **NOTE**
> After you create an attribute, you cannot change its type or whether it stores a single value or a list of values. You must delete the attribute and create a new one of the desired type. There are two exceptions to this. First, you can change the type from Octet String to Text String, and vice versa. Second, if the type is numeric (Integer, Counter, Enumeration, Gauge, or Time Ticks), you can change from one of these numeric types to another.

Flags

Flags -- also referred to as descriptor flags -- inform the SpectroSERVER of the characteristics of the attribute, for example, who can access the attribute's value. The following describes each flag.

- **External**
  Indicates the attribute value is maintained outside of the SpectroSERVER and that update of the value is done either at a polling interval or upon user request.

  NOTE
  If you set this flag, you must supply an OID prefix, which specifies the location of the managed variable in the MIB. Also note that if you set this flag, you cannot set the Shared flag.
- **Readable**
  Informs the SpectroSERVER that a client or other application can read the attribute value from the SpectroSERVER database.
  If you set the External flag, you should set this flag in accordance with the MIB definition of the Readable variable for the attribute. Otherwise, you can set this flag as desired.
- **Writable**
  Informs the SpectroSERVER that a client or other application can write the attribute value to the SpectroSERVER database.
  If you set the External flag, you should set this flag in accordance with the MIB definition of the Writable variable for the attribute. Otherwise, you can set this flag as desired.
- **Shared**
  Declares that only one value exists for the attribute and that all models of the given model type share the same value. The value is *not* duplicated for each model in memory or in the database.

  NOTE
  You can only set this flag if you also set the Database flag or the Memory flag. Also, if you set the External flag or the Polled flag, you cannot set this flag.
- **Guaranteed**
  Guarantees that the attribute will continue to exist and can be used in future model type derivations. Once set, this flag cannot be disabled except by the developer who created the attribute.

  NOTE
  Setting this flag only guarantees the presence of the attribute, not its value or values.

  If this flag is disabled, any Model Type Editor user can enable (set) or disable the Extended flags of the attribute. If this flag is enabled, users having developer IDs other than the one used to create the attribute can only set the Extended flags; they cannot disable them. The user having the developer ID used to create the attribute can set or disable the Extended flags at any time.
- **Global**
  Indicates that the attribute's value will be kept consistent across duplicate models in all landscapes in a distributed SpectroSERVER (DSS) environment.
  Global attributes are only maintained for models of the User and UserGroup model types. These are duplicate model types, that is, across a distributed environment, multiple models of these types effectively represent the same user or user group. As such, a change to a model in one landscape should be propagated to all corresponding, duplicate models in all other landscapes.

  NOTE
  You can only set this flag if you also set the Memory flag or the Database flag.
- **Preserve Value**
  Indicates that imported files will not overwrite the attribute's default value currently stored in the database.
  If you customize the default values of one or more model types to meet specific requirements, and then you set this flag, your customizations (the specialized default values) will remain in place when the model types are updated by subsequent versions of DX NetOps Spectrum.

If you are the owner of the attribute (that is, the attribute was created using the developer ID that is currently active), you can modify all of the flags described in this section *in the originating model type* regardless of whether you are the owner of the associated model type.

If you are not the owner of the attribute, or if the attribute is inherited, you cannot modify these flags. However, you can modify the attribute's extended flags.

Group Name and Group ID

A *group* is a logical collection of related attributes in a model type. Groups make working with related attributes easier because they let you to define and use a user-defined sorting mechanism in the Model Type Editor. You can create groups, assign attributes to them, and then add the Group Name or Group ID as a column header in the table of attributes on the Attributes tab in the Contents panel. This lets you to then click the column header to quickly group together and view together all of the attributes within a group.

Group Name specifies the name of the group to which the attribute is assigned, and *Group ID* specifies the ID of that group.

Like for any standard descriptor, you can change the group to which an attribute is assigned if you are modifying the model type in which the attribute was created, and if you are using the developer ID that was used when the attribute was created (that is, you own the attribute).

By default, an attribute has a Group ID value of 0x00000000, which indicates the attribute is not assigned to a group. If you assign an attribute to a group, and you subsequently decide it should not be assigned to a group, you must reassign the attribute to the Root group. You cannot restore a Group ID value of 0x00000000 in the Model Type Editor.

> **NOTE**
> If you set an attribute's Group Name to the name of another developer's attribute group, and that developer's attribute group is not distributed with the next version of DX NetOps Spectrum, the attribute's Group Name value is reset to <no group>, and its Group ID value is reset to 0x00000000 to indicate it is not assigned to a group.

Special Attribute Descriptors

Special Attribute Descriptors

As discussed earlier in this section, every attribute is described by a set of characteristics called *attribute descriptors*. The following are attribute descriptors that you can specialize; you can modify them at any level of the inheritance hierarchy:

Default Value

The initial value or values for the attribute. An attribute can inherit its default value from a base model type or specify its own default value (a process called specialization). In the latter case, all model types derived from the specialized model type inherit the changed attribute value.

> **NOTE**
> While you can specify a default value for an attribute using this attribute descriptor of a model type, the actual value or values of the attribute are often different in models. This is definitely the case for external attributes (attributes for which the External flag is enabled), since these attributes maintain their values by polling devices at specified intervals or making updates upon user request.

Extended Flags

Extended flags -- also referred to as extended descriptor flags -- inform the SpectroSERVER of additional characteristics of the attribute, for example, whether the attribute should be polled.

You enable and disable an attribute's extended flags using the Model Type Editor, but the flags are used by the SpectroSERVER.

If an attribute's Guaranteed flag is disabled, any Model Type Editor user can enable or disable the extended flags. If the Guaranteed flag is enabled, users having developer IDs other than the one used to create the attribute can only enable the Extended flags; they cannot disable them. The user having the developer ID used to create the attribute can enable or disable the extended flags at any time.

The following list describes each extended flag.

- **Memory**
  Stores a copy of the attribute's value in memory. When the SpectroSERVER is restarted, the value is reset to the default value; the value in memory is not preserved.

  NOTE
  You must set either this flag or the Database flag if you set either the Shared flag or the Global flag.
- **Database**
  Stores a copy of the attribute's value in the database so that it is preserved across SpectroSERVER restarts.

  NOTE
  You must set either this flag or the Memory flag if you set either the Shared flag or the Global flag.
- **Polled**
  Informs the SpectroSERVER that the attribute should be polled at the polling interval in order to update its value. This is only meaningful if the External flag is also set. If the Memory flag is also set for the attribute, the value retrieved by the poll is also stored in memory.

  NOTE
  You cannot set this flag if you set the Shared flag.

  If you set this flag, you should assign the attribute to an appropriate polling group; all attributes of a polling group are polled together. If you set both this flag and the Logged flag, you must group the attribute with other attributes that also have both the Polled and Logged flags set.
- **Logged**
  Causes the value of the attribute to be recorded in the Distributed Data Manager (DDM) database. If you enable this flag, you should assign the attribute to an appropriate polling group; all attributes of a polling group are logged together. If you enable both this flag and the Polled flag, you must group the attribute with other attributes that also have both the Polled and Logged flags enabled.

  NOTE
  Logging occurs at a user-specified interval stored in the Poll_Log_Ratio attribute. By default, this attribute is set to 0 for device model types, which effectively disabled DX NetOps Spectrum's native logging method. If you require the logging of device, attribute, and port statistics, it is recommended that you use [assign the value for sslog in your book] instead of the native method, the latter of which writes the information to the Distributed Data Manager (DDM) database. [assign the value for sslog in your book] is a DX NetOps Spectrum command-line application that lets you to log statistics directly to ASCII files, which reduces the load on the DDM database and eliminates the need to export the data. Of equal importance, [assign the value for sslog in your book] gives you greater control over what data to log and how frequently to log it. For more information, see the *[assign the value for sslog in your book]* User *section.*

External attributes that are set to be polled and logged may return "noSuchName" errors when a management module is based on a more current firmware version than the managed device supports. To reduce unnecessary network traffic, DX NetOps Spectrum automatically suspends normal polling and logging for attributes that return this error, and moves the attribute to the unsupported polling attribute group.

Once an attribute has been moved to the unsupported polling attribute group, DX NetOps Spectrum generates an event (0x10970). By default, this event is not logged and does not generate an alarm. However, you can change this event processing using the Event Configuration application in OneClick. DX NetOps Spectrum attempts to read the attribute at

the interval specified by the unsupported_attr_poll_interval. By default, the value of the unsupported_attr_poll_interval is 12 hours. This value can be changed by manually adding the parameter and the desired interval (in seconds) to DX NetOps Spectrum's .vnmrc file.

When an attribute that had previously been reporting a "noSuchName" error reports a successful poll, DX NetOps Spectrum generates an event (0x10971). By default, this event is not logged and does not clear an alarm. However, you can also change this event processing using the Event Configuration application.

Thus, the unsupported_attr_poll_interval lets normal polling and logging for an attribute to resume automatically without requiring a SpectroSERVER restart or the destruction and recreation of the models that have the attribute.

> **NOTE**
> For more information about the unsupported_attr_poll_interval, see the *Distributed SpectroSERVER* Administrating *section*. For more information about the Event Configuration application, see the Event Configuration *section.*

OID Prefix and OID Reference

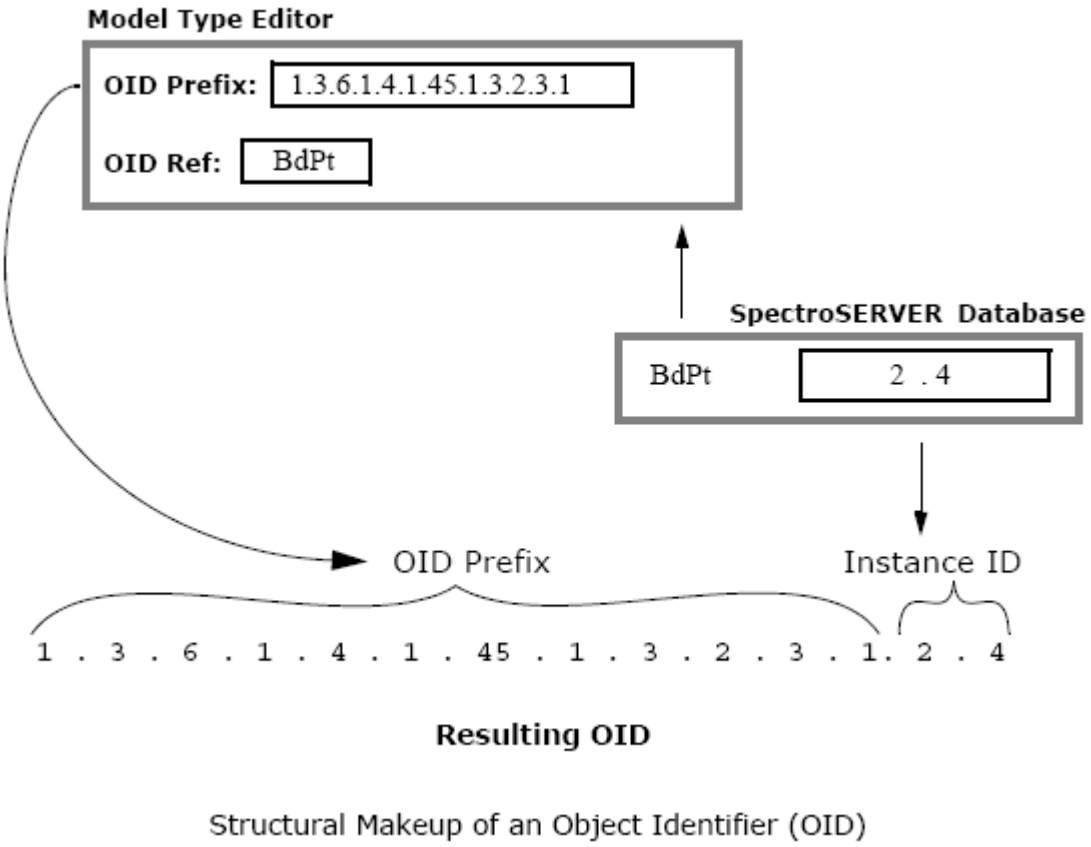
The OID Prefix descriptor and OID Reference descriptor apply only to attributes that have the External flag enabled, that is, attributes that represent managed variables within tables in a MIB.

The *OID Prefix* specifies the column within the MIB table that contains the variable. You must use dotted-decimal notation when entering the OID prefix.

The *OID Reference* (instance ID) specifies the name of an attribute whose value serves as an index used to define the instance of the variable within the column.

The OID prefix is concatenated with the OID reference to define a complete object identifier (OID) for the variable being monitored. As an example, the following image shows the resulting OID formed using the following:

- An OID Prefix set to the OID for EnetPortColls
- An OID Reference set to the ID of an internal attribute, defining the instance ID.



Structural Makeup of an Object Identifier (OID)

NOTE
A managed variable does not always require an OID reference. You can enter a complete OID with instance ID in the OID Prefix field.

Polling Group

The polling group to which the attribute belongs. All of the attributes in a group are polled together and logged together. The SpectroSERVER polls groups of pollable attributes by polling group, one at a time beginning with the group with the lowest number.

Specify a number between 0 (zero) and 255 inclusive. If you do not specify a value for a new or existing attribute, the attribute is automatically given a value of 0.

When attributes are polled but not logged (that is, the Polled flag is enabled, but the Logged flag is disabled), the only limit to the number of attributes within a polling group is the transmission length limits imposed by the following:

- The transmission protocol (Ethernet, FDDI, and so on)
- The management protocol (CA proprietary, SNMP, and so on)

Search for and Display Model Types

You can search for a model type in the working catalog by name or ID.

Follow these steps:

1. In the Navigation panel, click the Model Types tab.
   The names of all of the model types in the modeling catalog are listed.

2. In the list, select the name of the model type that you want to examine.
   To locate and select a specific model type, you can take the following steps:
   – Enter a text string in the Filter text box to filter the list to include only the model types whose names or IDs contain the string. To filter the list by ID, the ID column must be displayed in the table.
   – Click the Model Type bar at the top of the list to change the alphabetical sorting from ascending to descending or vice versa.

   The selected model type becomes the current model type, and information about it is displayed in the Contents panel.
3. To navigate to a base (parent) or derived (child) model type of the current model type, take the following steps:
   a. Click the Hierarchy tab in the Contents panel.
   b. Double-click a base or derived model type to make it the current model type.

      NOTE
      You can filter the list of base or derived model types using the Filter text boxes.
   c. Repeat the preceding step as many times as needed to navigate to the desired model type in the model type hierarchy.

Search for and Display Attributes

You can search for an attribute in the working catalog by name or ID.

Follow these steps:

1. In the Navigation panel, click the Attributes tab.
2. In the Search text box, enter a text string to examine against the attribute names and IDs. (You do not need to display the ID column in the table to search by ID.)
   The attributes with names or IDs that include the string that you entered are displayed in the list. In addition, the *originating model type* for each attribute is displayed. The originating model type is the model type where the attribute was created. Use this model type to modify all of the descriptors for an attribute.
3. Select the name of the attribute that you want to examine from the list.
   The corresponding originating model type is made the current model type in the Contents panel, and information about the attribute you selected is displayed in the Component Detail panel.

Create a Model Type

When you want to represent a new device or some other entity that is not currently defined as a model type in the DX NetOps Spectrum database, you must create a model type.

Follow these steps:

1. Determine the attributes that are required for the new model type.
2. Identify the base model types from which the new model type can inherit its attributes or inherit as many of them as possible.
3. Set the existing model type that has *most* of the attributes that you need for the new model type as the current model type.
   This is the model type from which you will directly derive the new model type.
4. Click the Derive a new Model Type

   icon  .

   NOTE
   If you are not able to click the button, verify that the current model type has its Derivable flag set. You cannot derive a model type from the model type unless this is the case.

   The Create Derived Model Type dialog opens.

5. For Name, enter the name of the new model type.
   The name should be a maximum of 128 characters and should only consist of letters, numbers, underscore characters (_), or dash characters (-).

   WARNING
   A model type name is not required to be unique across the modeling catalog. However, we recommend using unique names across the model types that were created under the currently active developer ID. DX NetOps Spectrum differentiates model types using both the model type name and the developer ID component in the model type ID. In addition, reusing a model type name is not recommended.
6. Click OK.
   The new model type is created and is set as the current model type.
   If you click the Attributes tab, you can examine its attributes, which are those inherited from the base model type that you selected in step 1.
7. If the new model type requires additional attributes that can be inherited from other base model types, add those model types as base model types.
8. If the new model type requires additional attributes that cannot be inherited from other base model types, add those attributes directly to the new model type.
9. Set the model type flags for the new model type as appropriate.
   For example, if the new model type is a final model type (that is, it is meant to be instantiated and used by models represented in OneClick), set the Instantiable flag.
10. Restart the OneClick web server.
    You can now create a model of this new model type in the OneClick console.

Delete a Model Type

Deleting a model type involves deleting all models of that model type, removing all derived model types for the model type, and finally removing all base model types for the model type. In effect, this completely removes all dependencies on the model type from the model type hierarchy so that the model type can safely be destroyed in the database.

Follow these steps:

1. In OneClick, use the Locater tab to find all of the models of the model type you intend to delete, and delete the models.

   NOTE
   For more information, see Modeling and Managing Your IT Infrastructure .
2. Shut down OneClick and the SpectroSERVER, and start the Model Type Editor.
3. Set to current the model type that you want to delete.
4. Examine the hierarchy of the model type in order to identify the consequences of deleting it. For example, check whether any attributes that originate in the model type are critical to any derived model types that inherit them. Then resolve any predictable problems with inheritance factors.
5. Remove all derived model types from the model type that you want to delete:
   a. Make the first derived model type the current model type instead.
      The model type you want to delete is now displayed in the list of base model types for the new current model type.
   b. In the list of base model types, select the model type that you want to delete, and click the Remove selected base Model Type
      icon  .

      NOTE
      The tooltip displayed when you hover over the button indicates whether this action will result in only the removal of the selected model type as a base model type or also the *deletion* of the current model type. If the current model type has no derived model types, it will also be deleted when you remove the last of its base model types because this means it is no longer a part of the model type hierarchy.

A confirmation dialog opens.

c. Click Yes.

d. Repeat the preceding three steps as many times as needed until the model type that you want to delete is no longer being used as a base model type for any model types.

6. Remove all base model types from the model type that you want to delete:

a. Set current the model type that you want to delete.

b. In the list of base model types, select the first model type, and click the Remove selected base Model Type 

NOTE
As previously mentioned, if the current model type has no derived model types, it will also be deleted when you remove the last of its base model types.

A confirmation dialog opens.

c. Click Yes.

d. Repeat the preceding two steps until the model type that you want to delete no longer has any base model types.

NOTE
Removing the last base model type will also delete the model type that you want to delete. You can only remove the last base model type from the current model type when the current model type has no derived model types.

Working with Base Model Types

If a model type requires additional attributes above and beyond those inherited from the model type from which it is first derived, you can add additional base model types. This can add attributes and inference handlers to the model type.

While the addition of attributes typically does not cause any problem, you may add inference handlers that lock attributes, which may make old inference handlers fail. Also, be aware that if a model type has two or more base model types that share a common ancestor model type, the model type has more than one way to inherit attributes and intelligence originating in that common ancestor. As described in Model Type Precedence, DX NetOps Spectrum resolves this type of situation by assigning rankings to base model types. The base model type with the *lower* ranking (that is, the base model type that is *higher* in the list of base model types) is the base model type from which the derived model type inherits the shared attribute.

NOTE
You can change a base model type's ranking by removing the base model type and re-adding it in a specific location in the ranked list of base model types.

How to Determine the Base Model Types for a New Model Type

To identify the model types that you want to use as base model types, use the Hierarchy tab to navigate up and down through the model type hierarchy to specific model types, and then use the Attributes tab to examine their attributes. Continue this process until you have identified the following:

- The existing model type that contains *most* of the attributes needed for the new model type. You should derive the new model type directly from this model type.
- The other model types that can provide some or all of the other attributes needed for the new model type.

As you identify the base model types for the new model type, keep the following guidelines in mind:

- You can only use derivable model types as base model types, that is, model types that have the Derivable flag set.
- Use as few base model types as possible in order to keep the hierarchy simple.
- Avoid adding base model types that do not contribute significantly to the model type being created. And avoid base model types that contain a significant number of unnecessary attributes. Because you cannot remove inherited attributes, ignoring this guideline can quickly add an excessive number of attributes, wasting storage space and perhaps affecting performance.
- You might want to add one or more base model types that provide access to specialized MIB attributes and intelligence. We recommend creating a set of MIB-specific model types, each one containing the intelligence and attributes related to a specific MIB. Create a new model type based on GnSNMPMibDerPt and give it a name that identifies associated MIB. Then import the MIB into the model type. This approach lets you add the MIB-specific model type as a base model type to multiple model types. The associated attribute IDs remain the same across all derived model types.

  WARNING
  For new device model types, the GnSNMPDev model type is often the best starting point. This model type contains the basic attributes and intelligence that are typically required for integration with core DX NetOps Spectrum functionality. For new application model types, select from several possible starting points, such as GnSNMPMibDerPt and GnSNMPAppDerPt. For more information, see the Certifications .

Add a Base Model Type to a Model Type

You can add a base model type to an existing model type.

Follow these steps:

1. Set current the model type for which you want to add a base model type.
2. Do one of the following:
   – To give the new base model type the highest ranking of all of the listed base model types (that is, place the base model type last in the list), proceed to the next step.
   – To give the new base model type a lower ranking (that is, place the base model type higher in the list), select the base model type directly *beneath* the location where you want to insert the new base model type. This step adds the new base model type in that location.

     NOTE
     When a derived model type can inherit the same attribute from two or more inheritance paths that have a common originating model type, the derived model type inherits the attribute from the base model type with the lowest ranking.
3. Under Base Model Types, click the Add a base Model Type icon 
   The Select New Base Model Type dialog opens.
4. Select the model type to add as a base model type.

   NOTE
   To rapidly locate and select a specific model type, enter a text string in the Filter text box to filter the list.
5. Click OK.
   The selected model type is added as a base model type of the current model type.

Remove a Base Model Type from a Model Type

Removing a base model type from a model type is the way in which you remove inherited attributes, inherited meta-rules, or intelligence from the model type. Essentially, this removes the hierarchical relationship between the model type and the base model type in which the undesirable attributes originate (referred to as the *originating model type*).

You can remove base model types from the current model type if the current model type was creating using the developer ID that is currently active.

You cannot remove the last base model type from the current model type if the current model type has derived model types. In order to break such a connection, you must first navigate to the derived model types and use the following procedure to remove the model type of interest as a base model type with respect to the derived model types. You can then navigate back to the model type of interest and remove its last remaining base model type.

> **NOTE**
> Inference handlers are code segments that define the behavior and intelligence of a model type. Problems can occur if you remove a base model type from a derived model type, and the derived model type has associated inference handlers that refer to attributes that used to be inherited from the removed base model type. This sort of dependency can be difficult to detect. Also be aware that removing a base model type also may remove inference handlers that were inherited from that base model type. This may cause anomalies if the removed inference handlers performed some vital function for the model type or for other model types derived from it.

You can remove a base model type from a model type.

Follow these steps:

1. Set current the model type for which you want to remove a base model type.
2. Click the Hierarchy tab, and under Base Model Types, select the model type that you want to remove, and click the Remove selected base Model Type icon  .

   > **NOTE**
   > The tooltip for the button indicates whether this action only removes the selected model type as a base model type or also deletes the current model type. If the current model type has no derived model types, it is also deleted when you remove the last of its base model types because it is no longer a part of the model type hierarchy.

   The selected model type is removed as a base model type.

Import MIBs

DX NetOps Spectrum manages devices according to the requirements and values that are specified in their MIB documents. A *MIB (Management Information Base)* is a database that resides on a network device and represents that device as a hierarchical collection of objects. A MIB object represents an individual element of information, such as the uptime of a device. MIBs themselves are text files with a special syntax. A device MIB defines all of the objects that can be managed on the associated device. The MIB organizes this information in a tree structure with branches that organize the managed objects into logical groups.

You can use the Model Type Editor to import both SMIv1 and SMIv2 MIBs. However, when you import an SMIv2 MIB, the Model Type Editor maps the MIB data type to the corresponding data type that is defined in SMIv1. The Model Type Editor also supports most standard text conventions and associated enumerations that can be used in a MIB.

When you create a model type, you typically want to add base model types that provide access to specialized MIB attributes and intelligence. We recommend creating a set of MIB-specific model types, each one containing the intelligence and attributes of a specific MIB. Create a model type from GnSNMPMibDerPt and assign it a name that identifies the associated MIB. Then import the MIB into the model type. This approach lets you add the MIB-specific model type as a base model type to multiple model types and keep the associated attribute IDs consistent across all derived model types.

> **NOTE**
> You can only import a MIB into a model type that was created by the currently active developer ID. This rule prevents you from importing the MIB into a model type that you cannot subsequently export.

Using the Model Type Editor to import a MIB into a model type.

Follow these steps:

1. Select the model type from which you plan to derive a model type for the MIB import.
   Typically, the starting point is some developer-specific (vendor-specific) model type that is derived from the Manufacturer model type, as illustrated in the following figure:

   However, it can also be a model type that was derived from EntityTypes, MMDeveloper, or another model type in the modeling catalog. Another alternative is GnSNMPMibDerPt, which was designed specifically for importing MIBs into the DX NetOps Spectrum database. That model type already contains many needed attributes and relations. Regardless of your selection, you can create device model types at appropriate places in the model type hierarchy later for each device receiving the attributes of the MIB.

   NOTE
   For more information about designing a new model type, see Certifications .
2. Click the Hierarchy tab, and create a model type into which to import the MIB information:
   a. Click the Derive a new Model Type
   icon 
   b. Enter a model type name.
   The name cannot exceed 128 characters and can only consist of letters, numbers, underscore characters (_), or dash characters (-).

      WARNING
      A model type name is not required to be unique across the modeling catalog. However, supply a name that is unique across the model types that were created under the currently active developer ID. DX NetOps Spectrum differentiates model types using both the model type name and the developer ID component in the model type ID. To know more about the 'Developer ID' see, the Getting Started with the Model Type Editor section.
   c. Click OK.
   The derived model type is created and is set as the current model type.
3. Click File, Import MIB.
   The MIB Import dialog opens.

   NOTE
   Sometimes a single file contains multiple MIBs that are delineated with BEGIN and END statements. Include only a single MIB in the file that you import.
4. Click Browse, navigate to the MIB file to import, select the file, and click Open.
5. Click OK to begin the import.
   When the import is complete, the MIB Import Complete dialog is displayed to inform you of the number of attributes and attribute groups that were created.
   If issues are encountered during the import process, a warning is displayed to inform you that the import was successful but issues were encountered. If the import process fails, an error is displayed.
6. Click OK to close the dialog.

WARNING
When you create a model type, typically you also add support for traps, events, and alarms. You can use the MIB Tools utility in OneClick to add trap support and perform initial event configuration. For more information, see Certifications . You can then fully configure the events and alarms using the Event Configuration application in OneClick, as described inManaging Network. For more information about creating a management module (including creating model types), see Certifications .

Set Model Type Flags

To set and change the flags for a model type, you must be using the developer ID that was active when the model type was created.

Follow these steps:

1. Select the model type whose model type flags you want to set.
2. Click the Flags tab and click the Edit
   icon 
   The Edit Flags dialog opens.
3. Select (enable) and clear (disable) the flags as desired.
4. Click OK.

Working with Attributes

You can add or remove attributes from a model type directly and indirectly:

- To add or remove attributes *indirectly*, add or remove base model types, as described in Working with Base Model Types.
- To add or remove attributes *directly*, create or delete the attributes from the model type itself, as described in the topics in this section.

Add an Attribute to a Model Type

Typically, you will add attributes to model types that you own, that is, types that were created using the currently active developer ID. Because you own the model types, you can subsequently export them and their attributes.

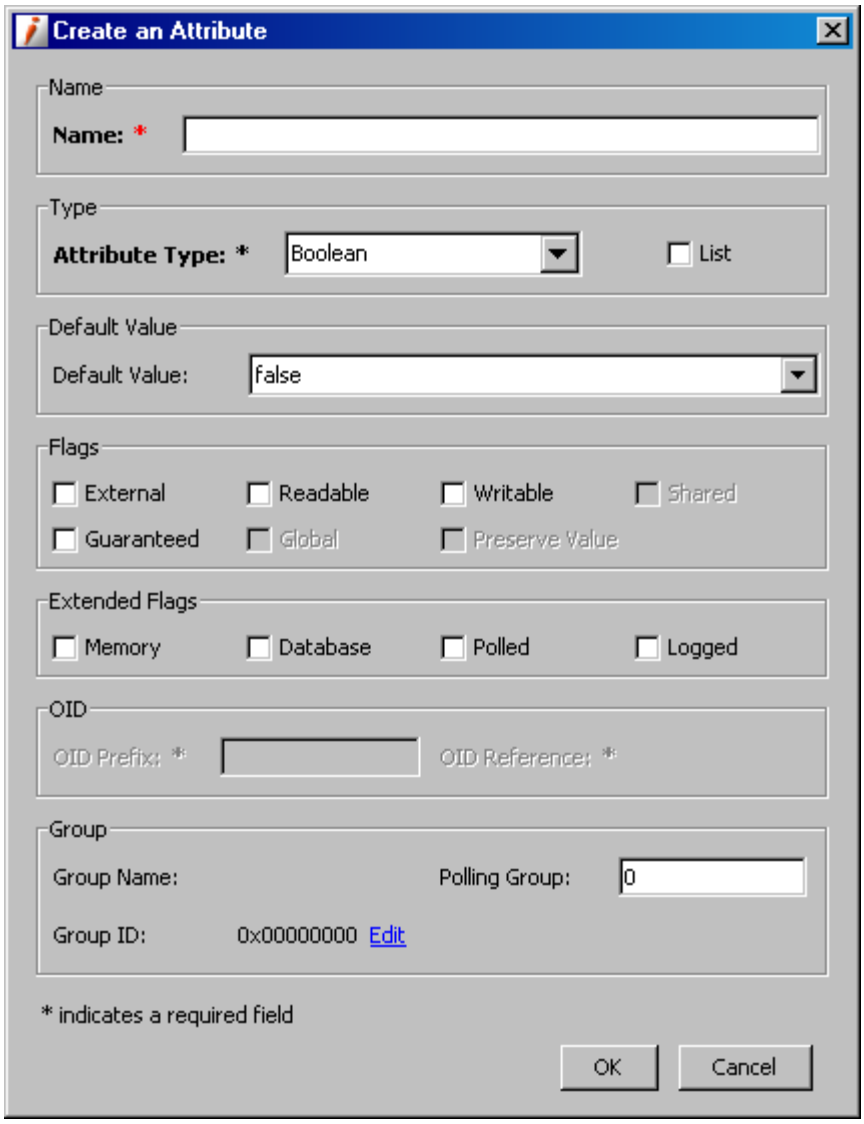
While you can also add attributes to model types that you do not own, you cannot export these model types or their attributes. Typically, exporting model types that you do not own is only required for storing information in the related models when no available attribute is suitable.

WARNING
We recommend recording all changes that you make with the Model Type Editor. Some changes are not migrated when the database is updated to a later version of DX NetOps Spectrum Specifically, if you modify attributes (such as flag settings), the model type hierarchy, or relations and the associated meta-rules in the model types supplied by CA or another vendor, the changes are typically not migrated on database upgrade. You will have to reapply these changes manually. For more information, see *Migrate Changes to a New Version of* DX NetOps Spectrum.

Follow these steps:

1. Select the model type to which you want to add an attribute.

2. Click the Attributes tab and click the Add a new Attribute icon  .
   The Create an Attribute dialog opens.



3. Enter values for the attribute's descriptors.

   NOTE
   An attribute name does not need to be unique across the modeling catalog, but you should enter a name that is unique across the attributes in the model type that were created using the same developer ID. In other words, within a single model type, two attributes can have the same name if they were created using different developer IDs. In addition, while it is allowed, reusing an attribute name is not recommended.

4. Click OK.
   The attribute is created and added to the working catalog, and it is displayed in the list of attributes on the Attributes tab.

Remove an Attribute from a Model Type

You can remove an attribute from the model type in which it was created (referred to as the *originating model type*) if you own the model type, that is, the model type was creating using the developer ID that is currently active.

When you remove an attribute from a model type, it is also removed from all derived model types that inherit it.

> **WARNING**
> We recommend recording all changes that you make with the Model Type Editor. Some changes are not migrated when the database is updated to a later version of DX NetOps Spectrum Specifically, if you modify attributes (such as flag settings), the model type hierarchy, or relations and the associated meta-rules in the model types supplied by CA or another vendor, the changes are typically not migrated on database upgrade. You will have to reapply these changes manually. For more information, see *Migrate Changes to a New Version of* DX NetOps Spectrum.

To remove an attribute from a model type

1. Verify the attribute to be removed is not critical to a derived model type.

   > **NOTE**
   > If necessary, you can provide an alternate path via a different base model type, or you can recreate the attribute at the derived model type level.
2. Select the model type for which you want to remove an attribute.
3. Click the Attributes tab, select the attribute you want to remove, and click the Delete selected Attribute icon 
   A confirmation dialog opens.
4. Click Yes.
   The attribute is deleted from the working catalog.

Edit an Attribute

Typically, you will want to modify the attributes of the model types that you own, that is, that were created using the developer ID that is currently active. Because you own the model types, you can subsequently export them and their attributes.

While you can also modify the attributes of model types that you do not own, you cannot export these model types or the changes to their attributes.

You can edit an attribute by doing the following:

- Changing its default value. See Modifying an Attribute's Default Value.
- Changing its other descriptor values. See Modifying an Attribute's Descriptors.

However, before editing an attribute's characteristics, you should verify that derived model types that inherit the attribute will not be adversely affected by the changes.

> **WARNING**
> We recommend recording all changes that you make with the Model Type Editor. Some changes are not migrated when the database is updated to a later version of DX NetOps Spectrum Specifically, if you modify attributes (such as flag settings), the model type hierarchy, or relations and the associated meta-rules in the model types supplied by CA or another vendor, the changes are typically not migrated on database upgrade. You will have to reapply these changes manually. For more information, see *Migrate Changes to a New Version of* DX NetOps Spectrum.

Modify an Attribute's Default Value

An attribute can inherit its default value from a base model type or specify its own value (a process called specialization). In the latter case, all model types derived from the specialized model type inherit the changed attribute value.

To modify the default value of an attribute

1. Set current the model type that has the attribute with the default value you want to change.
2. Click the Hierarchy tab, note any derived model types, and verify that they will not be adversely affected by the change you want to make.
3. Click the Attributes tab, select the attribute from the displayed list, and click the Edit icon  .
   The Edit an Attribute dialog opens.
4. Do *one* of the following to change the default value:
   - If the attribute requires a single value, modify the value as desired.
   - If the attribute requires a list of values, click Edit, and modify the values as desired in the Edit List Values dialog.
   - To add a value, click the Add icon  .
   - Enter an appropriate Object ID index value (typically, an SNMP object identifier) and enter the value to associate with that index entry.

     The Object ID value is optional, and, if you specify the first one, the Model Type Editor uses that Object ID to generate a default, modifiable Object ID for each subsequent value that you add.

     To delete a value, click the Delete icon  .

     NOTE
     If the Default Value field does not have scroll bars, you can enter a value that fits in the provided area. If there are scroll bars, the field automatically enlarges as needed, and the only limitation is the impact on system performance.
5. Click OK twice.

Modify an Attribute's Descriptors

You can modify two types of attribute descriptors:

- **Standard attribute descriptors**
  When you modify one of these descriptors in a base model type, all derived (child) model types inherit the change.
- **Attribute descriptors you can specialize**
  When you modify one of these descriptors in a base model type, derived model types that have been specialized (specify their own values) do *not* inherit the change, but derived model types that have not been specialized do inherit the change.

If you are the owner of the attribute (that is, the attribute was created using the developer ID that is currently active), you can modify all of an attribute's descriptors *in the originating model type* regardless of whether you are the owner of the model type.

If you are not the owner of the attribute, or if the attribute is inherited, you can specialize a subset of the attribute descriptors. That is, you can modify the values of some of the descriptors at any level of the inheritance hierarchy; you are not limited to modifying the values in the originating model type.

To edit the descriptors of an attribute

1. Set current the model type that has the attribute with the descriptor values you want to change.
2. Click the Hierarchy tab, note any derived model types, and verify that the model types will not be adversely affected by the changes you want to make.
3. Click the Attributes tab, select the attribute from the displayed list, and click the Edit selected Attribute icon 
   The Edit an Attribute dialog opens.
4. Modify the attribute descriptors as needed.

   NOTE
   All changes that you make to flag settings are subject to the relationships described in Flags.
5. Click OK.

Working with Attribute Groups

Working with Attribute Groups

An *attribute group* is a logical collection of related attributes in a model type. Groups make working with related attributes easier in the Model Type Editor because they allow you to define and use a user-defined sorting mechanism. You can create groups, assign attributes to them, and then add the Group Name or Group ID as a column header in the table of attributes on the Attributes tab in the Contents panel. This lets you then click the column header to quickly group together and view together all of the attributes within a group.

Creating an Attribute Group

You can create attribute groups.

NOTE
When you add an attribute group, you add it to a specific model type, and the group is inherited by derived model types in the same way that other attributes of a model type are inherited. Like for other attributes, if you add an attribute group to a model type that you do not own (its developer ID does not match the one that is currently active), you will not be able to export the group.

To Create an Attribute Group

1. Set current the model type in which you want to create the attribute group.
2. Click the Attributes tab, and double-click any attribute that was created using the developer ID that is current active.
   The Edit an Attribute dialog opens.
3. Under Group, click Edit beside the value for Group ID.
   The Select Group dialog opens displaying a table view and a tree view of all of the attribute groups inherited from base model types or originating in the current model type.
   The Model Type column displays the originating model type for each group (that is, the model type in which the group was created).
4. Specify whether the new attribute group has a parent group:
   - If you do not want the attribute group to have a parent group, do nothing. This is the default behavior.
   - If you want the attribute group to have a parent group, select the group using either of the following methods:
     - Click the Table View tab, and use the table to select the desired parent group.

To help you find the group, for Filter, you can enter a text string to filter the list to include only the groups whose names include the string. You can also click any column heading to change the sort order from ascending to descending and vice versa.

- Click the Tree View tab, and navigate the hierarchical tree of parent groups and child groups to select the desired parent group.

5. Click the Add icon  .
   The Create Group dialog opens.
6. Enter a name for Group Name

   NOTE
   Do not enter a name that is being used by another attribute group created using the same developer ID. In addition, use a maximum of 128 characters, and use only numbers, letters, and underscore characters (_).
7. Click OK.
   The new attribute group is created.

Modifying an Attribute Group

You can modify the name or parent group of an attribute group in the originating model type, that is, in the model type in which the group was created. You cannot modify the name or parent group of an inherited attribute group.

In addition, to modify an attribute group, you must be the owner of the model type in which the group was created. In other words, the active developer ID is the one that was used to create the model type.

To modify an attribute group

1. Set current the model type in which the attribute group was created.
2. Click the Attributes tab, and double-click any attribute that was created using the developer ID that is currently active.
   The Edit an Attribute dialog opens.
3. Under Group, click Edit beside the value for Group ID.
   The Select Group dialog opens. The dialog displays a table view and a tree view of all of the attribute groups inherited from base model types or originating in the current model type. The Model Type column displays the originating model type for each group (that is, the model type in which the group was created).
4. Select the attribute group to modify using either of the following methods:
   – Click the Table View tab, and use the table to select the desired group.
   To help you find the group, for Filter, you can enter a text string to filter the list to include only the groups whose names include the string. You can also click any column heading to change the sort order from ascending to descending and vice versa.
   – Click the Tree View tab, and navigate the hierarchical tree of parent groups and child groups to select the desired group.
5. Click the Edit icon  .
   The Edit Group dialog opens.
6. If you want to change the group name, enter a new name for Group Name.

   NOTE
   Do not enter a name that is being used by another attribute group created under the same developer ID. In addition, use a maximum of 128 characters, and use only numbers, letters, and underscore characters (_).
7. If you want to change the group's parent group, do the following:
   a. Click Edit beside the value for Parent Group ID.

b. In the Select Parent Group dialog, select a new parent attribute group using the Table View tab or the Tree View tab, and click OK.

8. Click OK.
   Your changes are saved and the Edit Group dialog closes.

Deleting an Attribute Group

You can delete an attribute group if the following two conditions are met:

- The group has no assigned attributes. If this is not the case, you can delete the group after you have reassigned the attributes.
- The group has no subgroups. If this is not the case, you can delete the group after you have reassigned or deleted the subgroups.

To delete an attribute group

1. Set current the model type in which the attribute group was created.
2. Click the Attributes tab, and double-click any attribute that was created using the developer ID that is currently active.
   The Edit an Attribute dialog opens.
3. Under Group, click Edit beside the value for Group ID.
   The Select Group dialog opens. The dialog displays a table view and a tree view of all of the attribute groups inherited from base model types or originating in the current model type. The Model Type column displays the originating model type for each group (that is, the model type in which the group was created).
4. Select the attribute group to delete and click the Delete icon 
   A confirmation dialog opens.
5. Click Yes.
   The attribute group is deleted.

Working with Relations and Meta-Rules

About Working with Relations and Meta-Rules

The modeling catalog provided with the basic DX NetOps Spectrum package contains a number of predefined relations, many of which have associated meta-rules. These relations provide a framework that can replicate most relationships in a network. However, you can create additional relations as needed for your network design.

If you add a new relation, you must also do the following:

- Create meta-rules in <met> that implement the new relation for specific model types.
- Add intelligence to the model types so that models of those types react appropriately when they are associated based on the new meta-rules. You must implement the intelligence programmatically using the CORBA API.
  As an example, assume that you create the following meta-rule:

  ```
  User Sends_mail_to User
  ```

  When the meta-rule is instantiated (for example, when one User model sends mail to a second User model), the first model may need to react to the fact that it (the user that it represents) has sent mail, and the second model may need to react to the fact that it has received mail. In this case, you must add intelligence to the User model type to implement these reactions.

  NOTE
  For information about using the CORBA API, see the Development API Reference section

Search for and Display Relations

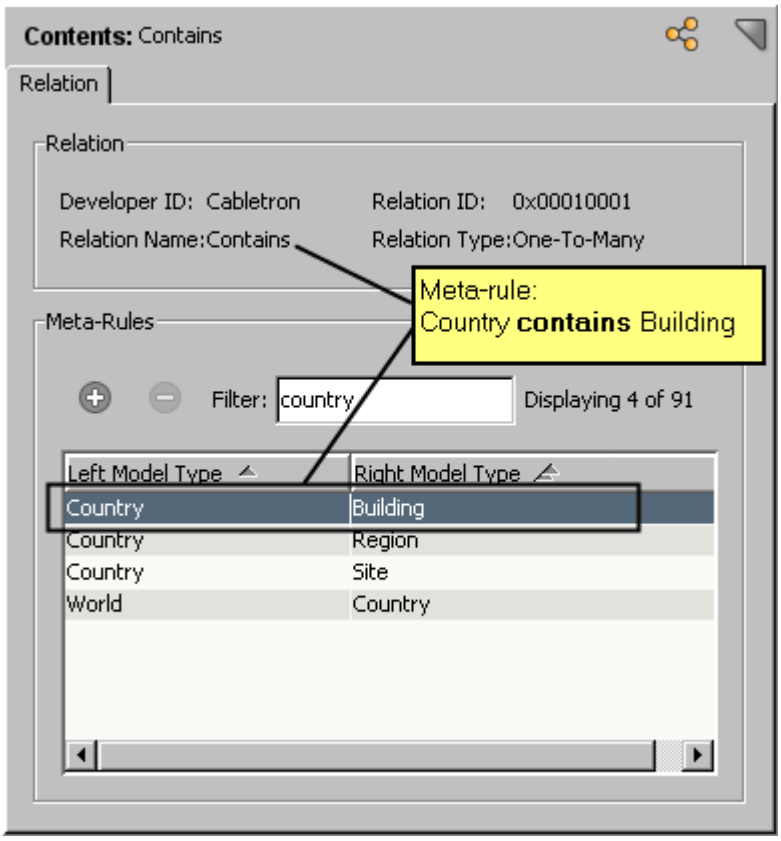
You can search for relation by filtering the list of all relations in the modeling catalog to include only those that contain the text string you specify. By default, the Model Type Editor examines the supplied string against the names of the relations. However, if you display the Relation ID column in the Navigation panel, it will also examine the string against the relation IDs (handles).

Follow these steps:

1. In the Navigation panel, click the Relations tab.
   The names of all of the relations in the modeling catalog are listed.
2. In the list, select the name of the relation that you want to examine.
   To locate and select a specific relation, you can take the following steps:
   - Enter a text string in the Filter text box in order to filter the list to include only the relations whose names or IDs contain the string. To filter the list by ID, the ID column must be displayed in the table.
   - Click the Relation bar at the top of the list to change the alphabetical sorting from ascending to descending or vice versa.

   The selected relation becomes the current relation. The following information about the relationship is displayed in the Contents panel:
   - **Developer ID**
     Specifies the developer ID that was active when the relation was created.
   - **Relation Name**
     Specifies the name of the relation.
   - **Relation ID**
     Specifies the ID (handle) that is assigned to the relation.

     NOTE
     A handle is never reused even if you delete a relation.
   - **Relation Type**
     Specifies the type of relation, either One-to-Many or Many-to-Many.
   - **Meta-Rules**
     Specifies the list of meta-rules that apply the relation to specific model types, thereby defining how the model types can interact with one another.
3. To filter the list of meta-rules to include only those for a specific model type, enter the full or partial name of the model type in the Filter text box:



Create Relations

You can create relations.

To create a relation

1. Click the Relations tab and in the Navigation panel, click the Create Relation icon 
   The Create Relation dialog opens.
2. Enter a name for the relation.
   The name should be a maximum length of 31 characters and should include alphanumeric characters and underscores but not spaces or punctuation.

   WARNING
   The relation name does not need to be unique across the modeling catalog, but you should enter a name that is unique across the relations created under a given developer ID. In addition, while it is allowed, reusing a relation name is not recommended.
3. Select the type of relation to create:
   - **One-to-Many**
     Relations of this type relate one model type to many model types.
   - **Many-to-Many**
     Relations of this type relate many model types to many model types.

     NOTE
     Once you create the relation, you cannot change the relation type. To specify a different relation type, you must delete the relation and create a new one.

4. Click OK.
   The relation is created and assigned a relation ID, and its information is displayed in the Contents panel.

   NOTE
   A handle is never reused even if you delete the relation.
5. Create one or more meta-rules that use the relation.
6. Add intelligence to the relevant model types so that models of those types react appropriately when they are associated based on the new meta-rules. You must implement the intelligence programmatically using the CORBA API.

   NOTE
   For information on using the CORBA API, see the Development API Reference section.

Relation Meta - Rules

Each relation normally has one or more meta-rules, each of which applies the relation to specific model types. Many of the model types in the core database have relations that are supplied without meta-rules; these function as "placeholders" for which you can supply customized meta-rules that are appropriate for your network design.

NOTE
When a new model type is derived from one that is specified as a member of a meta-rule in a relation, the meta-rule automatically applies to the derived model type. For example, the modeling catalog provided with the basic DX NetOps Spectrum package has a relation called Contains and two model types named Room and Device. One of the meta-rules for the Contains relation is the following:

Room Contains Device

The modeling catalog also contains a Workstation model type that is derived from Device. As a result, the "Room Contains Device" also applies to the Workstation model type in the form of "Room Contains Workstation." You do not have to explicitly create a meta-rule that includes the Workstation model type.

About Creating Meta-Rules for General Model Types

Whenever possible, create meta-rules for general model types (model types near the top of the model type hierarchy) in order to maximize their application and reduce the need for more specific meta-rules. The more general the model type that contains the meta-rules, the more derived model types it has, and, therefore, the more model types inherit its meta-rules.

As an example, the Device model type is a general model type that is used in the following meta-rule for the Is_Adjacent_to relation:

Device Is_Adjacent_to Device

Consequently, any model type derived from Device or one of its descendants can be adjacent to any other model type derived from Device or one of its descendants.

Create Meta - Rules

You can create a meta-rule without restriction if you own the corresponding relation, that is, the relation was created using the developer ID that is currently active.

If the relation was created using a different developer ID, you can still create a meta-rule for it if at least one of the model types used in the rule was created using the developer ID that is currently active.

To create a meta-rule

1. Search for and display the relation for which to create the meta-rule.
   The relation is displayed in the Contents panel.

2. On the Relation tab, in the Contents panel, click the Create a new Meta-Rule icon  .
   The Create Meta Rule dialog opens.
3. In the list of model types on the left, select the antecedent (left) model type to include in the meta-rule.

   NOTE
   To help you locate and select a specific model type, you can enter a text string in the corresponding Filter text box in order to filter the list accordingly.
4. In the list of model types on the right, select the predicate (right) model type to include in the meta-rule, and click OK.
   The new meta-rule is added to the list of meta-rules for the current relation; it is inserted into the list alphabetically according to the antecedent model type.

   NOTE
   You now need to add intelligence to the model types so that models of those types react appropriately when they are associated based on the new meta-rule. You must implement the intelligence programmatically using the CORBA API.

Delete Relations

You can delete a relation if the following two conditions are met:

- The relation was created using the developer ID that is currently active.
- The relation does not have any associated meta-rules. If this is not the case, first delete the meta-rules.

To delete a relation

1. Search for and display the relation to delete.
2. On the Relations tab in the Navigation panel, select the relation, and click the Delete selected relation icon  .
   A confirmation dialog opens.
3. Click Yes.
   The relation is deleted.

Delete Meta - Rules

You can delete a meta-rule without restriction if you own the corresponding relation, that is, the relation was created using the developer ID that is currently active.

If the relation was created using a different developer ID, you can still delete the meta-rule if at least one of the model types used in the rule was created using the developer ID that is currently active.

To delete a meta-rule

1. Search for and display the relation that contains the meta-rule to delete.
2. On the Relation tab in the Contents panel, select the meta-rule and click the Delete selected meta-rule icon  .
   A confirmation dialog opens.
3. Click Yes.
   The meta-rule is deleted.

Importing and Exporting Model Types

About Importing and Exporting Model Types

As your network grows, you may need to add new management modules and model types to your database to support additional types of devices. Moreover, you may want to add these new model types to your database without installing a completely new database, so you can keep intact all of the model types you have already created or modified. DX NetOps Spectrum provides two database utilities that lets you to import and export model types:

- **Import and export commands in the Model Type Editor:** These commands let you import and export model types from the *working catalog* for the current session. Because the commands do not operate on the permanent catalog in the SpectroSERVER database, you can make an explicit decision after an import as to whether to commit or discard the changes. Since you can only import or export one catalog file at a time, use these commands when you have only one or a few files to process.
- **A command-line utility named dbtool:** This command-line utility program lets you import and export model types from the *permanent catalog* in the SpectroSERVER database. Because you can specify multiple files as command-line arguments, use this utility to batch process a set of files.

In both cases, the transfer vehicle is a binary export file that has a .e extension. These files are referred to as *catalogs*.

Import Model Types Using the Model Type Editor

You can use the Model Type Editor to import model types, attributes, relations, and meta-rules into the SpectroSERVER database. The modeling catalog objects must be defined in a catalog file (.e file) that was created using the export feature in the Model Type Editor or the dbtool command-line utility.

Import Constraints

> **WARNING**
> You can only import modeling catalog objects that are stored in a compatible DX NetOps Spectrum database (a database that is running the same version of DX NetOps Spectrum as the destination database). For information about updating a DX NetOps Spectrum database, see the *Installation section.*

New model types are imported into the modeling catalog according to the following constraints:

- If the catalog file to import contains a model type that does not exist in the destination database, the model type is imported according to the rest of the constraints described in this section.
- All of the base model types for a new model type must already exist in the destination database. If they do not, you must import them before importing the new model type. Typically, the "core catalog" contains these prerequisite model types, and documentation accompanying any new catalog informs you of any such dependencies.
  If a base model type for a new model type does not exist, the import process is terminated. In this situation, you can identify the missing model type in the DX NetOps Spectrum Control Panel. You must then import a catalog file that contains the missing base model type, and then reinitiate the import process that was terminated.
- If the catalog file to import contains a model type that already exists in the destination database, the existing version is modified to match the version to import, for example:
  - The model type's derivation is updated
  - New attributes are added
  - Existing attributes are updated
  - Attributes in the existing model type that have the same developer ID as the existing model type are deleted if they originate in the existing model type but are not included in the version being imported
- If an error occurs due to an inability to write to the destination database or due to insufficient memory or system resources, the import process is terminated, and you are notified with an appropriate error message. Because this situation can leave the database in an incomplete or corrupted state, you should always back up the database before beginning an import operation.

Import Model Types

When you import model types using the Model Type Editor, the model types and associated catalog objects are imported into the working catalog. This lets you perform the import and then make an explicit decision as to whether to discard the changes or permanently commit them to the SpectroSERVER database.

To import the contents of a catalog

1. Back up the SpectroSERVER database into which you are importing a catalog.

   NOTE
   For information about how to back up the database using the database utilities provided with DX NetOps Spectrum, see the Database Management *section.*
2. Select File, Import Model Types.
   The Open dialog opens.
3. Navigate to the catalog file (.e file) you want to import, select the file, and click Open.
   The modeling catalog information in the selected file is imported into the working catalog for the current session. At this point, you can manually commit the changes to the permanent catalog in the SpectroSERVER database , or you can do so when you are prompted when you exit the application. Alternatively, you can exit the application without committing the changes to discard them.

Export Model Types Using the Model Type Editor

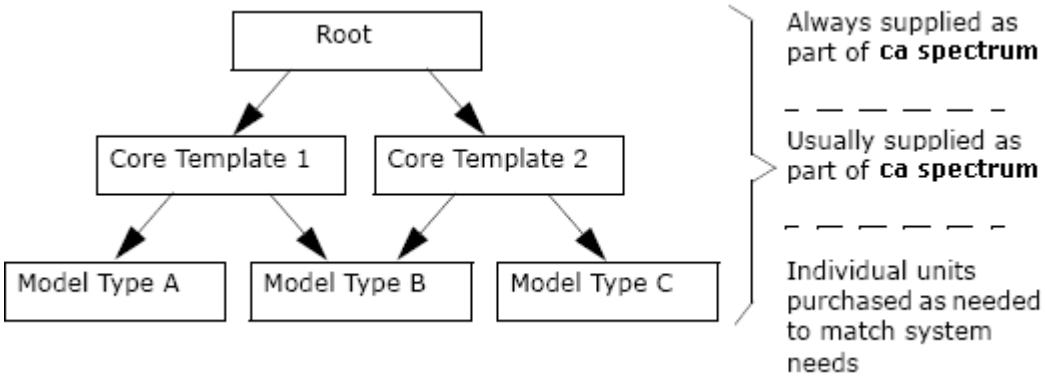
You can use the Model Type Editor to export a specific list of model types from the SpectroSERVER database to a catalog file. A catalog file is a .e file, and it is sometimes referred to as a DX NetOps Spectrum database export file.

When you are exporting model types and associated catalog objects, bear the following in mind:

- The export feature in the Model Type Editor exports the working catalog that is stored in memory. As a result, the resulting export file includes any changes you have made to model types and associated objects during the current session even if you have not yet committed those changes to the SpectroSERVER database.
  To export the permanent catalog only, you can commit the changes and use the export feature in the Model Type Editor, or you can use the dbtool command-line utility instead.
- The .e file produced by the export process contains the following information:
  - The attribute descriptors that originated in the model type being exported.
  - The attribute descriptors that have been specialized (for example, by specifying a default value to override an inherited one).
  - The relations and associated meta-rules in which the model type and/or any ancestor model types participate as an antecedent or a predicate.
- You can only export the model types, attributes, and relations (including their associated meta-rules) that were created using the active developer ID.

To export one or more model types to a catalog file

1. Identify the model types to export.
   Typically, the list of model types to export should include any base model types that are required by the model types being exported and that do not exist in the destination database.
   However, in general practice, dependencies normally are limited to certain commonly-used base model types that are contained in one or more "core" catalogs that are included as part of the basic DX NetOps Spectrum system. These core catalogs are a part of every installation, as shown in the following illustration.



2. Select File, Export Model Types.
   The Model Type Export dialog opens.
   By default, all unmodified model types that were created using the active developer ID are initially displayed in the Model Types column on the left.
   In addition, all model types that were created using the active developer ID and that have been modified during the current session are initially displayed in the Model Types to Export column on the right. *Modified model types* are those you have changed regardless of whether the changes are currently in the working catalog or committed to the database. Note that once you export a model type, it is no longer identified as modified because you have saved it to a catalog, in this case, to a DX NetOps Spectrum database export file.
3. Move the model types that you want to export to the Model Types to Export list.
   To search for the model types to export, in the Filter text box, you can enter a text string to filter the list to include only the model types with names that contain or match the string. The filter is not case-sensitive.
   To move all of the model types available for export to the Model Types to Export list,
   click ▷▷.
   To move a single model type to the list, double-click the model type name, or select the model type and
   click ▷.
   Similarly, you can remove model types from the export list by double-clicking them or using the corresponding left-arrow buttons.
4. Click Browse, and in the Save dialog, navigate to the folder in which to save the catalog file.

   WARNING
   By default, the Save dialog opens to the DX NetOps Spectrum database (modeling catalog) directory. However, it is recommended that you save exported catalog files in a directory outside of the DX NetOps Spectrum installation area in order to prevent the loss of the files during a DX NetOps Spectrum update process.
5. Enter a name for the file (you do not need to include the .e extension) or select an existing .e file to overwrite, and click Save.
6. In the Model Type Export dialog, click OK.
   The model types are exported to the specified catalog file.

Import and Export Model Types Using dbtool

The DX NetOps Spectrum command-line utility program named dbtool can import or export model types from the permanent modeling catalog in the SpectroSERVER database. The dbtool utility lets you specify multiple files as command-line arguments. Therefore, it is a better tool to use than the import and export features of the Model Type Editor for batch processing a set of files.

When you use dbtool, you can export only the model types that you "own," that is, types that were created using the currently active developer ID. If a model type is not owned, an error message describes the relevant model types, and the export process is terminated.

Run the dbtool utility from the directory that contains the SpectroSERVER database that is used in the import or export. In addition, while the import or export is underway, *no* other program or process (for example, a VNM or the Model Type Editor) can access the database. Keep in mind that while CA-developed applications automatically lock out other CA-developed applications, third-party applications may not. The competition can result in database corruption.

NOTE
For more information about running dbtool, see the Database Management *section.* This section also contains information about how to back up the database using the DX NetOps Spectrum database utilities. Perform the backup before you perform an import.

Send an Exported Catalog to a File or Printer

DX NetOps Spectrum includes a command-line utility program named *dbtool* that you can use to send or "dump" the contents of a catalog file (.e file) to a file or printer. You can use this tool to store or print the contents of a catalog file that was created using the export feature of the Model Type Editor or using dbtool itself.

Before running dbtool, you must shut down the SpectroSERVER and any other program that accesses the SpectroSERVER database.

NOTE
For information about running the dbtool utility, see the Database Management *section.*

Running Reports on Model Types and Relations

About Running Reports on Model Types and Relations

DX NetOps Spectrum includes a command-line utility program named reports that you can use to display, print, or export (to a file) information about the model types and relations in the modeling catalog.

You must run the reports utility from the directory that contains the SpectroSERVER database that contains the data you want to access. While the report is being generated, no other program or process (for example, a VNM or the Model Type Editor) can access the database.

NOTE
For information about running the reports utility, see Database Management *section.*

Hide a Model Type Name

OneClick provides a flexible platform for administrators to modify aspects of the application to meet specific requirements.

To Hide a Model Type Name on Containers such as LAN or Network in Topology view:

On the OneClick web server machine, follow these steps:

1. Copy the **$SPECROOT/tomcat/webapps/spectrum/WEB-INF/topo/config/oneclick-container-iconbase-config.xml file** to the **$SPECROOT/custom/topo/config/** directory.

2. Edit the **$SPECROOT/custom/topo/config/oneclick-container-iconbase-config.xml** file and comment out the following line:

NOTE

<!-- <column idref="column-devicetype-config"/> -->

3. Save the file.

4. Launch the OneClick Console.

5. The Modeltype_Name is no longer visible in Topology view for the containers.

OneClick Customization

OneClick provides a flexible platform for administrators to modify aspects of the application to meet specific requirements. For example, you can modify OneClick behavior to support the unique structure of a site, an enterprise and network environment, work processes, and software deployments. Make your modifications using the OneClick UI or by coding the changes in the XML files that are provided for that purpose.

> **WARNING**
>
> ! Do not add customizations to the files in their default location (<*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/). The customizations in that directory are ignored. In addition, these files are overwritten when you perform DX NetOps Spectrum and OneClick upgrades.

Prerequisites for Customizing OneClick XML Files

Before you attempt to customize OneClick files, be aware of the following requirements:

- You must be able to create and modify files on the OneClick server.
- You must be familiar with the fundamentals of XML coding as well as the DX NetOps Spectrum and OneClick directory structure.
- You must know the following:
  - The file whose functionality you want to extend with your modifications.
  - The directory in the <*$SPECROOT*>/custom directory structure in which to create your custom file.

Extend Factory XML Files

You can extend default XML files to accomplish OneClick customizations without overriding the entire factory default file. Customized XML files are not removed during a DX NetOps Spectrum/OneClick software upgrade or reinstallation.

To extend the default OneClick XML configuration files, create a file with the same name as the default file in the appropriate custom directory. Use the XML idref attribute in the new file to refer to the default OneClick file of the same name. Code the new functionality in this file. When OneClick parses the XML files, the changes in the new file are added to the existing factory file referenced using idref.

By extending factory files, you are able to take advantage of new features and functionality available in software updates to the factory XML code while preserving your customizations.

Although you can still override a factory XML file by creating a copy of it in the <*$SPECROOT*>/custom directory and making your changes in the copy, using the IDREF XML attribute provides the ability to inherit and extend the factory file, while maintaining customizations in streamlined files.

Override Factory Files

Override a factory configuration file by copying the original file to the appropriate custom directory, and then adding new XML code or modifying the existing XML code. OneClick reads the files in the custom directory first. If the file exists in the custom directory and does not contain an idref statement referencing the original factory file, OneClick does not read the original factory file, and the new file overrides the original factory file.

WARNING

! Do not add customizations to the files in their default location (<*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/). The customizations in that directory are ignored. In addition, these files are overwritten when you perform DX NetOps Spectrum and OneClick upgrades.

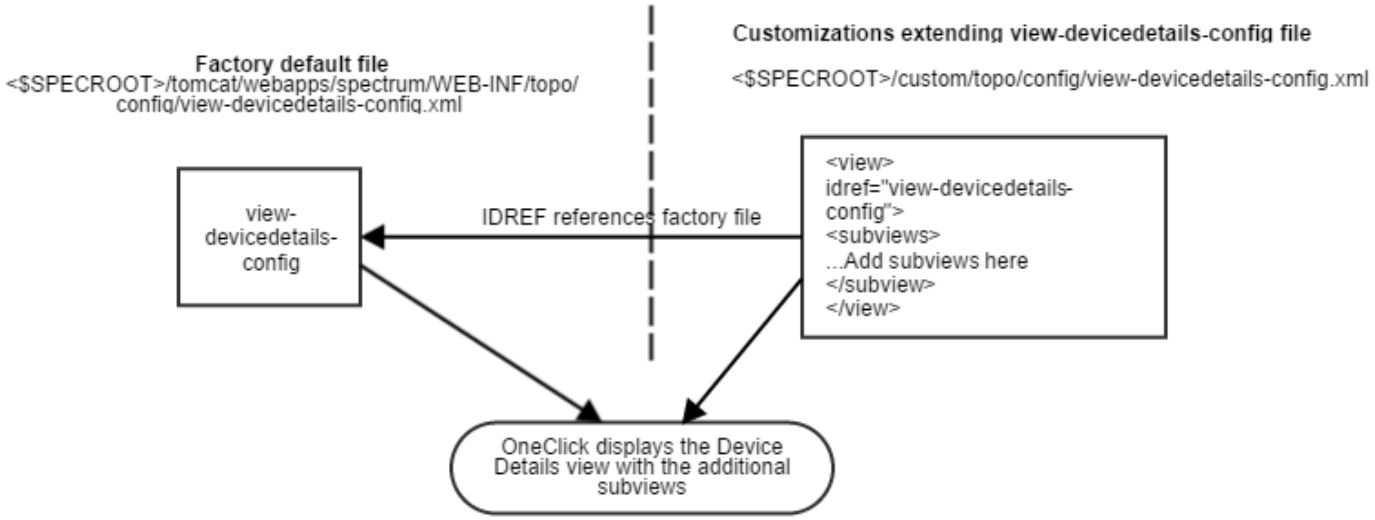
Inherit Features in Factory XML Files

Using idref to extend XML files has applications beyond extending the factory file with the same name. You can use this technique to inherit or reuse features in any file of the same type. For example, you can create your own model types that have a customized details view defined in view-mymtypedetails-config.xml. This model type can also inherit the default device views configured in view-devicedetails-config using idref. The new custom file extends the functionality of the default file while also inheriting the views in the default file.

Example Extending Factory XML File

The example in the following figure extends the functionality of the factory default <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/
config/view-devicedetails-config.xml file by adding the code for the new subviews in <*$SPECROOT*>/custom/topo/config/view-devicedetails-config.xml. The default factory file view-devicedetails-config is specified in an "idref" statement.

Figure 79: Extending Factory XML File



OneClick Directory Structure

This section explains the directory structure of the XML files used to create the OneClick interface. You must be familiar with the structure to find the files necessary for customization and to implement customization in directories that are not overwritten when you upgrade or reinstall DX NetOps Spectrum.

Existing OneClick Files

The OneClick user interface is installed with a default layout, panel, menu, toolbar, and submenu content. The files that reside on the OneClick server controls all of these features. These files and their locations are identified in this section.

The console/config Directory

The files in the *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config directory support menus, topology views, privileges for user interface elements, branding elements, and other aspects of the OneClick user interface. The files that are located in this directory are placeholder files that resemble templates for customizations to OneClick functionality. The files and their functions are described as follows:

- **custom-app-config.xml**
  General OneClick registrations, and topology support for DX NetOps Spectrum model types, including icons and views.
- **custom-branding-config.xml**
  Customizes the following UI branding elements of OneClick:
  - Application brand name
  - Application suite name
  - Image to display in the splash screen
  - Image to display as the logo button in the lower-left corner
  - Name of the root node in the tree in the Navigation panel
  - About dialog

    NOTE
    For information about the XML elements to specify these branding elements, see the comments in the file that is named custom-branding-config.xml in *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config/.
- **custom-menu-config.xml**
  OneClick menus and toolbars.
- **custom-privileges.xml**
  Registers custom privileges that are applied to the menu items, columns, and subviews.

To customize the OneClick user interface, copy these files to the *<$SPECROOT>*/custom/console/config directory and then edit them.

WARNING

Do not add customizations to the files in their default location (*<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config/). The customizations in that directory are ignored. In addition, these files are overwritten when you perform DX NetOps Spectrum and OneClick upgrades.

Check the <$SPECROOT>/custom/console/config directory before copying files there. Some actions, such as creating custom searches in the Explorer, automatically create a copy of the custom-app-config.xml if one does not exist. If the config files already exist in the <$SPECROOT>/custom/console/config directory, add your customizations to those existing files.

The topo/config Directory

The files in this directory create the components of the OneClick topology views. These components include icons, subviews, and tables that display data.

All of the table files are named after the functionality that they display. For example, the file that builds the interface table for each model type is table-common-ifconfig-config.xml.

The common/config Directory

The files in this directory create various topology elements that can be used by all of the other files that create the OneClick interface. This includes colors, columns for tables, and tables.

The alarm/config Directory

The files in this directory create the OneClick alarm views and contents, including the Alarms table and the Alarm Details information tab.

Save Customized XML Files

OneClick customization files must be placed in specific “custom” directories so that OneClick finds and reads the customized code and associates it with the correct default factory file. The following lists the custom directories for the OneClick component categories.

- **Alarms**
  <*$SPECROOT*>/custom/alarm/config/
- **Common**
  <*$SPECROOT*>/custom/common/config/

  WARNING
  Do *not* copy the <*$SPECROOT*>/custom/common/config/custom-jnlp-config.xml file to another computer when you migrate and upgrade DX NetOps Spectrum. This file can contain memory settings that are not compatible with the computer where you are copying the custom directories.
- **Console components**
  <*$SPECROOT*>/custom/console/config/
- **Event format and probable cause files**
  <*$SPECROOT*>/custom/Events/
- **Images**
  <*$SPECROOT*>/custom/images/
- **Background images**
  <*$SPECROOT*>/custom/images/Background/
- **Stored SSL certificates**
  <*$SPECROOT*>/custom/keystore/
- **Report Manager**
  <*$SPECROOT*>/custom/repmgr/config/
- **Topologies**
  <*$SPECROOT*>/custom/topo/config/

Preserve XML Customizations

OneClick does not delete or overwrite files in the custom directory during an upgrade of DX NetOps Spectrum or OneClick.

Customized OneClick XML files may be overwritten in the following situation:

- Uninstalling SpectroSERVER
- Reinstalling the same version of SpectroSERVER if you have installed OneClick under the DX NetOps Spectrum installation directory.
  In this case, you should save off the customized files to an area unaffected by the uninstall process, and re-insert them once you have reinstalled SpectroSERVER.

  NOTE
  For more information on upgrades and installation of DX NetOps Spectrum and OneClick, see the Fresh Install section.

Preserve Custom Images

You must place all image files that you create or customize in the *<$SPECROOT>*/custom/images directory. Otherwise, all new or customized images are deleted or overwritten during an upgrade or reinstallation of DX NetOps Spectrum or OneClick.

Customizing the OneClick Login Dialog

Custom Login Message

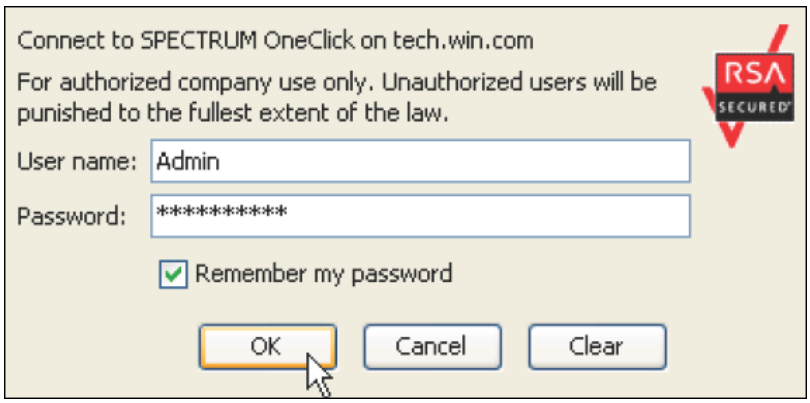
Custom messages can be added to the Login dialog for the OneClick Console. You can use this message to inform OneClick users about your usage policies, legal rights, consequences of unauthorized usage, or other important information they must know before they log in. The custom message appears in the Login dialog for the OneClick Console only.

Add a Custom Message to the OneClick Login Dialog

To inform OneClick users about usage policies, legal rights, or other important information needed before logging in, you can add a custom message to the OneClick Login dialog.

Follow these steps

1. Open the *<$SPECROOT>*/tomcat/webapps/spectrum/oneclick.jnlp file with WordPad.
2. Add the following argument into the <application-desc> section:
   ```
   <argument>-loginTitle Message_Text</argument>
   ```
   For example, you can replace the *Message_Text* variable with your own message, as follows:
   ```
   <argument>-loginTitle For authorized company use only. Unauthorized users will be punished to the fullest
    extent of the law.</argument>
   ```
3. Click File, Save.
   Your custom message is added to the OneClick Login dialog.



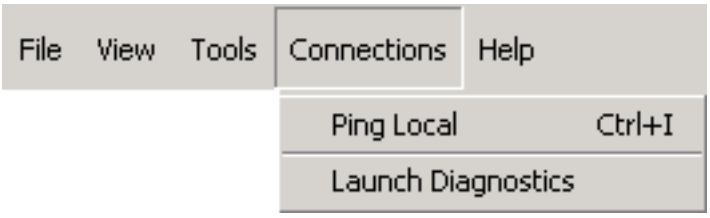
Customizing the OneClick Console Menu

This section describes how to add new menus and new menu items to the OneClick console. You can use new menu items to launch URLs, third-party applications, and scripts, and to pass parameters to them.

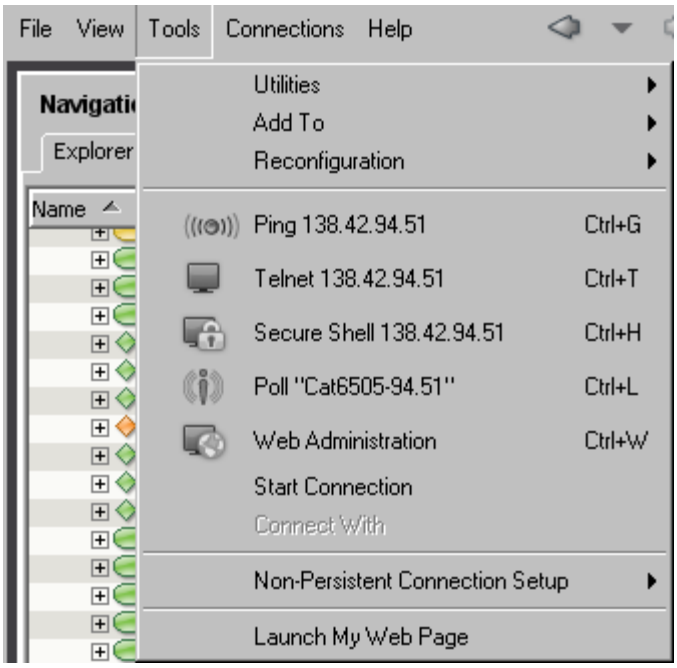
The custom-menu-config.xml File

The <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/custom-menu-config.xml file contains examples on how to add custom menus and custom menu items to your OneClick console as shown in the images. You need to copy this file in to the <*$SPECROOT*>/custom/console/config/ directory if the file is not already in this directory.

The following image shows the Connections menu and its two new menu items: Ping Local and Launch Diagnostics:



The following image shows that a new menu item called Launch My Web Page, which has been added to the existing Tools menu. This menu item has been created to launch a specified web page.



You create OneClick menus and menu items using the <menu> and <item> XML elements. The <menu> element can enclose one or more <item> elements that define the commands that are available on the menu. The <item> element can enclose several other elements that define how the menu item appears and behaves. See the following table for information about these elements.

Element	Parent Element	Description
<menu>	<root>	Defines the menu. The name attribute is used to define the name of the menu.
<separator>	<menu>	Used just before an <item> element to define a separator line as shown in the first figure in this section.
<item>	<menu>	Defines an item on a specific menu. The name attribute is used to define the name of the item.
<privilege>	<item>	Associates a privilege to the menu item. If the user is not given this privilege, the menu item is not displayed for that user.

<toolbar-image>	<item>	Specifies the image to display for the menu item and its associated toolbar button when the functionality is available to the user.
<toolbar-image-rollover>	<item>	Specifies the toolbar image that is displayed when a user places the cursor over the toolbar button.
<toolbar-image-disabled>	<item>	Specifies the toolbar image that is displayed when the functionality is disabled (not available to the user). A typical representation for this state is an image that is 80percent “grayed out.”
<accelerator>	<item>	Defines a keyboard sequence that executes the menu item.
<action>	<item>	Defines the action that takes place when the user clicks the menu item.
<hot-key>	<item>	Underlines the first instance of the indicated letter and enables the user to activate the menu item using this letter as a keyboard shortcut.

The subsequent sections of this chapter describe how to use the <menu> element to create a new menu and how to use the <item> element and its child elements to add menu items to a new or existing menu.

Add a New Menu

The <menu> element is used to create a OneClick console menu.

To add a new menu

1. Open the existing *<$SPECROOT>*/custom/console/config/custom-menu-config.xml file.
2. If the file does not exist, copy the file *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config/custom-menu-config.xml into the *<$SPECROOT>*/custom/console/config directory, and then open it.
   The <root> element is the root element for this file. Define all new menus inside the <root> element.
3. Use the <menu> element to create new menus. This element has a single attribute, name, which defines the name of the menu.

   NOTE
   Some of the examples in the custom-menu-config.xml file show a fully qualified menu name that references a Java class created by OneClick engineers. For example, com.aprisma.spectrum.app.swing.window.menu.Tool is used as the value for the name attribute in the <menu> element that defines the Tools menu. You don't have to use a fully qualified name to create a new menu or to refer to an existing menu. Simply use the exact text that you would like to appear as the menu name on the toolbar.
4. Add items to the new menu by specifying them using the <item> element and its available child elements. If you do not specify menu items for a menu, the menu is not visible in the OneClick console.
5. Save the changes that you have made to custom-menu-config.xml.
6. To view and test the new menus, restart the OneClick console.

Example: Creating a New Menu

The following lines of XML create the Connections menu shown in The custom-menu-config.xml File.

```
<menu name="Connections">
   <item name="Ping Local">
    .
    .
    .
   </item>
   <item name="Launch Diagnostics">
       .
       .
       .
```

```
    </item>
</menu>
```

Add a New Menu Item

To add an item to an existing OneClick console menu or to a new menu that you created, you must create a new <item> element inside the <menu> element that you are customizing. The <item> element uses the <name> attribute to specify the name of the menu item.

NOTE
The new menu item is also added automatically to the right-click menu.

To add a new menu item

1. Open <*$SPECROOT*>/custom/console/config/custom-menu-config.xml.
2. Find the <menu> element that you created in Add a New Menu that defines the menu to which you want to add items. If the <menu> item does not yet exist, add it using the name attribute to define either an existing or a new menu.

   NOTE
   Some of the examples in custom-menu-config.xml show a fully qualified menu name that references a Java class created by OneClick engineers. For example, com.aprisma.spectrum.app.swing.window.menu.Tool is used as the value for the name attribute in the <menu> element that defines the Tools menu. You do not have to use a fully qualified name to create a new menu or to refer to an existing menu. For example, you can use <menu name="Tools"> to refer to the Tools menu.
3. Use the <item> element to create each new menu item. This element has one attribute, name, which defines the name of the menu item.
4. The <item> element has a series of child elements that enable you to define how the item behaves. These elements are listed in the table in the custom-menu-config.xml File, and they are further defined in the rest of this chapter. Use these elements to define the behavior of the menu item you have added.
5. Save the changes that you have made to custom-menu-config.xml.
6. To view the new menu items, restart the OneClick Console.

Example: Creating New Menu Items

The following example adds a menu item that is called Ping Local to a menu called Connections.

```
<menu name="Connections">
   <item name="Ping Local">
    <accelerator modifiers="2">VK_I</accelerator>
    <action>
        <filter>
            <has-attribute>AttributeID.NETWORK_ADDRESS</has-attribute>
        </filter>
        <context>com.aprisma.spectrum.app.topo.client.render.ModelContext </context>
        <context>com.aprisma.spectrum.app.alarm.client.group.AlarmContext</context>
        <launch-application>
            <platform>
                <os-name>Windows 9x</os-name>
                <command>command.com /c start "Local ping {0}" cmd.exe /c
            "ping.exe {0} &#38;&#38; pause"</command>
            </platform>
            <platform>
                <os-name>Windows</os-name>
                <command>cmd.exe /c start "Local ping {0}" cmd.exe /c "ping.exe
            {0} &#38;&#38; pause"</command>
            </platform>
```

```
            <platform>
                <command>/usr/dt/bin/dtterm -e ping -s {0}</command>
             </platform>
                <param>
                  <attribute>AttributeID.NETWORK_ADDRESS</attribute>
                </param>
        </launch-application>
     </action>
    </item>
 </menu>
```

Add Toolbar Images

To have a toolbar image available for each of the three toolbar image states, you must specify them in your menu item definition. The elements for toolbar states are:

- <toolbar-image>
- <toolbar-image-rollover>
- <toolbar-image-disabled>

You can use the following image formats for OneClick toolbar images: .png, .gif, .jpg, and .jpeg.

The recommended toolbar image size is 24 x 24 pixels. Store custom images in the *<$SPECROOT>*/custom/images directory. When you reference an image that is placed in this directory, specify the path from the images directory, for example, images/myimage.png.

The following line of code specifies a toolbar image using the relative path to the image file.

```
<toolbar-image>images/hints.gif</toolbar-image>
```

For a listing of all of the elements that are used in defining OneClick menu items, see the table in Contextually Apply the Action.

Define a Keyboard Accelerator

The <accelerator> element specifies a combination of keyboard input that executes a corresponding menu item.

Specify the code for the accelerator key using the capitalized letter on the keyboard, which is preceded by “VK_”.

The modifiers attribute indicates the modifier key combinations as an integer where:

- 1 = Shift
- 2 = Ctrl
- 3 = Ctrl+Shift
- 8 = Alt
- 9 = Alt+Shift
- 10 = Ctrl+Alt

You are not required to specify a keyboard accelerator for a customized menu item.

```
<accelerator modifiers="2">VK_L</accelerator>
```

In the preceding example, the specified action of the menu item is performed if the 'L' key is pressed while holding down the Control key (Ctrl+L).

Perform an Action

The <action> element specifies the action that is performed when the menu item is selected. You can use the child elements that are shown in the table in Contextually Apply the Action to specify a particular action.

The <context> element specifies the context in which the menu item is active so that the action can be executed. This applies to both the standard and the right-click menu.

Contextually Apply the Action

Actions do not always apply in all situations, such as an action that is applicable only when the user selects a model. Therefore, you can specify one of the following contexts for your actions:

- **ModelContext**
  Indicates that the action should be available when the user selects a model. The format for this context is as follows:
  ```
  <context>com.aprisma.spectrum.app.topo.client.render.ModelContext</context>
  ```
- **AlarmContext**
  Indicates that the action should be available when the user selects an alarm. The format for this context is as follows:
  ```
  <context>com.aprisma.spectrum.app.alarm.client.group.AlarmContext</context>
  ```
- **TableContext**
  Indicates that the action should be available when the user selects any table. The format for this context is as follows:
  ```
  <context>com.aprisma.spectrum.app.util.table.TableContext</context>
  ```
  If no tablename is specified, context is limited to any table. However, you can also limit context to a single table using the following format:
  ```
  <context>com.aprisma.spectrum.app.util.table.TableContext</context>
      <table-name>TableName</table-name>
  ```

You can specify one or a combination of contexts. If no specified context matches the current window context, the menu item is disabled. If no contexts are specified, the menu item is displayed in all contexts.

The following table describes the elements that are used to implement an action.

Element	Parent Element	Description
<context>	<action>	Limits the context in which the menu item is enabled and can perform the action.
<table-name>	<action>	Used with <context>, specifies the tablename when limiting the action to a single table. Works with TableContext only.
<column-name>	<param>	Used with <context> and <command>, specifies which values in a table column to pass into a script from a selected row in the table. Works with TableContext only.
<filter>	<action>	Limits the availability of menu items.
<has-attribute>	<filter>	Specifies the attribute on which to filter.
<and>, <or>, <value>, <equals>	<filter>	Creates an expression that can be used with a filter.
<launch-browser>	<action>	Launches a browser.
<launch-sso-browser>	<action>	Launches a browser and, if single sign-on is enabled in OneClick, includes a single sign-on token associated with the current session in the URL. This token can be used to reauthenticate the session across integrated web applications instead of prompting the user repeatedly for a username and password. **Note:** For information about how to set up single sign-on in OneClick using CA SiteMinder® or CA Embedded Entitlements Manager, see the Integration section for that application.
<url>	<launch-browser>	Specifies the URL to launch in the browser.

<launch-application>	<action>	Launches an application.
<launch-web-server-script>	<action>	Launches a script available on the web server.
<display-output>	<launch-application>, <launch-web-server-script>	Displays the output from the launched script.
<display-exit-status>	<launch-application>, <launch-web-server-script>	Displays the exit status of a launched script.
<command>	<launch-application>, <launch-web-server-script>, <platform>	Specifies the application or script that the menu item launches.
<run-for-multiple-alarms>	<launch-web-server-script>	Runs a script on web browser for selected multiple alarms. Applicable for alarms only. Starting from 10.3, DX NetOps Spectrum users are allowed to add the following tag, which runs a script for multiple alarms in combined mode. <multiple-contexts-enabled mode= "combined-execution" delimiter= ";"/> You can configure with the following modes: combined-execution - multiple alarms single executionseparate-execution (default value) - multiple alarms multiple executions (one execution per an alarm) For more information, see the Launch a Web Server Script For Multiple Alarms At The Same Time section in this page. **Note:** If you do not mention any mode or the mode name is incorrect or if the <multiple-contexts-enabled mode= /> tag is completely removed, then the default mode (separate-execution) is applied.
<platform>	<launch-application>	Used with <os-name>, specifies the application to launch based on the operating system of the OneClick client.
<validate>	<launch-application>	Used with the <command> element, specifies that the menu item should only be added to the menu if the command exists on the OneClick client and has execute permissions. If either condition is found to be false during OneClick startup, the menu item is not added to the menu. If the <validate> element is not used, the menu item is always added to the menu, but its state is determined by the value of other elements.
<os-name>	<platform>	Used with <platform>, specifies the application to be launched specific to the operating system of the OneClick client.
<param>	<url>, <command>	Specifies a parameter that is passed to a browser, executable, or script.
<attribute>	<param>	Specifies an attribute used as a parameter.

Limit the Availability of Menu Items

The <filter> element specifies a filter that further restricts the enabled state of the menu item. You can filter on any attribute of the selected context.

```
<filter>
   <has-attribute>AttributeID.NETWORK_ADDRESS</has-attribute>
```

```
</filter>
```

In the preceding example, the action needs the IP address of the alarmed model. Therefore, it should only be enabled if the alarmed model has the Network_Address (ID 0x12d7f) attribute.

You can specify complex attribute filters with any combination of nested “and” and “or” filters.

Example: Nesting Filters

The following example enables the item if the selected model has the Network_Address attribute and the Condition (ID 0x1000a) attribute is RED.

```
<filter>
   <and>
    <has-attribute>AttributeID.NETWORK_ADDRESS</has-attribute>
    <equals>
        <attribute id="AttributeID.CONDITION">
            <value>3</value> <!--red-->
        </attribute>
    </equals>
   </and>
</filter>
```

The file *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/common/schema/attribute-filter.xsd contains the complete syntax for attribute filters.

The following table defines commonly used attributes where an attribute ID is expected.

Constant	Attribute
AttributeID.NETWORK_ADDRESS	Network Address (ID 0x12d7f)
AttributeID.MTYPE_ID	Model Type Handle (ID 0x129ab)
AttributeID.MTYPE_NAME	Model Type Name (ID 0x10000)
AttributeID.MODEL_OBJECT	Model Handle (ID 0x11f53)
AttributeID.MODEL_NAME	Model Name (ID 0x1006e)
AttributeID.MODEL_CLASS	Model Class (ID 0x11ee8)
AttributeID.CONDITION	Condition (ID 0x1000a)
AttributeID.DOMAIN_ID	Landscape Handle (ID 0x129ac)
AttributeID.DOMAIN_NAME	Landscape Name (ID 0x11d42)
AttributeID.MAC_ADDRESS	MAC Address (ID 0x110df)
AttributeID.DEVICE_TYPE	Device Type (ID 0x23000e)

You can use the constants defined in the following table for alarm attributes:

Constant	Alarm Attribute
AlarmAttrID.ACKNOWLEDGED	Acknowledged (ID 0x11f4d)
AlarmAttrID.ALARM_FILTER_MH	Alarm Filter (ID 0x12a56)
AlarmAttrID.ALARM_ID	Full Alarm ID (ID 0x11f9c)
AlarmAttrID.INT_ALARM_ID	Integer Alarm ID (ID 0x4820067)
AlarmAttrID.ALARM_SOURCE	Alarm Source (ID 0x11fc4)
AlarmAttrID.ALARM_STATUS	Alarm Status (ID 0x11f4f)
AlarmAttrID.CAUSE_CODE	Cause Code (ID 0x11f50)

AlarmAttrID.CAUSE_LIST	Cause List (ID 0x12a05)
AlarmAttrID.CAUSE_TITLE	Cause Title (ID 0x4820020)
AlarmAttrID.CREATION_DATE	Creation Date (ID 0x11f4e)
AlarmAttrID.CLEARED_BY_USER_NAME	Cleared By User Name (ID 0x11f51)
AlarmAttrID.IMPACT_SEVERITY	Impact Severity (ID 0x1290d)
AlarmAttrID.OCCURRENCES	Occurrences (ID 0x11fc5)
AlarmAttrID.ORIGINATING_EVENT	Originating Event (ID 0x1296e)
AlarmAttrID.PERSISTENT	Persistent (ID 0x12942)
AlarmAttrID.PRIMARY_ALARM	Primary Alarm (ID 0x11f54
AlarmAttrID.SEVERITY	Severity (ID 0x11f56)
AlarmAttrID.TROUBLESHOOTER	Troubleshooter (ID 0x11f57)
AlarmAttrID.TROUBLE_TICKET_ID	Trouble Ticket ID (ID 0x12022)
AlarmAttrID.USER_CLEARABLE	User Clearable (ID 0x11f9b)

If you need to use an attribute other than one of the attributes listed in the 2 preceding tables, specify the attribute using its hexadecimal attribute ID.

Launch a Browser

The <launch-browser> element lets you launch a specified URL in a browser and pass parameters to the URL. These parameters can be hard-coded values or values from model attributes.

Example: <launch-browser> Code

The following example launches the default browser on the client machine. The <url> element specifies the URL pattern. You can specify parameters to substitute in the URL pattern by enclosing the parameter number (starting at 0) in curly braces {}. You then specify <param> elements for each parameter.

```
<launch-browser>
   <url>http://{0}</url>
   <param>
    <attribute>AttributeID.NETWORK_ADDRESS</attribute>
   </param>
</launch-browser>
```

DX NetOps Spectrum processes the <param> elements in order so the first one corresponds to the 0th parameter in the URL pattern. A <param> element has a specific syntax. The most commonly used is the <attribute> element. This element substitutes the value of the specified attribute for the selected context. In the preceding example, the value of the Network Address attribute is substituted in the URL pattern. For more complex parameters, see the definition of <param-type> in the file.

```
<$SPECROOT>/tomcat/webapps/spectrum/WEB-INF/common/schema/basic-config.xsd
```

Important Information About Specifying URLs

Provide the following information when specifying URLs.

Use Standard Characters

Whenever a URL is specified in XML customization code for OneClick, the URL formatting must adhere to the standards published in the Internet Engineering Task Force (IETF) RFC 1738. Use of non-standard characters in URLs results in unreliable browser performance including the browser not locating the specified web page.

URL Encoding of Spaces and Commas

If you are using spaces or commas, or other "reserved" or "unsafe" characters in URLs (see the tables later in this section), convert them to their ASCII equivalent value with the proper URL encoding. URL encoding of a character consists of a "%" symbol, followed by the two-digit hexadecimal representation (case-insensitive) of the ISO-Latin code point for the character. Examples for "space" and "comma" are:

- For spaces, use %20
- For commas, use %2C

> **NOTE**
> Some browsers may encounter problems processing URLs even when using this encoding.

Use of Ampersands

If you are using an ampersand in a URL or in XML customization code, you must convert it to &amp.

Use CDATA in XML

You can place URLs inside a CDATA section so that they are not parsed. This avoids possible problems with URLs and the XML parser.

Be sure to follow the requirements for CDATA, including:

- A CDATA section cannot contain the string "]] >", therefore, nested CDATA sections are not allowed.
- Also ensure there are no spaces or line breaks inside the "]] >" string.

URL Unsafe Characters

Some characters can be misunderstood within URLs for various reasons. These characters should also always be encoded. Unsafe characters and their hexadecimal encoding are provided in the following table.

Character	Code Points (Hex)
Space	20
Quotation marks (")	22
'Less Than' symbol ("<")	3C
'Greater Than' symbol (">")	3E
Pound' character ("#")	23
Percent symbol ("%")	25
Left Curly Brace ("{")	7B
Right Curly Brace ("}")	7D
Vertical Bar/Pipe ("|")	7C
Backslash ("\")	5C
Caret ("^")	5E
Tilde ("~")	7E
Left Square Bracket ("[")	5B
Right Square Bracket ("]")	5D
Grave Accent ("`")	60

URL Reserved Characters

URLs use some characters for special use in defining their syntax. When these characters are not used in their special role inside a URL, they need to be encoded. These characters and their hexadecimal encoding are provided in the following table.

Character	Code Points (Hex)
Dollar ("$")	24
Ampersand ("&")	26
Plus ("+")	2B
Comma (",")	2C
Forward slash/Virgule ("/")	2F
Colon (":")	3A
Semi-colon (";")	3B
Equals ("=")	3D
Question mark ("?")	3F
'At' symbol ("@")	40

Specify a Username

You can pass the OneClick username of the current user to an application, Web browser, or executable requiring a username. Use the following expression to specify the logged-in username of the user:

```
<param>
   <expression>
    com.aprisma.spectrum.app.util.context.DefaultApplicationContext.getGlobal
Parameter(com.aprisma.spectrum.app.util.context.ApplicationContext.
USER_PARAMETER_NAME)
   </expression>
</param>
```

Example: Pass Username to Browser

The following example launches a browser to a specified URL and passes the username to the browser.

```
<launch-browser>
   <url> http://acme.com?user={0}</url>
   <param>
    <expression>
 com.aprisma.spectrum.app.util.context.DefaultApplicationContext.getGlobalParameter(com.aprisma.spectrum.app.util.conte
    </expression>
   </param>
</launch-browser>
```

Launch an Application From OneClick

The <launch-application> element enables you to launch a specified command or executable.

Example 1: <launch-application>

The following example launches an application called myapp on the client machine and passes in the IP address of the selected model. As with the <launch-browser> action, you can substitute any number of parameters.

```
<launch-application>
   <command>myapp {0}</command>
   <param>
    <attribute>AttributeID.NETWORK_ADDRESS</attribute>
   </param>
</launch-application>
```

The <command> element specifies the command or executable to execute. You can provide the path to the command or executable in one of two ways:

- You can specify the path on each client via an environment variable. To create an environment variable in the Windows environment, select My Computer,Properties,Advanced, and then select the Environment Variables button.
- You can specify an absolute path to the command or executable. If you do this, keep in mind that the path must be the same on each OneClick client. Path statements in the Windows environment should use a double backslash instead of a single backslash, for example:
  ```
  C:\\Windows\\system32\\cmd.exe
  ```

  NOTE
  You can use the <validate> element to verify that the command or executable exists on the OneClick client and has execute permissions. If either of these conditions is found to be false during OneClick startup, the associated menu item is not added to the OneClick menu. (If the <validate> element is not used, the menu item is always added to the menu, but its state is determined by the value of other elements.)

If you use the <validate> element, you must specify an absolute path in the <command> element, as shown in the following example:

```
<launch-application>
   <command>c:\\windows\\system32\\notepad.exe</command>
   <validate/>
</launch-application>
```

The <command> element must conform to the following syntax rules:

- The command arguments are delimited by only spaces. If you would like to have a space within an argument, you must either place quotes around the argument or use the escape character '\' prior to the internal space(s).
- If you would like to embed quotes within an argument, you must place the escape character '\' prior to the quote.
- If any of your command arguments contain commas, DX NetOps Spectrum automatically places the argument within quotes. This is important to know in case that you are going to parse an argument that is a numeric value that contains commas.
- DX NetOps Spectrum replaces arguments that return null or have a string length of zero with empty quotes (“ ”).

Example 2: <launch-application>

The following example uses the <platform> element to specify different commands for different platforms. The <os-name> element specifies the operating system name and the <command> element specifies the command to execute on that operating system. The <os-name> element is optional. If you do not specify the <os-name>, the associated command is the default such that if no other platforms match, the default command is executed.

```
<launch-application>
   <platform>
    <os-name>Windows</os-name>
    <command>cmd.exe /c start "ping {0}" cmd /c "ping.exe {0}
    &#38;&#38;pause"</command>
   </platform>
   <platform>
    <os-name>SunOS</os-name>
    <command>>/usr/dt/bin/dtterm -e ping {0}</command>
```

```
    </platform>
    <param>
     <attribute>AttributeID.NETWORK_ADDRESS</attribute>
    </param>
 </launch-application>
```

At runtime, DX NetOps Spectrum compares the specified OS names to the OS name returned by the “os.name” Java property. DX NetOps Spectrum uses a best-match algorithm so only a prefix of the OS name need be specified. You may specify any of the following OS names:

- Windows for all Windows platforms
- Windows XP for Windows XP
- Windows 7 for Windows 7
- Linux for the Linux platform
- Mac for the Macintosh platform

If no specified platforms match, the associated menu item is disabled.

Launch a Web Server Script

The <launch-web-server-script> element launches a script on the web server machine. The <command> element specifies the script to execute. As with the <launch-browser> action, any number of parameters can be substituted. Since the script resides on the web server, which is restricted to a Windows machine, you do not use a <platform> element to denote the platform on which the script is running.

> **NOTE**
> This action can only be used to launch a script; it cannot be used to launch a user interface.

Example: <launch-web-server-script> Code

The following example launches “myscript” on the web server, passing it the model name and model type name of the selected model. Note that the path that is shown in the <command> element is a path for a Windows web server.

```
<launch-web-server-script>
       <command>c:/scripts/myscript {0} {1}</command>
       <param>
        <attribute>AttributeID.MODEL_NAME</attribute>
       </param>
       <param>
        <attribute>AttributeID.MTYPE_NAME</attribute>
       </param>
</launch-web-server-script>
```

Use the <platform> tag with the <launch-web-server-script> as described in Launch an Application From OneClick.

Launch a Web Server Script For Multiple Alarms in Combined Mode

Till 10.2.3, when you use the <run-for-multiple-alarms> tag with <launch-web-server-script>, it runs a script for selected multiple alarms in the OneClick console. Selected alarm attributes are passed as command line arguments to script for each selected alarm. The same script is run multiple times, once per selected alarm.

Starting from 10.3, you can use the following sub-element/tag to run a combined script in combined mode for multiple alarms. You can configure the<multiple-contexts-enabled mode= /> tag to run a script for several alarms at the same time in the alarm console.

<multiple-contexts-enabled mode= "combined-execution" delimiter= ";"/>

By default a space is considered as the 'delimiter' value. You can specify the delimiter value according to your requirement.

If you do not provide mode then the default value is applied as 'separate-execution' (<multiple-contexts-enabled mode=" separate-execution" />).

In combined execution mode, DX NetOps Spectrum creates a temporary file in $SPECROOT/tmp folder, which contains details of specified attributes of all alarms selected separated by delimiter. This file is passed as an argument to the combined execution script.

The temporary file contains the list of alarm attributes separated by a delimiter in a single line. Each line specifies a single alarm.

NOTE

After the script is complete for combined execution, you need to manually delete the temporary file which was created in the $SPECROOT/tmp folder.

Pass Table Values to a Script

Used with the <context> and <command> elements, the <column-name> element lets you add menu items in OneClick that execute a command using data from a selected row in a table. With this feature, DX NetOps Spectrum eliminates the need to look up attributes separately to build the logic. Instead, you can build the logic from selected column headings within a table and can pass the values from any row in the table to the script. This ability to pass values directly from a table is helpful when you need to use the data in an external script. For example, you can build an interface between DX NetOps Spectrum and an issue-tracking system. Then, you can create a menu item that creates trouble tickets from table data in OneClick.

NOTE

The <column-name> element works with TableContext only in the <context> element.

Example: <command> and <column-name> Commands

The following example passes values from three columns (Condition, Status, and Type) to the "NewTicket" command. The <command> element specifies the command pattern. You specify parameters to substitute in the command by enclosing the parameter number (starting at 0) in curly braces {}. You then specify <param> elements for each column that passes values to the command.

```
<context>com.aprisma.spectrum.app.util.table.TableContext</context>
<command>$SCRIPT_PATH/NewTicket.exe {0} {1} {2} {3}</command>
   <param>
    <column-name>Condition</column-name>
   </param>
   <param>
    <column-name>Status</column-name>
   </param>
   <param>
    <column-name>Type</column-name>
   </param>
```

DX NetOps Spectrum processes the <param> elements in order so the first one corresponds to the 0th parameter in the command pattern. By default, DX NetOps Spectrum passes the raw value to the command. To preserve the formatting information from the table, use the <formatted/> option, as follows:

```
<param>
   <column-name>Condition
    <formatted/>
   </column-name>
```

```
</param>
```

NOTE
The formatted option attempts to render the specified column as seen in the table. However, DX NetOps Spectrum cannot pass images as arguments to commands and, therefore, passes the raw value only.

Display the Status of a Launched Application or Script

Use the <display-exit-status> and <display-output> elements with <launch-web-server-script> and <launch-application> to display the exit status and the output from the script or application.

By default <display-exit-status> displays “Success” if the exit code is 0 and “Failed with error code #” otherwise. You can change the default behavior by specifying <status> child tags that map an exit code to a custom message to display.

Example: <display-exit-status> Code

Examine the following example using <display-exit-status>:

```
<display-exit-status>
   <status code="1">Could not open file</status>
   <status code="2">Bad parameter</status>
   <status code="3">Could not connect to the server</status>
   <status default="true">Unknown error code {0}</status>
</display-exit-status>
```

This example maps status codes 1, 2, and 3 to specific message strings. The last status code specifies default=“true”, mapping all other error codes except 0, which by default maps to “Success”. If exit code 0 does not indicate success, you can override it with a <status> tag. The {0} in the message string substitutes the exit code.

By default, <display-output> displays both the standard output and standard error output from the process. You can display only the standard output by specifying:

```
<display-output stdout="t"/>
```

or only the standard error output by specifying:

```
<display-output stderr="t"/>
```

NOTE
The <display-exit-status> and <display-output> elements can only be used for command line applications or scripts and not GUI applications. OneClick waits for the script to complete before being available to the user again.

Customizing OneClick Alarms

You can create custom alarm attributes and add them to the Alarm table and Information views.

Adding customized alarm attributes that display in OneClick is a multi-step process that requires using the Model Type Editor and the Alarm Preferences dialog, in addition to modifying the Alarm table and the Alarm Information view to display the custom alarm attributes.

To create and view custom alarm attributes

1. Create the custom alarm attributes by adding them to the GlobalAlarm model type using the Model Type Editor. The attribute group ID value must be set to equal 11f4c.

   NOTE
   For information on how to add custom alarm attributes to the GlobalAlarm model type see Model Type Editor. The section provides complete instructions on accessing and using the Model Type Editor.

2. Add a column to the Alarm table that displays the new customized alarm attribute by customizing the alarm-table-config.xml file. Modify Table Columns provides an example showing how to add a column to a table configuration file.
3. Add a field to the Alarm Details view configuration that displays the alarm attribute in the alarm's Information tab by customizing the view-alarmdetails-config.xml file. Extend or Modify an Information View provides information and examples on how to add a subview to an existing information view.
   You can also apply a custom privilege to the new alarm attribute by customizing the custom-privileges.xml file. Doing this limits which users or user groups or specific privileges are required to view the customized alarms. The name of the privilege must use the following syntax:
   ```
   alarm-write-<attribute ID in hex>
   ```
   The following example adds the new privilege to the Alarm Management group.
   ```
   <alarm-write-ffff0000 type="write">
       <group scope="alarm-manager">alarm-mgmt</group>
       <label>New Alarm Attr</label>
   </alarm-write-ffff0000>
   ```
4. Save and close the XML files you edited.
5. You must restart the OneClick server in order to apply the new privilege.
6. You must restart the OneClick Console to view the changes made to the Alarms table and Alarm Information view.

Customizing OneClick Tables

This section discusses some of the ways that you can modify existing tables found in the OneClick Console. A list of the table elements available in OneClick and their descriptions are presented in Example: Defining a Table Column. Specific examples for modifying table columns are presented in the sections listed below.

Modify Table Columns

If you want to display additional attributes in a OneClick console table, you can do so by making modifications to the XML using a customization file. The modifications need to be made in a separate XML file in the appropriate directory under <*$SPECROOT*>/custom/.

Extend a Factory Default File Using IDREF

OneClick requires that you write your customization code in a new file located in the <*$SPECROOT*>/custom/topo/config directory that uses the same name as the factory default file that builds the table you are modifying. Use the IDREF attribute to "reference" the factory file and extend it with the new customization file. See Create Customizations for details on creating customization files in OneClick.

Example: Referencing a Column File from a Table Configuration File

The following example shows a portion of an XML file used to define a table. Rather than defining each column in the same file that defines the entire table, the example uses separate files to define the first two columns in the table. The example uses the idref attribute with each <column> element to link to the file that defines the column.

```
<table id="table-licenses-config"
   xmlns="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com
   ../../common/schema/table-config.xsd">
   <swing-row-template>
    <enumerated-color idref="alternatingrow-color-config"/>
   </swing-row-template>
   <swing-table-template>
```

```
     <show-vertical-lines>true</show-vertical-lines>
     <show-horizontal-lines>false</show-horizontal-lines>
    </swing-table-template>
    <swing-header-row-template>
     <static-color idref="row-header-color-config"/>
    </swing-header-row-template>
    <column-list>
     <column idref="column-servicestate-config"/>
     <column idref="column-modelname-config">
     <default-width>300</default-width>
     </column>
    </column-list>
    .
    .
 </table>
```

The first column is defined in the column-servicestate-config.xml file. The beginning portion of this file is shown below. Note the id attribute used with the <column> element to define this file as “column-servicestate-config”.

```
 <column id="column-servicestate-config"
    xmlns="http://www.aprisma.com"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.aprisma.com
    ../../common/schema/table-config.xsd">
```

Modify a Table Column

The following steps describe the general process for modifying table columns in OneClick. Specific examples are provided in the following sections.

To modify a table column

1. Identify the default factory XML file that builds the table that you want to modify.
   Many of the table files used to display data in the OneClick console are located in *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/topo/config. All of the table files are named for the functionality that they display. For example, the table used to display interface information for each model is called table-common-ifconfig-config.xml.
2. Create the file in which to add your modifications.
   In this example the default file is *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/topo/configtable-common-ifconfig-config.xml. Create a file with the same name in the *<$SPECROOT>*/custom/topo/config directory. If a file with that name already exists in this directory, that is an indication that previous customizations have been made to this table. In this case, add your customized code to the existing file.
3. Open the file in a text editor in order to make the appropriate modifications.
4. Use idref to reference the table configuration you are extending with this new column configuration (see Step 1).
5. Construct a new column using the XML elements defined in Example: Defining a Table Column. The example that follows this procedure shows how some of these elements are used to define a column.
6. Find the <column-list> element in the XML file. The <column-list> element contains all of the <column> elements used to define each column in the table.
7. Define a <column> element within the <column-list> element. The columns display in the order they appear within the <column-list> element.
8. Insert the <name> element to define the title of the column.
9. Insert a <content> and an <attribute> element to define the contents you want to display in the column.
10. (Optional) Use the <default-width> element to define the default width of the column.
11. Save and close the modified file, and restart the OneClick console to view the changes.

Example: Defining a Table Column

```
<column-list>
    <column>
        <name>Interface</name>
        <content>
            <attribute>0x100c4</attribute>
        </content>
        <default-width>30</default-width>
    </column>
    .
    .
    .
</column-list>
```

The following table describes the elements used for modifying a table.

Element	Parent Element	Description
<table>	Not applicable	This is the root element, and encloses all child elements used to create a table.
<swing-table-template>	<table>	Used to define the appearance of the table.
<show-vertical-lines>	<swing-table-template>	Defines whether to show vertical lines in the table, values are true or false.
<show-horizontal-lines>	<swing-table-template>	Defines whether to show horizontal lines in the table, values are true or false.
<line-color>	<swing-table-template>	Defines the color of the lines used to create the table. The default value is light-background_color. Other values can be found in the *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/common/config/common-color-config.xml file.
<show-tree-lines>	<swing-table-template>	Defines whether the table will be shown with dashed lines connecting tree nodes, values are true or false.
<preferred-width>	<swing-table-template>	Defines (in pixels) the default width of the table.
<preferred-height>	<swing-table-template>	Defines (in pixels) the default height of the table.
<swing-header-row-template>	<table>	Used to define the appearance of the header row of the table.
<static-color>	<swing-header-row-template>	Specifies the color for the header row. Use value idref=row-header-color-config for consistency.
<swing-row-template>	<table>	Used to define the appearance for the body rows in the table.
<enumerated-color>	<swing-row-template>	Used to specify different colors for each row of the table, the default value used is alternating row-color-config.
<static-color>	<swing-row-template>	Used to specify a single color used for all of the rows in the table.
<column-list>	<table>	Used to define the list of columns to be used in the table
<column>	<column-list>	Used to define a column in the column list.
<name>	<column>	The name of the column. The text used here will appear in the table header for this column.
<editable>	<column>	Defines whether the value in the table can be edited. If this value is set to true, a set link appears next to the value.
<content>	<column>	Defines the value placed in the column. This is the value used for sorting and filtering. See "Rendering a value" for information on what child elements can be specified. The final displayed text can be further manipulated by defining a <swing-cell-template> tag. See Define How Cells Display in Table Columns for information on <swing-cell-template>.

<renderer>	<content>	Specifies the renderer to be used for the content of the column. See Customize the Port Name Column of the Interface Table for more information.
<dynamic-renderer>	<content>	Enables you to specify a renderer depending on model class or model type. See About <dynamic-renderer> for detailed instructions on usage.
<expression>	<content>	Used to define an expression to produce a value for the column. See XML Usage Common to All Customization Files for more information
<message>	<content>	Used for specifying a plain text value for the column.
<select>	<content>	Used to select a value for the column based on certain criteria. See XML Usage Common to All Customization Files for more information.
<attribute>	<content>	Used to specify an attribute ID. The value of the attribute will be placed in the column.
<swing-cell-template>	<column>	Used to define how the cell in the column is displayed. See Define How Cells Display in Table Columns for detailed information on using this element.
<image>	<swing-cell-template>	Used to display an image in a cell.
<attribute>	<image>	The attribute used to determine the image selection.
<select>	<image>	Used to define the image that is selected. See XML Usage Common to All Customization Files for more information.
<text>	<swing-cell-template>	Used to display a string of text in a cell.
<renderer>	<text>	The renderer used to manipulate the text. See Customize the Port Name Column of the Interface Table for an example. See Manipulate Attribute Output Using Renderers for detailed information on OneClick renderers.
<param>	<renderer>	Specifies any parameters to be used by the renderer. See About Parameters for detailed information.
<renderer-class>	<swing-cell-template>	The class to use for rendering something other than an image or text.
<editable>	<column>	Allows the user to edit the value in a column. See Make a Table Column Editable for more information.
<hidden-by-default>	<column>	Use this element to hide the column by default. The user must add the column to the table using the preferences dialog.
<default-width>	<column>	The default width of the column in pixels.
<default-sort>	<column-list>	Used in conjunction with the <sort-column-list> element to determine how the table is sorted by default.
<sort-column-list>	<default-sort>	A list of columns that will be sorted on (maximum of three).
<sort-column>	<sort-column-list>	The column to be sorted on. Columns will be sorted in the order that they are listed.
<name>	<sort-column>	The name of the column to sort on. This must match the name defined for the column.
<direction>	<sort-column>	The direction of the sort, values can be ascending or descending.

Define How Cells Display in Table Columns

The <swing-cell-template> defines the final presentation of content within the cell of a table column. Use this element in conjunction with the <content> element to specify how the content is presented to users. This element gives the developer flexibility in processing raw OneClick data using buttons, scrollable lists, wrapping text, and other techniques.

If you do not specify <swing-cell-template> in a column cell definition, the raw output from the <content> element is displayed without refinement. The elements you can use in defining <swing-cell-template> are described in the following table.

Element	Parent Element	Description
<image>	<swing-cell-template>	Defines an image displayed in the cell.
<text>	<swing-cell-template>	Defines the text to display in a cell. If no child elements are specified, then the text from the <content> element is displayed.
<renderer-class>	<swing-cell-template>	Specifies a Java class to use for the final presentation of data in a cell. See Use Renderers to Present Data in Column Cells for the renderers available to use with this element.

The following Java classes are available to use with <renderer-class> to render or manipulate and format raw data for display in table column cells.

TextAreaCellRenderer

Use this renderer to display text that wraps at the cell width.

Classname: com.aprisma.spectrum.app.swing.table.render.TextAreaCellRenderer

Supported Parameters: None

Example: Displaying Wrapping Text in a Cell

The following example creates a cell that displays text and allows it to wrap at a defined width, displaying in multiple lines of fixed width. This technique is used in the Notes field on the device's Information tab. Text entered by operators in this field wraps at a predetermined column width.

```
<swing-cell-template>
   <text/>
   <renderer-class>
    com.aprisma.spectrum.app.swing.table.render.TextAreaCellRenderer
   </renderer-class>
</swing-cell-template>
```

ListAttributeRenderer

Displays the values from a list-type attribute in a scrollable list.

Classname: com.aprisma.spectrum.app.swing.table.render.ListAttributeRenderer

Supported Parameters:

- <attrID> - Required parameter. ID of the DX NetOps Spectrum attribute displayed in the cell.
- <maxRowsToDisplay> - Integer; specifies the maximum number of viewable list entries, scrolling is turned on after this maximum is exceeded.
- <order> - True or false; if true, the users can modify the list order if the column is editable.
- <add> - True or false; if true, users can add new entries to the list if the column is editable.
- <remove> - True or false; if true, users can remove entries from the list if the column is editable.
- <valuePrompt> - The text displayed when prompting the user to add a new value to the list. If not specified, a default prompt is used.

Example: Displaying a Scrollable List in a Cell

The following example defines the maximum number of rows displayed in the cell as four; if there are more than four rows, the list becomes scrollable.

```
<swing-cell-template>
   <renderer-class>
    com.aprisma.spectrum.app.swing.table.render.ListAttributeRenderer
    <param name="maxRowsToDisplay">4</param>
    <param name="attrID">0x25e0039</param>
    <param name="add">true</param>
    <param name="remove">true</param>
    <param name="valuePrompt">SNMP Port</param>
   </renderer-class>
</swing-cell-template>
```

ListAttributeOIDRenderer

Displays the OIDs from a list-type attribute in a scrollable list.

Classname: com.aprisma.spectrum.app.swing.table.render.ListAttributeOIDRenderer

Supported Parameters: See ListAttributeRenderer.

- <oidPrompt> - The text displayed when prompting the user to add a new OID to the list. If not specified, a default prompt is used.

ActionButtonCellRenderer

Displays a button in the cell that sends an action to the model when clicked.

Classname: com.aprisma.spectrum.app.topo.client.render.ActionButtonPanelCellRenderer

Supported Parameters:

- <actionID> - Required parameter; the DX NetOps Spectrum attribute ID for the action the button sends.
- <text> - Required parameter; the text displayed on the button.
- <toolTipText> - The text displayed in a tooltip for the button.
- <prompt> - The text displayed when prompting the user to confirm a button click. If not specified, no prompt is displayed.
- <confirmSuccess> - True or false; if true, a message is displayed if the action was successful.

Example: Displaying an Action Button in a Cell

```
<swing-cell-template>
   <renderer-class>
    com.aprisma.spectrum.app.topo.client.render.ActionButtonCellRenderer
    <param name="actionID">0x0001011f</param>
    <param name="text">Reevaluate Model Names</param>
    <param name="toolTipText">
        Reevaluates all model names based on the model naming order of VNM
    </param>
    <param name="confirmSuccess">true</param>
   </renderer-class>
</swing-cell-template>
```

ActionButtonPanelCellRenderer

Displays one or more buttons that each send an action to the model. All parameters are specified as a semi-colon separated list, one per button.

Classname: com.aprisma.spectrum.app.topo.client.render.ActionButtonPanelCellRenderer

Supported Parameters: See ActionButtonCellRenderer.

Example: Displaying Multiple Action Buttons in a Cell

The following example defines two buttons, “Reconfigure Model” and “Discover Connections.” The parameters with a value for each button separate each value with a semi-colon (;).

```
<swing-cell-template>
   <renderer-class>
    com.aprisma.spectrum.app.topo.client.render.ActionButtonPanelCellRenderer
    <param name="actionID">0x1000e;0x25e0022</param>
    <param name="text">Reconfigure Model;Discover Connections</param>
    <param name="confirmSuccess">true;true</param>
   </renderer-class>
</swing-cell-template>
```

AttrToggleButtonCellRenderer

Displays a button with text that can be one of two values based on two specified values of an attribute. When the button is clicked, the opposite value is written to the attribute.

Classname: com.aprisma.spectrum.app.topo.client.render.AttrToggleButtonCellRenderer

Supported Parameters:

- <attrID> - Required parameter. ID of the DX NetOps Spectrum attribute that the button toggles the value of.
- <firstValueMapping> - Required parameter. Specifies the first attribute value and the text to display when the attribute equals this value, separated by a semi-colon.
- <secondValueMapping> - Required parameter. Specifies the second attribute value and the text to display when the attribute equals this value, separated by a semi-colon.
- <promptOnFirstValue> - Specifies the text used to prompt the user for confirmation when the button is clicked and the attribute equals the first value. If not specified, no prompt is displayed.
- <promptOnSecondValue> - Specifies the text used to prompt the user for confirmation when the button is clicked and the attribute equals the second value. If not specified, no prompt is displayed.
- <disableOnFirstValue> - True or false; if true, the button is disabled when the attribute equals the first value.
- <disableOnSecondValue> - True or false; if true, the button is disabled when the attribute equals the second value.

Example: Displaying a Toggle Action Button in a Cell

```
<swing-cell-template>
   <renderer-class>
    com.aprisma.spectrum.app.topo.client.render.AttrToggleButtonCellRenderer
    <param name="attrID">0x11b6e</param>
    <param name="firstValueMapping">true;Start</param>
    <param name="secondValueMapping">false;Stop</param>
    <param name="promptOnSecondValue">Are you sure you want to stop?</param>
   </renderer-class>
</swing-cell-template>
```

BoldAttributeTableCellRenderer

Displays the cell text in bold.

Classname: com.aprisma.spectrum.app.swing.table.render.BoldAttributeTableCellRenderer

Example: Displaying Bold Text in a Cell

```
<swing-cell-template>
```

```
    <text/>
    <renderer-class>
     com.aprisma.spectrum.app.swing.table.render.BoldAttributeTableCellRenderer
    </renderer-class>
 </swing-cell-template>
```

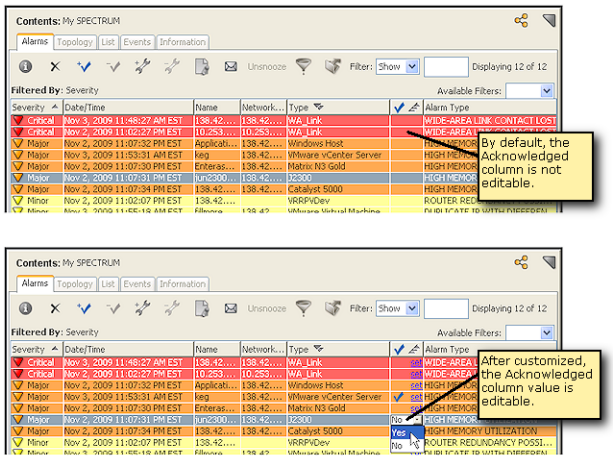
Make a Table Column Editable

In some cases, you can allow the user to edit the value found in a particular table cell in the column. The Acknowledged column in the Alarms table and the Admin Status column in the Interface Configuration table are examples of columns that allow users to edit.

Customize the Alarm Table Acknowledge Field

Some organizations may prefer to see text displayed in the Acknowledged column (“yes” or “no”) instead of the default checkmark or blank space. This section describes how to make the Acknowledged column in the Alarms table editable by extending the factory XML file.

The following figure shows the default Acknowledged field in the Alarms table and the Acknowledged field after customizing it to make it editable.



Check to see if the file *<$SPECROOT>*/custom/alarm/config/alarm-table-config.xml already exists. It exists in this directory if previous customization has been made to this file. If the file does not exist, create it.

To create an editable Acknowledged column

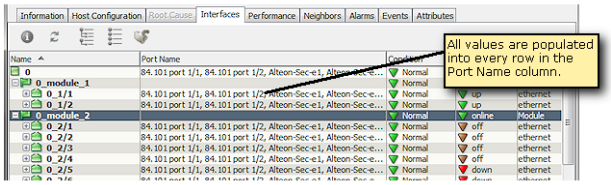
1. Open the file and add the following XML

```
<table idref="alarm-table-config">
    <column-list>
        <column idref="column-alarmacknowledge-config">
            <editable/>
            <default-width>37</default-width>
        </column>
    </column-list>
</table>
```

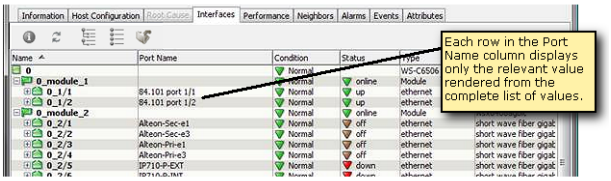
2. Save and close the alarm-table-config.xml file.
3. Restart the OneClick client for the changes to take effect.
   This code overrides the "column-alarmacknowledge-config" entry in the factory alarm-table-config.xml file.

Display Instanced Attribute Values in Separate Table Rows

If you add a new table column for attributes with instanced values (such as, PortName and BoardToPortMap), adding ObjectIDValueListRenderer *and* the <refID> to your XML file helps ensure the data displays correctly. Using this renderer without the <refID> value, DX NetOps Spectrum displays all values returned for the selected OID value list attribute in every row.



When the <refID> value is added to the XML file, DX NetOps Spectrum displays the attribute values correctly, rendering only the particular value from the list that applies to a given row.



The supported parameters include the following:

- <attrID> - Required parameter. ID of the DX NetOps Spectrum attribute displayed in the cell.
- <refID> - Required parameter. Reference ID for the DX NetOps Spectrum attribute that is used for indexing the attribute values.

Example: Displaying a Single OID Value in Each Row of a Column

The following example shows the contents of the column-portname-config.xml file used to create a custom table column for the Port Name attribute.

```
<?xml version="1.0" encoding="UTF-8"?>
<column id="column-portname-config"
    xmlns ="http://www.aprisma.com"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.aprisma.com
         ../../common/schema/column-config.xsd">
   <name>Port Name</name>
   <content>
    <attribute>0x11c0056</attribute>
    <renderer>
         <param name="attrID">0x11c0056</param>
         <param name="refID">0x1297f</param>
         com.aprisma.spectrum.app.util.render.ObjectIDValueListRenderer
    </renderer>
   </content>
</column>
```

Other Customizations in Tables

Customize Alarm Table Row Colors

You can customize the background color displayed in each row of the Alarms table. By default, each row in the Alarms table takes on the background color associated with the alarm listed in the row.

Customize the Alarms table to display in alternating gray and white rows by changing the swing-row-template definition from enumerated-severity-color-config to alternatingrow-color-config.

To customize the Alarm table colors

1. Create an alarm-table-config.xml file (if one does not already exist) in the <*$SPECROOT*>/custom/alarm/config directory.
2. Use the idref attribute to reference the factory file being extended: alarm-table-config.xml.
3. Define <enumerated-color> to reference alternatingrow-color-config.
4. Save and close the file.
5. Close and restart the OneClick Console to view the changes.

Example: Modifying the Alarm Table Row Color

```
<table idref="alarm-table-config">
   <swing-row-template>
    <enumerated-color idref="alternatingrow-color-config"/>
   </swing-row-template>
</table>
```

Set Up a Default Sort

You can create default sort criteria for a table using the <default-sort> element and its child elements. You can sort on a maximum of three columns. DX NetOps Spectrum sorts the columns in the order in which they are listed in <sort-column-list>.

To set up a default sort

1. Identify the appropriate XML file that is used to build the table. All of the table files that are used to display data in the OneClick console are located in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config directory. All of the table files are named after the functionality that they display. For example, the table used to display interface information for each model is called table-common-ifconfig-config.xml.
2. Determine if this file exists in the <*$SPECROOT*>/custom/topo/config directory. It exists in this directory if previous customizations were made to this file. If it is not there, copy the factory table file into the <*$SPECROOT*>/custom/topo/config directory.
3. Open the file in a text editor in order to make the appropriate modifications.
4. Find the closing tag for the column-list element, </column-list>.
5. Insert the XML to create the default sort after the </column-list> using the <default-sort> element.
6. Save and close the XML file.
7. Restart the OneClick client for your changes to take effect.

Example: Using <default-sort>

```
<table>
<column-list>
.
.
```

```
.
</column-list>
<default-sort>
   <sort-column-list>
    <sort-column>
        <name>Name_of_first_column_to_sort</name>
        <direction>ascending</direction>
    </sort-column>
    <sort-column>
        <name>Name_of_second_column_to_sort</name>
        <direction>ascending</direction>
    </sort-column>
    <sort-column>
        <name>Name_of_third_column_to_sort</name>
        <direction>ascending</direction>
    </sort-column>
   </sort-column-list>
</default-sort>
```

NOTE
Include the specific text for the contents of each <name> element based on the column list entries.

Customize the Port Name Column of the Interface Table

You can change the tree column in the interface table to display something other than the model name which is the default attribute displayed. This type of customization requires you to override the factory content-iftree-config.xml file.

To customize the port name column

1. Determine if the file *<$SPECROOT>*/custom/topo/config/content-iftree-config.xml exists. It already exists in this directory if previous customizations have been made to this file. If the file does not exist, create this file in the specified directory by copying it from *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/topo/config and pasting it into *<$SPECROOT>*/custom/topo/config.
2. Find the following code in the content-iftree-config.xml file that creates the column containing the model name attribute:

```
<content id="content-iftree-config"
    xmlns ="http://www.aprisma.com"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.aprisma.com
    ../../common/schema/column-config.xsd">
    <attribute>AttributeID.MODEL_NAME</attribute>
<!-- If the model name is not filled in or it's a GnPort, use Component_OID-->
    <expression>
        (((String)value()).length() == 0 ||
        ((String)value()).equals("GnPort")) ?
        attr(0x1006a).toString(): value()
    </expression>
</content>
```

NOTE
The contents of the <expression> element are specific to the use of the Model_Name attribute and should be removed when specifying other attributes.

3. Customize the attribute displayed in the Port Name column by changing the <attribute><value></attribute> element to contain the attribute you want to display. To display a different attribute, change <value> to the desired attribute ID.

You can specify the integer ID (for example, 0x129e0) or a predefined constant. The table beneath this procedure lists the predefined Port Attributes and their integer IDs.
To display the port description, edit the file as follows:

```
<content id="content-iftree-config"
    xmlns ="http://www.aprisma.com"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.aprisma.com
    ../../common/schema/column-config.xsd">
    <attribute>AttributeID.PORT_DESCRIPTION</attribute>
</content>
```

4. Save and close <*$SPECROOT*>/custom/topo/config/content-iftree-config.xml.
5. Close and restart the OneClick client to see the changes take effect.

Predefined Port Attribute Value Constant	Integer ID
AttributeID.PORT_DESCRIPTION	0x129e0 (ifDescr)
AttributeID.PORT_TYPE	0x129ed (ifType)
AttributeID.COMPONENT_OID	0x1006a

Sort Interfaces Table by ifIndex

DX NetOps Spectrum sorts the interfaces in the Interfaces table by the first column, which is the interface model name. DX NetOps Spectrum sorts this field alphabetically based on the textual values.

To sort the interfaces table numerically by ifIndex value

1. Edit the definition of the interfaces table content definition file acquire the ifIndex data. Check the <*$SPECROOT*>/custom/topo/config directory to see if the content-iftree-config.xml file exists. The file exists in this directory if previous customizations have been made to it.
2. If the file is not in this custom directory, create it by copying it from <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config and pasting it into the <*$SPECROOT*>/custom/topo/config directory.
3. Open the file and find the line that reads:
   ```
   <attribute>AttributeID.MODEL_NAME</attribute>
   ```
4. Change this line to read:
   ```
   <attribute>0x1006a</attribute>
   ```

   NOTE
   The 0x1006a attribute is Component_OID (which is rolled from ifIndex).The contents of the <expression> element are specific to the use of the Model_Name attribute and should be removed when specifying other attributes.
5. Save your changes to the content-iftree-config.xml file.
   In the following steps, you edit the interface table column definition file to relabel the Model Name column to be the Index column, as it will display the interface index value instead of the model name.
6. Open the <*$SPECROOT*>/custom/topo/config directory and check to see if the column-iftree-config.xml file already exists there. If it does not, go to the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config directory and find the column-iftree-config.xml file. Copy it and paste it into the <*$SPECROOT*>/custom/topo/config directory.
7. Find the line that reads:
   ```
   <name>com.aprisma.spectrum.app.util.render.ModelNameColumn</name>
   ```
8. Change this line to read:
   ```
   <name>Index</name>
   ```

9. Save your changes to the column-iftree-config.xml file.
   In the following steps, you edit the interface table configuration file to change the name element value from the model naming java class to the text “Index”.
10. Open the <*$SPECROOT*>/custom/topo/config directory and check to see if the interfaces-table-config.xml file already exists there. If it does not, go to the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config/ directory and find the interfaces-table-config.xml file. Copy it and paste it into the <*$SPECROOT*>/custom/topo/config directory.
11. Find the line that reads:
    ```
    <name>com.aprisma.spectrum.app.util.render.ModelNameColumn</name>
    ```
12. Change this line to read:
    ```
    <name>Index</name>
    ```
13. Save your changes to the interfaces-table-config.xml file.
14. Close all of the text files and restart the OneClick console in order for the changes to take effect.

If you would like to retain the interface model name in the table, implement the following additional instructions:

1. Open the <*$SPECROOT*>/custom/topo/config/interfaces-table-config.xml file.
2. Find the following entry within the <column-list> element:
   ```
   <column idref="column-iftree-config">
       <default-width>150</default-width>
   </column>
   ```
3. Add the following three lines to the end of this entry.
   ```
   <column idref="column-ifmodelname-config">
       <default-width>150</default-width>
   </column>
   ```
4. Save your changes and close the XML file.
5. Close and restart the OneClick console in order for the changes to take effect.

Adding Support for Model Types or Model Classes

This section describes how to add or extend OneClick support for a DX NetOps Spectrum model type or model class. For example, you may want to add specific OneClick support for a management module that you have created with the Generic SNMP Toolkit in DX NetOps Spectrum.

Create a Registration

If you have created a new model type or model class, you can use the XML elements described in this chapter to configure the associated model appearance, available information, and views within the OneClick interface.

Register the Model Type or Model Class in custom-app-config.xml

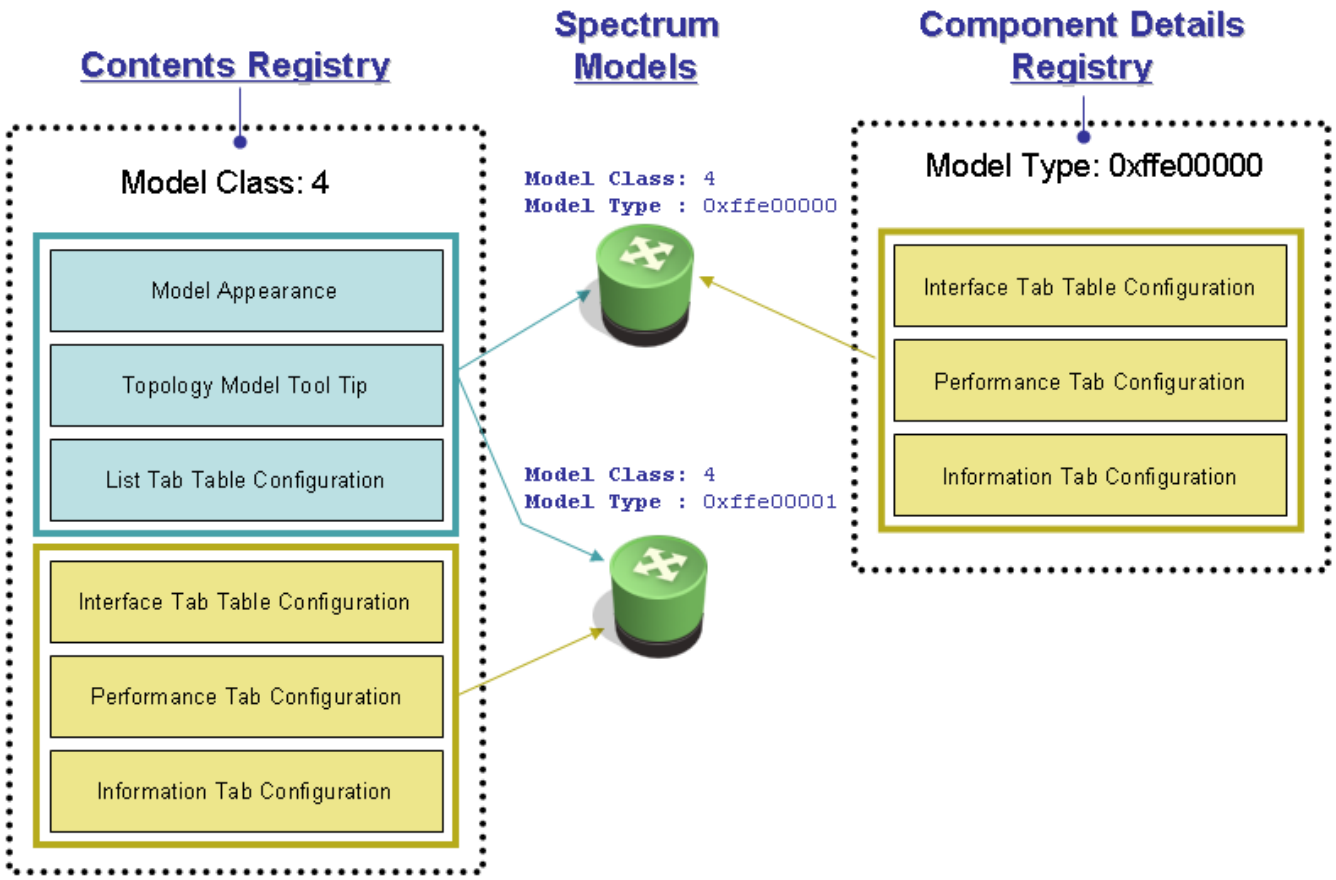
OneClick registration for new model types and model classes is performed within the custom-app-config.xml file. Doing so enables one to configure OneClick support on a per model type and/or model class basis. There are two methods for registration:

- Contents registry
- Component details registry

Both of these registrations work in conjunction with each other to provide effective OneClick support for DX NetOps Spectrum models. The component details registry acts as an extension of the contents registry in order to define general and specific OneClick device support.

Because most models of a given model class will share the same OneClick device support, typically you define a contents registry for the model class to define this general support. However, for a given model class, you might want to expose different information in the Component Details panel based on model type. To accomplish this, you define a component details registry for the applicable model type. As a result, the model receives its general, shared content from the contents registry, and it receives its more specific component details content from the component details registry.

Consider the example illustrated in the following figure. There are two routers of model class 4 (switch-router). They both receive their general information from the contents registry that has been registered with model class 4. However, the model of type 0xffe00000 receives its component details content from the component details registry. Because the model of type 0xffe00001 does not have a component details registry, it receives all of its configuration content from the contents registry.



Define General OneClick Device Support Based on Model Class

The contents registry (denoted by the <oi> element) is primarily used to define the general, shared configuration for a model class or a group of model types. By default, DX NetOps Spectrum defines this general behavior for most model classes. Therefore, if you set the appropriate model class for your custom model type, it automatically inherits this generic content.

If the default configuration meets most of your requirements, but you want to modify the information in the Component Detail panel, you should only create a component details registry for the applicable model type.

However, if you create a new model class, or you want to define a specific model appearance for a model type, you need to create a contents registry entry using the XML elements described in the following table.

Element	Parent Element	Description
<app-config>	ot applicable	The root element for the custom-app-config.xml file.
<contents-registry>	<app-config>	Used to associate a single or group of model classes and/or model types to configuration files that define model appearance and tooltip content. (Optional) You can use the scope attribute to specify the location of the configuration xml files you are using (when you are not using the default locations of console, topo, or common). The scope attribute has to match the directory name where the existing configuration xml files reside, as follows: <$SPECROOT>/tomcat/webapps/spectrum/ WEB-INF/<scope>/config For example, <contents-registry scope="devman"> specifies the devman/config directory, which contains the configuration xml files for device management views and subviews.
<model-class>	<contents-registry>	Registers a model class for this contents registry.
<model-type>	<contents-registry>	Registers a model type for this contents registry. Model types should only be registered for a content registry if you need a unique topology icon or tooltip. If you only want to configure component detail content for a model type, use the <component-details-registry> instead of the <contents-registry>.
<is-derived-from>	<contents-registry>	Registers a parent model type and all of its derived model types for this contents registry. Model types should only be registered for a contents registry if you need a unique topology icon or tooltip. If you want to configure only component detail content for a model type, use the <component-details-registry> instead of the <contents-registry>.
<icon-reg-id>	<contents-registry>	The icon registration ID that identifies the icon configuration to use. The icon configuration defines the appearance of the icon in OneClick.
<tooltip-config>	<contents-registry>	The XML that defines the tooltip content for topology icons.
<table-config>	<contents-registry>	Specifies the XML that configures the columns available on the List tab in the Contents panel.
<information-config>	<contents-registry>	Specifies the XML that defines the content of the model's Information tab.
<performance-config>	<contents-registry>	Specifies the XML that defines the contents of the model's Performance tab, where one or more graphs can be defined to show the values of model attributes over time. The contents of these graphs are real time; the data is only available for the current OneClick client session.
<interface-table-config>	<contents-registry>	Specifies the XML that configures the table on the Interfaces tab.

Define Specific OneClick Device Support Based on Model Type

As mentioned earlier in this chapter, the contents registry defines the general OneClick device support. If you want to define specific device support on a per model type basis in the OneClick client, you should define a component details registry (denoted by the <component-details-registry> element). The component details registry defines the contents for the views within the Component Detail panel.

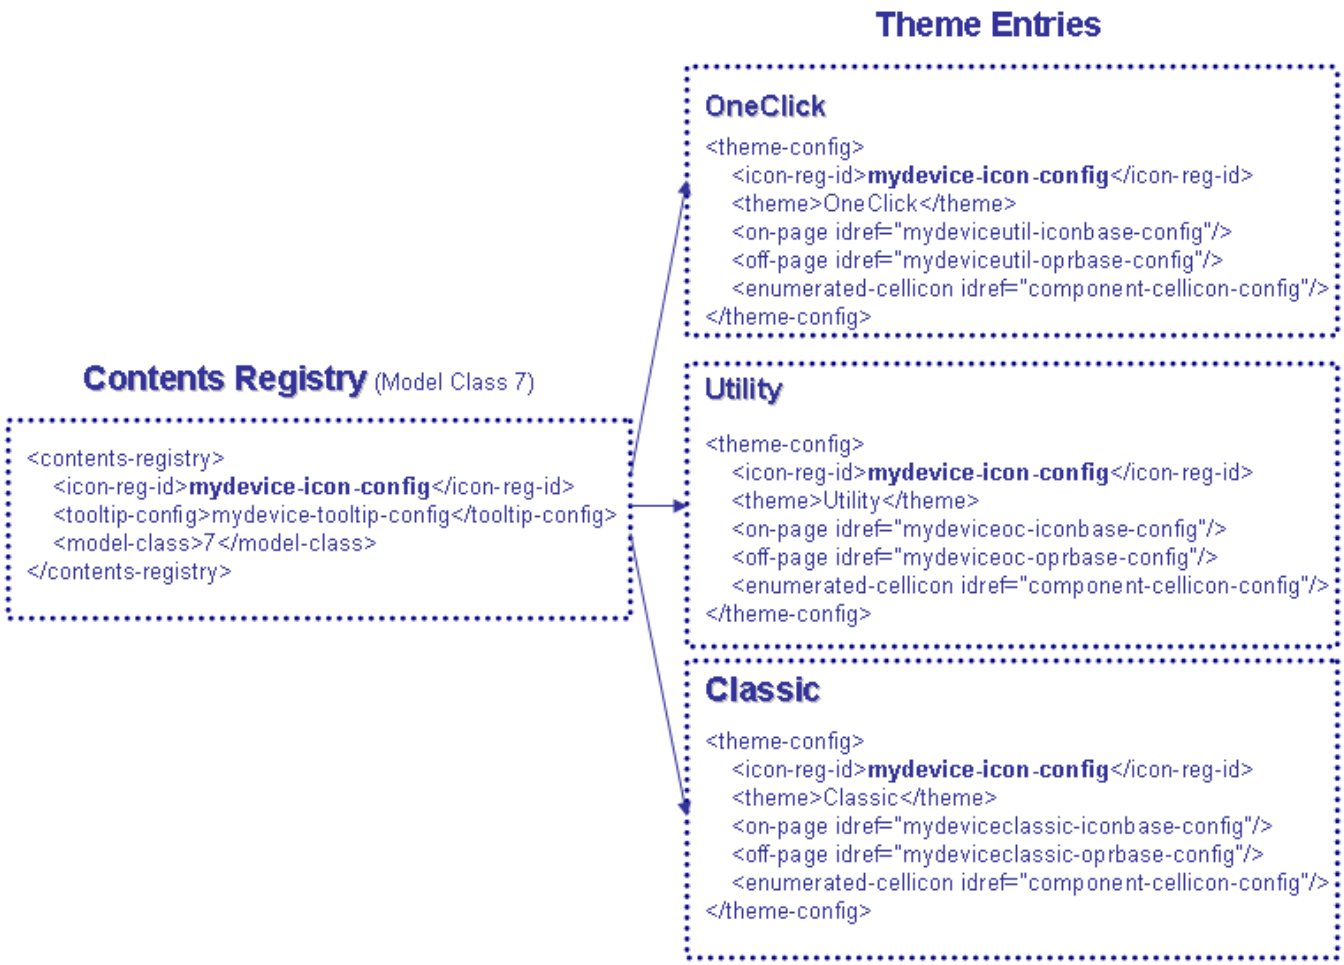
Element	Parent Element	Description
<app-config>	Not applicable	The root element for the custom-app-config.xml file.

<component-details registry>	<app-config>	Used to associate a single or group of model classes and/or model types to configuration files that define the content in the Component Detail panel. The same child elements of <component-details-registry> are supported within <contents-registry>. However, since <component-details-registry> is an extension of <contents-registry>, all elements that are not defined are inherited from <contents-registry>. If both are registered for the same model type or model class, <component-details-registry> takes precedence over <contents-registry>.
<model-class>	<contents-registry>	Registers a model class for this component details registry.
<model-type>	<contents-registry>	Registers a model type for this component details registry.
<is-derived-from>	<contents-registry>	Registers a parent model type and all of its derived model types for this contents registry.
<information-config>	<contents-registry>	Specifies the XML that defines the content of the model's Information tab.
<performance-config>	<contents-registry>	Specifies the XML that defines the contents of the model's Performance tab, where one or more graphs can be defined to show the values of model attributes over time. The contents of these graphs are real time; the data is only available for the current OneClick client session.
<interface-table-config>	<contents-registry>	Specifies the XML that configures the table on the Interfaces tab.

Define Model Appearance

You can define the model appearance as it will look within the OneClick client through XML configuration (for example, topology, Component Detail header, navigation hierarchy, and so on). This is accomplished using the contents registry on a per model class and/or model type basis.

Within the contents registry entry, you need to specify an icon registration ID (<icon-reg-id>). As shown in the following figure, this ID maps to theme configuration entries (<theme-config>) that define the XML files used to construct the model appearance for a specific theme. By default, OneClick includes three icon themes: OneClick, Utility, and Classic.



In the preceding XML example, the contents registry for model class 7 specifies the <icon-reg-id> as mydevice-icon-config. For this ID, a theme configuration is created for each of the three themes included with OneClick: OneClick, Utility, and Classic. Within the theme configurations, the XML files that construct the icons are specified.

The following procedure outlines the process to define a model's appearance in the OneClick user interface using each of these elements.

To define a model's appearance in the OneClick user interface

1. If it does not already exist, create a file named <*$SPECROOT*>/custom/console/config/custom-app-config.xml by copying <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/custom-app-config.xml.
   If the file already exists, it already contains customized changes to the factory default file, and you should make your additional changes in it.
2. Open the file with a text editor.
3. Create a contents registry entry for the applicable model types and/or model classes.

```
<contents-registry>
    ...
        <model-type>0xffff0000</model-type>
        <model-class>2</model-class>
    ...
</contents-registry>
```

4. Within the contents registry, specify an icon registration ID. This ID will map to theme configuration entries.
5. For each desired theme, create a <theme-config> entry. These entries will be identified using the registration ID from the previous step.
6. Design the appearance of the icon for each theme as described in Design On-Page and Off-Page Reference Icons.
7. Define the tooltips for the icons as described in Define Model Icon Tooltips.
8. Once you have created support for a model's appearance, you may want to customize the views and information available in the model's Component Detail panel.
9. Save and close the <*$SPECROOT*>/custom/console/config/custom-app-config.xml file.
10. Restart the OneClick client for your changes to take effect.

Configure Icons for OneClick Themes

By default, OneClick includes three icon themes:

- OneClick (default theme)
- Utility
- Classic

The default OneClick theme is the most robust and, therefore, is the recommended theme for use.

The elements that you can use to create a theme configuration are described in the following table:

Element	Parent Element	Description
<theme-config>	<app-config>	Defines the theme configuration for a specific icon registration ID.
<icon-reg-id>	<theme-config>	The icon registration ID that maps the theme configuration to the contents registry for one or more model types and/or model classes.
<enumerated-cellicon>	<theme-config>	Specifies that an enumerated cell icon image should be used for the model hierarchy tree. The idref attribute of this element defines the id of the chosen cellicon. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config directory and follow the naming pattern *-color-config.xml.
<dynamic-cellicon>	<theme-config>	Specifies that a dynamic cell icon image should be used for the model hierarchy tree. The idref attribute of this element defines the id of the chosen cellicon. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/topo/config directory and follow the naming pattern *-color-config.xml.
<static-cellicon>	<theme-config>	Specifies that a static cell icon image should be used for the model hierarchy tree. The idref attribute of this element defines the id of the chosen cellicon. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/topo/config directory and follow the naming pattern *-color-config.xml.
<theme>	<theme-config>	The name of the theme to which this configuration is applied. OneClick, Classic, or Utility should be specified to configure the existing themes. Specifying a new name generates a new theme.
<on-page>	<theme-config>	The icon configuration for the standard icon for the designated theme.
<off-page>	<theme-config>	The icon configuration for the referenced icon for the designated theme.

The <on-page> and <off-page> elements specify the XML files used to construct the standard version and off-page reference version of the icon as they would appear within the Topology.

The image used within the Navigation panel hierarchy is defined by one of the following three <*-cellicon> elements:

- <enumerate-cellicon>
- <dynamic-cellicon>
- <static-cellicon>

Using the <theme-config> Element to Create Icon Appearance

The following example shows how the theme configuration for the icon registration ID mydevice-icon-config is defined using the <theme-config> element. Notice that the icon's appearance is defined for each of the OneClick themes: Utility, Classic, and OneClick.

Example: <theme-config> Code

```
<theme-config>
   <icon-reg-id>mydevice-icon-config</icon-reg-id>
   <theme>Utility</theme>
   <on-page idref="mydeviceutil-iconbase-config"/>
   <off-page idref="mydeviceutil-oprbase-config"/>
   <enumerated-cellicon idref="component-cellicon-config"/>
</theme-config>
<theme-config>
   <icon-reg-id>mydevice-icon-config</icon-reg-id>
   <theme>Classic</theme>
   <on-page idref="mydeviceclassic-iconbase-config"/>
   <off-page idref="mydeviceclassic-oprbase-config"/>
   <enumerated-cellicon idref="component-cellicon-config"/>
</theme-config>
<theme-config>
    <icon-reg-id>mydevice-icon-config</icon-reg-id>
    <theme>OneClick</theme>
    <on-page idref="mydeviceoc-iconbase-config"/>
    <off-page idref="mydeviceoc-oprbase-config"/>
    <enumerated-cellicon idref="component-cellicon-config"/>
</theme-config>
```

Design On-Page and Off-Page Reference Icons

A model can have two different appearances within the OneClick topology:

- On-page
- Off-page

The on-page representation is the standard appearance of the model and, therefore, the more important appearance. The off-page representation is used when the model is drawn in a topology as a reference to a model that exists in a different topological view. That is, when the model is connected to another model that resides in a different topology.

If the model supports connections (links) within the OneClick topology, you should specify an off-page reference icon (image) in addition to an on-page version.

You specify the on-page and off-page icons within the theme configuration using the <on-page> and <off-page> elements. These elements specify the XML that constructs the corresponding model icon.

The following table defines the elements that can be used within the XML files referenced by the <on-page> and <off-page> elements.

Element	Parent Element	Description
<icon-config>	Not applicable	This is the root element for the icon configuration file.

<static-cellicon>	<icon-config>	A single color foreground/background or image. You can use the idref attribute to refer to another file that defines the image or color. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/topo/config directory and follow the naming pattern *-color-config.xml.
<dynamic-cellicon>	<icon-config>	More than one color or image. You can use the idref attribute to refer to another file that defines the image or color. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/topo/config directory and follow the naming pattern *-color-config.xml.
<enumerated-cellicon>	<icon-config>	Displays an image or color based on the value of an attribute. You can use the idref attribute to refer to another file that defines the image or color. Predefined icons exist in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/topo/config directory and follow the naming pattern *-color-config.xml.
<shape>	<icon-config>	See Define the Icon Shape.
<stroke>	<icon-config>	The type of line used to create the shape. The following values can be used: - Bump1: Bump stroke of width 1. - Bump2: Bump stroke of width 2. - Dash1x1x1: Dashed Stroke of width of 1, and repeats dash of length 1 followed by a blank of length 1. - Dash1x1x3: Dashed Stroke of width of 1, and repeats dash of length 1 followed by a blank of length 3. - Dash1x2x2: Dashed Stroke of width of 1, and repeats dash of length 2 followed by a blank of length 2. - Dash1x3x1: Dashed Stroke of width of 1, and repeats dash of length 3 followed by a blank of length 1. - Dash2x1x1: Dashed Stroke of width of 2, and repeats dash of length 1 followed by a blank of length 1. - Dash2x1x3: Dashed Stroke of width of 2, and repeats dash of length 1 followed by a blank of length 3. - Dash2x2x2: Dashed Stroke of width of 2, and repeats dash of length 2 followed by a blank of length 2. - Dash2x3x1: Dashed Stroke of width of 2, and repeats dash of length 3 followed by a blank of length 1. - DashDot: Dashed Stroke of width of 1, and repeats dash of length 3 followed by a blank of length 1 followed by a dot of length 1 followed by a blank of length 1. - DashDotDot: Dashed Stroke of width of 1, and repeats dash of length 3 followed by a blank of length 1 followed by a dot of length 1 followed by a blank of length 1 followed by a dot of length 1 followed by a blank of length 1. - DashedSeparator: Dashed Stroke used for display a separator lines for the DX NetOps Spectrum look and feel. - PenStroke Ditch1: Ditch stroke with a width of 1. - Ditch2: Ditch stroke with a width of 2. - Ditch4: Ditch stroke with a width of 4. - Hole1: Hole stroke of width 1. - Hole2: Hole stroke of width 2. - Invisible: Invisible Pen Stroke. - Ridge2: Ridge stroke with a width of 2. - Ridge4: Ridge stroke with a width of 4. - Solid1: Solid Pen Stroke with a width of 1. - Solid2: Solid Pen Stroke with a width of 2. - Solid3: Solid Pen Stroke with a width of 3. - StepBump1: Step Bump with a width of 1. - StepBump2: Step Bump with a width of 2. - StepHole2: Step Hole with a width of 2.
<pipe-connection>	<icon-config>	See Define Pipe Connection Location.

<components>	<icon-config>	This element encloses the image, label, and text components that define the icon. The different components are layered on top of each other, and the index value for each of these components determines the drawing order. The lowest number (1) will be drawn first. See Define Image Components, Define Text Components, and Define Selection Components.

Use <on-page> and <off-page> Elements

If you create an icon configuration file called mydevice-utility-iconbase-config.xml that defines the on-page reference for your icon in the Utility theme, you must define the <on-page> reference element in the appropriate theme configuration as in the following example.

Example: <on-page> and <off-page> Code

```
<theme-config >
   <icon-reg-id>mydevice-icon-config</icon-reg-id>
   <theme>Utility</theme>
   <on-page idref="mydevice-utility-iconbase-config"/>
   <off-page idref="mydevice-utility-oprbase-config"/>
   <enumerated-cellicon idref="component-cellicon-config"/>
</theme-config>
```

Example: Icon Configuration File

This example shows an icon configuration file using the XML elements described in the table in Design On-Page and Off-Page Reference Icons.

```
<?xml version="1.0" encoding="UTF-8"?>
<icon-config id="mydevice-utility-iconbase-config">
   <static-color idref="default-iconbase-color-config"/>
   <shape-rectangle >
    <x>0</x>
    <y>0</y>
    <width>139</width>
    <height>84</height>
   </shape-rectangle>
   <stroke>Invisible</stroke>
<!-- ============================================================
- Specify the location of where pipes will connect to the icon.-
 ============================================================ -->
   <pipe-connection>
    <x>73</x>
    <y>36</y>
   </pipe-connection>
   <components>
<!-- ============================================================
- Definition of the model's base image. The color of this
- image is determined by the condition of the model.-
 ============================================================ -->
    <image-component index="2">
        <x>0</x>
        <y>0</y>
        <width>139</width>
        <height>84</height>
        <image idref="oneclick-orgservice-iconbase-image-config"/>
```

```
    </image-component>
   </components>
</icon-config>
```

Define the Icon Shape

The base shape of the icon defines the area for the icon that the user clicks on to activate the model. The base shapes for a OneClick icon are the following:

- Rectangle
- Rounded Rectangle
- Ellipse
- Polygon
- Line

Define each of these shapes using the <icon-config> element.

Rectangle

Elements used to specify a rectangle in OneClick is defined in the following table.

Element	Parent Element	Description
<shape-rectangle>	<icon-config>	Defines a rectangle.
<x>	<shape-rectangle>	The upper left X coordinate of the rectangle.
<y>	<shape-rectangle>	The upper left Y coordinate of the rectangle.
<width>	<shape-rectangle>	The width of the rectangle.
<height>	<shape-rectangle>	The height of the rectangle.

Example: Rectangle Code

```
<shape-rectangle>
   <x>26</x>
   <y>24</y>
   <width>45</width>
   <height>14</height>
</shape-rectangle>
```

Rounded Rectangle

Elements used to specify a rounded rectangle in OneClick are defined in the following table.

Element	Parent Element	Description
<shape-roundrectangle>	<icon-config>	Defines a rounded rectangle.
<x>	<shape-roundrectangle>	The upper left X coordinate.
<y>	<shape-roundrectangle>	The upper left Y coordinate.
<width>	<shape-roundrectangle>	The width.
<height>	<shape-roundrectangle>	The height.
<arcwidth>	<shape-roundrectangle>	The width of the arc that defines the corners.
<archeight>	<shape-roundrectangle>	The height of the arc that defines the corners.

Example: Rounded Rectangle Code

```
<shape-roundrectangle>
   <x>0</x>
   <y>0</y>
   <width>89</width>
   <height>68</height>
   <arcwidth>12</arcwidth>
   <archeight>12</archeight>
</shape-roundrectangle>
```

Ellipse

Elements used to specify an ellipse in OneClick are defined in the following table.

Element	Parent Element	Description
<shape-ellipse>	<icon-config>	Creates an ellipse.
<x>	<shape-ellipse>	The upper left X coordinate of the ellipse.
<y>	<shape-ellipse>	The upper left Y coordinate of the ellipse.
<width>	<shape-ellipse>	The width of the ellipse.
<height>	<shape-ellipse>	The height of the ellipse.

Example: Ellipse Code

```
<shape-ellipse>
   <x>26</x>
   <y>24</y>
   <width>45</width>
   <height>14</height>
</shape-ellipse>
```

Polygon

Elements used to specify a polygon in OneClick are defined in the following table.

Element	Parent Element	Description
<shape-polygon>	<icon-config>	Defines a polygon.
<point>	<shape-polygon>	A point defining an edge of the polygon. The x attribute of this element defines the x coordinate position of the point. The y attribute of this element defines the y coordinate position of the point.

Example: Polygon Code

```
<shape-polygon>
   <point x="0" y="28" />
   <point x="10" y="10" />
   <point x="28" y="0" />
   <point x="116" y="0" />
   <point x="134" y="10" />
   <point x="144" y="28" />
   <point x="144" y="65" />
   <point x="134" y="80" />
```

```
    <point x="116" y="92" />
    <point x="28" y="92" />
    <point x="10" y="80" />
    <point x="0" y="65" />
</shape-polygon>
```

Line

Elements used to specify a line in OneClick are defined in the following table.

Element	Parent Element	Description
<shape-line>	<icon-config>	Defines a line.
<x1>	<shape-line>	X coordinate for the start of the line.
<y1>	<shape-line>	Y coordinate for the start of the line.
<x2>	<shape-line>	X coordinate for the end of the line.
<y2>	<shape-line>	Y coordinate for the end of the line.

Example: Line Code

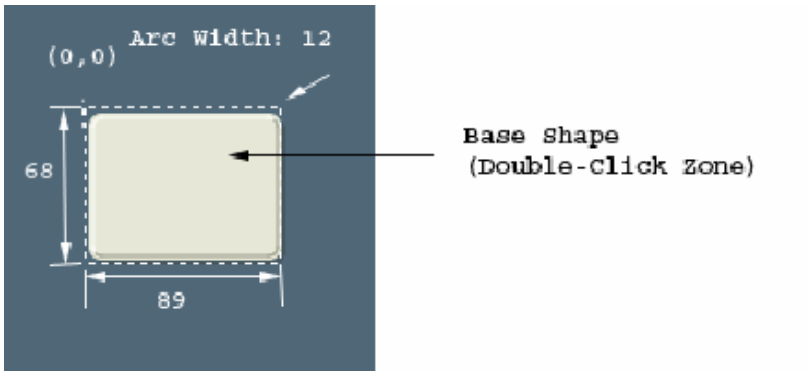
```
<shape-line>
   <x1>5</x1>
   <y1>5</y1>
   <x2>40</x2>
   <y2>40</y2>
</shape-line>
```

Create an Icon Shape

The icon shape defines the area of the icon the user can click in and select the device. The following example defines the rounded-rectangle icon shape shown in the image that follows the example.

Example: Icon Shape Code

```
<icon-config id="device-iconbase-config">
   <static-color idref="device-iconbase-color-config"/>
   <shape-roundrectangle >
    <x>0</x>
    <y>0</y>
    <width>89</width>
    <height>68</height>
    <arcwidth>12</arcwidth>
    <archeight>12</archeight>
   </shape-roundrectangle>
```



X and Y Coordinates

The x and y coordinates define the upper left-hand corner of the image. As the value of x increases, the upper left-hand corner of the image moves from the left to the right. As the value of y increases, the upper left-hand corner of the image moves from the top to the bottom. The image in the preceding section shows the upper left corner of the icon shape at 0,0, defined in Example: Icon Shape Code.

Define Pipe Connection Location

The pipe location defines where pipes get connected to the icon. Elements used to define pipe connection locations are listed in the following table.

Element	Parent Element	Description
<pipe-connection>	<icon-config>	Defines the pipe location on an icon.
<x>	<pipe-connection>	The x coordinate for the pipe location.
<y>	<pipe-connection>	The y coordinate for the pipe location.

Example: <pipe-connect> Code

```
<pipe-connection>
   <x>73</x>
   <y>36</y>
</pipe-connection>
```

Define Image Components

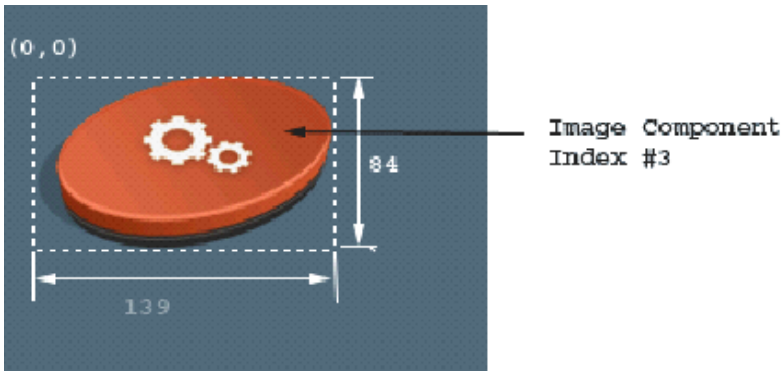
Image components enable you to add static or dynamic images to a model based on the model attributes. Image components are defined in the table after the following example.

Example: <image-component> Code

The following example defines an image component in an icon configuration file:

```
<image-component index="1">
   <x>0</x>
   <y>0</y>
   <width>139</width>
   <height>84</height>
   <image idref="oneclick-orgservice-iconbase-image-config"/>
</image-component>
```

The <image> element references the image definition file shown in Example: Image Definition File. This generates the image component shown in the following figure, showing the model in the CRITICAL (3) state.



The following table describes the elements used for defining image components.

Element	Parent Element	Description
<components>	<icon-config>	Defines all components for the icon.
<image-component>	<components>	Defines the image component. The index attribute of this element defines the order that the image is drawn relative to the other image, text, and selection components defined for this icon. Each index value must be unique, for example you cannot have two <*-component> elements with an index value of 1 in the same file. If you do, only the first <*-component> element is used. Index values must begin at 1.
<x>	<image-component>	The x coordinate of the upper left corner of image.
<y>	<image-component>	The y coordinate of the upper left corner of image.
<width>	<image-component>	The width of the image in pixels. There are no size restrictions on the image, however, it is recommended that you use a size relative to the other images used in OneClick.
<height>	<image-component>	The height of the image in pixels. There are no size restrictions on the image, however, it is recommended that you use a size relative to the other images used in OneClick.
<image>	<image-component>	The image to be rendered. The idref attribute references the XML file that builds the image. It is put in a separate file for organizational purposes only. Images should be in png file format and should be placed in the <*$SPECROOT*>/tomcat/webapps/spectrum/images directory.
<shape-*>	<image-component>	Shape component to be drawn with image.
<enumerated-color>	<image-component>	Colors used for the shape.
<static-color>	<image-component>	Color used for the shape.
<selection-component>	<image-component>	Indicates whether this is to be shown only when the user selects the image component.

Example: Image Definition File

The following XML code defines the image used for <image-component index =“2”> in Example: Icon Configuration File. The example uses the <select>, <case>, and <expression> elements to conditionally select an image based on the value of the condition attribute. The example uses the <yield> to define which image should be used when a condition is met. Note that the image is in PNG file format. Images used for customization purposes should be stored in the <

$SPECROOT>/tomcat/webapps/spectrum/images directory. Express the path to an image placed in this directory from the images directory, as images/myimage.png.

```
<?xml version="1.0" encoding="UTF-8"?>
<image id="oneclick-orgservice-iconbase-image-config">
   <select>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 0
            <!-- GREEN_CONDITION -->
        </expression>
        <yield>
            images/oneclick_org_service_green.png
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 1
        </expression>
        <yield>
            images/oneclick_org_service_yellow.png
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 2
        </expression>
        <yield>
            images/oneclick_org_service_orange.png
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 3
        </expression>
        <yield>
            images/oneclick_org_service_red.png
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 4
        </expression>
        <yield>
            images/oneclick_org_service_brown.png
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 5
        </expression>
        <yield>
            images/oneclick_org_service_grey.png
```

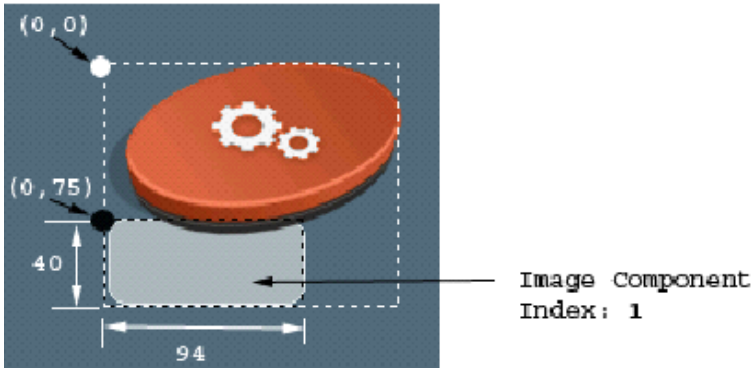
```
        </yield>
    </case>
    <case>
        <expression>
            attrInt(AttributeID.CONDITION) == 6
        </expression>
        <yield>
            images/oneclick_org_service_blue.png
        </yield>
    </case>
        <default>
            images/oneclick_org_service_blue.png
        </default>
       </select>
</image>
```

Example: Icon Configuration File

This icon configuration example generates the image that follows it. The example assumes that the condition of the model is CRITICAL (3).

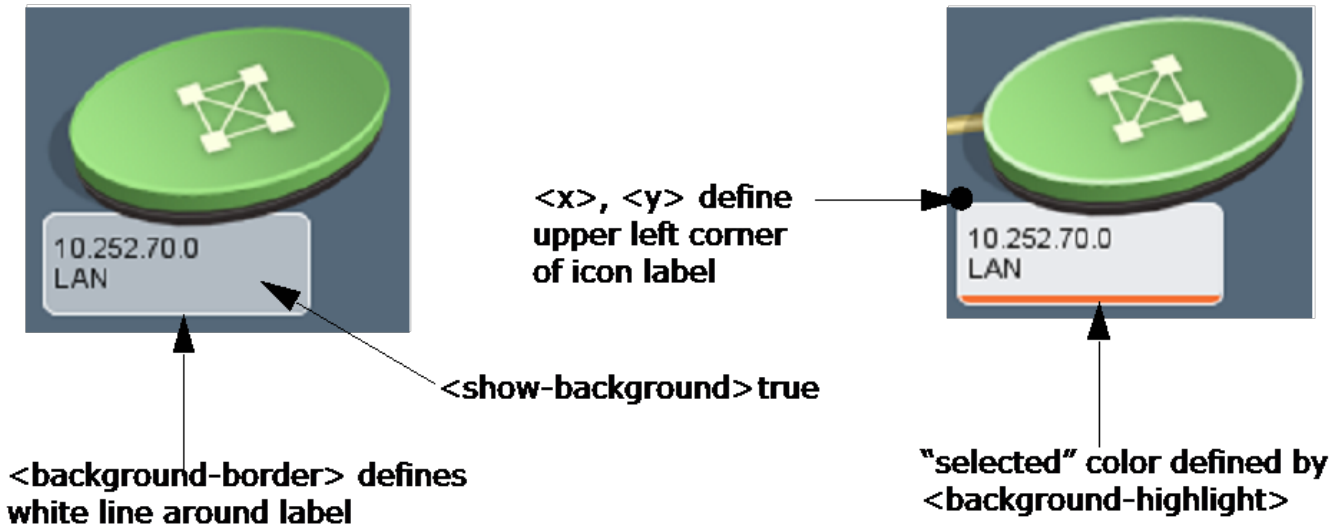
```
<?xml version="1.0" encoding="UTF-8"?>
<icon-config id="oneclick-orgservice-iconbase-config">
   <static-color idref="oneclick-default-iconbase-color-config"/>
   <shape-rectangle >
    <x>0</x>
    <y>0</y>
    <width>139</width>
    <height>84</height>
   </shape-rectangle>
   <stroke>Invisible</stroke>
<!-- ============================================================
Specify the location of where pipes will connect to the icon.
============================================================-->
   <pipe-connection>
    <x>73</x>
    <y>36</y>
   </pipe-connection>
   <components>
<!-- ============================================================
Definition of the model label.
============================================================ -->
    <label-component idref="default-iconlabel-config" index="1">
        <x>0</x>
        <y>77</y>
        <column-list>
            <field-column>
                <column idref="column-modelname-config"/>
                <column idref="column-devicetype-config"/>
            </field-column>
        </column-list>
    </label-component>
<!-- ============================================================
Definition of the model's base image. Image color is determined by model condition.
```

```
========================================================== -->
    <image-component index="2">
        <x>0</x>
        <y>0</y>
        <width>139</width>
        <height>84</height>
        <image idref="oneclick-orgservice-iconbase-image-config"/>
    </image-component>
   </components>
</icon-config>
```



Create an Icon Label

OneClick model or device type icons have labels to identify them to OneClick operators. Use the <label-component> elements listed in the table in the default-iconlabel-config.xml file to add labels to the icons you create. The following figure shows how some of the elements can be used in defining an icon label.



The default-iconlabel-config.xml File

The file *<$SPECROOT>*/SPECTRUM/tomcat/webapp/spectrum/WEB-INF/topo/config/default-iconlabel-config.xml contains examples and more information on using the <label-component> element and its attributes to create icon labels.

Example: <label-component> Code

```
<!-- ================================================================
Definition of the model label.
=================================================================-->
<label-component idref="default-iconlabel-config" index="1">
   <x>0</x>
   <y>67</y>
   <column-list>
    <field-column>
        <column idref="column-modelname-config"/>
        <column idref="column-devicetype-config"/>
    </field-column>
   </column-list>
</label-component>
```

This example defines the model label by extending the functionality of the default-iconlabel-config.xml file. This example creates a label that displays two fields of text defined in the two column statements. The column statements create two rows in the label for the content defined by the column configuration files they reference. This label displays the model name and device type in the icon label. The code does not specify a minimum or maximum column width for the label (see the following table), so it has a fixed width of 95 pixels, the default condition.

Element	Parent Element	Description
<components>	<icon-config>	Defines all components for the icon.
<label-component>	<component>	Defines a label component. The index attribute defines the order that the label is drawn in with respect to other image, text, and label components defined for the same icon. Each index value must be unique. If you have two <*-components> with the same index value - only the second one is drawn. Index values begin at 1.
<x>	<label-component>	Defines the x coordinate of the upper left corner of the label relative to the icon image component.
<y>	<label-component>	Defines the y coordinate of the upper left corner of the label relative to the icon image component.
<column-list>	<label-component>	Constructs a list of columns used to create the labels. Only one column is supported.
<field-column>	<column-list>	Constructs a column of information
<column>	<field-column>	Defines the data for the <field-column>. The idref attribute allows you to associate another XML file with the <column> that defines the data for the column. The data for the <column> does not have to reside in another file.
<max-background-width>	<label-component>	Defines the maximum width of the label background. The label background expands and contracts in width based on the longest column value.
<min-background-width>	<label-component>	Defines the minimum width of the label background.
<default-transparency>	<label-component>	Defines transparency value for label background when the icon is not selected. 0 - 255; 0=completely transparent, 255=completely opaque.
<selected-transparency>	<label-component>	Defines transparency value for label background when the icon is selected. 0 - 255; 0=completely transparent, 255=completely opaque.

<show-background>	<label-component>	Indicate whether or not to show the label's background.
<enumerated-color>	<label-component>	Defines the label background color. <enumerated-color> uses expressions and enumerations to determine the color.
<static-color>	<label-component>	Defines the label background color. <static-color> uses a specific color.
<vertical-spacing>	<label-component>	Specifies the spacing between rows of text in pixels.
<border-spacing>	<label-component>	Defines the border height above the first column and below the last column in pixels.
<background-border>	<label-component>	True or False. If true, a one-pixel wide line is used to outline the label border.
<enumerated-color>	<background-border>	Defines the color of <background-border>. For details, see <enumerated-color> in this table.
<static-color>	<background-border>	Defines the color of <background-border>.
<background-highlight>	<label-component>	Defines the line that displays at the bottom of the label when the icon is selected.
<enumerated-color>	<background-highlight>	Defines label background color when the icon is selected. For details, see <enumerated-color> in this table.
<static-color>	<background-highlight>	Defines the color of <background-highlight>, the label background that displays when the icon is selected.
<field-value>	<label-component>	Defines the values displayed in the icon label.
<enumerated-color>	<field-value>	Defines the color of text of the icon label.
<static-color>	<field-value>	Defines the color of text of the icon label.
<font>	<field-value>	Defines the font used for the icon label text.

Adjust Icon Label Background Width

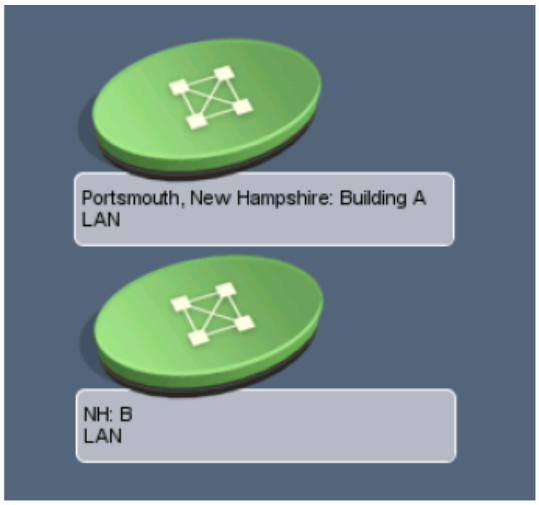
The icon label background widens and narrows according to the length of the longest text entry in the label, up to the maximum width specified in <max-background-width>, and down to the minimum width specified in <min-background-width>. If the label background is not wide enough to accommodate the length of the label text, increase the <max-background-width> value.

Default Label Width Settings

When you create an icon label using label-component, the default label size is fixed at 95 pixels. Both <max-background-width> and <min-background-width> have a default value of 95. This creates a label background with a fixed width of 95. If you do not specify either of these elements, they assume the default value.

Create Fixed Width Icon Labels

To create an icon label that has a fixed width, set <max-background-width> and <min-background-width> to the same value that provides enough line space for the icon label text. The following image shows an icon label with a fixed width of 200.

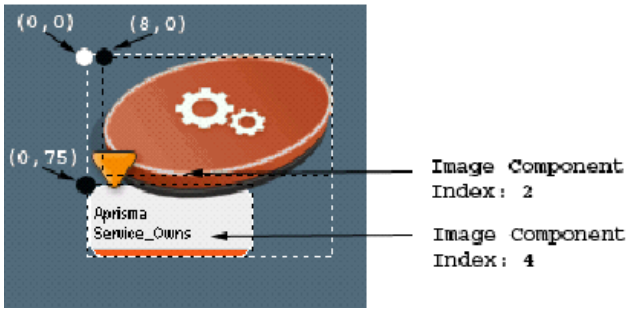


Define Text Components

Refer to versions of this manual for release 8.0 or earlier on the DX NetOps Spectrum support and documentation web site.

Define Selection Components

In order to make the icon standout when selected, you may want to specify images that will appear only during selection. You do this via the <selection-component> element. In the example below there are two components added that are defined as Selection Components (image component #2 and #4). If the user selected the component, these image components would become visible. Otherwise, they remain invisible. The following figure shows the two selection components:



```
<?xml version="1.0" encoding="UTF-8"?>
<icon-config id="oneclick-orgservice-iconbase-config">
<static-color idref="oneclick-default-iconbase-color-config"/>
<shape-rectangle >
   <x>0</x>
   <y>0</y>
   <width>139</width>
   <height>84</height>
</shape-rectangle>
<stroke>Invisible</stroke>
<!-- ============================================================
Specify the location of where pipes will connect to the icon. -
 ============================================================ -->
```

```
<pipe-connection>
   <x>73</x>
   <y>36</y>
</pipe-connection>
<components>
<!-- ============================================================

============================================================= -->
   <image-component index="1">
    <x>0</x>
    <y>75</y>
    <width>94</width>
    <height>40</height>
    <image>
        <select>
            <default>
                com/aprisma/spectrum/app/topo/images/
                icon_text_background.png
            </default>
        </select>
    </image>
   </image-component>
   <image-component index="2">
    <x>0</x>
    <y>75</y>
    <width>94</width>
    <height>40</height>
    <selection-component>true</selection-component>
    <image>
        <select>
            <default>
                com/aprisma/spectrum/app/topo/images
                icon_selected_text_background.png
            </default>
        </select>
    </image>
   </image-component>
<!-- ============================================================
Definition of the model's base image. The color of this image is
determined by the condition of the model.
============================================================= -->
   <image-component index="3">
    <x>0</x>
    <y>0</y>
    <width>139</width>
    <height>84</height>
    <image idref="oneclick-orgservice-iconbase-image-config"/>
   </image-component>
<!-- ============================================================

        <y>54</y>
        <width>19</width>
        <height>19</height>
        <image idref="oneclick-rollup-triangle-image-config"/>
       </image-component>
</components>
```

```
</icon-config>
```

Define Model Icon Tooltips

You can configure the content of a tooltip that displays when a OneClick user moves the cursor over the model icon. In the contents registry of the custom-app-config.xml file, the <tooltip-config> element specifies the file that defines the tooltip. The custom tooltip file, mydevice-tooltip-config.xml must be placed into the *$SPECROOT*/custom/topo/config folder.

A tooltip configuration for models of model class 2, 5, 11, and 12 is registered to use the tooltip that is defined within the mydevice-tooltip-config.xml file. Verify the following example:

```
<contents-registry>
   <reg-id>device-icon-config</reg-id>
   <tooltip-config>mydevice-tooltip-config</tooltip-config>
   <model-class>2</model-class>
   <model-class>5</model-class>
   <model-class>11</model-class>
   <model-class>12</model-class>
</contents-registry>
```

The following example shows the contents of a tooltip file. Each element is explained in the table with examples.

```
<?xml version="1.0" encoding="UTF-8"?>
<tooltip-config id="mydevice-tooltip-config"
xmlns ="http://www.aprisma.com"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.aprisma.com../../common/schema/column-config.xsd">
<format><![CDATA[
<html><table>
   <tr>
    <td><b>{0}</b></td>
    <td>{1}</td>
   </tr>
   <tr>
    <td><b>{2}</b></td>
    <td>{3}</td>
   </tr>
   <tr>
    <td><b>{4}</b></td>
    <td>{5}</td>
   </tr>
</table></html>
</format>
<param>
   <localize>com.aprisma.spectrum.app.util.render.ModelNameColumn</localize>
</param>
<param>
   <attribute>AttributeID.MODEL_NAME</attribute>
   <renderer>com.aprisma.spectrum.app.util.render.NullRenderer
   </renderer>
</param>
<param>
   <localize>
   com.aprisma.spectrum.app.util.render.NetworkAddressColumn
   </localize>
```

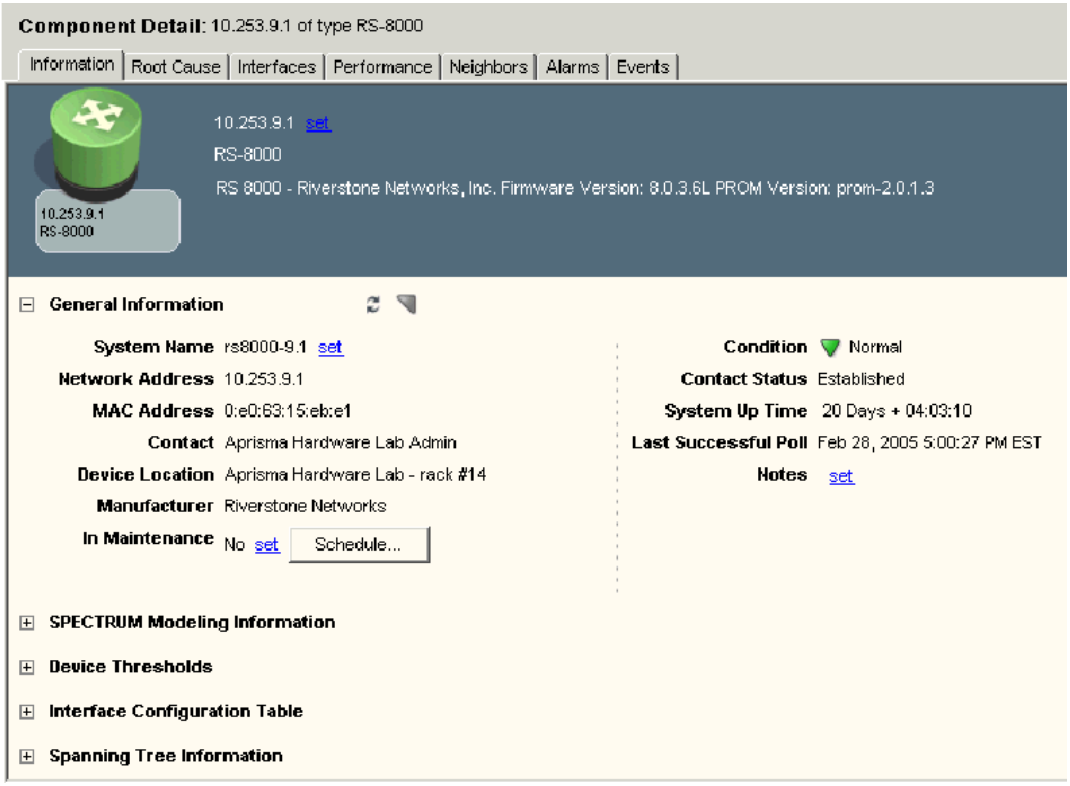
```
</param>
<param>
   <attribute>AttributeID.NETWORK_ADDRESS</attribute>
   <renderer>com.aprisma.spectrum.app.util.render.NullRenderer
   </renderer>
</param>
<param>
   <localize>
   com.aprisma.spectrum.app.util.render.MACAddressColumn
   </localize>
</param>
<param>
   <attribute>AttributeID.MAC_ADDRESS</attribute>
   <renderer>com.aprisma.spectrum.app.util.render.NullRenderer
   </renderer>
</param>
</device-tooltip-config>
```

NOTE
The numbers that are used in the curly brackets reference the parameters that are defined by the following <param> elements. {0} references the first parameter, {1} references the second parameter and so on.

Element	Parent Element	Description
<tooltip-config>	Not applicable	The root element for the file that defines the tooltip. The id attribute for this element must be set equal to the value used for the <tooltip-config> element in the <content-registry> found in the custom-app-config.xml file.
DO NOT USE	<tooltip-config>	Use this to define how the data will be displayed in the tooltip. In the above example, an HTML table is used. The number in the curly brackets, e.g. {3}, references the corresponding parameter, for example, the third parameter defined in the file.
<param>	<tooltip-config>	Use this to define the value to be displayed.
<localize>	<param>	Converts the string specified in the parameter to a localized value. Use this if you are using a parameter value obtained from a OneClick XML file that shipped with DX NetOps Spectrum and begins with “com.aprisma.spectrum”.
<renderer>	<param>	See Customize the Port Name Column of the Interface Table.
<attribute>	<param>	Use this to identify the attribute you want to be displayed.
<message>	<param>	Use this for specifying a plain text value for a parameter.

Customizing a Model's Information View

Each model displayed in OneClick has an Information view as shown in the following figure. You access this view using the Information tab in the Component Detail panel.



Information views are constructed from separate XML files called Information Configuration files. The primary file is the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config/topo-app-config.xml file. In this file, for each model type, the <contents-registry> element specifies the <information-config> elements that link an Information Configuration file to the model type.

The <contents-registry> in the following example is found in topo-app-config.xml. It links the 0x2100c (Rtr_Cisco) model type with view-devicedetails-config.xml, which specifies the format for the Information view.

```
<contents-registry>
   <reg-id>router-icon-config</reg-id>
   <tooltip-config>device-tooltip-config</tooltip-config>
   <information-config>view-devicedetails-config</information-config>
   <performance-config>performance-data-rtrcisco-config</performance-config>
   <!-- All Model Types derived from Rtr_Cisco (0x21000c) -->
   <model-type>0x21000c</model-type>
   <!-- Rtr_Cisco -->
</contents-registry
```

NOTE
Several model classes and model types may be specified within the contents or component details registries. Information views can be reused in one or more <contents-registry> elements.

This section describes how to add and edit information displayed in the Information view for a particular model type or model class.

Extend or Modify an Information View

You can modify or create an Information view to display information available in a device MIB that DX NetOps Spectrum and OneClick do not support by default. You can decide whether to add this parameter to one of the existing subviews in the Information view for that device type, or to create a new subview.

When you create or modify an Information view, you must create a new Information Configuration file in the <*$SPECROOT*>/custom/console/config/ directory. This file must have the same name as the factory default Information Configuration file that you need to modify. You then associate the Information Configuration file with the appropriate model type using the <*$SPECROOT*>/custom/console/config/custom-app.config.xml file.

> **NOTE**
> You must create the file <*$SPECROOT*>/custom/console/config/custom-app-config.xml and add your customization code to it. See OneClick Customization .

Follow these steps:

1. If you are modifying or extending an existing Information view for an existing model type or model class, identify the current Information view configuration file that is used to create the Information view.
   a. Open the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config/topo-app-config.xml file and find the <contents-registry> element for the appropriate model type or model class. (For an example, see the XML code example at the start of this chapter.)

      > **NOTE**
      > OneClick uses the hierarchy that model_type definitions override the same definition found in a model_class.

   b. Find the <information-config> element within the <contents-registry> element, and note the name of the Information Configuration file that is described by this element. All of the existing Information Configuration files are located in the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config directory.
2. To extend an existing information configuration, take the following steps:
   a. Create a new file in the <*$SPECROOT*>/custom/topo/config directory with the same name as the Information Configuration file determined in the next step. Use idref to extend the existing factory file with the contents of this new file.
   b. Open the file using a text editor and use the XML syntax outlined in Create an Information Configuration File to build the file.
   c. Continue to step 4.
3. To modify an existing information configuration:
   a. Copy the Information configuration file identified in step 1 from <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config directory into the <*$SPECROOT*>/custom/topo/config directory.
   b. Open the file using a text editor and use the XML syntax outlined in Create an Information Configuration File to modify the file.
   c. Continue to step 4.
4. Save and close the file.
5. Associate the new Information Configuration file with the appropriate model types or model classes. Follow the instructions in Associate an Information Configuration File with a Model Class or Model Type.

Create an Information Configuration File

The XML that defines the Information Configuration is split up into two major sections: the header definition and the subview definition. Each define that portion of the model's information tab as shown in the following figure.

The XML elements used to build the header and subview in the Information view are listed in the following table.

Element	Parent Element	Description
[set the view variable for your book]	Not applicable	This is the root element for the Information Configuration file. The ID attribute for this element defines the value that should be used for the <information-config> element in the custom-app-config.xml file.
<view-header>	[set the view variable for your book]	Defines the header portion of the view.
<subviews>	[set the view variable for your book]	Defines the available subviews.

Define the Header

The Information tab header is identified by the <view-header> element. The header specifies the model's graphical depiction and textual information as shown in the image in Create an Information Configuration File.

Example: Code for Information Tab Header

```
<view-header>
   <show-icon>true</show-icon>
   <show-labels>false</show-labels>
   <field-column>
    <column idref="column-modelname-config"/>
    <column idref="column-modeltype-config"/>
   </field-column>
```

```
</view-header>
```

Element	Parent Element	Description
<view-header>	[set the view variable for your book]	Defines the header portion of the view.
<show-icon>	<view-header>	Indicates whether or not to show the icon. Values: true or false.
<show-labels>	<view-header>	Indicates whether or not to show field labels Values: true or false
<field-column>	<view-header>	Constructs a column of information.
<column>	<field-column>	Defines the data for the field column. The idref attribute enables you to associate another XML file, which will define the data for the column. The data for the column does not have to be in another file, it is done for organizational purposes only.

Define the Subview

The subview section defines one or more subviews that display in the Information tab as shown in the image in Create an Information Configuration File. You can define one or more subviews using the <subviews> element and the child elements shown in the following table. As shown in the Example: Subview Definition, all subview definitions are enclosed within one <subviews> element.

Element	Parent Element	Description
<subviews>	[set the view variable for your book]	Encloses all of the elements which define each type of subview.
<field-subview>	<subviews>	Defines a field subview.
<table-subview>	<subviews>	Defines a table subview.
<application-subview>	<subviews>	Defines an application subview.
<related-model-subview>	<subviews>	Defines a related model subview.
<related-model-table-subview>	<subviews>	Defines a related model table subview.
<subview-group>	<subviews>	Groups subviews together under one subview.

Example: Subview Definition

```
<subviews>
   <field-subview>
   .
   .
   .
   </field-subview>
   <application-subview>
   .
   .
   .
   </application-subview>
   <table-subview>
   .
   .
   .
   </table-subview>
```

```
</subviews>
```

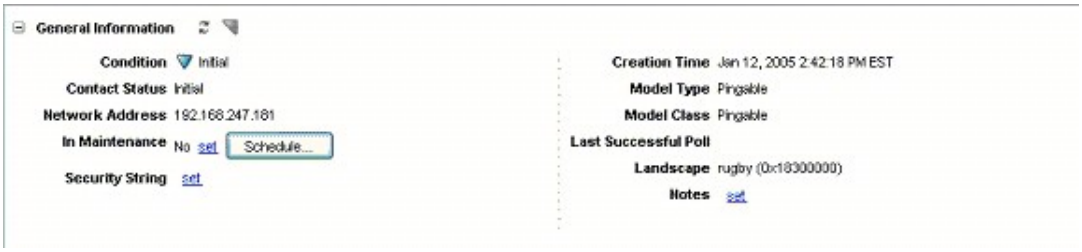
Add a Field Subview

Field subviews are used to display a list of non-list attributes available on the selected device model. The following is an example of XML syntax used to create a field subview.

Example: Field Subview

```
<field-subview>
   <title>General Information</title>
   <privilege>
    <name>GeneralInfo</name>
   </privilege>
   <field-column>
    <column idref="column-condition-config"/>
    <column idref="column-contactstatus-config"/>
    <column idref="column-networkaddress-config"/>
    <column idref="column-ismanaged-config">
        <editable/>
    </column>
    <column idref="column-securitystring-config">
        <editable verifier=
    "com.aprisma.spectrum.app.swing.widget.SecStringInputVerifier"/>
    </column>
   </field-column>
   <field-column>
    <column idref="column-modelcreationdate-config"/>
    <column idref="column-modeltypename-config"/>
    <column idref="column-modelclass-config"/>
    <column idref="column-lastsuccessfulpoll-config"/>
    <column idref="column-landscape-config"/>
    <column idref="column-modelnotes-config">
        <editable/>
    </column>
   </field-column>
</field-subview>
```

This code generates a subview similar to the one shown in the following figure.



You can use the elements shown in the following table to create a field subview.

Element	Parent Element	Description
<field-subview>	<subviews>	Defines a field subview. If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<field-subview>	The title of the subview. In our example above, the title is “General Information”.
<display-if>	<field-subview>	Enables the author to specify whether the subview should be displayed via an expression.
<display-if-app-installed>	<field-subview>	Enables the author to specify that the defined view only be added if the specified application is installed.
<privilege>	<field-subview>	Associates a privilege to the subview. If the user is not given this privilege, the subview will not be displayed for that user.
<show-labels>	<field-subview>	Indicates whether or not to show field labels. Values: true or false.
<field-column>	<field-subview>	Constructs a column of information.
<column>	<field-column>	Defines the data for the field column. The idref attribute enables you to associate another XML file, which will define the data for the column. The data for the column does not have to be in another file, it is done for organizational purposes only.
<editable>	<column>	Specifies if the column is editable.

Add Field Subviews Using IDREF

The example in this section shows how to extend the factory default view-devicedetails-config.xml file with a customized field subview using the IDREF attribute. The code shown is in the file *<$SPECROOT>*/custom/topo/config/view-devicedetails-config.xml, the same name as the file it extends, but in the /custom directory.

Example: Field Subview using IDREF

```
<view idref="view-devicedetails-config">
<subviews>
   <field-subview >
    <title>My Subview</title>
    <field-column>
        <column idref="column-networkaddress-config">
        <editable/>
        </column>
    </field-column>
   </field-subview>
</subviews>
</view>
```

This example creates a field subview titled My Subview that displays information defined by the file column-networkaddress-config.xml.

The line <view idref="view-devicedetails-config"> adds the field subview “My Subview” to the factory default view-devicedetails-config.xml file.

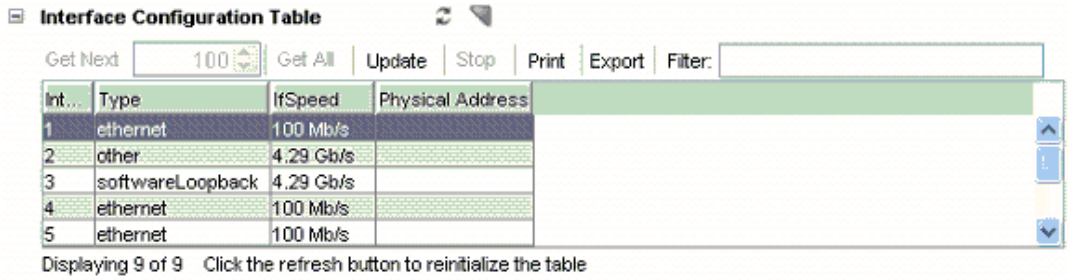
Add a Table Subview

A table subview enables you to display a group of list attributes available from the selected model. These list attributes are displayed in table format. The following is an example of XML syntax used to create a table subview.

Example: Table Subview

```
<table-subview>
   <title>Interface Configuration Table</title>
   <privilege>
    <name>InterfaceConfigurationTable</name>
   </privilege>
   <swing-header-row-template>
    <static-color idref="row-header-color-config"/>
   </swing-header-row-template>
   <swing-row-template>
   </swing-row-template>
   <column-list>
    <column>
        <name>Interface</name>
        <content><attribute>0x100c4</attribute>
        </content>
            <default-width>30</default-width>
    </column>
    <column>
        <name>Type</name>
        <content>
            <attribute>0x100c6</attribute>
            <renderer>
            <param name="attrID">0x100c6</param>
            com.aprisma.spectrum.app.util.render.EnumeratedAttrRenderer
            </renderer>
        </content>
        <default-width>100</default-width>
    </column>
    <column>
        <name>IF Speed</name>
        <content>
            <attribute>0x100c8</attribute> <!-- IfSpeed -->
            <renderer>com.aprisma.spectrum.app.topo.client.
            interfaces.render.IfSpeedRenderer
            </renderer>
        </content>
        <default-width>60</default-width>
    </column>
    <column>
        <name>Physical Address</name>
        <content>
            <attribute>0x100c9</attribute>
        </content>
        <default-width>90</default-width>
    </column>
   </column-list>
</table-subview>
```

The code in this example generates a subview similar to the one shown in the following image.



You can use the elements shown in the following table to create a table subview.

Element	Parent Element	Description
<table-subview>	<subviews>	Adds a table subview. If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<table-subview>	The title for the table.
<privilege>	<table-subview>	Associates a privilege to the subview. If the user is not given this privilege, the subview will not be displayed for that user.

NOTE
All of the elements that can be used to modify a table can be used to create the table for the table subview.

Add an Application Subview

An application subview enables you to display attributes affiliated with an application model type related to the selected model type by specified criteria. The example below uses DX NetOps Spectrum's PossPrimApp (0x230000) relation.

Example: Application Subview

```
<application-subview>
   <title>SNMP2 IP Routing Table</title>
   <model-type>0x230010</model-type>
   <subviews>
       <table-subview idref="table-ip2-ip-routingtable-config"/>
   </subviews>
</application-subview>
```

The attribute used within the <model-type> element defines the model type to which the subview pertains. In the example above, the value 0x230010 is used. This attribute value corresponds to the SNMP2_Agent Application model type. This

means that this particular table definition applies only to the SNMP2_Agent application. If the current device does not implement this application, this table will not be visible.

Element	Parent Element	Description
<application-subview>	<subviews>	Creates an application subview. If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<application-subview>	The title of the subview.
<model-type>	<application-subview>	The model type to which the subviews will pertain.
<subviews>	<application-subview>	Enables you to add a prebuilt table-subview or field- subview to the detail components that reside within the application subview. Values: table-subview and/or field-subview.
<criteria>	<application-subview>	The search criteria used to find the related models.
<privilege>	<application-subview>	Associates a privilege to the subview. If the user is not given this privilege, the subview will not be displayed for that user.

Add a Related Model Subview

A related model subview enables the user to display the attributes of models related to the current, selected model via a search criteria, for example, models that are related by a specific association. The user can then display attributes of the found models in field or table format. Add a Related Models Table Subview shows how you can display the attributes in table format.

You can use the elements in the following table to create related model subview.

Element	Parent Element	Description
<related-model-subview>	<subviews>	If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<related-model-subview>	The title of the subview.
<model-type>	<related-model-subview>	The model type to which the subviews will pertain.
<subviews>	<related-model-subview>	Enables you to add a prebuilt table-subview or field- subview to the detail components that reside within the subview. Values: table-subview and/or field-subview.
<criteria>	<related-model-subview>	The search criteria used to find the related models.
<privilege>	<related-model-subview>	Associates a privilege to the subview. If the user is not given this privilege, the subview will not be displayed for that user.

Add a Related Models Table Subview

You can use the <related-models-table-subview> to display a table of models that are associated with the current selected model based on specified search criteria.

You can use the elements in the following table to create a related model table subview.

Element	Parent Element	Description
<related-model-table-subview>	<subviews>	If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<related-model-table-subview>	The title of the subview.
<privilege>	<related-model-table-subview>	Associates a privilege to the subview. If the user is not given this privilege, the subview will not be displayed for that user.
<table>	<related-model-table-subview>	This elements and its sub-elements define the table. See the table in Modify a Table Column for a list of sub-elements.
<criteria>	<related-model-table-subview>	The search criteria used to find the related models.

In the example that follows, the <subviews> element is used to place a view within a view allowing multiple views to be nested within each other. Each column in the table represents the value of an attribute for each of the models that have passed the search criteria.

Example: Related-Model-Table Subview (demo-details-config.xml)

```
<subviews>
   <related-models-table-subview>
    <title>Demo Table Title</title>
    <criteria>demo-search-criteria</criteria>
    <table>demo-table-config</table>
   </related-models-table-subview>
</subviews>
```

Example: Referenced Criteria XML (demo-search-criteria.xml)

```
<search-criteria id="demo-search-criteria"
   xmlns="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com
   ../../common/schema/search-criteria-config.xsd">
   <child-models>
    <relation>Collects</relation>
   </child-models>
</search-criteria>
```

Example: Referenced Table XML (demo-table-config.xml)

```
<?xml version="1.0" encoding="utf-8"?>
<table id="demo-table-config"
   xmlns="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com
      ../../common/schema/table-config.xsd">
   <swing-header-row-template>
    <static-color idref="row-header-color-config"/>
   </swing-header-row-template>
```

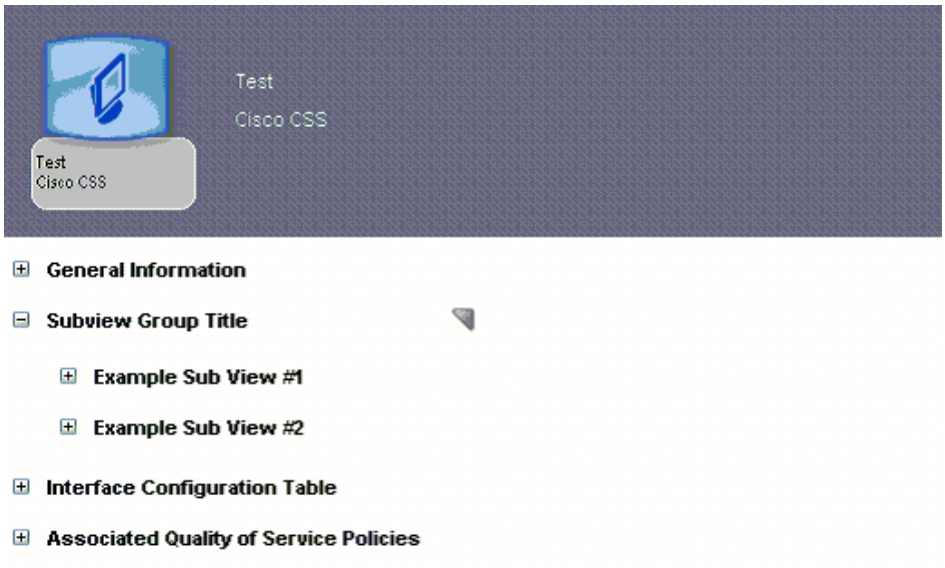
```
    <swing-row-template>
     <enumerated-color idref="alternatingrow-color-config"/>
    </swing-row-template>
    <column-list>
     <column>
         <name>Model Name</name>
         <content>
             <attribute>AttributeID.MODEL_NAME</attribute>
         </content>
     </column>
     <column>
         <name>Condition</name>
         <content>
             <attribute>AttributeID.CONDITION</attribute>
         </content>
     </column>
    </column-list>
 </table>
```

Define a Subview Group

You can group together one or more subviews under a single collapsible group using the <subview-group> element.

```
 <subview-group>
    <title>Subview Group Title</title>
    <display-if>
     <expression>
         attrInt(AttributeID.MTYPE_HANDLE) == 0x3cc0002
     </expression>
    </display-if>
    <subviews>
     <table-subview idref="example-table1-config">
         <title>Example Sub View #1</title>
     </table-subview>
     <table-subview idref="example-table2-config">
         <title>Example Sub View #2</title>
     </table-subview>
    </subviews>
 </subview-group>
```

This example generates a subview group similar to the one shown in the following figure.



Use the elements shown in the following table to create a subview group.

Element	Parent Element	Description
<subview-group>	<subviews>	If you set the expanded attribute of this element to true, the subview will be expanded by default. The idref attribute enables you to associate an XML file that defines the data for this subview. The data for the subview does not have to be in another file, it is done for organizational purposes only.
<title>	<subview-group>	The title of the subview group. In the example above, this is Subview Group Title.
<privilege>	<subview-group>	Associates a privilege to the subview group. If the user is not given this privilege, the subview group will not be displayed for that user.
<display-if>	<subview-group>	Adds an expression that will determine whether or not the group will be visible.
<subviews>	<subview-group>	Adds any type of subview (besides group) to this subview group.

Associate an Information Configuration File with a Model Class or Model Type

Once you have created the Information view with an Information Configuration file, you must follow the instructions below to associate the Information Configuration file with the model type or model class.

To associate an Information Configuration File with a Model

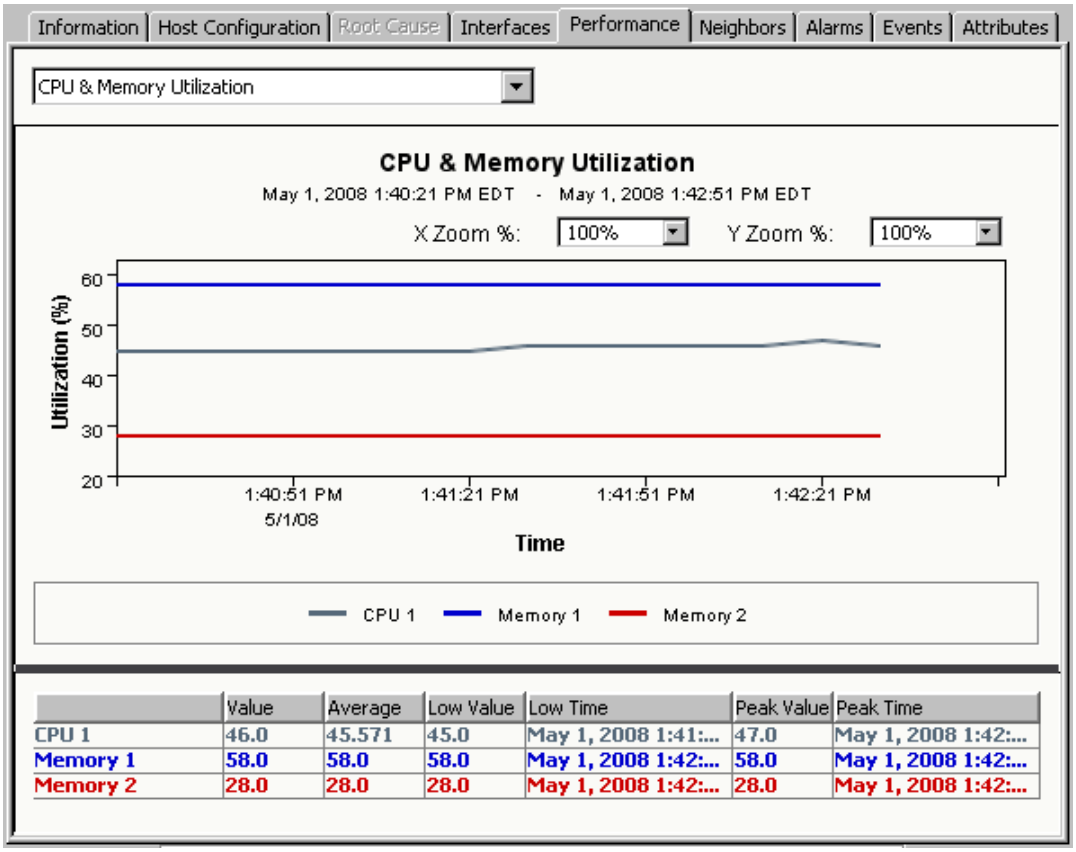
1. If it does not already exist there, copy the *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config/custom-app-config.xml to the *<$SPECROOT>*/custom/console/config directory.
2. Open this file with a text editor.
3. Add the following block of XML code to link the appropriate model type(s) or model class(es) to the Information Configuration file. Use the XML elements shown to define the information appropriate to your model type or model class.

```
<contents-registry>
    <icon-reg-id>your-icon-registration</icon-reg-id>
    <tooltip-config>your-tooltip-config</tooltip-config>
    <information-config>your-information-config-file</information-config>
    <model-class>your-model-class</model-class>
</contents-registry>
```

4. Save and close the custom-app-config.xml file.
5. Restart the OneClick client for your changes to take effect.

Creating a Models Performance View

By default, some model types are configured to have a Performance view that shows changes in attributes, such as CPU utilization or memory, over time. In OneClick, you access this device view by clicking the Performance tab in the Component Detail panel.



A Performance view is composed of two XML files:

- **A performance data configuration file**
  This XML file specifies the data that can be displayed in any of the graphs within the Performance tab. Typically, this data includes attributes of the associated model type.
- **A performance view configuration file**
  This XML file defines the appearance of each graph available within the Performance tab. Each graph can display any of the lines defined within the performance data configuration file.

If the data or the format of one of the default Performance views does not meet your requirements, you can customize it for a particular model type or model class. For example, if you have added support in DX NetOps Spectrum for additional MIBs that are supported by a device, you might want to customize the view to graph some of the data that is available in the MIB. You can also create your own custom Performance views.

If a Performance view is not configured for the model currently selected in OneClick, the Performance tab is disabled.

Create a New Performance View

When you create a Performance view for a model type or model class from scratch, you should place the configuration files that define the view in the <*$SPECROOT*>/custom/topo/config directory. This helps to ensure they are not overwritten during an upgrade of DX NetOps Spectrum.

You associate the view's performance data configuration file with each applicable model type or model class in a file named custom-app-config.xml. While you can use either the <contents-registry> element or the <component-details-registry> element to do this, a best practice is to use the <component-details-registry> element because it configures only the Component Detail panel for the given model type or model class. For a description of the different registries available, see Chapter 5: Add Support for Model Types or Model Classes.

To create a new Performance view

1. In the <*$SPECROOT*>/custom/topo/config directory, create the performance data configuration file that specifies the data to be graphed in the view.
2. In the <*$SPECROOT*>/custom/topo/config directory, create a performance view configuration file that defines the appearance of each graph in the view.
3. In custom-app-config.xml, associate the performance data configuration file with the appropriate model types or model classes:
   a. If it does not already exist there, copy <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/custom-app-config.xml to the <*$SPECROOT*>/custom/console/config directory.

      NOTE
      Ensure to copy the file to the specified location. Do not modify the default custom-app-config.xml file that is provided with DX NetOps Spectrum because it is overwritten when you upgrade to a newer version.

   b. In custom-app-config.xml, add a block of XML code similar to the following example using a text editor. This code links the appropriate model types and model classes to the performance configuration data file.
      The following XML code example associates a model type whose ID is 0x3250004 to a performance data configuration file named <*$SPECROOT*>/custom/topo/config/performance-data-ciscovoiceapp-config.xml.

```
<component-details-registry>
  <performance-config>performance-data-ciscovoiceapp-config</performance-config>
  <model-type>0x3250004</model-type>
  <!-- CiscoVoiceApp -->
</component-details-registry>
```

      NOTE
      You can specify several model classes and model types within the contents or component details registries. You can also reuse Performance views in one or more <contents-registry> elements.

   c. Save and close the custom-app-config.xml file.
4. Restart the OneClick client for your changes to take effect.

Create a Performance Data Configuration File

The *performance data configuration file* specifies the data that can be displayed in any of the graphs within the Performance tab. A recommended naming convention for this XML file is performance-<descriptor>-data-config.xml.

Use the XML elements described in the following table to create a performance data configuration file.

Element	Parent Element	Description
performance-config	Not applicable	Represents the top-level parent element. You specify multiple graphs for a Performance view using multiple instances of the <graph> element in the performance view configuration file.

display	performance-config	Specifies the XML file that defines the view for presenting the graph data. This name must exactly match the simple file name of the actual performance view configuration file.
line	performance-config	Defines a line in the graph.
name	line	Specifies the label (name) for the line defined by the <line> parent element as it will be seen in the graph. The value for name needs to match its corresponding line definition in the performance graph view configuration file. If you are graphing a list attribute, you can also specify an attr-id attribute for the name element. This specifies an attribute ID whose value is appended to the name of each instance in the list. If not specified, the instance number is appended to the name of each list instance. In the following example, attribute 0x12ac6 represents the list of labels for the multiple lines defined by <list-content>. <line> <name attr-id="0x12ac6"> Memory Utilization </name> <list-content> <attribute>0x12ac6</attribute> </list-content> </line>
content	line	Specifies scalar data to the graph as a single line defined by the <line> parent element, for example: <content> <attribute>0x2100cc</attribute> </content>
list-content	line	Specifies list data to the graph as multiple lines defined by the <line> parent element. In the following example, the attribute 0x12ac6 is an integer list attribute that represents memory utilization. There will be a separate line graphed for each instance in the list. <line> <name attr-id="0x12ac6"> Memory Utilization </name> <list-content> <attribute>0x12ac6</attribute> </list-content> </line>
attribute	content, list-content	Specifies the ID of the attribute to graph as the line defined by the <line> parent element.
expression	content, list-content	Used to define an expression to produce a value for the column, for example: (attrInt(0xd054c) + attrInt(0xd054d))/8
applications	line	You can also graph data from related application models. Within the <applications> element, use the <model-type> element to specify the model type handle of the related application model. If the model in context has an application model related to it of this type, the data is retrieved from that application model. <applications> <model-type>0xc40043</model-type> </applications>
model-type	applications	The model type handle of the application model from which the data is retrieved. If no application models of this type are related to the model in context, the line is not shown.

The following example specifies the data to display in a 2-line performance graph that shows the change in both active and total VoIP calls over time for a Cisco device.

```
<performance-config id="performance-data-ciscovoiceapp-config">
   <display>performance-ciscovoiceapp-config</display>
   <line>
    <name>Active VoIP Calls</name>
<content>
        <attribute>0x325012b</attribute><!-- VoIP_Current_Calls -->
</content>
   </line>
   <line>
    <name>Total VoIP Calls</name>
<content>
        <attribute>0x3250129</attribute> <!-- VoIP_Total_Calls -->
</content>
   </line>
</performance-config>
```

NOTE
For additional, more complex examples of performance data configuration files, see the supporting files for the Performance views included with DX NetOps Spectrum. You can find these files by navigating to the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF directory and searching for files named perf*.

Create a Performance View Configuration File

The *performance view configuration file* defines the appearance of each graph available within the Performance tab. A recommended naming convention for this XML file is performance-<descriptor>-view-config.xml.

Use the XML elements described in the following table to create a performance view configuration file.

Element	Parent Element	Description
performance-view	Not applicable	Represents the top-level parent element.
graph	performance-view	Within the performance view configuration file, you can configure multiple graphs. Each graph is denoted by this <graph> element. The id attribute of this element is used as the graph title and displayed in the pulldown menu on the view (which is used for switching between multiple graphs for a single model). <graph id="CPU Utilization"> <y-axis-label>Utilization</y-axis-label> <y-axis-units>%</y-axis-units> <line> <name>CPU Utilization</name> </line> </graph>
y-axis-label	graph	Specifies the label for the Y axis.
y-axis-units	graph	Specifies the units for the Y axis, for example, % or Bits per Second.
line	graph	Defines a line in the graph, for example: <line color="#ffff00"> Use the color attribute to specify the hexadecimal RGB value of the color to use.

name	line	Specifies the label (name) for the line defined by the <line> parent element. This value must match the value for the same line in the performance data configuration file that defines the view's data. If you are graphing a list attribute, you may also specify an attr-id attribute for the name element. This represents the attribute id of which the value is appended to the name of each instance in the list. If not specified, the instance number is appended to name of each list instance.
display-if	line	Specifies the line should be displayed in the graph only if the expression defined in the <expression> child element evaluates to TRUE.
expression	display-if	Used to define an expression to define a complex condition for whether or not to graph the line. For more information, see Chapter 9: XML Usage Common to All Customization Files.
fill	line	If this element is included, the area below the line is filled in with color.

The following example specifies the format for a 2-line performance graph that shows the change in both active and total VoIP calls over time for a Cisco device.

NOTE
This is the format for the example graph whose data is defined in Create a Performance Data Configuration File.

```
<performance-view id="performance-ciscovoiceapp-config">
   <graph id="VoIP Calls Title">
    <y-axis-label>Calls</y-axis-label>
<y-axis-units>unit</y-axis-units>
<line>
   <name>Active VoIP Calls</name>
</line>
<line>
    <name>Total VoIP Calls</name>
</line>
   </graph>
</performance-view>
```

NOTE
For additional, more complex examples of performance view configuration files, see the supporting files for the Performance views included with DX NetOps Spectrum. You can find these files by navigating to the <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF directory and searching for files named perf*.

Customize an Existing Performance View

In general, you customize an existing Performance view by overriding the default configuration files for the view with versions that contain your customizations.

To customize an existing Performance view

1. Identify the default configuration files that define the Performance view you want to customize:
   a. Open <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/topo/config/topo-app-config.xml and find the <contents-registry> or <component-details-registry> element for the appropriate model type or model class.

      NOTE
      If your model qualifies for both a model type and a model class registration, the model type registration takes precedence and is applied. Also, even though you can define the Performance view configuration in both the contents registry and the component details registry, the component details registry takes

precedence. The contents registry is primarily for model appearance and typically is applied to only the model class.

b. Find the <performance-config> element within the <contents-registry> or <component-details-registry> element, and note the name of the specified performance data configuration file.

NOTE
All of the default performance configuration files -- both the data configuration files and the view configuration files -- are located in the *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/*/config directories.

c. Open the *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/topo/config directory, and then open the performance data configuration file you identified in the previous step.

d. Find the <display> element within the <performance-config> element, and note the name of the specified performance view configuration file.

2. Copy over one or both of the performance configuration files that you identified in step 1 to the *<$SPECROOT>*/custom/topo/config directory. You only need to copy over a file if it requires customizations.

NOTE
To override the factory default performance configuration files, the copied files (that will contain your customizations) must have the same names as the original, default files.

3. If necessary, modify the copied performance data configuration file per your requirements, and then save and close the file.
4. If necessary, modify the copied performance view configuration file per your requirements, and then save and close the file.
5. If necessary, in custom-app-config.xml, change the model types or model classes that are associated with the performance data configuration file:

a. If it does not already exist there, copy *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/console/config/custom-app-config.xml to the *<$SPECROOT>*/custom/console/config directory.

NOTE
Make sure to copy the file to the specified location. Do not modify the default custom-app-config.xml file that is provided with DX NetOps Spectrum because it is overwritten when you upgrade to a newer version.

b. In custom-app-config.xml, add a block of XML code similar to the following example using a text editor. This code links the appropriate model types and model classes to the performance configuration data file.
The following XML code example associates a model type whose ID is 0x3250004 to a performance data configuration file named *<$SPECROOT>*/custom/topo/config/performance-data-ciscovoiceapp-config.xml.

```
<component-details-registry>
  <performance-config>performance-data-ciscovoiceapp-config</performance-config>
  <model-type>0x3250004</model-type>
  <!-- CiscoVoiceApp -->
</component-details-registry>
```

NOTE
You can specify several model classes and model types within the contents or component details registries. You can also reuse Performance views in one or more <contents-registry> elements.

The <component-details-registry> element within custom-app-config.xml *overrides* the equivalent registration for the model type or model class within an *-app-config.xml file. These registrations are used in the factory XML files in *<$SPECROOT>*/tomcat/webapps/spectrum/WEB-INF/*/config/*-app-config.xml.

c. Save and close the custom-app-config.xml file.

6. Restart the OneClick client for your changes to take effect.

Creating Custom Privileges

This section describes how to restrict access to menu items, attributes, and subviews using privileges.

Define a Custom Privilege

Define each new privilege in the custom-privileges.xml file. This file registers custom privileges that can be applied to the following components:

- Menu items
- Columns
- Subviews

If an administrator has not assigned the corresponding privilege to a user, that user cannot access the menu item, column, or subview.

Follow these steps:

1. Copy <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/console/config/custom-privileges.xml to the <*$SPECROOT*>/custom/console/config directory.
2. Open this file with a text editor.

   NOTE
   Define all new privileges inside the <privileges> element, which is the root element for the file.
3. Create the privilege. Use the elements shown in the table that follows this procedure.
4. Save and close the custom-privileges.xml file.
5. Restart the Tomcat web server, and then restart OneClick so that changes to the custom-privileges.xml file are available in OneClick.
6. You can now use the privilege to do the following:
   - Create a custom menu item, column, or subview that is accessible to only users who have the privilege. For more information, see Reference a Privilege When Defining a Menu Item, Column, or Subview.
   - Create a search that is accessible only to users who have the privilege.

   NOTE
   For more information, see OneClick Administration .

You can use the elements in the following table to create a privilege:

Element	Parent Element	Description
<privileges>	Not applicable	The root element for the custom-privileges.xml file.
<*your_privilege_name*>	<privileges> or <*your_group_name*>	Defines the privilege. You create an element for each new privilege. The type attribute for this element defines the default role to which you assign the privilege. Possible values for the type attribute are “read” or “write”. If you are grouping privileges, place all defined privileges for that group within the element that defines your group.
<label>	<*your_privilege_name*>	The name of the privilege, which will be shown on the privilege list.
<desc>	<*your_privilege_name*>	The description of the privilege.
<model-view-*attr*>	<privileges>	For more information, see Restrict Access to Attribute Values in Model Subviews.
<model-write-*attr*>	<privileges>	For more information, see Restrict Access to Attribute Values in Model Subviews.

[set the product group or family]	*<your_privilege_name>*	The new privilege appears in one of the existing groups if you use the [set the product group or family] element. The scope attribute defines group scope. The following list includes existing groups and their scope values: • <group scope="alarm"> alarm-manager </group> • <group scope="topo">tools</group> • <group scope="topo">model-tab</group> • <group scope="topo">model-view-group</group> • <group scope="topo">model-write-group</group> For more information see Group Privileges.

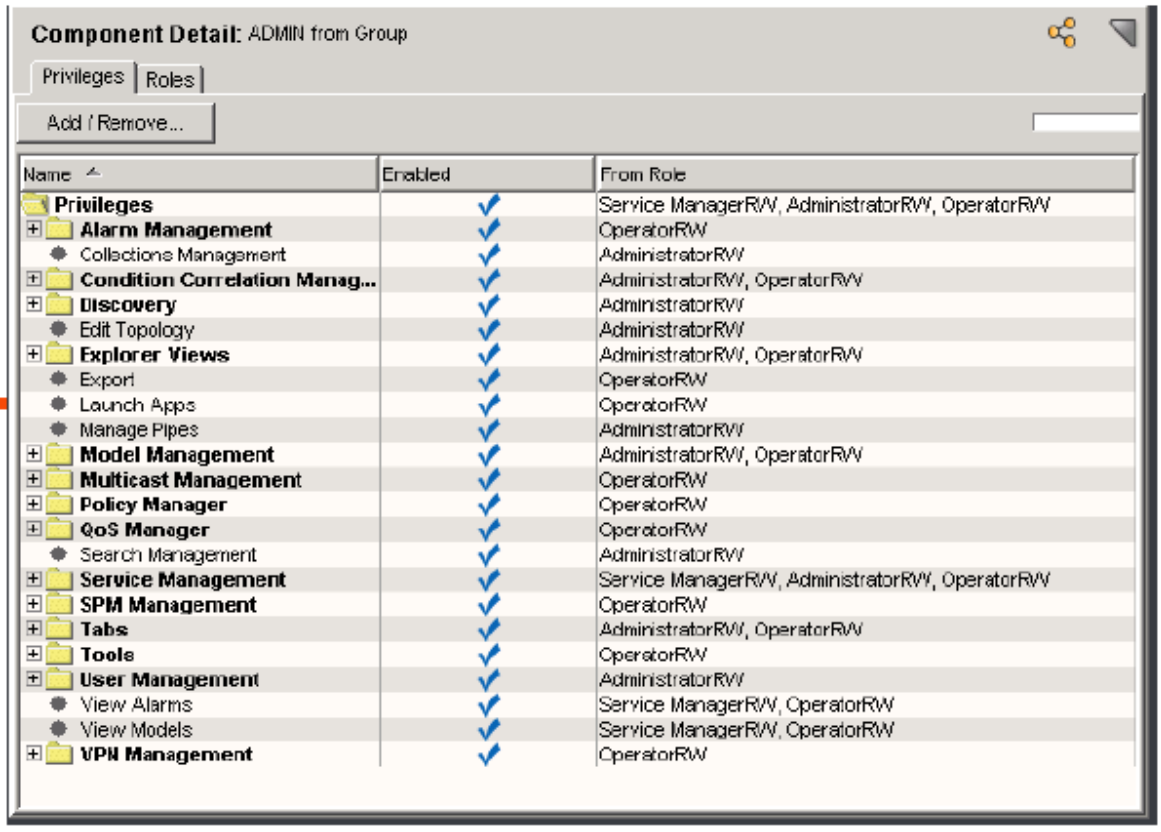
Example: Create a Privilege

NOTE
When you create a privilege, you are creating a new XML element. In the example above, the <launch-app> element creates the launch-app privilege. The type attribute defines the default role to which the privilege is assigned. Two values are possible: "read" and "write". A privilege with the "read" type is assigned to the OperatorRO role, and a privilege with the "write" type is assigned to the OperatorRW role.

The following example defines the launch-app privilege, as shown in the image:

```
<privileges>
   <launch-app type="write">
    <label>Launch Apps</label>
    <desc>Ability to launch application from the tools menu.</desc>
   </launch-app>
</privileges>
```

A newly defined "Launch Apps" privilege is made available in the privileges list.



Restrict Access to Attribute Values in Model Subviews

You can restrict a user's access to certain attributes using the <model-view-attr> and <model-write-attr> elements, where attr is equal to the attribute ID of the attribute you want to restrict. These elements are used in the custom-privileges.xml file and regulate the attributes that show up in the OneClick Privilege list's Model Management>View Attributes folder and the Model Management>Model Write folder.

The <model-view-attr> element enables you to create a privilege that determines whether or not a user can see an attribute. For example, if you added the following XML to the custom-privileges.xml file, you will create a privilege called Community Name. This privilege restricts view access to attribute 10024, community name. This privilege will appear in the Model Management > View Attributes folder as specified with the [set the product group or family] element. If the user does not have this privilege in any access group, they will not be able to see the community name attribute.

```
<model-view-10024 type="read">
   <label>Community Name</label>
   <group scope="topo">model-view-group</group>
</model-view-10024>
```

The <model-write-attr> element enables you to create a privilege that determines whether or not a user can edit an attribute. For example, if you added the following XML to the custom-privileges.xml file, you will create a privilege called Community Name. This privilege restricts write access to attribute 10024, community name. This privilege will appear in the Model Management > Model Write folder as specified with the [set the product group or family] element. If the user does not have this privilege in any access group, they will not be able to edit the community name attribute.

```
<model-write-10024 type="write">
   <label>Community Name</label>
   <group scope="topo">model-write-group</group>
</model-write-10024>
```

Group Privileges

If you want to group privileges together, you can create groups in the custom-privileges.xml file. To specify a group, nest the element that defines the privilege (<*your_privilege_name*>) between the element that defines the group (<*your_group_name*>). The group's <label> element defines the name that represents the group in the privileges tree (see the image later in this section).

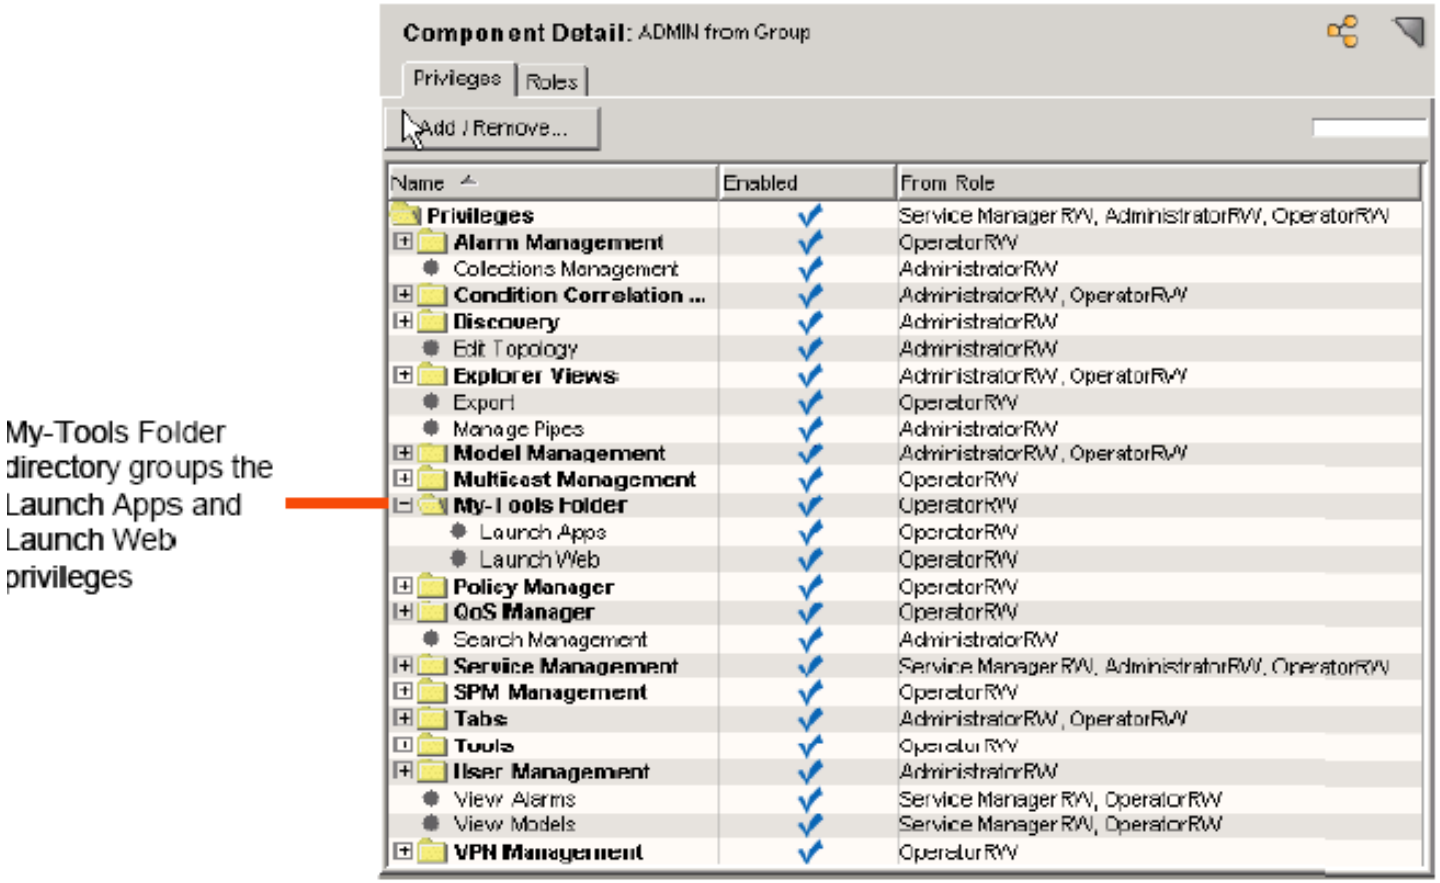
Element	Parent Element	Description
<privileges>	Not applicable	This is the root element for the custom-privileges.xml file.
<your_group_name>	<privileges>	This element defines the group. You create a new element for each group you define.
<label>	<your_group_name>	The name of the group, which will be shown on the privilege list.

NOTE
In order for changes made to the custom-privileges.xml file to be available in OneClick, you must restart the Tomcat web server and then restart OneClick.

In the following example, the <my-tools> element creates a group in which privileges can be nested. The value defined for the group's <label> is "My-Tools Folder". This will create a "My-Tools Folder" group in the privileges list as shown in the image that follows. The <launch-app> and <launch-web> privileges will appear in this group.

```
<privilege>
   <my-tools>
    <label>My-Tools Folder</label>
    <launch-app type="read">
        <label>Launch Apps</label>
```

```
        <desc>Ability to launch Applications.</desc>
    </launch-app>
    <launch-web type="read">
        <label>Launch Web</label>
        <desc>Ability to launch Web URLS.</desc>
    </launch-web>
   </my-tools>
</privilege>
```



Reference a Privilege When Defining a Menu Item, Column, or Subview

When you create a menu item, column, or subview, you can use the <privilege> element to reference a custom privilege. Custom privileges are defined in the custom-privileges.xml file. For example, if you have defined the "launch-app" privilege in the custom-privileges.xml file, you can use the following XML when you define a menu item, column, or subview:

```
<privilege>
   <name>launch-app</name>
</privilege>
```

This XML associates the "launch-app" privilege with the menu item, column, or subview. The user must have an associated role that grants the launch-app privilege in order for the menu item, column, or subview to be displayed. If granted, the menu item is always enabled.

NOTE
For more information, see OneClick Administration .

XML Usage Common to All Customization Files

This section explains common XML elements and strategies that can be used across customization files.

About Parameters

You can use the <param> element in many different instances to reference parameter values within a OneClick XML file. Here are several common cases where you will likely use the <param> element.

- If you need to pass a parameter to a web page, use the <param> element as a child element of the <url> element. See Launch a Browser for an example.
- If you need to pass a parameter to an application, use the <param> element as a child element of the <launch-application> element. See Launch an Application From OneClick for an example.
- If you need to pass a parameter to a command, use the <param> element as a child element of the <command> element. See Launch a Browser, Launch an Application From OneClick, and Launch a Web Server Script.
- If you need to format a series of values, use the <param> element in conjunction with standard HTML formatting elements. See Define Model Icon Tooltips for an example.
- If you need to manipulate the value of an attribute, you may need to use the <param> element when accessing one of the renderers.

See Acquire Data Render a Value for information on what you can specify using the <param> tag.

Acquire Data -- Render a Value

Acquiring data from OneClick about a model type parameter that you then act on is a fundamental process in customizing the OneClick interface. A set of elements provide the ability to acquire or render data from OneClick. These elements or tags are used in acquiring data to display in a table column, a field-subview column, an <param> element for a menu item, and the <render> element in a <dynamic-renderer>, and are shown in the following table.

Element	Description
<attribute>	Used to specify a DX NetOps Spectrum attribute
<select>	Used to specify something based on the value of another attribute, parameter, etc. Used to select a value based on certain criteria being met. Very generally, <select> this <if>condition1, <select> that <if> condition2.
<expression>	Used to define an arithmetic expression.
<renderer>	Used to define or access any number of renderers that process raw data and refine it into a specific format for presentation to the user.
<dynamic-renderer>	Specifies a renderer based on the value of an attribute criteria filter.
<message>	Used for specifying a plain text value for the column.

You can use any number and combination of these elements chained together, with the output from one element serving as the input to the next element in the chain. The <attribute> tag must be first in a chain of elements because it yields an attribute value and does not accept input. The <message> tag must be first in a chain of elements used to render a value. because it does not accept input.

Use a Select Case

If you want to conditionally display something in the OneClick interface, you may use the <select> and the <case> elements to create a decision structure similar to those used in many programming languages. Use the <select> and <case> elements as follows:

```
<select>
   <case>
    <expression>the expression to evaluate</expression>
    <yield>what to yield if the expression is true</yield>
   </case>
   <case>
    <expression>the expression to evaluate</expression>
    <yield>what to yield if the expression is true</yield>
   </case>
    .
    .
    .
   <default>what to yield if no matches are found</default>
</select>
```

Example: Image Definition File shows an example of the <select> and <case> elements used to select the image to be displayed on a OneClick device model icon depending on the model's condition.

Manipulate Attribute Output Using Renderers

There are several built-in attribute renderers that you can use to manipulate how the attributes you have specified in a OneClick table are displayed. You use the <renderer> element to access one of these renderers. The text of the element must be a fully-qualified Java class name; each allowable Java class name is explained below.

NOTE
You will need some background in programming to fully understand the renderer concepts presented below.

You can pass parameters to a renderer using the <param> element. The text of the <param> element is the parameter value. An <param> element must have a name attribute that specifies the name of the parameter.

Example

The following example specifies the BooleanRenderer with parameter trueTag set to No and parameter falseTag set to Yes. Each renderer has a set of parameters, and each renderer is defined differently.

```
<renderer>
   <param name="trueTag">Enabled</param>
   <param name="falseTag">Disabled</param>
   com.aprisma.spectrum.app.util.render.BooleanRenderer
</renderer>
```

Boolean Renderer

The class name for the boolean renderer is com.aprisma.spectrum.app.util.render.BooleanRenderer. This renderer outputs an enumerated String for an input Boolean value. By default, "Yes" is rendered for TRUE and “No” is rendered for FALSE, but other elements or text may be specified via the following parameters:

- trueTag - the tag or text to render for TRUE
- falseTag - the tag or text to render for FALSE

The following example reverses the TRUE/FALSE output:

```
<renderer>
```

```
   <param name="trueTag">No</param>
   <param name="falseTag">Yes</param>
   com.aprisma.spectrum.app.util.render.BooleanRenderer
</renderer>
```

If the input value is TRUE, “No” is rendered and if FALSE, “Yes” is rendered.

Commented Text Renderer

The class name for the commented text renderer is com.aprisma.spectrum.app.util.render.CommentedTextRenderer. This renderer strips off the HTML-commented prefix that is added by some renderers (for example, DateRenderer). It searches for the first occurrence of the ending character sequence of an HTML comment, such as <!---comment text --->, and returns the rest of the string.

Date Renderer

The class name for the date renderer is com.aprisma.spectrum.app.util.render.DateRenderer. This renderer outputs date and time using Java’s DateFormat. If the input to the renderer is a long integer (for example, of type java.lang.Long), it is assumed to represent the date and time in milliseconds. If the input is any other numeric type, it is assumed to be an integer representing the date and time in seconds. Otherwise, the only other valid input type is java.util.Date. The output string is prefixed by the numeric date and time value enclosed in HTML comments (<!---comment text --->). An example output would be:

```
<!--1089808869000-->Jul 14, 2004 8:41:09 AM EDT
```

You use the numeric value prefix in the comments tag for sorting. Without the prefix, DX NetOps Spectrum would sort on the formatted date and time string, and this would not work correctly. Therefore, you should only use the DateRenderer in the <content> element section of a column. To strip off the prefix for display, use the CommentedTextRenderer in the <swing-cell-template> section. For example:

```
<content>
   <attribute>0x11620</attribute>
   <! -- an attribute that contains an integer date/time in seconds >
   <renderer>
    com.aprisma.spectrum.app.util.render.DateRenderer
   </renderer>
</content>
<swing-cell-template>
   <text>
    <renderer>
        com.aprisma.spectrum.app.util.render.CommentedTextRenderer
    </renderer>
   </text>
</swing-cell-template>
```

Enumerated Attribute Renderer

Classname: com.aprisma.spectrum.app.util.render.EnumeratedAttrRenderer.

This renderer outputs an enumerated String for an attribute value. The renderer obtains the enumerations from the DX NetOps Spectrum database. You must specify the attribute ID via the “attrID” parameter. This renderer is most commonly preceded by an <attribute> element with the same attribute ID as the “attrID” parameter. The following sample XML renders the enumerated value for the Model_Class attribute (ID 0x11ee8):

```
<attribute>0x11ee8</attribute>
<renderer>
   <param name="attrID">0x11ee8</param>
   com.aprisma.spectrum.app.util.render.EnumeratedAttrRenderer
```

```
</renderer>
```

List Renderer

The classname for the list renderer is com.aprisma.spectrum.app.util.render.ListRenderer. This renderer outputs the components of a Java Collection or an array of any type as a comma-separated string.

Null Renderer

Classname: com.aprisma.spectrum.app.util.render.NullRenderer.

This renderer outputs a null input value as an empty string.

Object ID Renderer

This renderer outputs an object identifier (OID). The expected input value is type CsObjectID.

Classname: com.aprisma.spectrum.app.util.render.ObjectIDRenderer.

Supported parameters:

- term -- an integer value that specifies the index of a particular term of the OID to render
- startTerm -- an integer value that specifies the index of the first term of the OID to render
- endTerm -- an integer value that specifies the index of the last term of the OID to render

The term indices start at 1. If you specify the startTerm without the endTerm, then the portion of the OID from the startTerm to the last term of the OID is rendered. If you specify the endTerm without the startTerm, then the portion of the OID from the first term to the endTerm is rendered.

The ObjectIDRenderer is most commonly used to render the row instance of a MIB table. You obtain the row instance via the getRowId() method in an <expression> element. You can then pass the result to the ObjectIDRenderer. For example, the following column renders the first term of the row instance:

```
<column>
   <name>com.aprisma.spectrum.app.topo.client.ifIndex</name>
   <content>
    <expression>getRowId()</expression>
    <renderer>
        <param name="term">1</param>
        com.aprisma.spectrum.app.util.render.ObjectIDRenderer
    </renderer>
   </content>
</column>
```

The following example renders terms 5 through 8:

```
<column>
   <name>com.aprisma.spectrum.app.topo.client.NetworkAddr</name>
   <content>
    <expression>getRowId()</expression>
    <renderer>
        <param name="startTerm">5</param>
        <param name="endTerm">8</param>
        com.aprisma.spectrum.app.util.render.ObjectIDRenderer
    </renderer>
   </content>
</column>
```

The following example combines an expression with the ObjectID renderer to enable you to display the last term of an OID value in a table:

```
<column>
   <name>com.aprisma.spectrum.app.topo.client.ifIndex</name>
   <content>
    <expression>
        ((com.aprisma.spectrum.global.CsObjectID)value()).get_sub_oid(
        ((com.aprisma.spectrum.global.CsObjectID)value()).get_term_count(),
        ((com.aprisma.spectrum.global.CsObjectID)value()).get_term_count())
    </expression>
    <renderer>
        <param name="term">1</param>
        com.aprisma.spectrum.app.util.render.ObjectIDRenderer
    </renderer>
   </content>
</column>
```

Round Number Renderer

The classname for this renderer is com.aprisma.spectrum.app.util.render.RoundNumberRenderer. This renderer outputs a number rounded to the nearest 100th (or 2 decimal places).

System Up Time Renderer

This renderer outputs a numeric time value represented in one-hundredths of a second. The time representation is used in MIB objects such as sysUpTime. The output is expressed in days, hours, and minutes (for example, 30 days 1 hr 55 min).

Classname: com.aprisma.spectrum.app.util.render.SysUpTimeRenderer

Byte Renderer

This renderer outputs an integer value in byte units (byte, KB, MB, GB, or TB).

Classname: com.aprisma.spectrum.app.util.render.ByteRenderer

Inet Address Renderer

This renders an MIB object of type InetAddress as defined in RFC-3291.

Classname: com.aprisma.spectrum.app.util.render.InetAddressRenderer

Supported parameters:

- addressAttrID - the ID of the InetAddress attribute
- type - the InetAddressType as defined in RFC-3291
- typeAttrID - the ID of an attribute used to obtain the InetAddressType

List Instance Renderer

Renders the value of a specific instance of a list-type attribute.

Classname: com.aprisma.spectrum.app.util.render.ListInstanceRenderer

Supported parameters:

- oid -- the OID of the instance to render
- index -- the index of the instance to render

You must specify either the oid or index parameter.

Simple Integer Renderer

Renders an integer value without using comma grouping; 123456 instead of 123,456. Use this to substitute an integer value in a URL used in a menu item where commas are not acceptable input.

Classname: com.aprisma.spectrum.app.util.render.SimpleIntegerRenderer

Type Prepended Inet Address Renderer

Renders a MIB object of type InetAddress as defined in RFC-4293 with the type added to the beginning of the address.

Classname: com.aprisma.spectrum.app.util.render.TypePrependedInetAddressRenderer

Supported parameter:

addressAttrID - the ID of the InetAddress attribute

About <dynamic-renderer>

Use the <dynamic-renderer> element to specify a renderer that depends on the value of an attribute criteria such as <model_class>, <model-type>, or other attribute criteria. You select an attribute ID as the key and specify one or more <dynamic-renderer> elements in the custom-app-config.xml file. Each <dynamic-renderer> element defines a criteria and the renderer to use if the criteria is satisfied.

The structure to use with <dynamic-renderer> is as follows:

```
<dynamic-renderer>
   <attribute><KEY_ATTRIBUTE_ID></attribute>
   CRITERIA
    <render>
    .
    .
    .
    </render>
   <default/>
</dynamic-renderer>
```

The following table describes the elements you can use with <dynamic-renderer>.

Element	Usage and Description
<attribute>	Specifies the <KEY_ATTRIBUTE_ID> used to bind or tie together a set of dynamic-renderers.
CRITERIA	Defines an attribute filter criteria used to determine which renderer is used based on the filter output.
<render>	Defines what to render.
<default>	Specifies the dynamic-renderer to use as the default when none of the other dynamic-renderer criteria are met.

Attribute Filter Criteria and <dynamic-renderer>

It is common to use <model-class> and <model-type> for attribute filter criteria. You can use any attribute and any set of complex attribute filters with any combination of nested “and” and “or” filters. The file <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/common/schema/attributefilter.xsd contains the complete syntax for attribute filters.

Specify a Default <dynamic-renderer>

You define the default dynamic renderer for use when none of the conditions for using the <dynamic-renderer> specified in the CRITERIA statement are met. You can specify only one default dynamic-renderer per dynamic renderer set. Do not specify a filter criteria for the default.

Example: Using Attribute Filtering Criteria with <dynamic-renderer>

This example creates a column that displays an attribute based on the value of the model_type attribute. The attribute displayed for the model_type filter criteria conditions are shown in the following table.

Attribute to display...	if model_type is...
<attribute> 0xffff0000	<model-type> 0x12
<attribute> 0xffff0001	<model-type> 0x34 and 0x56
<attribute> 0xffff0002	for all other model types (default)

You must select one of the attributes specified in your filter criteria to be the key. This example uses 0xffff0002. Add the following <dynamic-renderer> elements to the custom-app-config.xml file:

```
<dynamic-renderer>
   <attribute>0xffff0002</attribute>
   <model-type>0x12</model-type>
   <render>
    <attribute>0xffff0000</attribute>
   </render>
</dynamic-renderer>
<dynamic-renderer>
   <attribute>0xffff0002</attribute>
   <or>
    <model-type>0x34</model-type>
    <model-type>0x56</model-type>
   </or>
   <render>
    <attribute>0xffff0001</attribute>
   </render>
</dynamic-renderer>
<dynamic-renderer>
   <attribute>0xffff0002</attribute>
   <render>
    <attribute>0xffff0002</attribute>
   </render>
   <default/>
</dynamic-renderer>
```

Example: Use a Key Attribute ID with <content>

This example creates a column specifying the <dynamic-renderer> element with the key attribute ID defined in the <content> element.

```
<column>
   <name>My Column</name>
   <content>
    <dynamic-renderer>0xffff0002</dynamic-renderer>
   </content>
</column>
```

About Expressions

When you are customizing the OneClick interface, there are several places where you may want to use an expression to display a calculated value. For example, you may want to display a calculated value in a table or subview. The section below explains how to use expressions to manipulate attribute information.

NOTE
Expressions are created using standard Java expressions. You must be familiar with Java code in order to implement the following instructions that create expressions in the OneClick XML files. If you are not familiar with Java code, you should refer to a Java reference before attempting to create expressions when customizing OneClick files.

Manipulate Attribute Information

The most common use of an expression is to manipulate attribute information. The attribute information available is dependent upon the OneClick context in which you are using the expression.

You can use the methods listed in the following table in the context of an expression to retrieve attribute information:

java.lang.Object	**attr (int attrID)**
boolean	attrBoolean (int attrID)
byte	attrByte (int attrID)
char	attrChar (int attrID)
double	attrDouble (int attrID)
float	attrFloat (int attrID)
int	attrInt (int attrID)
long	attrLong (int attrID)
short	attrShort(int attrID)

The following example shows a column configuration that displays the contact person for a device. In this example, an expression displays the attribute 0x23000c (AttributeID.CONTACT_PERSON) if the attribute 0x10b5a (AttributeID.SYS_CONTACT) is null or has no value.

Example: Specifying a Contact for a Device Using an Expression

```
<column id="column-contact-config"
   xmlns ="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com
   ../../common/schema/column-config.xsd">
   <name>Contact Person</name>
   <content>
    <expression>
        ( attr( AttributeID.SYS_CONTACT ) == null ||
        ((String)attr(AttributeID.SYS_CONTACT)).length() == 0) ?
        attr( AttributeID.CONTACT_PERSON ) : value()
    </expression>
   </content>
</column>
```

Another way to accomplish the same result is to use the attribute renderer to retrieve the SYS_CONTACT attribute value. You can then access the value returned using an expression that uses the value() method.

Example: Using Attribute Renderer to Retrieve Attribute Value

```
<column id="column-contact-config"
   xmlns ="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com
   ../../common/schema/column-config.xsd">
```

```
    <name>Contact Person</name>
    <content>
     <attribute>AttributeID.SYS_CONTACT</attribute>
     <expression>
         (value() == null || ((String)value()).length() == 0) ?
         attr( AttributeID.CONTACT_PERSON ) : value()
     </expression>
    </content>
 </column>
```

The two examples shown above produce the same value for the column.

Append Suffix to Values

Use an expression to append a suffix to values to increase readability of information displayed in tables.

Example

This example appends a “%” character to a value so that the value displays in a table as <value>%.

<expression>value().toString() + "%"</expression>

You can use this method to append a “%” character to a “percentage of disk space used” value, so that the value displays in a table as <percentage of disk spaced used>%, or 64%.

Precautions for Using Expressions

The following list describes major exceptions to the rules for standard Java code that are used to create OneClick expressions.

- **Comparison Operator**
  You cannot use the comparison operator, &&, due to restrictions on XML formatting. In place of && you must use &&.
- **Less Than, Greater Than Operators**
  You cannot use the less than (<) or greater than (>) operators. Instead, you must use < and > respectively.
- **Subtraction Expressions**
  OneClick processes subtraction expressions using non-standard associativity. Subtraction is done using a right-to-left associativity instead of the standard left-to-right associativity.
  OneClick processes subtraction as follows:
  A - B - C = A - (B - C)
  compared with standard subtraction expression processing:
  A - B - C = (A - B) - C

Reference XML Files

As you are customizing OneClick XML files, you may find it necessary to split a single XML file into two or more XML files for the following reasons:

- Some XML files are so complex that they become unreadable. In this case breaking the XML file down into two or more files assists you in keeping your code organized and making it readable and editable in the future.
- You may want to reuse certain sections of XML code. Putting this XML code in a separate file allows you to reference it from multiple files instead of copying and pasting it into new files, or new sections of the same file.

Use the standard XML id and idref attributes to label and reference the split up code.

NOTE
For information on XML standards, including id and idref, see .

Reference Images

You may need to reference image files from within your XML. When you reference image files in either the factory <*$SPECROOT*>/tomcat/webapps/spectrum/images directory or the custom <*$SPECROOT*>/custom/images directory, express the path starting from the images directory, for example, images/myimage.png. See Example: Icon Configuration File for an example.

You must place all image files that you add or customize in the <*$SPECROOT*>/custom/images directory. Otherwise, all new or customized images you add will be deleted or overwritten during a DX NetOps Spectrum or OneClick upgrade or reinstallation.

Verify User Input Using Verifiers

You can verify user input by specifying a verifier class along with the <editable> element before committing the change. If the input is invalid, an error message is displayed. The verifiers available are described in the following section.

Specify the <verifier> element inside the <editable> element. Inside the <verifier>, you specify a verifier Java class and optional parameters to pass to the verifier class.

Example: Using Verifiers

This verifies the input value is from 0-100, inclusive.

```
<editable>
   <verifier>
    <class>
        com.aprisma.spectrum.app.swing.widget.IntegerContainedInRangeInputVerifier
    </class>
    <param name="lowValue">0</param>
    <param name="upperValue">100</param>
   </verifier>
</editable>
```

OneClick Input Verifiers

IntegerContainedInRangeInputVerifier

Description: Verifies the input is an integer value within a specified range.

Class:com.aprisma.spectrum.app.swing.widget.IntegerContainedInRangeInputVerifier

Parameters:

- lowValue - the lower bound of the range
- upperValue - the upper bound of the range

AttrIDInputVerifier

Description: Verifies the user input is a valid attribute.

Class: com.aprisma.spectrum.app.swing.widget.AttrIDInputVerifier

DoubleInputVerifier

Description: Verifies the user input is a valid real number.

Class: com.aprisma.spectrum.app.swing.widget.DoubleInputVerifier

IPAddressInputVerifier

Description: Verifies the user input is a valid IP address.

Class: com.aprisma.spectrum.app.swing.widget.IPAddressInputVerifier

IntegerInputVerifier

Description: Verifies the user input is a valid integer.

Class: com.aprisma.spectrum.app.swing.widget.IntegerInputVerifier

LongInputVerifier

Description: Verifies the user input is a valid long integer.

Class: com.aprisma.spectrum.app.swing.widget.LongInputVerifier

MACAddressInputVerifier

Description: Verifies the user input is a valid MAC address.

Class: com.aprisma.spectrum.app.swing.widget.MACAddressInputVerifier

NonEmptyStringInputVerifier

Description: Verifies the user input is a non-empty string.

Class: com.aprisma.spectrum.app.swing.widget.NonEmptyStringInputVerifier

UnsignedIntInputVerifier

Description: Default verifier for all integer attributes; verifies the user input is an unsigned integer.

Class: com.aprisma.spectrum.app.swing.widget.UnsignedIntInputVerifier

Customizing OneClick for CA Service Desk

For a DX NetOps Spectrum and CA Service Desk integration, you can modify the behavior of finding and creating Service Desk assets from OneClick. This customization is done by changing the attribute mapping between DX NetOps Spectrum models and Service Desk assets. Customizing asset reporting lets you prioritize the information used to identify a device and determine which information to record within Service Desk. How information is recorded in Service Desk can enhance the user's efficiency and reporting capabilities to best suit your organization.

> **NOTE**
> For more information about customizing asset reporting for CA Service Desk, see CA Service Desk and DX NetOps Spectrum .

TL1 Gateway

What Is TL1?

Transaction Language 1 (TL1), occasionally referred to as MML (Man Machine Language), is a widely used protocol in telecommunications management. The TL1 protocol can be used to manage most telecom network elements in North America.

Unlike SNMP, TL1 is a human-machine interface that contains human-readable strings. Also, unlike SNMP, TL1 includes no concept of a MIB. TL1 was originally specified by Bellcore in 1986 and is now maintained by Ericsson.

What Is TL1 Gateway?

The TL1 Gateway for DX NetOps Spectrum translates TL1 events and alarms originating from a TL1 device into DX NetOps Spectrum events and alarms. The gateway acts as a mediator between TL1 devices and DX NetOps Spectrum.

Each TL1 device is represented by a corresponding device model within DX NetOps Spectrum. As a result, you can launch the Enterprise Alarm Manager application for a particular model so that you can check for certain alarm conditions and initiate corrective action. TL1 Gateway also supports TL1 devices that are accessible through proxy devices, also known as Gateway Network Element (GNE) devices.

TL1 Gateway implements the full range of TL1 Condition Types as specified by Telcordia. Telcordia has been acquired by Ericsson. Multiple websites provide lists of current network element and transport surveillance messages.

What Does TL1 Gateway Include?

TL1 Gateway for DX NetOps Spectrum provides the following components:

- TL1-specific inference handlers that plug into a SpectroSERVER.
- A daemon (TL1d) that handles communication between the TL1 devices and the SpectroSERVER.
- A model type (Gen_TL1_Dev) for generic TL1 devices.
- A utility (tl1map) to manage TL1 AlarmMaps.

Installing TL1 Gateway

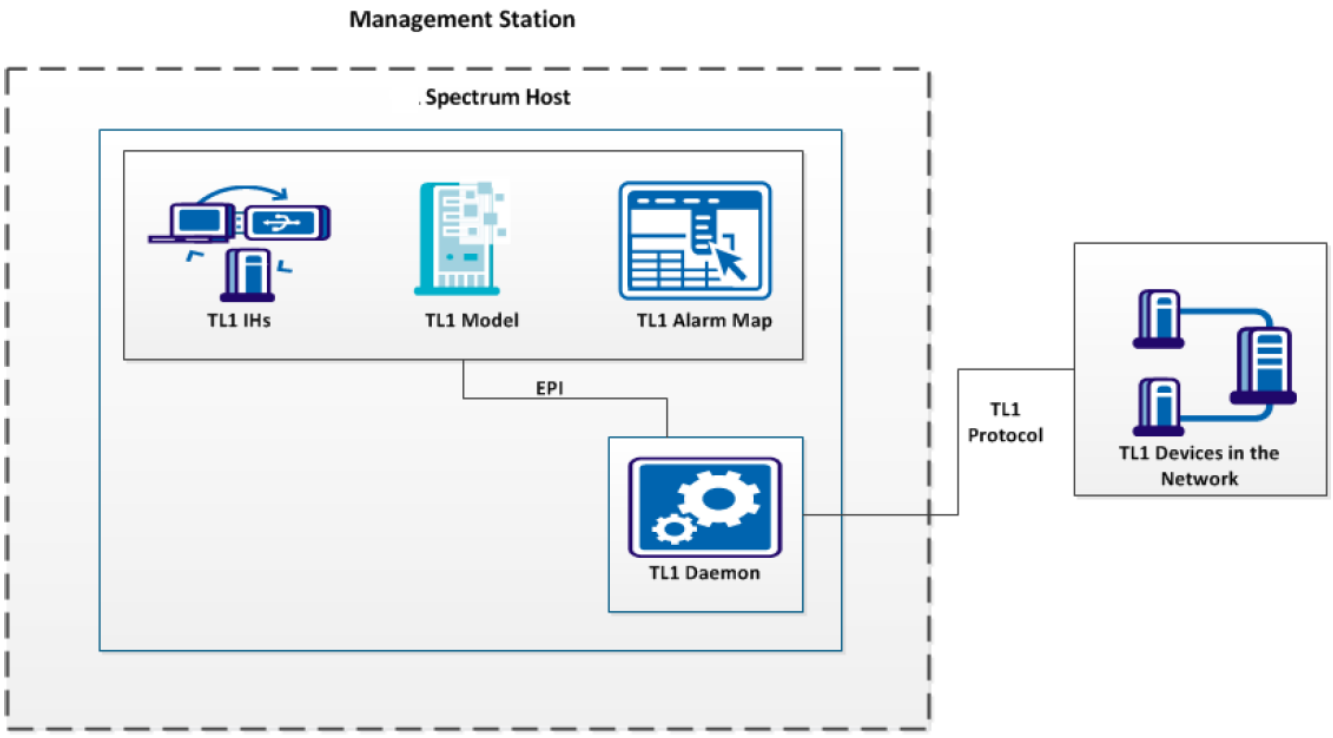
Prerequisites for TL1 Gateway

TL1 Gateway is designed such that it can either be run on the same machine DX NetOps Spectrum is running on, or on a separate machine. Diagrams illustrating both installation models are provided on the subsequent pages. Running TL1 Gateway on a separate machine is recommended if any of the following conditions apply:

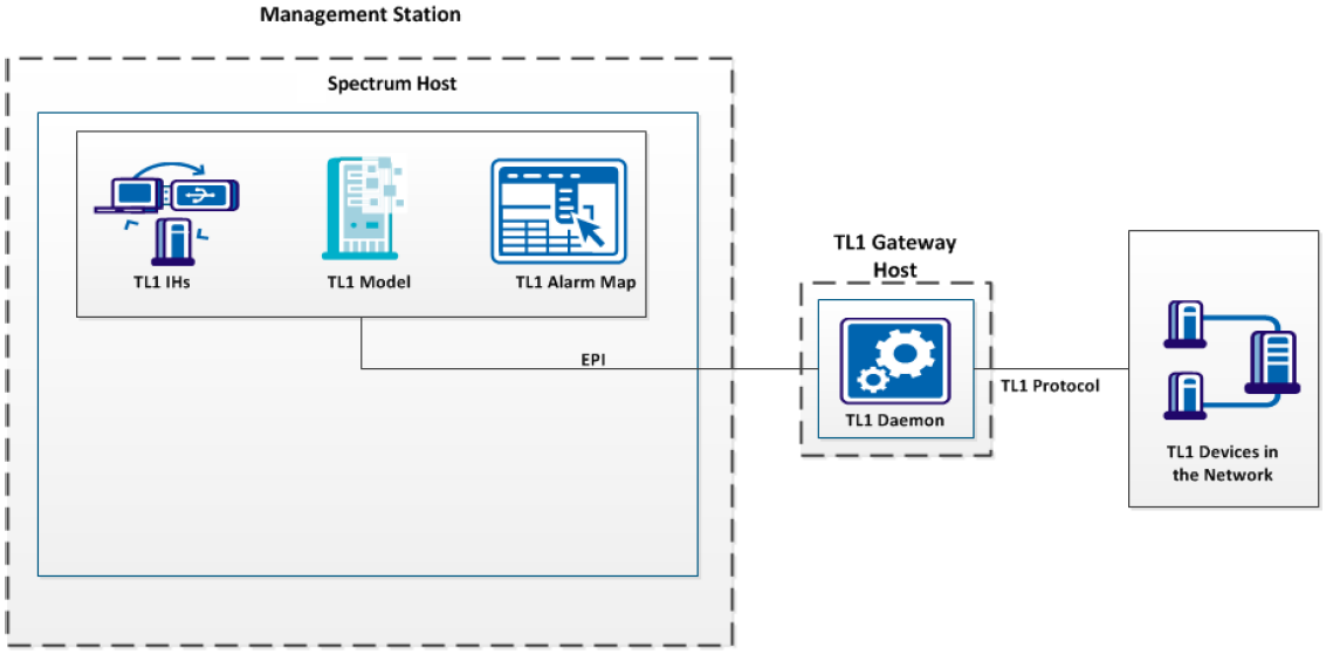
- The DX NetOps Spectrum machine hosts a SpectroSERVER that has a high workload.
- The DX NetOps Spectrum machine is short on resources like CPU and RAM.
- The DX NetOps Spectrum machine is also used by applications other than DX NetOps Spectrum.
- A high volume of TL1 traffic has to be processed.

> **NOTE**
> TL1 Gateway does not support IPv6.

The following diagram shows an example of a TL1 Gateway installed on DX NetOps Spectrum host:



The following diagram shows an example of a TL1 Gateway installed on a remote host:



Installation Options

If your configuration requires TL1 Gateway to be run on the same machine DX NetOps Spectrum is running on, then the gateway has already been installed during the major DX NetOps Spectrum installation. In this case, all required TL1

Gateway components can be found in a subdirectory called TL1Apps, which is located in your top-level DX NetOps Spectrum directory. The TL1 Apps directory contains the following files:

- TL1d -- the gateway daemon
- tl1map -- the AlarmMap utility

Install on a Non-DX NetOps Spectrum Machine

In some cases, where a certain level of performance is needed, it is preferable to install the TL1 daemon component on a separate server that is dedicated to TL1 message processing. The instructions vary slightly depending on the platform you are using. In either case, you must find and run the self-extracting installer file available with the DX NetOps Spectrum application.

The installer launches a series of dialogs that prompt you to supply the following information:

- confirmation of the license agreement
- the extraction key
- installation target area

> **NOTE**
> Regardless of the platform on which DX NetOps Spectrum is running (Windows), the TL1 daemon component can be installed and operated.

Follow these steps on Windows:

1. Navigate to the TL1GW folder on the DX NetOps Spectrum application installer.
2. Run the tl1inst.exe program.
3. Copy the resulting files (listed below) to the proper locations on the NT machine:
   - TL1d.exe
   - tl1map.exe
   - orb.dll
   - orb_p.dll

   Copy the executables TL1d.exe and tl1map.exe to the preferred locations. Copy the DLL files to the system area that is used for third-party DLL files.

Setting up Port Numbers

When you create a TL1 device model, specify the two port numbers that are described below. Before, you assign any port numbers, first check the local system administration or security policies.

- **TL1 Gateway Port**
  Used for communication between the TL1 daemon (TL1d) and the SpectroSERVER. At model creation, a default port number of 64222 is supplied. When choosing a different port number, we urge you not to use Port 65535. Ask a system administrator to find a port number in the dynamic/private range 49152 to 65534.
  The TL1 Gateway port number can be specified as a command-line argument when launching TL1d; otherwise, the default of 64222 is assumed.
- **TL1 Device Port**
  Used for communication between the physical TL1 device and the TL1 daemon. Check with the network administrator for the port number to use; it depends on device configuration. It is likely to be a port number specified in the IANA standard document. Check the “Registered Port Numbers” section. Likely candidates are: 2361, 3081, 3082 and 3083. IANA port assignments are available on the Internet.
  Supply the TL1 port number in the model creation dialog.

Creating a TL1 Device Model

The TL1 Device models are used to check for alarm conditions and initiate corrective action through Enterprise Alarm Manager. The TL1 devices must be modeled manually as they cannot be modeled through Spectrum Discovery. For more information about Discovery, see Modeling and Managing Your IT Infrastructure .

Follow these steps:

1. From any OneClick Topology tab view, select the Model by Type toolbar icon.
2. Select the 'All Model Types' tab and enter TL1 into the Filter field.
3. Select Gen_TL1_Dev to model a generic TL1 device and click OK.
4. Complete the following fields to configure the TL1 device model:
   - **Model Name**
     Specifies a unique name for this model.
   - **TL1 Gateway Address**
     Specifies the IP address of the server that hosts the TL1 daemon (TL1d).
   - **TL1 Gateway Port**
     Specifies the port number for communication between the TL1 daemon and DX NetOps Spectrum.
     Default: 64222
   - **TL1 Device Address**
     Specifies the IP address of the TL1 device.

     NOTE
     Sometimes, this address is the IP address of a dedicated TL1 device that acts as a proxy for all the other TL1 devices in the network.
   - **TL1 Device Port**
     Specifies the port number where the TL1 device agent is listening (also known as the “craft” port).
   - **Max Telnet Sessions**
     Specifies the total number of Telnet sessions TL1 Gateway can make to Gateway Network Element (GNE).
     Default: 1
   - **Max Logins Per Telnet**
     Specifies the number of logins that are permitted to be active simultaneously per telnet session. This field value depends on the GNE.
   - **TID**
     Specifies the “Target ID” for the TL1 device. This parameter is part of the TL1 addressing concept, and is required to uniquely identify a device. The TID is a predefined alphanumeric string. Obtain it from the local Network Administrator.
   - **User Name**
     Specifies the user ID for the maintenance user, as configured in the TL1 device.
   - **Password**
     Specifies the password for the maintenance user.
   - **Security String**
     Prevents selected users from viewing this model.
   - **Poll Interval (sec)**
     Specifies the frequency at which the device is polled for status updates. Change the value as needed, to increase or decrease the polling interval.
     Default: 60 (300 for some model types)

NOTE
If you increase the time between polling intervals, less bandwidth is required for traffic management. However, you receive device status updates less frequently.We recommend using the default polling interval for critical devices and using 600 seconds for less important devices.

– **Log Ratio**
Defines how many times DX NetOps Spectrum polls devices for updates before logging the results.
Default: 10 (DX NetOps Spectrum logs the polling results after it polls the device every tenth time).

NOTE
No entries or adjustments to the defaults are required for the remaining fields. For more information about field settings, see OneClick Administration.

5. Click OK.
A TL1 device model icon is displayed.

Max Telnet Sessions and Max Logins Per Telnet Attribute Considerations

Max Telnet Sessions

The Max Telnet Sessions field enables you to specify the total number of telnet sessions that TL1 Gateway can make to Gateway Network Element (GNE). Default is 1.

TL1 devices exist in a ring or group. The Gateway Network Element acts as a go-between the rest of the network and the TL1 devices within the ring. Therefore, DX NetOps Spectrum makes a telnet connection to the GNE.

This varies with hardware maximum device specifications. DX NetOps Spectrum can use as many sessions as the Max Telnet Sessions value has been set to allow. You can specify Max Telnet Sessions to one less than the hardware maximum to leave one available for the Network Administrator, but it is not required.

For any given ring, the number of telnet sessions that are used is the highest Max Telnet Sessions value among all the Gen_TL1_Dev models that are associated with that ring. So, if you have ten devices that are modeled for a single ring, if all the Max Telnet Sessions values are 1, then the TL1 daemon (TL1d) uses at most one telnet session when communicating with all the devices on that ring. If nine of the models have a Max Telnet Sessions value of 1 and one of the models has a Max Telnet Sessions value of 4, then the TL1d can use up to four concurrent telnet sessions when communicating with ANY of the devices on that ring.

The recommended usage for Max Telnet Sessions is to set it to the desired value on the Gen_TL1_Dev model which represents the TL1 proxy device and to leave the value at its default for other Gen_TL1_Dev models. That way, if you want to change the value, you only have to change it on one model.

Max Logins Per Telnet

The Max Logins Per Telnet field enables you to enter the number of logins that are permitted to be active simultaneously per telnet session. This depends on the GNE. Some authorize one active login at a time, others allocate more.

As with Max Telnet Session, when two or more devices from the same ring are modeled, the TL1 deamon (TL1d) uses the highest Max Logins Per Telnet value among all the Gen_TL1-Dev models that are associated with that ring.

The recommended usage for Max Logins Per Telnet is to set it to the desired value on the Gen_TL1_Dev model which represents the TL1 proxy device and to leave the value at its default for other Gen_TL1_Dev models. That way, if you want to change the value, you only have to change it on one model.

Important Processing Information for Max Telnet Sessions and Max Logins Per Telnet

It is important to understand the difference between having a value for Max Logins Per Telnet of 1 versus a value greater than 1.

When Max Logins Per Telnet Equals 1

When Max Logins Per Telnet equals one, the telnet connections are time-shared. Therefore, polls cannot occur simultaneously, but instead, are carried out in sequence. The maximum number of devices manageable is dependent primarily on the polling interval and the value of Max Telnet Sessions. Congestion and slow device response can adversely affect the management of the devices by DX NetOps Spectrum.

When Max Logins Per Telnet Is Greater Than 1

When Max Logins Per Telnet is greater than one, polls can occur simultaneously. The maximum number of devices manageable is a hard limit of Max Telnet Sessions multiplied with Max Logins Per Telnet. Therefore, congestion and slow device response has less impact on the ability of DX NetOps Spectrum to properly manage the devices.

The TL1 daemon (TL1d) communicates with TL1 devices over shared telnet sessions. That is, if you have say, ten TL1 devices on a single TL1 ring, TL1 Gateway can send ping requests to and can receive messages from all ten devices over a single telnet connection.

The TL1 daemon (TL1d) can also have several concurrent telnet sessions open to the same TL1 ring. So, TL1 Gateway could be using three telnet sessions open simultaneously to communicate with ten TL1 devices on a single ring.

Congestion Considerations

Because communication is shared over the connections, congestion can occur. The amount of congestion is determined through:

- Number of concurrent telnet sessions available to TL1 Gateway for use to the TL1 ring in question
- Number of TL1 devices on the ring that is managed in DX NetOps Spectrum
- Polling interval of the TL1 models
- Frequency of alerts sent to TL1 Gateway from the TL1 devices
- Time delay in the TL1 devices responding to commands from TL1 Gateway

If congestion over the telnet session is bad enough, ping requests that the SpectroSERVER sends does not return in time, and the TL1 models will sporadically go into a contact lost state.

If the network congestion is caused by too many alerts from the TL1 devices, a solution might be to specify an autonomous port for the devices.

If Max Logins Per Telnet equals one, the following two solutions are available:

- Increase the polling interval of the TL1 models -- the devices are polled less often causing less congestion, resulting in better performance.
- Increase the telnet sessions to TL1 devices ratio, by either increasing the number of concurrent telnet sessions the TL1d can use or by decreasing the number of TL1 devices on the ring.

Upgrade Considerations

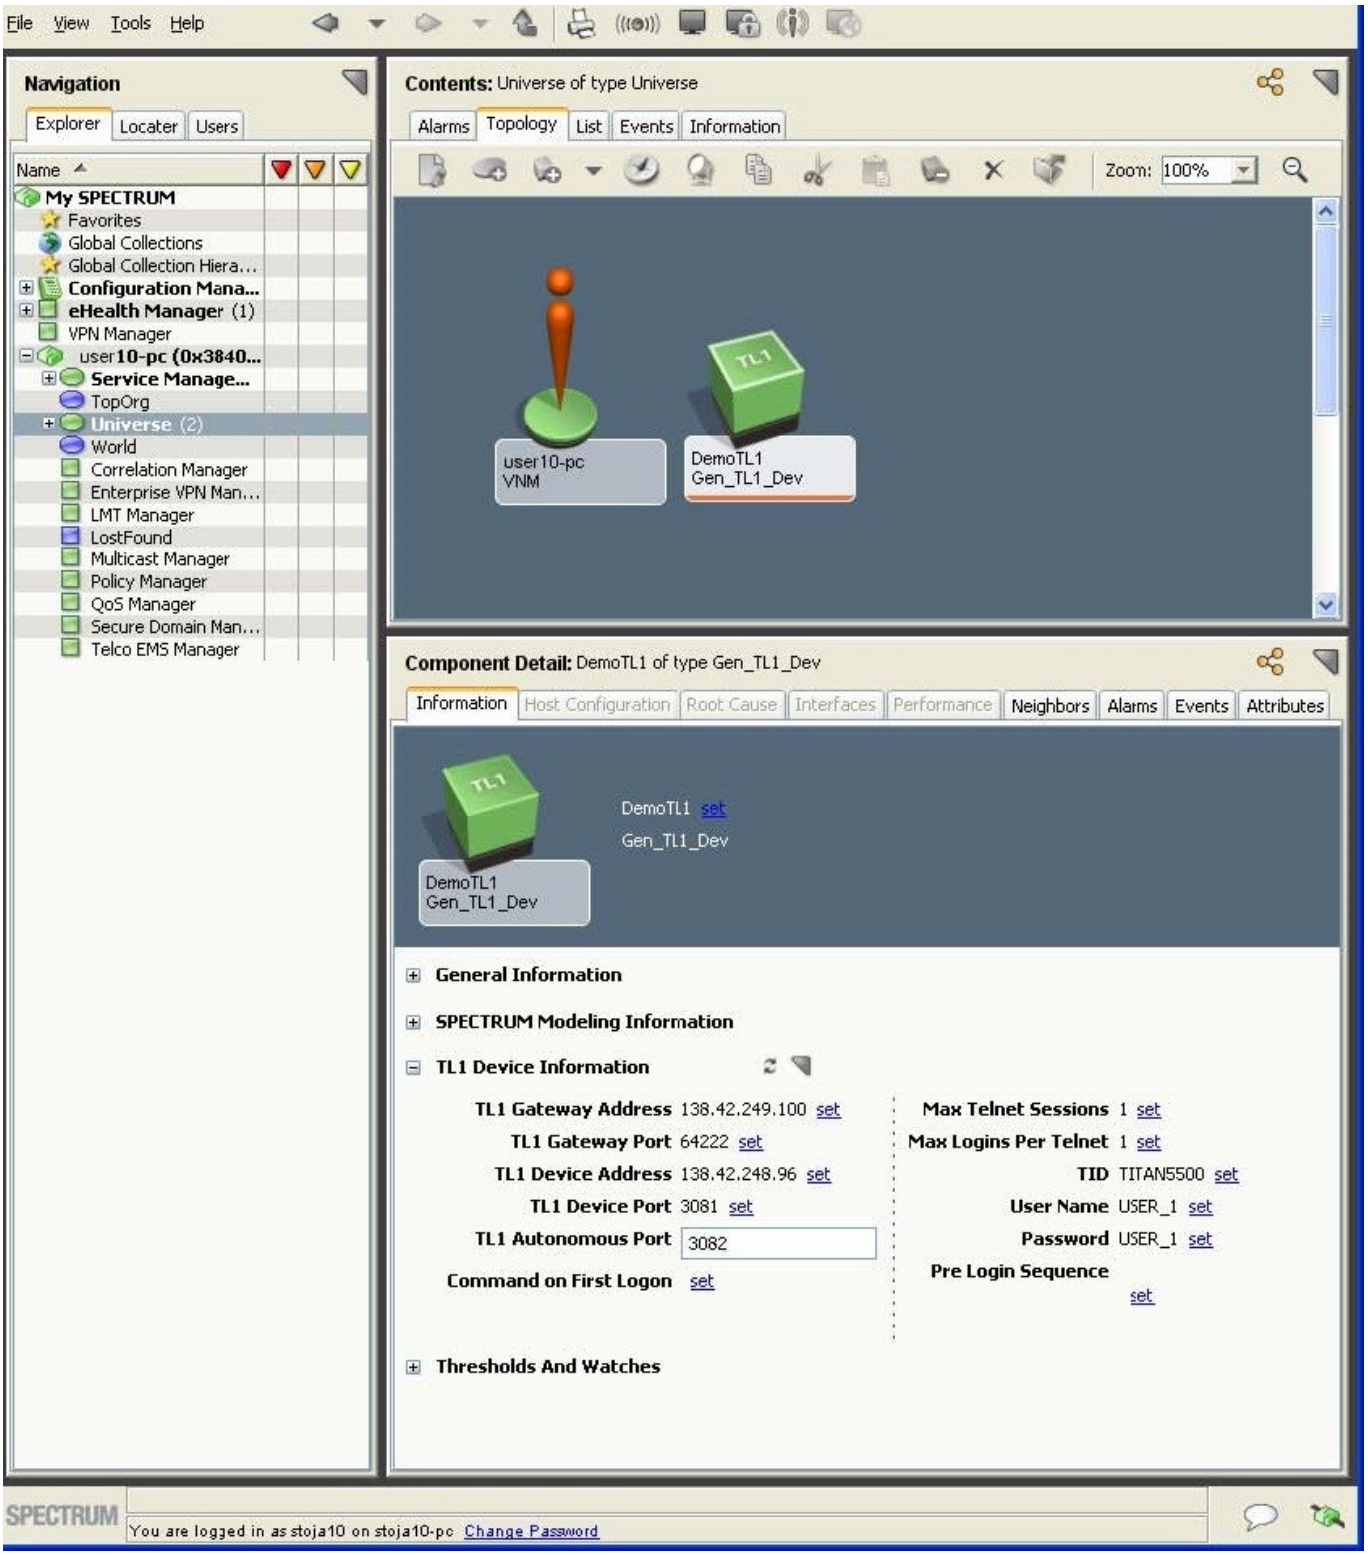
Of particular importance to customers who are upgrading:

- Due to the overhead caused by the new functionality, we have increased the default value for the DCM Timeout attribute (0x110c4) from 3000 to 5000. However, if the customer is upgrading, this change is not made because the Timeout attribute has the 'Preserve Value' flag set.
- If the DMC timeout value is left at 3000, the ping requests sent by the SpectroSERVER will probably time out sporadically. After upgrading, customers change the Timeout value for all Gen_TL1_Dev models that they have currently modeled to be 2000 milliseconds higher than their current value. Likewise, they must also increase the Gen_TL1_Dev model type default value for Timeout by 2000 milliseconds.

TL1 Devices with Autonomous Port

Some TL1 devices support command ports only and have a port dedicated to autonomous messages. TL1 Gateway supports this option.

To use it, highlight the TL1 device icon and select the Information tab in the Component Detail view. The TL1 Autonomous Port can be set in the TL1 Device Information section.



Command on First Logon

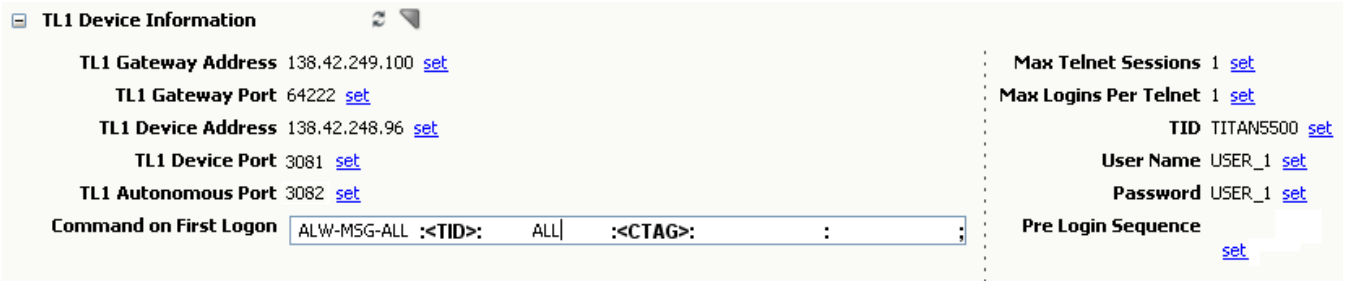
The value that appears in the Command on First Logon field is issued to the device the first time you log into that device. In the image shown below, the ALW-MSG-ALL command enables the device to send alerts to the TL1 Gateway. Note that some devices do not send alerts automatically. The gateway can then relay the alerts to DX NetOps Spectrum as it receives them.

You can customize the Command on First Logon for any command that requires customization. DX NetOps Spectrum automatically replaces the <TID> and <CTAG> values. The <TID> value uses the TID value that you specified in the Create Model Type dialog. The <CTAG> value is automatically generated by the TL1 Gateway for proper communication.

The following image shows an example of the Command on First Logon field in the TL1 Device Information subview.

NOTE

The TL1 Device port and TL1 Autonomous port can be same.



Pre Login Sequence

Before logging into a TL1 device, the TL1 daemon can send a few characters to the device to wake up the telnet session. These characters are stored in the Pre Login Sequence attribute. The default is a single newline character.

For some cases, multiple newlines may be more appropriate. To change the Pre Login Sequence, highlight the TL1 device icon and select the Information tab in the Component Detail view. The Pre Login Sequence can be set in the TL1 Device Information section.

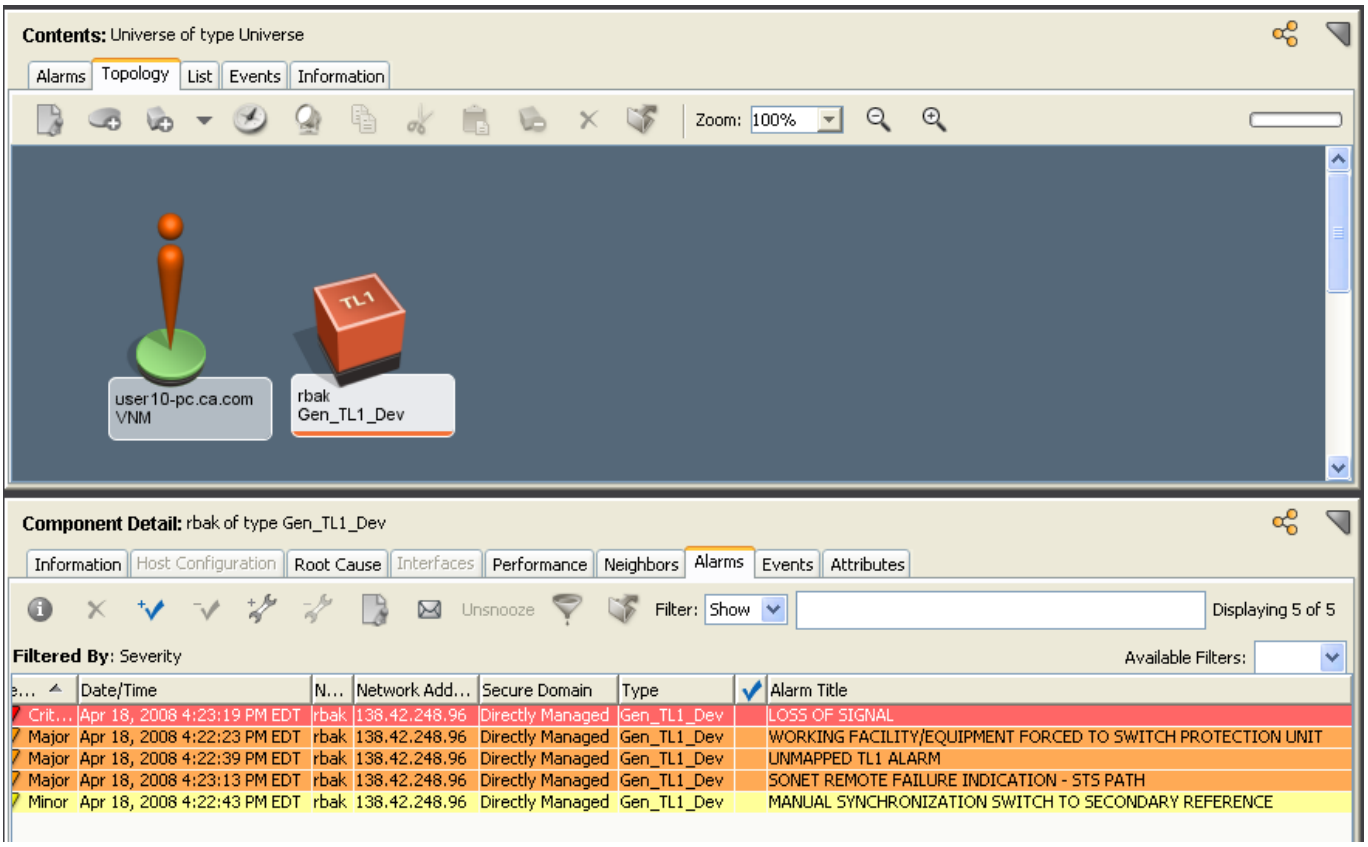
The TL1 AlarmMap

The TL1 Gateway AlarmMap is an internal mapping of TL1 events and alarms to DX NetOps Spectrum alerts. The AlarmMap is used by the TL1 daemon to determine whether an incoming TL1 event or alarm is discarded or be converted to an alert code and forwarded to DX NetOps Spectrum. Thus the AlarmMap functions as a filter to discard unnecessary TL1 events or alarms.

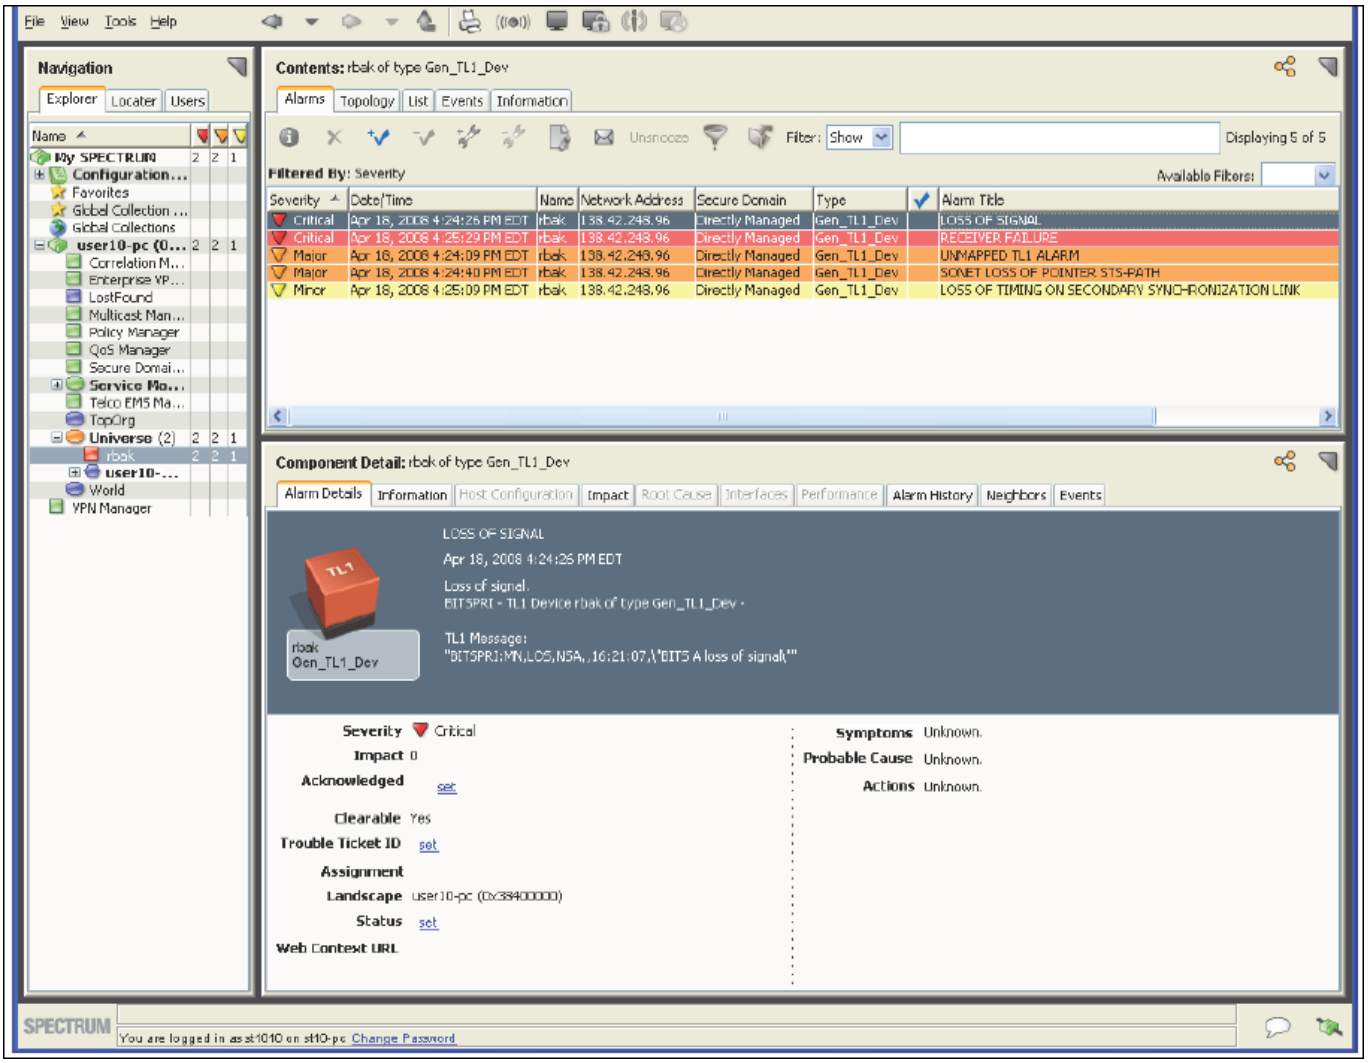
Another mapping file is also required to support the AlarmMap. The alert code that is specified in the TL1 AlarmMap is processed by a corresponding AlertMap file on the SpectroSERVER. If the AlertMap file is missing, TL1 alerts are not properly mapped to events. For more information, see AlertMaps for TL1.

An AlarmMap usually includes a default entry, which is used for any TL1 events or alarms that lack a specific mapping. That is, all unmapped TL1 events/alarms result in the same DX NetOps Spectrum alert that is specified in the default entry.

TL1 alarms are displayed in the following image:



TL1 details per alarms are displayed in the following image:



Format of the AlarmMap

The AlarmMap is a sequence of records, each comprising the following five comma-separated fields:

```
<type>,<condition>,<alert-code>,<clr-alert-code>,<process>
```

- **<type>**
  A text string specifying the entry type as either “ALM” (for alarm) or “EVT” (for event).
- **<condition>**
  A text string identifying a TL1 condition type (TL1 alarms) as specified in the Telcordia standards document GR-833-CORE. If this string is blank, or empty, the record serves as the default entry for the AlarmMap. If the string ends in a hyphen (e.g., OGCCS-), all conditions that start with that string are mapped by this entry. It resembles a “wildcard.”
- **<alert-code>**
  A hexadecimal literal with a leading “0x” that specifies the alert code to be used by DX NetOps Spectrum for this TL1 event/alarm.
- **<clr-alert-code>**

A hexadecimal literal with a leading “0x” that specifies the code that DX NetOps Spectrum uses to clear the TL1 event/alarm.

- **<process>**
  Is a boolean value (TRUE or FALSE) that specifies whether the event/alarm is processed. If TRUE, an alert is generated for DX NetOps Spectrum. If FALSE, the incoming TL1 event/alarm is discarded and nothing is forwarded to DX NetOps Spectrum.
  The following is an example of an AlarmMap:
  ALM, ,0x3d50001 ,0x3d50002 ,TRUE <------ DEFAULT
  ALM,LINETERM ,0x3d500f3 ,0x3d500f4 ,TRUE
  ALM,ECOI ,0x3d501b9 ,0x3d501ba ,TRUE
  ALM,SLOR ,0x3d501c9 ,0x3d501ca ,TRUE
  EVT,NTYDGSP ,0x3d5009d ,0x3d5009e ,TRUE
  The commas can be surrounded by spaces. Everything after the <process> field and a space is treated as comment for better readability.

The contents of the AlarmMap are critical to the performance of TL1 Gateway. Configure the AlarmMap such that only those TL1 alarms in which you are interested are processed. In other words, verify that the <process> value is set to FALSE for all TL1 alarms that you do not want to generate a DX NetOps Spectrum alert.

WARNING

If an “unwanted” TL1 event/alarm does not appear in the map, it is still processed through the default mapping, assuming that the map has a default entry. To prevent this extra processing, you can take one of the following steps:

- Include all unwanted TL1 events/alarms in the map with their <*process*> values set to FALSE.
- Remove the default entry.

The tl1map Utility

TL1 Gateway includes a command-line tool that is called tl1map that lets you inspect the AlarmMap and perform either of the following two operations:

- Extract an AlarmMap from either a TL1 device model or from the TL1 device model type (Gen_TL1_Dev).
- Import an AlarmMap in the form of a text file either to a TL1 device model or to the Gen_TL1_Dev model type.

The tl1map tool is located in your top-level DX NetOps Spectrum directory's TL1Apps subdirectory. You can run tl1map either from the shell command line or from within scripts (if you need to perform more complicated AlarmMap manipulations). In either case, tl1map is a SpectroSERVER client, so SpectroSERVER must be up and running.

NOTE
The tl1map utility is dedicated to models/model types of the Gen_TL1_Dev hierarchy only. It is not intended to be used with any other models/model types and could cause potential data corruption if not used properly.

Syntax

```
.tl1map {load | dump} -f mfile {-t | -m} handle [host]
```

- **dump**
  Extracts the internal AlarmMap in text format and saves it to the file specified by the -f option, in text format.
- **load**
  Processes the input file that is specified by the -f option and writes an AlarmMap to the corresponding attribute.
- **-f mfile**
  Indicates that the next entry will provide the name of a particular map file (mfile). In load mode, the supplied input file is expected to have AlarmMap syntax, and it is converted into an internal TL1 AlarmMap object. When in dump mode, the contents of the already existing, internal AlarmMap is extracted, formatted, and written to the specified mfile. This

file is then suitable for visual inspection and processing by a text editor, so it can be changed, and re-imported using the load option.

- **-t**
  Specifies that the handle provided is the model type handle of the TL1 device model type.
- **-m**
  Specifies that the handle provided will the model handle of a TL1 device model.
- **handle**
  Specifies the handle of either the TL1 device model type (if the -t flag is used) or the TL1 device model (if the -m flag is used).
  Limits: Hexadecimal format
- **host**
  The name of the DX NetOps Spectrum host. This is only needed when accessing a remote host, or if the Unix hostname command reports a mixed-case name, while the “true” host name was advertised in lower-case format. In any case, tl1map should be run on the local host.

NOTE
The -f, -t, and -m -f options can appear in any order.

AlarmMap Extraction

If tl1map is invoked with the dump option, it will read the current AlarmMap attribute value from either a model (-m option), or a model-type (-t option), convert it into a human-readable format, and write it to the file specified by the -f option. That file will also contain an informational header, which includes things like model name, model type name, model handle, model type handle, host name, and the current time stamp (based on the machine where the utility was invoked). The header is formatted as a comment, so it will not affect any subsequent import operation using this machine-generated file.

Typically, you would examine this AlarmMap file with a text editor, make any desired modifications, and then import the file again by invoking tl1map with the load option.

NOTE
The entries in the output file are in no particular order. If you want to compare two different AlarmMaps, you need to do the following:

- Strip off the comment header.
- Sort the files.
- Perform the actual comparison.

Importing an AlarmMap

To import an AlarmMap under any of the following scenarios, use the tl1map utility with the load option:

- Creating an initial AlarmMap based on documents from a TL1 device vendor or on TL1 standards documents.
- Extracting a previously stored AlarmMap, applying some changes, and importing the changed version again.
- Extracting the AlarmMap from one model/model type, and importing it to another model/model type (possibly on another host)

When importing an initial AlarmMap from a file, you have to make sure that the file conforms with the format specifications for AlarmMap files.

The tl1map utility displays limited diagnostic messages if it encounters illegal entries in the AlarmMap file. If there were any errors, no data is written to the model/model type attribute.

Examples of tl1map Usage

The following examples illustrate how the tl1map utility might be used to perform various specific tasks. Note that the examples use /dev/stdin and /dev/stdout. Since these are not available on NT, you would therefore use intermediate files instead of Unix-style pipes.

To import an AlarmMap to model 0x146007

```
tl1map load -f custom.amap -m 0x146007
```

To export the AlarmMap to a file

Exporting the AlarmMap to a file enables it to be modified. The modified file can be reloaded/imported.

```
tl1map dump -f exp.amap -t 0x4010000
```

...then, after you edit and save exp.amap ...

```
tl1map load -f exp.amap -t 0x4010000
```

To copy the AlarmMap from one model to another

```
tl1map dump -m0x1503fcc -f/dev/stdout |
tl1map load -m0x1504003 -f/dev/stdin
```

To delete the “LINETERM” entry from the AlarmMap

```
tl1map dump -m0x1504003 -f/dev/stdout |
sed '/LINETERM/d' |
tl1map load -m0x1504003 -f/dev/stdin
```

To copy a model-based map from one host to a model type-based map on another host:

```
tl1map dump -m0x1504003 -f/dev/stdout hosta |
tl1map load -t0x25040cc -f/dev/stdin hostb
```

The following example shows a shell script that could be used to implement a simple AlarmMap editor:

```
#! /bin/ksh
#
# A simple AlarmMap editor
#
# Syntax:  tl1edit { -m | -f } handle [ host ]
#

# Your favorite text editor
if [[ -z $EDITOR ]] ; then
EDITOR=vi
fi

# Generate a unique, temp file name
MF=`date '+%Y%m%d%H%M%S.almap'`

# Dump the AlarmMap to that temp file
tl1map dump -f $MF $*

# Make a backup copy
cp $MF $MF.orig

# Invoke your favorite editor on that file
```

```
$EDITOR $MF

# If there are no changes, remove temp mapfiles & exit
diff $MF $MF.orig > /dev/null && rm -rf $MF $MF.orig && exit

# If there were changes, load them into the attribute
tl1map load -f $MF $*
```

AlertMaps for TL1

The TL1 AlarmMap converts a TL1 autonomous message into an alert (not an event) that is processed by DX NetOps Spectrum. DX NetOps Spectrum handles these alerts similarly to SNMP traps. Configure the AlertMap with the alert code that is specified in the TL1 Alarm Map.

NOTE
The alert code that is specified in the AlertMap is a decimal number rather than an SNMP trap OID.

Each alert from the TL1 Gateway offers the following standard, unchangeable varbinds:

- Varbind 1: AID
- Varbind 2: Severity
- Varbind 3: Condition
- Varbind 4: Alarm Message
- Varbind 5: Alert Code (as specified in the TL1 AlarmMap)

The AlertMap must map these alert variables to event variables, one for one.

A supported entry in the AlertMap resembles the following syntax:

```
64352257 0x3d5f001 1(1,0) 2(2,0) 3(3,0) 4(4,0) 5(5,0)
```

The previously mentioned entry maps alert code 64352257 (0x3d5f001 in decimal) to event code 0x3d5f001, and copies each of the five alert variables to the event.

For more information about the AlertMap, EventDisp, CsEvFormat, and CsPCause files, see Event Configuration .

Managing TL1 Gateway Daemon

TL1 Gateway Daemon

A TL1 Gateway daemon (TL1d) must be up and running in order to translate alarms from the modeled TL1 device into DX NetOps Spectrum events and alarms. The daemon is located in your top-level DX NetOps Spectrum directory's TL1Apps subdirectory. It has the following syntax:

```
TL1d [-p gw-port]
```

- **-p gw-port**
  Specifies that a TL1 Gateway port (gw-port) other than the one specified at model creation will be designated for communication between the daemon and SpectroSERVER.
  Default: 64222

  NOTE
  CA recommends that you *not* use the value 65535, as it is likely to conflict with other applications.

Start the TL1 Daemon on a DX NetOps Spectrum Server

Start the TL1 daemon to start handling alarms from TL1 devices.

This procedure varies only slightly (see Step 3) for the Windows platforms.

Follow these steps:

1. Launch a command shell window.
2. Navigate to the TL1Apps subdirectory in your top-level DX NetOps Spectrum directory.
3. Enter the command:

   ```
   TL1d
   ```

   or, if you want to use a different gateway port...

   ```
   TL1d  -p <your-gw-port number>
   ```

   As soon as you see “@(#)” followed by the actual port number, the daemon is running. You can minimize the command shell window.

Start the TL1 Daemon on a Remote Server

It is recommended to know the IP address of the server that hosts the CORBA osagent in your environment. This server is most likely the same computer where DX NetOps Spectrum is running.

Take a few steps to start the TL1 Daemon on a remote server on Windows.

Follow these steps:

1. Launch a command shell window.
2. Navigate to the directory where your TL1d.exe file resides.
3. Enter one of the following commands:

   ```
   TL1d
   ```

   Or, to use a different gateway port, enter the following command:

   ```
   TL1d -p <your-gw-port number>
   ```

   As soon as you see “@(#)” followed by the actual port number, the daemon is running. You can minimize the command shell window.

Terminating the TL1 Daemon

The specific command or procedure for gracefully terminating the TL1 daemon depends on the platform the daemon is running on.

- On NT, bring up the Task Manager, select the TL1d process, and then terminate it.

Customize the Tomcat Log Path

From 10.4.2.1, you can customize the OneClick WebServer Tomcat log path to a non-default location.

Follow these steps:

Windows:

1. Open the **OneClickService.conf** file from the `%SPECROOT%/tomcat/bin/` directory.
2. Add a new `jvm_opt` property and set the property value as the new path for tomcat log file.

   ```
   jvm_opt=-DCATALINA_OUT=C:\tomcat-log\stdout.log
   ```

3. Modify the `log_file` path to new log location.

   ```
   log_file=C:\tomcat-log\stdout.log
   ```

4. Save and close the file.
5. Restart the Tomcat.

Linux:

1. Update the `catalina.sh` file located at the `$SPECROOT/tomcat/bin/` directory.
2. Add `CATALINA_OUT` property to the `JAVA_OPTS` property section.

```
JAVA_OPTS="-DOneClick -server -Xmx10000M -XX:+HeapDumpOnOutOfMemoryError -Djava.awt.headless=true
 -Djavax.net.ssl.trustStore=$SPECROOT/custom/keystore/cacerts -Dfile.encoding=UTF-8 -
Dcom.sun.management.jmxremote -Dorg.apache.coyote.USE_CUSTOM_STATUS_MSG_IN_HEADER=true -DCATALINA_OUT=/
var/log/tomcat/catalina.out"
```

3. Set the CATALINA_OUT property value as the new path for tomcat log file.

```
CATALINA_OUT="/var/log/tomcat/catalina.out"
```

4. Save and close the file.
5. Restart the Tomcat.

The Tomcat log file will be generated in the new location post this change.

Integrating

This section contains information about integrating DX NetOps Spectrum with other CA products.

Integration with UIM

NOTE
Previously, Unified Infrastructure Management (UIM)-DX NetOps Spectrum integration sync status was not getting updated for hosts and VMware in the OneClick view. Now, in 10.4.1, the integration sync status is updating correctly under the **UIM Host Sync Configuration** section and **UIM Virtualization Sync Configuration** section (**Navigation** view, **UIM Manager**, **Information**, **Configuration**), as appropriate. For more information, see the related section UIM-DX NetOps Spectrum Sync Status in this article.

WARNING

There are major changes to the GUI for configuring the integration from 10.2.3 and spectrumgtw probe v8.67. Refer to the spectrumgtw AC documentation for configuring the integration.

NOTE
From the 10.1.2 release, the SNMP Gateway probe and SBGW / Southbound gateway are no longer recommended for alarms synchronization from UIM to DX NetOps Spectrum. CA recommends using the Spectrum Gateway (spectrumgtw) probe for alarm synchronization from this release.
We recommend that you go through the DX NetOps Spectrum-UIM Integration using spectrumgtw probe - FACT SHEET to understand the changes to the integration whether you are new to this integration or an existing user.
For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.
We recommend you deploy the latest hotfix that is available for the probes.

NOTE

In previous releases of UIM, the nisapi_service_host package was deployed to the service_host probe. As of UIM release 8.47, the service_host probe was deprecated and its functionality was moved to the wasp probe. This change has the following implications for your DX NetOps Spectrum integration: You no longer have to deploy nisapi separately. By default, your DX NetOps Spectrum integration uses the nisapi package deployed in wasp as part of a UIM installation or upgrade.

- By default, the wasp probe uses port 80. However, because the wasp probe is a core component in UIM, this port should already be open in a properly functioning UIM environment. For more information, refer to the wasp probe documentation.

Overview

The DX NetOps Spectrum - Unified Infrastructure Management (UIM) (formerly known as CA Nimsoft or CA Nimsoft Monitor) Integration expands the DX NetOps Spectrum monitoring capabilities of the infrastructure with information and alarms from UIM and provides the following benefits:

- Provides a holistic view of the availability of host servers and VMware environment across the network and their performance data for fault management in a single pane of the application. It also provides end to end root cause and impact analysis across network and server elements, extending DX NetOps Spectrum core capabilities to other infrastructure domains.
- Advance condition correlation between UIM and DX NetOps Spectrum helps in building robust fault management.
- Leverage UIM capabilities for server management and use the DX NetOps Spectrum network management capabilities for an end to end infrastructure management.

The following video describes how you can integrate DX NetOps Spectrum and UIM to monitor your infrastructure and to use DX NetOps Spectrum root cause analysis feature to rapidly troubleshoot and resolve issues:

- Integrating DX NetOps Spectrum and UIM through the Web Server for Server Management
- Integrate DX NetOps Spectrum and UIM for Virtualization Management

DX NetOps Spectrum and UIM bidirectional Integration

You can enable bidirectional integration between CA Spectrum r10.3 and CA UIM r8.5.1 using the **spectrumgtw** probe v8.67.

This integration enables reception of all UIM alarms by DX NetOps Spectrum and reception of DX NetOps Spectrum inventory information and all DX NetOps Spectrum alarms by UIM.

For more on the bidirectional integration see DX NetOps Spectrum and UIM Bidirectional Integration.

Please see the following video to understand more about the bidirectional integration and its capabilities:

Enhancements and Improvements to the DX NetOps Spectrum and UIM Integration

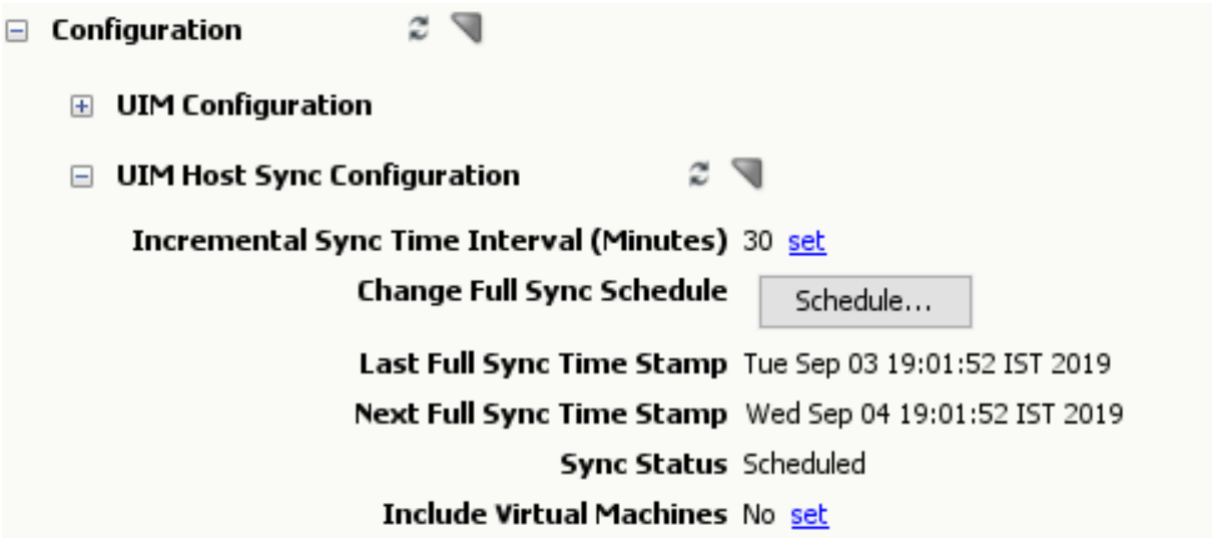
This section includes enhancements and improvements made to the integration.

UIM-DX NetOps Spectrum Sync Status

Previously, UIM-DX NetOps Spectrum integration sync status was not getting updated for hosts and VMware in the OneClick view. Now, in 10.4.1, the integration sync status is updating correctly under the **UIM Host Sync Configuration** section and **UIM Virtualization Sync Configuration** section (**Navigation** view, **UIM Manager, Information, Configuration**), as appropriate.

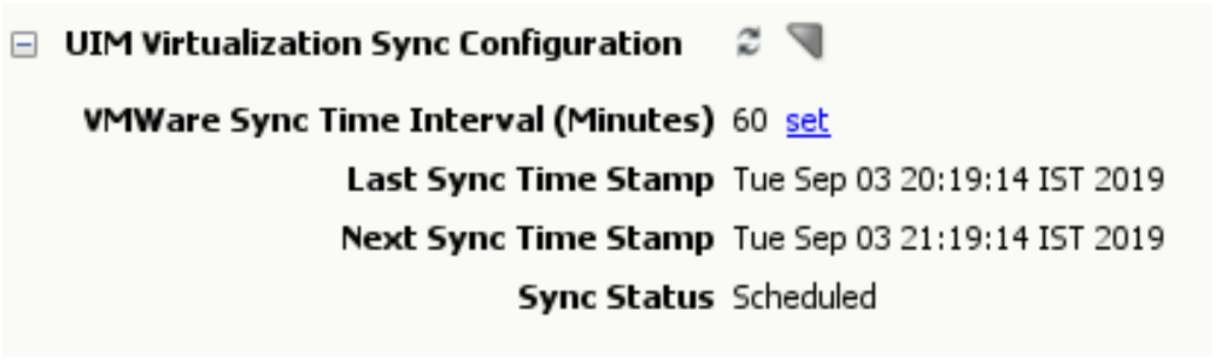
- Under the **UIM Host Sync Configuration** section, the sync status in the following parameters now gets updated correctly:
  - Last Full Sync Time Stamp
  - Next Full Sync Time Stamp
  - Sync Status

  The following screenshot shows the required information:



- Under the UIM Virtualization Sync Configuration section, the sync status in the following parameters now gets updated correctly:
  - Last Sync Time Stamp
  - Next Sync Time Stamp
  - Sync Status

  The following screenshot shows the required information:



GUI Changes to the UIM Configuration page in DX NetOps Spectrum

From the current release of DX NetOps Spectrum, major GUI changes are done to the UIM configuration section in the DX NetOps Spectrum Administrations page. You can choose the integration option to configure it from DX NetOps Spectrum or UIM's spectrumgtw probe. For more details, see the Changes in Integration Architecture section in the Integration Architecture page.

Following are the available configuration options:

- **No Integration** - Select this option to disable DX NetOps Spectrum-UIM integration.
- **Legacy Integration** - Select this option if you are using the spectrumgtw probe v8.67 with CA Spectrum 10.2.3
- **SpectrumGateway Integration** - Select this option if you are using the spectrumgtw probe v8.65. The Spectrum-UIM integration is configured through UIM's spectrumgtw probe.

Configuring Integration through UIM's spectrumgtw Probe v8.65

If you are using UIM's spectrumgtw probe (v8.65) and CA Spectrum r10.2.3, the integration between DX NetOps Spectrum and UIM is configured through UIM's spectrumgtw probe (v8.65) Admin Console. Select the 'SpectrumGateway

Integration' option in the DX NetOps Spectrum OneClick Admin pages > UIM Configuration page. Click 'Save' then go to UIM's spectrumgtw probe (v8.65) Admin Console to complete the configuration. For configuration instructions, see the Deploy and Configure the Probe section, in the spectrumgtw probe documentation.

NOTE

Before switching the existing integration from **Legacy Integration** to **SpectrumGateway Integration**, ensure that you have installed the patch **10.02.03.PTF_10.2.303** on top of 10.2.3. This patch is a solution to retain the UIMEventAdmin Models after moving integration from Legacy Integration to SpectrumGateway Integration.

VHM Enhancements

From 10.2.3, DX NetOps Spectrum can monitor both UIM models and SystemEdge models when DX NetOps Spectrum-UIM Integration is enabled with Multi-tenancy.

When the integration is enabled with Multi-tenancy, UIM origins are mapped to DX NetOps Spectrum landscapes. In this scenario, DX NetOps Spectrum monitors UIM models on the landscapes which are part of Multi-tenancy mapping and can monitor SystemEdge AIM based models on the landscapes which are not part of Multi-tenancy mapping.

When the DX NetOps Spectrum-UIM Integration is enabled without Multi-tenancy, DX NetOps Spectrum monitors UIM models only. All the SystemEdge AIM based models are deleted on all the landscapes.

vMotion Support Enhancements

From r10.2.3, when a VM is migrated (vMotion) in VMware, then the spectrumgtw probe picks the changes and sends it to DX NetOps Spectrum. The changes are shown in the DX NetOps Spectrum hierarchy. The reflection time for the changes in the DX NetOps Spectrum hierarchy is based on the frequency at which the UIM VMware probe publishes the changes to UIM. This functionality is supported for both legacy integration and integration through spectrumgtw probe 8.65 version.

NOTE
After deploying and starting the spectrumgtw 8.6.5, you must restart the UIM VMware probe.

Reconciliation Enhancements

In earlier releases, when DX NetOps Spectrum models UIM host Server if the network devices such as routers or switches have the same IP address then DX NetOps Spectrum reconciles based on IP address and network devices are displayed as part of UIM Manager Hierarchy.

Starting from 10.2.3, for the same scenario, DX NetOps Spectrum will create UIM Host Server/UIM VM models in the UIM Manager Hierarchy and stop reconciling with the network devices with IP Address.

Support for Customized Alarms

From r10.2.3, you can manage customization (changing the severity) for UIM alarms in DX NetOps Spectrum. The spectrumgtw probe 8.65 version is enhanced to allow the Spectrum users for this customization. For more information, see the Support for Customized Alarms section in the spectrumgtw AC Configuration documentation.

Maintenance Schedule Synchronization

From r10.2.3, the Maintenance Mode schedules on devices from DX NetOps Spectrum will be synchronized to UIM and from UIM to DX NetOps Spectrum, using the integration via spectrumgtw probe v8.65. For more information, see the Schedule Maintenance Mode section.

Multi-Tenant support in DX NetOps Spectrum

From r10.2.2, DX NetOps Spectrum supports multi-tenancy by leveraging the multi-tenant capability of UIM through the bidirectional DX NetOps Spectrum-UIM integration enabled by the Spectrum Gateway (spectrumgtw) probe. The Multi-

tenancy model in UIM is based on the Origin tag (Ownership). Using REST calls provided by DX NetOps Spectrum the spectrumgtw probe leverages this origin information. The spectrumgtw probe allows DX NetOps Spectrum to map Origin with Landscape. For more information on multi-tenancy in DX NetOps Spectrum see Multi-Tenant support in DX NetOps Spectrum.

Filter and Synchronize Specific Alarms

The DX NetOps Spectrum and UIM integration support filtering and synchronizing specific alarms from Spectrum to UIM or UIM to Spectrum. The alarm filter solution reduces clutter and eliminates the sync of alarms that you do not want to monitor. After applying the alarm filters you can see only the filtered alarms in Spectrum or UIM. You can configure the alarm filtering in the Spectrum Gateway (spectrumgtw) probe. For more information, see Synchronize Specific Alarms.

Selective Inventory Synchronization

From r10.2.1, the DX NetOps Spectrum and UIM integration support selective synchronization of Server Management entities only. This functionality allows you to avoid full inventory synchronization and select only the server inventory which you want to get synced from UIM to Spectrum. For more information, see 'Selective Inventory Synchronization' section in the Integrating DX NetOps Spectrum and UIM through the Web Server for Server Management page.

Custom Attributes Synchronization

You can synchronize custom attributes from UIM to DX NetOps Spectrum. When you enable the DX NetOps Spectrum-UIM Bidirectional Management integration, the following custom attributes are synced from UIM to DX NetOps Spectrum. For more information see, custom attributes section.

Supporting AWS (Amazon Web Services) Cloud Monitoring

AWS Cloud (Amazon Web Services) Monitoring is supported by DX NetOps Spectrum using the UIM and DX NetOps Spectrum integration. The aws (Amazon Web Services) The monitoring probe deployed in UIM enables the metric data collection from the AWS instances. This data is then synchronized from UIM to DX NetOps Spectrum. For more information, see Supporting AWS (Amazon Web Services) Monitoring.

Supporting Azure (Microsoft Azure Monitoring)

Microsoft Azure Monitoring is supported by DX NetOps Spectrum using the UIM and DX NetOps Spectrum integration. The azure (Microsoft Azure Monitoring) probe deployed in UIM enables the metric data collection from the AWS instances. This data is then synchronized from UIM to DX NetOps Spectrum. For more information, see Supporting azure (Microsoft Azure Monitoring).

ESX Host Server Maintenance Mode enhancement

From DX NetOps Spectrum 10.2.1, you can now choose whether to retain the default correlation between the ESX host and the VMs during Maintenance mode. By default, all the VMs under the ESX Host are automatically placed in maintenance mode. You can now choose to set only the parent ESX host server in maintenance mode and not the child virtual machines that are hosted on the ESX server. For more information see, Place ESX Host in Maintenance Mode or Hibernation.

SNMP profile Synchronization

From this release, SNMP profiles for DX NetOps Spectrum inventory in a Global Collection is synchronized by the Spectrum gateway (spectrumgtw) probe to SNMP Collector so that it can monitor those without re-entering SNMP credentials.

When inventory data is synchronized from DX NetOps Spectrum to UIM via spectrumgtw probe, the SNMP credentials are also synchronized and stored in the UIM database. The SNMP profiles synchronized from DX NetOps Spectrum

are shared with the Discovery server, and once the SNMP Collector probe provides the IP range relevant to the profiles synchronized, you no longer need to re-enter the SNMP credentials while logging in to the UIM interface.
The configuration of integration parameters is done in the Spectrum gateway configuration. This capability is only available for the integration between DX NetOps Spectrum 10.2.1 and CA UIM 8.5.1 using the spectrumgtw probe 8.6 versions.

SSL communication between Spectrum Gateway (spectrumgtw) probe and DX NetOps Spectrum

The DX NetOps Spectrum- UIM integration between DX NetOps Spectrum 10.2.1 and CA UIM 8.5.1 using Spectrum Gateway (spectrumgtw) probe 8.6, supports secure (https) communication the gateway probe and DX NetOps Spectrum. You need to ensure that the DX NetOps Spectrum OneClick Server is configured for SSL (HTTPs) and that https is selected as the communication protocol in the Spectrum Gateway (spectrumgtw) probe configuration.

For more information, see Configure OneClick for Secure Sockets Layer

DX NetOps Spectrum Fault-Tolerant Scenarios

Back-end changes have been made to DX NetOps Spectrum to prevent modeling new entities, reported by UIM, in a particular SpectroSERVER if it is a Secondary SpectroSERVER. However, updating the models and their relationships will still be done in secondary SpectroSERVER.

> **NOTE**
> While triggering DC Migration, ensure that both source and destination SpectroSERVER are running on the primary SpectroSERVER in the Fault-Tolerant environment.

Logging Improvements

Improved the OneClick Server logging for DX NetOps Spectrum-UIM integration to give insights into what has been modeled a what was not, movement of VMs across different ESX hosts, relationship additions and deletions and so on.

Reconciliation Enhancements

Till now DX NetOps Spectrum used to reconcile entities like Vcenters, VMs, and Hosts. DX NetOps Spectrum is able to reconcile logical entities like Datacenters, Clusters and Resource Pools with existing models of corresponding entity types if they were modeled previously to prevent duplication in error scenarios.

DX NetOps Spectrum will now reconcile ESX hosts with existing ESX hosts or UIMHostServer models only. If ESX host is reconciled with a UIM Host Server model then the existing UIMHostServer model will be deleted and a new ESX model will be created for that ESX host. This newly created model will be part of both Virtualization and Server hierarchies.

> **NOTE**
> If an ESX server is already modeled in DX NetOps Spectrum with a model type other than UIMVirtualMachineHost or UIMHostServer, the ESX Server is not reconciled as part of the DX NetOps Spectrum-UIM integration.

Out of box solution for managing VM as a server

You no longer need to deploy the **VMware probe** to synchronize VMware inventory. If VMs are being monitored as a server in UIM it can be pulled into DX NetOps Spectrum for Server management.

> **NOTE**
> The VMware probe allows you to monitor standalone ESX Host Servers and it's corresponding hierarchy in a UIM context. DX NetOps Spectrum does not support this. This is only supported if you are monitoring ESX Servers through VCenter using VMware probe.

Delete Unreported Entities in DX NetOps Spectrum (Virtualization Management)

In previous versions of the DX NetOps Spectrum-UIM integration, the virtual entities/ models that were not reported during a synchronization cycle were auto-deleted. From this release, these models will be placed in the Unreported Entities/ Models container, instead of being deleted.
See Delete Unreported Entities.

Integration Architecture

Changes in DX NetOps Spectrum 10.4.2

In the current release, DX NetOps Spectrum-DX Infrastructure Manager integration has the following changes:

Handling of Unreported Inventory

From 10.4.2, DX NetOps Spectrum identifies unreported inventory from DX Infrastructure Manager entities and deletes the unreported inventory if inventory does not exist in DX Infrastructure Manager. When the inventory exists in DX Infrastructure Manager after the sync, it retains the unreported inventory to verify after the next synchronization. By default, the attribute is enabled. If **deleteUnreportedEntities** attribute is enabled in DX NetOps Spectrum, DX NetOps Spectrum checks the presence of the unreported inventory models in DX Infrastructure Manager and deletes the models that are no longer present in DX Infrastructure Manager.

Follow these steps:

1. Log in to the OneClick WebApp.
2. On the **Locator** tab, navigate to **UIM Manager**.
3. In the **Components Detail** section, select **Attribute** tab.
4. Search **deleteUnreportedEntities** to view the current setting, enabled by default.
5. Right-click the **deleteUnreportedEntities** attribute and select **Edit**.
6. In the **Edit UIM Manager** popup, change the setting if required.
7. Select **OK** to apply the change.
   The **Attribute Edit Results** window shows the status.
8. Close the window, on the successful assignment of the attribute.

Changes in DX NetOps Spectrum 10.4.1

In the current release, DX NetOps Spectrum-UIM integration has the following changes:

Customize the HostSsync Payload Size in OneCLick

From 10.4.1, you can customize the maximum size of the payload that you want to receive from the spectrumgtw probe to DX NetOps Spectrum during the host server sync. Set the org.`apache.cxf.stax.maxInputSizeInMB` parameter to a desired value in the `Spectrum_HOME\tomcat\webapps\spectrum\WEB-INF\web.xml` file.
Default: 8 MB

Include Virtual Machines

When you select the **Include Virtual Machines** checkbox, DX NetOps Spectrum syncs only the non-VMWare VMs

> **NOTE**
> From the spectrumgtw probe 8.68, the vmware probe-managed VMs are not synchronized as part of the host server sync.

Disable the Host Server Integration

When you disable the **Host Server Integration**, the sync stops and deletes the existing entities from DX NetOps Spectrum. You can change the retaining of the models in DX NetOps Spectrum by using the **RetainModelsAndRelations** attribute in the UIM Manager model.

The following are the supported integration modes and the resulting actions in DX NetOps Spectrum:

- DELETE_MODELS: Delete models from DX NetOps Spectrum. **Default value**
- DELETE_RELATIONS: Retain the models and delete the relationships of models.
- RETAIN_ALL: Keep both relations and models in DX NetOps Spectrum

Disable the VMWare Integration

When you disable the **VMWare Integration**, the sync stops and deletes the existing VMWare entities from DX NetOps Spectrum. You can change the retaining of the models in DX NetOps Spectrum by using the **RetainModelsAndRelations** attribute in the UIM Manager model.

The following are the supported integration modes and the resulting actions in DX NetOps Spectrum:

- DELETE_MODELS: Delete models from DX NetOps Spectrum. **Default value**
- DELETE_RELATIONS: Retain the models and delete the relationships of models.
- RETAIN_ALL: Keep both relations and models in DX NetOps Spectrum.

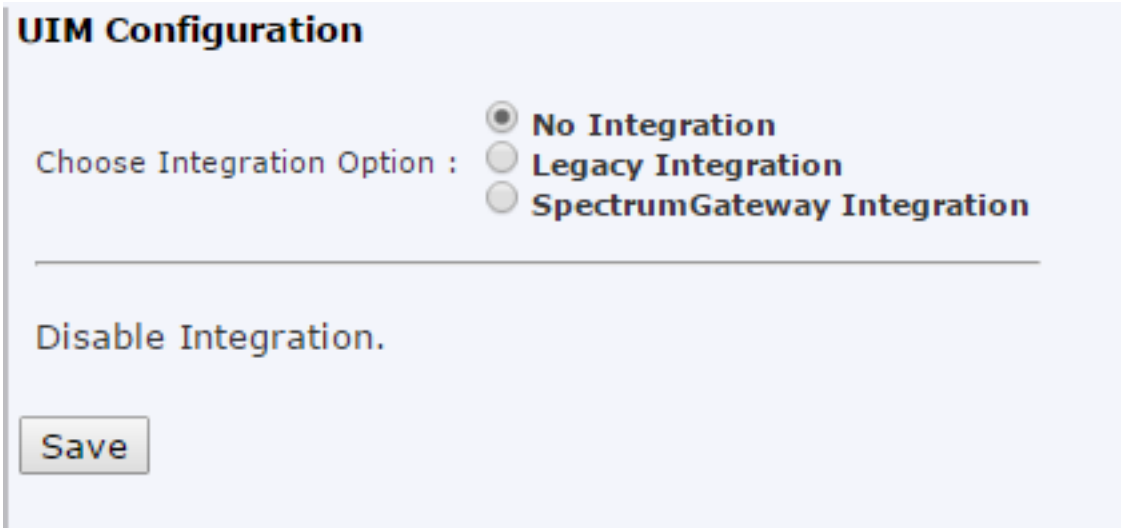
Changes in 10.2.3

From the 10.2.3 release, the DX NetOps Spectrum and UIM integration has undergone major changes. You can now configure the integration between DX NetOps Spectrum and UIM through either DX NetOps Spectrum or CA UIM's spectrumgtw probe (v8.65) Admin Console.

You can see the following options in the UIM Configuration page:

- **No Integration**
- **Legacy Integration**
- **SpectrumGateway Integration** - If you are using the spectrumgtw probe v8.65 or higher, select this option to configure the integration through spectrumgtw probe.

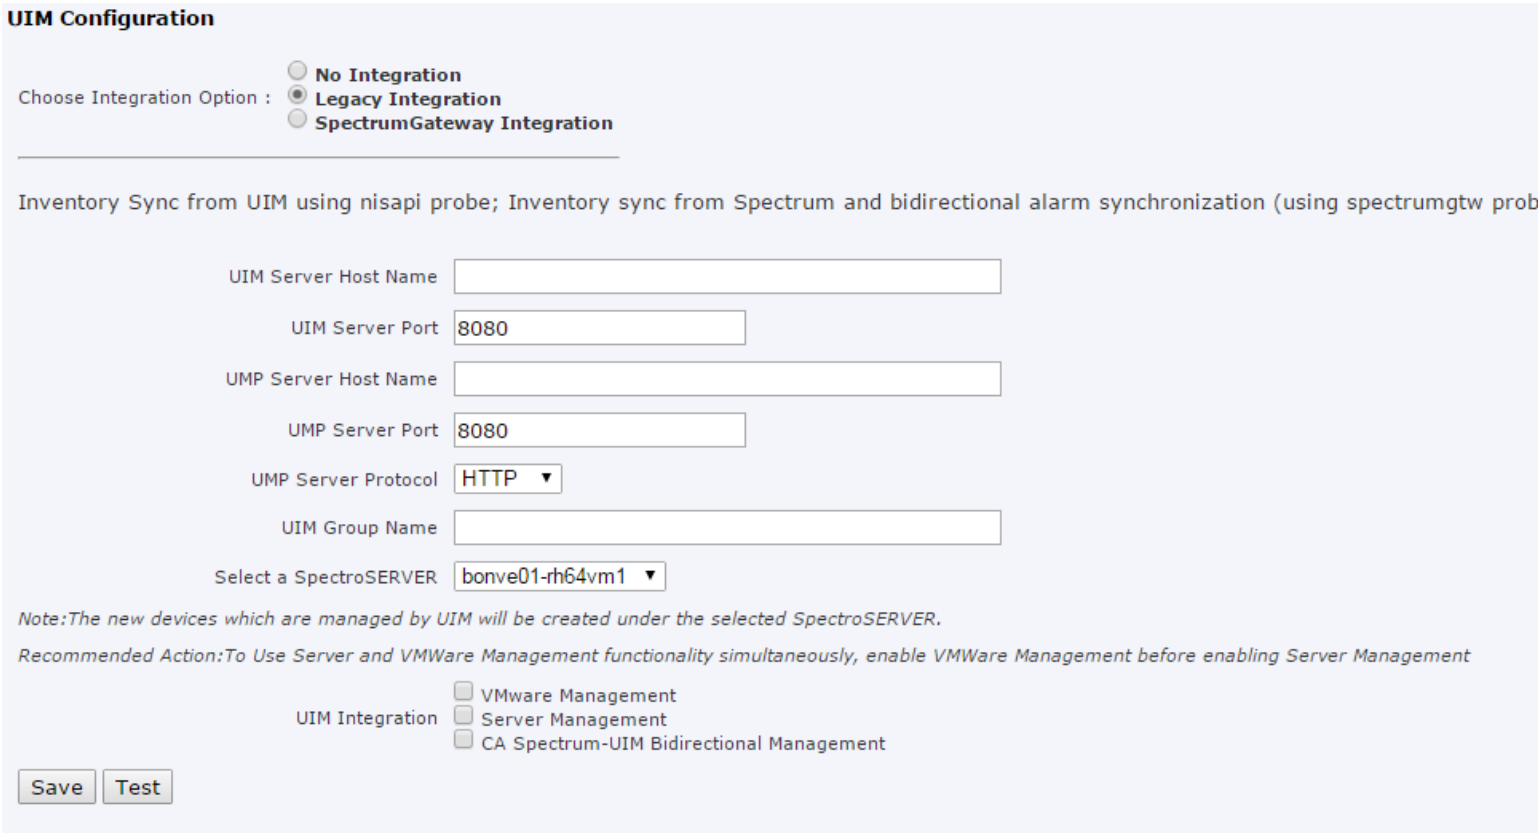
No Integration - Select this option button and click Save to disable the integration.



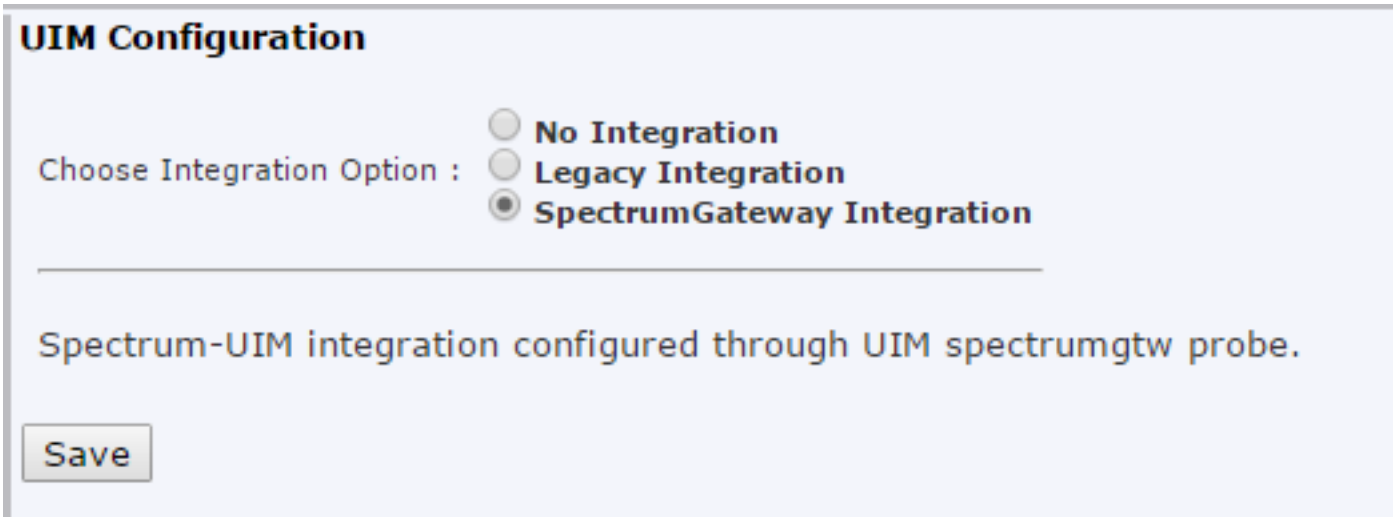
Legacy Integration - Select this option to configure the integration through DX NetOps Spectrum.

NOTE

The Legacy Integration option is used when you are using the spectrumgtw 8.64 for the integration. If the integration is already enabled before upgrading DX NetOps Spectrum, after the upgrade, the 'Legacy Integration' appears as selected by default.



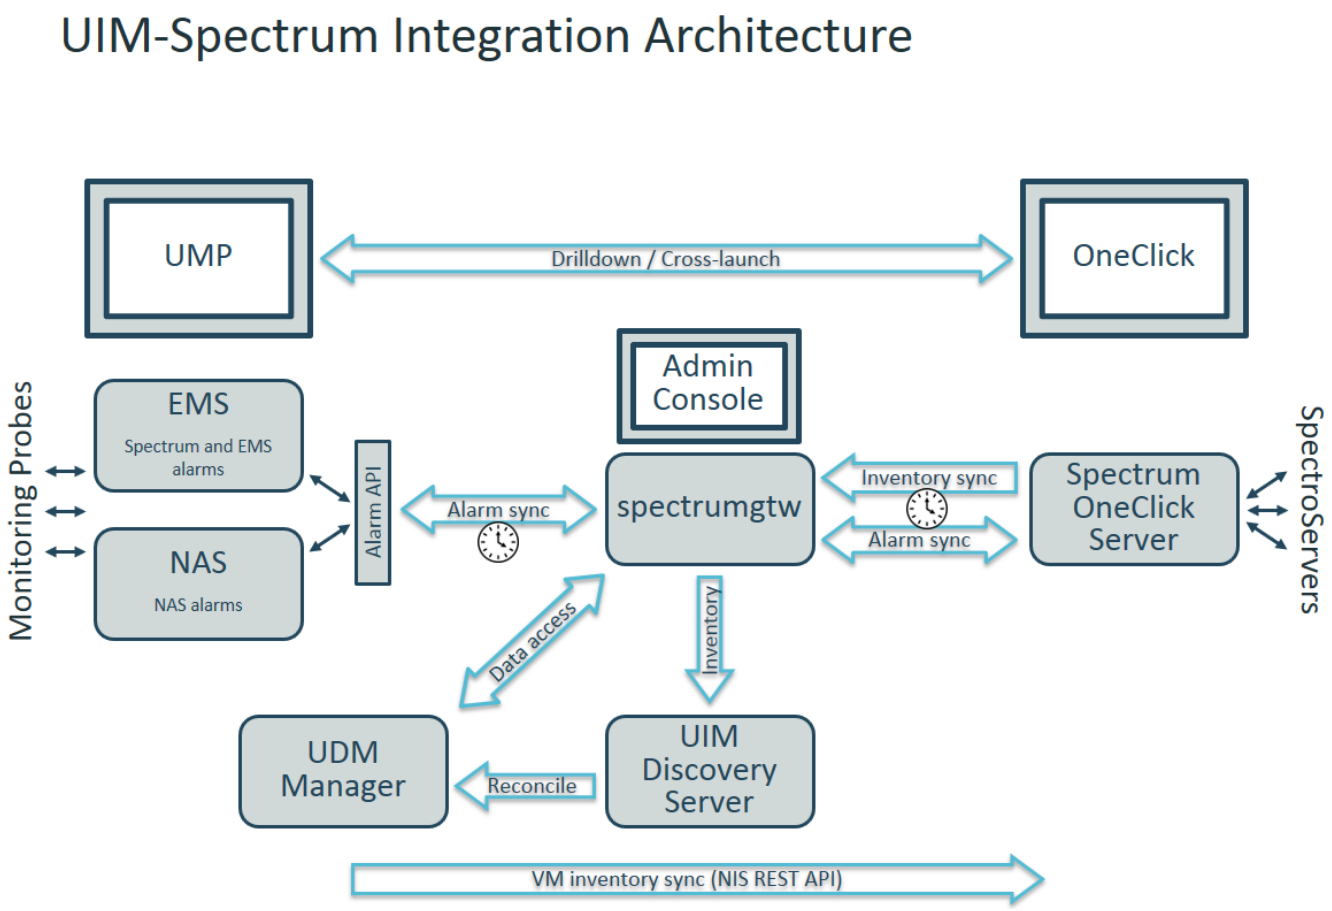
SpectrumGateway Integration - Select this option to configure the integration through UIM spectrumgtw probe v8.65. For instructions, see the Deploy and Configure the Probe section the spectrumgtw probe documentation.



The architecture for the DX NetOps Spectrum and UIM integration has undergone major changes from 10.1.2. We recommend you to go through the DX NetOps Spectrum-UIM Integration using spectrumgtw probe - FACT SHEET to understand the changes to the integration if you are new to this integration or an existing user.
Here are some key changes to the integration architecture:

- Alarms sent from UIM to DX NetOps Spectrum will no longer leverage the SNMP Gateway or DX NetOps Spectrum Southbound gateway. Instead, they will be routed through the new DX NetOps Spectrum Gateway Probe.
- Nisapi-service-host is replaced by nisapi-wasp for inventory sync from UIM to DX NetOps Spectrum
- Server Management
  - Has removed dependency on dedicated role
  - Added ability to monitor VM as a server without dependency on Vmware probe
  - Pulls inventory with one of the roles in the database as DatabaseServer, Host, VirtualMachine, VirtualMachineHost, WebServer, vCenter.
- Vmware Management
  - Handle Flapping inventory/relationships from UIM
  - Unreported inventory by UIM will be kept in a separate container in DX NetOps Spectrum and can be deleted by the user when no more needed

Here's an overview of the updated integration architecture:



Architectural Overview - using SBGW component /snmpgtw probes (till r10.1.1)

When an issue occurs in the infrastructure, alert data is sent from UIM to the SpectroSERVER of DX NetOps Spectrum through the Southbound Gateway component. SpectroSERVER is a primary server for DX NetOps Spectrum. For more information, see the SpectroSERVER and DX NetOps Spectrum Databases section.

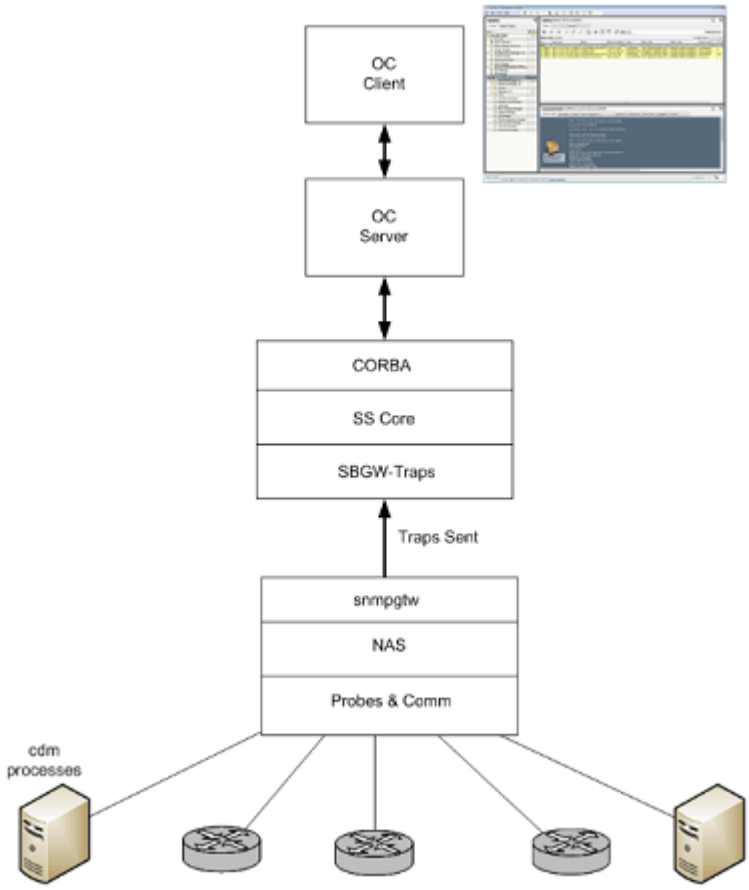
Using the Southbound Gateway, you can centralize network management, allowing DX NetOps Spectrum to capture and display data. Alert data is organized into DX NetOps Spectrum event and alarm data as appropriate and is displayed within OneClick.

The Southbound Gateway can be used with any incoming alert data stream format. The Southbound Gateway provides a simple, non-programmatic integration point for systems that can generate SNMP traps. It is also useful for managing non-SNMP environments. Southbound Gateway supplies an import tool that accepts XML-formatted alert data in case the system with which you are integrating cannot generate SNMP traps. For more information, see the Southbound Gateway Toolkit section.

Once the Southbound Gateway receives the alert data, the data is mapped to a DX NetOps Spectrum event in an AlertMap file. The Southbound Gateway determines the appropriate EventAdmin model to receive the alert data based on the IP address of the host computer that is sending the data. The IP address of the host computer should match the IP address that is used to create the EventAdmin model.

The DX NetOps Spectrum EventAdmin model receives the trap and translates it into a DX NetOps Spectrum event. If the event corresponds to a critical, major, or minor condition, the corresponding alarm is raised on a DX NetOps Spectrum model. The model where the alarm is raised depends on a few factors. We recommend having a previously modeled device in DX NetOps Spectrum. If the device model is present in DX NetOps Spectrum, the alarm is asserted against the existing device model. If the device model does not exist in DX NetOps Spectrum the alarm is asserted against an auto-created EventModel of the Nimsoft Robot that is reporting the condition.

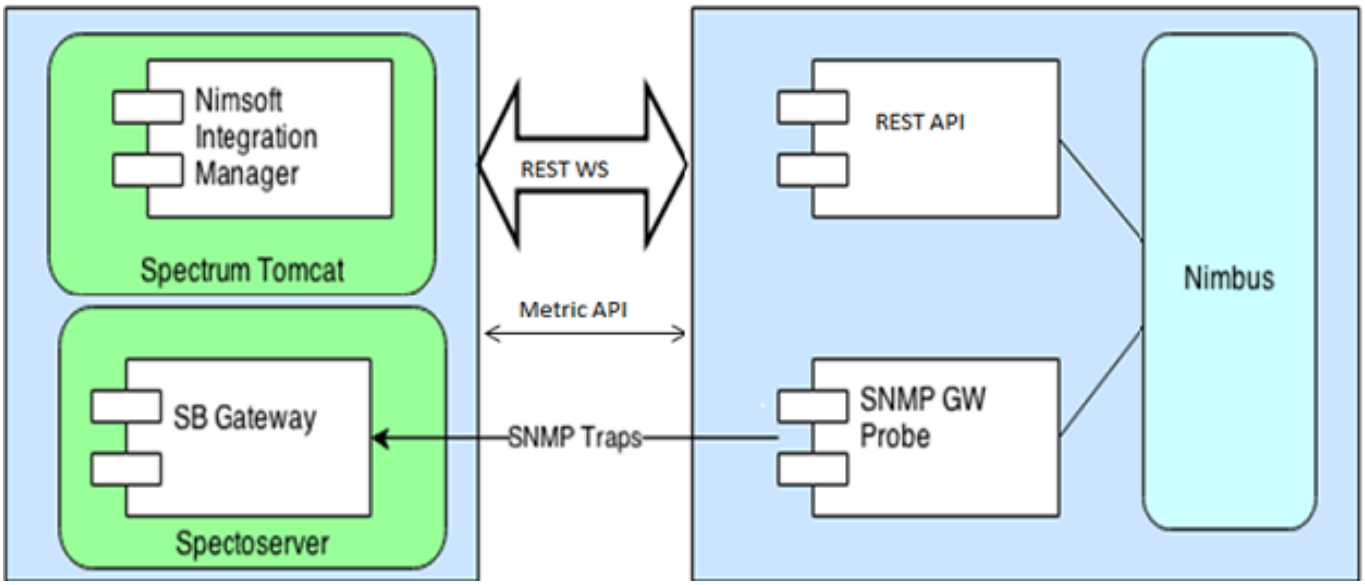
The following diagram illustrates an overview of the UIM - DX NetOps Spectrum Integration Architecture, till 10.1.1:



The integration between DX NetOps Spectrum and UIM through Web Server is designed to support server management. The HostServer models resulting from the integration provides traditional DX NetOps Spectrum capabilities such as layer2 connectivity and fault isolation with the features supported by UIM. You can use the Launch-in-Context feature to launch the CA Unified Management Portal (UMP) view from the server models in DX NetOps Spectrum to view the server information.

When the UIM and DX NetOps Spectrum integration is enabled from the OneClick Administration page, DX NetOps Spectrum receives the data from UIM through the Rest API. Once we get the data from the Rest API, UIM hosts are modeled in DX NetOps Spectrum. The alert data is sent from UIM to the SpectroSERVER of DX NetOps Spectrum through the Southbound Gateway component. The received data is mapped to a DX NetOps Spectrum event. The Southbound Gateway determines the appropriate EventAdmin model to forward the event. Metric violation traps that are coming from UIM are asserted on the respective Nimsoft host models in DX NetOps Spectrum.

The following diagram illustrates the architecture of the UIM - DX NetOps Spectrum Integration for Server Management through the Web Server (till v10.1.1):



- **UIM Probes**
  Provide the intelligence to manage specific components on a managed device. For example, the CDM processes probe is responsible for monitoring CPU, disk, and memory usage on target hosts. Over 135 UIM probes are available, to let you manage the entire IT infrastructure, including servers, network devices, applications, and databases.
- **Nimsoft Alarm Server (NAS)**
  Receives and manages incoming alarm messages. The Nimsoft Alarm Server supports message suppression and provides clients with services such as event updates, message filtering, automated actions, and mirroring capabilities.
- **SNMP Gateway Probe (snmpgtw)**
  Sends out the traps from UIM to DX NetOps Spectrum. This probe converts alarms to SNMP-Trap messages which are readable by any SNMP-based management system. It subscribes to UIM internal alarms and processes these alarms into SNMP traps with all the information about the alarm that is encoded in the trap varbinds.

Bidirectional Integration

This page describes the DX NetOps Spectrum and CA UIM Bidirectional integration by covering the following topics:

> **WARNING**
>
> If you are setting up the integration for the first time using CA Spectrum 10.2.3 and CA UIM 8.5.1/ 8.5.1 (SP1) using the spectrumgtw probe v8.65; you can no longer enable the bidirectional integration from the DX NetOps Spectrum OneClick Administration > UIM Configuration page. You need to first select **SpectrumGateway Integration** from the OneClick Admin > UIM Configuration page, enable the Alarm Integration checkbox and then configure additional parameters in the Alarm Configuration section of the spectrumgtw Admin Console, to initiate the bidirectional alarm integration.
> For more information, see spectrumgtw Admin Console.

Integration Compatibility

For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

NOTE

In previous releases of CA UIM, the nisapi_service_host package was deployed to the service_host probe. As of CA UIM release 8.47, the service_host probe was deprecated and its functionality was moved to the wasp probe.

- By default, the wasp probe uses port 80. However, because the wasp probe is a core component in CA UIM, this port should already be open in a properly functioning CA UIM environment. For more information, refer to the wasp probe documentation.

Overview

You can enable bidirectional integration between CA Spectrum r10.3 and CA UIM 8.5.1 using the spectrumgtw probe v8.66. This bidirectional integration enables the following functionalities:

- Reception of all CA UIM alarms by DX NetOps Spectrum.
  This functionality enables DX NetOps Spectrum users to update (acknowledge, unacknowledge, clear, assign and unassign troubleshooter, and create service desk ticket) CA UIM alarms in OneClick. CA UIM receives such updates when its alarms are updated in OneClick.
- Reception of DX NetOps Spectrum inventory information and all DX NetOps Spectrum alarms by CA UIM.
  This functionality enables:
  - CA UIM to maintain an updated DX NetOps Spectrum inventory information based on a specific global collection in OneClick.
  - CA UIM to receive all DX NetOps Spectrum alarms. As a result, CA UIM users can update (acknowledge, unacknowledge, clear, assign and unassign troubleshooter, and create service desk ticket) DX NetOps Spectrum alarms. DX NetOps Spectrum receives such updates when its alarms are updated in CA UIM.

NOTE

- If you were using the uni-directional integration, you should turn off the associated profile in the snmpgtw probe before you start using the spectrumgtw probe for bidirectional integration.
- Ensure that the snmpgtw probe is not configured with the SpectroSERVER you are configuring, for the bidirectional integration using spectrumgtw probe.

NOTE

Information:

- Inventory is a list of devices from single or multiple landscapes.
- The deletion of DX NetOps Spectrum models in CA UIM is not supported.
- Even if you have enabled the integration for Server Management and VMware Management, you can enable this bidirectional integration provided that you deploy and configure the spectrumgtw probe. In this case, integration for Server and VMware Management, and the bidirectional integration work without any conflict.

Enable the Bidirectional Integration

You need to complete the following steps to enable this integration:

- Verify the following prerequisites:

  - CA Spectrum v10.3 and CA UIM v8.51 are deployed.
  - The spectrumgtw probe (v8.66) is deployed and configured. For more information on the Spectrum Gateway probe, see spectrumgtw AC Configuration.
  - The CA Unified Infrastructure Management Alarm Server (nas) probe v9.00 or higher must be installed and activated.
  - The CA Unified Infrastructure Management Event Management Services (v10.17 or higher) probe must be deployed and configured for the **spectrumgtw** probe to run successfully.
  - The CA Unified Infrastructure Management trellis probe should be active and the **Spectrum UIM Services** service should be running.
- Configure the **UIM Configuration** page on the DX NetOps Spectrum OneClick Administration page.
- Select the bidirectional integration option on the **UIM Configuration** page

NOTE

For more information on configuring the spectrumgtw probe, see spectrumgtw Admin Console Configuration.

To enable the bidirectional integration, follow these steps:

1. Launch the DX NetOps Spectrum OneClick home page, and click **Administration**.
2. From the left Navigation pane, select UIM Configuration.
3. In the UIM Configuration section, enter the following information in the corresponding fields:
   a. UIM Server Host Name
   b. UIM Server Port
   c. UMP Server Host Name
   d. UMP Server Port
   e. UMP Server Protocol
   f. UIM Group Name

NOTE

Please specify the UIM group name in this field if you want selective inventory synchronization (of the UIM group specified) from CA UIM to DX NetOps Spectrum.

4. Select the dedicated SpectroSERVER from the drop-down list.

NOTE

The new devices that are managed by CA UIM will be created under the selected SpectroSERVER.

5. Select the **DX NetOps Spectrum-UIM Bidirectional Management** checkbox.
6. Click **Save.**
7. Verify that the UIMAdmin container model of type EventAdmin is created in **OneClick-> Universe topology**.
   You have enabled the DX NetOps Spectrum and CA UIM bidirectional integration successfully.

Share DX NetOps Spectrum inventory with CA UIM

You need to create a global collection of the devices (and their interfaces) that you want to share with CA UIM. Once the global collection is created with all the required devices, CA UIM receives that inventory information. DX NetOps Spectrum inventory information is synchronized in CA UIM when new devices are included or deleted from that global collection.

DX NetOps Spectrum inventory need not include devices that belong to the following model types or their derivatives:

- Pingable
- ContainerDevice
- ClusterBaseResource
- GenCblModem
- GenSetTop
- VMwareESXHost
- SolarisZonesHost
- IBMLPARHost
- HyperVHost

The following procedure describes the search criteria that exclude these devices. If these devices are included in the global collection, they do not appear in CA UIM.

Follow these steps:

1. From **OneClick->Navigation pane** right-click **Global Collections**, and select **Create Global Collection**.
2. Enter the following details in the **Create Global Collection** dialog for this global collection:
   – Name
   For example, enter "InventoryGC".
   – Security String
3. Click **Landscapes** to include devices from all the required landscapes in a DSS environment.
4. Click **Search Options** to specify the search criteria for including devices in this global collection.
   The Search Options dialog appears.
5. In the **Search Criteria** pane, click the **Show Advanced >>** button.
   The **Hints** pane appears.
6. Click the **Add Existing** button.
   The **Add Existing Search** dialog appears.
7. Expand **Models**, and select **UIM Bidirectional Search**.
8. Click **OK**.
   You come back to the **Search Options** dialog.
9. In the **Update Options** pane, select **Real-Time update** and then Click **OK**.
   You come back to the Create Global Collection dialog.
10. Click OK.
    A global collection called "InventoryGC" is created, and then based on the search criteria devices are added to InventoryGC.

NOTE

- In a Fault-Tolerant environment, to avoid model mismatch between SpectroSERVERs, perform Online Backup from a Primary MLS/Non-MLS SpectroSERVER to the respective Secondary SpectroSERVER.
- You must enable the bidirectional integration and run a successful full synchronization of inventory and alarms, before performing the online backup.

- If the CA UIM-DX NetOps Spectrum integration is enabled in an FT setup, it is recommended that you synchronize the Primary and Secondary SpectroSERVERs after the first successful synchronization. This will ensure that you have the integration data backed up in case the Primary/ dedicated SS (specified in the OneClick Admin > UIM Configuration) goes down.
- It is also recommended that you synchronize the Primary and Secondary SpectroSERVERs, after a successful synchronization job, if you are moving Datacenters from an MLS to a Non-MLS landscape.

Custom Attributes Synchronization

Using the Spectrum and UIM integration you can synchronize the UIM custom attributes from UIM to Spectrum. When you enable the DX NetOps Spectrum-UIM Bidirectional Management integration, the following custom attributes are synced from UIM to DX NetOps Spectrum.

- User Tag 1
- User Tag 2
- Custom 1
- Custom 2
- Custom 3
- Custom 4
- Custom 5

Follow these steps to view the custom attributes in DX NetOps Spectrum:

1. Open the OneClick Administration page.
2. Navigate to **Administration** tab > **UIM Configuration** link in the left panel.
3. Select the **DX NetOps Spectrum-UIM Bidirectional Management** option.
   The integration is enabled.
   After the integration is enabled, the alarms are synced from UIM to Spectrum.
4. In the Alarms table, right-click a column heading to open the Table Preferences dialog.
5. Select the custom attributes that you want to display.
   The selected custom attributes are added to the Alarms Table. The custom attributes are updated in the Alarms Table for the latest updates.

   NOTE

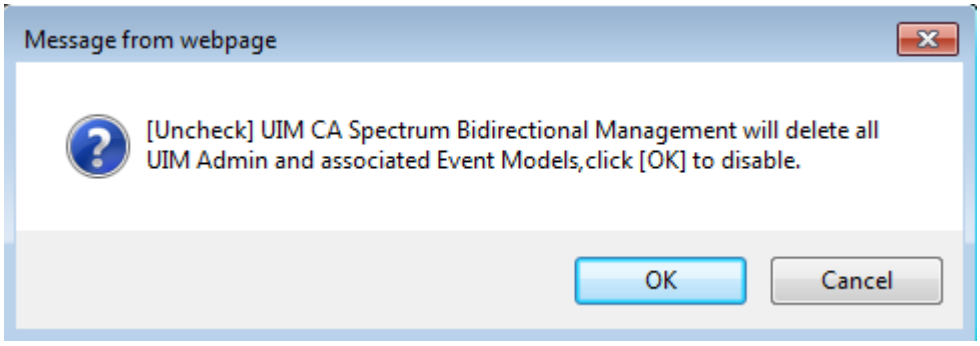
   The Alarm Details tab also displays the custom attributes and description that is synced from UIM. The Alam Details tab will not be updated for the latest updates. You can see the latest updates only in the Alarm Table.

Disable the Bidirectional Integration

You can disable the DX NetOps Spectrum and CA UIM bidirectional integration from the OneClick Administration page.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Navigate to **Administration** tab > **UIM Configuration** link in the left panel.
   The UIM Configuration window opens.
3. Clear the **DX NetOps Spectrum-UIM Bidirectional Management** option.
   The following dialog appears.



4. To confirm, click Ok.

DX NetOps Spectrum-UIM Bidirectional integration is disabled successfully.

Troubleshooting

Symptom: EventModel not created on dedicated SpectroSERVER when any SpectroSERVER within the DSS setup is down
Scenario: When an alarm is raised on a device that is modeled in a SpectroSERVER that is not integrated into UIM, and the device is present in the Global collection. When the SpectroSERVER holding the device goes down, the EventModel is not created on that SpectroSERVER.
Resolution: You need to manually restart the SpectroSERVER which has the EventAdmin modeled.

Symptom: Source attribute is Empty or Null for alarms generated from IP Services related logical models.
Resolution: You need to clear alarms with Source attribute Empty or Null manually, in DX NetOps Spectrum or in CA UIM to maintain consistency across both DX NetOps Spectrum and CA UIM applications.

For more known issues and troubleshooting tips for the integration using the gateway probe, see spectrumgtw Troubleshooting and Known Issues.

Multitenant support

Introduction

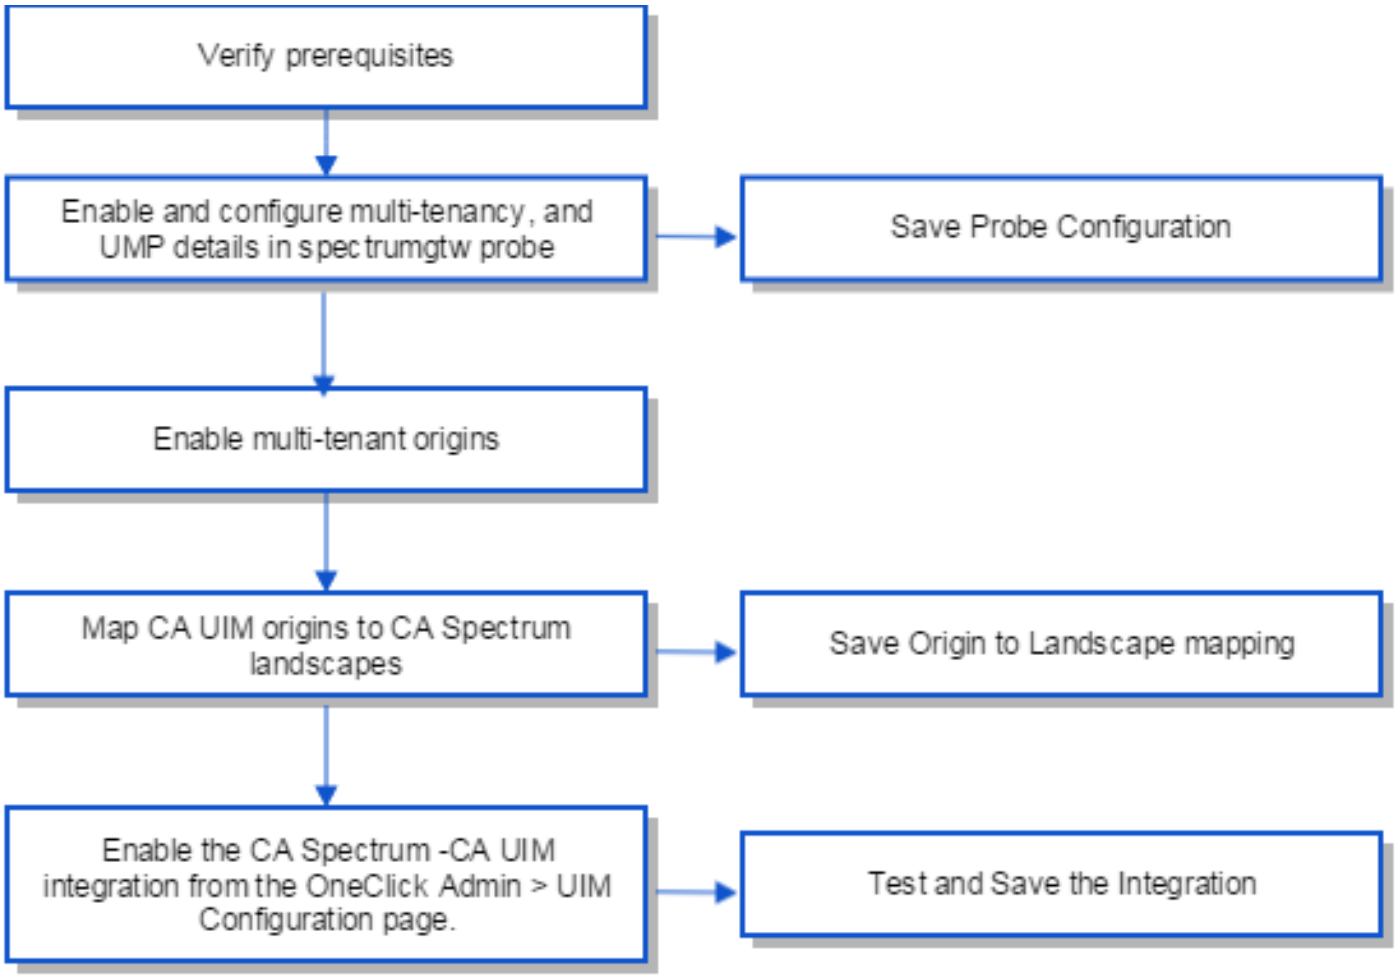
From the release 10.2.2, DX NetOps Spectrum supports multitenancy for DX NetOps Spectrum-UIM integration that is configurable in the Spectrum Gateway (spectrumgtw) probe.

The Multitenancy model in UIM is based on the Origin tag (Ownership). DX NetOps Spectrum-UIM integration leverages this origin tag information. The spectrumgtw probe allows you to map Origin with Landscape. Mapping UIM origins to DX NetOps Spectrum landscapes, ensures that the inventory belonging to a specific origin is modeled in the landscape it is mapped to.

> **WARNING**
>
> To enable and configure multitenancy, you need to install spectrumgtw probe v8.64 on CA UIM 8.51 or 8.51 SP1 This capability is not supported by previous versions of the probe. You also need to deploy the webservices_rest package version 8.51 or later on the same robot where UMP is deployed.

The following diagram outlines the process to enable multitenancy in DX NetOps Spectrum.

Figure 80: Multi-tenancy Configuration workflow



In deployments where there is a clear distinction in terms of UIM and DX NetOps Spectrum installation setups, i.e. one UIM hub and one SpectroSERVER per tenant (where the tenant has one origin), simply mapping origin to landscape is enough.

However, for deployments where there are multiple origins per tenant (with overlapping IP addresses that need to be modeled in same landscape), or where entities of multiple UIM tenants have to be modeled in the same landscape, you need to configure Secure Domain Connectors on the landscape and map the SDC + landscape combination to an origin.

The probe retrieves the list of origins in your UIM environment. You can then map your DX NetOps Spectrum landscapes to UIM origins.

> **WARNING**
>
> While you can map multiple origins to the same landscape, the same origin cannot be mapped to multiple landscapes.

How multitenancy works in the DX NetOps Spectrum-UIM integration

Once you manually map the origins to landscapes, using REST calls provided by DX NetOps Spectrum, spectrumgtw probe sends the Origin to Landscape mapping. These mappings are sent to DX NetOps Spectrum every time DX NetOps

Spectrum OneClick server or spectrumgtw probe restarts. Once the mappings are in place, Spectrum ensures that entities belonging to an origin are modeled on the landscape, its origin is mapped to.

NOTE

The spectrumgtw probe restarts every time you change mapping and save the configuration

When spectrumgtw probe gets alarms from DX NetOps Spectrum, the probe determines the landscape for each alarm and fetches the corresponding origin (by checking against the mapping and filling the origin in the alarm) before sending it to UIM.

Until 10.2.2, at the most two UIM Event admin models were created (one in selected landscape and another in MLS if the selected SS is down) to handle alarms coming from UIM. When origins are mapped to landscapes then one UIM event Admin model is created per landscape as specified in the map. This allows the segregation of alarms into their respective landscapes.

Event models are created for alarms whose IP or hostname are not present in DX NetOps Spectrum. In cases like overlapping IPs or duplicate hostnames, chances are that same event model is used as a place holder for asserting such alarms. Now origin in the alarm will be used to identify the correct event model to assert the alarm.

Configuring Multitenancy for DX NetOps Spectrum-UIM Integration

To enable multitenancy, follow these steps:

1. In the probe Admin Console, navigate to the spectrumgtw probe configuration interface/ GUI.
2. In the **UMP Connection Details** section, enable the **Configure multitenancy** option, update the UMP details and save the configuration.
   The probe configuration interface displays the **Multitenant Mapping** node.
3. In the **Multitenant Mapping** node > **Landscape Mapping** section, click **New** to create a new landscape to origin mapping.
4. Map UIM Origins to DX NetOps Spectrum Landscapes, from the list of options displayed and save the mapping changes.
5. In the OneClick Administration web server, click the Administration tab and navigate to the UIM Configuration page.
6. Update the integration configuration details, enable the integration(s).
7. Test and Save integration.

NOTE

For more information about configuring and enabling multitenancy on the spectrumgtw probe, see spectrumgtw Advanced Configuration.

Upgrade Scenarios and Mapping Behavior

Go through the following scenarios for the expected behavior of models in DX NetOps Spectrum after you complete configuring and enabling multi-tenancy.

Upgrade Scenarios

Enabling Multi-tenancy after upgrading to 10.2.2, from a 10.2.1 DSS environment which is already integrated with UIM

Scenario: I am currently on 10.2.1 and the bidirectional integration with UIM (with VMware and Server management) are enabled in my DSS environment. What happens to the models that already exist in my DX NetOps Spectrum environment in specific landscapes in the Universe view when I configure and enable Multi-tenancy?

Expected Behavior: After you have successfully upgraded to 10.2.2, ensure that all the models exist in the selected Landscape.

1. Map DX NetOps Spectrum landscapes (or Landscape + SDC) to UIM Origins from the **Landscape Mapping** section and enabled multi-tenancy from the spectrumgtw probe Admin Console. The following behavior is expected:

- – If the models already exist in the mapped landscape, then they should be retained and ensure that the UIMOrigin (0x1337f) attribute has the correct value.
  – If the models exist in a different landscape, they should be removed and modeled in the new landscape which is mapped to the origin.

Enabling multi-tenancy on a new 10.2.2 DSS setup (Install 10.2 and upgrade to 10.2.2)
Scenario: I have a new 10.2.2 setup, after I upgraded from 10.2.2 from 10.2.

Expected Behavior: After you complete the upgrade to 10.2.2. from 10.2, validate the modeling behavior before and after receiving the mapping.

1. Integrate 10.2.2 with UIM [In DSS].
2. Enable Server and VMware management for a selected landscape.
3. Map DX NetOps Spectrum landscapes (or Landscape + SDC) to UIM Origins from the **Landscape Mapping** section and enabled multi-tenancy from the spectrumgtw probe Admin Console.
   The following behavior is expected:

- – If the models already exist in the mapped landscape then they should be retained and ensure that the origin attribute has the correct value.
  – If the models exist in a different landscape, they should be removed and modeled in the new landscape which is mapped to the origin.

  NOTE

  If the DX NetOps Spectrum-UIM integration via spectrumgtw probe is already in place, but some of the device models have origin not mapped to a landscape, the related models (coming from from the origin that is not mapped) are not removed from the Landscape they are currently modeled in. You need manually remove those models.

Mapping Behavior
Points to note:

- Once the Origin to Landscape mapping is in place, any new entities coming in from UIM (with an origin that is not mapped to a landscape), are not modeled in DX NetOps Spectrum. Alarms are not be stopped but are asserted to Main Location Server's UIM EventAdmin model. Existing alarms will remain with previous EventAdmin, even after multi-tenancy is enabled. If you do not need the models, you have to remove the models manually.
- If the origin gets mapped to a new landscape, then the existing models corresponding to that origin are deleted from the old landscape and are modeled in the new landscape.
- If a new SDC is specified for an origin, in the origin to landscape map, then all the entities are associated with that SDC. Similarly, if you change the mapped SDC all entities are associated with the SDC most recently mapped.
- If Origin to Landscape mapping is removed, corresponding device models are not removed from DX NetOps Spectrum. If you do not need the models, you have to remove the models manually.
- When a new configuration of Origin to Landscape mapping is added, device models of that origin are synced during the next inventory full synchronization, after the map update is received by DX NetOps Spectrum.
- Till 10.2.1, you could see all the VMware Datacenters in the **UIM Manager** > **Information Tab** > **VMWare Configuration** > **VMWare Datacenter Modeling** table, irrespective of where they were modeled, i.e. across landscapes. From 10.2.2, VMWare datacenter(s) modeled in specific landscapes, will show up under the **UIM Manager** > **Information Tab** > **VMWare Datacenter Modeling** table, view of the landscape where they are modeled.

Reconciling Entity Data Integration Using Web Server for Server Management

WARNING

From 10.1.2, the SNMP Gateway probe and SBGW /Southbound gateway are no longer recommended for alarms synchronization from UIM to DX NetOps Spectrum. It is recommended to use the Spectrum Gateway (spectrumgtw) probe for this purpose. For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

We recommend that you go through the DX NetOps Spectrum-UIM Integration using spectrumgtw probe - FACT SHEET to understand the changes to the integration whether you are new to this integration or an existing user.

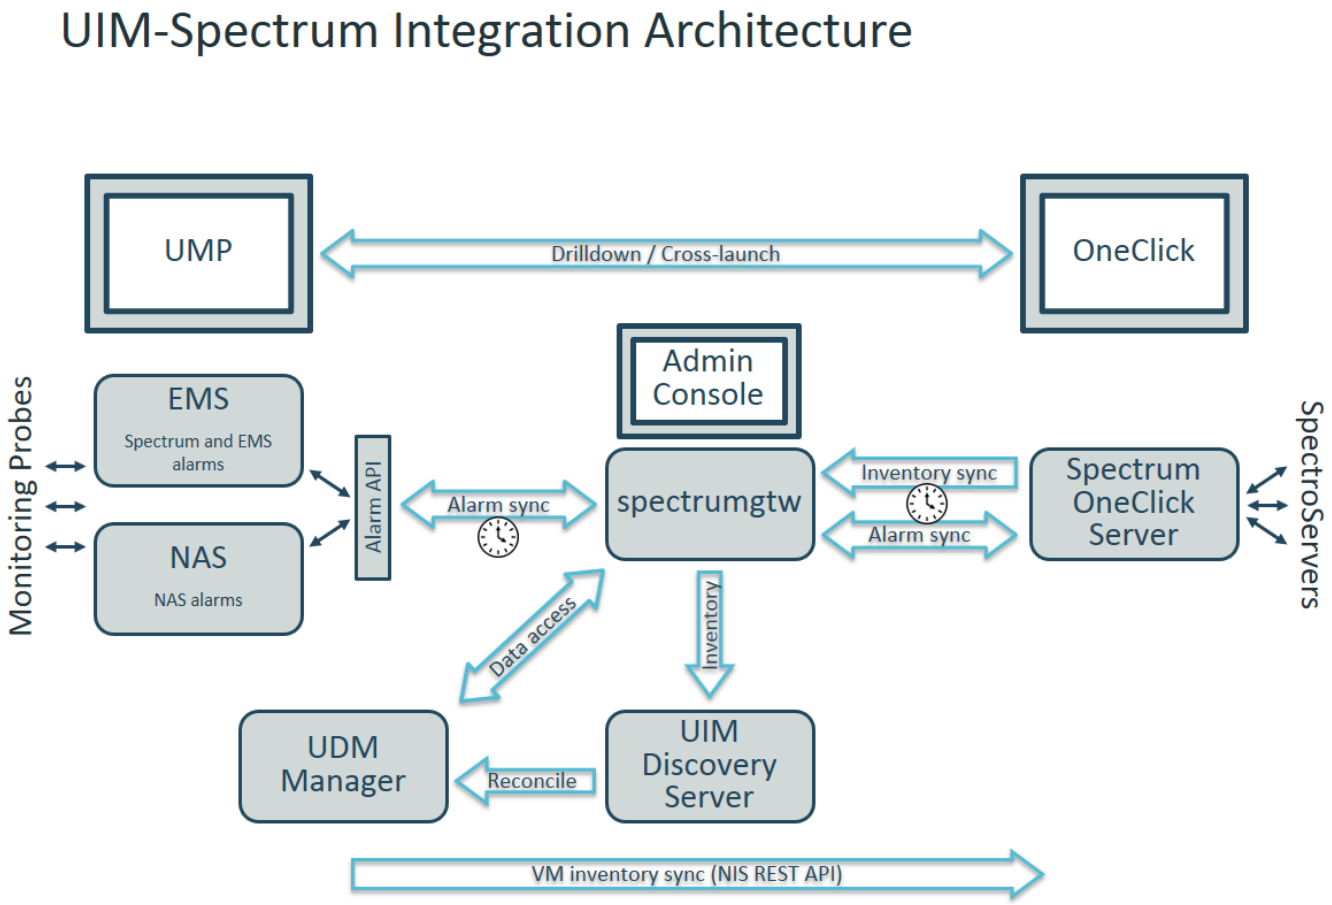
This section describes how to set up the integration between DX NetOps Spectrum and UIM through the webserver for server management. It also describes how to use its features to perform specific tasks such as synchronize inventory, manage alarms and events, and run reports.**Contents**

How to Integrate DX NetOps Spectrum and UIM through the Web Server

The integration between DX NetOps Spectrum and UIM through Web Server is designed to support server management. The HostServer models resulting from the integration provides traditional Spectrum capabilities such as layer2 connectivity and fault isolation with the features supported by UIM. You can use the Launch-in-Context feature to launch the CA Unified Management Portal (UMP) view from the server models in DX NetOps Spectrum to view the server information.

When the UIM and DX NetOps Spectrum integration is enabled from the OneClick Administration page, DX NetOps Spectrum receives the data from UIM through the Rest API. Once we get the data from the Rest API, UIM hosts are modeled in DX NetOps Spectrum.

The following diagram illustrates the UIM - DX NetOps Spectrum Integration Architecture:

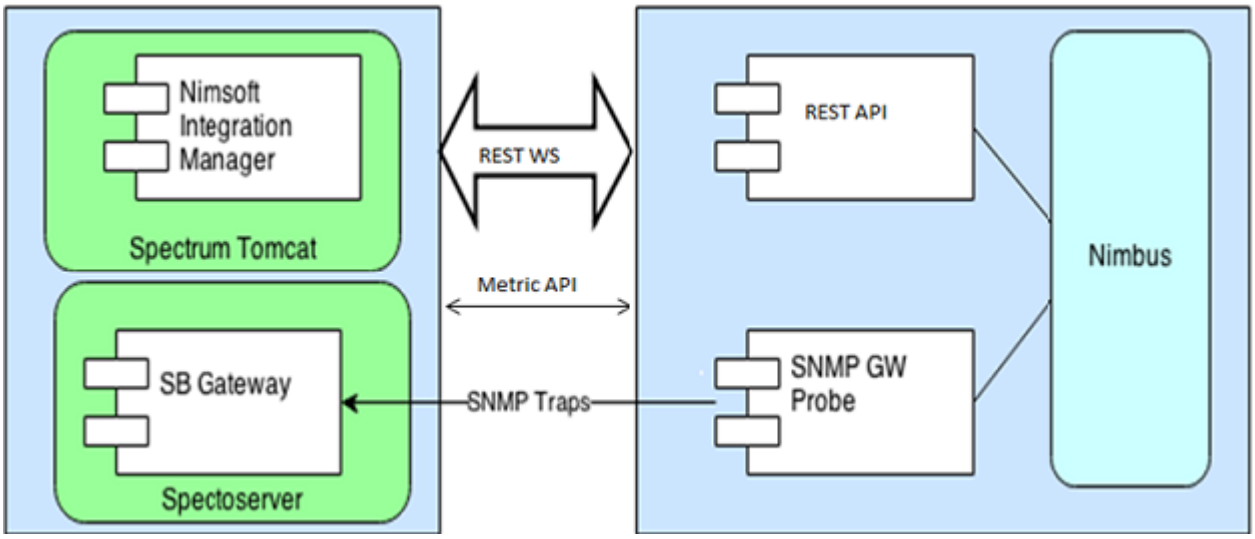


NOTE

Existing DX NetOps Spectrum – UIM integration for alarms through southboundgateway and UIM's snmpgtw probe should be stopped by deleting the associated Spectrum profile from UIM's snmpgtw probe.

Alarms sent from UIM to DX NetOps Spectrum will no longer leverage the SNMP Gateway or Spectrum Southbound gateway. Instead, they will be routed through the new Spectrum Gateway Probe.
Nisapi-service-host is replaced by nisapi-wasp for inventory sync from UIM to DX NetOps Spectrum.

The following diagram illustrates the UIM - DX NetOps Spectrum Integration Architecture till 10.1.1:



The alert data is sent from UIM to the SpectroSERVER of DX NetOps Spectrum through the Southbound Gateway component. The received data is mapped to a DX NetOps Spectrum event. The Southbound Gateway determines the appropriate EventAdmin model to forward the event.

Metric violation traps that are coming from UIM are asserted on the respective Nimsoft host models in DX NetOps Spectrum.

Review the following process to integrate UIM and DX NetOps Spectrum through the Web Server:

1. Review the Prerequisites and Considerations
2. Deploy and Configure Probes
3. Enable the Integration

Prerequisites and Recommendations

Consider the following prerequisites for the DX NetOps Spectrum and UIM integration (for releases prior to 10.1.1):

- Licensed installation of CA Spectrum 10.1 and CA UIM 8.2 or 8.3 provided that nisapi_service_host v8.04 /nisapi-wasp v8.4.2 or higher probe is deployed.
- The snmpgtw, cdm, and net_connect must be deployed and configured before integrating UIM and DX NetOps Spectrum through the Web Server
- For Launch-in-Context to work, UMP must be configured to UIM.

Consider the following prerequisites for the DX NetOps Spectrum and UIM integration (for CA Spectrum r10.1.2 or later):

- UIM Server should be at version 8.4.7 or later.
- Existing DX NetOps Spectrum – UIM integration for alarms through southboundgateway and UIM's snmpgtw probe should be stopped by deleting the Spectrum profile from UIM's snmpgtw probe
- cdm and net_connect must be deployed and configured before integrating UIM and DX NetOps Spectrum.
- ems 8.4.3, nas, and trellis probes should be deployed and running.
- spectrumgtw probe must be deployed on a robot connected to the primary hub.
- spectrum-uim-service-impl has to be deployed on the primary robot where Trellis is installed and Trellis has to be restarted.
- For server/vmware inventory synchronization:

  - nisapi-wasp 8.4.2 or higher
  - vmware probe version 6.72 or higher
- Use the latest ticketing gateway probes for Ticket ID synchronization and ensure the key **create_incidents_for_spectrum_alarms** is set to **“yes”** to allow probe to create tickets for spectrum alarm

Consider the following recommendations for the integration:

- If a new SpectroSERVER is added to the Distributed SpectroSERVER (DSS) setup, you must restart the OneClick server.
- If a child SpectroSERVER is removed from the DSS setup, restart the OneClick server.
- If anyone of the available SpectroSERVER is initialized to a legacy database or another database, restart the OneClick server.
- Specify a SpectroSERVER that has less load as the dedicated SpectroSERVER for UIM integration.
- Use an OneClick web server that is not integrated with Spectrum Report Manager.

Deploy and Configure Probes

To enable the DX NetOps Spectrum and UIM integration, deploy and configure the following UIM probes on UIM server:

- **snmpgtw**
  Sends traps from UIM to DX NetOps Spectrum. The SNMP gateway converts alarms to SNMP trap messages that are readable by any SNMP-based event manager.
- **net_connect**
  net_connect (Network Connectivity Monitoring) probe measures network connectivity that is based on "ping" (ICMP ECHO) and the TCP connections to a list of user-defined services. The service can be NetBIOS, Telnet, FTP, and HTTP. The probe supports the UIM family of solutions by sending the quality of service (QoS) messages.
- **(nisapi) service_host or wasp**
  Queries the CA Nimsoft Manager using the Restfull Services API to retrieve the list of UIM models to be monitored. Deploy service_host v8.04/ wasp v8.4.2 or higher.

  NOTE

  In previous releases of UIM, the nisapi_service_host package was deployed to the service_host probe. As of UIM release 8.47, the service_host probe was deprecated and its functionality was moved to the wasp probe.

  - By default**,** the wasp probe uses port 80. However, because the wasp probe is a core component in UIM, this port should already be open in a properly functioning UIM environment. For more information, refer to the wasp probe documentation.
- **cdm** The CPU, Disk, Memory Performance Monitoring (cdm) probe monitors the performance and resource load on the system with the robot. The probe provides the following benefits:
  - Generate alarms that are based on configured threshold values. The probe generates alarms that can trigger corrective actions immediately.
  - Generate trending Quality of Service (QoS) data. The information is measured and sent to the data_engine probe to process and store in the UIM database. The historical data facilitates capacity planning for monitored systems in the IT environment. Some examples are as follows:
    - View how disks are filling up over time
    - Plan batch jobs according to the CPU utilization
    - Upgrade systems which consistently operate near capacity
- **spectrumgtw** The spectrumgtw (Spectrum Gateway) probe provides a bidirectional (UIM to DX NetOps Spectrum and DX NetOps Spectrum to UIM) integration between CA Unified Infrastructure Management and DX NetOps Spectrum enabling you to perform the following actions:

- Export and correlate DX NetOps Spectrum Inventory from a Global Collection to UIM inventory.
- Bi-directional synchronization of alarms
- Bi-directional Clear / Update of alarms
- View symptomatic DX NetOps Spectrum alarms in the context for the root-cause alarm in UIM
- Ticket ID synchronization between DX NetOps Spectrum and UIM

WARNING

From 10.2.1, all UIM events (apart from events related to VMWare and servers) are no longer considered as generic events.
Specific events raised on UIM from the following probes are mapped to unique events created in DX NetOps Spectrum. This allows you to manage the events (raised on UIM) from DX NetOps Spectrum more efficiently.

Additional event mapping for select metrics from the following probes (along with cdm and net_connect probes) is added from 10.2.1. Additional event mapping for Please refer to Additional event mapping from UIM Probes to DX NetOps Spectrum.

- **logmon** The Log Monitoring (logmon) probe scans ASCII-based systems and application log files by matching specified expressions. Alarms are generated when the log file content matches the defined expression.
- **rsp (Remote System probe)** The Remote System Probe (rsp) allows you to monitor system metrics. The probe collects performance data in an agentless manner without installing proprietary software on the system.
- sqlserver The SQL Server Monitoring (sqlserver) probe constantly monitors the internal performance and space allocation of SQL Server databases. The probe can run locally on the database server or it can be configured to run as a remote client. The probe feeds essential information that is based on predefined criteria to the UIM availability manager for appropriate alert notification, as required. An extensive range of checkpoints can be selected and individually scheduled to meet your monitoring requirements. The probe will run selected SQLs to extract vital information about your SQL Servers. The information is presented to database-administrator as alarms or reports. For more information, see sqlserver Metrics.
- **processes (Process Monitoring)**
  The (Process Monitoring) processes probe monitors the specified processes to detect any error situation. The probe also retrieves information about the process, for example, the CPU usage, memory usage, and so on. For more information, see processes Metrics.

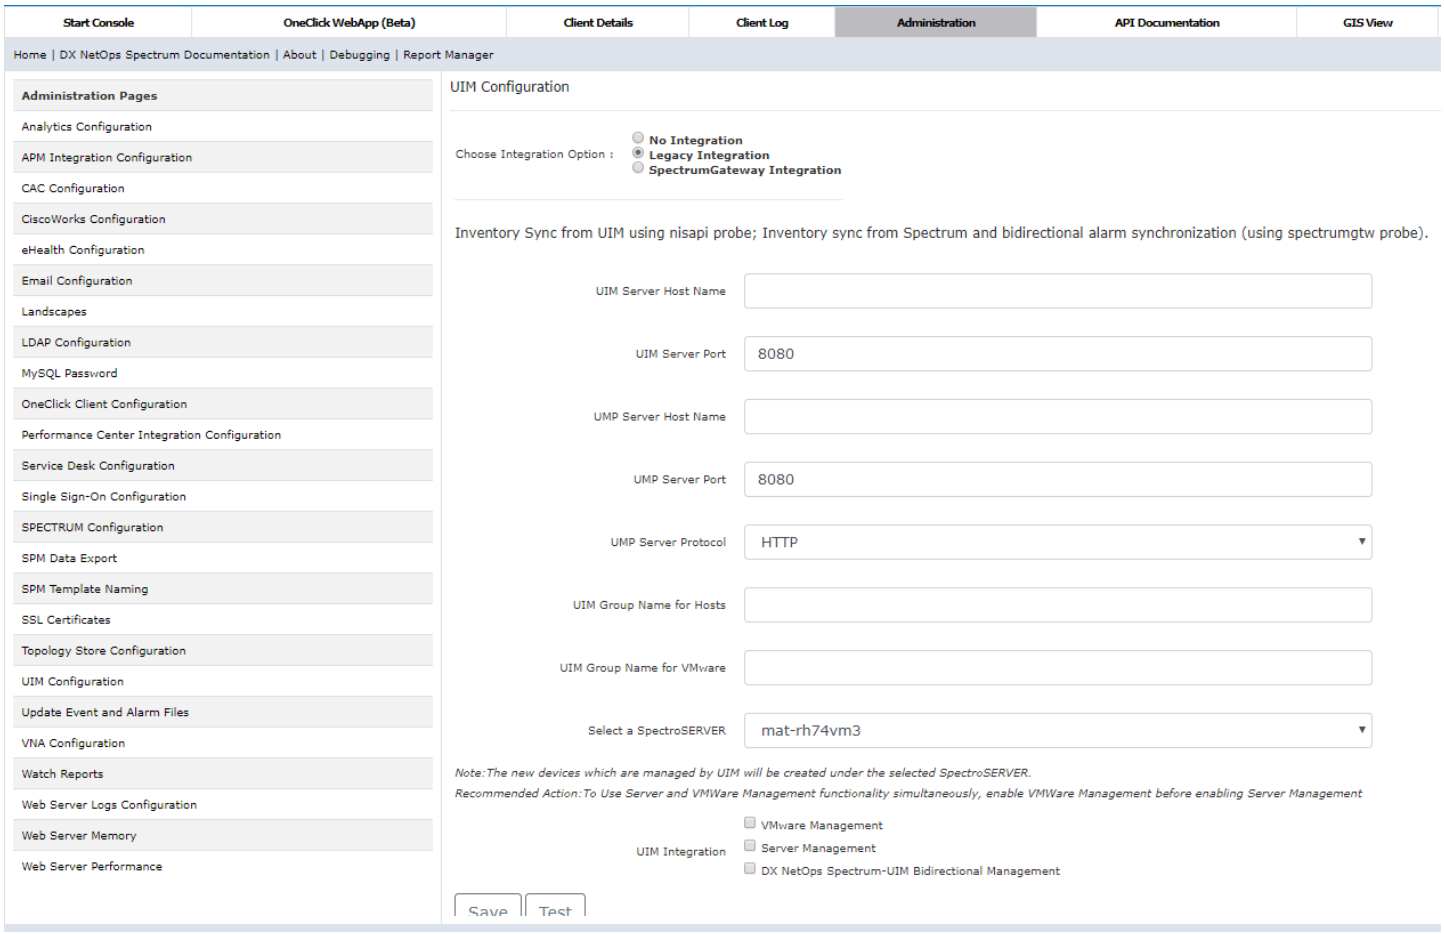
You can configure the UIM probes through the Probe Configuration interface. For more information, see the Unified Infrastructure Management Probe Space.

Enable the Integration

You can enable the DX NetOps Spectrum and UIM integration through the webserver from the OneClick Administration page. Specify the UIM Configuration information such as UIM Server Host Name, UIM Server Port, Unified Management Portal (UMP) Server Host Name, and UMP Server Port to enable the integration.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages are displayed.
3. Click the UIM Configuration link in the left panel.
   The UIM Configuration page opens.
   The following image illustrates the configuration options that are available in the UIM Configuration window:



If the integration was already enabled before the upgrade, then the **Legacy Integration** radio button would appear as selected by default.

- **UIM Server Host Name**
  Indicates the IP address/hostname of the UIM Server.
- **UIM Server Port**Indicates the server port number of UIM.
- **UMP Server Host Name**
  Indicates the IP address/hostname of UMP.
- **UMP Server Port**
  Indicates the server port number of UMP.
- **UMP Server Protocol:**
  Indicates the network protocol of the CA UMP server.

  NOTE
  For successful encrypted communication (https protocol) between DX NetOps Spectrum and UIM UMP Server, you must import SSL Certificate of UIM UMP Server into Spectrum OneClick Server. To import the certificate, from the OneClick home page select **Administration**, **SSL Certificates**, upload the certificate file then click **Save**. Restart the OneClick web server for the changes to take effect.

NOTE
From spectrumgtw 8.67 onwards, the UIM Group Name field in the UIM configuration section, has been changed to Group Name for Hosts.

- **UIM Group Name for Hosts**: Specify the UIM group name in this field for selective inventory synchronization of hosts (of the UIM group specified) from UIM to DX NetOps Spectrum. This is applicable to Server Management entities only.
- **UIM Group Name for VMware**: Specify the UIM group name in this field for selective inventory synchronization of VMware entities (of the UIM group specified) from UIM to DX NetOps Spectrum. To address the challenges in providing filtering of VMware data from UIM to Spectrum, a 'UIM Group Name for VMware' field is introduced from spectrumgtw v.8.67.

NOTE

- Ensure that you add vCenter and ESX hosts and the corresponding virtual machines to be synced to Spectrum.
- If the vCenter is not part of the group, ESX and VMs are not modeled in Spectrum even though they are part of the group.
- If vCenter and VMs are part of the group and ESX is not, then the VMs are created without any relationship with the vCenter in Spectrum.

NOTE
Inventory from the group you specify in this field is synchronized from UIM to Spectrum. For more information, see Create and Manage Groups in USM.

4. Select the SpectroSERVER under which the new UIM Host models hierarchy is to be created.
5. To enable the integration, select **Server Management** and click Test. (**Till 10.2.2 and spectrumgtw probe v8.65**)
   If the test is successful, Successfully connected to the UIM message appears.

   NOTE
   If you are setting up the integration using 10.2.3 and spectrumgtw probe v8.65, you can no longer enable the Server Management capability from the UIM Configuration page. To enable and configure the Server Management capability for Host servers, please refer to the spectrumgtw AC documentation.
6. Click Save.
   Successfully saved configuration to the database message appears.
   UIM Integration is now enabled.

   NOTE
   If you change any settings on any of the OneClick server other than the integration OneClick server. The message, "Saving details on this OC will change the Integration OC Server. Click [OK] to continue" appears. If you click Save, the integration OneClick server changes and the details are saved. If you click Cancel, the details are saved but the OneClick server remains the same.

Incremental and Full Synchronization

This Integration supports incremental and full synchronization. When the DX NetOps Spectrum and UIM integration is enabled, synchronization occurs automatically with the default scheduled timings displayed in the OneClick view. From 10.2.2, you have the option to configure including or excluding virtual machines (VMs) during the UIM Host Server Synchronization.

WARNING
From 10.2.3 and spectrumgtw probe v8.65, the Incremental and Full Synchronization configuration for Host servers are moved to the spectrumgtw Admin Console. For more information, please refer the spectrumgtw Admin Console documentation.

Incremental Synchronization

NOTE
Additions and modifications of devices in UIM are reflected in DX NetOps Spectrum after incremental synchronization. You can set the Incremental Sync interval in the OneClick view. (Till 10.2.2 and spectrumgtw probe v8.64)

Full Synchronization

Full synchronization occurs when the DX NetOps Spectrum and UIM integration is enabled. Thereafter, the full synchronization occurs at a scheduled time based on the schedule that is selected in the OneClick view. During full sync DX NetOps Spectrum queries UIM for all the hosts that are managed by UIM. Once Spectrum receives this data, reconciliation is performed and new hosts (if any) are modeled in Spectrum. The un-managed hosts are removed.

The minimum schedule time for full sync is one day. The last full sync time in the OneClick view displays the previous full sync completion time. The sync times are based on the OneClick Tomcat server time.

NOTE
Do not schedule the incremental or full sync at smaller intervals, you may experience a performance impact if a large number of servers is being monitored by UIM.

WARNING
Schedule full synchronization during non-business hours.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. From the Navigation panel, select **UIM Manager**.
   The contents pane for UIM Manager opens.
3. Click the **Information** tab and select **Configuration** > **UIM Host Sync Configuration**.
   Information on incremental and full synchronization is displayed.
4. To schedule incremental sync, click **Set**.
   The Time interval window opens.
5. Specify the time interval and click Ok.
   Default: 300 minutes
   Minimum: 10 minutes
   Incremental sync is now scheduled.
6. To schedule full sync, click the **Schedule** button that is available in the **UIM Sync Configuration** section.
   The **Create Schedule** window opens.
7. Specify the following Recurrence information:
   – Days
     Default: 7
     Maximum: 31
   – Hours
     Default: 00:01
     Maximum: 23:59
8. Click Ok.
   Full sync is scheduled.
9. In the **Include Virtual Machines** field, do one of the following:

- Select Yes, to include virtual machines.
- Select No, to exclude virtual machines.
  When you select the **Include Virtual Machines** checkbox, spectrum syncs only the non-VMWare VMs.

Reconciling UIM entity data with existing DX NetOps Spectrum models

During full synchronization or incremental synchronization, when a new UIM entity is reported to DX NetOps Spectrum from UIM, DX NetOps Spectrum will perform a search to identify if this entity was modeled during DX NetOps Spectrum

discovery and modeling. If such an existing model is found, DX NetOps Spectrum will reconcile the UIM entity information with the existing model, instead of creating a new model. This search is performed on all landscapes in the Distributed SpectroSERVER (DSS) setup.
In cases where an existing model is not found and reconciliation is not performed, DX NetOps Spectrum will model the entity in the SpectroSERVER specified in the **OneClick Admin Configuration**> **UIM Configuration** page.

> **NOTE**
> DX NetOps Spectrum uses the IP Address reported by the entity to perform this search. If the IP Address is not reported, the search is performed using the reported MAC address.
> If neither (IP or MAC Address) are reported, DX NetOps Spectrum will not be able to reconcile that entity even if the entity is discovered and modeled in DX NetOps Spectrum.

Selective Inventory Synchronization

Starting from the 10.2.1 release, the DX NetOps Spectrum, and UIM integration support selective synchronization of Server Management entities only. This functionality allows you to avoid full inventory synchronization and select only the server inventory which you want to get synced from UIM to Spectrum.

To enable the selective inventory synchronization, follow these steps:

1. Launch the DX NetOps Spectrum OneClick home page, and click Administration.
2. From the left Navigation pane, select UIM Configuration.
3. Contact the UIM Administrator for the following information, and enter it in the corresponding fields:
   a. UIM Server Host Name
   b. UIM Server Port
   c. UMP Server Host Name
   d. UMP Server Port
   e. UIM Group Name
   Inventory from the group you specify in this field is synchronized from UIM to Spectrum. The Synchronization happens only for the specified UIM group. The group name is created in UIM/UMP and it can be static or dynamic.
   > **NOTE**
   > If the Group Name field is empty or does not match with the UIM group name, then DX NetOps Spectrum pulls all server management entities from UIM during the sync.
   > You can only specify a single (static/dynamic) group from UMP at a time.
4. Select the dedicated SpectroSERVER from the drop-down list.

   > **NOTE**
   > The new devices that are managed by UIM will be created under the selected SpectroSERVER.
   > **Recommended Actions:**
   > To use Server and VMWare Management functionality simultaneously, enable VMWare Management before enabling the Server Management.
   > If both functionalities are enabled and you want to use only one of them then you must disable both and enable the functionality which you want to use.
5. Select the **Server Management** checkbox and click Test. (**Till 10.2.2 and spectrumgtw probe v8.65**)
   If the test is successful, Successfully connected to the UIM Server message appears.

   > **NOTE**
   > If you are setting up the integration using 10.2.3 and spectrumgtw probe v8.65, you can no longer enable the Server Management capability from the UIM Configuration page. To enable and configure the Server Management capability for Host servers, please refer to the spectrumgtw AC documentation.
6. Click **Save.**
   Successfully saved configuration to the database message appears.

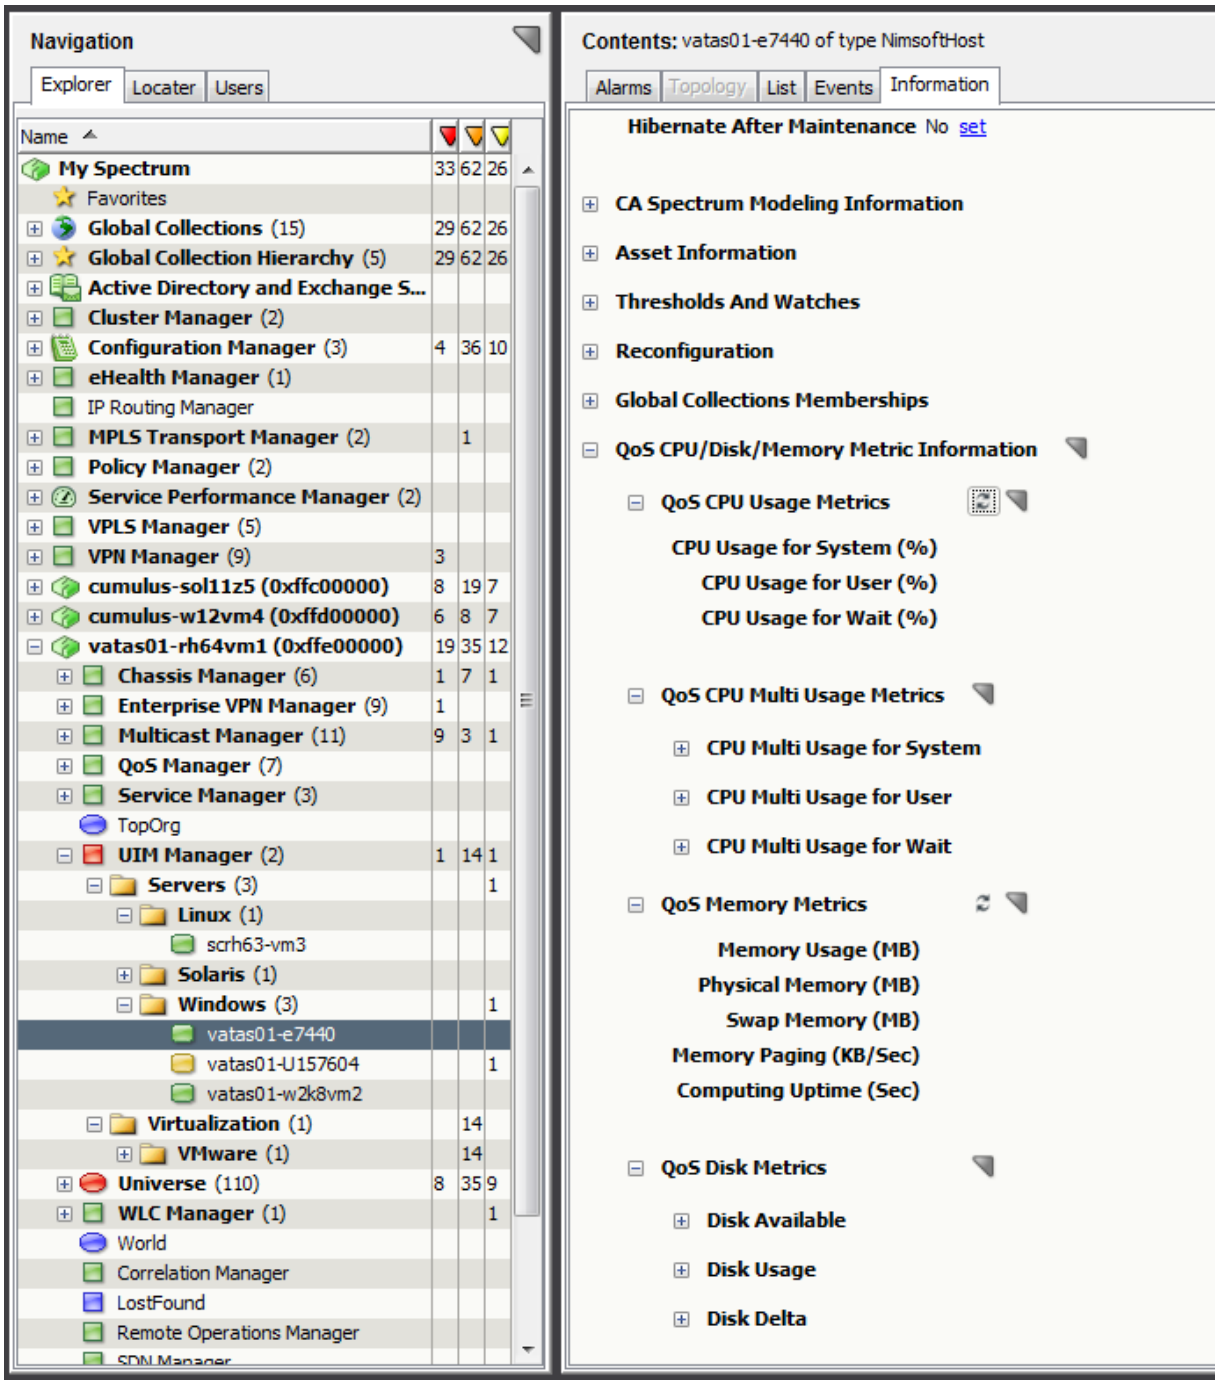
QoS Metrics

QoS Metric Information provides the metrics for both CPU and memory usage. From the Navigation Pane of OneClick Console, you can access the QoS metrics information of the available NimsoftHost Models. The following metrics are available for each UIM Host Model modeled in DX NetOps Spectrum:

- QoS CPU Usage Metrics
- QoS Multi Usage Metrics
- QoS Memory Metrics
- QoS Disk Metrics

Follow these steps:

1. From the OneClick Console, select the UIM Host Model available in the Navigation Panel.
   Contents Pane for the selected UIM Host Model is displayed.
2. Click the Information tab on Contents Pane.
   UIM Host Model information is displayed.
3. Expand QoS Metric Information SubView.
   QoS Metrics for the selected UIM Host Model is displayed.
   The following image displays the QoS Metrics for the UIM Host Model in DX NetOps Spectrum:



The following QoS Metrics are supported in this integration:

- **CPU Usage for System**
  Specifies the time that CPU spends on system tasks in percent.
- **CPU Usage for User**
  Measures the time that CPU spends on user tasks in percent.
- **CPU Usage for Wait**
  Measures the time the CPU waits when accessing external memory or another device in percent.
- **CPU Multi Usage for System**

Measures the time the CPU spends on system tasks in percent.

- **CPU Multi Usage for User**
  Measures the time that CPU spends on user tasks in percent.
- **CPU Multi Usage for Wait**
  Measures the time the CPU waits when accessing external memory or another device in percent.
- **Disk Available**
  Measures the amount of total available disk space for the file system. The Disk Available metrics are populated for only Network file systems.
- **Disk Usage**
  Measures the amount of total used disk space in the file system.
- **Disk Delta**
  Measures the amount of total disk usage change in the file system.
- **Memory Usage**
  Measures the amount of total available memory (physical and virtual memory) used in megabytes
- **Physical Memory**
  Measures the amount of total available physical memory that is used in megabytes.
- **Swap Memory**
  Measures the space on the disk that is used for the swap file in megabytes.
- **Memory Paging**
  Measures the amount of memory that is sent or reads from virtual memory in kilobytes/second.
- **Computing Uptime**
  Measures the computer uptime in seconds every hour.

  NOTE
  You may experience latency in loading QoS Metrics as the values are generated dynamically from UIM server, when queried.

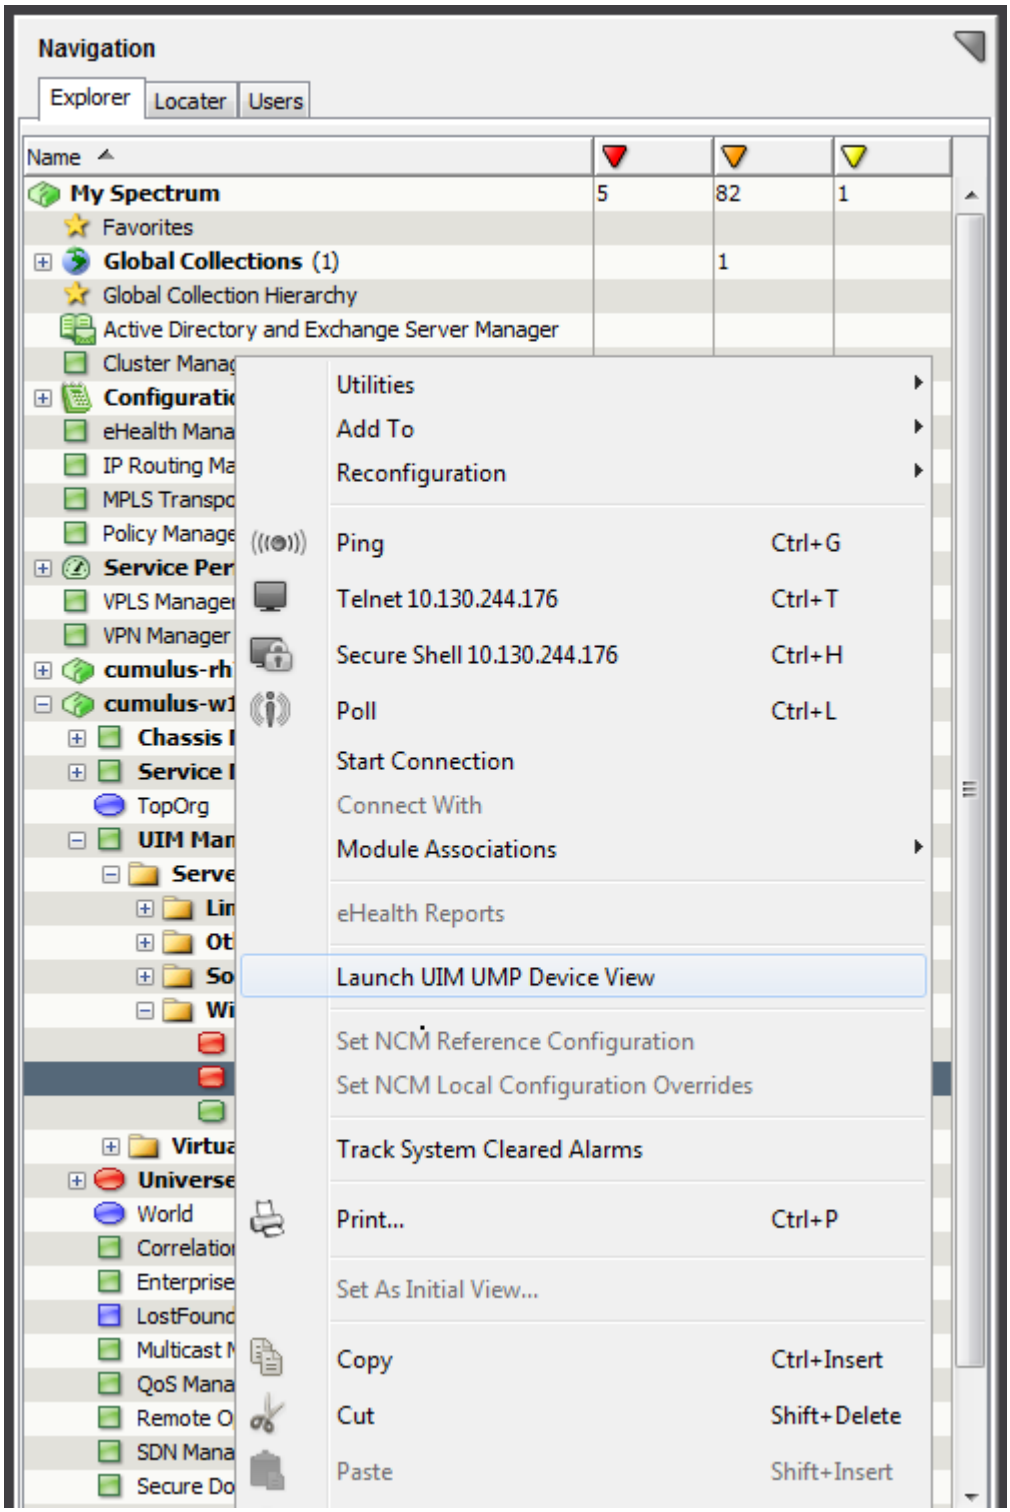
Launch-in-Context

The Launch-in-context feature is used to view the Unified Management Portal (UMP) of the host for the UIM host model. This feature provides detailed information about the UIM host model such as disk usage, CPU usage, processor queue length, paging, and memory usage. The information about the UIM host model is displayed graphically.

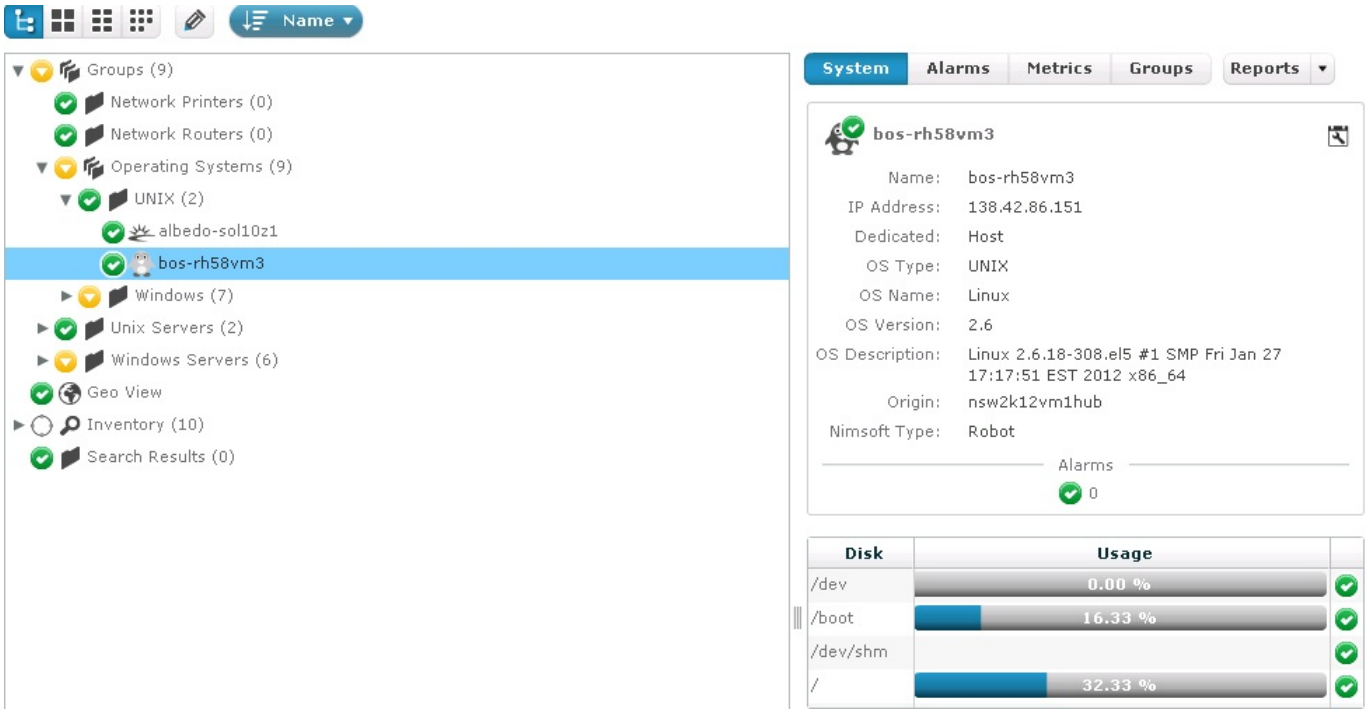
If you are launching the UMP view for the first time in a browser, a dialog for user credentials appears. The user credentials dialog does not appear if you are launching the UMP view using the same browser instance.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. From the Navigation panel, select UIM Manager and Servers.
   A complete list of host models is displayed in respective folders.
3. Right-click a host model and select Launch UIM UMP View.
   The UIM UMP login page opens.
   The following image displays the available host models and the option to launch the UMP view from the OneClick console:



4. Enter the UIM UMP credentials and click Login.
   The selected model details are displayed and the UIM UMP login is successful.
   The following image displays the UIM UMP view:

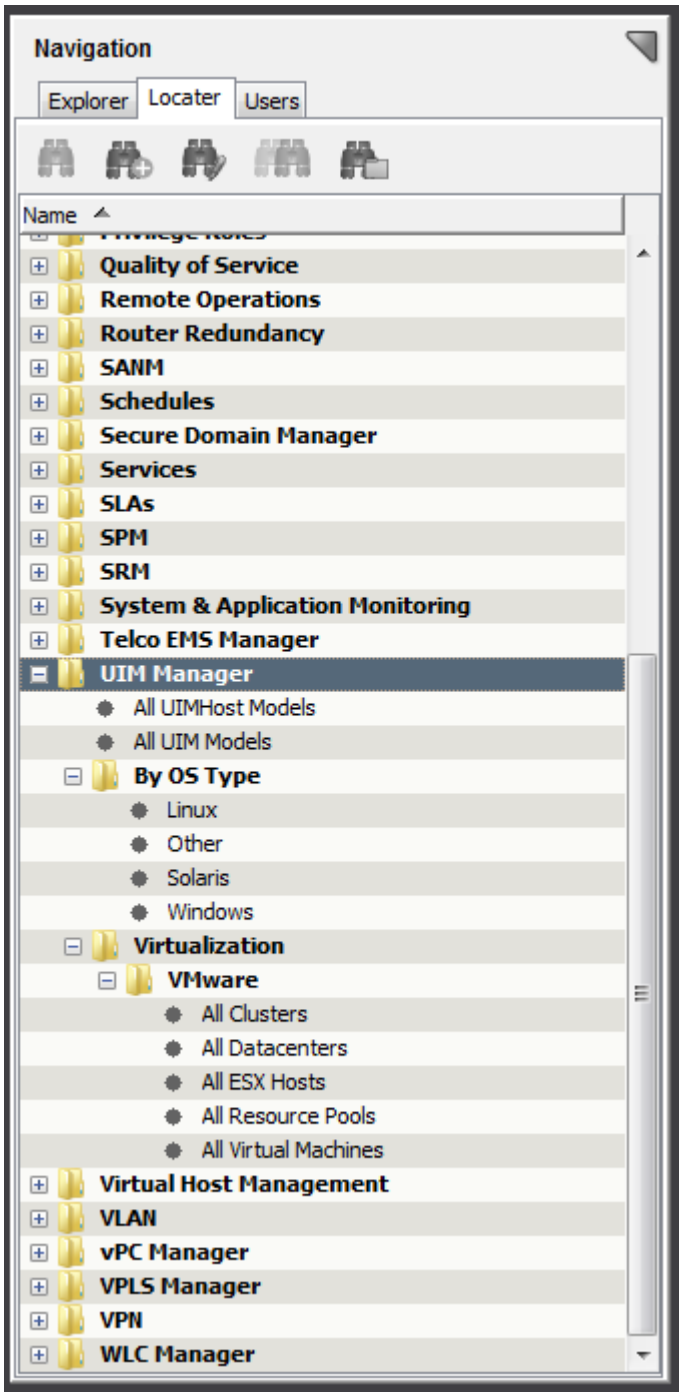


Locater Search

You can use the search functionality in the Locater tab to find the UIM related devices that are available in the DX NetOps Spectrum environment. Search can be performed based on the Operating system type such as Windows, Linux, and Other. Using this functionality, you can also search for all the NimsoftHostServer models and UIM models that are available in DX NetOps Spectrum. The search results appear in the Results tab of the Contents panel. Detailed information for application models that are selected in the results list appears in the Component Detail panel. Access Locater search from the Locater tab of the Navigation Panel.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick Console.
2. From the Navigation Panel, Click the Locater tab.
   The Search Options window opens.
3. Expand UIM Manager and select the models.
   The Locater Search results are displayed in the Contents pane.
   The following figure displays the Locater Search results for UIM Configuration Manager:



Reports

You can generate asset, alarm, availability, and WEBI reports for the UIM hosts. You can access InfoView from the OneClick home page to generate and manage reports. For more information, see the Report Manager section.

Outage Events

This section lists the events that mark the beginning and end of either a planned or unplanned model outage. The following list of events is used for the calculation of availability reports for UIM Host Server Models.

- Up events
  - 0x6330057
  - 0x6330000
- Down events
  - 0x6330003
  - 0x6330056

Standard up and down events are ignored for UIM Host Server Models while calculating the outages. For an existing spectrum model the outage is calculated based on standard up and down events.

Traps and Alarms Support

This integration supports the following alarms:

Generic Alarms

If any threshold violation occurs on UIM hosts, generic alarms are raised.

Event Code Range: 0x6330000 – 0x6330005

Disk Alarms

If the disk usage is high or the disk space availability is low on UIM hosts, disk alarms are raised.

Event Code Range: 0x6330030 – 0x6330035

Memory Alarms

If low memory or any threshold violations are noticed on UIM hosts, raise memory alarms.

Event Code Range: 0x6330040 – 0x6330045

CPU Alarms

If CPU utilization is high on UIM hosts, CPU alarms are raised.

Event Code Range: 0x6330050 – 0x6330055

Condition Correlation and Fault Isolation in UIM Integration

If a managed device stops responding to polls, the DX NetOps Spectrum fault isolation algorithm determines whether to create a critical alarm for the UIM hosts or suppress its alarm state. The unreachable device is the root cause of the alarm.

After the integration of DX NetOps Spectrum and UIM, the events/alarms are received from both Spectrum polling and UIM. Consider the following scenarios to apply condition correlation:

Scenario 1

If a Spectrum event is generated on the UIM host before the UIM event, condition correlation applies and the UIM event suppresses the Spectrum event.

Scenario 2

If a UIM Event is generated on the UIM host before the Spectrum event, condition correlation applies and the events are asserted on their respective host.

Scenario 3

If only Spectrum event is generated on the UIM host, condition correlation cannot be performed until the UIM event is generated and the Spectrum Event is displayed on the UIM host.

Scenario 4

If only UIM event is generated, you cannot perform condition correlation and the Nimsoft Event is displayed on the Nimsoft host.

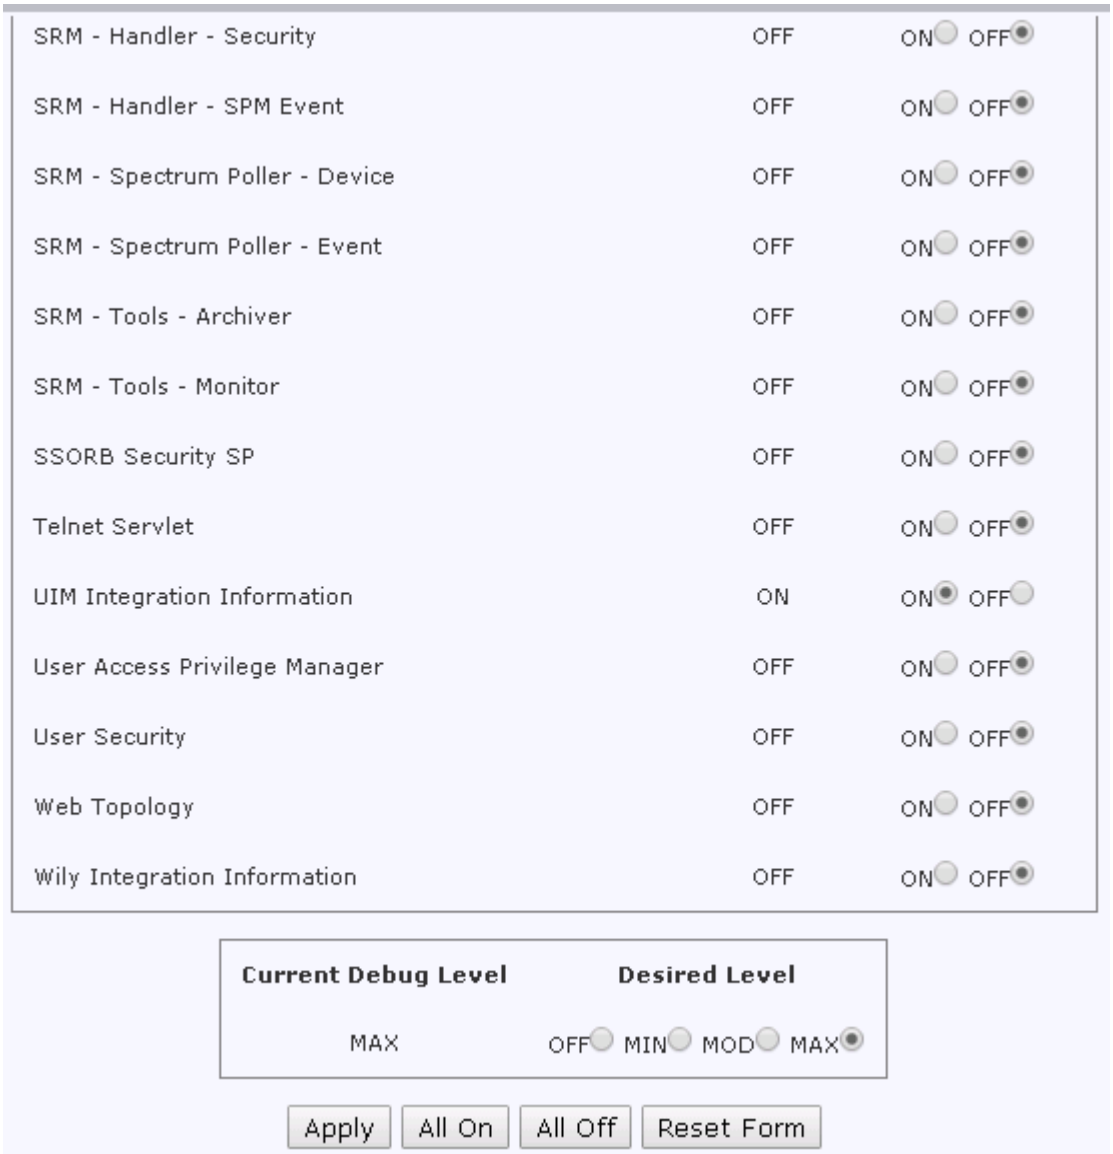
Debugging

Debugging in DX NetOps Spectrum lets you track the data flow from UIM to DX NetOps Spectrum. It investigates and resolves integration related issues. The Start Client Debug Console contains various debug modules. Turn on UIM Integration Information to track alerts and CIs that flow from UIM to DX NetOps Spectrum.

To use Start Client Debug Console, you must first have a running OneClick client. This debug tool lets you turn on debugging output that can be seen in the Java Web Start log.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages is displayed.
3. Click the Debugging tab.
   A panel with various links to view debugging output opens.
4. Click Web Server Debug Page (Runtime).
   A list of debug modules is displayed.
   The following image displays the list of available debug modules:



5. To enable debug, select On for the UIM Integration Information debug module.
6. Select Max as Desired Level and click Apply.
   Debug is enabled.
7. To disable debug, select OFF and click Apply.
   Debug is disabled.

Disable the Integration

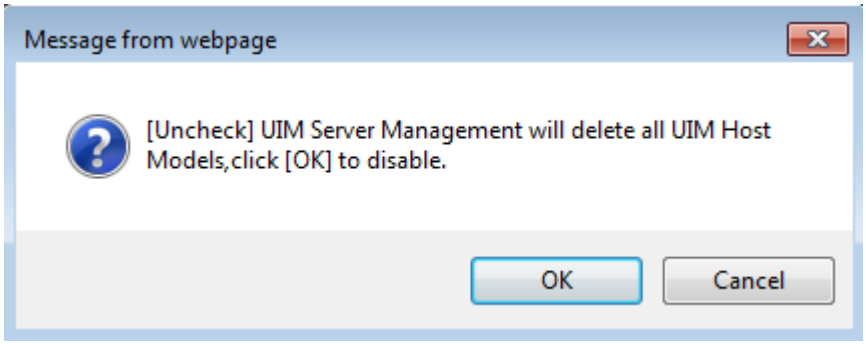
You can disable the DX NetOps Spectrum and UIM Integration from the OneClick Administration page.

NOTE
From 10.2.3, select the No integration option from the UIM Configuration page to disable the integration.

NOTE
You must disable UIM integration from the web server on which the integration is enabled.

Follow these steps (till 10.2.2):

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages is displayed.
3. Click the UIM Configuration link in the left panel.
   The UIM Configuration window opens.
4. To disable the UIM integration, select Disable and click Save.
   The confirmation dialog appears.
   The following image displays the confirmation dialog that appears after disabling the integration:



5. To confirm, click Ok.
   UIM integration is disabled successfully.

NOTE
Wait for the all the UIM Host server models and the folder hierarchy to be cleared from the UIM Manager in the OneClick view after disabling the integration. To validate, search for any UIM Host Server models, using the search option.

Integrate with UIM for Virtualization Management

WARNING

From the 10.1.2 release, the SNMP Gateway probe and SBGW /Southbound gateway are no longer recommended for alarms synchronization from UIM to DX NetOps Spectrum. Please use the DX NetOps Spectrum Gateway (spectrumgtw) probe for this.

For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

We recommend that you go through the DX NetOps Spectrum-UIM Integration using spectrumgtw probe - FACT SHEET to understand the changes to the integration whether you are new to this integration or an existing user.

This section describes how to set up the integration between the current releases of DX NetOps Spectrum and UIM for Virtualization Management. It also describes how to use its features to perform specific tasks such as synchronize inventory at regular intervals, manage alarms and events, and run reports.

The following video describes how you can integrate DX NetOps Spectrum and UIM for Virtualization Management to monitor virtual datacenters and to use DX NetOps Spectrum root cause analysis feature to rapidly troubleshoot and resolve issues:

Prerequisites for DX NetOps Spectrum and UIM Integration for Virtualization Management

Consider the following prerequisites for the integration:

WARNING

If you have enabled DX NetOps Spectrum and UIM integration for server management in 9.4, then while upgrading to 10.1.2, you must configure the latest UIM REST API (nisapi_WASP).

If you are integrating UIM with CA Spectrum 10.1.1 (or earlier), follow these steps:

1. 8.0.4 probe must be downloaded and configured before enabling the integration.
2. To migrate nisrest to nisapi, take the following steps:
   a. Stop svchost service.
   b. Navigate to C:\Program Files (x86)\CA UIM\probes\service\service_host\catalinaBase\webapps
   c. Remove nisrest.war and the nisrest directory
   d. Add the latest nisapi to archive.
   e. Deploy nisapi and restart svchost service.

   NOTE

   Migrating nisrest to nisapi is a one-time activity that is performed before enabling the integration.
3. Verify that the VMware (**vmware**) and SNMP Gateway (**snmpgtw**) probes are configured before enabling the DX NetOps Spectrum and UIM integration.
4. All the primary SpectroSERVERs should be up and running while enabling the DX NetOps Spectrum and UIM integration.
5. Enable QoS metrics and alarms in UIM for DX NetOps Spectrum OneClick views and condition-correlation to work.
6. UIM integration must be enabled on the OneClick server, which is configured to Main Location Server (MLS) (preferably server which does not have SRM).
7. DX NetOps Spectrum models virtual machines (VMs) whose PrimaryDNSName and PrimaryIPV4address attribute data are not reported to DX NetOps Spectrum by UIM. For UIM to report these attributes, deploy VMware Tools on all the VMs.

   NOTE

   In previous releases of UIM, the nisapi_service_host package was deployed to the service_host probe. As of CA UIM release 8.47, the service_host probe was deprecated and its functionality was moved to the wasp probe.

   - By default**,** the wasp probe uses port 80. However, because the wasp probe is a core component in UIM, this port should already be open in a properly functioning UIM environment.

Deploy and Configure Probes

To optimize the DX NetOps Spectrum and UIM integration, deploy and configure the following UIM probes on UIM server:

- **snmpgtw** Sends traps from UIM to DX NetOps Spectrum. The SNMP gateway converts alarms to SNMP trap messages that are readable by any SNMP-based event manager.
- **vmware (VMware Monitoring)** The vmware probe automates all common monitoring and data collection tasks, and lets you focus on problems as they arise. The vmware probe collects and stores data and information from the monitored components through VMware Virtual Center (vCenter), or by connecting to ESX servers directly, at customizable intervals. You can define alarms to be generated when specified thresholds are breached or when the service is unavailable.
- **net_connect** The net_connect (Network Connectivity Monitoring) probe measures network connectivity that is based on "ping" (ICMP ECHO) and the TCP connections to a list of user-defined services. The service can be NetBIOS, Telnet, FTP, and HTTP. The probe supports the UIM family of solutions by sending quality of service (QoS) messages.
- **(nisapi) service_host or wasp** Queries the CA Nimsoft Manager using the Restfull Services API to retrieve the list of UIM models to be monitored. Deploy service_host v8.04/ wasp v8.4.2 or higher.
- **cdm** The CPU, Disk, Memory Performance Monitoring (cdm) probe monitors the performance and resource load on the system with the robot. The UIM CPU, Disk & Memory (cdm) probe generates alarms that are based on configured threshold values and trending statistics.

The probe provides the following benefits:
  - Generate alarms that are based on configured threshold values. The probe generates alarms that can trigger corrective actions immediately.
  - Generate trending Quality of Service (QoS) data. The information is measured and sent to the data_engine probe to process and store in the UIM database. The historical data facilitates capacity planning for monitored systems in the IT environment. Some examples are as follows:
    - View how disks are filling up over time
    - Plan batch jobs according to the CPU utilization
    - Upgrade systems which consistently operate near capacity
- **spectrumgtw** The spectrumgtw (DX NetOps Spectrum Gateway) probe provides a bidirectional (UIM to DX NetOps Spectrum and DX NetOps Spectrum to UIM) integration between CA Unified Infrastructure Management and DX NetOps Spectrum enabling you to perform the following actions:
  - Export and correlate DX NetOps Spectrum Inventory from a Global Collection to UIM inventory.
  - Bi-directional synchronization of alarms
  - Bi-directional Clear / Update of alarms
  - View symptomatic DX NetOps Spectrum alarms in the context for the root-cause alarm in UIM
  - Ticket ID synchronization between DX NetOps Spectrum and UIM

    WARNING

    From 10.2.1, all UIM events (apart from events related to VMWare and servers) are no longer considered as generic events.
    Specific events raised on UIM from the following probes are mapped to unique events created in DX NetOps Spectrum. This allows you to manage the events (raised on UIM) from DX NetOps Spectrum more efficiently.

Additional event mapping for select metrics from the following probes (along with cdm and net_connect probes) is added from 10.2.1. Additional event mapping for Please refer to Additional event mapping from UIM Probes to DX NetOps Spectrum.

- **logmon** The Log Monitoring (logmon) probe scans ASCII-based systems and application log files by matching specified expressions. Alarms are generated when the log file content matches the defined expression.
- **rsp (Remote System probe)** The Remote System Probe (rsp) allows you to monitor system metrics. The probe collects performance data in an agentless manner without installing proprietary software on the system.
- **sqlserver** The SQL Server Monitoring (sqlserver) probe constantly monitors the internal performance and space allocation of SQL Server databases. The probe can run locally on the database server or it can be configured to run as a remote client. The probe feeds essential information that is based on predefined criteria to the UIM availability manager for appropriate alert notification, as required. An extensive range of checkpoints can be selected and individually scheduled to meet your monitoring requirements. The probe will run selected SQLs to extract vital information about your SQL Servers. The information is presented to database-administrator as alarms or reports.
- **processes (Process Monitoring)** The (Process Monitoring) processes probe monitors the specified processes to detect any error situation. The probe also retrieves information about the process, for example, the CPU usage, memory usage, and so on.

You can configure the UIM probes through the Probe Configuration interface. For more information, see the CA Unified Infrastructure Management Probe Space.

How to Integrate DX NetOps Spectrum and UIM for Virtualization Management

From the OneClick Administration page, you can enable the integration between DX NetOps Spectrum and UIM for Virtualization Management. When you enable the integration all the virtual entities managed by UIM appear in DX NetOps Spectrum.

NOTE

If you want to change any details on the Administration page, refresh the page before making any changes.

WARNING

- If you enable the integration for VMware Management, all the entities that are managed by Virtual Host Manager (VHM) such as VMware, Hyper-V, Zones, Huawei SingleCloud, and LPAR through CA Virtual Application Insight Module (VAIM) are disabled permanently and all the existing VHM models are deleted. You must reinstall DX NetOps Spectrum for CA VAIM based Virtualization Management.
- From 10.2.3, DX NetOps Spectrum can monitor both UIM models and SystemEdge models when DX NetOps Spectrum-UIM Integration is enabled with Multi-tenancy. When the integration is enabled with Multi-tenancy, UIM origins are mapped to DX NetOps Spectrum landscapes. In this scenario, DX NetOps Spectrum monitors UIM models on the landscapes which are part of Multi-tenancy mapping and can monitor SystemEdge AIM based models on the landscapes which are not part of Multi-tenancy mapping.When the DX NetOps Spectrum-UIM Integration is enabled without Multi-tenancy, DX NetOps Spectrum monitors UIM models only. All the SystemEdge AIM based models are deleted on all the landscapes.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages is displayed.

   1. a. Click the UIM Configuration link in the left panel.
      The following image illustrates the configuration options that are available in the UIM Configuration window:

      If the integration was already enabled before the upgrade, then the **Legacy Integration** radio button would appear as selected by default.

      UIM Server Host Name Indicates the IP address/hostname of the UIM Server.

      UIM Server Port Indicates the server port number of UIM.

      UMP Server Host Name Indicates the IP address/hostname of UMP.

      UMP Server Port Indicates the server port number of UMP.

      UMP Server Protocol Indicates the network protocol to connect to the CA UMP server.

      NOTE

      From spectrumgtw 8.67 onwards, the UIM Group Name field in the UIM configuration section has been changed to Group Name for Hosts.

UIM Group Name for Hosts: Specify the UIM group name in this field for selective inventory synchronization of hosts (of the UIM group specified) from UIM to DX NetOps Spectrum. This is applicable to Server Management entities only.

UIM Group Name for VMware: Specify the UIM group name in this field for selective inventory synchronization of VMware entities (of the UIM group specified) from UIM to DX NetOps Spectrum. To address the challenges

in providing filtering of VMware data from UIM to DX NetOps Spectrum, a 'UIM Group Name for VMware' field is introduced from spectrumgtw v.8.67.

1. a.

NOTE

1. Ensure that you add vCenter and ESX hosts and the corresponding virtual machines to be synced to DX NetOps Spectrum.

2. If the vCenter is not part of the group, ESX and VMs are not modeled in DX NetOps Spectrum even though they are part of the group.

3. If vCenter and VMs are part of the group and ESX is not, then the VMs are created without any relationship with the vCenter in DX NetOps Spectrum.

NOTE

Inventory from the group you specify in this field is synchronized from UIM to DX NetOps Spectrum.

NOTE

For successful encrypted communication (https protocol) between DX NetOps Spectrum and UIM UMP Server, you must import SSL Certificate of UIM UMP Server into DX NetOps Spectrum OneClick Server. To import the certificate, from the OneClick home page select **Administration**, **SSL Certificates**, upload the certificate file then click **Save**. Restart the OneClick web server for the changes to take effect.

WARNING

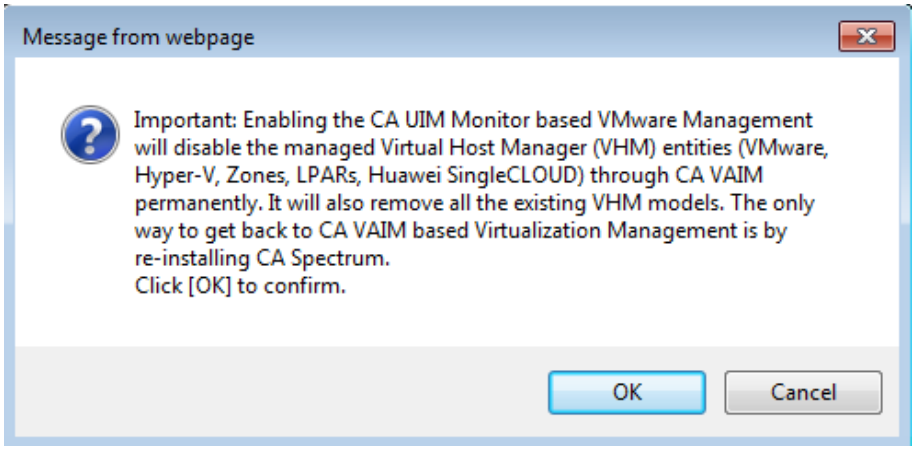
Inventory from the group you specify in this field is synchronized from UIM to DX NetOps Spectrum. If you leave the UIM/UMP Group Name field blank, all inventory from the specified UIM server is synchronized with DX NetOps Spectrum.

3. Select the SpectroSERVER under which the new models for devices managed by UIM are to be created.
4. To enable the UIM integration for VMware, select VMware Management. (**Till 10.2.2 and spectrumgtw probe v8.65**)

NOTE

If you are setting up the integration using 10.2.3 and spectrumgtw probe v8.65, you can no longer enable/disable the VMware Management capability from the UIM Configuration page. To enable and configure the VMware Management capability for VMware, please refer to the spectrumgtw AC documentation.

The following warning message appears:



5. To confirm, click **OK.**

WARNING

In the OneClick Admin page, do not enable or disable the '**VMware Management**' or '**Server Management**' options when the MLS is down. This may cause unexpected errors.

In the DX NetOps Spectrum OneClick console, do not create any container of type '**UIMInventoryContainer**'.

6. Click **Test.** If the test is successful, "**Test connection to UIM Server was successful**", the message appears.
7. Click **Save.**Successfully saved configuration to the database message appears.
   UIM integration is now enabled.

NOTE

If you change any settings on any of the OneClick server other than the integration OneClick server. The message, "Saving details on this OC will change the Integration OC Server. Click [OK] to continue" appears. If you click Save, the integration OneClick server changes and the details are saved. If you click Cancel, the details are saved but the integration OneClick server remains same.

WARNING

If the Main Location Server (MLS) in a Distributed SpectroSERVER (DSS) setup is down and if it does not have a secondary SpectroSERVER, the configuration information that is specified in the UIM Configuration page fails to save to the database. We recommend that you use the Fault Tolerance (FT) setup for MLS to avoid any inconsistent behavior.

WARNING

- If the UIM-DX NetOps Spectrum integration is enabled in a FT setup, it is recommended that you synchronize the Primary and Secondary SpectroSERVERs after the first successful synchronization. This will ensure that you have the integration data backed up in case the Primary/ dedicated SS (specified in the OneClick Admin > UIM Configuration) goes down.
- It is also recommended that you synchronize the Primary and Secondary SpectroSERVERs, after a successful synchronization job, if you are moving Datacenters from a MLS to a Non-MLS landscape.

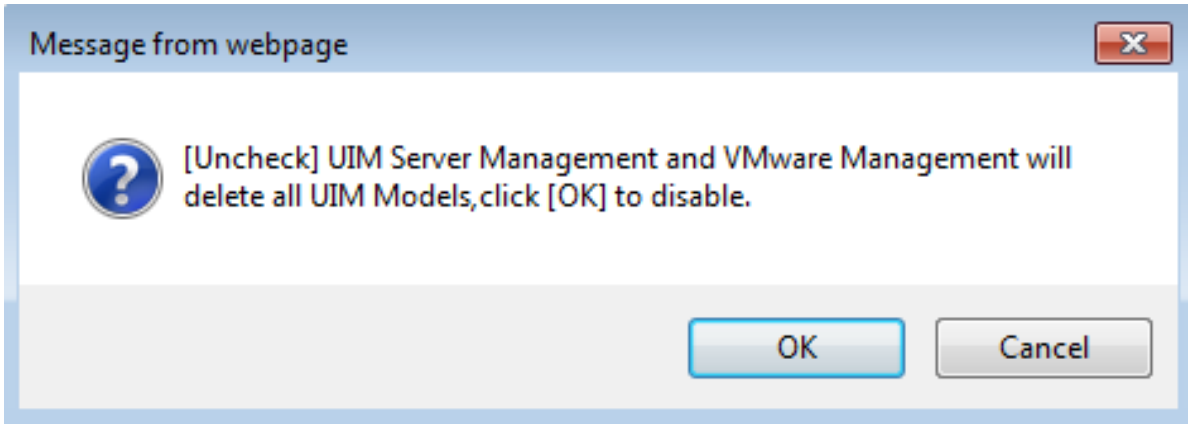
Disable the Integration

You can disable the DX NetOps Spectrum and UIM Integration for Virtualization Management from the OneClick Administration page.

NOTE
From 10.2.3, select the No Integration option from the UIM Configuration page to disable the integration. To disable only VMware integration capabilities you need to disable the VM Server Integration from the VMware Configuration section of the spectrumgtw probe Admin Console. For more information, please refer to the spectrumgtw Admin Console documentation.

Follow these steps(Till 10.2.2):

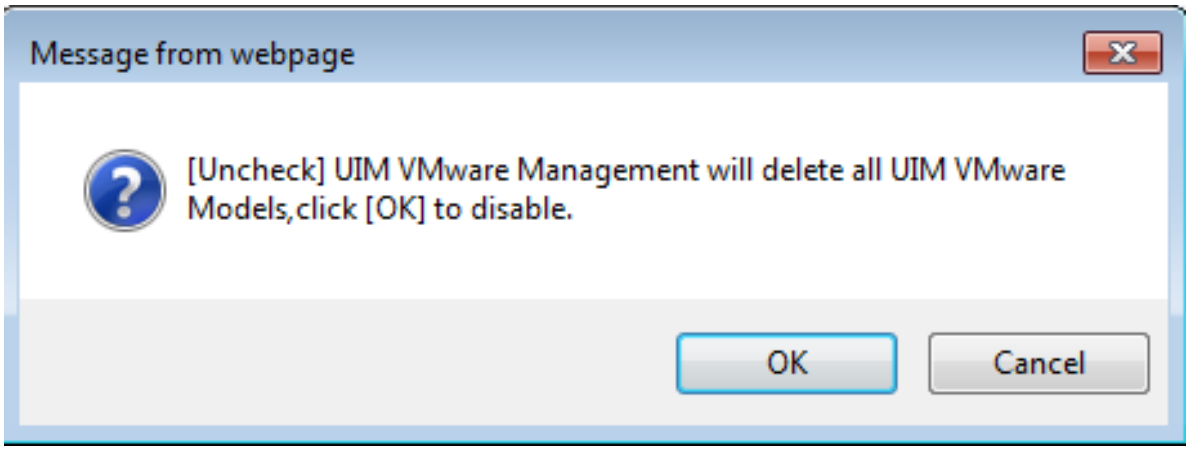
1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages is displayed.
3. Click the UIM Configuration link in the left panel.
   The UIM Configuration window opens.
4. Consider the following scenarios to disable the UIM integration:
5. Clear both Server and VMware Management options and click **Save**.
   The following message appears:



6. Click Ok, DX NetOps Spectrum and UIM integration for both Server Management and Virtualization Management is disabled.

   NOTE
   Wait for the all the UIM Host server models and the folder hierarchy to be cleared from the UIM Manager in the OneClick view after disabling the integration. To validate, search for any UIM Host Server models, using the search option.

7. If you clear the VMware Management checkbox and click **Save.**
   The following message appears:



8. Click OK.
   DX NetOps Spectrum and UIM integration for Virtualization Management is disabled.

Supported Features (UIM Integration)

This section briefly describes the following features that are supported in DX NetOps Spectrum and UIM integration for Virtualization Management:

Models Created for VMware (UIM Integration)

UIM Manager includes the following models and icons for VMware devices:

VMware vCenter Server

Represents a physical or virtual host that contains the vCenter application to manage your VMware virtual environment.

Icon:

ESX Host

Represents an ESX host, as configured in your VMware virtualization technology. An *ESX host* is a physical computer that uses ESX Server virtualization software to run virtual machines. Hosts provide the CPU and memory resources that virtual machines use and give virtual machines access to storage and network connectivity. In the Universe topology, these models group your virtual entities into a separate view while showing how the virtual environment interacts with the physical network. The ESX host cannot be contacted directly for status information. Instead, the status of these models is inferred from the status of the items that it contains.

Icon:

Virtual Machine

Represents a virtual machine, as configured in your VMware virtualization technology. A *virtual machine (VM)* is a software computer that, like a physical computer, runs an operating system and applications. A virtual machine dynamically consumes resources on its physical host, depending on its workload. Because virtual machines are flexible computing units, their deployment comprises a wide range of environments. Examples include environments such as data centers, cloud computing, test environments, or desktops and laptops. In data center implementations, they are used for server consolidation, workload optimization, or higher energy efficiency.

Icon:

Nimsoft Manager also creates models these additional VMware entities that organize the ESX hosts and their virtual machines:

Datacenters

Represents a datacenter, as configured in your VMware virtualization technology. A *datacenter* serves as a container for your hosts, virtual machines, resource pools, or clusters. Depending on their virtual configuration, datacenters can represent organizational structures, such as geographical regions or separate business functions. You can also use datacenters to create isolated virtual environments for testing or to organize your infrastructure. Components can interact within datacenters, but interaction across data centers is limited. A datacenter can contain clusters or hosts.

Icon:

Clusters

Represents a cluster, as configured in your VMware virtualization technology. A *cluster* is a group of ESX hosts and their associated virtual machines. When a host is added to a cluster, the host resources become part of the cluster resources. The cluster manages the resources of all hosts within it. A cluster can contain hosts, resource pools, or virtual machines.

Icon:

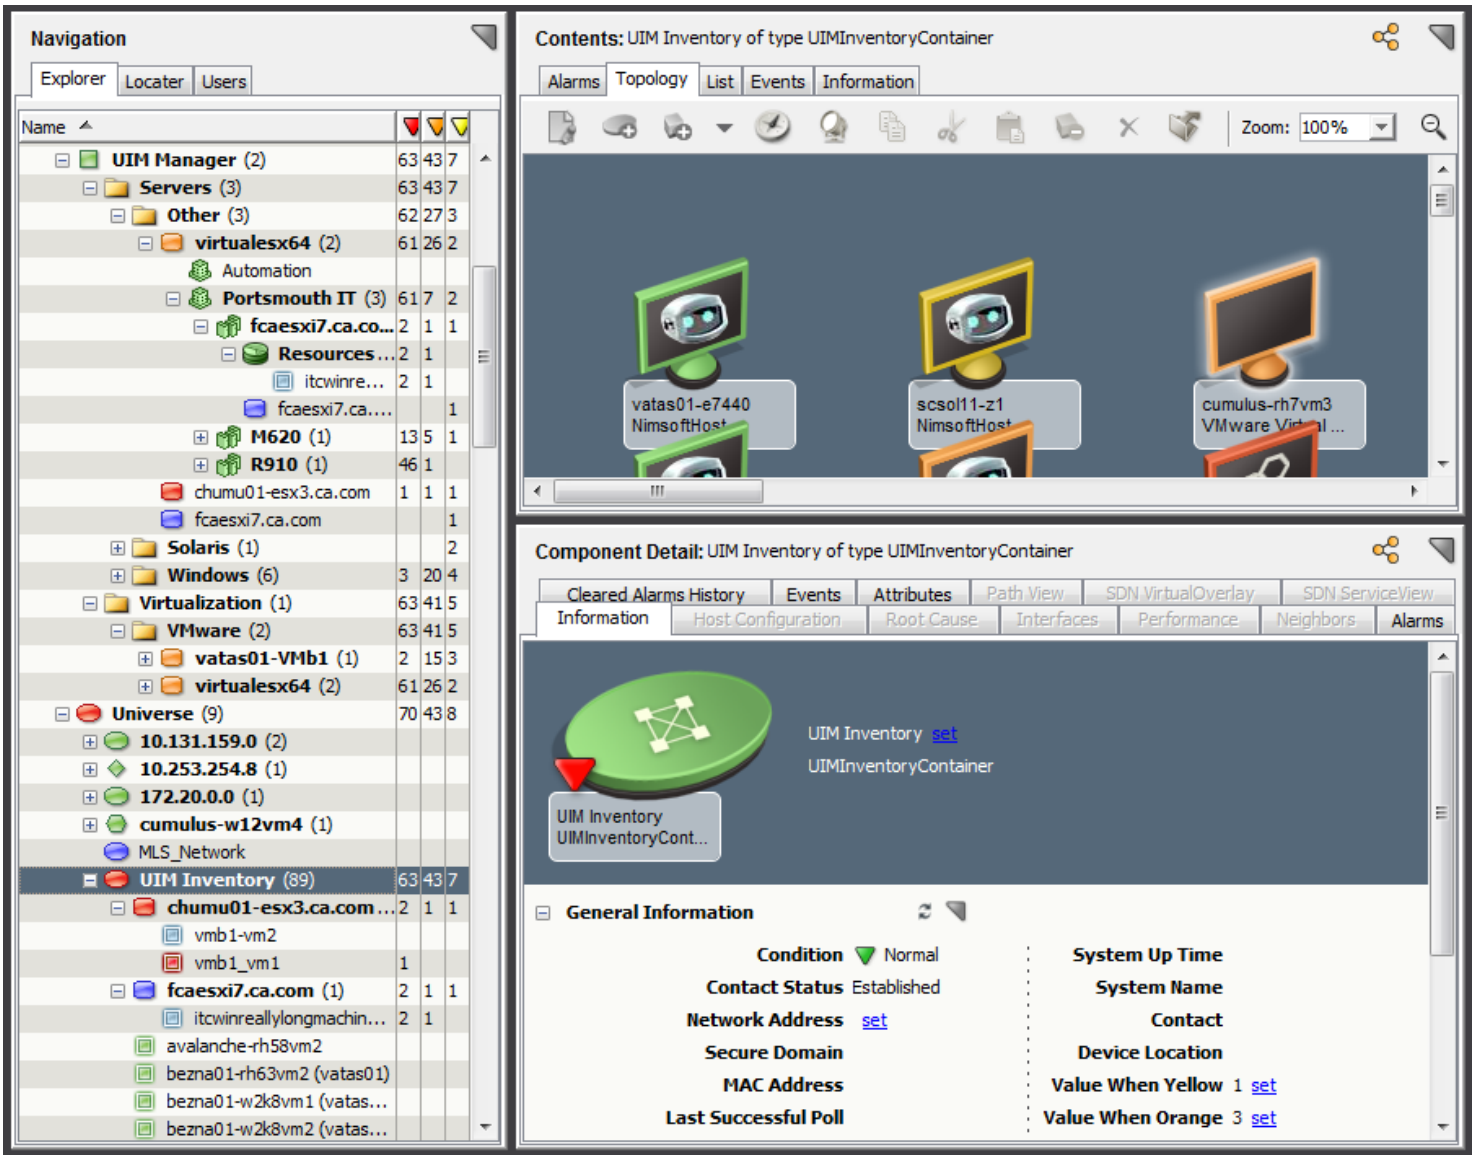
Resource Pools

Represents a resource pool, as configured in your VMware virtualization technology. A *resource pool* defines partitions of physical computing and memory resources of a single host or a cluster. You can partition any resource pool into smaller resource pools to divide and assign resources to specific groups or for specific purposes. You can also hierarchically organize and nest resource pools. A resource pool can contain virtual machines or more resource pools.

Icon:

Hierarchy in the OneClick Navigation Page

You can view the virtual entities such as Virtual Center (VC), and Virtual Machines (VM)s that are created for VMware under **UIM Manager** node in the OneClick console. Logical entities such as Clusters, Data Centers, and Resource Pools can also be viewed in the OneClick Navigation page. A new container '**UIM Inventory**' is created under the Universe view, this container will have the ESX Hosts, Nimsoft Hosts, Vcenter servers and corresponding VMs. ESX hosts are also displayed under the **UIM Manager > Servers** hierarchy. In the Explorer View, **UIM Manager** provides a more detailed hierarchy i.e. ***VCenters > Data Centers > Clusters > Resource Pools > VMs*** , compared to the **UIM Inventory** view, which only displays the hierarchy of ESX Hosts and associated VMs.



ESX Hosts are placed under the UIM Manager hierarchy and in the Universe > UIM Inventory hierarchy, in the OneClick console. To organize the Universe hierarchy, move(cut/paste) the ESX hosts to other containers within the Universe.

NOTE

Do not move containers before running a synchronization job, else, duplicate models are created in DX NetOps Spectrum.

NOTE

If you move (cut/paste) the UIM inventory container model frequently, (and VMs within the UIM inventory Container model are connected to upstream switches), the pipes (connectors) might appear in black color.

To fix the black pipes (connectors) error, follow these steps:

1. Navigate to ***$SPECROOT/tomcat/webapps/spectrum/WEB-INF/web.xml***
2. In the web.xml file, you need to add the below context:

```
<context-param xmlns="">
```

```
<param-name>com.aprisma.topo.Topology.PipeUpdateTardiness</param-name>
<param-value>1000</param-value>
<description>
This parameter defines the amount of time in seconds after which a pipe connection is established.
</description>
</context-param>
```

If you already you have the above context in the web.xml file, ensure that the param-value is greater than or equal to 1000.

Distribution of Virtual Center (VC) Across Landscapes

In a Distributed SpectroSERVER (DSS) environment, DX NetOps Spectrum, and UIM integration has the capability to distribute the Virtual Centers (VCs) across landscapes rather modeling all the VCs on the selected landscape which helps to show the connectivity (layer 2 or 3) between the Virtual Machine (VM) and upstream devices. If no upstream devices are available, the VC and all the entities that are managed by that VC are modeled in the dedicated SpectroSERVER.

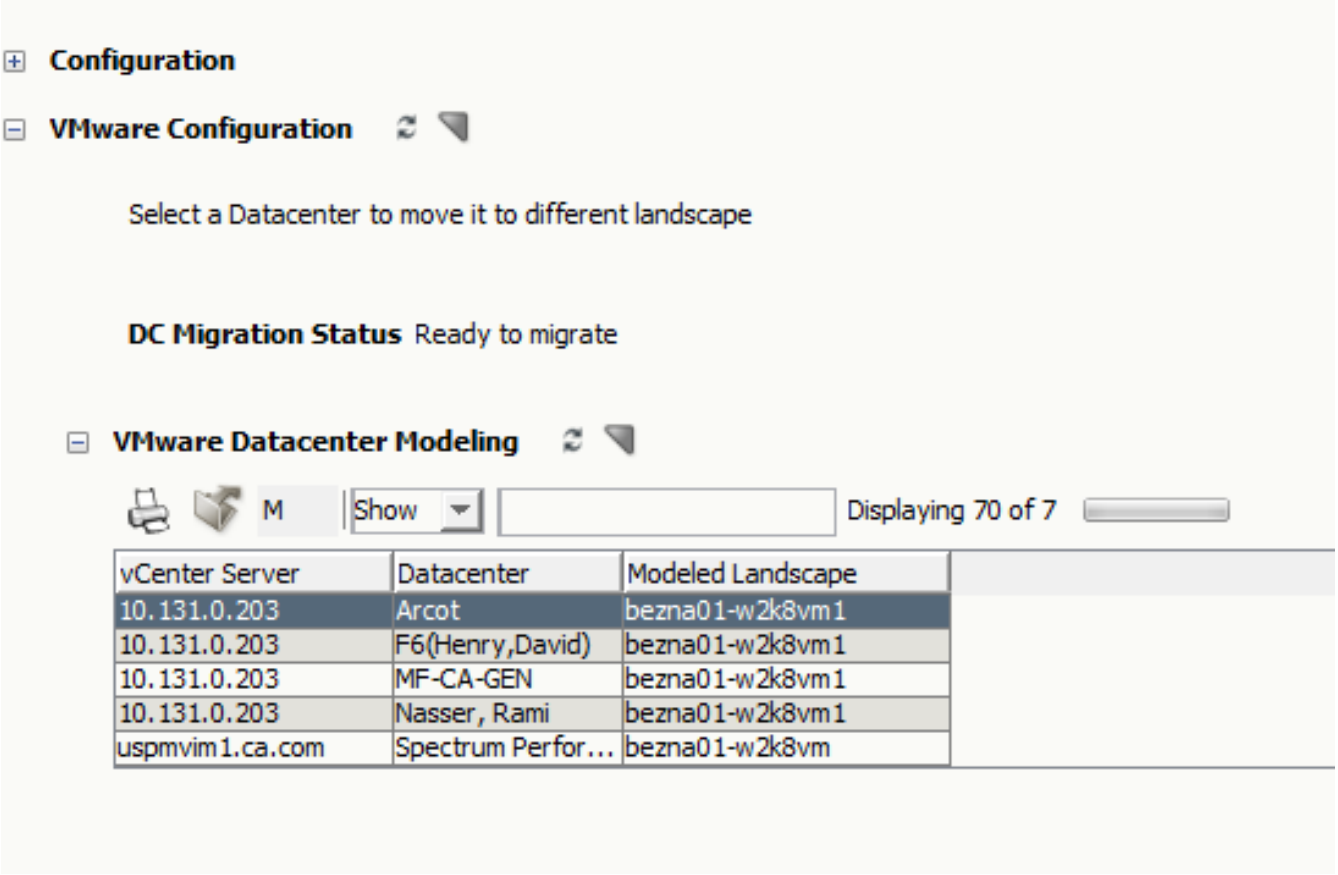
Migrating DataCenters across Landscapes

You can move Datacenters from an existing landscape to a new landscape where the upstream devices are discovered. If a Datacenter migration is in-progress, you cannot migrate another DataCenter. Also, if a virtualization sync is in-progress, the Datacenter migration is not allowed.

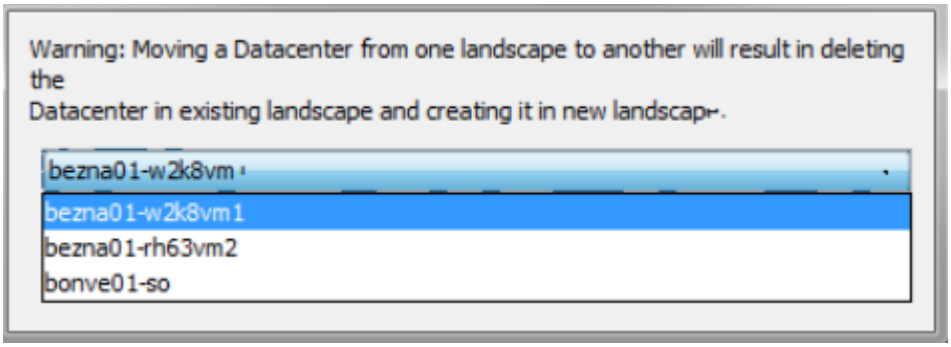
> **NOTE**
>
> If you move a Datacenter from one landscape to another, it results in the deletion of Datacenter from the previous landscape. Any existing events or alarms that are present on the Datacenter and its entities are lost.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. Select Nimsoft Manager and select the Information tab on the Content pane.
   VMware Configuration information is displayed.
3. Expand VMware Configuration and VMware Datacenter Modeling.
   A list of datacenters and the modeled landscapes are displayed.
   The following image displays the table with a list of Datacenters and the modeled landscapes:



4. Select a Datacenter and select Move.
   The Select Landscape dialog appears.
   The following image shows the list of landscapes that are available in DX NetOps Spectrum:



5. Select a landscape and select Ok.
   The confirmation window opens.
6. Select Ok.
   The datacenter is moved to the selected landscape successfully.

NOTE

If Datacenters are migrated from landscapes that are down, then the migrated datacenter and its entities are deleted from the old landscape, during the subsequent sync, once that landscape is up.

Migrating Multiple DataCenters across Landscapes Via REST API

Previously, as a user, you could only migrate one Datacenter a time from one landscape to another using the OneClick console. Each time the user migrated the Datacenter, triggering the discover connection, caused a delay in completing the migration. To address this challenge, 10.3.1 introduces a new feature under the DX NetOps Spectrum-UIM integration, to migrate multiple Datacenters at a time from an existing landscape to a new landscape. To achieve this execute a post request through a REST call with the required information payload. The new approach triggers discover connections only once during the migration of multiple Datacenters.

GET Request:

GET action issues an action request to OneClick Server to get complete Datacenters information across landscapes using the get request via REST API.

GET URL

Open any REST Client and perform the below GET request.

```
http://<OC server Name>:<Port number>/spectrum/restful/datacenters
```

Sample Output:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<datacenter-response status="Success">
<dc-elements>
<vcid>62</vcid>
<vcip>10.131.159.5</vcip>
<dcid>C566c8be11d7e9700a63d2cdf5579df06</dcid>
<dcname>ITC-SPECTRUM</dcname>
<currentlandscape>0xc00000</currentlandscape>
<newlandscape>0xc00000</newlandscape>
 </dc-elements>
<dc-elements>
<vcid>109</vcid>
<vcip>138.42.93.28</vcip>
<dcid>Ca0a997f0b109e2e542d8699eb5f718b3</dcid>
<dcname>Engineering</dcname>
<currentlandscape>0xc00000</currentlandscape>
<newlandscape>0xc00000</newlandscape>
</dc-elements>
</datacenter-response>
```

In the above response, each <dc-elements> tag contains an individual data center information. In case you have ten Datacenters, in the response, you get ten <dc-elements> with appropriate details. If you want to move any datacentre from one landscape to another, simply copy the <dcelements> of that specified Datacenter and update the new landscape field name in <dc-elements> with new landscape information.

POST Request:

POST URL

Open any REST Client and perform the below POST request with needed payload information.

```
http://<OC server Name>:<Port number>/spectrum/restful/dcmigration
```

Sample Post Payload:

This payload has the same <dc-elements> information that we received from the get request with an updated new landscape name where you have to move the Datacenter. Following is an example of migrating two data centers from landscape 0xc00000 to another landscape 0x1800000.

```
<?xml version="1.0" encoding="UTF-8"?><datacenter-migration-info xmlns="http://www.ca.com/spectrum/restful/
schema/request">
<dc-migration-list>
<dc-elements>
<vcid>62</vcid>
<vcip>10.131.159.5</vcip>
<dcid>C566c8be11d7e9700a63d2cdf5579df06</dcid>
<dcname>ITC-SPECTRUM</dcname>
<currentlandscape>0xc00000</currentlandscape>
<newlandscape>0x1800000</newlandscape>
</dc-elements>
<dc-elements>
<vcid>109</vcid>
<vcip>138.42.93.28</vcip>
<dcid>Ca0a997f0b109e2e542d8699eb5f718b3</dcid>
<dcname>Engineering</dcname>
<currentlandscape>0xc00000</currentlandscape>
<newlandscape>0x1800000</newlandscape>
</dc-elements>
</dc-migration-list>
</datacenter-migration-info>
```

Schedule Virtualization Sync

Contents

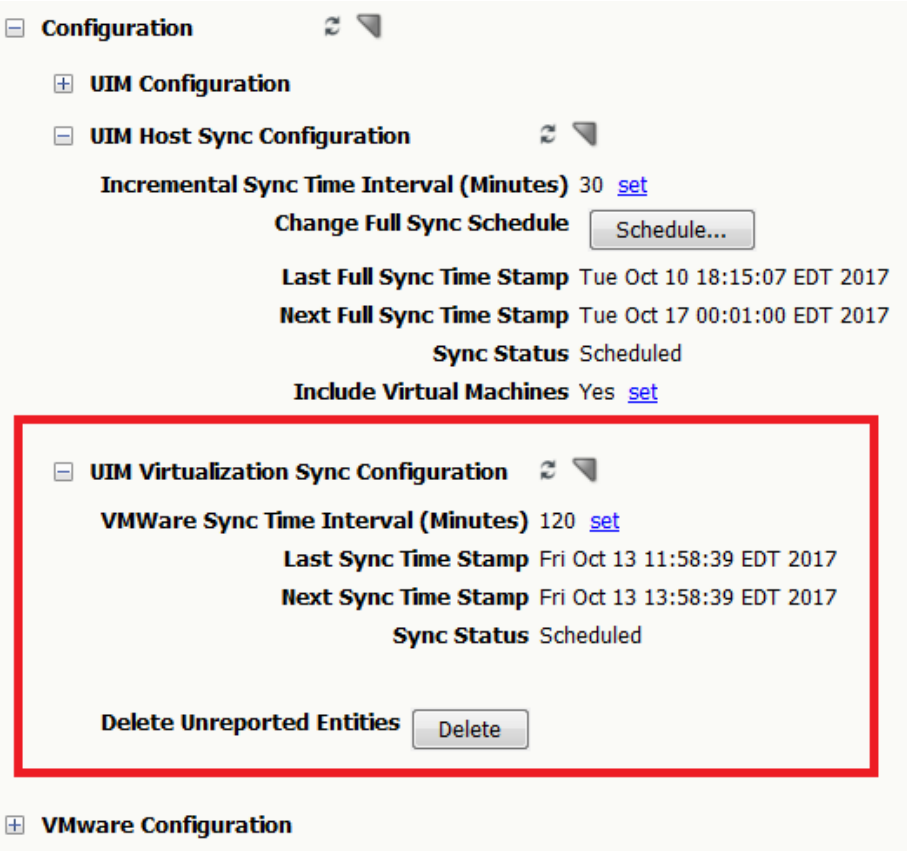
Overview

This integration supports Virtualization sync. When the DX NetOps Spectrum and UIM integration is enabled, synchronization happens automatically at the scheduled time interval displayed in the OneClick view. Additions, deletions and modifications of VMWare entities in UIM are reflected in DX NetOps Spectrum after the Virtualization sync. You can schedule the Virtualization sync at regular intervals through the OneClick view.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. Select **UIM Manager** from the Navigation panel on any landscape.
   The **Contents** pane for UIM Manager opens.
3. Click the **Information** tab and expand **Configuration.**
4. Expand **UIM Virtualization Sync Configuration.**
   Information on Virtualization sync is displayed.

   The following image displays the option to schedule Virtualization sync:



5. Click set to schedule Virtualization sync.
   The Time interval window opens.
6. Specify the time interval and click **OK.**
   Default: 300 minutes.
   Minimum: 60 minutes.
   You can confirm whether the Virtualization sync is complete, based on **Sync Status** value.

Delete Unreported Entities

The **Delete Unreported Entities** button, allows you to delete entities/models that are no longer reported as part of virtualization integration.
The entities/ models that were previously reported only as part of virtualization integration will be placed in the Unreported Entities/ Models container, if they are no longer reported. (These entities/ models were auto-deleted previously. You will now have to manually delete these entities using the Delete Unreported Entities button).

1. Click **Delete**.
   A relevant confirmation dialog appears.
2. Select **Yes** to delete the entities/models from this container across landscapes.
   An appropriate confirmation message is displayed.

Reconciling UIM virtual entity data with existing DX NetOps Spectrum models

During virtualization synchronization, when a new UIM virtual entity is reported to DX NetOps Spectrum from UIM, DX NetOps Spectrum will perform a search to identify if this virtual entity was modeled during DX NetOps Spectrum discovery and modeling. If such an existing model is found, DX NetOps Spectrum will reconcile the UIM entity information with the existing model, instead of creating a new model.

This search is limited to the SpectroSERVER in which the parent VCenter UIM entity was destined to be modeled. In cases where an existing model is not found and reconciliation is not performed, DX NetOps Spectrum will model the virtual entity in the SpectroSERVER specified in the **OneClick Admin Configuration**> **UIM Configuration** page.

NOTE
DX NetOps Spectrum uses the IP Address reported by the entity to perform this search. If the IP Address is not reported, the search is performed using the reported MAC address.
If neither (IP or MAC Address) are reported, DX NetOps Spectrum will not be able to reconcile that entity even if the entity is discovered and modeled in DX NetOps Spectrum.

QoS Metrics

From the OneClick console, you can view the QoS VMware Metric information of the logical entities such as Nimsoft ResourcePool and Nimsoft Clusters and the virtual entities such as ESX Host and Virtual Machine (VM).

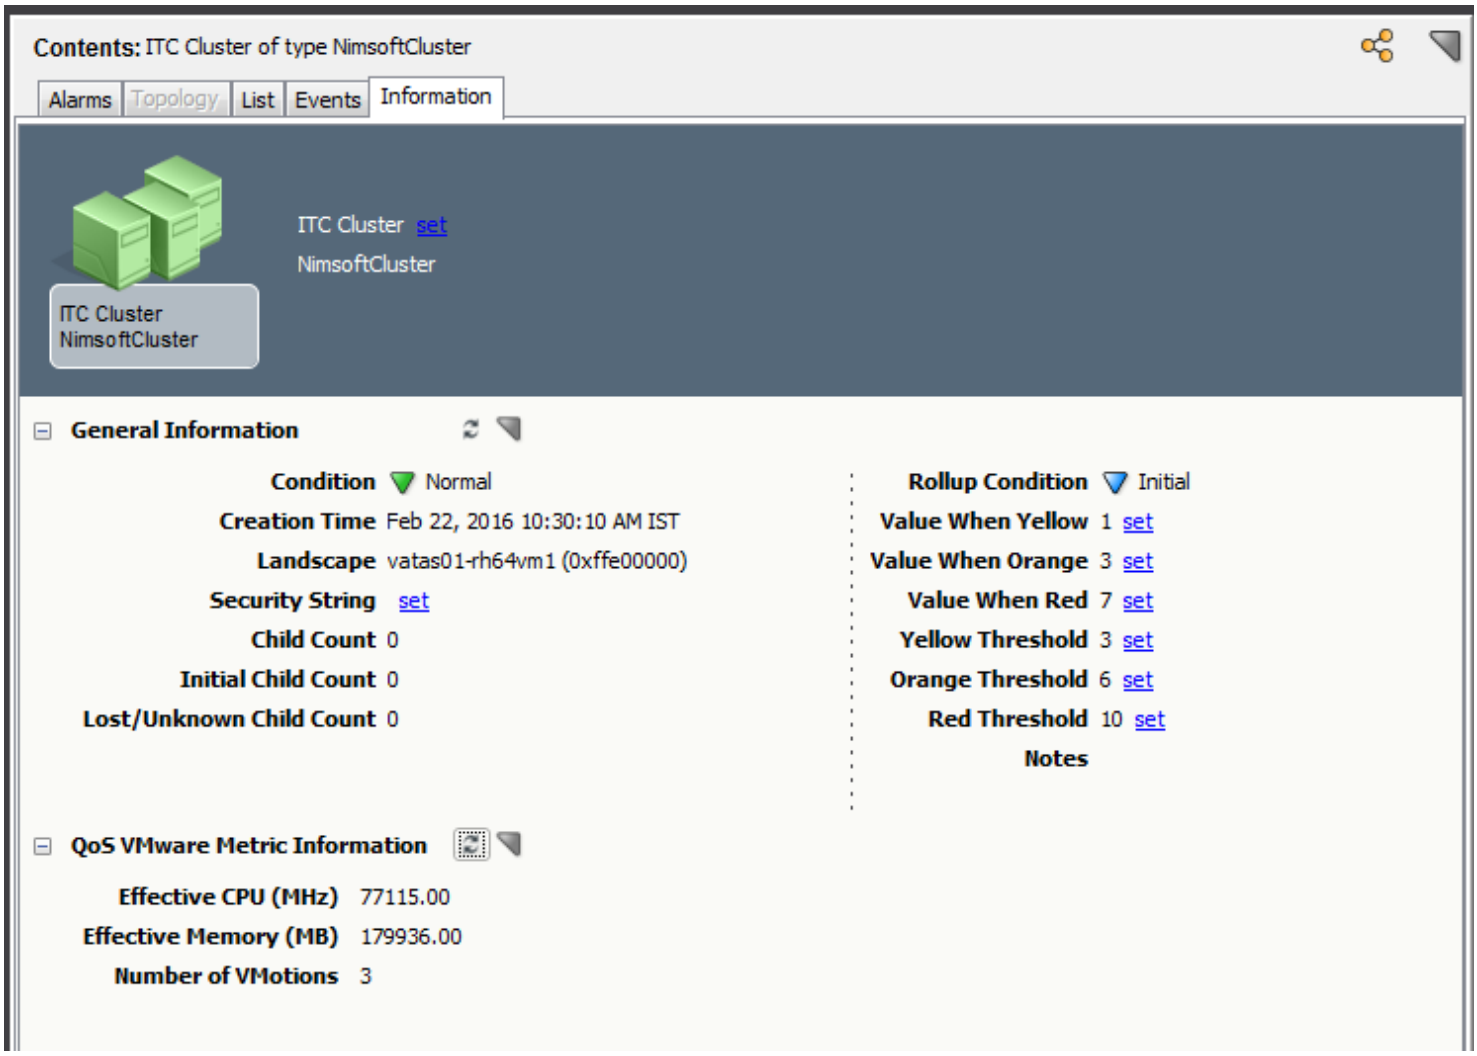
NOTE

You can also view the QoS CPU/Disk/Memory Metric Information for ESX and VMs. Verify that the QoS metrics related monitors are configured on the respective probes such as Vmware and CDM.

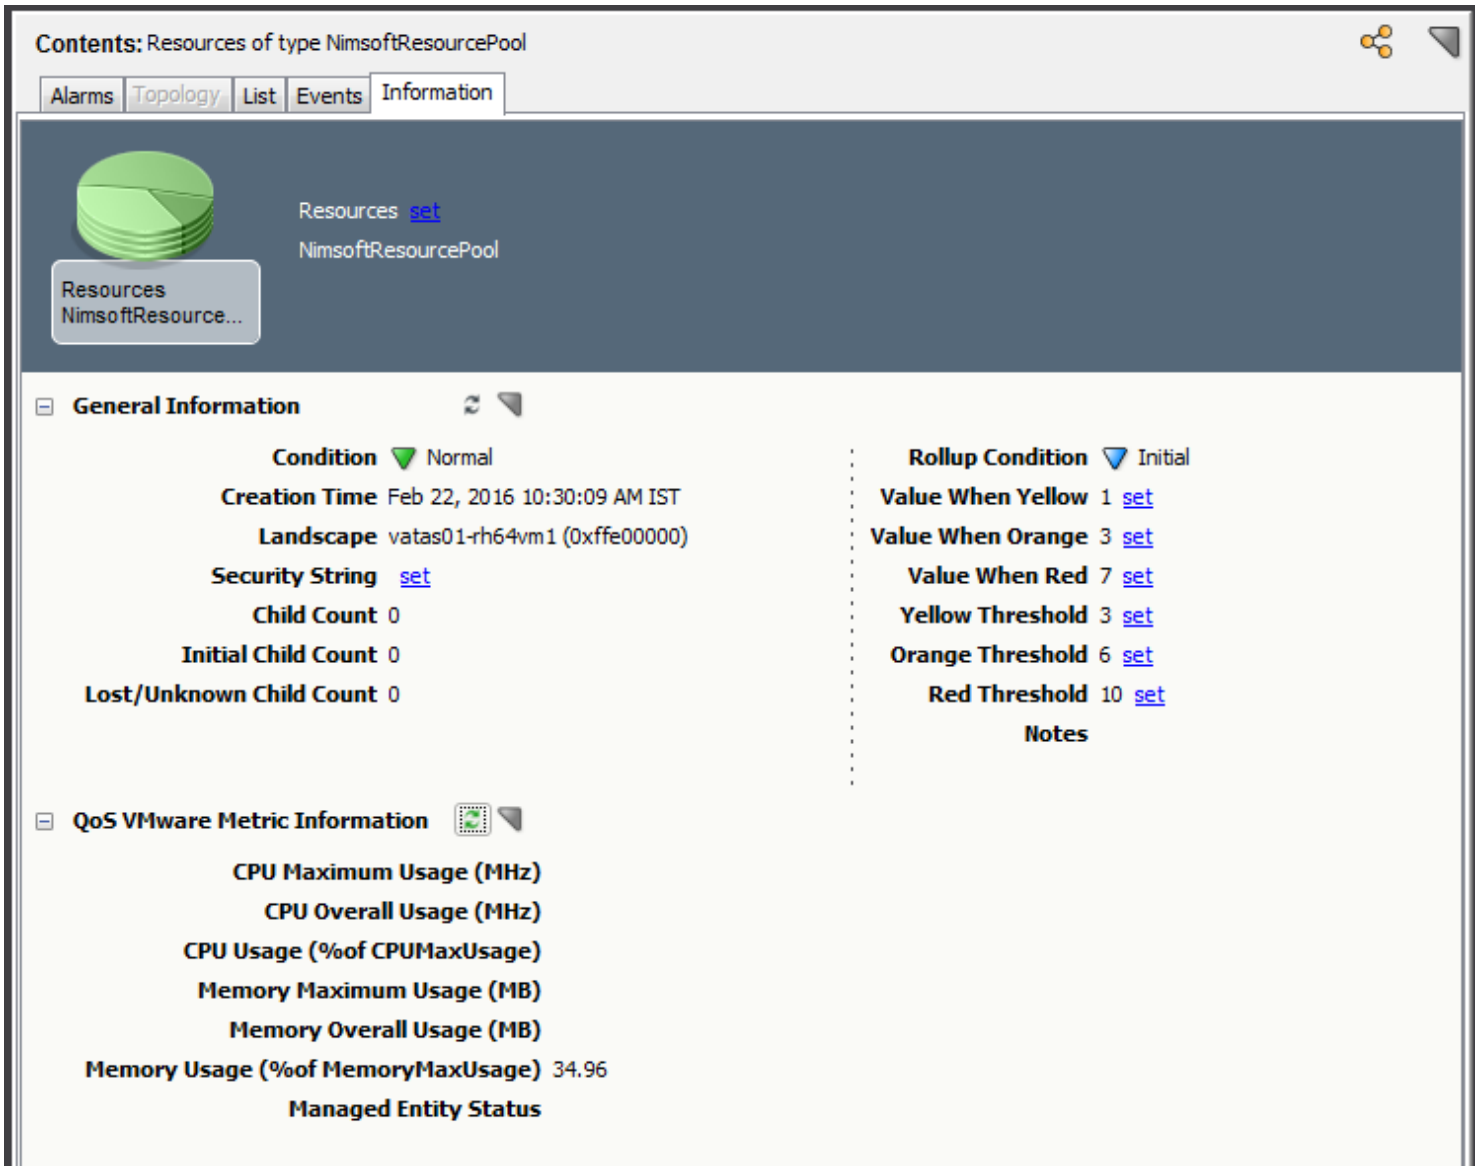
From r10.2.1 you can view QoS metrics information for AWS Cloud (Amazon Web Services) and Microsoft Azure.

Follow these steps:

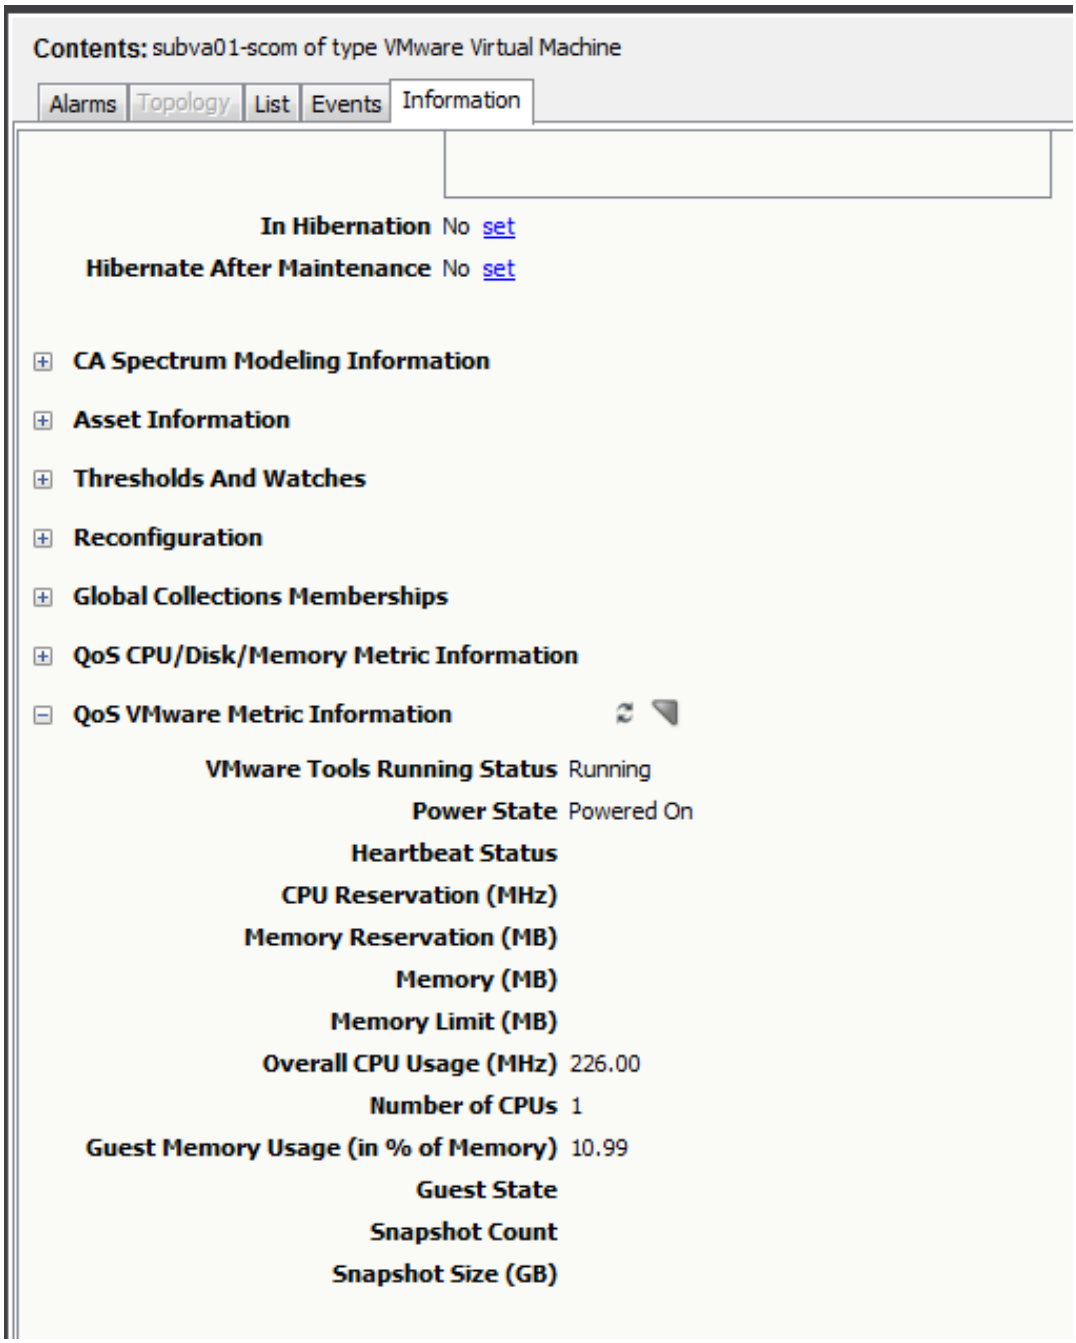
1. Open the DX NetOps Spectrum OneClick console.
2. Select **UIM Manager**, **Virtualization, VMware** and click **Cluster** from the Navigation panel.
   The **Contents** pane opens.
3. Click the **Information** tab.
   NimsoftCluster information is displayed.
4. Expand **QoS VMware Metric Information**.
   QoS Metrics for the selected Cluster is displayed.
   The following image displays the QoS VMware Metric Information of a NimsoftCluster:



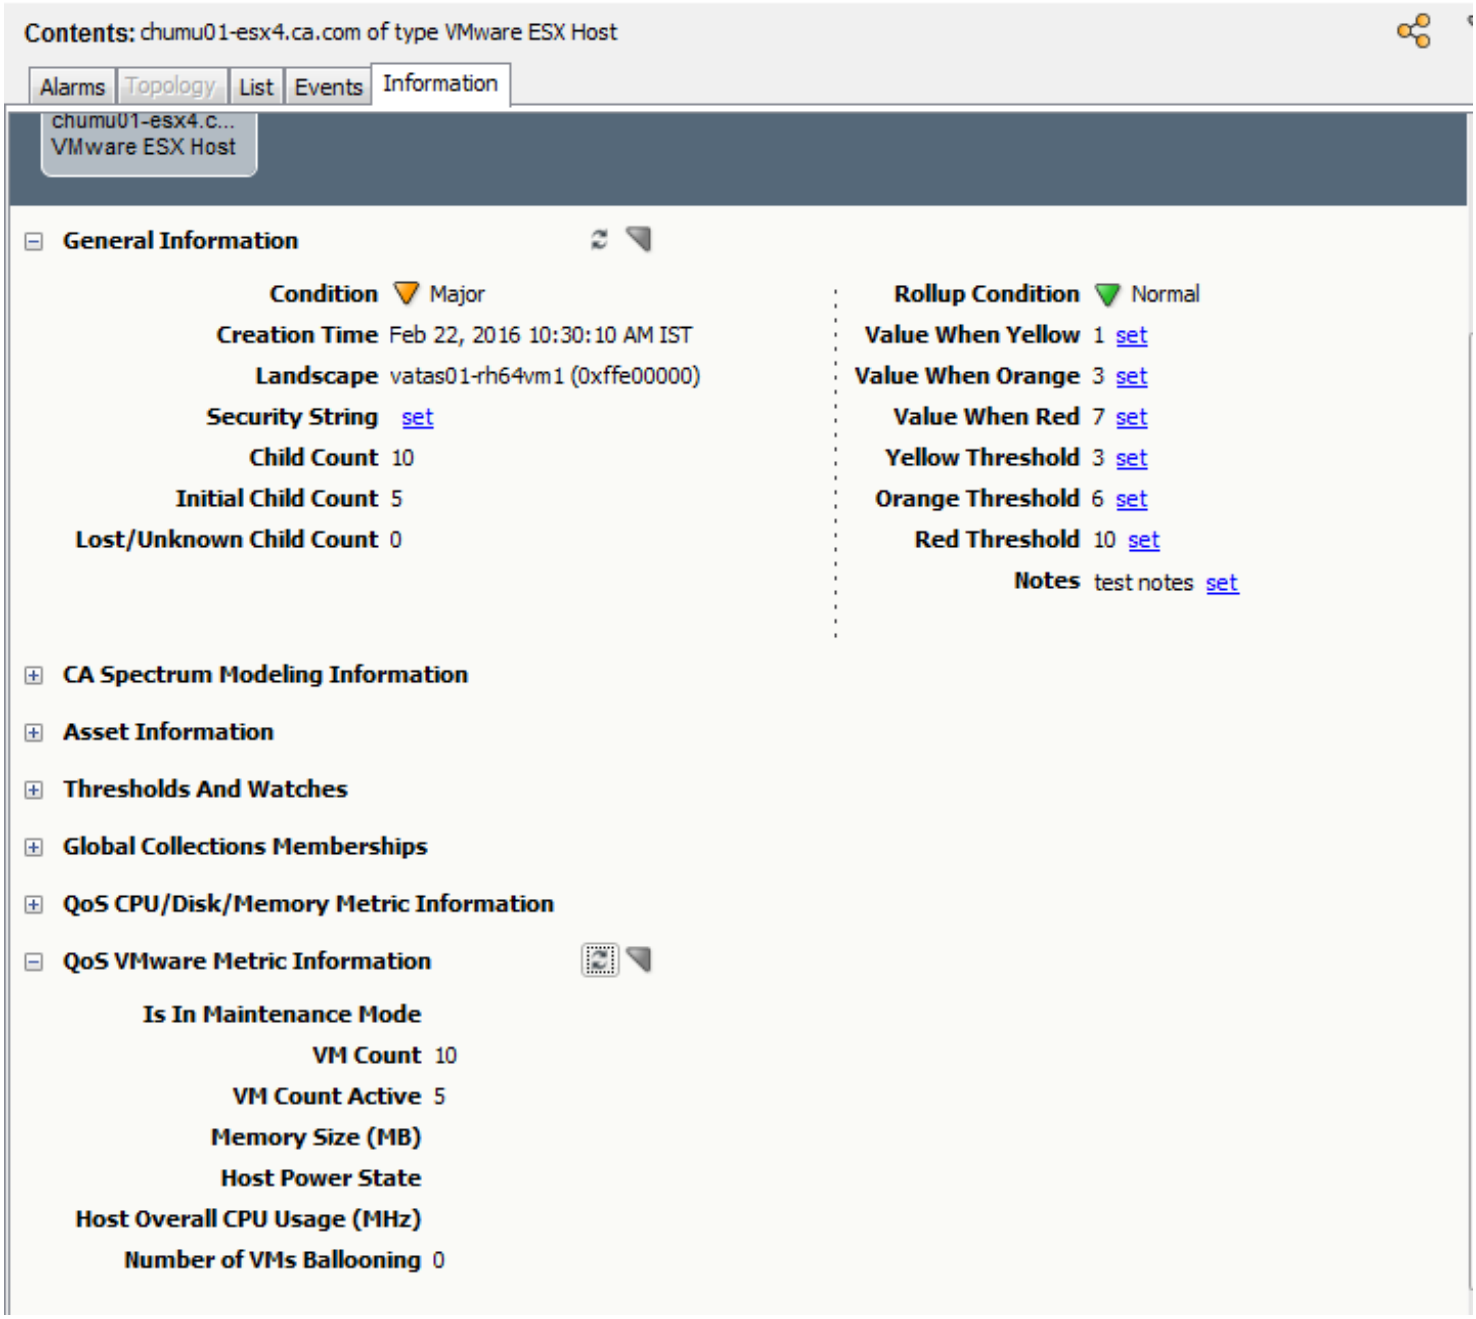
5. **To view QoS VMware Metric Information of a ResourcePool,** select a ResourcePool from the Navigation Panel.
   The **Contents** pane opens.
6. Click the **Information** tab.
   QoS Metrics for the selected NimsoftResourcePool information is displayed.
   The following image displays the QoS VMware Metric Information of a NimsoftResourcePool:



7. To view the QoS VMware Metric Information of a VM, select a VM that is available in Resources from the Navigation Panel.
   The **Contents** pane opens.
8. Click the **Information** tab.
   QoS Metrics for the selected VM is displayed.
   The following image displays the QoS VMware Metric Information of a VM:

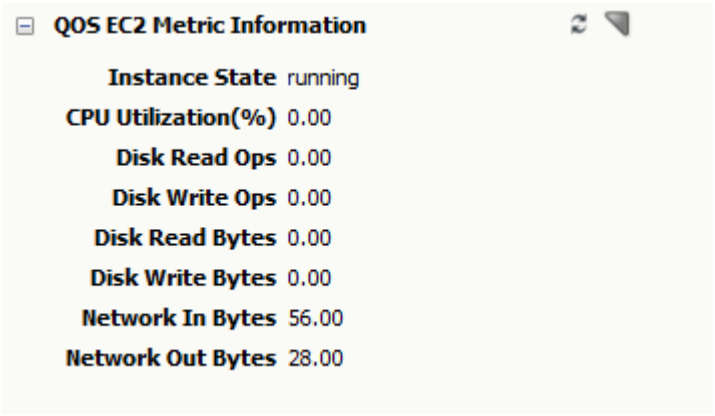


9. To view the QoS VMware Metric Information of an ESX Server, select an ESX or ESXi server that is available in Clusters from the Navigation Panel.
   The **Contents** pane opens.
10. Click the **Information** tab.
    QoS Metrics for the selected ESX server is displayed.
    The following image displays the QoS VMware Metric Information of an ESX server:



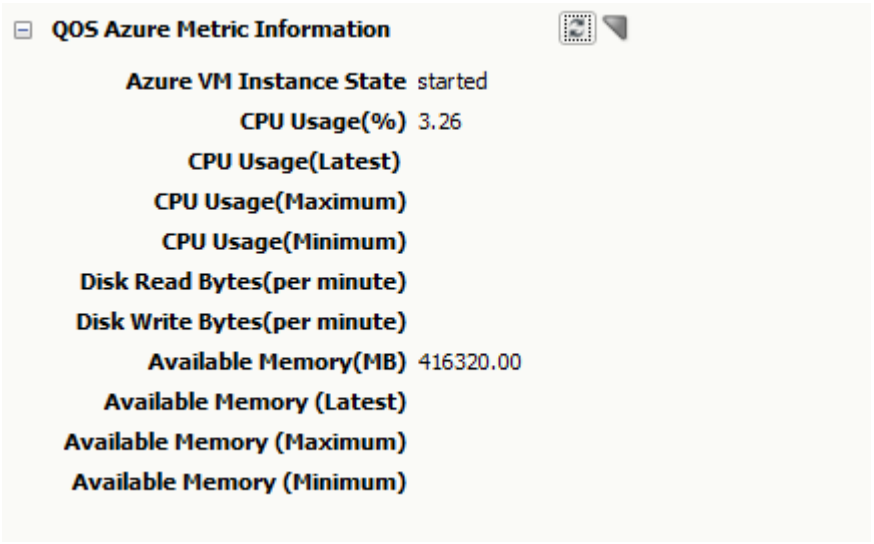
AWS related QOS Metrics

The following QoS Metric information for EC2 Instances are displayed in the **EC2 instance > Information Tab** view:



Azure related QoS metrics

The following QOS Metric information for EC2 Instances are displayed in the **Azure instance > Information Tab** view:



Launch-in-Context

The Launch-in-Context feature allows you to launch a UIM-UMP device view, from DX NetOps Spectrum for performance views of the device, in the given context. The UIM-UMP device view provides detailed information about the IP elements such as Virtual Center (VC), ESX hosts, and Virtual Machines (VM). The information (such as disk usage, cpu usage, processor queue length, paging, and memory usage) about the UIM virtual entities is displayed graphically.

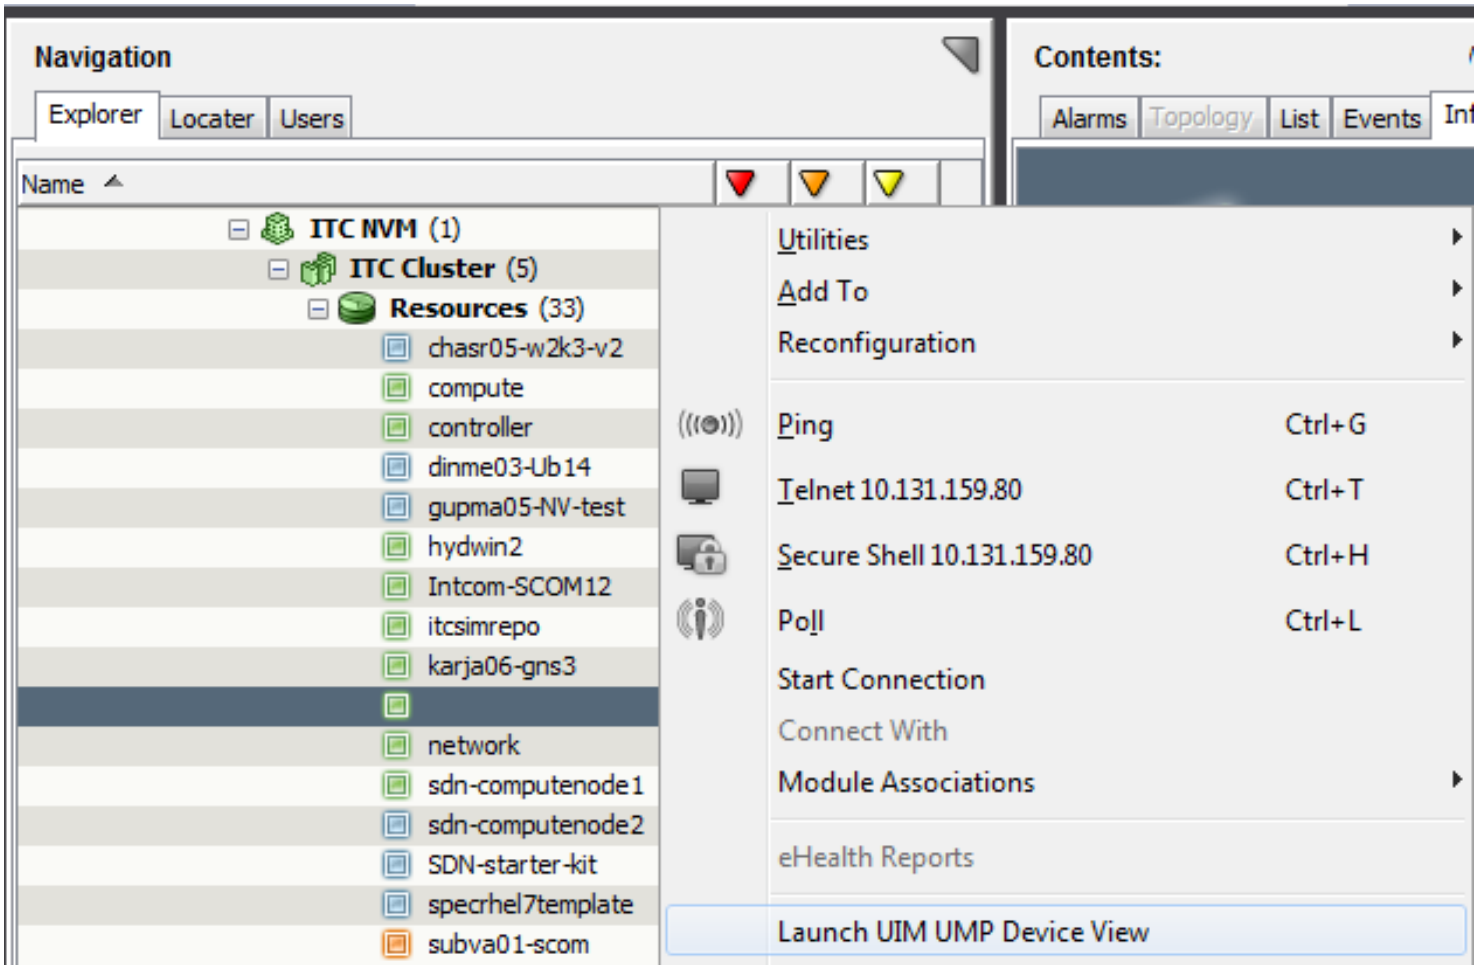
If you are launching the UMP view for the first time in a browser, a dialog for user credentials appears. The user credentials dialog does not appear if you are launching the UMP view using the same browser instance.

> **NOTE**
>
> The Launch-in-Context feature is available only for the IP elements. This feature is disabled for logical entities such as Data Centers, ResourcePools, and Clusters.

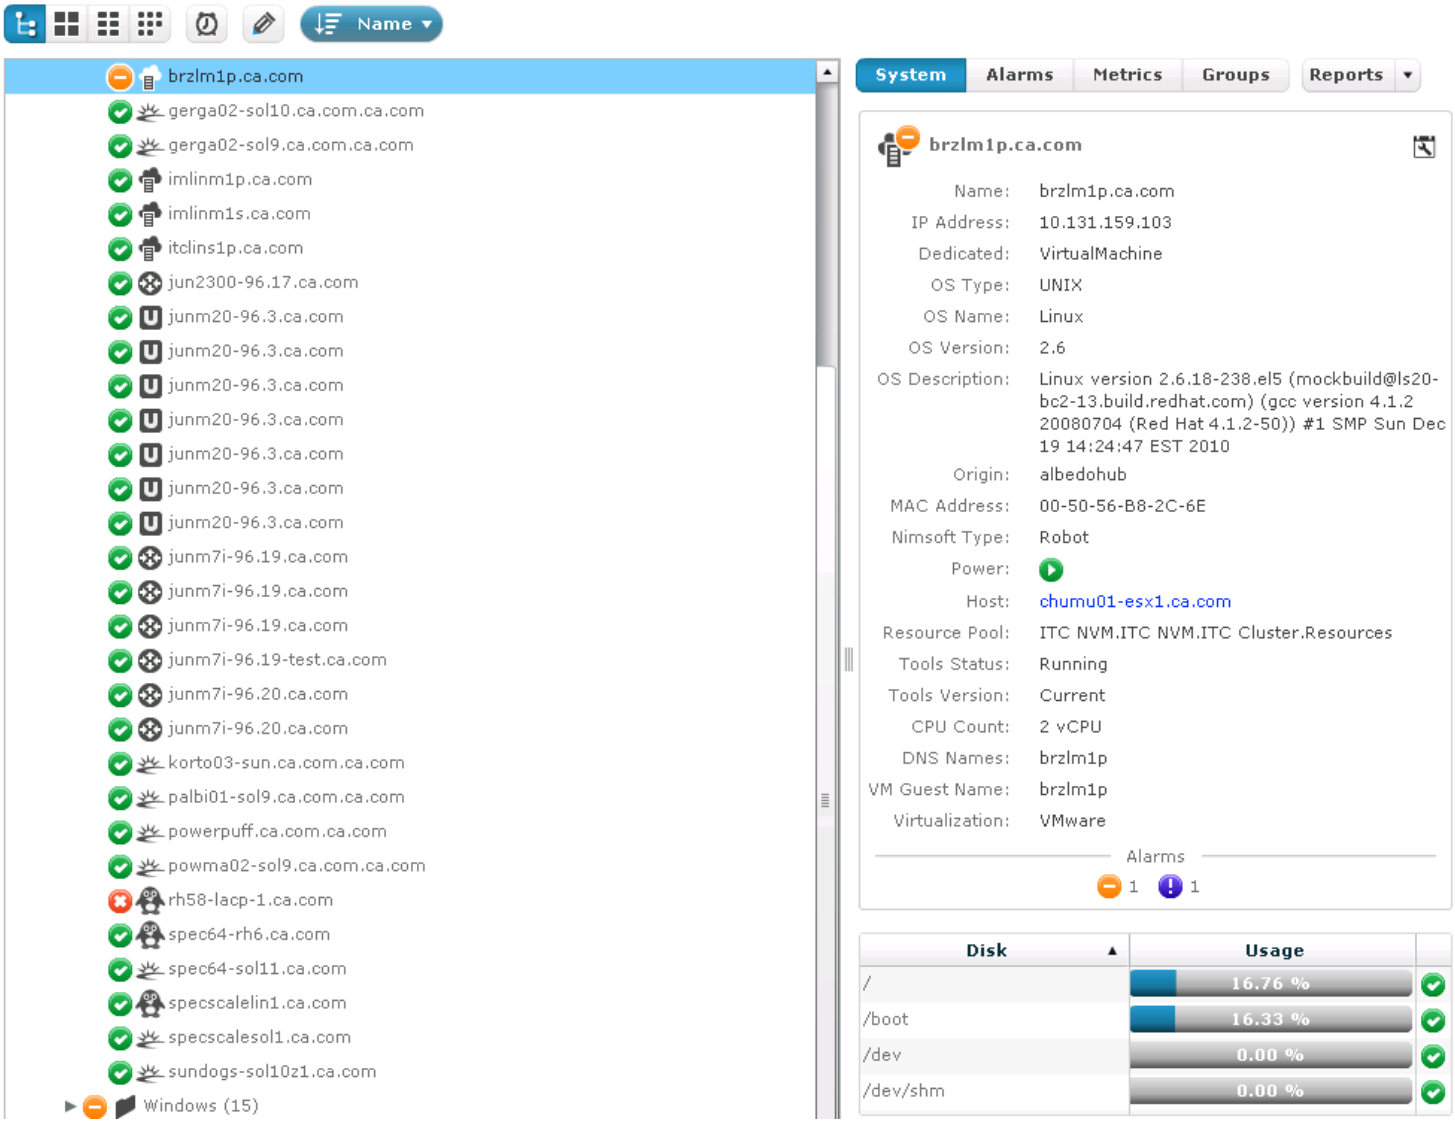
Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. Select **UIM Manager**, **Virtualization,** and click **VMware**.
   A list of all virtual entities such as VC, ESX, and VM is displayed.

3. Right-click one of the IP elements and select **Launch UIM UMP View**.
   The UIM UMP login page opens.
   The following image displays the IP elements and the option to launch the UMP view from the OneClick console:



4. Enter the UIM UMP credentials and click Login.
   The UMP view opens with the detailed information about the IP elements.
   The following image shows the UIM UMP view:



Condition Correlation - (UIM Integration)

If you enable the DX NetOps Spectrum and UIM Integration from the OneClick web page, the VMware inventory is modeled within the Nimsoft Manager hierarchy. The VMs that are modeled are of model type NimsoftVMPingable. Consider the following scenarios to apply Condition Correlation:

Scenario 1:

If you enable Monitors and shut down VM in the UIM with the following settings:

- Message token: EventWarning
- PowerState Monitor: VM
- HostPowerState Monitor : ESX Hosts

Events 0x10d35, 0x6330058, and 0x6330064 are generated in OneClick with Critical alarm. The alarms 0x10d35 and 0x6330058 are made symptom of 0x6330064.

Scenario 2:

Enable Monitors and shut down an ESX server with the following settings:

- Message token: EventWarning
- PowerState Monitor: VM
- HostPowerState Monitor: ESX Hosts

Events 0x10d35, 0x6330058 are generated with Critical alarm and the alarm 0x10d35 is made symptom of 0x6330058.

Scenario 3:

Enable Monitors and shut down ESX and VM with the following settings:

- Message token: EventWarning
- PowerState Monitor: VM
- HostPowerState Monitor: ESX Hosts

Events 0x6330058, 0x6330064 are generated with Critical alarm and the alarm 0x6330058 is made symptom of 0x6330064.

> **NOTE**
>
> If you place the ESX server in maintenance mode, an event 0x6330066 is generated in DX NetOps Spectrum. If the ESX server comes out of maintenance mode, an event 0x6330067 is generated in DX NetOps Spectrum and the VMs in the ESX host Server are moved out of Maintenance mode

Traps and Alarm Support

DX NetOps Spectrum and UIM integration for virtualization management supports the following alarms:

Alarms generated for the ESX Servers,

- If you enable the HostPowerState monitor and shutdown the ESX server, an alarm is generated with the event code 0x6330060.
- If you enable the HostPowerState monitor and the status of the ESX server to Unknown, an alarm is generated with the event code 0x6330061.
- If you enable the IsInMaintenanceMode monitor and the status of the ESX server to True, an alarm is generated with the event code 0x6330066.

Alarms generated for Virtual Machine (VM)s,

- If you enable the PowerState monitor and shutdown the VM, an alarm is generated with the event code 0x6330058.
- If you enable the PowerState monitor and the status of VM to Suspended, an alarm is generated with the event code 0x6330059.
- If you enable the GuestState monitor and the status of VM to notRunning, an alarm is generated with the event code 0x6330058.
- If you enable the GuestState monitor and the status of VM to Unknown, an alarm is generated with the event code 0x6330058.

Common Events for both ESX and VMs,

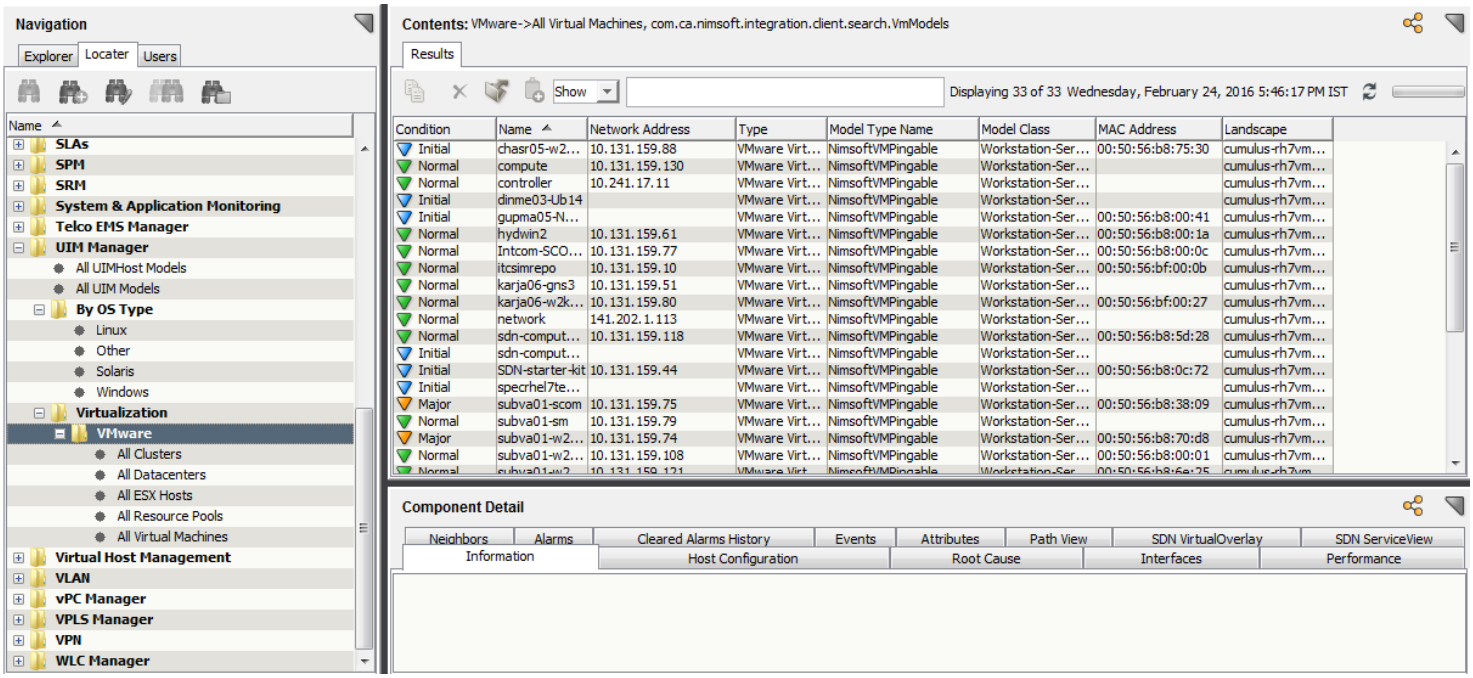
- If you enable the Event monitor and shut down both the ESX server and VM, an alarm is generated with the event code 0x6330064.
- If you enable the Event monitor and shut down both the ESX server and VM, an alarm is generated with the event code 0x6330064.
- If you enable the Status monitor and shut down both the ESX server and VM, an alarm is generated with the event code 0x6330064.

Locater Search

You can use the search functionality in the Locater tab to find both the logical entities (such as Nimsoft ResourcePool and Nimsoft Clusters) and virtual entities (such as ESX Host and Virtual Machine (VM)) that are available in the DX NetOps Spectrum environment. You can access Locater search from the Locater tab of the Navigation Panel. The search results appear in the Results tab of the Contents panel.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick Console.
2. From the Navigation Panel, Click the Locater tab.
   The Search Options window opens.
3. Expand UIM Manager, VMware, Virtualization, and double-click the appropriate VMware entity to search.
   The Locater Search results are displayed in the Contents pane.
   The following figure shows the Locater Search results for all the VMware entities:



Reports (UIM Integration)

You can generate the availability report of all the ESX servers and virtual machines that are available in a DX NetOps Spectrum environment. Access InfoView from the OneClick home page to generate and manage reports. For more information, see the Spectrum Report Manager section.

The following list of events are used for the calculation of availability reports:

ESX Servers

- Up Events
  - 0x06330063
  - 0x6330065
- Down Events
  - 0x6330060
  - 0x6330061
  - 0x6330064

Virtual Machines

- Down Events
  - 0x6330058
  - 0x6330059
  - 0x6330064
- Up Events
  - 0x6330062
  - 0x6330065

Integration with UIM Through the Southbound Gateway

UIM and DX NetOps Spectrum are integrated through the DX NetOps Spectrum Southbound Gateway component (SBGW). This integration is unidirectional (UIM to DX NetOps Spectrum), and supports multiple outstanding alarms, of various types, per device.

The DX NetOps Spectrum - UIM Integration expands the DX NetOps Spectrum model of the infrastructure with information and alarms from UIM and provides the following benefits:

- Receive events and alerts in DX NetOps Spectrum from UIM probes.
- Obtain extended DX NetOps Spectrum monitoring capabilities leveraging the intelligence of UIM probes
- Use the Nimsoft SLA rules to trigger events that create alert conditions in DX NetOps Spectrum.
- Use DX NetOps Spectrum the root cause analysis capabilities to perform basic root cause analysis on events and alerts that are created by UIM.

Integrate with UIM Through the Southbound Gateway

> **WARNING**
>
> From the 10.1.2 release, the SNMP Gateway probe and SBGW /Southbound gateway are no longer recommended for alarms synchronization from UIM to DX NetOps Spectrum. Use the Spectrum Gateway (spectrumgtw) probe for this purpose.
>
> For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.
>
> We recommend that you go through the DX NetOps Spectrum-UIM Integration using spectrumgtw probe - FACT SHEET to understand the changes to the integration whether you are new to this integration or an existing user.

UIM and DX NetOps Spectrum are integrated through the DX NetOps Spectrum Southbound Gateway component (SBGW). This integration is unidirectional (UIM to DX NetOps Spectrum), and supports multiple outstanding alarms, of various types, per device. The component asserts the alarm against the existing device model or against an auto-created event model of UIM Robot. DX NetOps Spectrum EventModel is used when a full device model for the network entity does not exist in DX NetOps Spectrum. This integration supports multiple alarms types per model, such as Low Disk, Excessive CPU usage, and Traffic Threshold violation.

Overview

The DX NetOps Spectrum - UIM Integration expands the DX NetOps Spectrum model of the infrastructure with information and alarms from UIM and provides the following benefits:

- Receive events and alerts in DX NetOps Spectrum from UIM probes.
- Obtain extended DX NetOps Spectrum monitoring capabilities leveraging the intelligence of UIM probes
- Use the UIM SLA rules to trigger events that create alert conditions in DX NetOps Spectrum.
- Use DX NetOps Spectrum the root cause analysis capabilities to perform basic root cause analysis on events and alerts that are created by UIM.

As an administrator, configure UIM to send alert data to DX NetOps Spectrum. UIM sends the trap data to the hostname and port where the SpectroSERVER is running. By default, DX NetOps Spectrum uses standard SNMP trap port 162. DX NetOps Spectrum accepts an individual SNMP trap packet to a maximum size of 65467 bytes. You can modify the port by changing the snmp_trap_port parameter in the DX NetOps Spectrum ".vnmrc" file that is located in the DX NetOps Spectrum directory.

Perform the following tasks to integrate UIM and DX NetOps Spectrum through the Southbound Gateway:

Review the Prerequisites and Considerations

Verify the following prerequisites before installing and configuring the DX NetOps Spectrum - UIM Integration:

- Licensed installations of CA Spectrum 10.1 (or later) and CA UIM 8.2 (or later) are required.

  NOTE
  If you plan to install DX NetOps Spectrum as a user other than Administrator, disable User Account Control (UAC) on Windows. For more information, see the Fresh Install section.
- Verify that the system where you want to install DX NetOps Spectrum has a static IP address.
- Standard DX NetOps Spectrum supported platforms and hardware are required.

Verify the following considerations:

- The current integration does not attempt to upgrade previous (that is field-developed) integrations. We plan to support upgrades to future versions of this integration.
- This integration requires DX NetOps Spectrum to use the SNMP Trap port (162) for communication from UIM.
- This integration connects to only a single UIM instance.
- This integration depends on trap reception because typical SNMPv1 traps are unconfirmed. Traps can be dropped in transit and not recognized.
- For the events and alarms to be raised on the correct DX NetOps Spectrum model, use an IP address instead of hostname to model the entity on UIM. If a hostname is used for entities that are modeled in UIM, DX NetOps Spectrum alarms are raised on the EventModel of the robot hosting the probe.

Install and Configure DX NetOps Spectrum

DX NetOps Spectrum installation software requires administrator privileges to evaluate available resources and run custom installation scripts. An initial installation generates residual files with administrator ownership. Subsequent upgrade installations also require administrator privileges.

WARNING
The C:\Program Files\CA directory on Windows platforms and the /opt/CA directory on Linux platforms are automatically created during the DX NetOps Spectrum first-time installation. DX NetOps Spectrum components that are also common to other CA products are intentionally installed into this directory. This directory is automatically updated as needed during a DX NetOps Spectrum upgrade. Do not remove files from this directory.

A DX NetOps Spectrum installation is required to integrate UIM and DX NetOps Spectrum through the Southbound Gateway. You can install DX NetOps Spectrum on Windows and Linux platforms.

Follow these steps:

1. Stop all non-DX NetOps Spectrum running applications.

2. Perform the following actions:
   - Log off from OneClick in the Client Details web page and shut down the OneClick client.

     NOTE
     For more information, see the OneClick Administration section.
   - Click Stop SpectroSERVER to stop the SpectroSERVER and the Archive Manager in the DX NetOps Spectrum Control Panel and then close the DX NetOps Spectrum Control Panel.

     NOTE
     For more information, see the OneClick Administration section.
   - Stop all VnmSh connections.

     NOTE
     For more information, see the Command Line Interface section.
   - Close all Bash shells.

     WARNING
     Disable your antivirus software real-time protection before installing DX NetOps Spectrum. Disabling helps avoid potential problems with files that can be in use by the real-time protection software.
3. Log in as a user with administrator rights.
4. Insert the installation medium into the appropriate drive. If auto-run is disabled, you can double-click the setupnt.exe file from the Explorer view to start the installation.
   The installation starts.
5. Install DX NetOps Spectrum. For more information, see the Fresh Install section.

Deploy and Configure Probes

UIM Probes are small, dedicated applications that monitor specific resources or events. Each probe can be easily configured for your specific monitoring requirements.

The SNMP Gateway probe sends traps from UIM to DX NetOps Spectrum. To integrate UIM with DX NetOps Spectrum, configure the SNMP Gateway probe (snmpgtw) through CA Unified Infrastructure Manager.

The SNMP gateway converts alarms to SNMP trap messages that are readable by any SNMP-based event manager. The SNMP gateway maps the various severity levels to enterprise-specific trap types. For more information, see the Unified Infrastructure Management documentation.

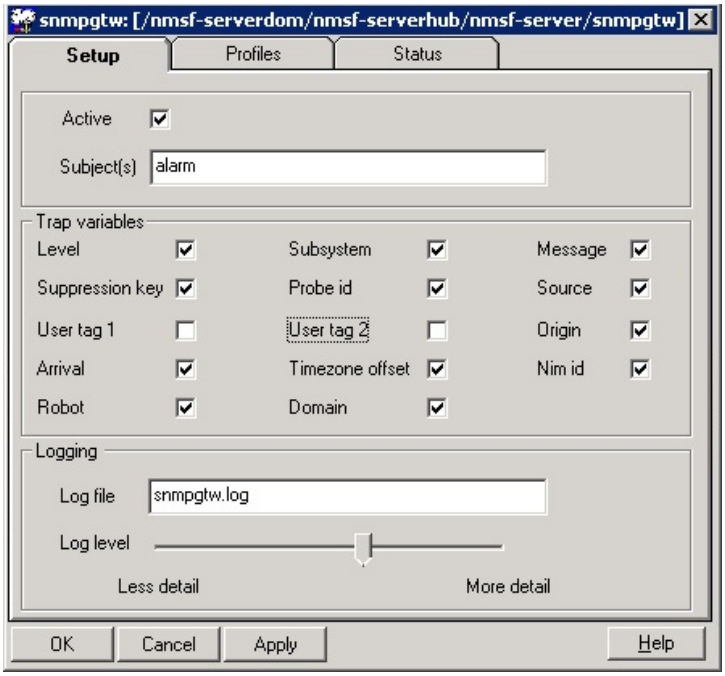
Follow these steps:

1. Open Unified Infrastructure Manager.
2. From the Console window, select Archive, UIM Server hub, and Robot.
   A list of predefined probes is displayed.
3. Select a package name in the archive folder.
4. Drag and drop the package name to the domain/hub/robot.
   A View Distribution Progress dialog opens.
5. Click Close Dialog after distribution has completed.
   The probe is deployed to the specified location.
6. To configure the probe, double-click the probe that you deployed.
   The Probe Configuration window opens.
7. Click the Setup tab.
   The Setup window opens with the following options:
   - **Active**
     Activates or deactivates this probe.
   - **Subject(s)**

Specifies the UIM subject that is transformed. Subject is a text string, that classifies the UIM message for all components of UIM.
Default: Alarm

- **Trap variables**
  Indicates a unique identifier of the SNMP operation where the traps are triggered.
- **Log file**
  Specifies the file where the probe logs information about its internal activity.
- **Log level**
  Sets the level of details for the data that is written to the log-file. We recommend logging as little data as possible during normal operation to minimize disk consumption. You can then increase the amount of detail when debugging.

The following image illustrates the options that are available in the Setup window:



8. Click the Profiles tab.
   The Profile window opens. For more information, see Configure CA Unified Infrastructure Manager.
9. Click Ok.
   The snmpgtw probe is deployed and configured.

Configure CA Unified Infrastructure Manager

The CA Unified Infrastructure Manager is the primary interface for the configuration and management of the UIM system.

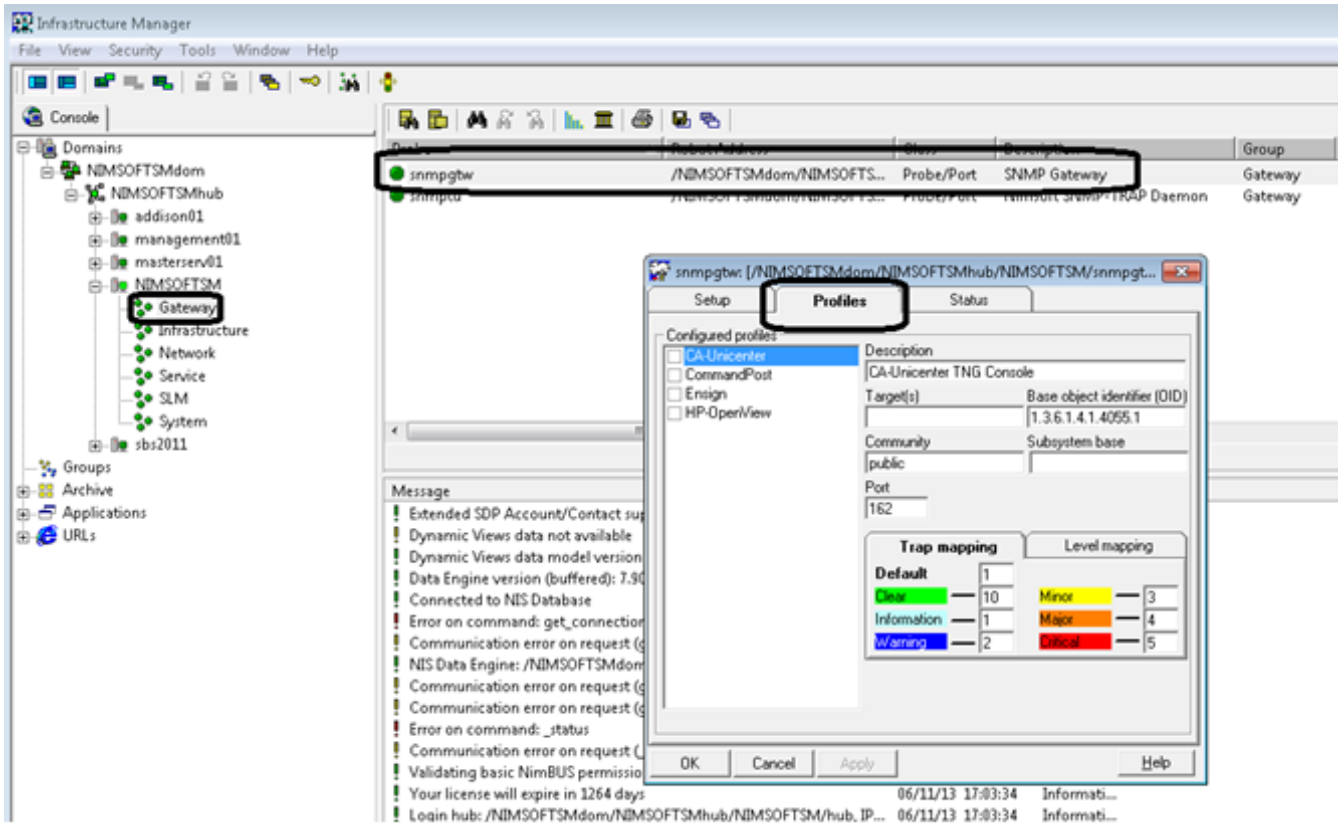
Configure UIM to manage entities on your network through CA Unified Infrastructure Manager or the Unified Management Portal. To integrate UIM with DX NetOps Spectrum, configure the SNMP Gateway probe (snmpgtw) through CA Unified Infrastructure Manager. For more information, see Deploy and Configure Probes.

A profile is created in the SNMP Gateway Probe to communicate to the UIM about the traps to send, the conditions under which to send them, and where to send them.

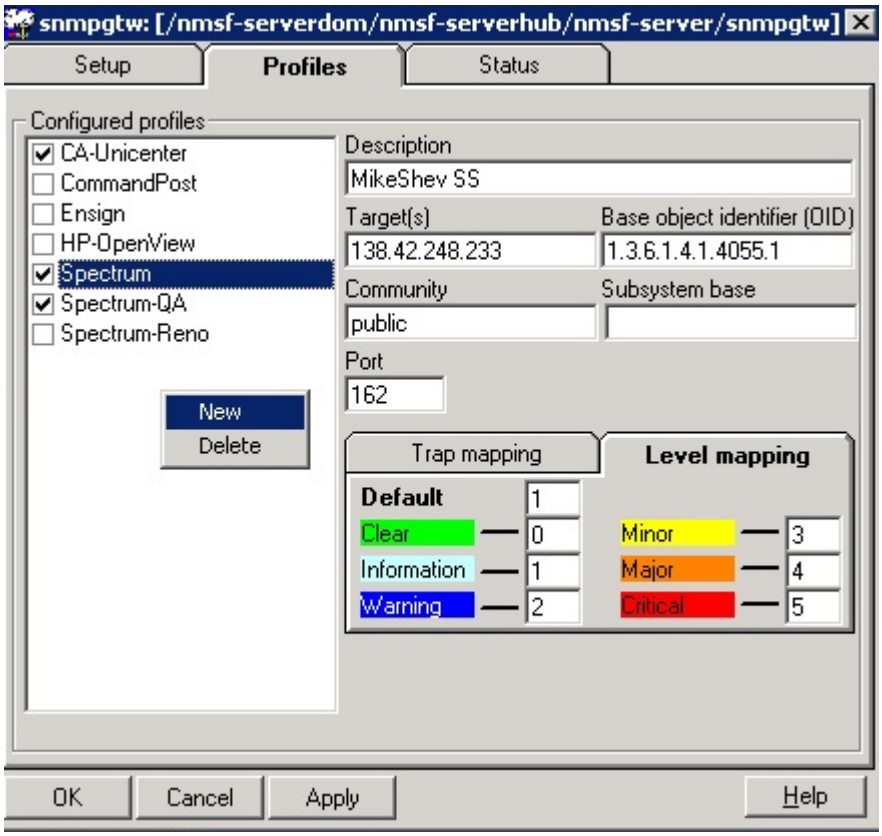
Follow these steps:

1. Open Unified Infrastructure Manager.
2. From the Console window, select Domains, UIM Server Domain, UIM Server Hub, UIM Primary Hub and then Gateway.

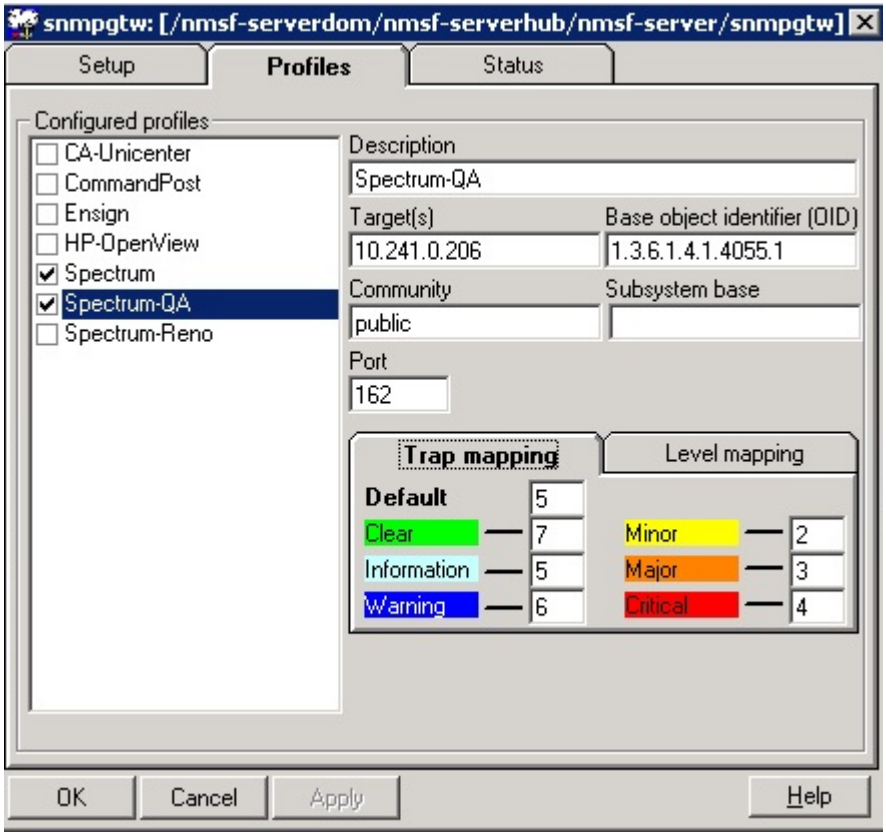
A list of Probes is displayed.
The following image displays the navigation to snmpgtw probe:



3. Double-click the snmpgtw probe.
   The Probe Configuration window opens.
4. Click the Profiles tab.
5. Right-click the Configured Profiles workspace and select New.
   The following image illustrates the procedure to create a new profile:



6. Enter the name of the profile. For example, you can supply Spectrum-*Server name*.
7. To enable the profile, click DX NetOps Spectrum in the list of Configured profiles.
   The following image illustrates the options that are available in the Profiles window.



- **Target(s)**
  Specifies the SpectroSERVER IP address. Indicates the network node where the SNMP traps can be sent.
- **Base Object Identifier (OID)**
  Indicates the SNMP Object identifier to be used in the trap packages generated.
  Default: 1.3.6.1.4.1.4055.1
- **Community String**
  Indicates the SNMP community string that is used in the SNMP traps.
- **Trap Mapping**
  Classifies the incoming traps by trap type and takes different actions for different trap types. You can map the severity levels of the alerts to SNMP traps.
  For example, provide the following values for trap mapping:
  Default: 5
  - Clear: 7
  - Informational: 5
  - Warning: 6
  - Minor: 2
  - Major: 3
  - Critical: 4

  NOTE
  If you want to disable informational and warning messages at the source level, remove the mappings for Default, Warning, and Informational in Trap Mapping.
- **Level Mapping**
  Identifies the severity levels with different codes. You can map the UIM severity levels to the corresponding level in the receiving system by specifying the correct code.
  For example, provide the following values for level mapping:

Default: 1

- Clear: 0
- Informational: 1
- Warning: 2
- Minor: 3
- Major: 4
- Critical: 5

8. Click Apply and Ok.
   Unified Infrastructure Manager is configured to integrate with DX NetOps Spectrum.

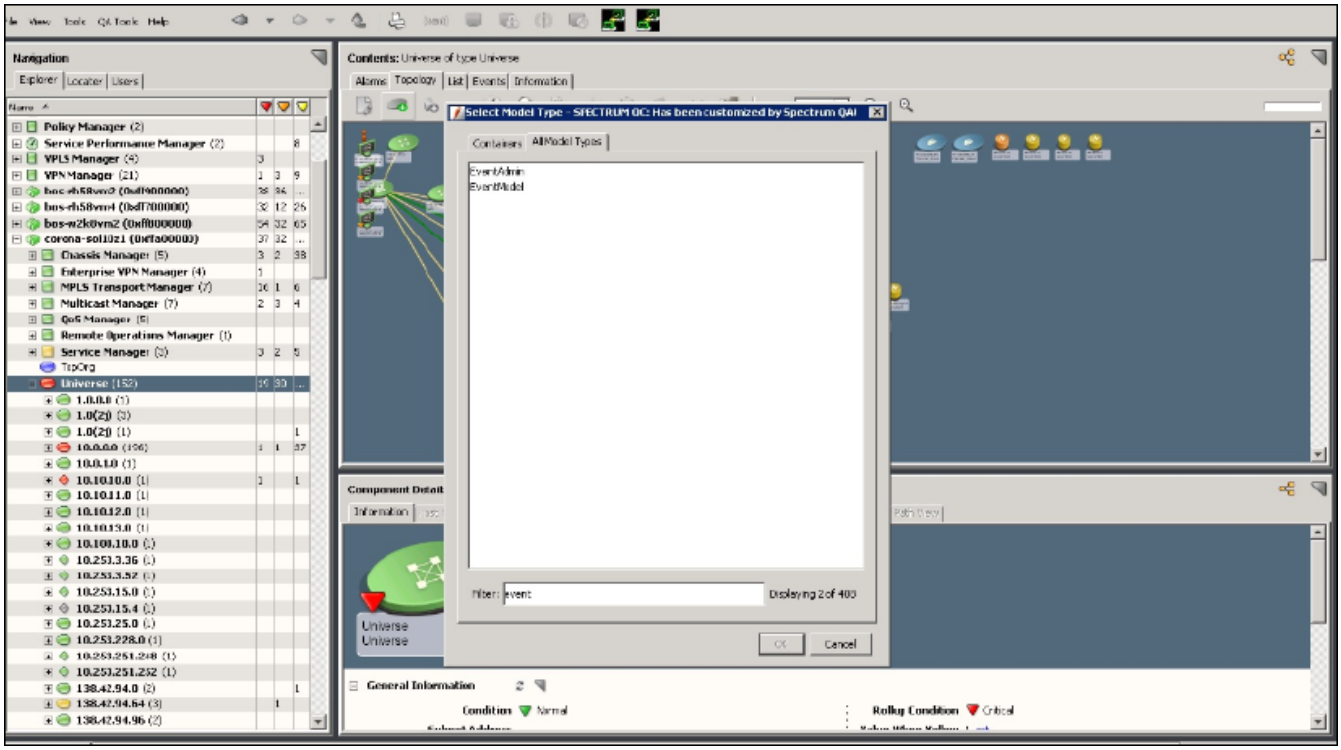
Create an EventAdmin Model for the UIM Server

The DX NetOps Spectrum EventAdmin model receives events from the Southbound Gateway and transfers the event data to EventModels or device models depending on how the integration is configured. Alarms can be created from this event data.

The EventModel is a model type that represents a unique source of event data on the system that is managed by the EventAdmin application. A given EventAdmin model can contain one or many instantiated EventModels. Each event that is received through the Southbound Gateway contains information that uniquely identifies the source of that event. The EventAdmin model receives the event, finds the unique event source, and passes the event to the target destination. Create an EventAdmin model for the UIM server to support the integration.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick Console.
2. From the Navigation Panel, select SpectroSERVER, and then Universe.
3. Click the Topology tab in the Contents panel and click Create New Model by Type.
   The Select Model Type dialog opens.
   The following image displays the model types to be created:



4. In the All Model types tab, click EventAdmin.

5. Click OK.
   The Create Model of Type EventAdmin dialog opens.
6. Configure the following parameters:
   - **Name**
     (Optional) Defines the EventAdmin model name. This model name appears in the field at the top of the EventAdmin icon.
   - **Network Address**
     Specifies the network address of the event source host computer. Required for all integrations that are based on the SNMP traps.
   - **Security String**
     (Optional) Defines who can view and edit this model.
   - **Manager Name**
     When this attribute is set on the EventAdmin model, all EventModels contained within this EventAdmin also have this attribute.
   - **EventModel Prefix**
     Verifies the naming prefix for all EventModels that are associated with a particular EventAdmin model. This field is related to the EventModel Name for all the EventModels contained by this EventAdmin. It is also useful for sorting and filtering.
     Default: 0x06330000
7. Click OK.
   The EventAdmin model is generated. A default EventModel is also created and is contained in the EventAdmin model. This model is used for fault tolerance functionality that represents the unique source.

Verify the Received Events and Alarms in OneClick

The EventAdmin Model receives an event from UIM and sends it to the EventModel in OneClick. The event generates an alarm on this model. To verify that the integration is configured correctly, we recommend viewing the details of the alarm data from the Alarm Details tab in OneClick. The generic and subsystem-specific events are created in OneClick. You can also verify the design pattern of these events/alarms.

Follow these steps:

1. Open the OneClick Console.
2. Select the EventModel in the Navigation panel.
3. To view events, click the Events tab in the Contents panel.
   Events are displayed with the following event types:
   - **Generic Events**
     Indicates the events that are not related to CPU, Disk, and Memory subsystems.
     The range starts from 0x06330000 - 0x6330005.
   - **Subsystem Specific Events**
     Indicates the events that are related to CPU, Disk, and Memory subsystems. You can verify the following event range for the subsystem-specific events:
     - CPU
       0x06330050 - 0x6330055
     - Disk
       0x06330030 - 0x6330035
     - Memory
       0x06330040 - 0x6330045
4. Verify the following design pattern of these events/alarms:

- 0x063300x0 Clear Event
- 0x063300x1 Minor Event / Alarm
- 0x063300x2 Major Event / Alarm
- 0x063300x3 Critical Event / Alarm
- 0x063300x4 Informational Event

NOTE
You can review the following table to know how the UIM message severities are mapped to DX NetOps Spectrum events and alarms:

5. UIM DX NetOps Spectrum
   - Informational Event only
   - Warning Event only
   - Minor Minor Alarm
   - Major Major Alarm
   - Critical Critical Alarm
6. To view alarms, click the Alarms tab.
   Alarms are displayed.
7. Click the Alarm Details tab in the Component Detail panel to view the alarm details.
   Events and Alarms that are generated in OneClick are verified.

NOTE
Alarms that are manually cleared in the UIM Alarm Console do not clear the corresponding alarms in DX NetOps Spectrum. This behavior is caused by a known limitation of the SNMP Gateway probe (snmpgtw). Therefore, when you clear alarms in UIM, the alarms accumulate in DX NetOps Spectrum, causing high alarm counts. These alarms must be manually cleared in DX NetOps Spectrum.

Performance Considerations

UIM - DX NetOps Spectrum integration through the Southbound Gateway supports and implements all severities and traps (such as Informational, Warning, Minor, Major, Critical, Clear).

NOTE
By default, UIM snmpgtw is configured to send alerts (traps) for messages of all severity levels.

The volume of events and alarms that are generated by UIM in DX NetOps Spectrum depends on the number, type, and condition of managed elements. In situations where performance is an issue, you can disable these messages at the Unified Infrastructure Manager.

For example, if the trap storm detection threshold of DX NetOps Spectrum exceeds a certain level, it indicates that performance is degraded. By default, this threshold is configured for 20 traps/second from a single device. In a moderately large UIM installation, the DX NetOps Spectrum default trap storm threshold can be exceeded easily, and when it is exceeded, traps are dropped. To preserve the most critical traps, we recommend disabling the informational and warning messages. In this way, bandwidth is not used in less severe situations and the critical traps can be handled by DX NetOps Spectrum.

To handle this situation, you can disable the informational messages that are sent by UIM. In this way the problem can be resolved at the source level. If the trap storm threshold is exceeded, the warning messages can be disabled and not sent to DX NetOps Spectrum. You can also raise the trap storm threshold to 25 or 30 traps/second, if the SpectroSERVER has sufficient capacity.

If after disabling the informational and warning messages, the number of alerts from UIM still exceeds the trap storm threshold, consult UIM documentation to determine ways to limit the number or types of traps being sent to DX NetOps Spectrum. By default, all alarms are filtered. Therefore, you can change the alarm messages that are filtered by snmpgtw. You can also change the alarm setting to alarm_new and alarm_clear messages, which can reduce the total traffic from UIM to DX NetOps Spectrum.

NOTE
If you change the alarm setting to alarm_new and alarm_clear message, the alarm counts may not be correctly incremented in DX NetOps Spectrum as a single message for each occurrence of an alarm that is received.

Disable the Integration

You can disable the UIM - DX NetOps Spectrum Integration, if you want to stop generating alarms and events in OneClick. On disabling the integration, the EventAdmin model no longer receives events from UIM and the events are not forwarded to the EventModel model in OneClick.

Follow these steps:

1. Open Unified Infrastructure Manager.
2. From the Console page, select Gateway.
   The SNMP Gateway window opens.
3. Click the Profiles tab.
   The Configured Profiles window opens.
4. Right-click a Profile, select Delete.
   Profile is deleted.
5. Click Ok.
   Integration is disabled.

Supporting AWS (Amazon Web Services) Cloud Monitoring

Overview

From 10.2.1, AWS Cloud (Amazon Web Services) Monitoring is supported by DX NetOps Spectrum using the UIM and DX NetOps Spectrum integration. The AWS Monitoring probe deployed in UIM enables the metric data collection from the AWS instances. This data is then synchronized from UIM to DX NetOps Spectrum. Currently, we are synchronizing the AWS resources drilling down to the following hierarchy: **VPC** domain > **Subnet** domain **> EC2 instances**.

All AWS Cloud entities are modeled as UIM Host Servers (model type UIMHostServer).

A *virtual private cloud* (VPC) is a virtual network dedicated to your AWS account. It is logically isolated from other virtual networks in the AWS cloud. You can launch your AWS resources, such as Amazon EC2 instances, into your VPC. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings.

A *subnet* is a range of IP addresses in your VPC. You can launch AWS resources into a subnet that you select. Use a public subnet for resources that must be connected to the Internet, and a private subnet for resources that won't be connected to the Internet.

Amazon VPC is the networking layer for Amazon EC2. Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) cloud. Amazon EC2 is hosted in multiple locations worldwide. These locations are composed of regions and Availability Zones. Each region is a separate geographic area. Each region has multiple, isolated locations known as Availability Zones.

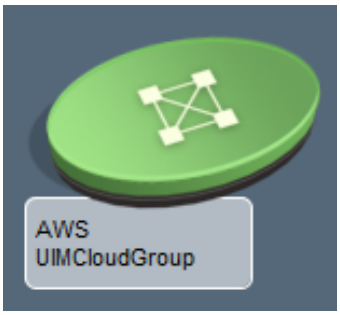
IP addresses enable resources in your VPC to communicate with each other, and with resources over the Internet. Amazon EC2 and Amazon VPC support the IPv4 and IPv6 addressing protocols. By default, Amazon EC2 and Amazon VPC use the IPv4 addressing protocol. When you create a VPC, you must assign it an IPv4 CIDR block (a range of private IPv4 addresses). Private IPv4 addresses are not reachable over the Internet. To connect to your instance over the Internet, or to enable communication between your instances and other AWS services that have public endpoints, you can assign a globally-unique public IPv4 address to your instance.

Each AWS entity will have both Public and Private IP's, provided by the corresponding attributes: **PrimaryIPV4Address** and **OtherIPAddresses.** Some times public and private IPs are not unique and will be the same, thus the VM will be

unreachable by SpectroSERVER. In such cases DX NetOps Spectrum uses the **AWSInstanceState** attribute/ **Instance State** field, to find out the state of the VM and to show the condition in the SpectroSERVER. DX NetOps Spectrum also stops polling that particular device, till public and private IP's are updated.

Topology View

The following icons represent the AWS entities after they are synced from UIM to DX NetOps Spectrum:

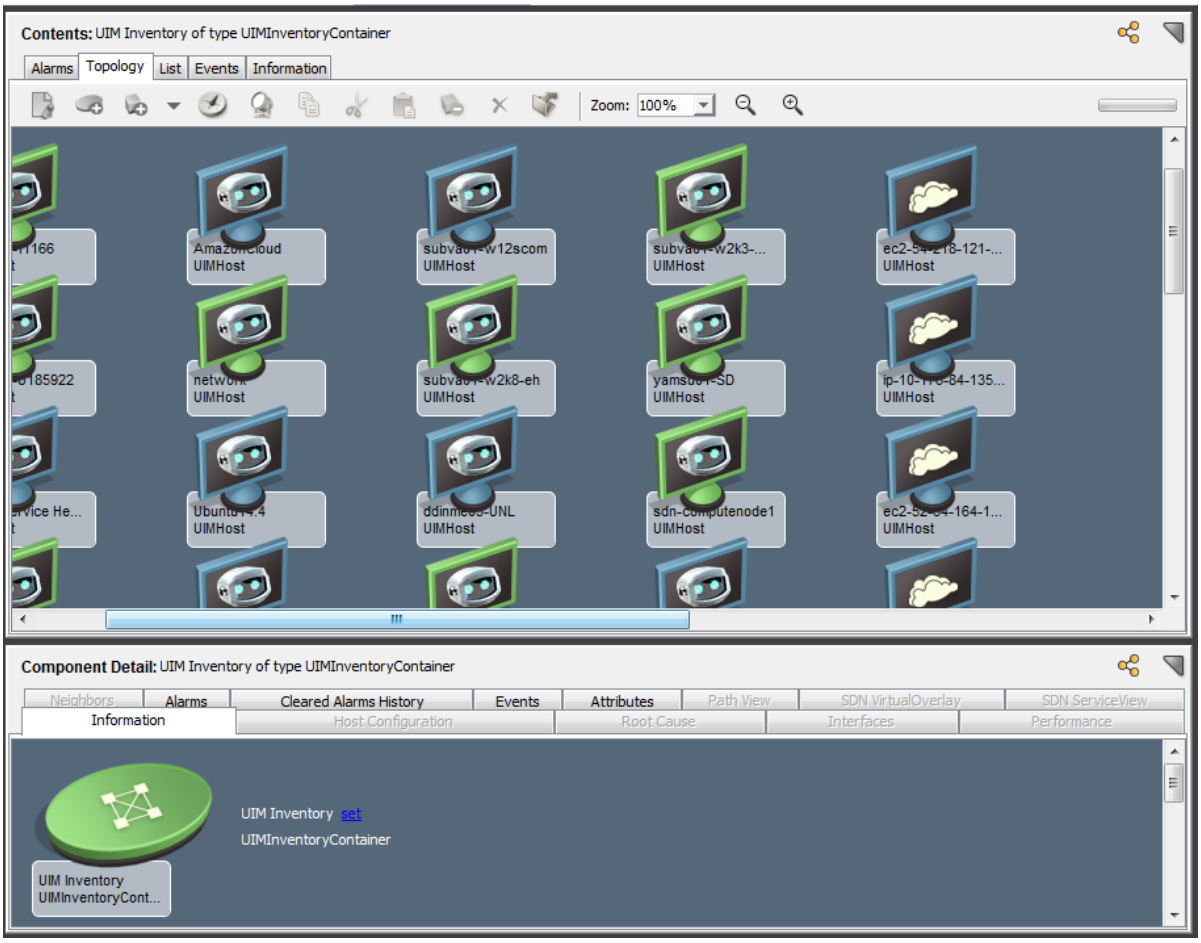


represents the container or network group icon for AWS Cloud entities, VPCs and subnets.

represents the AWS EC2 instances.

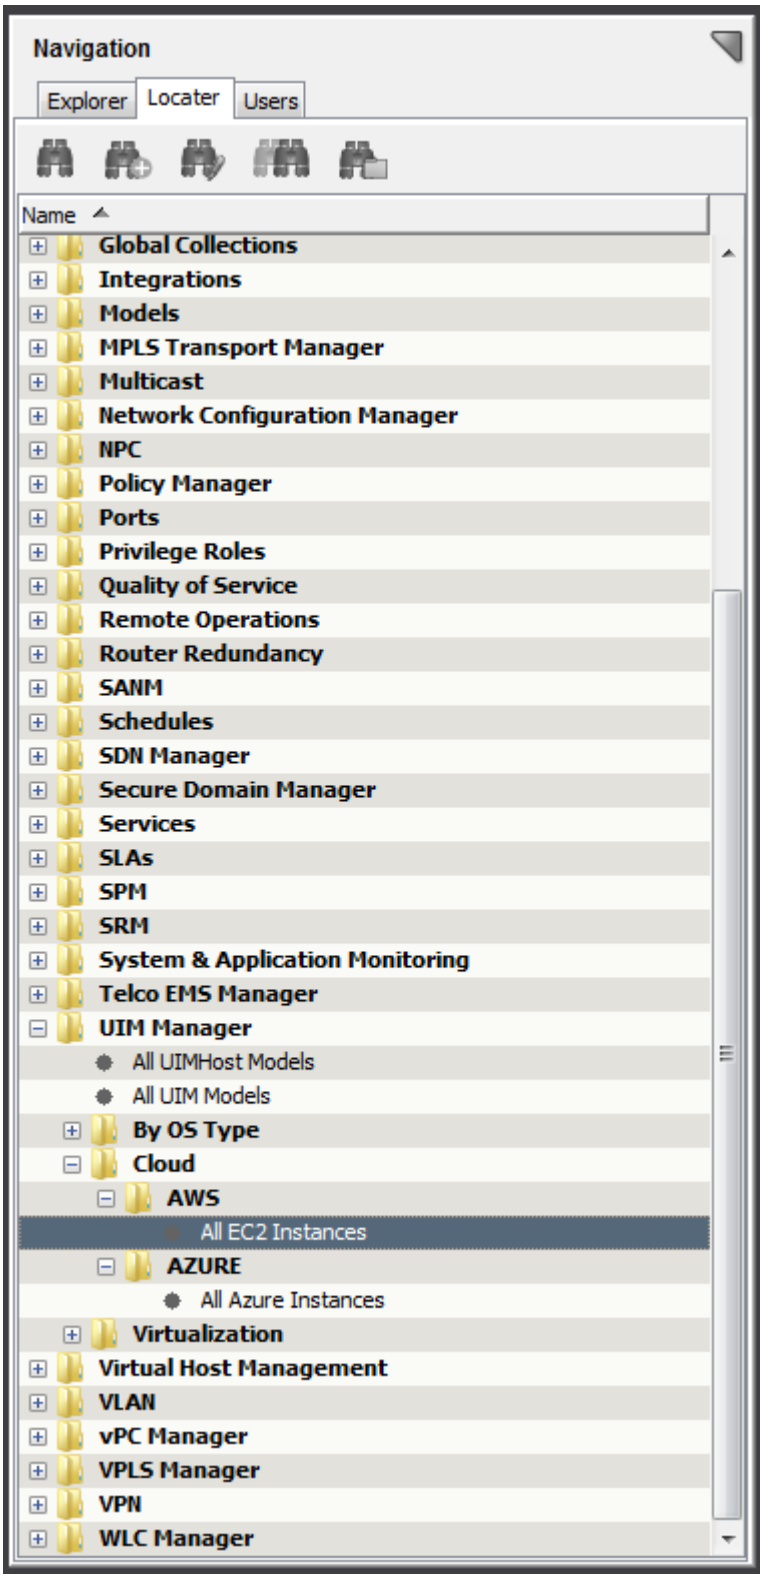
To view the EC2 instance models in its relevant context, follow these steps:

In the DX NetOps Spectrum OneClick Console, **Explorer View**, navigate to the **Universe > UIM Inventory** container, and select the **Topology** tab.
The Topology view displays all the inventory from UIM (which you have configured) that is synced to DX NetOps Spectrum:



Locater Search

You can use pre-configured searches to locate all AWS EC2 instances, in the DX NetOps Spectrum database quickly. The searches are grouped under the **UIM Manager > Cloud > AWS > All EC2 instances** folder in the **Locater** tab of the **Navigation** panel, as shown below:



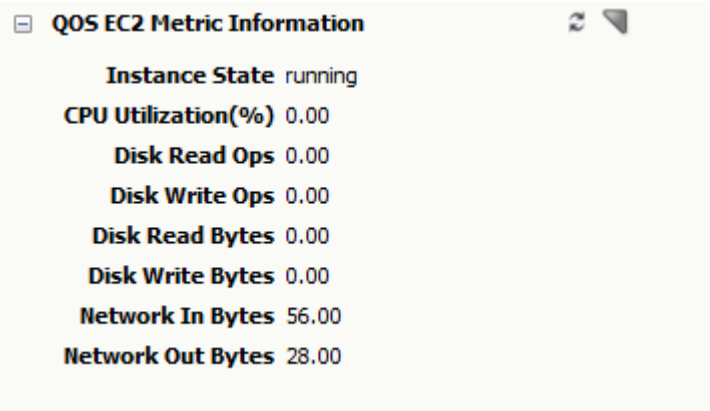
Follow these steps, to view All EC2 instances associated to AWS entities:

1. Navigate to **Locater** tab, **UIM Manager > Cloud > AWS**, and select **All EC2 instances**.

2. Select the landscapes you wish to search against, in the **Select Landscapes to Search** dialog box.
3. Click **OK.**
   The results matching your query is displayed in the **Contents** pane.

AWS related QOS Metrics

The following QOS Metric information for EC2 Instances are displayed in the **EC2 instance > Information Tab** view:



Metric Name	Description	Units
Instance State	This metric is the operational status of the EC2 instance. You can set up the threshold for status using a numeric value between 0 and 2. Each number is assigned a status value, as follows: 0: Instance is executing 1: User has stopped the instance 2: Instance has crashed	State
CPU Utilization (%)	This metric is the percentage of allocated EC2 compute units that are currently in use on the instance. You can use the information to identify the processing power required to execute an application on the selected instance.	Percent
Disk Read Ops	This metric is the number of completed read operations from all ephemeral disks available to the instance. You can use the information to identify the rate at which an application reads from a disk.	Count
Disk Write Ops	This metric is the number of completed write operations to all ephemeral disks available to the instance. You can use the information to identify the rate at which an application writes to a disk.	Count
Disk Read Bytes	This metric is the number of bytes read from all ephemeral disks available to the instance. You can use the information to determine the volume of data that the application reads from the hard disk of the instance.	Bytes
Disk Write Bytes	This metric is the number of bytes written to all ephemeral disks available to the instance. You can use the information to determine the volume of data that the application writes to the hard disk of the instance.	Bytes
Network In Bytes	This metric is the number of bytes received on all network interfaces by the instance. You can use the information to identify the volume of incoming network traffic to an application on the instance.	Bytes
Network Out Bytes	This metric is the number of bytes sent on all network interfaces by the instance. You can use the information to identify the volume of outgoing network traffic from an application on the instance.	Bytes

Supporting azure (Microsoft Azure Monitoring)

Overview

From 10.2.1, Microsoft Azure Monitoring is supported by DX NetOps Spectrum using the UIM and DX NetOps Spectrum integration. The azure (Microsoft Azure Monitoring) probe deployed in UIM enables the metric data collection from the AWS instances. This data is then synchronized from UIM to DX NetOps Spectrum.
Currently, we are synchronizing the Azure resources drilling down to the following hierarchy: **Subscription ID** > **Resource Group > Virtual Network > Virtual machines /Azure Instances**.

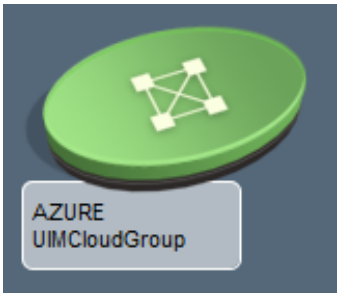
Microsoft Azure is a cloud computing platform and infrastructure, created by Microsoft that provides on-demand computing and storage to host, scale and manage Web applications and services through a global network of Microsoft-managed datacenters.

The Microsoft Azure Monitoring probe remotely monitors the health and performance of Azure infrastructure and services. The probe enables you to connect to Microsoft Azure using certificates and discover Azure resources to be monitored. The probe fetches all the service data from different geographical locations and lets you create profiles that monitor your cloud services including virtual machines (VMs), websites and storage. The probe lets you configure various monitoring parameters for each of these services. For example, you can check the health status of data services and VMs, a number of requests made to the storage service, CPU utilization, and so on. Based on the configured parameters, the probe generates Quality of Service (QoS) metrics.

In DX NetOps Spectrum, the parent/ domain hierarchy (Azure, Subscription ID and Resource Group) entities are modeled as separate containers (model type **UIMCloudGroup**), and all AWS Cloud entities (that is virtual machines) are modeled as UIM Host Servers (model type **UIMHostServer**).

Topology View

The following icons represent the Azure entities after they are synced from UIM to DX NetOps Spectrum:

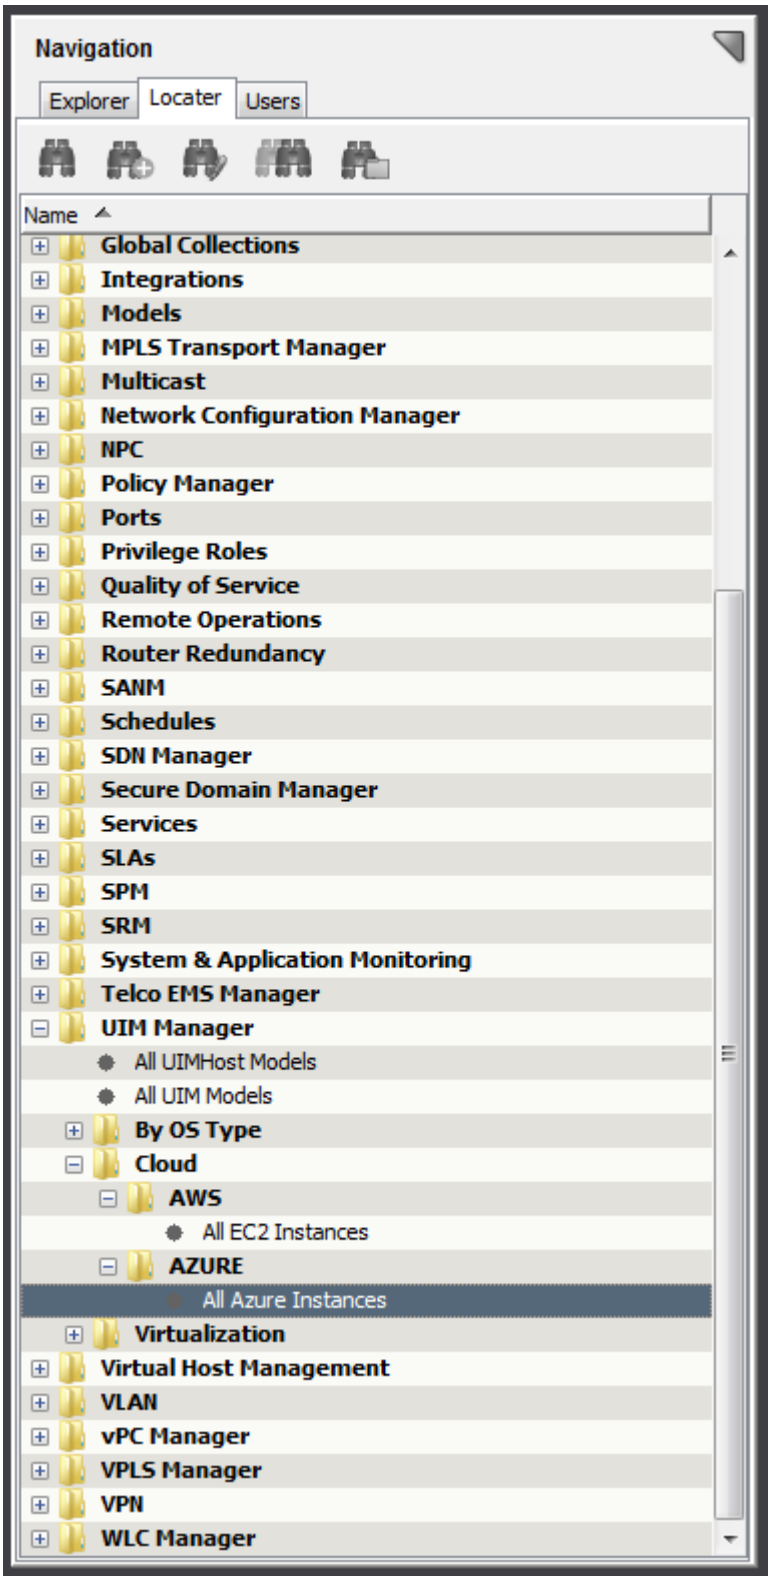


represents the container or network group icon for Microsoft Azure Cloud entities, Subscriptions, and Resource Groups.

represents the Azure VM entity/instance.

Locater Search

You can use pre-configured searches to locate all AWS EC2 instancaes, in the DX NetOps Spectrum database quickly. The searches are grouped under the **UIM Manager > Cloud > Azure> All Azure instances** folder in the **Locater** tab of the **Navigation** panel, as shown below:



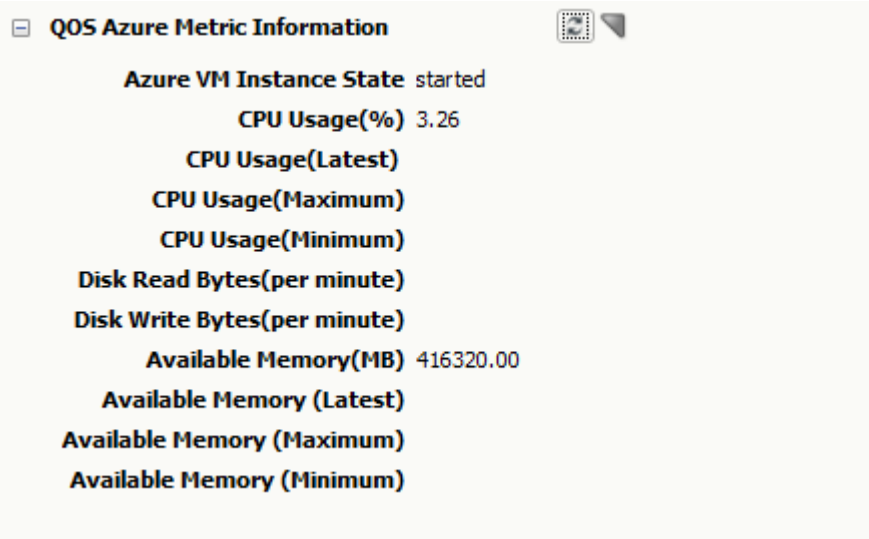
Follow these steps, to view All Azure instances associated to Microsoft Azure entities:

1. Navigate to **Locater** tab, **UIM Manager > Cloud > Azure**, and select **All Azure Instances**.

2. Select the landscapes you wish to search against, in the **Select Landscapes to Search** dialog box.
3. Click **OK.**
   The results matching your query is displayed in the **Contents** pane.

Azure related QOS metrics

The following QOS Metric information for EC2 Instances are displayed in the **Azure instance > Information Tab** view:



QOS Metric	Description	Unit
Azure VM Instance State	This metric is the current state of the virtual machine. The values indicating the state are: 0-Started, 1-Starting, 2-Stopping, 3-Stopped, 4-Unknown	State
CPU Usage (%)	This metric is the average percentage of elapsed time that the processor spends to execute non-idle threads for the virtual machine during the time period specified as the data collection interval.	Percent
CPU Usage (Latest)	This metric is the current percentage of elapsed time that the processor spends to execute non-idle threads for the virtual machine.	Percent
CPU Usage (Maximum)	This metric is the maximum percentage of elapsed time that the processor spends to execute non-idle threads for the virtual machine during the time period specified as the data collection interval.	Percent
CPU Usage (Minimum)	This metric is the minimum percentage of elapsed time that the processor spends to execute non-idle threads for the virtual machine during the time period specified as the data collection interval.	Percent
Disk Read Bytes (per minute)	This metric is the average disk read bytes per minute for the disk partition on the virtual machine during the time period specified as the data collection interval.	Bytes/ Min
Disk Write Bytes (per minute)	This metric is the average disk write bytes per minute for the disk partition on the virtual machine during the time period specified as the data collection interval.	Bytes/ Min
Available Memory (MB)	This metric is the average available memory in megabytes for the virtual machine during the time period specified as the data collection interval.	Megabytes
Available Memory (Latest)	This metric is the current available memory in megabytes for the virtual machine	Megabytes

Available Memory (Maximum)	This metric is the maximum available memory in megabytes for the virtual machine during the time period specified as the data collection interval.	Megabytes
Available Memory (Minimum)	This metric is the minimum available memory in megabytes for the virtual machine during the time period specified as the data collection interval.	Megabytes

Debugging

Debugging in DX NetOps Spectrum lets you track the data flow from UIM to DX NetOps Spectrum. It investigates and resolves integration related issues. The Start Client Debug Console contains various debug modules. Turn on UIM Integration Information to track alerts and CIs that flow from UIM to DX NetOps Spectrum.

To use Start Client Debug Console, you must first have a running OneClick client. This debug tool lets you turn on debugging output that can be seen in the Java Web Start log.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages are displayed.
3. Click the Debugging tab.
   A panel with various links to view debugging output opens.
4. Click Start Client Debug Console.
   A list of debug modules is displayed.
   The following image displays the list of available debug modules:

5. To enable debug, select On for the Nimsoft Integration Information debug module.
6. Select Max as Desired Level and click Apply.
   Debug is enabled.
7. To disable debug, select OFF and click Apply.
   Debug is disabled.

Troubleshooting Integration with UIM

DX NetOps Spectrum Not Receiving Alerts from UIM

Symptom: The alarm sync functionality of spectrumgtw is not working; previously, it was working without any issue. No changes to the spectrumgtw configuration were made.

Cause:
Check whether the state of the trellis probe is in a failed state. The trellis probe is used in the integration with the spectrumgtw probe. If it is in a failed state, the spectrumgtw service will not work.

Solution: To resolve the issues, 'cold start' (Deactivate-Activate) the trellis probe.

Issues with the spectrumgtw Configuration While Integrating CA Spectrum 10.2 with CA UIM 8.47 and 8.51

Symptom:
An error message is displayed when saving the spectrumgtw probe configuration through the Admin Console.

Cause:
The DX NetOps Spectrum OneClick web server machine is not responding to heartbeat restful post. http://<OneClick_hostname>:<port>/spectrum/restful/heartbeat

> **NOTE**
>
> This issue has been resolved in the CA Spectrum 10.2.1 (and above) integration with CA UIM 8.5.1.

Solution:
There are missing entries in the $SPECROOT/tomcat/webapps/spectrum/WEB-INF/web.xml file on the DX NetOps Spectrum OneClick web server machine.

```
com.ca.spectrum.restful.servlet.OneClickServlet
com.ca.spectrum.restful.servlet.HeartbeatServlet
com.ca.spectrum.restful.servlet.EventAlarmServlet
com.ca.spectrum.restful.servlet.HeartbeatAlarmResponseServlet
com.ca.spectrum.restful.servlet.UniversemhServlet
```

Alarm Forwarding Not Working for UIM

Symptom:

On a Distributed SpectroSERVER (DSS) setup, when the UIM managed hosts are modeled in DX NetOps Spectrum on landscapes other than Main Location Server (MLS), the UIM alarms that are raised on hosts may not get forwarded to the host models in non-MLS landscapes.

Solution:

To fix this issue, create the EventAdmin models manually for UIM Integration on all the landscapes in DSS when the integration is enabled. Review the following scenarios before creating the EventAdmin model manually:

Scenario 1:

For fresh integration or if the UIM models (existing models or UIM host models) are on landscapes other than MLS, create the EventAdmin models manually on other landscapes so that the alarms are forwarded to hosts.

> **NOTE**
>
> Use the default options while creating the EventAdmin model and do not enable the Alert_Forwarding_Enabled attribute.

Follow these steps:

1. To launch the OneClick Console, select Start Console at the top of the OneClick page, and log in as a DX NetOps Spectrum administrator.
2. Select the SpectroSERVER and Universe on the Explorer tab of the OneClick Navigation panel.
3. Select the Topology tab on the Contents panel and click the Create a New Model by Type icon.
   The Select Model Type dialog appears.
4. Click the All Model Types tab.
5. Select EventAdmin and click OK.
   The Create Model of Type dialog appears.

6. Enter the name and IP address of the UIM server and click OK.
   The UIM server is added to the topology as the selected model type.
   For more information about creating a model in OneClick, see the Modeling and Managing Your IT Infrastructure section.

Scenario 2:

If UIM Integration is enabled through the Southbound Gateway and an EventAdmin model already exists on a landscape, the attribute SBG_AlertForwardingEnabled must be enabled for the existing EventAdmin. The EventAdmin models must be created manually on other landscapes.

Follow these steps:

1. To create an EventAdmin model manually, follow the instructions that are documented for Scenario 1.
2. To enable the SBG_AlertForwardingEnabled attribute, select the EventAdmin in the OneClick Topology.
3. Select the Attributes tab in the Component Detail panel.
4. Select SBG_AlertForwardingEnabled in the left window of the Attributes panel.
   The attribute is added to the right window of the Attributes panel.
5. Double-click SBG_AlertForwardingEnabled in the right window, and select Yes. Click OK.
   The SBG_AlertForwardingEnabled attribute is enabled.

   NOTE
   You must delete EventAdmin and the associated event models when the integration is disabled.

Unnecessary minor alarms are noticed on VMware models

Symptom:

You may notice unnecessary minor alarms on VMware models

Solution:

To fix this issue, configure the SNMP gateway probe to avoid unnecessary minor alarms. For more information, see Deploy and Configure Probes.

If DX NetOps Spectrum and CA Unified Infrastructure Management Integration is disabled on second SpectroSERVER, you may notice Stale Nimsoft models on primary SpectroSERVER.

Stale Nimsoft Models on Primary SpectroSERVER

Symptom:

If DX NetOps Spectrum and UIM Integration is disabled on second SpectroSERVER, you may notice Stale Nimsoft models on primary SpectroSERVER.

Solution:

To fix this issue, you can delete the VMs and the rest of the entities in DX NetOps Spectrum OneClick console. To delete the entities, follow these steps:

1. In the DX NetOps Spectrum OneClick console, select the corresponding model, click the attribute tab, and search **“EditModelMask”.**
2. Change the value of **“EditModelMask”** from 255 to 0 and click **Save.**
3. Right-click that entity and select the **Delete** option.

Traps sent from snmpgtw are not being processed in DX NetOps Spectrum after enabling the DX NetOps Spectrum-UIM integration.

Symptom analysis:

This behavior is observed mainly in environments where the snmpgtw (snmp gateway) probe is deployed on a different server, i.e. other than the integrated UIM server (as mentioned in UIM Configuration page).

Solution:
You have to manually create an **EventAdmin** with the IP address of server/machine where the snmpgtw probe is deployed, and the traps will be handled properly using the SBGW probe (South Bound gateway) functionality.

> **NOTE**
>
> You also need to set the **SBGW_AlertForwarding** attribute to **Yes**.

Unknown alerts received for the NimsoftHost model

Symptom analysis: Unknown alert received trap mainly occurs on **NimsoftHostServer** models. The machine on which snmpgtw probe is deployed is also reported as **NimsoftHostServer** model in DX NetOps Spectrum, hence the models are found with the same IP address; as **EventAdmin** and as **NimsoftHostServer** model types.

When a trap is received, DX NetOps Spectrum forwards the trap to both the models with same IP Address.
As SBGW functionality works with EventAdmin model it processes the trap and **NimsoftHostServer** model fails to recognize it. Hence these unknown alerts are generated.

Solution:
Navigate to **NimsoftHost** model > **DX NetOps Spectrum Modeling Information** sub view > Select **Yes** for the **Disable Trap-Based Events** drop-down option.
The default value is **No**.
No unknown alert events are observed after you disable this option.

Missing Inventory due to Vcenter being hosted on a VM

Scenario 1: UIM reports two entities with different CS_ID for the same host which is a VM and has a vcenter deployed on it (Vcenter hosted on VMs managed by other vcenters), which causes the hierarchy in DX NetOps Spectrum to be deleted during the subsequent syncs with UIM.

Solution: Model the Vcenters first, consequently the VM which is acting as a vcenter will not be modeled, thus preserving the hierarchy in DX NetOps Spectrum

Scenario 2: UIM reports one entity for a host which is a VM and has a vcenter hosted on it. Sometimes the relationship for such a VM with its parent ESX host is not reported from UIM in subsequent syncs which causes that VM to be deleted in DX NetOps Spectrum and since it is also a vcenter the hierarchy also gets deleted in DX NetOps Spectrum.

Solution: The relationship between such a VM and its parent ESX host will not be modeled thus preserving the hierarchy in DX NetOps Spectrum.

UIM Models in Lost and Found/Cluttered Universe view

Symptom: Sometimes the relationships between ESX host and child VMs are not reported in some syncs. This causes all such VMs to be moved to the Lost and Found node. Also, All the UIM models are modeled under Universe by default which clutters the topology view of the Universe

Solution: A new container called **UIM Inventory** is now introduced where all the UIM entities will be placed upon creation in DX NetOps Spectrum. Also, in case the ESX to VM relation is not reported then such VMs will be moved to the said container thus preventing the models in the Lost and Found issue.

> **NOTE**
>
> The customer can move this UIM Inventory container across the navigation hierarchy and rename it as per his needs.

Not all UIM models are modeled in DX NetOps Spectrum

Symptom: In some instances, ESX hosts, Resource Pools and VMs are reported as children of an entity whose type is “COMPUTE_RESOURCE”. This is an entity type which DX NetOps Spectrum does not recognize which causes DX NetOps Spectrum to not process the children of such entities.

Solution: DX NetOps Spectrum has been modified to recognize **“COMPUTE_RESOURCE”** entity type, thus enabling modeling the children of such entities

OneClick Client hangs when metric views of UIM models are expanded

Symptom: Sometimes OneClick Client becomes unresponsive when the user clicks the metric views of the UIM models. OneClick Server makes individual REST calls for each metric and till the response is received from the UIM, the OneClick client becomes unresponsive.
Solution: A single **nisapi** call is made to fetch data of all the metric types for each metric family instead of multiple calls in order to improve the performance.

Models found in LostFound container

Symptom: Models found in LostFound container
Probable Cause: If there are any Virtual Machines under vApp, after disabling VMware Management integration, those VMs might be found under LostFound container
Solution: Users should manually delete those models from the LostFound container before integrating DX NetOps Spectrum and UIM (VMware or Server Management) again.

Multiple JSON exception(s) in Tomcat log

Symptom: Users might observe multiple JSONException in tomcat log (See below for exception details) during DX NetOps Spectrum- UIM Integration:

```
Error in getting the property PrimaryOSNameorg.json.JSONException: JSONObject["PrimaryOSName"] not found.
at org.json.JSONObject.get(JSONObject.java:516)
at com.ca.nimsoft.integration.nis.nisservice.NimsoftRESTEntity.getProperty(NimsoftRESTEntity.java:37)
at com.ca.nimsoft.integration.manager.NimosftHostServerModelTask.call(NimosftHostServerModelTask.java:55)
at java.util.concurrent.FutureTask.run(FutureTask.java:266)
at java.util.concurrent.ThreadPoolExecutor.runWorker(ThreadPoolExecutor.java:1142)
at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
at java.lang.Thread.run(Thread.java:745)
```

Probable Cause: If any inventory from UIM does not contain Primary OperatingSystem Name, JSONException is thrown in the tomcat log
Solution: Users can ignore these as they do not impact the functionality

Unable to delete UIM Inventory container from source landscape

Symptom: UIM Inventory container doesn't delete from source landscape even though there are no datacenters after migration
Solution: Users should manually delete the 'UIM Inventory' container. However, leaving it as is, without deleting, will not affect any functionality

Server Hierarchy under UIM manager is empty in source landscape

Symptom: Under UIM Manager, Server hierarchy remains empty in source landscape even though there are no datacenters after migration
Probable Cause: If there are many Virtual machines that were part of a datacenter, migration process will take more time than expected if the 'Incremental Sync Time Interval' and 'VMWare Sync Time Interval' are less than 15 minutes

Solution: You should set '**Incremental Sync Time Interval**' and '**VMWare Sync Time Interval**' to its default value. You can manually delete **'Server'** hierarchy. However, leaving it as is, without deleting, will not affect any functionality

Servers does not migrate immediately when Datacenter(s) are migrated.

Symptom: Servers does not migrate immediately when Datacenter is migrated. Server migration happens only after subsequent syncs
Probable Cause: When there are many host servers that were part of a datacenter, and if the '**Incremental Sync Time Interval**' and '**VMWare Sync Time Interval'** are less than 15 minutes, the migration process will take more time than expected,
Solution: You should set '**Incremental Sync Time Interval**' and '**VMWare Sync Time Interval**' to its default value.

Errors in Unidirectional alarms synchronization, when the synchronization options are flipped in the spectrumgtw probe Admin Console

Symptom: Unidirectional alarms sync has a problem when the option is flipped between '**DX NetOps Spectrum to UIM**' and '**UIM to DX NetOps Spectrum**' or vice-versa,
Probable Cause: If users are using any ems version lesser than v8.4.3 this problem is observed
Solution: Deploy latest version on ems probe version 8.4.3

Appendix. Event Management using spectrumgtw probe

DX NetOps Spectrum-UIM Integration Events Mapping (Unidirectional and Bidirectional)

DX NetOps Spectrum receives a trap from UIM. DX NetOps Spectrum uses originating events based on AlertMap mapping to raise different event codes based on event conditions/severity.
DX NetOps Spectrum uses 0x06330010, 0x06330011, 0x06330012,0x06330013 event codes as originating events. For a detailed list of event code mappings based on the originating event, please go through the rest of the page.

If you have integrated DX NetOps Spectrum with UIM using the SNMP Gateway probe and SBGW / Southbound gateway, and want to understand the changes in how events and event codes are managed using spectrumgtw probe, please refer to the mappings below.

If the originating event used is **0x6330010**, subsequently, based on event conditions, appropriate events are generated as shown in the table below:

Event Condition	Generated event Code	Severity	Cleared Cause Codes
If the powerState of UIM Model is OK	0x06330062	Clear	0x06330058, 0x06330059
If the communication of UIM model through Ping is successful	0x06330057	Clear	0x06330056
If the HostPowerState of UIM Model is OK	0x06330063	Clear	0x06330060, 0x06330061
If Power On Event is generated	0x06330065	Clear	0x06330064
if Powered On Event is generated	0x06330065	Clear	0x06330064
If UIM Model is in connected state	0x06330065	Clear	0x06330064
if the Status of UIM Model is Power On	0x06330065	Clear	0x06330064
If the GuestState of UIM Model is OK	0x06330062	Clear	0x06330058, 0x06330059

If the Maintenance Mode of UIM Model is OK	0x06330067	Clear	0x06330066
Default (if above event conditions don't match)	0x06330000	Clear	0x06330001, 0x06330002, 0x06330003
if varbind 102 value matches with octet String 1.1.1.1 (Then Disk alarm is raised)	0x06330030	Clear	0x63300031, 0x63300041, 0x63300051,
if varbind 102 value matches with octet String 1.1.1.2 (Then memory alarm is raised)	0x06330040	Clear	0x63300032, 0x63300042, 0x63300052,
if varbind 102 value matches with octet String 1.1.1.3 (Then CPU alarm is raised)	0x06330050	Clear	0x63300033, 0x63300043, 0x63300053,

NOTE
No event/alarm is raised on DX NetOps Spectrum using 0x06330010, this is used for internal event condition mapping.

If the originating event used is **0x06330011**, later, based on event conditions, appropriate events are generated as shown in the table below:

Event Condition	Generated event Code	Severity
If Powered Off Event is generated	0x6330064	Critical
if UIM Model is in not connected State	0x6330064	Critical
If Powered Off Event is generated	0x6330064	Critical
if UIM Model is in not running state	0x6330058	Critical
if UIM model is in unknown state	0x6330058	Critical
UIM Model's maintenance state is true	0x6330066	Major
if UIM Model has entered maintenance state	0x6330066	Major
if UIM Model has exited maintenance state	0x6330067	Clear
if varbind 102 value matches with octet String 1.1.1.1 (Then Disk alarm is raised)	0x06330031	Minor
if varbind 102 value matches with octet String 1.1.1.2 (Then memory alarm is raised)	0x06330041	Minor
if varbind 102 value matches with octet String 1.1.1.3 (Then CPU alarm is raised)	0x06330051	Minor
Default (if above event conditions don't match)	0x6330001	Minor

NOTE

No event/alarm is raised on DX NetOps Spectrum using 0x06330011, this is used for internal event condition mapping.

If the originating event used is **0x06330012**, later, based on event conditions, appropriate events are generated as shown in the table below:

Event Condition	Generated event Code	Severity
UIM Model communication failed through Ping	0x06330056	Critical
HostPowerState of UIM Model is poweredOFF	0x06330060	Critical
HostPowerState of UIM Model is Unknown	0x06330061	Critical
PowerState of UIM Model is poweredOff	0x06330058	Critical
PowerState of UIM Model is Suspended	0x06330059	Critical
UIM Model is Power Off event generated	0x06330064	Critical
UIM Model is PoweredOff, an event is generated	0x06330064	Critical
The Status of UIM Model is Power Off	0x06330064	Critical
The GuestState of UIM Model is not running	0x06330058	Critical
The GuestState of UIM Model is unknown	0x06330058	Critical
if varbind 102 value matches with octet String 1.1.1.1 (Then Disk alarm is raised)	0x06330032	Major
if varbind 102 value matches with octet String 1.1.1.2 (Then memory alarm is raised)	0x06330042	Major
if varbind 102 value matches with octet String 1.1.1.3 (Then CPU alarm is raised)	0x06330052	Major
Default (if above event conditions don't match)	0x06330002	Major

NOTE

No event/alarm is raised on DX NetOps Spectrum using 0x06330012, this is used for internal event condition mapping

If the originating event used is **0x06330013**, later, based on event conditions, appropriate events are generated as shown in the table below:

Event Condition	Generated event Code	Severity
HostPowerState of UIM Model is poweredOFF	0x06330060	Critical
HostPowerState of UIM Model is Unknown	0x06330061	Critical
PowerState of UIM Model is poweredOff	0x06330058	Critical
PowerState of UIM Model is Suspended	0x06330059	Critical
UIM Model is Power Off event generated	0x06330064	Critical
UIM Model is PoweredOff, an event is generated	0x06330064	Critical
The Status of UIM Model is Power Off	0x06330064	Critical
The GuestState of UIM Model is not running	0x06330058	Critical

The GuestState of UIM Model is unknown	0x06330058	Critical
if varbind 102 value matches with octet String 1.1.1.1 (Then Disk alarm is raised)	0x06330033	Critical
if varbind 102 value matches with octet String 1.1.1.2 (Then memory alarm is raised)	0x06330043	Critical
if varbind 102 value matches with octet String 1.1.1.3 (Then CPU alarm is raised)	0x06330053	Critical
Default (if above event conditions don't match)	0x06330003	Critical

NOTE

No event/alarm is raised on DX NetOps Spectrum using 0x06330013, this is used for internal event condition mapping

NOTE

In case the device is in maintenance mode, event 0x06330066 is raised to put device in maintenance mode and, event 0x06330067 is raised to remove the device from maintenance mode.

DX NetOps Spectrum- UIM Bidirectional Events:
DX NetOps Spectrum receives alarms from spectrumgtw probe, an originating event **0x06330071,** is used in Spectrum to raise events based on event conditions.

Event Condition	Generated event Code	Severity	Cleared Cause Codes
if UIM Model has entered maintenance state	0x6330066	Maintenance	
if UIM Model has exited maintenance state	0x6330067	Clear	0x06330066
if UIM Model maintenance state is true	0x6330066	Maintenance	
if UIM Model maintenance state is OK	0x6330067	Clear	0x06330066

Minor, Major, Critical alarms will be raised based on severity varbind {S 101).

Event	Generated event Code	Severity	Cleared Cause Codes
If Minor event raised	0x0633006e	Minor	0x0633006f, 0x06330070
If Major event is raised	0x0633006f	Major	0x0633006e, 0x06330070
If Critical Event is raised	0x06330070	Critical	0x0633006e, 0x0633006f
Default (If we receive an event from UIM and no event condition or severity is matched)	0x06330076		

NOTE

No event/alarm is raised on Spectrum using 0x06330071, this is used for internal event condition mapping.

Events Codes for unidirectional and bidirectional UIM Integration		
Severity	**Using SouthBound Gateway Functionality (Unidirectional Integration)**	**Using Spectrum Gateway (Bidirectional Integration)**
Major	0x6330066, 0x06330032,0x06330042, 0x06330052, 0x06330002	0x0633006f
Minor	0x06330031, 0x06330041, 0x06330051, 0x06330001	0x0633006e
Critical	0x06330064 , 0x6330058, 0x06330056, 0x06330060, 0x06330061, 0x06330059, 0x06330064, 0x06330033, 0x06330043, 0x06330053, 0x06330003	0x06330070, 0x06330072, 0x06330074
Clear	*Refer below*	Cleared using IH

	event Code	**Cause Codes cleared**
	0x06330062	0x06330058, 0x06330059
	0x06330057	0x06330056
	0x06330063	0x06330060, 0x06330061

Additional Event Mapping from UIM Probes

Till 10.2, apart from events related to VMWare and servers, events from UIM were considered as generic events by DX NetOps Spectrum. As a result users were unable to create specific rules for those events due to lack of unique event codes. From the 10.2.1 release those events are also to be mapped to unique event code so that you can customize them and manage the events raised on UIM more effectively.

Please see the tables below to see the mapping of events from the probes to unique event codes in DX NetOps Spectrum:

sqlserver (SQL Server Monitoring) probe

The SQL Server Monitoring (sqlserver) probe constantly monitors the internal performance and space allocation of SQL Server databases. The probe can run locally on the database server or it can be configured to run as a remote client. The probe feeds essential information that is based on predefined criteria to the UIM availability manager for appropriate

alert notification, as required. An extensive range of checkpoints can be selected and individually scheduled to meet your monitoring requirements. The probe will run selected SQLs to extract vital information about your SQL Servers. The information is presented to database-administrator as alarms or reports. For more information, see sqlserver Metrics.

Checkpoint Metric	Description	Metric Type	DX NetOps Spectrum Event ID	Units
active_connection_ratio	Monitors the numbers of active connections.	4.2:51	0x06330077	Percent
active_users	Monitors the number of users having an active transaction at the moment of the snapshot.	4.2:1	0x06330078	Count
agent_job_failure	Monitors failed agent jobs in a defined time interval. **Note:** This monitor does not generate a clear alarm, by default. You can change the value of the **clear_alarms** key to **1**, using the **Raw Configure** option, to generate a clear alarm.	4.2:57	0x06330079	Count
alloc_space	Monitors allocated space.	4.2:2	0x0633007a	Percent
av_fragmentation	Monitors average fragmentation.	4.2:3	0x0633007b	Percent
average_waittime	Monitors average lock wait time interval in ms. High wait time causes performance degradation, consider an increase number of locks available or computer memory.	4.2:4	0x0633007c	Milliseconds
backup_status	Monitors in minutes, since the last database backup has been taken. For all databases that have never been backed up, this checkpoint returns -1 value.	4.2:5	0x0633007d	Minutes
blocked_users	Monitors the number of blocked users.	4.2:48	0x0633007e	Count
buf_cachehit_ratio	Percentage of pages found in the buffer cache without having to read from the disk. The ratio is the interval number of cache hits divided by the interval number of cache look-ups. **Note**: As reading from the cache is less expensive than reading from disk, you want this ratio to be high. Generally, you can increase the buffer cache hit ratio by increasing the amount of memory available to the SQL Server.	4.2:6	0x0633007f	Percent

check_dbalive	Attempts to connect to the server. This checkpoint cannot be deactivated and returns two values with which threshold comparison is done: • Sql Server instance connection failure: 0 • Sql Server instance connection success: 1	4.2:7	0x06330080	State
connection_memory	Monitors the amount of memory in KB that is used to maintain connections to SQL Server.	4.2:8	0x06330081	Kilobytes
database_count	Change in the number of databases on the server.	4.2:9	0x06330082	Count
database_size	Monitors the database status value. The status value is actually a combination of some configuration options and a status, therefore, there can be multiple values set simultaneously (such as "torn page detection" and "loading").	4.2:10	0x06330083	Megabytes
database_state	State of the sql_server database. For example, the database can be in any one of the following states: • Online • Offline • Restoring • Suspect	4.2:11	0x06330084	State
deadlocks	Monitors the number of deadlocks per second in an interval. **Note:** As deadlocks can cause a severe performance penalty, the count must be close to 0. Use trace 1204 or 1205 to identify the deadlocked resources and involved applications. Procedure such as sp_lock delivers useful information about locking.	4.2:12	0x06330085	Count/s
differential_backup_status	Monitors time in minutes since last differential backup.	4.2:50	0x06330086	Minutes
fg_free_space	Monitors the amount of free space in database file groups in percent. If there is at least one file with "unlimited" growth in a file group, the space in this file group is considered as 100 percent free.	4.2:64	0x06330087	Percent
free_connections	Monitors the percentage of free connections to SQL Server instance, specified by parameter 'user connections' (the maximum value must be 32676).	4.2:14	0x06330088	Percent

free_space	Monitors the amount of free space in data files in percentage. **Note:** If there is at least one file with "unlimited" growth, the space in the whole database is considered as 100% free. If you are using file groups, this could be misleading; therefore, you must deactivate this checkpoint and use only the "fg_free_space" checkpoint.	4.2:15	0x06330089	Percent
full_scans	Monitors the number of full table or index scans per second in the interval. If this value is high (2-10), then you must analyze your queries.	4.2:16	0x0633008a	Count/sec
latch_waits	Monitors the number of latch requests in an interval that could not be granted immediately and has to go in a wait state. **Note:** If this number is high, the system experiences a low cache hit ratio and is forced to perform physical I/O operations. Add more memory or increase the bandwidth of your system.	4.2:17	0x0633008b	Request/sec
lock_memory	Monitors the amount of allocated lock memory in KB.	4.2:18	0x0633008c	Kilobytes
lock_requests	Monitors the number of lock requests per second in the interval.	4.2:19	0x0633008d	Requests/Sec
lock_timeouts	Monitors number of lock-timeouts per second in interval with a precision of 0.001sec	4.2:20	0x0633008e	Count/sec
lock_waits	Monitors the number of locks waits per second in the interval.	4.2:21	0x0633008f	Count/sec
locked_users	Monitors the number of users suspended by locks at a given moment. Also, the blocked user and its current SQL are displayed.	4.2:22	0x06330090	Count
locks_used	Monitors the percentage of used lock and lock owner blocks.	4.2:23	0x06330091	Percent
log_cachehit_ratio	Monitors the percentage of pages found in the log cache without having to read from disk. The ratio is the interval number of cache hits divided by the interval number of cache look-ups. **Note**: Reading from the cache consumes less resources than reading from disk. You want this ratio to be high. You can increase the log cache hit ratio by increasing the amount of memory available to the SQL Server.	4.2:24	0x06330092	Percent

log_file_growths	Monitors the number of times in an interval the transaction log for the database has been expanded. If this happens often, you must consider re-sizing your log files.	4.2:25	0x06330093	Count
log_file_shrinks	Monitors the number of times in an interval the transaction log for the database has been decreased. If this happens often, you must consider re-sizing your log files.	4.2:26	0x06330094	Count
log_flush_waits	Monitors the number of commits per second waiting on the log flush in an interval. When commits are waiting for log flushes, the log device is usually the bottleneck.	4.2:27	0x06330095	Count/sec
logfile_size	Monitors the size of transaction log in MB for at least one transaction log file with "unlimited" growth in a database. **Note:** For this checkpoint, wherever the given database is in the recovery or restore mode, no metric values are reported for given interval of execution.	4.2:52	0x06330096	Count
logfile_usage	Monitors the amount of free space in the transaction log in percentage. If there is at least one transaction log file with "unlimited" growth in a database, the space in the transaction log is considered as 100 percent free. **Note:** For this checkpoint, wherever the given database is in the recovery or restore mode, no metric values would be reported for a given interval of execution.	4.2:28	0x06330097	Percent
logic_fragment	Monitors the number of cluster index pages that are out of order. Any number higher than 10% indicates external fragmentation. The index should be rebuilt. **Note:** Non-cluster indexes are not monitored because a table can have only one clustering sequence.	4.2:29	0x06330098	Percent
login_count	Monitors the number of users having an open connection to the server at a given time	4.2:30	0x06330099	Count
long_jobs	Monitors all jobs running longer than the defined threshold in seconds.	4.2:31	0x063300a0	Count
long_queries	Monitors all queries running longer than the defined threshold in seconds.	4.2:32	0x063300a1	None
mirror_sqlinstance	Monitors the availability of SQL server instance hosting the mirror database.	4.2:55	0x063300a2	State

mirror_state	Monitors mirror database state.	4.2:53	0x063300a3	State
mirror_witness_server	Monitors state of the witness server in the database mirror session.	4.2:54	0x063300a4	State
optimizer_memory	Monitors amount of memory in KB that is used for SQL optimizer.	4.2:33	0x063300a5	Kilobytes
page_reads	Monitors the number of physical database page-reads that are issued per second in an interval. **Note:** Since physical I/O is expensive, you can minimize the cost, either by using a larger data cache, intelligent indexes, more efficient queries, or by changing the database design.	4.2:34	0x063300a6	Counts/sec
page_writes	Monitors the number of databases page-writes that are issued per second in an interval. **Note:** Page-writes are generally expensive. Reducing page-write activity is important for optimal tuning. One way to do this is to ensure that you do not run out of free buffers in the free buffer pool. If you do, page-writes occurs while waiting for an unused cache buffer to flush.	4.2:35	0x063300a7	Counts/sec
scan_density	Monitors the ratio between the best number of extents to the actual number of extents. It should be near 100 percent. A lower number indicates external fragmentation and the object must be reorganized.	4.2:36	0x063300a8	Ratio
server_cpu	Monitors the percentage of CPU usage by SQL Server instance in the interval.	4.2:37	0x063300a9	Percent
server_io	Monitors the percentage of I/O busy for SQL Server instance in the interval.	4.2:38	0x063300aa	Percent
server_startup	Number of days the database server is up and running.	4.2:39	0x063300ab	Days
suspect_pages	Monitors suspect pages logged for databases.	4.2:56	0x063300ac	Gauge
sqlcache_memory	Monitors the amount of memory in KB that is used for SQL statement cache.	4.2:40	0x063300ad	Kilobytes
table_space	Monitors the amount of space (in KB/MB) reserved for a particular table in a database. This checkpoint can be used to control the size of fast-growing tables.	4.2:41	0x063300ae	Kilobytes
total_memory	Monitors the total amount of dynamic memory (in KB) that the server uses currently.	4.2:42	0x063300af	Kilobytes

transaction_backup_status	Sends QoS and Alarms for those databases that are running in full or bulk-logged recovery mode. **Note**: This checkpoint does not send QoS and Alarms for databases that are running in simple recovery mode.	4.2:49	0x063300b0	Minutes
transactions	Monitors the number of transactions per second in the interval.	4.2:43	0x063300b1	Transactions/sec
user_cpu	Monitors the percentage of CPU usage by user in interval. **Note:** The checkpoint **user_cpu** reports **$spid.$hostid** in the QoS target. This results in the creation of new data series for each new **$spid** or **$hostid**. CA recommends disabling the QoS for this checkpoint.	4.2:44	0x063300b2	Percent
user_waits	Monitors time in seconds for session spent waiting for a lock and length of blocking. **Note:** You can add schedules in the **Exclude** and **Include** lists. The match expression, which is added will be executed in the given time period mentioned in the schedule.	4.2:45	0x063300b3	Seconds
workspace_memory	Monitors the amount of memory in KB that is used for executing processes such as hash, sort, bulk copy, and index creation operations.	4.2:46	0x063300b4	Percent
ls_primary_status	Monitors the collective status of agents for the primary log shipping database. This checkpoint must run from the primary server or monitor server. The status can be as follows: • healthy and no-agent failures 1 • otherwise 0	4.2:58	0x063300b5	Status
ls_time_since_last_backup	Monitors time in minutes since the last backup.	4.2:60	0x063300b6	Minutes
ls_secondary_status	Monitors the collective status of agents for the secondary log shipping database. This checkpoint must run from a secondary server or monitor server. The status can be as follows: • healthy and no-agent failures 1 • otherwise 0	4.2:59	0x063300b7	Status
ls_time_since_last_copy	Monitors time in minutes since the last copy.	4.2:61	0x063300b8	Minutes
ls_time_since_last_restore	Monitors time in minutes since the last restore.	4.2:62	0x063300b9	Minutes
ls_last_restored_latency	Monitors time in minutes since last restored latency.	4.2:63	0x063300ba	Minutes

fg_freeSpace_with_avail_disk	Monitors the amount of free disk space in database file groups in %. Free space for file groups (with auto-growth enabled) is calculated after considering the available disk size on which the file group is located. **Notes:** • A single query is executed for all the databases of the SQL server. If any of the databases fails to execute the query, the query is considered as failed for the SQL server. • You require System Administrator privileges on the database server to execute this checkpoint.	4.2:64	0x063300bb	Percent
logfile_usage_with_avail_disk	Monitors free space in the database log files after considering the available disk size. **Note:** You require System Administrator privileges on the database server to execute this checkpoint.	4.2:65	0x063300bc	Percent
aag_cluster_members_state	Monitors the state of the nodes of all AlwaysOn availability groups of WSFC. Each number is assigned a value, as follows: • Offline: 0 • Online: 1	4.2.3:2	0x063300bd	State
aag_cluster_quorum_state	Monitors the quorum state of all AlwaysOn availability groups of Windows Server Failover Clustering (WSFC) cluster. Each number is assigned a value, as follows: • Unknown quorum state: 0 • Normal quorum: 1 • Forced quorum: 2	4.2.3:1	0x063300be	State

aag_db_page_status	Monitors the page state of each database in all the AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Queued for request from partner: 2 • Request sent to partner: 3 • Queued for automatic page repair (response received from partner): 4 • Automatic page repair succeeded and the page should be usable: 5 • Irreparable: 6 (This indicates that an error occurred during page-repair attempt, for example, because the page is also corrupted on the partner, the partner is disconnected, or a network problem occurred. This state is not terminal; if corruption is encountered again on the page, the page will be requested again from the partner.)	4.2.3:9	0x063300bf	State
aag_db_replica_synchronization_state	Monitors the synchronization state of each database replica in all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Not synchronizing: 0 • Synchronizing: 1 • Synchronized: 2 • Reverting: 3 • Initializing: 4	4.2.3:8	0x063300c0	State
aag_listener_state	Monitors the listener state of all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Offline: 0 • Online: 1 • Pending restart: 2 • Online: 3	4.2.3:10	0x063300c1	State
aag_replica_connected_state	Monitors the connected state of a replica in all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Disconnected: 0 • Connected: 1	4.2.3:5	0x063300c2	State

aag_replica_operational_state	Monitors the operational state of a replica in all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Pending failover: 0 • Pending: 1 • Online: 2 • Offline: 3 • Failed: 4 • Failed, no quorum: 5 • Replica is not local: NULL	4.2.3:7	0x063300c3	State
aag_replica_recovery_health	Monitors the recovery health of a replica in all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Online_in_progress: 0 • Online: 1 • NULL	4.2.3:6	0x063300c4	State
aag_replica_synchronization_health	Monitors the synchronization health of a replica in all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Not healthy: 0 (At least one joined database is in the NOT SYNCHRONIZING state.) • Partially healthy: 1 (Some replicas are not in the target synchronization state: synchronous-commit replicas should be synchronized, and asynchronous-commit replicas should be synchronizing.) • Healthy: 2 (All replicas are in the target synchronization state: synchronous-commit replicas are synchronized, and asynchronous-commit replicas are synchronizing.)	4.2.3:4	0x063300c5	State
aag_synchronization_health	Monitors the synchronization health of all AlwaysOn availability groups of the server. Each number is assigned a value, as follows: • Not healthy: 0 (None of the availability replicas have a healthy synchronization_health) • Partially healthy: 1 (The synchronization health of some, but not all, availability replicas is healthy.) • Healthy: 2 (The synchronization health of every availability replica is healthy.)	4.2.3:3	0x063300c6	State

wait_stats_count	Monitors the count of all the wait checkpoints, and displays the delta value of two intervals in the QoS. For example, if the current interval value is 20, and the previous interval value is 15, the delta value displayed is 5 (20-5). The alarm is generated if the delta value breaches the defined threshold.	4.2:71	0x063300c7	Count
wait_stats_time	Monitors the total wait time in milliseconds for each wait checkpoint, and displays the delta value of two intervals in the QoS. For example, if the current interval value is 30 seconds, and the previous interval value is 20 seconds, the delta value displayed is 10 seconds (30-20). The alarm is generated if the delta value breaches the defined threshold.	4.2:72	0x063300c8	Milliseconds

cdm (CPU, Disk, Memory Performance Monitoring) probe

The CPU, Disk, Memory Performance Monitoring (cdm) probe monitors the performance and resource load on the system with the robot. The UIM CPU, Disk & Memory (cdm) probe generates alarms that are based on configured threshold values and trending statistics. For more information see cdm Metrics.

Metric Name	Description	Metric Type	DX NetOps Spectrum Event ID	Units
system_uptime	Details how long the system has been on since its last restart.	1:1	0x063300c9	Seconds
system_reboot		1:2	0x063300ca	
system_disk_usage_mb	Aggregated disk usage in megabytes	1.1:2	0x063300cb	Megabytes
system_disk_usage_pct	Aggregated disk usage in percentage	1.1:3	0x063300cc	Percent
system_inode_usage_cnt	Total number of free file nodes in file system	1.1:4	0x063300cd	Count
system_inode_usage_pct	Total number of free file nodes in file system in percentage.	1.1:5	0x063300ce	Percent
system_shared_folder_availability	Populates the data depending upon the disk availability. The available options are: Missing, New and Ok.	1.1:7	0x063300cf	State
system_disk_usage_delta	Disk Usage Delta Error Warning Threshold - 8, Error Threshold - 200	1.1:8	0x063300d0	
system_disk_size_gb	Total size of the disk	1.1:9	0x063300d1	Gigabytes
system_read_throughput	Disk bytes read per second	1.1:58	0x063300d2	Bytes/Second
system_write_throughput	Disk bytes written per second	1.1:59	0x063300d3	Bytes/Second
system_total_throughput	Disk bytes read and written per second	1.1:60	0x063300d4	Bytes/Second

system_disk_partition_used_pct	Aggregated disk usage in percentage	1.1.2:2	0x063300d5	Percent
system_disk_partition_used_mbytes	Aggregated disk usage in megabytes	1.1.2:11	0x063300d6	Megabytes
system_user_cpu	The sum of CPU time when all CPUs of the system were executing the kernel or operating system	1.5:1	0x063300d7	Percent
system_user_cpu_pct	The percentage of time for which all CPUs of the system were used.	1.5:2	0x063300d8	Percent
system_system_cpu_pct	The CPU Usage Percentage detailis	1.5:3	0x063300d9	Percent
system_wait_cpu_pct	The percentage of time for which all CPUs of the system were waiting for I/O.	1.5:4	0x063300da	Percent
system_idle_cpu_pct	The percentage of time for which all CPUs of the system were idle.	1.5:5	0x063300db	Percent
system_multi_cpu_usage_diff_pct	Multi-CPU Usage Difference in percentage	1.5:6	0x063300dc	Percent
system_multi_cpu_usage_pct	The percentage of time for which an individual CPU of the system was used.	1.5:7	0x063300dd	Percent
system_data_collection	System data collection	1.5:8	0x063300de	
system_processor_queue_length	The current calculated average load of the system.	1.5:9	0x063300df	Processes
system_load_avg_1min	The average system load over the last one minute. **Note:** This metric is supported only on the Linux, AIX and HP-UX platforms.	1.5:68	0x063300e0	Count
system_load_avg_5min	The average system load over the last five minutes. **Note:** This metric is supported only on the Linux, AIX and HP-UX platforms.	1.5:69	0x063300e1	Count
system_load_avg_15min	The average system load over the last fifteen minutes. **Note:** This metric is supported only on the Linux, AIX and HP-UX platforms.	1.5:70	0x063300e2	Count
system_multi_cpu_system_pct	Multi-CPU System Usage in percentage	1.5.1:3	0x063300e3	Percent
system_multi_cpu_idle_pct	Multi-CPU System Idle in percentage	1.5.1:5	0x063300e4	Percent
system_memory_usage_mb	Total memory usage in megabytes	1.6:1	0x063300e5	Megabytes
system_memory_usage_pct	Total memory usage in percentage	1.6:2	0x063300e6	Percent
system_memory_data_collection	System memory usage in percentage	1.6:3	0x063300e7	Percent
system_system_memory_usage_pct	Total System memory utilization in percent. This metric is supported only on the Windows, Linux and AIX platforms.	1.6:57	0x063300e8	Percent
system_user_memory_usage_pct	Total User memory utilization in percent. This metric is supported only on the Windows, Linux and AIX platforms.	1.6:58	0x063300e9	Percent

system_physical_memory_usage_mb	The size of the physical memory used on the system in megabytes. **Note:** For this metric, the buffer cache will be subtracted from physical memory value if the key **mem_buffer_used** is set as **No**. This support is added for Linux, AIX, and HPUX platforms.	1.6:6	0x063300ea	Megabytes
system_physical_memory_usage_pct	Total Swap memory usage in percent	1.6:7	0x063300eb	Percent
system_swap_memory_usage_mb	Total Swap memory usage in megabytes	1.6:8	0x063300ec	Megabytes
system_inbound_traffic	The total number of bytes per second received by the server.	2.1.1:1	0x063300ed	Bytes/Second
system_outbound_traffic	The total number of bytes per second sent by the server.	2.1.1:2	0x063300ee	Bytes/Second
system_aggregated_traffic	The total number of bytes per second sent and received by the server.	2.1.1:3	0x063300ef	Bytes/Second

net_connect

net_connect (Network Connectivity Monitoring) probe measures network connectivity that is based on "ping" (ICMP ECHO) and the TCP connections to a list of user-defined services. The service can be NetBIOS, Telnet, FTP, and HTTP. The probe supports the UIM family of solutions by sending the quality of service (QoS) messages. For more information see net_connect Metrics.

Metric Name	Description	Metric Type	DX NetOps Spectrum Event ID	Units
net_connect_misc		2.2:1	0x063300f0	
net_connect_response_time	Response time for network connectivity.	2.2.1:1	0x063300f1	Milliseconds
net_connect_packet_loss	Percentage of Packet Loss in network connectivity response. Packet Loss = icmp_lost_count/ icmp_packet_count. Refer **Jitter and Latency QoS Calculation** in net_connect Metrics.	2.2.1:2	0x063300f2	Milliseconds
net_connect_nw_connectivity_response_pkt	Delay in time it takes a packet to cross a network. Latency = average(round_trip_latency); if icmp_lost_count is icmp_packet_count, then latency is NaN. (Nan - NULL QoS). Refer **Jitter and Latency QoS Calculation.**	2.2.1:3	0x063300f3	
net_connect_nw_conn_response_packet_loss_jitter	Variable Latency in a network. Jitter = stardard_deviation(round_trip_latency); if icmp_lost_count is icmp_packet_count, the jitter is 0. Refer **Jitter and Latency QoS Calculation in** net_connect Metrics	2.2.1:4	0x063300f4	Milliseconds

net_connect_tcp_response_time	Response time for network connectivity.	2.2.2:1	0x063300f5	Milliseconds

processes (Process Monitoring) probe

The (Process Monitoring) processes probe monitors the specified processes to detect any error situation. The probe also retrieves information about the process, for example, the CPU usage, memory usage, and so on. For more information see processes Metrics.

Metric Name	Description	Metric Type	DX NetOps Spectrum Event ID	Units
ipc_number_processes_cnt	The number of Instances of a process	1.26:1	0x063300f6	Count
ipc_processes_util	The percentage of the number of processes currently running in the system to the maximum number of processes configured in the system	1.26:2	0x063300f7	Percent
ipc_number_semaphore_sets	The number of semaphore sets currently used by the system	1.26:3	0x063300f8	Number
ipc_number_semaphore_sets_util	The percentage of Semaphore Sets currently used by the System to the maximum number of semaphore sets configured in the system	1.26:4	0x063300f9	Percent
ipc_message_queue_cnt	The number of message queues currently used by the system	1.26:5	0x063300fa	Count
ipc_message_queue_util	The percentage of message queues currently used by system to the maximum number of message queues configured in the system	1.26:6	0x063300fb	Percent
ipc_number_shared_mem_segments	The number of Shared Memory Segments currently used by the system	1.26:7	0x063300fc	Count
ipc_number_shared_mem_seg_util	The percentage of Shared Memory Segments currently used by the System to a maximum number of shared memory segments configured in the system.	1.26:8	0x063300fd	Count
processes_instances	The number of processes currently running in system	1.3:2	0x063300fe	Number
processes_state	The availability (up/down) of a process	1.3:3	0x063300ff	State (Up/Down)
processes_mem_usage	The bytes of memory utilized by a process	1.3:4	0x06330100	Bytes
processes_cpu_usage	The percentage of CPU utilization by a process	1.3:5	0x06330101	Percent
processes_threads	The number of threads of a process	1.3:6	0x06330102	Count
processes_unexpected_user	The process not running with expected user	1.3:22	0x06330103	Count
processes_handles_cnt	The number of handles of a process	1.3:42	0x06330104	Count

processes_resident_mem_usage	Process exceeds the expected resident memory usage **Note:** This metric is only supported on Linux.	1.3:45	0x06330105	Kilobytes

logmon (log monitoring) probe

The Log Monitoring (logmon) probe scans ASCII-based systems and application log files by matching specified expressions. Alarms are generated when the log file content matches the defined expression. The probe also extracts and stores metric data from the matched log file entry in the QoS database. For more information, see logmon Metrics.

Metric Name	Description	Metric Type	DX NetOps Spectrum Event ID
logmon_exit_code (only for Command profile)	Exit code threshold breach/ clear	1.2.3:4	0x06330106
logmon_url_response_probe_state (only for URL profile)	Contact Success (Clear) / Contact Failed	1.2.4:4	0x06330107
logmon_url_load_state	URL load success (Clear)/ Failed.	1.2.4:5	0x06330108
logmon_misc		1.2.5:4	0x06330109

rsp (Remote Systems) probe

The Remote System Probe (rsp) allows you to monitor system metrics. The probe collects performance data in an agent-less manner without installing proprietary software on the system. For more information, see rsp Metrics.

Metric Name	Description	Metric Type	DX NetOps Spectrum Event ID	Units
rsp_processes_owner	Alarm to be issued when the configured threshold is satisfied	1.3:1	0x0633010a	
rsp_processes_instances	A number of process instances.	1.3:2	0x0633010b	Number
rsp_processes_state	Process availability.	1.3:3	0x0633010c	State
rsp_processes_memory_usage	Process memory usage.	1.3:4	0x0633010d	Kilobytes
rsp_processes_cpu_usage	Process CPU usage.	1.3:5	0x0633010e	Percent
rsp_processes_threads	A number of process threads.	1.3:6	0x0633010f	Number
rsp_service_state	Network Service Availability	1.4:1	0x06330119	State
rsp_processor_queue_length	Processor queue length. The current calculated average load of the system.	1:3	0x06330116	Processes
rsp_multi_cpu_usage_pct	Difference between highest and lowest CPU usage on Multi-CPU systems. The metric calculates data in percentage for the individual CPU idle time, user time, system time, wait time, and CPU usage.	1.5.1:1	0x06330117	Percent
rsp_cpu_usage_pct	CPU usage. The metric calculates data in percentage for total usage, user time, system time, wait time, and idle time.	1.5:1	0x06330118	Percent

rsp_mem_usage_pct	Total memory usage in percent.	1.6:2	0x06330114	Percent
rsp_mem_paging	Memory paging in kilobytes per second.	1.6:4	0x06330115	Kilobytes/Second
rsp_number_events	Number of events in interval. This metric sends the count of matched events, irrespective of the profile.	1.2.1:1	0x06330113	Count
rsp_disk_availability		1.1:1	0x06330110	
rsp_disk_usage_mb	Aggregated disk I/O rate in megabytes.	1.1:2	0x06330111	Megabytes
rsp_disk_usage_pct	Aggregated disk I/O rate in percentage.	1.1:3	0x06330112	Percent

Integration with DX NetOps Performance Management

10.4 supports the SD-WAN monitored items such as Tunnels and SLA Paths that are reconciled in NetOps across Spectrum and Performance Management. This ensures performance threshold events are associated with the tunnel or path in Spectrum and the alarm console.

DX NetOps Spectrum - DX NetOps Performance Management integration lets you share models, Global Collections, and events between two powerful infrastructure management systems.

> **NOTE**
>
> The integration can be done between a single instance of DX NetOps Spectrum and a single instance of DX NetOps Performance Management. You cannot integrate one instance of DX NetOps Spectrum with multiple instances of DX NetOps Performance Management.

The DX NetOps Spectrum data source contributes the following item types to DX NetOps Performance Management:

- Devices - Like SNMP and non-SNMP (SD-Router)
- Interfaces
- Groups
- SDN_Tunnels
- SLA_Paths

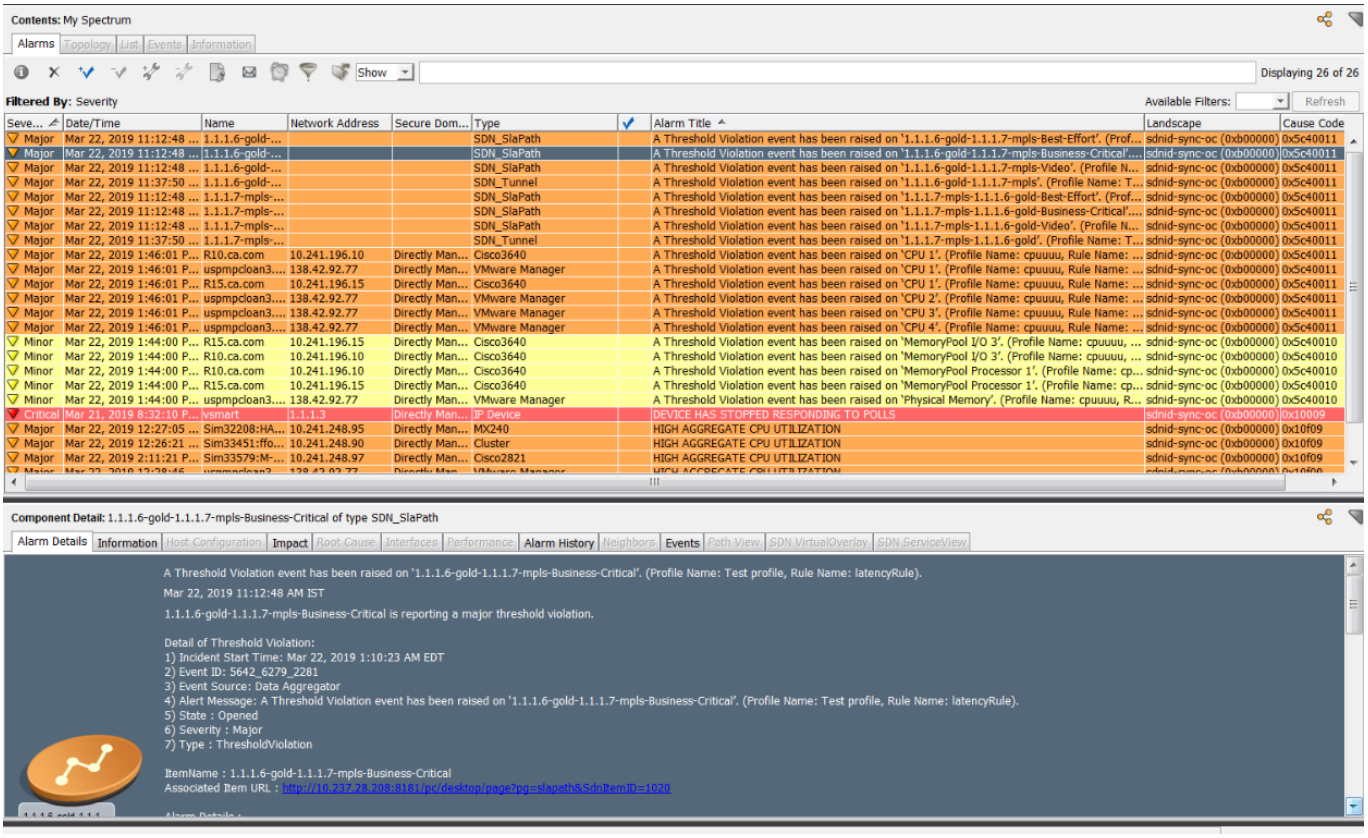
DX NetOps Spectrum also retrieves and displays infrastructure performance events from the DX NetOps Performance Management Event Manager. As a result, you can see performance and fault alarms side-by-side in OneClick.

DX NetOps Performance Management retrieves devices from DX NetOps Spectrum to extend the DX NetOps Performance Management device Inventory. You can determine which devices are retrieved. The interfaces that are associated with each device are added to the Inventory automatically; however, they are subject to CA Infrastructure Management Data Aggregator interface filtering.

DX NetOps Performance Management IP domains are synchronized and displayed in OneClick. You can add device models to them. The items in these IP domains are synchronized with DX NetOps Performance Management, and their data is included in dashboards. Your DX NetOps Spectrum Global Collections become groups in the DX NetOps Performance Management Groups tree.

The integration extracts event data from the DX NetOps Performance Management Event Manager and converts it into DX NetOps Spectrum events. These events then raise DX NetOps Spectrum alarms on models in the SpectroSERVER topology. As clear events are processed, corresponding DX NetOps Spectrum alarms are cleared automatically. Polling for supported events begins when synchronization has completed. These events are converted into DX NetOps Spectrum alarm set or clear events and asserted on models in each landscape.

Alarms based on device performance, such as Time over Threshold and Deviation from Normal events, are generated in DX NetOps Spectrum to supplement fault and availability monitoring. The DX NetOps Spectrum alarms that originate in the Event Manager can be viewed in the OneClick Console. The following image shows the alarm details in the OneClick console:



Finally, the integration enables a Data Aggregator data source to discover DX NetOps Spectrum devices without requiring you to manually create discovery profiles. The system creates discovery profiles, which are scheduled by default but can also be run manually.

Solution Architecture

The following facts describe the architecture of the DX NetOps Spectrum - DX NetOps Performance Management integration:

> **WARNING**
> DX NetOps Performance Management and OneClick Web Server should be in time sync. That is, time difference must not be there between these two machines, otherwise, it causes CA PM alarms missing in DX NetOps Spectrum.

- One SpectroSERVER or a Distributed SpectroSERVER (DSS) can be synchronized with DX NetOps Performance Management by specifying the OneClick web server as a DX NetOps Performance Management data source.
  - Full synchronization occurs when the data source is first added to DX NetOps Performance Management.

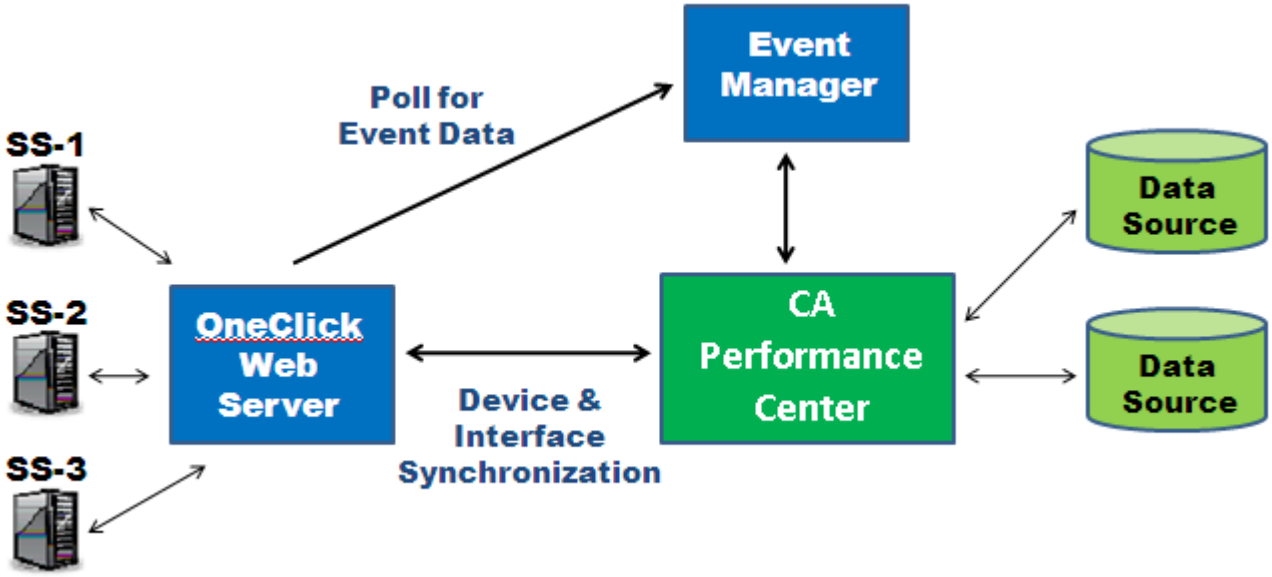
    > **WARNING**
    > If a full synchronization is required after you add the data source, we recommend running it during nonbusiness hours.
  - Incremental synchronization occurs every 5 minutes.

Additions, removals, and modifications of devices, interfaces, and Global Collections in DX NetOps Spectrum are reflected in DX NetOps Performance Management after incremental synchronization.

- Each landscape in the DSS is defined as a DX NetOps Performance Management group.
- Devices and interfaces in the DSS are synchronized with DX NetOps Performance Management and added to the appropriate landscape group.
- OneClick polls the Event Manager for events that are relevant to a specified landscape group. This polling happens every 60 seconds by default. Any retrieved events are then translated to DX NetOps Spectrum events, which can generate or clear alarms.

  WARNING
  DX NetOps Performance Management-related alarm processing in DX NetOps Spectrum applies to device and interface models that have been synchronized to DX NetOps Performance Management. Only events that are related to devices or interfaces that are modeled in DX NetOps Spectrum are processed by OneClick.
- The Event Manager database is polled for supported events at each polling interval. With DX NetOps Performance Management v2.0.00 and later, you can modify supported events.

The following image illustrates the architecture of the DX NetOps Spectrum - DX NetOps Performance Management integration:



Upgrade Considerations

In previous versions of the DX NetOps Spectrum - DX NetOps Performance Management integration, all DX NetOps Spectrum models were contributed to the DX NetOps Performance Management Inventory. And these models were always associated with the Default IP Domain. From DX NetOps Spectrum Release 9.4 and DX NetOps Performance Management Release 2.3, you can precisely control the items that DX NetOps Spectrum contributes to CA Infrastructure Management, and you can control IP domain membership. The OneClick features for creating and maintaining Global Collections can now be applied to IP domains.

Be sure to account for the following key considerations when you are planning for the integration:

- Only those models that you have added to a DX NetOps Performance Management IP Domain model in OneClick are synchronized with DX NetOps Performance Management.
- The devices are added to DX NetOps Performance Management based on the specific DX NetOps Performance Management IP Domain with which the device models are associated in DX NetOps Spectrum.
- If you are upgrading an existing integration, you must at a minimum define the contents of the default DX NetOps Performance Management IP Domain model in DX NetOps Spectrum. You can add additional IP domains as required in the DX NetOps Performance Management Admin pages.
- To move a device from the DX NetOps Performance Management Default IP Domain to another domain, you must first add the device to the desired IP Domain in DX NetOps Spectrum.
  If the device already exists in DX NetOps Performance Management, however, you must delete the device from the Default IP Domain. At the next synchronization, the device will be added to the updated IP domain in DX NetOps Performance Management.

Supported Features

Earlier versions of DX NetOps Spectrum integrate with both CA NetQoS Performance Center v6.1 and DX NetOps Performance Management v2.0.00 through r2.2.00. To integrate with DX NetOps Performance Management versions that predate r2.300, consult an earlier version of this section.

The following list identifies supported features in the integration between CA Spectrum starting from 9.4 and DX NetOps Performance Management 2.3.00.

Events

- ThresholdViolation events: These events from Data Aggregator and CA Network Flow Analysis data sources are integrated and supported by default in DX NetOps Spectrum.
- Other events: By updating an XML file and some event support files, you can instruct OneClick to handle events in the Event Manager database that were reported by other data sources.

IP Domains

- DX NetOps Performance Management IP domains are synchronized as DX NetOps Performance Management IP Domain models in OneClick. Place device models into DX NetOps Performance Management IP Domains manually, or define collection rules to dynamically collect device models. The contents of the DX NetOps Performance Management IP domain model are used to keep the IP domain membership up to date in DX NetOps Performance Management. As new devices are sent to DX NetOps Performance Management from DX NetOps Spectrum, they are assigned to the IP domain that corresponds to their DX NetOps Performance Management IP Domain membership in DX NetOps Spectrum.

Groups

- Your DX NetOps Spectrum Global Collections and landscapes are synchronized with DX NetOps Performance Management and displayed as groups in the DX NetOps Performance Management Groups tree. As part of the Groups tree, you can leverage the synchronized Global Collections in a variety of ways:
  - Create reporting groups
  - Define site membership
  - Drive the content of other custom groups and collections
- DX NetOps Spectrum devices can be added to DX NetOps Performance Management Service Provider groups and shared among multiple tenant users.

Drilldown from OneClick to DX NetOps Performance Management Performance Data

- You can access DX NetOps Performance Management performance data from DX NetOps Spectrum device and interface models. You gain rapid access to information about device performance issues in context.

Synchronized Discovery

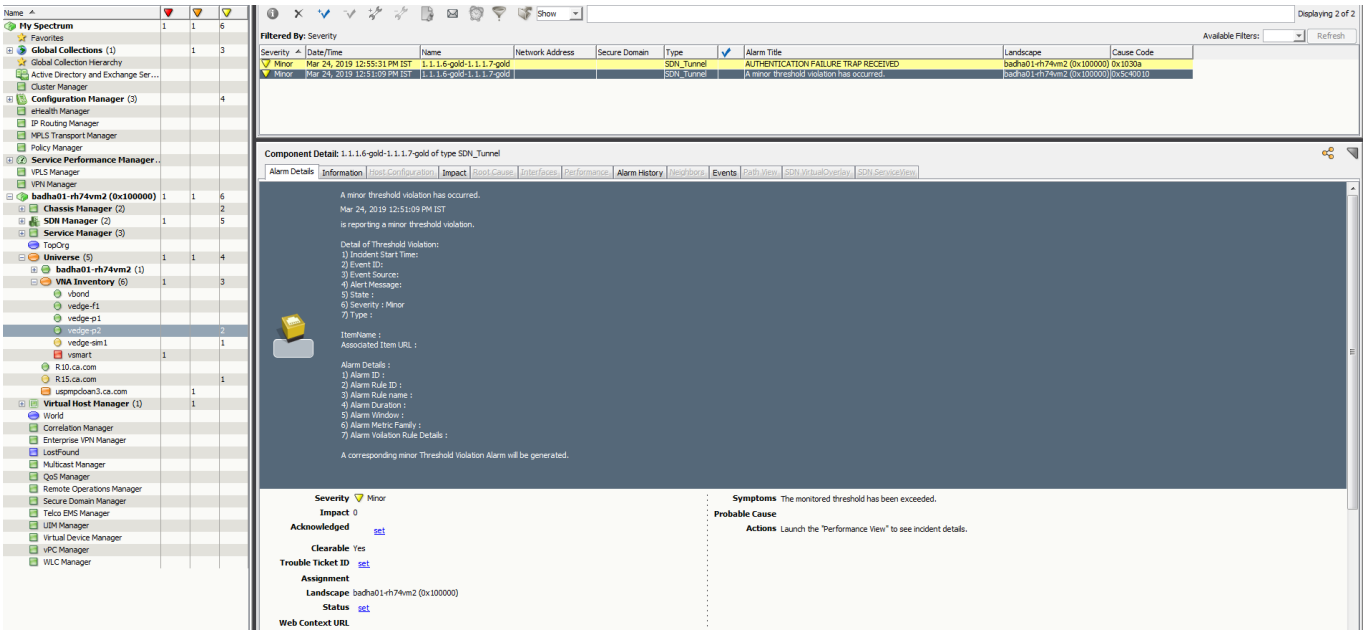
- Shared discovery eases the administrative burden.
- Place CA Infrastructure Management Data Collectors where you require them and leverage discovery data from multiple SpectroSERVERs. Determine the appropriate number of IP Domains that are required, and deploy a Data Collector for each IP Domain.
  At device inventory synchronization, Data Aggregator determines whether each device is new or is already in the inventory. When Data Aggregator encounters a device that it is not monitoring, it adds the IP address to a predefined Discovery profile. A discovery profile is defined for each IP Domain. The IP address for each device is added to the corresponding discovery profile based on its membership in a DX NetOps Performance Management IP Domain model within DX NetOps Spectrum. You can then run this Discovery profile manually, or you can let it run once a day through an automatically configured threshold.

Intelligent Interface Synchronization

- Device monitoring by DX NetOps Spectrum always includes all associated interfaces. DX NetOps Performance Management retrieves information about all interfaces from DX NetOps Spectrum.
  However, the interface inventory in DX NetOps Performance Management does not include interfaces that have only been contributed by DX NetOps Spectrum. Instead, the inventory is filtered to include interfaces that are monitored by a performance monitoring data source, such as Data Aggregator or CA Network Flow Analysis.

SDN_Tunnels and SLA_Paths

Following is a screenshot of the Threshold Alarm on SDN_TUNNEL:



Life cycle management

- Using DX NetOps Spectrum you can control the life cycle state of devices in DX NetOps Performance Management. Changes in DX NetOps Spectrum trigger changes in DX NetOps Performance Management. For more information, see the Manage Device Life Cycles section in the DX NetOps Performance Management - documentation.

Component Requirements

Contents

DX NetOps Spectrum - DX NetOps Performance Management integration requires the following component versions:

For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

Model Synchronization Eligibility

One of the following sets of criteria must be met for a DX NetOps Spectrum model to be eligible for synchronization with DX NetOps Performance Management:

Models that are derived from DX NetOps Spectrum model type *Device* that have:

- A valid IP address
- Membership in a DX NetOps Performance Management IPDomain model
- A Model_State (attribute 0x1007c) of Active.

> **NOTE**
> If Model_State is not Active, the processing of the model is postponed until the next synchronization.

Models that are derived from DX NetOps Spectrum model type *Port* that have:

- A parent device that has been synchronized, which means that the parent device is Active and is a member of a DX NetOps Performance Management IP Domain
- A valid IfIndex value.

Device Model Synchronization

For device model synchronization, DX NetOps Spectrum-DX NetOps Performance Management integration uses Model_Class (attribute 0x11ee8) to determine the DX NetOps Performance Management SubType of a device, as follows:

Model_Class	SubType
Router	Router
Switch-Router	Router
Switch	Switches
Workstation-Server	Workstations

The default SubType of 'Other' is used for models whose Model_Class is not specified in the table.

> **NOTE**
> The table above shows the specific mappings of Model_Class to the device SubType for DX NetOps Spectrum data sources. If the device is contributed by additional data sources, such as Data Aggregator, it is possible that DX NetOps Performance Management will display a different SubType for the device.

How to Integrate with DX NetOps Performance Management

This section discusses the steps to configure the DX NetOps Spectrum and DX NetOps Performance Management integration:

If you plan to have Data Aggregator discover the devices that DX NetOps Spectrum contributes (the optional Step 5, below), register the Data Aggregator data source first, and enable the option to Discover Devices from other Data Sources. Data Collectors must also be installed for each IP Domain to which DX NetOps Spectrum will contribute to device models.

Follow these steps:

1. Configure DX NetOps Spectrum as a Data Source in DX NetOps Performance Management.
2. Enable Event Polling in DX NetOps Spectrum.

3. Configure SNMP Profiles in DX NetOps Performance Management.
4. Add Models to IP Domain Global Collections.
5. (Optional) Enable Discovery Synchronization with CA Infrastructure Management Data Aggregator.

The optional step to enable discovery synchronization involves some configuration in DX NetOps Performance Management and in the Data Aggregator component.

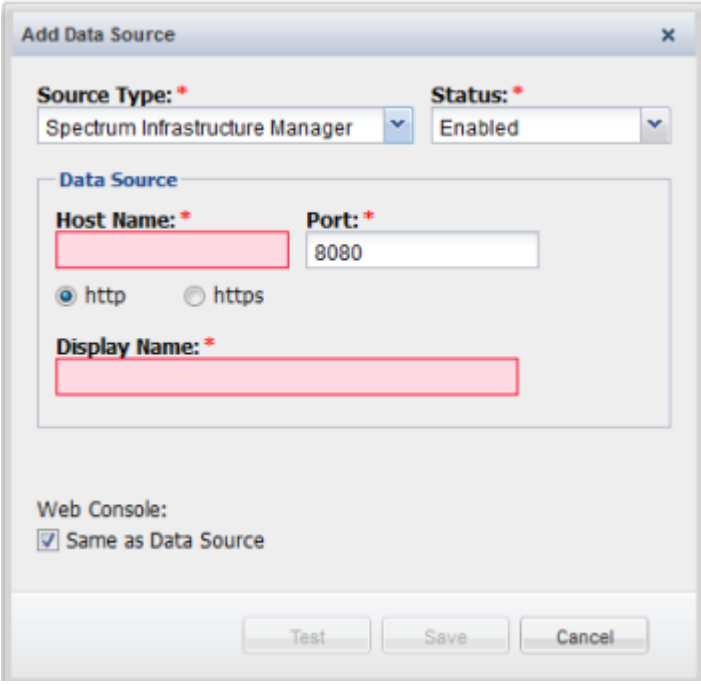
> **NOTE**
> After the integration, if you cannot view the DX NetOps Performance Management events in DX NetOps Spectrum, check whether any firewall settings block the communication between DX NetOps Performance Management and DX NetOps Spectrum OneClick server.

Configuring as a Data Source in DX NetOps Performance Management

Add DX NetOps Spectrum as a data source in DX NetOps Performance Management so that these components can share information.

Follow these steps:

1. Launch the **DX NetOps Performance Management** console and click **Admin, Data Sources**.
   The **Manage Data Sources** page opens.
2. Click **Add**.
   The **Add Data Source** dialog opens.
3. Select '**Spectrum Infrastructure Manager**' in the **Source Type** field.



4. Complete the following fields:
   – **Status**. Select **Enabled** in the **Status** field.

NOTE
You can select Disabled to disable the data source without deleting it.

- **Host Name**. Provide the IP address or DNS hostname of the OneClick server.
- **Port**. Provide the port number to use when contacting the OneClick server.
- **Protocol**. Select the protocol to use to contact the data source. Select the **https** option if your network uses SSL for communications. Verify that you have configured the system correctly before you select the https **option**.

  NOTE
  Before you select **https**, ensure that you have enabled SSL on your OneClick web server host by configuring the "server.xml" and "axis2.xml" file appropriately. For more information about enabling SSL on OneClick web server host, see OneClick Administrator section.
- **Display Name**. Provide a name for the data source. By default, the data source type and the hostname are combined to create the display name.
- **Same as Data Source**. Select the checkbox if the Web Console is on the OneClick server.
  Or clear the Same as Data Source checkbox if the Web Console is on a different server. Then complete the following fields:
  - **Host Name**. Provide the IP address or DNS hostname of the Web Console server.
  - **Port**. Provide the port number to use when contacting the Web Console server.
  - **Protocol**. Select the protocol to use to contact the Web Console server: http or https.

5. Click **Test** to verify that DX NetOps Performance Management can contact the OneClick server and the Web Server.
6. Click **Save.**
   You have added DX NetOps Spectrum as a data source and the synchronization process is initiated.

NOTE

When you delete a data source, the deletion does not remove everything from the system. If you register the same data source, unexpected behavior might occur. To remove a data source temporarily, edit the data source, and set the status to disabled. The changes will be applied to the system only after the next synchronization.

Enable Event Polling

Enable event polling that takes place between the SpectroSERVER and DX NetOps Performance Management. You can specify how often DX NetOps Spectrum queries the DX NetOps Performance Management Event Manager component for events. Perform this step in the OneClick Administration pages.

Follow these steps:

1. Click Administration on the OneClick home page.
   The Administration Pages open.
2. Click Performance Center Integration Configuration in the left panel.
   The Performance Center Integration Configuration page opens.
3. Enter the desired polling interval, in seconds, in the Event Polling Interval field.
   The default value is 60 seconds. Enter a value greater than or equal to 30 seconds.
4. Select the Enabled option in the Event Polling field.
5. Click Save.
   DX NetOps Spectrum - DX NetOps Performance Management integration is now enabled. The event polling settings take effect on the next polling cycle.

Enable Device Monitoring with CA Infrastructure Management

The integration between DX NetOps Spectrum and DX NetOps Performance Management lets a Data Aggregator monitor DX NetOps Spectrum devices. This configuration is optional and requires some additional configuration. We recommend performing these optional steps before you register the DX NetOps Spectrum data source.

To enable CA Infrastructure Management monitoring of the devices and interfaces that DX NetOps Spectrum discovers, take the following steps:

1. Create SNMP profiles in DX NetOps Performance Management for the SNMP-capable devices that are modeled in DX NetOps Spectrum.
2. Create IP domains in DX NetOps Performance Management. For more information, see the online Help for DX NetOps Performance Management.
   When database synchronization occurs, all IP domains are sent to DX NetOps Spectrum, where they appear in OneClick as special Global Collections, with a unique icon.
3. Install and assign a Data Collector for each IP domain.
4. Enable the CA Infrastructure Management Data Collector to discover DX NetOps Spectrum devices.
   Synchronized discovery requires less administration and enables your SpectroSERVERs to provide data to the Data Collectors that you can position where they are required.
5. Add the models to the appropriate IP Domains in OneClick.
   During synchronization, all DX NetOps Spectrum models that are associated with the DX NetOps Performance Management IP Domains are passed to the CA Infrastructure Management Data Aggregator. The associated DX NetOps Spectrum devices are discovered for CA Infrastructure Management Data Aggregator monitoring.
6. Create custom monitoring profiles for DX NetOps Spectrum devices and apply them to collections in the Data Aggregator administration pages.
   Monitoring profiles for a limited set of metrics are applied to the device items as Data Aggregator discovers them. These profiles determine how devices are polled for performance data. For more information, see the online Help for CA Infrastructure Management Data Aggregator.

As DX NetOps Spectrum adds devices to DX NetOps Performance Management, they are added to discovery profiles. Each discovery profile is automatically configured to run with a daily schedule. You can also run them manually or adjust the schedule as required to keep the Data Aggregator up-to-date with new devices from DX NetOps Spectrum.

If SNMP throttling is configured on DX NetOps Spectrum, it does not apply to ongoing polling by Data Aggregator. This feature protects critical devices from failing in case too many polling flows are configured. The throttling mechanism applies to any monitoring or discovery activities. Therefore, if you have configured DX NetOps Spectrum to throttle SNMP requests for a given device, apply the same setting in Data Aggregator.

Add an SNMP Profile to Gather Performance Data

To supply the information that is required to enable SNMP polling for performance metrics, create SNMP profiles in DX NetOps Performance Management. Global administrators and tenant administrators can create SNMP profiles to let DX NetOps Performance Management data sources query devices for performance data. You can create these profiles for SNMPv1/v2c or for SNMPv3.

Device models are contributed to DX NetOps Performance Management with specific IP Domains. The IP domain may be part of the default tenant or a user-created tenant. When you create SNMP Profiles to discover devices that DX NetOps Spectrum contributes, verify that the SNMP Profiles are created in the appropriate tenant space

Follow these steps:

1. Log in to DX NetOps Performance Management as a global administrator or tenant administrator.
2. (Optional) If you have logged in as a global administrator, administer a selected tenant.
3. Select Admin, SNMP Profiles in the menu bar.
   The Manage SNMP Profiles page displays the current list of SNMP profiles.
4. Click New.
   The Add SNMP Profile dialog opens.

5. Complete the following fields and change any default settings as needed. Some fields apply only to SNMPv3.
   - **Profile Name**
     Defines a name for the SNMP profile. Profile names must be unique, cannot be duplicated across SNMP versions, and are not case-sensitive.
   - **SNMP Version**
     Specifies the version of SNMP that the profile uses. Because SNMPv1 and SNMPv2C are similar from a security standpoint, they share a single option. SNMPv3 is a separate option.
   - **Port**
     Identifies the port that is used to make SNMP connections to devices associated with this profile.

     NOTE
     Optional parameter for SNMPv1/v2C.

     Default: 161.
   - **User Name**
     (SNMPv3 Only) Identifies the user for the profile, whose secret keys were used potentially to authenticate and encrypt the SNMPv3 packets. The User Name is a character string.
   - **Context Name**
     (SNMPv3 Only) Identifies the collection of management information that is accessible by an SNMP entity. An octet string that is necessary for providing end-to-end identification and for retrieving data from an SNMPv3 agent.
   - **Community Name**
     (SNMPv1/v2C Only) Defines a secure string that lets the data source query the MIB of the associated device. The community that you supply must provide read-only access to the device MIB.

     NOTE
     In the default SNMP profile, the community is 'public'.
   - **Verify Community Name**
     Confirms the secure community string (name).
   - **Authentication Protocol**
     (SNMPv3 Only) Specifies the authentication protocol to use when contacting devices associated with this profile. The following algorithms for authenticating SNMPv3 packets are supported:
     - None (do not attempt authentication)
     - MD5 (Message Digest 5)
     - SHA (Secure Hash Algorithm)
   - **Authentication Password**(SNMPv3 Only) Specifies the password for authentication using SNMPv3 and the selected authentication protocol.

     NOTE
     Supply an authentication password that contains at least eight characters. Some data sources do not support authentication passwords or privacy passwords that fall below this minimum length. They treat the SNMP profile as invalid, and some data is not collected. Blank passwords are not supported for SNMPv3 profiles with MD5 or SHA as the Authentication Protocol.
   - **Verify Authentication Password**Confirms the authentication password.
   - **Privacy Protocol**
     (Optional) Specifies the encryption protocol to use for data flows sent to any devices or servers associated with this profile, as follows:
     - None (do not encrypt communications)
     - DES
     - AES 128
     - Triple DES

     NOTE
     The privacy protocol option is not enabled until authentication is enabled for this profile.

- **Privacy Password**
  Defines the password used when exchanging encryption keys. See the Note for a possible length requirement.
- **Verify Privacy Password**
  Defines the password used when exchanging encryption keys.
- **Use by default for new devices**
  Specifies whether the information in this profile is used by default. DX NetOps Performance Management uses this information to contact any new items that are discovered from monitored traffic. If it fails, the next profile in priority order is used. Disable this parameter to exclude a profile from discovery

6. Click Save.
   The Manage SNMP Profiles page opens. The new profile appears in the list.
   DX NetOps Performance Management automatically performs a global synchronization to send the profile information to all registered data sources.

Add Device Models to DX NetOps Performance Management IP Domain Models

After database synchronization occurs, the IP domains that you created in DX NetOps Performance Management are displayed as DX NetOps Performance Management IP Domains in OneClick. The device models that you add to these IP Domains are associated with IP domain definitions in DX NetOps Performance Management, polled by Data Aggregator, and included in dashboards.

You can also apply Search criteria to an IP Domain or Global Collection so that its membership is updated dynamically.

NOTE
Although DX NetOps Performance Management IP Domain models are not Global Collections, they share many properties. Consequently, the configuration of a DX NetOps Performance Management IP Domain uses many of the common Global Collection dialogs. But these IP Domain models are designated with a special icon in OneClick.

NOTE
DX NetOps Spectrum devices can only be members of a single IPDomain model type. If you attempt to add a model to multiple IP domains, you see an error message.

Follow these steps:

1. In any topology, take *one* of the following steps to select a device model to add to an IP Domain:
   - **Single model selection:** In the Navigation panel, right-click a modeled element and select Add To, Global Collection(s).
     The Select Global Collections dialog opens. DX NetOps Performance Management IP Domain models appear in the list among your Global Collections.

     NOTE
     Or you can right-click a single model in a topology view and select Add To, Global Collection(s).
   - **Multiple model selection:** To multi-select models in a topology view, take the following steps:
   a. Press and hold the SHIFT key and individually select the modeled elements.
   b. While the SHIFT key is pressed, right-click the last selected modeled element and select Add To, Global Collection(s).
2. Select the name of the IP Domain model where you want to add the models.
   IP Domains are designated with a special icon:

3. Click OK.
   If Data Aggregator has been configured to discover devices from other data sources, the devices from DX NetOps Spectrum are discovered by Data Aggregator at the next synchronization. The devices are added to DX NetOps Performance Management with an IP domain association that mirrors the DX NetOps Performance Management IP Domain membership in DX NetOps Spectrum.

Verify that SNMP profiles for monitored devices are available in DX NetOps Performance Management and create them if necessary.

Update IP Domain Membership Dynamically

In addition to selecting individual models for DX NetOps Performance Management IP Domain models, you can populate IP Domains with dynamic members. Adding dynamic members to the models that represent DX NetOps Performance Management IP domains lets you precisely populate IP domains with devices that belong to them.

Dynamic membership is based on rules and on search criteria that you specify. Dynamic members of a DX NetOps Performance Management IP Domain only remain in the DX NetOps Performance Management IP Domain as long as they meet the specified search criteria. Changes are automatically synchronized with DX NetOps Performance Management.

Follow these steps:

- a. In the Explorer tab of the Navigation panel, navigate to the Global Collections node, and locate the DX NetOps Performance Management IP Domains.
  b. Right-click a DX NetOps Performance Management IP Domain, and select Edit Global Collection.
  IP Domains are designated with a special icon:
  
  The Edit Global Collection dialog opens.
  c. Click 'Search Options'.
  d. Complete any of the following fields to create a single search expression:
    - **Attribute**
      Specifies the attribute of a device to filter. From the drop-down list of commonly used attributes, select the attribute that you want to use. The predefined list might not include the attribute that you want. In this case, click Attribute to specify the model type (device, port, or other) and its associated attribute that you want to find.

      NOTE
      If you choose an alphabetic attribute value, you can either clear (ignore) or select (include) the Ignore Case checkbox.
    - **Comparison Type**
      Specifies the type of comparison to be made against the value that is specified in the Attribute field. Only the comparison types appropriate to the attribute data type are available.
    - **Ignore Case**
      Determines whether the comparison is case-sensitive. If you do not select this checkbox, the comparison is case-sensitive. This selection is only enabled when it is appropriate for the data type of the attribute you selected.
    - **Attribute Value**
      Enter the desired attribute value to search.
    - **Devices Only**
      Specifies that the search results list includes only devices.
  e. (Optional) To use a wildcard character or regular expression in the Attribute Value field, select a valid attribute in the Attribute field. Select 'Matches Pattern' in the Comparison Type field. Then select one of the following options:
    - **Specify Wildcard Now**
      Lets you search for a value using a wildcard. For more information about the available wildcards, see the Modeling and Managing Your IT Infrastructure section.
    - **Specify RegExp Now**
      Lets you create a search using Perl Compatible Regular Expression (PCRE) matching on attributes of the type 'text string'. Text string searches are available only for Matches Pattern comparison types. PCRE matching helps you to find and group models using specific pattern searches that are more advanced than existing searches or wildcard searches.

f. (Optional) Click the Show Advanced button to create a search that is based on a compound clause. For example, you can choose to populate the DX NetOps Performance Management IP Domain based on existing Global Collections, or Secure Domain Connector information. For more information, see the Modeling and Managing Your IT Infrastructure section.
g. (Optional) Select the Real-Time Update checkbox.
This option disables the update interval. It also adds or removes models from the DX NetOps Performance Management IP Domain when they meet or no longer meet the search criteria.
h. (Optional) Supply a value in the 'Run search to update Global Collection membership every <> hours' field.
This value determines how often OneClick conducts a search to update the dynamic membership of the DX NetOps Performance Management IP Domain.
i. Click OK.
The Search Options dialog closes and the Global Collection dialog opens.
j. Click Landscapes to identify the landscapes to include when searching models to populate the DX NetOps Performance Management IP Domain.
k. Click OK.
The DX NetOps Performance Management IP Domain model now has a dynamic membership. Any adjustments that are automatically applied to the membership of this DX NetOps Performance Management IP Domain are synchronized to DX NetOps Performance Management.

Enable Synchronized Discovery

When you enable the Data Aggregator component to discover DX NetOps Spectrum devices, you enable a large set of functionality. The integration can enhance DX NetOps Spectrum fault and availability monitoring with device performance alerts that are based on the analysis of historical data. You can also drill down into device performance data in context from OneClick. And you can monitor the same devices with two different infrastructure management systems without additional discovery administration.

Follow these steps:

1. Launch the DX NetOps Performance Management console and click Admin, Data Sources.
The Manage Data Sources page opens.
2. Select the Data Aggregator data source in the list, and click Edit.
The Edit Data Source dialog opens.
3. Select the option to Discover devices from other data sources.
4. Click Save.
Enabling the Data Aggregator component to discover devices from other data sources initiates a synchronization of the CA Infrastructure Management device inventory with DX NetOps Spectrum. If CA Infrastructure Management determines that a device known to DX NetOps Spectrum is not in the CA Infrastructure Management inventory, the IP address of the device is added to an automatically created discovery profile. This discovery profile is configured to run with a daily schedule by default. You can run the discovery manually or adjust the schedule to meet your requirements. For more information, see the CA Infrastructure Management Data Aggregator online Help.

Smart Interface Filtering

DX NetOps Spectrum can contribute interfaces to DX NetOps Performance Management that does not appear in the DX NetOps Performance Management Inventory unless they are monitored by another data source, such as Data Aggregator or Network Flow Analysis. This behavior results from the Data Aggregator interface filtering feature.

DX NetOps Spectrum does not collect performance data from interfaces. As a result, an interface that DX NetOps Spectrum discovers and sends to Data Aggregator does not have any visible data in DX NetOps Performance Management dashboards unless another data source is also monitoring that interface.

If you right-click an interface model in OneClick, the option to drill down into the matching data context in DX NetOps Performance Management is not available to you if that interface is filtered out of the corresponding monitoring profile in CA Infrastructure Management.

Maintaining the Integration

Modifying Data Sources After Integration

WARNING
The following guidelines must be followed to enable data synchronization between DX NetOps Spectrum and DX NetOps Performance Management.

Use the following guidelines when restoring a data source in DX NetOps Performance Management after DX NetOps Spectrum-DX NetOps Performance Management integration has already been configured:

- If DX NetOps Spectrum exists as a data source in DX NetOps Performance Management when you restore another data source, restart tomcat.
- If DX NetOps Spectrum does not exist as a data source in DX NetOps Performance Management, add other data sources first and then add DX NetOps Spectrum as a data source.

NOTE

For more information refer to Manage Data Sources and Synchronize Data Sources in DX NetOps Performance Management documentation.

Restoring the SpectroSERVER Database

To restore the SpectroSERVER database to a previous state after DX NetOps Spectrum - DX NetOps Performance Management integration, complete the following steps.

WARNING
The correct procedure must be followed to enable data to synchronize correctly between DX NetOps Spectrum and DX NetOps Performance Management.

Follow these steps:

1. Remove DX NetOps Spectrum as a data source in DX NetOps Performance Management.
2. Restore the SpectroSERVER database.

   NOTE
   For information about restoring the SpectroSERVER database, see Database Management .
3. Drop the netqos_integ database on the OneClick server

   ```
   SPECROOT/mysql/bin/mysql --defaults-file=$SPECROOT/mysql/my-spectrum.cnf -uroot -
   proot -e "drop database netqos_integ;"
   ```
4. Restart the OneClick server.
5. Add DX NetOps Spectrum as a data source in DX NetOps Performance Management.

Remove DX NetOps Spectrum as a Data Source in DX NetOps Performance Management

When restoring the SpectroSERVER database to a previous state, unregister the DX NetOps Spectrum data source. This process helps to establish correct synchronization between DX NetOps Spectrum and DX NetOps Performance Management after the database has been restored.

Deleting selected data sources from DX NetOps Performance Management can have negative consequences. Only administrators with the Delete Data Sources role right can delete a data source from DX NetOps Performance Management. This role right is not granted by default and must be assigned to the role as a separate step.

Follow these steps:

1. Log in as a user with the Administrator role.
2. Navigate to the Manage Roles page.
   The page displays the current list of roles.
3. Select the Administrator role, and click Edit. The role right to Delete Data Sources is only available to this predefined role.
   The Edit Role Rights dialog opens.
4. Select Performance Center, and click Edit.
   The Edit Role Rights dialog lets you select individual access rights for this role.
   Assigned role rights are grayed out because they are read-only for this role.
5. Select Delete Data Sources. Click the right arrow to move it from the Available Rights list to the Selected Rights list.
6. Click OK. Then click Save to save your change to the role.

   NOTE
   You must be logged in with a user account that has the Administrator role that you have just edited.
7. Click Admin, Data Source Settings, and select Data Sources.
   The Manage Data Sources page opens.
8. Select the DX NetOps Spectrum data source, and click Delete.
   The Delete Data Source page opens.
9. Click Delete, and then click Yes to confirm the deletion.
   The data source is successfully deleted, and synchronization between DX NetOps Spectrum and DX NetOps Performance Management no longer occurs.
   DX NetOps Performance Management IP Domain models in OneClick are automatically deleted.

Enabling Debug Logging

To facilitate the investigation of issues, enable DX NetOps Performance Management integration debug logging on the OneClick Web Server.

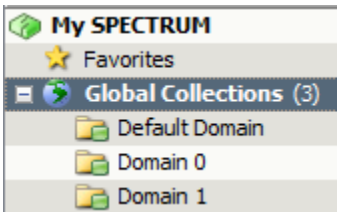
Follow these steps:

1. Navigate to the OneClick home page.
2. Click Administration, Debugging, Web Server Debug Page (Runtime) on the OneClick home page.
3. Select ON for the 'Performance Center Integration' option.
4. Select ON for the 'Performance Center Integration Sync' option.

   NOTE
   Enabling DX NetOps Performance Management integration debug logging can generate a large volume of data in a short amount of time.

Support for DX NetOps Performance Management IP Domains

When you register the DX NetOps Spectrum data source in DX NetOps Performance Management, database synchronization occurs. DX NetOps Spectrum retrieves a list of IP domains from DX NetOps Performance Management. All IP domain definitions are sent over, regardless of their association with individual tenants. OneClick displays these DX NetOps Performance Management IP Domain models in the same area as DX NetOps Spectrum Global Collections in the OneClick Navigation panel. The DX NetOps Performance Management IP Domain models have the same names as the DX NetOps Performance Management IP domain definitions:



Use these IP domains to determine which models are synchronized with CA Infrastructure Management. To include a device model in CA Infrastructure Management monitoring and make it available in DX NetOps Performance Management dashboards, add it to an IP domain in OneClick.

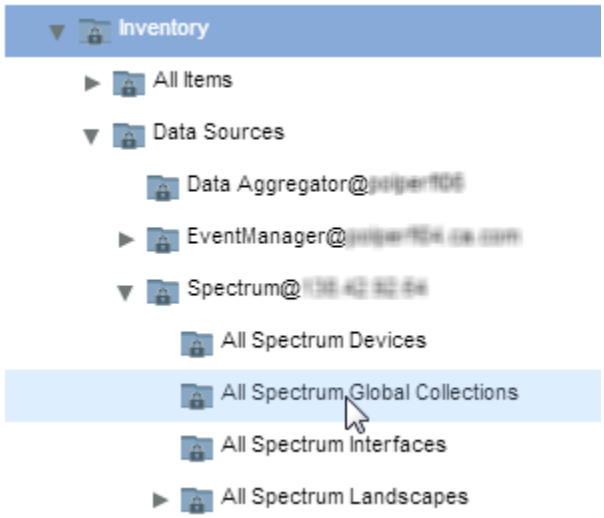
Take care to add only device models that should be synchronized with DX NetOps Performance Management. When the device models are synchronized, they are associated with the corresponding IP domain in DX NetOps Performance Management. The DX NetOps Performance Management IP domain may belong to the Default Tenant, or to any custom tenant. Do not add interface models. Device interfaces are automatically added to the IP domain with which their device is associated.

DX NetOps Spectrum devices can only be members of a single IPDomain model type. If you attempt to add a model to multiple IP domains, you see an error message.

Group Synchronization

If you already have DX NetOps Spectrum Global Collections that you want to continue to use, they are synchronized with DX NetOps Performance Management. All managed items in your Global Collections become members of groups, which are displayed in the DX NetOps Performance Management Groups tree.

NOTE
From 10.4.1, the LocalID for Landscape is sent as Landscape-Handle instead of Landscape Name.



You can also add those managed items to DX NetOps Performance Management Service Provider groups, which enable tenant users to manage them and view their data.

Enable Tenant Access to Data

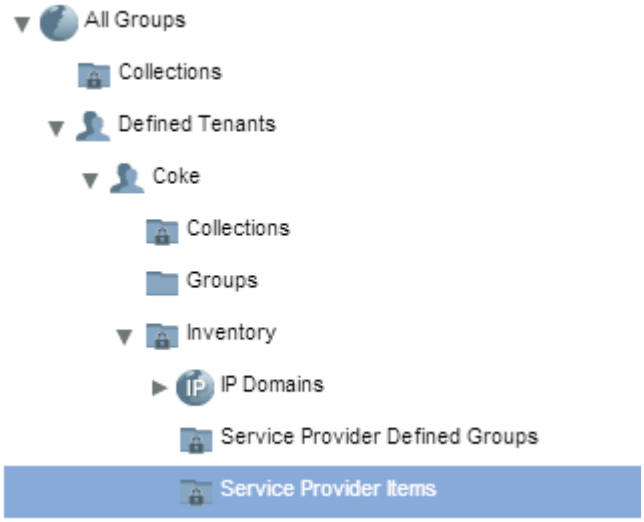
To monitor devices with both DX NetOps Spectrum and CA Infrastructure Management, you must explicitly add models to DX NetOps Performance Management IP Domains. At the first synchronization, DX NetOps Spectrum creates DX NetOps Performance Management IPDomain models in OneClick from all IP domains in DX NetOps Performance Management,

including the Default Domain. Device models within DX NetOps Spectrum can then be added to DX NetOps Performance Management IP Domains, enabling them to be synchronized with DX NetOps Performance Management. Those DX NetOps Spectrum devices are always associated with the same IP domain in CA Infrastructure Management and are also associated with the tenant that owns the IP domain.

If you choose to associate DX NetOps Spectrum device models with IP domains in the Default Tenant space only, you can leverage DX NetOps Performance Management Service Provider groups. These groups enable specific tenants to access the devices in DX NetOps Performance Management. You can thus grant access to device data to other tenant users. Set up Service Provider groups for tenant users so that they can monitor devices and components that are associated with the Default Domain.

Follow these steps:

1. In OneClick, add the device models that you want additional tenant users to monitor to the Default Domain Global Collection.
2. Log in to DX NetOps Performance Management as a user with the predefined Administrator role.
3. Initiate a manual synchronization of the DX NetOps Spectrum data source.
   For more information, see theDX NetOps Performance Management documentation.
4. Select Admin, Groups in the menu bar.
   The Manage Groups page displays current groups in a tree structure.
5. Expand the Defined Tenants group in the Groups tree.
6. Locate the tenant to which you want to grant access to selected DX NetOps Spectrum devices.
7. Expand the Inventory group under the tenant group.
8. Select the Service Provider Items group.



9. Click the Items tab in the right pane, and click Add Item Type.
   The Add Items dialog opens. You can begin adding the items to the Service Provider Items group.
10. Add all DX NetOps Spectrum models that you want the users who are associated with this tenant to be able to monitor.
11. Click Close when you have finished adding items.

Now the tenant users can see items that are being managed in the Default Tenant space in their inventory. Tenant users can also add these items to tenant groups to organize reporting.

Drill Down into DX NetOps Performance Management Performance Data

You can navigate to DX NetOps Performance Management performance data directly from models in OneClick. Drill down from any device or interface model that is also available in DX NetOps Performance Management.

Although DX NetOps Spectrum can contribute an interface model to DX NetOps Performance Management, an interface item only appears in DX NetOps Performance Management when a data source other than DX NetOps Spectrum is contributing performance data for it. If the interface is not being monitored by another data source, such as Data Aggregator or CA Network Flow Analysis, the right-click drill-down option is not available. For more information, see Smart Interface Filtering.

Follow these steps:

1. In the OneClick Navigation panel, expand the DX NetOps Performance Management IP Domains that were synchronized from CA Infrastructure Management.
2. Select a model in one of these collections.
3. Right-click the model, and select the option to navigate to DX NetOps Performance Management.

> **NOTE**
> This option is also available when you select the model on a Topology map or from Locater search results.The DX NetOps Performance Management user interface opens in a separate window. The device context associated with the selected model is preselected.

Known Anomalies - DX NetOps Performance Management Integration

DX NetOps Spectrum - DX NetOps Performance Management integration has the following known anomalies:

- Event processing behavior is undefined when a device is modeled as a nonproxy model on more than one landscape.
- Some data sources do not support IPv6 addresses. Proper mapping does not occur when DX NetOps Spectrum uses an IPv6 primary address for a device but the reporting data source does not support IPv6 addresses. To correct the mapping, destroy the DX NetOps Spectrum model and rediscover it using an IPv4 address. After the next incremental synchronization, the model will be mapped properly.
- When a DX NetOps Performance Management event is received for a model that is in maintenance mode in DX NetOps Spectrum, the event is not processed, in accordance with expected maintenance mode behavior.
- DX NetOps Spectrum can fall out of synchronization when the Event Manager data source is removed. If this situation occurs, follow these steps:
  a. Remove the DX NetOps Spectrum data source.
  b. Register the Event Manager data source again.
  c. Register the DX NetOps Spectrum data source again.

> **WARNING**
> This situation only applies to CA NetQoS Performance Center v6.1. It does not apply to DX NetOps Performance Management. Do not delete the data source from DX NetOps Performance Management unless product support advises you to do so.

How to Configure Events for Integration with DX NetOps Performance Management

With the integration of r9.2.2 and later and CA Performance Management v2.0.00 and later, events for which DX NetOps Spectrum polls are specified in an XML file. Based on the contents of the default XML file, DX NetOps Spectrum polls for ThresholdViolation events automatically. If you do not modify the XML file, information is obtained from the Event Manager database for ThesholdViolation events only.

You can also configure DX NetOps Spectrum to poll for any event in the Event Manager database. To do so, modify the XML file and set up other event support files in DX NetOps Spectrum. In addition, for DX NetOps Spectrum to process a modified event, the device or port must be modeled in DX NetOps Spectrum and included in the synchronization process.

To configure DX NetOps Spectrum to poll for specific events, take the steps that are listed here. A complete example is provided.

NOTE
To poll for ThresholdViolation events only, no action is required.

1. Obtain a developer ID to create event codes.
2. Update the netqos-integration-application-config.xml file to specify additional events and alarms.
3. Update the event disposition file to map the events to DX NetOps Spectrum event files.
4. Create an event format file for each event.
5. Create a probable cause file for each alarm code.
6. Deploy the changes by restarting the SpectroSERVER and OneClick servers.

Obtain a Developer ID

When defining events for the DX NetOps Spectrum - DX NetOps Performance Management integration, you use identifying event codes. The first 2 bytes of any event code contains a developer ID. You can obtain a registered developer ID from CA so that you can specify unique codes for your events. Using a unique developer ID lets you easily recognize your new codes in OneClick and prevents potential conflicts with other DX NetOps Spectrum event codes.

To obtain a developer ID from CA, contact CA Technical Support.

Update the netqos-integration-application-config.xml File

DX NetOps Spectrum uses the netqos-integration-application-config.xml file to determine the events for which to poll. DX NetOps Spectrum polls for ThresholdViolation events by default. To poll for more events, modify the netqos-integration-application-config.xml to define the event codes and associated alarms for each event.

The netqos-integration-application-config.xml file is located in the following directory:

```
$SPECROOT\tomcat\webapps\spectrum\WEB-INF\netqos\
config\container
```

Define Events

The eventTypeManager bean defines the events for which DX NetOps Spectrum polls. The entries for ThresholdViolation events appear in the file by default. You can manually add more events.

```
<bean id="eventTypeManager"
   class="com.ca.im.netqos.integration.event.type.EventTypeManager">
   <property name="interestingEventTypes">
     <map>
       <entry key="ThresholdViolation" value-ref="thresholdViolationAlarmCodes" />
       <entry key="TestEvent" value-ref="TestEventAlarmCodes" />
     </map>
   </property>
   <property name="alarmClearCodes">
     <map>
       <entry key="ThresholdViolation" value="0x5c40009" />
       <entry key="TestEvent" value="TestEventAlarmClearCode" />
     </map>
   </property>
```

```
</bean>
```

Update the following property elements to add events that DX NetOps Spectrum can include in polling:

- **interestingEventTypes**
  Specifies the types of events to include in polling. Each entry element identifies a specific event type and an alarm code map value. The ThresholdViolation entry is included by default. Add an entry element, as follows:
  ```
  <entry key="TestEvent" value-ref="TestEventAlarmCodes" />
  ```
  – ***TestEvent***
    Specifies the name of an event in the Event Manager database.
  – ***TestEventAlarmCodes***
    Specifies the value of the map that identifies the alarms for this event.

    NOTE
    The alarm code map is described in the next section.
- **alarmClearCodes**
  Specifies the alarm clear codes for polled events. The default alarm clear code for the ThresholdViolation event is 0x5c40009. For each event, add an entry element, as follows:
  ```
  <entry key="TestEvent" value="TestEventAlarmClearCode" />
  ```
  – ***TestEvent***
    Specifies the name of the event that was added for polling.
  – ***TestEventAlarmClearCode***
    Specifies the alarm clear code for the event.

Define Alarms

An alarm map defines the alarm code values that are associated with a particular event. For each polled event (or, each interestingEventTypes entry), a corresponding alarm map must be defined. The alarm map for the ThresholdViolation event appears in the file by default, and an alarm map for each custom event must be added manually.

```
<bean id="thresholdViolationAlarmCodes"
    class="org.springframework.beans.factory.config.MapFactoryBean">
    <property name="sourceMap">
      <map>
        <entry key="1" value="0x5c40010" />
        <entry key="2" value="0x5c40011" />
        <entry key="3" value="0x5c40012" />
      </map>
    </property>
</bean>
<bean id="testEventAlarmCodes"
    class="org.springframework.beans.factory.config.MapFactoryBean">
    <property name="sourceMap">
      <map>
        <entry key="alarmSev1" value="alarmCode1" />
        <entry key="alarmSev2" value="alarmCode2" />
        <entry key="alarmSev3" value="alarmCode3" />
      </map>
    </property>
</bean>
```

To add alarm maps for custom events, add a bean element for each event and update the following values:

- ***testEventAlarmCodes***

Specifies the alarm code map value for a particular event. This value is established on the interestingEventTypes entry and must match that value.

- ***alarmSev1 - alarmCode1, alarmSev2 - alarmCode2, alarmSev3 - alarmCode3***
  Specifies the *alarmSeverity* - *alarmCode* pairs for a particular event. For example, for the default ThresholdViolation event, the Minor (1), Major (2), and Critical (3) alarm codes are 0x5c40010, 0x5c40011, and 0x5c40012, respectively.

Update the Event Disposition File

The Event Disposition (EventDisp) file is used to determine how to process the events configured in the netqos-integration-application-config.xml file. Each event entry maps an event to a DX NetOps Spectrum event file.

The EventDisp file for DX NetOps Spectrum-DX NetOps Performance Management integration is located in:

```
<$SPECROOT>\SS\CsVendor\netqos
```

For the default ThresholdViolation event, the following entries map the alarm codes to individual DX NetOps Spectrum event files:

```
#PC Threshold
0x5c40010 E 50 A 1,0x5c40010,107
0x5c40011 E 50 A 2,0x5c40011,107
0x5c40012 E 50 A 3,0x5c40012,107
0x5c40009 E 50 C 0x5c40010,107 C 0x5c40011,107 C 0x5c40012,107
```

For each custom event, add new event map entries to the file. The following example shows syntax that generates or clears alarms that are based on the event code.

```
#New Event
alarmCode1E 50 A 1, alarmCode1_filename,107
alarmCode2E 50 A 2, alarmCode2_filename,107
alarmCode3E 50 A 3, alarmCode3_filename,107
alarmClearCode4E 50 C alarmCode1,107 C alarmCode2,107 C alarmCode3,107
```

For more information about using Event Disposition files, including syntax and examples, see Event Configuration.

Create Event Format Files

An event format file contains the message about the event that is displayed to users on the Events tab in OneClick. Each new event that is defined in the netqos-integration-application-config.xml file requires an event format file. The file enables the event to display correctly in the OneClick Events view.

The file name must match the alarm code (for example, alarm code 0x5c40010 uses the file "Event05c40010"). And the file must exist in the following directory:

```
<$SPECROOT>\SG-Support\CsEvFormat
```

The following is an example of the file format:

```
{d "%w- %d %m-, %Y - %T"} - {S 109} is reporting a minor threshold violation.
Detail of Threshold Violation:
        1) Incident Start Time: {D 111}
        2) Event ID: {S 107}
        3) Event Source: {S 113}
        4) Alert Message: {S 76620}
A corresponding minor Threshold Violation Alarm will be generated.
(event [{e}])
```

For more information, see Event Configuration .

Create Probable Cause Files

A probable cause file defines the symptoms, probable causes, and recommended corrective actions for an alarm. Each new alarm code requires a probable cause file so that the alarm displays correctly in the OneClick Alarms view.

The file name must match the alarm code (for example, alarm code 0x5c40010 uses the file "Prob05c40010"). And the file must exist in the following directory:

```
<$SPECROOT>\SG-Support\CsPCause
```

The following is an example of the file format:

```
A minor threshold violation has occurred.
SYMPTOMS:
The monitored threshold has been exceeded.
PROBABLE CAUSES:
RECOMMENDED ACTIONS:
Launch the "Performance View" to see incident details.
```

For more information, including syntax, see Event Configuration .

Deploy the Changes

After all configuration changes have been made, restart the SpectroSERVER and OneClick servers.

Event polling now reflects any changes that you have made.

Example

This example shows how to configure DX NetOps Spectrum to poll for a specific event in the Event Manager database. The event in this example identifies when a router device experiences high memory usage.

1. Identify a device or port for which you want DX NetOps Spectrum to poll for in the Event Manager database. If the device or port is not modeled in DX NetOps Spectrum, model the element. For example, to monitor specific events for a particular router, the router must be modeled in the DX NetOps Spectrum database.
2. Obtain a developer ID from CA Technical Support for use with DX NetOps Spectrum-DX NetOps Performance Management integration. This example uses the default developer ID value, 0xffff.
3. Identify the events for which DX NetOps Spectrum polls. For example, you can identify any occurrence when the router device experiences high memory utilization. This example refers to this event as "RouterHighMemory".
4. Define the event by modifying the XML file:
   a. Open the following file for editing:
      ```
      <$SPECROOT>\tomcat\webapps\spectrum\WEB-INF\netqos\config\container\netqos-integration-application-config.xml
      ```
   b. Define the custom event. Update the existing eventTypeManager element as follows: Add the RouterHighMemory event to the list of events for which to poll. Establish an alarm map value. Specify a default alarm clear code. The following code shows these changes. Notice that the alarm clear code uses a developer ID.
      ```
      <bean id="eventTypeManager"
         class="com.ca.im.netqos.integration.event.type.EventTypeManager">
         <property name="interestingEventTypes">
           <map>
             <entry key="ThresholdViolation" value-ref="thresholdViolationAlarmCodes" />
             <entry key="RouterHighMemory" value-ref="RouterHighMemoryAlarmCodes" />
           </map>
         </property>
         <property name="alarmClearCodes">
           <map>
      ```

```
        <entry key="ThresholdViolation" value="0x5c40009" />
        <entry key="RouterHighMemory" value="0xffff0004" />
      </map>
    </property>
  </bean>
```

c. Define the alarm map by adding the following new bean element:

```
<bean id="RouterHighMemoryAlarmCodes"
    class="org.springframework.beans.factory.config.MapFactoryBean">
    <property name="sourceMap">
      <map>
        <entry key="1" value="0xffff0001" />
        <entry key="2" value="0xffff0002" />
        <entry key="3" value="0xffff0003" />
      </map>
    </property>
</bean>
```

d. Save and close the file.

5. Specify how DX NetOps Spectrum processes the encountered event by updating the Event Disposition file:
   a. Open the following file for editing:

```
<$SPECROOT>\SS\CsVendor\netqos\EventDisp
```

   b. Add the following map entries for the RouterHighMemory event:

```
#RouterHighMemory Event
0xffff0001E 50 A 1, 0xffff0001,107
0xffff0002E 50 A 2, 0xffff0002,107
0xffff0003E 50 A 3, 0xffff0003,107
0xffff0004E 50 C 0xffff0001,107 C 0xffff0002,107 C 0xffff0003,107
```

   c. Save and close the file.
6. Create an event format file for each of the alarm codes using the following naming convention (*AlarmCode* - *EventFormatFile*):
   – 0xffff0001 - Eventffff0001
   – 0xffff0002 - Eventffff0002
   – 0xffff0003 - Eventffff0003
   – 0xffff0004 - Eventffff0004
   – Create a text file containing content similar to the following text:

```
{d "%w- %d %m-, %Y - %T"} - {S 109} is reporting a minor threshold violation.
Detail of Threshold Violation:
        1) Incident Start Time: {D 111}
        2) Event ID: {S 107}
        3) Event Source: {S 113}
        4) Alert Message: {S 76620}
A corresponding minor Threshold Violation Alarm will be generated.
(event [{e}])
```

     NOTE
     When creating Eventffff0004, use appropriate wording for clearing an alarm.

   – Save the file to the following location:

```
<$SPECROOT>\SG-Support\CsEvFormat
```

   – Repeat steps a and b for each alarm code.
7. Create a probable cause file for each of the alarm codes using the following naming convention (*AlarmCode* - *ProbableCauseFile*):

- 0xffff0001 - Probffff0001
- 0xffff0002 - Probffff0002
- 0xffff0003 - Probffff0003
- 0xffff0004 - Probffff0004
- Create a text file containing content similar to the following text:

```
A minor threshold violation has occurred.
SYMPTOMS:
The monitored threshold has been exceeded.
PROBABLE CAUSES:
RECOMMENDED ACTIONS:
Launch the "Performance View" to see incident details.
```

- Save the file to the following location:

```
<$SPECROOT>\SG-Support\CsPCause
```

- Repeat steps a and b for each alarm code.

8. Restart the SpectroSERVER and OneClick servers.
   When the integration is complete, DX NetOps Spectrum uses the updated files to poll for the RouterHighMemory event, generating events and alarms as specified.

Event Handling in FT Scenario 10.4.2.1

When DX NetOps Spectrum is set up in FT mode, and the primary host fails, DX NetOps Spectrum runs on the secondary host. In such a situation only events are pulled from DX Performance Management to DX NetOps Spectrum. However, inventory sync is not supported.

Troubleshooting DX NetOps Performance Management Integration

After DX NetOps Spectrum Upgrade, Integration Breaks with DX NetOps Performance Management in SSL Environment

Symptom:

DX NetOps Spectrum and DX NetOps Performance Management integration breaks after DX NetOps Spectrum upgrade. This happens when SSL is enabled and DX NetOps Spectrum is connected to DX NetOps Performance Management using **https**.

Solution (for 10.2.2 and previous versions):

Verify whether SSL is enabled on the OneClick web server host in the DX NetOps Spectrum environment. If so, verify that the "axis2.xml" file is updated with HTTPS protocol and appropriate port number.

Follow these steps:

1. Open the "axis2.xml" file in an editor from "$SPECROOT/tomcat/webapps/axis2/WEB-INF/conf".
2. Add the following section in axis2.xml after 'http' transportReceiver:

```
<transportReceiver name="https" class="org.apache.axis2.transport.http.AxisServletListener"> <parameter
 name="port">8443</parameter> </transportReceiver>
```

3. Restart the Webserver for these changes to take affect.

Solution (for 10.2.3)

The "axis2.xml" file contains the following section in commented format. After DX NetOps Spectrum upgrade, you can uncomment this code and update the port number to integrate DX NetOps Spectrum with DX NetOps Performance Management using **https**. You must restart the Webserver for these changes to take affect.

```
<transportReceiver name="https" class="org.apache.axis2.transport.http.AxisServletListener"> <parameter
 name="port">8443</parameter> </transportReceiver>
```

Unable to Add Spectrum Data as Source to DX NetOps Performance Management

Symptom:

I am unable to add DX NetOps Spectrum as a data source in NetOps Portal when I select **https** as the protocol.

Solution:

Verify whether SSL is enabled on the OneClick web server host in the DX NetOps Spectrum environment. If so, verify that the "axis2.xml" file is updated with HTTPS protocol and appropriate port number.

Follow these steps:

1. Open the "axis2.xml" file in an editor from "$SPECROOT/tomcat/webapps/axis2/WEB-INF/conf".
2. Locate the following section in axis2.xml:
```
<transportReceiver name="http"
                      class="org.apache.axis2.transport.http.AxisServletListener">
</transportReceiver>
```
3. Change the section as follows:
```
<transportReceiver name="https"
                      class="org.apache.axis2.transport.http.AxisServletListener">
        <parameter name="port">8443</parameter>
</transportReceiver>
```

Error When Adding Device to IP Domain

Symptom:

I tried to add a device to a NetOps Portal IP domain in OneClick. I received an error message that stated, "The following models could not be added to the Global Collection *Domain Name*." An additional statement claimed that the models did not exist. But I have verified that the models do exist in the landscape.

Solution:

You see this message if you attempt to add a device that is already associated with an existing IP domain to another IP domain. This error can occur if, for example, the device was added to the IP domain either manually or dynamically, using a Global Collection rule. The portion of the error message stating that "The model does not exist" is inaccurate. We plan to address this issue in a future version of the DX NetOps Spectrum software.

Pingable Devices in NetOps Portal Have Little Data

Symptom:

After synchronization, some devices that DX NetOps Spectrum contributed to NetOps Portal appear to have a Subtype of Pingable in the Inventory view. They should be classified as Router or Switch. They are legitimate devices that should be reporting lots of performance data.

Solution:

A *pingable device* refers to a device that does not allow SNMP polling and is therefore contacted using ICMP ping tests for status and reachability statistics. Devices that are sent over from DX NetOps Spectrum can appear to be Pingable and have only status and availability data because of configuration issues. Take the following steps:

- Make sure that NetOps Portal has an SNMP profile with the appropriate credentials to collect SNNP data from the device. For more information, see Add an SNMP Profile to Gather Performance Data.
- Make sure that the correct SNMP profiles are specified in the discovery profile that corresponds to the device.
- Check firewall configuration. If the SNMP and discovery configurations are correct, a network ACL or firewall adjustment can be required to enable the Data Collector to collect SNMP data for the device.

Make sure that the Data Collectors that are assigned to the IP domain of each pingable device have network access to the devices. The level of access must be comparable to that of the SpectroSERVER or Secure Domain Connector that monitors the device in DX NetOps Spectrum.

DX NetOps Performance Management alarms are missing in DX NetOps Spectrum

Symptom:

CAPM alarms are missing in DX NetOps Spectrum due to DX NetOps Performance Management and DX NetOps Spectrum machines are not in time sync.

Solution:

DX NetOps Performance Management and DX NetOps Spectrum machines need to be in time sync, contact the network administrator.

Integration with CA Service Desk

Overview of Functionality

The DX NetOps Spectrum and CA Service Desk Manager integration provides the following features:

- Associates DX NetOps Spectrum alarms with the CA Service Desk tickets in the following ways
  - Creates tickets when manually requested by OneClick operators.
  - Automatically creates tickets for each alarm type.
  - Automatically creates tickets using the DX NetOps Spectrum Alarm Notification Manager (SANM) functionality.
- Maintains the consistency of the following information that is shared between a DX NetOps Spectrum alarm and its associated CA Service Desk ticket:
  - Status of alarms and associated tickets
  - The current assignee (troubleshooter) assigned to tickets
- Provides a link to launch a CA Service Desk Manager view of a particular ticket directly from within the OneClick console.
- Provides an approval system for host configuration change requests that are initiated in Network Configuration Manager.
- Supports multiple CA Service Desk Manager servers.

> **NOTE**
> Starting with version 12.5 of CA Service Desk, the product name has changed to CA Service Desk Manager. The DX NetOps Spectrum integration supports earlier versions that used the previous name. As a result, the two product names are used interchangeably in this section. The name "CA Service Desk" is used to describe generic product features, such as tickets and assets.

Integration Details

Once the integration has been successfully configured, DX NetOps Spectrum and CA Service Desk Manager share data.

- OneClick uses CA Service Desk web services to:

  - Create CA Service Desk tickets.
  - Update alarm owners (the troubleshooters who are assigned to alarms).
  - Close the tickets.
- CA Service Desk Manager uses a custom notification that issues HTTP requests to OneClick to:
  - Update the assigned troubleshooter.
  - Clear the alarms.
- DX NetOps Spectrum and the CA Service Desk Manager integration work with SANM to provide automatic ticket creation. You configure the SANM automatic ticket creation using SANM policies. You can then specify which alarms create tickets by configuring alarm properties, such as the date, time, alarm severity, alarm cause, IP address, and the device type.
- DX NetOps Spectrum and the CA Service Desk Manager integration also provides an approval system for host configuration changes that are initiated in Network Configuration Manager. When a host configuration change is requested in NCM, a CA Service Desk ticket is created for the request. The ticket requires approval before it can be implemented.

Fault Tolerance

You can specify a list of multiple CA Service Desk Manager servers to enable fault tolerance when you configure the integration. When DX NetOps Spectrum detects a loss of connectivity to a CA Service Desk Manager, it attempts to connect to the next server in the list. DX NetOps Spectrum continues to step through the list to establish a connection until one is successful.

> **IMPORTANT**
> If CA Service Desk web services are down, DX NetOps Spectrum cannot create Service Desk tickets. Or if an alarm is cleared when CA Service Desk web services are down, that ticket is not closed, but remains open.

How to Install and Configure the Integration

To install and configure the DX NetOps Spectrum and CA Service Desk Manager integration successfully, complete the following procedures:

Verify Integration System Requirements

To perform the procedures in this section, administrator-level permission is required to the CA Service Desk Manager server host computer and the OneClick web server host computer. You must also be a CA Service Desk Manager and OneClick administrator on these computers.

Before you begin, verify that your servers meet the following requirements:

- **DX NetOps Spectrum OneClick server software** -- CA Spectrum 10.1. For system requirements, see System Requirements for Installing DX NetOps Spectrum.
- **CA Service Desk software** -- CA Service Desk 12.7 or 14.1. For system requirements, see Integration Compatibility.

> **NOTE**
> Starting with version 12.5 of CA Service Desk, the product name has changed to CA Service Desk Manager. The DX NetOps Spectrum integration supports earlier versions that used the previous name. As a result, the two product names are used interchangeably in this section. The name "CA Service Desk" is used to describe generic product features, such as tickets and assets.

For information about installing CA Service Desk software, see Service Desk and DX NetOps Spectrum . For information about configuring CA Service Desk software, see CA Service Manager .

- **A supported web browser** -- CA Service Desk and CA Service Desk Manager only support Microsoft Internet Explorer v10 if the browser is running in Compatibility Mode. Other versions of Internet Explorer are fully supported. Mozilla Firefox and Google Chrome are also supported.

Configure the CA Service Desk Manager Server

This section describes the procedures that are required to set up the CA Service Desk server for integration.

1. Download and Install Integration Components on the CA Service Desk Server
2. Create a Contact, Service Desk Ticket Template, Service Desk Web Services Policy, and Service Desk Notification Method
3. Configure the CA Service Desk Ticket Notifications

Download and Install Integration Components on the CA Service Desk Server

Before you configure CA Service Desk Manager and to communicate with each other, download and install the integration components on your CA Service Desk Manager server. Use one of the following methods, depending on your operating systems.

CA Service Desk and OneClick Web Server Use Different Operating Systems

Perform the following steps when your CA Service Desk Manager server uses a different operating system than the OneClick web server (Windows vs Linux):

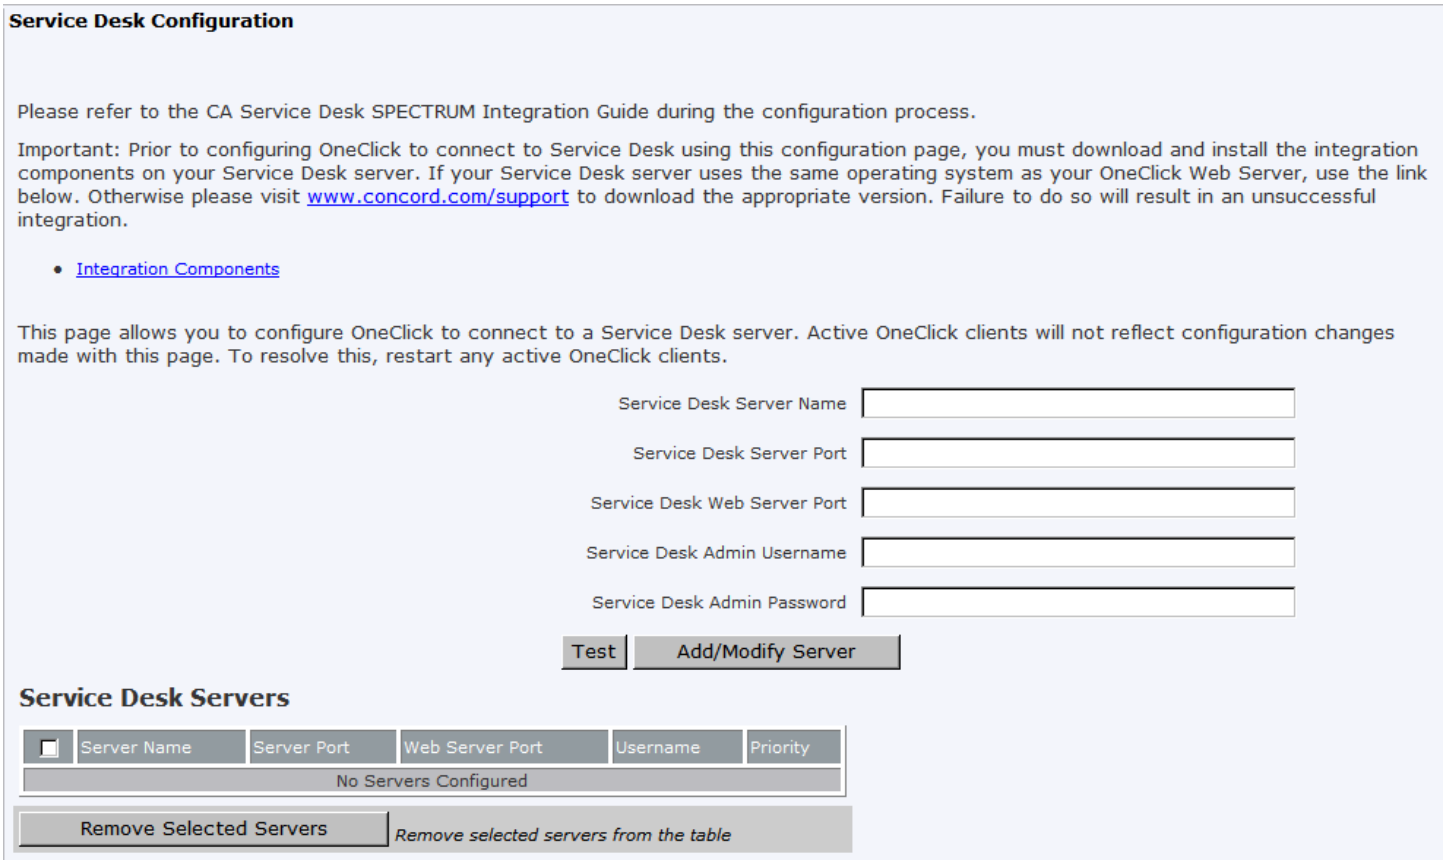
1. Visit support.broadcom.com to locate a version of the CA Service Desk Manager integration components that are appropriate for your CA Service Desk Manager server.
2. Download and save the appropriate version of the integration components for your operating system to the following directory on your CA Service Desk Manager server:
   ```
   Service_Desk_Installation_directory/bin
   ```
3. After you have saved the integration components to your CA Service Desk Manager server, follow the instructions for installing and configuring the integration components using the same operating system, beginning with Step 5.

CA Service Desk and OneClick Web Server Use the Same Operating System

Download the and CA Service Desk Manager integration components from the OneClick web server and install them on the CA Service Desk Manager server.

Follow these steps:

1. From your CA Service Desk Manager server, navigate to the OneClick Administration pages.
   ```
   http://OneClick Web server/spectrum/admin/index.jsp
   ```
2. Click the Service Desk Configuration link in the left panel of the Administration page.
   The Service Desk Configuration administration page opens in the right panel, as shown:



1. Click the Integration Components link to download the oc_components.exe file. This self-extracting archive file contains the executable programs to configure the CA Service Desk Manager server.
2. Save the oc_components.exe file to the directory on your CA Service Desk Manager server:
   ```
   Service_Desk_Installation_directory/bin
   ```
3. Log in to your CA Service Desk Manager server host computer and navigate to the *Service_Desk_Installation_directory*/bin directory.
4. Locate the oc_components.exe file you downloaded.
5. **Linux:** Run the following command to make the oc_components.exe file executable:
   ```
   chmod 755 oc_components.exe
   ```
   Windows: Do not edit the permissions of the downloaded file for the file to be executable.
6. Run the oc_components.exe file.
   The OneClickIntegrationSetup(.exe) file is extracted to the <*Service_Desk_Installation_directory*>/bin directory.
7. Run the *Service_Desk_Installation_directory*/bin/OneClickIntegrationSetup(.exe) configuration program. At each prompt, enter the requested information and press Enter to continue. The following table describes each prompt and the required information:

OneClick Integration Setup Prompt	Description
OneClick Server name?>	Enter the hostname of your OneClick Web server.
OneClick Server port?>	Enter the port of the OneClick Web server.

OneClick Homepage path [default="spectrum"]?>	If your OneClick home page URL uses the default value of http://<*oc*> *Web server*/spectrum, press Enter to accept it. Otherwise, enter the correct home page path portion of the OneClick home page URL at this prompt. This home page path value is <path>, as in the example http://*OneClick Web server*>/*path*. The default value in OneClick is “spectrum.”
Username?>	Enter the username of the OneClick Administrator. This name is the "super user" who installed the OneClick Web server.
Password?>	Enter the password of the OneClick Administrator.
Confirm password?>	Re-type the password of the OneClick Administrator and press Enter.
Enable logging? [yes|no]>	Type *yes* to enable logging or type *no* to disable logging and press Enter. We recommend enabling logging only when you are troubleshooting an integration problem. An active integration can create a large log file. When logging is enabled, the integration creates a file named oc-notification.log in the *Service_Desk_Installation_directory*/bin directory. When enabled, logging writes information about Service Desk notifications to this log file. Information is logged each time the notification occurs and includes the type of activity and whether or not it was a success. In the case of a failed notification, this log file may contain a possible solution such as an invalid port or that the OneClick web server is unavailable.
Enable SSL? [yes|no]>	Type *yes* to enable SSL or type *no* to disable SSL and press Enter. **Note:** To enable SSL in Tomcat, install OneClick and see OneClick Administration. To enable SSL in CA Service Desk Tomcat, see *Administration* in *CA* Service Desk documentation.
Path to the JRE root installation directory?>	Type the JRE root installation directory path and press Enter. Specify the JRE root installation directory so that appending "bin/java - version" becomes a successful command. **Note:** Java 2 Runtime Environment (JRE) version 1.5.0 or later is required.
Close keyword [default="Closed"]?>	If you created customized CA Service Desk notification messages that do not use the default keyword for Close (“Closed”), specify those custom keywords at this prompt. To use default values press Enter at the prompt without specifying a keyword. If you use custom notification messages for the Close action, type the associated keywords at the prompt. You can specify multiple keywords and they will be searched for sequentially. Keywords are case-sensitive. When you have finished entering keywords, leave the line blank and press Enter. **Note:** For more information, see Using Custom Keywords for CA Service Desk Notifications section in the References page.
Transfer keyword [default="Transfer"]?>	If you created customized CA Service Desk notification messages that do not use the default keyword for Transfer ("Transfer"), specify those custom keywords at this prompt. To use default values press Enter at the prompt without specifying a keyword. If you use custom notification messages for the Transfer action, type the associated keywords at the prompt. You can specify multiple keywords and they will be searched for sequentially. Keywords are case-sensitive. When you have finished entering keywords, leave the line blank and press Enter.

The OneClick Integration Setup program creates a file named NotifyOneClick(.bat or .sh, depending on the operating system), in the *Service_Desk_Installation_directory*/bin directory.

NOTE
To reconfigure this information later, run the OneClickIntegrationSetup program again or manually edit values in the *Service_Desk_Installation_directory*/bin/oc-integration.cfg configuration file. Any changes that are made to this file take effect immediately. No additional restart is required.

NOTE

If you have ennabled SSL during the OneClick Integration Setup, follow these steps to set One Click Keystore in the CA Service Desk Manager (SDM):

1. Copy the OC Keystore file: **<SPECROOT>/custom/keystore/cacerts** to the CA Service Desk Manager (SDM) machine. For example: **c:/spectrum_keystore/cacerts**
2. Update NotifyOneClick (.bat or .sh, depending on the operating system) as shown:
   ```
   <JRE_ROOT_PATH> \bin\java.exe -DFILE_NAME="%FILE_NAME%" -jar OCNotify.jar
   ```
   For example:
   ```
   C:\Program Files\Java\jre1.8.0_172\bin\java.exe" -
   Djavax.net.ssl.trustStore=c:/spectrum_keystore/cacerts -DFILE_NAME="%FILE_NAME
   %" -jar OCNotify.jar
   ```
   A customized setting in case OC is SSL enabled, can be for example:
   ```
   C:\Program Files\Java\jre1.8.0_172\bin\java.exe -DFILE_NAME="%FILE_NAME%" -jar
    OCNotify.jar2nd box
   ```

Create a Contact, Service Desk Ticket Template, Service Desk Web Services Policy, and Service Desk Notification Method

Create a DX NetOps Spectrum Contact on the CA Service Desk Manager Server

To enable CA Service Desk Manager to communicate with DX NetOps Spectrum, create a special DX NetOps Spectrum contact on the CA Service Desk Manager server.

Follow these steps:

1. Navigate to your CA Service Desk Manager home page:
   ```
   http://<Service Desk server>/CAisd/pdmweb.exe
   ```
2. Click the Service Desk tab.
3. Click File, New Contact.
   The Create New Contact window opens.
4. Enter *spectrum* in both the Last Name and System Login (or User ID) fields.
5. Select at least the Analyst option from the Contact Type list so that tickets are assigned to the user.
6. Click Save.

Create a CA Service Desk Ticket Template on the CA Service Desk Manager Server

Create a service desk ticket template for the CA Service Desk tickets that are created from DX NetOps Spectrum alarms. This ticket template specifies the format of CA Service Desk tickets that are created from OneClick alarms.

Follow these steps:

1. From the CA Service Desk Manager server home page, select the Service Desk tab.
2. Select File, New Issue.
   The Create New Issue window opens.

NOTE
You can configure CA Service Desk Manager to use Issues, Requests, or Incidents as the default ticket type that OneClick creates. The procedures in this section refer to Issues. To use Requests or Incidents instead (to support Incident and Problem type requests), replace all references to "Issues" with "Requests" or "Incidents". For example, in this step, replace 'File, New Issue' with 'File, New Request,' or with 'File, New Incident'. For an example using Requests, see the topic that describes creating CA Service Desk tickets automatically for a single alarm type.

3. In the Create New Issue window, type *spectrum* in the Affected End User field.
4. (Optional) Take the following actions to configure the integration to assign all CA Service Desk tickets that DX NetOps Spectrum creates to a specific troubleshooter by default:
   a. Click the Assignee link.
      The Analyst List page opens.
   b. Search for the contact name of the person you want to set as the default troubleshooter.
   c. Click the link in the Name column of the desired troubleshooter.
      The troubleshooter is added to the Assignee field as the default.
5. Select the Template tab at the bottom of the Create New Issue page.
6. Type *SPECTRUM_TEMPLATE* in the Template Name field.
7. (Optional) Type a description for this template in the Description field.
8. Click Save.
   The template is saved.

NOTE
You can customize your DX NetOps Spectrum and CA Service Desk Manager integration to use more than the default template. By editing the SPECTRUM_POLICY Web Services Policy, you can add different problem types that refer to different ticket templates. For more information about adding problem types (error types) to the Web Services Policy in CA Service Desk Manager, see CA Service Desk Manager Web Services .

Create a CA Service Desk Web Services Policy and Problem Type for DX NetOps Spectrum

Create a Web Services Policy and problem type (error type) for DX NetOps Spectrum. This policy controls how CA Service Desk Manager processes the requests for the creation of tickets from DX NetOps Spectrum alarms. CA Service Desk Manager uses the problem type to specify the SPECTRUM_TEMPLATE as the basis for new tickets when CA Service Desk Manager receives a DX NetOps Spectrum alarm.

Follow these steps:

1. From the CA Service Desk Manager home page, select the Administration tab.
2. Expand Web Services Policy and click Policies.
3. Click Create New.
   The Create New Web Services Access Policy window opens.
4. Take the following actions:
   a. Enter *SPECTRUM_POLICY* for Symbol.
   b. Enter *SPECTRUM_POLICY* for Code.
   c. (Optional) Type a description for the DX NetOps Spectrum policy.
   d. Click Save.
   The Create New Web Services Access Policy window closes.
5. Select the *SPECTRUM_POLICY* Web Service Policy that you created.
   The Web Services Access Policy Detail window for the *SPECTRUM_POLICY* opens.
6. Click Edit.
7. Click the Error Types tab.
8. Click Add an Error Type.

a. Enter *SPECTRUM_PT* in the Symbol field.
b. Enter *SPECTRUM_PT* in the Code field.
c. Select the Default check box.
d. Select Issue from the Ticket Template Type drop-down list.
e. Enter *SPECTRUM_TEMPLATE* in the Ticket Template Name field.
f. (Optional) Enter a description for the problem type (error type).
g. Select the Duplicate Handling tab, and take one of the following actions:
   - To create a unique ticket regardless of underlying cause, select Create Ticket (do not detect duplicates).
   - To avoid creating multiple tickets for the same underlying cause, select one of the following options:
     - Add Activity Log (do not create ticket)
     - Create Standard Log (do not create ticket)
     - Attach As Child (create a child ticket)

     Specify a value in the 'Maximum time interval for searching duplicates' field. This value must be at least 00:01:00 (one minute). The value the amount of time CA Service Desk Manager looks for duplicates.

     NOTE
     These options require support for the CA Service Desk Manager duplicate handling feature. To use this feature, make further modifications to the CA Service Desk Manager and OneClick servers.

     For more information, see the following topics:
   - Configure CA Service Desk Manager Duplicate Handling Feature
   - Disable Automatic Closing of Ticket

h. Click Save.

The window closes.

9. Click Save in the Policy Detail window.
   The policy and problem type (error type) are created.

   NOTE
   You can customize your DX NetOps Spectrum and CA Service Desk Manager integration to use more than the default template. By editing the SPECTRUM_POLICY Web Services Policy, you can add different problem types that refer to different ticket templates. For more information about adding problem types (error types) to the Web Services Policy in CA Service Desk Manager, see CA Service Desk Manager Web Services .

Create a Custom CA Service Desk Notification Method

Create a custom notification method for CA Service Desk Manager to send notifications to OneClick. This method communicates the CA Service Desk ticket changes to OneClick.

Follow these steps:

1. From the CA Service Desk Manager home page, click the Administration tab.
2. Expand the Notifications folder and click Notification Methods.
   The Notification Method List opens.
3. Click Create New.
   The Create New Notification Method dialog opens.
4. Enter the following information:

   1. Type **SPECTRUM_Notification** in the Symbol field.
   2. Specify the notification method as follows:
      For Windows: Type **NotifyOneClick.bat** for the Notification Method.
      For Linux: Type the full path to the NotifyOneClick script, such as **/opt/CA/ServiceDesk/bin/NotifyOneClick.sh**.

      NOTE
      The NotifyOneClick file must be present in the *Service_Desk_Installation_directory*/bin directory.
   3. (Optional) Enter a description of the notification method.

NOTE
Do not select *write to file* because the integration uses web services instead of reading the information from a file.

4. Click Save.

The notification method is created.

Configure the CA Service Desk Ticket Notifications

CA Service Desk Manager can send OneClick notifications when a ticket that is associated with a OneClick alarm changes. These notifications update the alarm that is associated with a ticket in OneClick to reflect changes to the ticket. The CA Service Desk Manager integration can be configured to generate an automatic Ticket Closed notification that causes OneClick to clear the associated alarm, when a ticket is closed. Similarly, when a ticket has been transferred, a Ticket Transfer notification causes OneClick to update the troubleshooter information for the associated alarm.

NOTE
OneClick only clears an associated alarm when a ticket is closed in the CA Service Desk Manager if the alarm is user-clearable.

These notifications use CA Service Desk "keywords," which must match keywords that are set in the integration for OneClick. Keywords are case-sensitive. By default, the keyword for the close action is "Closed", and the keyword for the transfer action is "Transfer" (in both CA Service Desk Manager and the integration setup). These keywords can be customized in CA Service Desk Manager and in the integration setup.

To configure the CA Service Desk notifications for the integration with CA Service Desk Manager, complete these procedures:

1. Enable notifications for the DX NetOps Spectrum contact.
2. Enable CA Service Desk notifications for "Ticket Close".
3. Enable CA Service Desk notifications for "Ticket Transfer" actions.

For more information, see the example of customizing CA Service Desk keywords. This example describes configuring a custom keyword for the Close action after you have completed and enabled the integration.

Enable Notifications for the Contact

Enable the CA Service Desk notifications for the special contact (*spectrum*) on the CA Service Desk Manager server:

Follow these steps:

1. From the CA Service Desk Manager home page, select the Service Desk tab.
2. Select Search, Contacts.
   The Create New Contact window opens.
3. Type **spectrum** in the Last Name field, and click Search.
   The Contact List opens.
4. Click the *spectrum* contact.
   The Detail dialog for the *spectrum* contact opens.
5. Click Edit and click the Notification tab.
6. For each of the Notification types (Low, Normal, High, and Emergency) in the list, select *SPECTRUM_Notification* for Method.
7. Click Save.
   Notifications are now enabled.

Enable CA Service Desk Notifications for “Ticket Close”

Configure CA Service Desk Manager to send a notification to when a ticket has been closed. A Ticket Closed notification causes to clear the associated alarm.

Follow these steps:

1. From the CA Service Desk Manager home page, select the Administration tab.
2. Expand the Notifications folder and select Activity Notifications.
   The Notification List opens.
3. Select Close activity.
   The Close Activity Notification Detail dialog opens.
4. Verify that the Object Type is set to the appropriate value. By default, this field is set to Requests. If you opted to create CA Service Desk Issues, select Issues.
5. Click Edit.
6. Take the following steps:
   a. Click the Notification Rules tab, and then click the name of the notification rule that the close activity uses.
   b. Click the message template for the transfer activity, and click Edit.
   c. Select Auto Notification.
7. Click the Contacts tab, and then click Update Contacts.
   The Contact Search window opens.
8. Click Search.
   The Notification Recipients Update window opens.
9. Add the *spectrum* contact from the Contacts list to the Notification Recipients list, and click OK.
   The Close Update Activity Notification window opens.

   NOTE
   Do not remove the information in the 'Description: @{call_req_id.description}' field. uses this information to associate alarms in with the CA Service Desk ticket. Without this information, alarms are not cleared in when a CA Service Desk ticket is closed.

1. Click Save.
2. Close the Close Activity Notification Detail window.
   CA Service Desk Manager sends notifications when tickets are closed.

Enable CA Service Desk Notifications for "Ticket Transfer" Actions

CA Service Desk Manager can notify when a ticket has been transferred. To configure this feature, enable CA Service Desk Manager to send notifications to when a ticket that has a alarm is transferred.

Follow these steps:

1. From the CA Service Desk Manager server home page, select the Administration tab.
2. Expand the Notifications folder and select Activity Notifications.
   The Notification List opens.
3. Select Transfer activity.
   The Transfer Activity Notification Detail window opens.
4. Verify that the Object Type is set to the appropriate value. The default is Requests. To create CA Service Desk Issues, select Issues.
5. Click Edit.
6. Take the following steps:
   a. Click the Notification Rules tab, and then click the name of the notification rule that the transfer activity uses.
   b. Click the message template that the transfer activity uses, and click Edit.
   c. Select Auto Notification.

7. In the Notification Message body, change the assignment information from:

   ```
   "Assigned to: @{call_req_id.assignee.combo_name}"
   ```

   to:

   ```
   "Assigned to: @{issue_id.assignee.userid}"
   ```

   NOTE
   Do not remove the information in the 'Description: @{call_req_id.description}' field. uses this information to associate alarms in with the CA Service Desk ticket. Without this information, alarms are not cleared in when a CA Service Desk ticket is closed. The 'issue_id' portion of the assignment is a variable that must match the type of ticket that you are using (in this case, an issue). For requests, use 'call_req_id'.
8. Click the Contacts tab, and then click Update Contacts.
   The Contact Search window opens.
9. Click Search.
   The Notification Recipients Update window opens.
10. Add the *spectrum* contact to the Notification Recipients list from the Contacts list, and click OK.
    The Transfer Update Activity Notification window opens again.
11. Click Save.
12. Close the Transfer Activity Notification Detail window.
    CA Service Desk Manager sends notifications when tickets are transferred.

Configure CA Service Desk Duplicate Handling

CA Service Desk Manager provides the duplication handling for scenarios where multiple tickets are created with the same underlying cause within a specified amount of time. To take advantage of this feature, make some modifications to the CA Service Desk Manager server.

NOTE
To support the duplication handling,enable the Specify Reported By Field when configuring the OneClick server. See Configure Communication and Enable Integration on the OneClick Server.

Configure support for CA Service Desk duplication handling on the CA Service Desk Manager server.

Follow these steps:

1. Log in to your CA Service Desk Manager server.
2. Take one of the following steps:
   For CA Service Desk r12.1:

   1. Open the following file: $SD_ROOT\bopcfg\majic\cm.maj
   2. Change the following line:

      ```
      log_agent SREL cnt WRITE_NEW REQUIRED SERVICE_PROVIDER_ELIGIBLE
      ```

      to

      ```
      log_agent SREL cnt REQUIRED SERVICE_PROVIDER_ELIGIBLE
      ```

   3. Save changes and close the file.

   For CA Service Desk Manager r12.5, and later versions:

   - Create the mod file in $SC_ROOT/site/mods/majic.
   - Include the following line:

     ```
     MODIFY cr log_agent NOT_WRITE_NEW;
     ```

   - Save changes and close the file.
3. Restart the CA Service Desk Manager Server service after making either of these changes.

Configure the OneClick Server

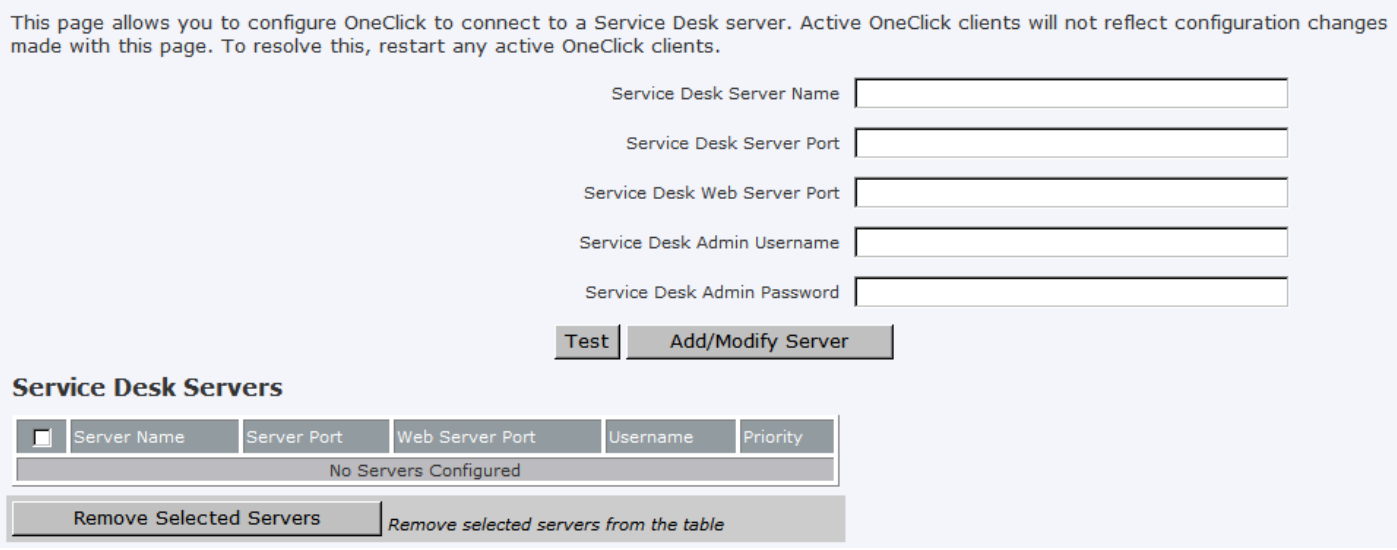
This section describes the procedures to set up the OneClick server for integration.

Configure Communication and Enable Integration on the OneClick Server

Complete the following procedure to configure and CA Service Desk Manager to communicate with each other.

Follow these steps:

1. Navigate to the OneClick Administration pages:
   `http://<oc> Web server/spectrum/admin/index.jsp`
2. Click the Service Desk Configuration link from the left panel of the Administration page.
   The Service Desk Configuration administration page opens.
3. Configure OneClick to connect to a CA Service Desk Manager server by entering valid values for the following fields:



- **Service Desk Server Name**
  The hostname of the CA Service Desk Manager server.
- **Service Desk Server Port**
  The HTTP port of the CA Service Desk Tomcat Port. uses this port to create CA Service Desk tickets.
- **Service Desk Web Server Port**
  The HTTP port of the CA Service Desk Web Server. This port is used when launching the CA Service Desk interface from OneClick.
  - To integrate with a CA Service Desk Manager server that is running on both a web server (IIS or Apache) and Tomcat, this port is *different* from the port that you specified in the previous Service Desk Server Port field.
  - To integrate with a CA Service Desk Manager server that is only running on Tomcat, this port is the *same* as the port that you specified in the previous Service Desk Server Port field.
- **Service Desk Admin Username**
  The user name of the CA Service Desk Manager server administrator.
- **Service Desk Admin Password**
  The password of the CA Service Desk Manager server administrator.

  NOTE
  OneClick clients that are running when you make configuration changes on this page do not reflect the changes. To resolve this problem, restart any active OneClick clients. If you change to a different CA Service Desk Manager server, restart the tomcat server for the changes to take effect.

4. Click Test to verify the connection between the CA Service Desk Manager server and OneClick.

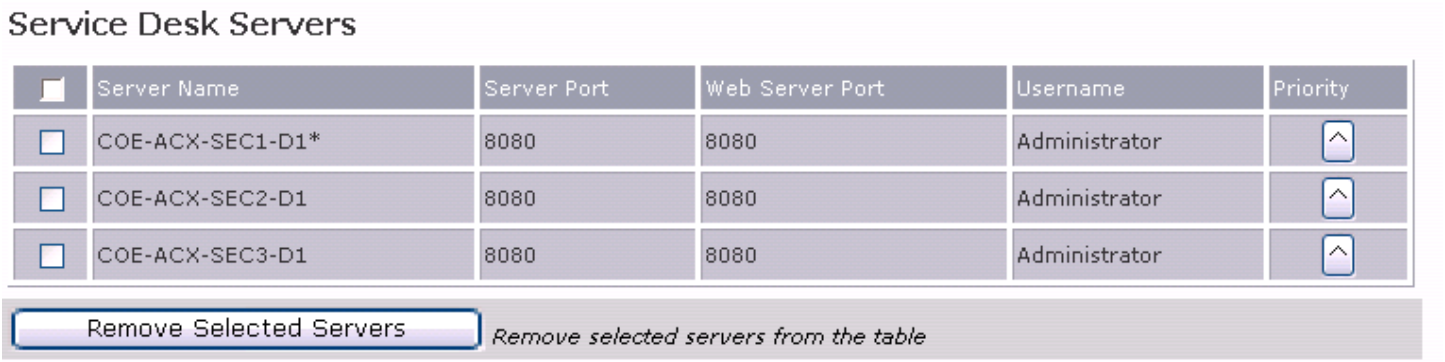
A successful test displays the following information:

```
Successfully connected to Service Desk web services and interface on server Service Desk Manager Server Name.
```

5. Click Add/Modify Server to add these settings to the Service Desk Manager Server table.

The server is added to the Service Desk Servers table.

NOTE
The settings are not saved until you click Save.



The table in this image displays all CA Service Desk servers that have been configured for this integration. The asterisk (*) indicates the connection that is currently in use.

6. Click Save to save these settings.

7. To add another Service Desk Manager server, specify the server details, click Add/Modify Server, and then click Save.

8. You can perform the following tasks from the Service Desk Servers table:

- Edit an existing Service Desk Manager Server by taking the following steps:
  a. Select the server to modify by highlighting the row in the table.

  NOTE
  Do not use the check boxes for the Modify operation.
- To test a server that has already been added, click that row in the server list, specify a password, and click the Test button.
- To increase the priority of a CA Service Desk Manager server, click the up arrow icon to move the server up by one row in the table. Connections are tried in the order that the servers appear in the table. Click Save.
- To remove a CA Service Desk Manager server, select the server, click 'Remove Selected Servers', and then click Save.

9. Supply values for the following additional fields:

- **SSL Support**
  Select the Enabled option to enable SSL.
- **Specify Reported By Field**
  Select Yes to include the submitting user in the Reported By field when you manually submit Request, Incident and Problem tickets.

  NOTE
  Modifications are required on the CA Service Desk Manager server for this feature to function correctly. For more information, see Configure CA Service Desk Duplication Handling.
- **Assign Assets/Configuration Items**
  If enabled, lets you associate assets with the CA Service Desk tickets from OneClick.

- **Reload Asset/CI Mapping**
  When Assign Assets/Configuration Items are enabled, click this button if you have modified the Service Desk asset/CI mapping in service-desk-asset-mapping.xml and you want to apply the changes without restarting the OneClick server.

  NOTE
  The exception "Unable to start ServiceDeskAssetMapping: java.lang.NullPointerException" is logged in the stdout.log file at $SPECROOT\tomcat\logs when you start OneClick and the SpectroSERVER is inactive. This problem is resolved automatically as performs Service Desk Asset Mapping when the first Service Desk ticket is generated. For information on setting alarm types, see Choose DX NetOps Spectrum Alarm Types in OneClick for Automatic Ticket Creation.

10. Click Save. The following message appears:

```
Successfully saved configuration.
```

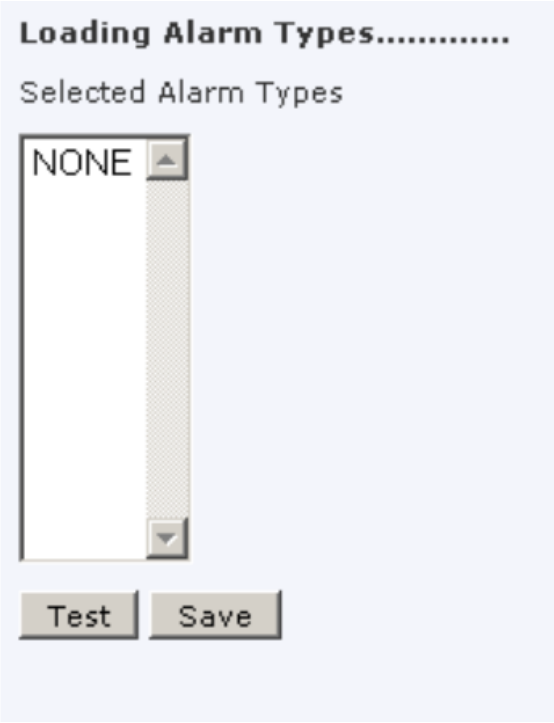
Select Alarm Types in OneClick for Automatic Ticket Creation

Configure the and CA Service Desk Manager integration to create CA Service Desk trouble tickets when generates alarms of certain types that you specify.

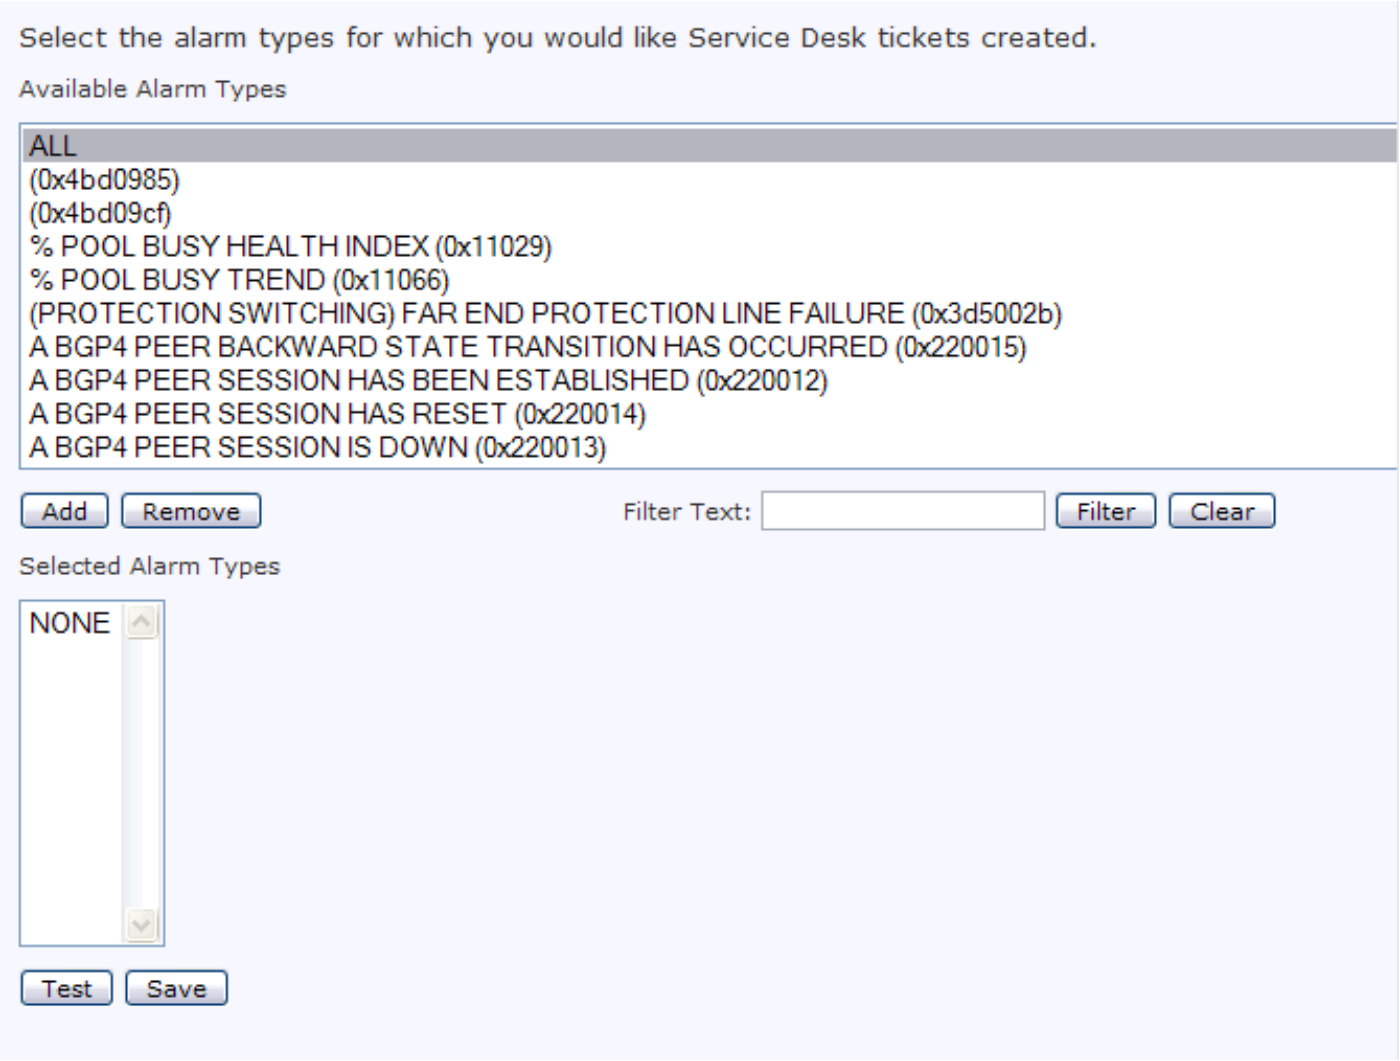
Note: Automatic ticket creation is an optional feature. Operators can instead create all tickets manually. By default, the integration does not automatically create tickets for any alarms.

Follow these steps:

1. Navigate to your OneClick Administration pages:
   `http://<oc> Web server/spectrum/admin/index.jsp`
2. Click the Service Desk Configuration link in the left panel of the Administration page. The Service Desk Configuration administration page opens.
3. Scroll to the bottom of the Service Desk Configuration administration page to the Alarm Types section. The first time that you open the Service Desk Configuration administration page and anytime the cache timeout (one hour) of the page expires, the “Loading Alarm Types” message is displayed as shown:



The available alarm types are displayed in the Available Alarm Types section of the Service Desk Configuration administration page:



4. In the Available Alarm Types section, select the alarms for which you want OneClick to create CA Service Desk tickets, and click Add.

   NOTE
   A delay can occur the first time you add alarm types. The delay occurs when all of the probable cause files are loaded for display in the Available Alarm Types section of the Service Desk Configuration administration page.

   To generate the CA Service Desk tickets for all alarms, select ALL from the Available Alarm Types list, and click Add.

   NOTE
   To select an individual alarm type, enter some text from the desired alarm type into the Filter Text field and click Filter.

5. Click Save when you have finished adding alarms.

Customizing Ticket Creation and Closure

Using Custom Ticket Creation Rules

Using custom ticket creation rules, you can extend the functionality of CA Service Desk Manager tickets. Custom rules are available for tickets that are created by DX NetOps Spectrum Alarm Notifier (SANM), or that are created manually through the OneClick interface. You can add contacts to CA Service Desk Manager or problem types to the SPECTRUM_POLICY Web Services Policy. Tickets that DX NetOps Spectrum creates can then use different templates or can be assigned to different end-users.

Set up custom ticket creation rules to notify the right person who must respond to an alarm. Apply a template with the required information to help IT staff resolve the issue more quickly.

With custom rules, the problem type or affected end user that is assigned to a CA Service Desk ticket is based on information from DX NetOps Spectrum. The following parameters can be used to determine the assignment:

- Alarm attribute
- Model attribute
- Model association

The CA Service Desk tickets that DX NetOps Spectrum creates use default settings if they are not associated with any of the ticket creation rules. These tickets use the following defaults, which are defined for the SPECTRUM_POLICY Web Services Policy:

- Default problem type (error type) (SPECTRUM_PT)
- Default end-user (DX NetOps Spectrum).

Add a Ticket Creation Rule

By editing the ticket configuration file (service-desk-ticket-config.xml), you can customize how the CA Service Desk tickets are created from DX NetOps Spectrum. You can add a ticket creation rule that is based on any attribute of the DX NetOps Spectrum alarm, any attribute of the DX NetOps Spectrum model, or any association of the DX NetOps Spectrum model.

Any attribute of the DX NetOps Spectrum alarm, any attribute of the DX NetOps Spectrum model, or any association of the DX NetOps Spectrum model can have a certain problem type, affected end user, or both, assigned to the ticket in CA Service Desk Manager. Creating CA Service Desk tickets that are based on custom ticket creation rules enhances the ability of the CA Service Desk Manager user to troubleshoot issues.

Follow these steps:

1. Copy the service-desk-ticket-config.xml and service-desk-ticket-config.xsd files from <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/svdsk/config to <*$SPECROOT*>/custom/svdsk/config.
2. Open the service-desk-ticket-config.xml file in a text editor.
3. Create an <sd-ticket> element inside the <service-desk-ticket-config> element for each rule that you want to define. Follow the instructions that are provided in the XML file.
   You can create rules that are based on the following information:
   - Alarm attribute
   - Model attribute
   - Model association

   For each rule, you can specify a problem type, a user ID, or both -- at least one of these attributes must be provided for each rule.

   NOTE
   If an alarm is generated for a model where multiple ticket creation rules can be applied, the rules that are defined earliest in the XML file take precedence over the rules that follow.
4. Save the file.
   Your ticket creation rules are added to CA Service Desk Manager.
5. Click the Reload Ticket Rules button that exists on the OneClick Administration page for the CA Service Desk Manager integration.

Your custom rules are applied, and CA Service Desk tickets that are created from DX NetOps Spectrum use your custom creation rules.

NOTE
If you restart Tomcat, the custom rules are applied automatically.

Examples: Create a Ticket Creation Rule Based on Alarm Attribute

The following examples show three ticket creation rules that are based on alarm attribute (alarm code). These examples demonstrate how to specify a problem type, a user ID, and both, respectively. For these examples, the SPECTRUM_MGT_PT is a problem type added to the SPECTRUM_POLICY Web Services Policy, and northeast_IT is the system name of a contact in CA Service Desk Manager.

```
<sd-ticket>
   <alarm-attribute>
    <attr-id>0x11f50</attr-id> <!-- attribute ID for alarm code -->
    <value>0x10701</value> <!-- alarm code attribute value -->
   </alarm-attribute>
   <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
</sd-ticket>
<sd-ticket>
  <alarm-attribute>
    <attr-id>0x11f50</attr-id> <!-- attribute ID for alarm code -->
    <value>0x119d3</value> <!-- alarm code attribute value -->
  </alarm-attribute>
  <sd-userid>northeast_IT</sd-userid>
</sd-ticket>
<sd-ticket>
  <alarm-attribute>
    <attr-id>0x11f50</attr-id> <!-- attribute ID for alarm code -->
    <value>0x10306</value> <!-- alarm code attribute value -->
  </alarm-attribute>
  <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
  <sd-userid>northeast_IT</sd-userid>
</sd-ticket>
```

Examples: Create a Ticket Creation Rule Based on Model Attribute

The following examples show three ticket creation rules that are based on model attribute (model handle). These examples demonstrate how to specify a problem type, a user ID, and both, respectively. For these examples, the SPECTRUM_MGT_PT is a problem type added to the SPECTRUM_POLICY Web Services Policy, and northeast_IT is the system name of a contact in CA Service Desk Manager.

```
<sd-ticket>
  <model-attribute>
    <attr-id>0x129fa</attr-id> <!-- attribute ID for model handle -->
    <value>0x1000d5</value> <!-- model handle attribute value -->
  </model-attribute>
  <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
</sd-ticket>
<sd-ticket>
  <model-attribute>
    <attr-id>0x129fa</attr-id> <!-- attribute ID for model handle -->
    <value>0x100012</value> <!-- model handle attribute value -->
  </model-attribute>
  <sd-userid>northeast_IT</sd-userid>
```

```
</sd-ticket>
<sd-ticket>
  <model-attribute>
    <attr-id>0x129fa</attr-id> <!-- attribute ID for model handle -->
    <value>0x100023</value> <!-- model handle attribute value -->
  </model-attribute>
  <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
<sd-userid>northeast_IT</sd-userid>
</sd-ticket>
```

Examples: Create a Ticket Creation Rule Based on Model Association

The following examples show three ticket creation rules that are based on model association (models dynamically collected by a global collection named 'switch routers collection', models that are monitored by the service container 'northeast service container', or models connecting to another model named 'northeast firewall'). These examples demonstrate how to specify a problem type, a user ID, and both, respectively. For these examples, the SPECTRUM_MGT_PT is a problem type added to the SPECTRUM_POLICY Web Services Policy, and northeast_IT is the system name of a contact in CA Service Desk Manager.

```
<sd-ticket>
  <model-association>
    <relation>0x1003a</relation> <!-- the relation ID for dynamicGlobalCollects -->
    <left-model-name>switch routers collection</left-model-name> <!-- model name of the lhs -->
   </model-association>
  <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
</sd-ticket>
<sd-ticket>
  <model-association>
    <relation>0x4500004</relation> <!-- the relation ID for SlmMonitors -->
    <left-model-name>northeast service container</left-model-name> <!-- model name of the lhs -->
   </model-association>
  <sd-userid>northeast_IT</sd-userid>
</sd-ticket>
<sd-ticket>
  <model-association>
    <relation>0x10005</relation> <!-- the relation ID for Connects_to -->
    <right-model-name>northeast firewall</right-model-name> <!-- model name of the rhs -->
   </model-association>
  <sd-problem-type>SPECTRUM_MGT_PT</sd-problem-type>
  <sd-userid>northeast_IT</sd-userid>
</sd-ticket>
```

Using the CA Service Desk Duplicate Handling Feature

CA Service Desk Manager provides the duplication handling for scenarios where multiple tickets are created with the same underlying cause within a specified amount of time. To take advantage of this feature, make the following modifications to both the CA Service Desk Manager server and the OneClick server.

The following actions serve as a checklist for enabling this feature:

- Configure the CA Service Desk Manager server to support DX NetOps Spectrum use of this feature. For more information, see Configure CA Service Desk Duplicate Handling Feature.
- Modify the OneClick server to disable automatic closing of tickets when the associated alarm is cleared. For more information, see Disable Automatic Closing of Ticket.
- Make sure that the error type specifies the appropriate duplicate handling action. For more information, see Create a CA Service Desk Web Services Policy and Problem Type (Error Type) for DX NetOps Spectrum.

  NOTE
  If the Error Type has already been created, you can edit the Error Type directly.
- Include the Reported By value when manually creating tickets. See the description of the 'Specify Reported By Field' in Configure Communication and Enable Integration on the OneClick Server.

Disable Automatic Ticket Closure

To use the CA Service Desk Duplicate Handling feature, disable automatic closing of tickets when the associated alarm is cleared. Otherwise, when tickets are closed automatically, duplicate handling does not occur because the ticket is closed before a new ticket request is received.

Follow these steps:

1. Shut down your Tomcat server if it is running.
2. Open the following file in a text editor:
   ```
   <$SPECROOT>/custom/svdsk/config/service-desk-config.xml
   ```

   NOTE
   This file is created after you have configured your OneClick server for integration with CA Service Desk Manager. If this file does not exist, open the following file instead:

   ```
   <$SPECROOT>/tomcat/webapps/spectrum/WEB-INF/svdsk/config/service-desk-config.xml
   ```
3. Remove the following lines:
   ```
   <handler-action>
    <action-tag>service-desk-clear</action-tag>
    <action-class>com.aprisma.spectrum.app.sd.handler.ServiceDeskClearAction</action-class>
   </handler-action>
   <alarm-handler-clear-action>
    <service-desk-clear />
   </alarm-handler-clear-action>
   ```
4. Save and close the file.
5. Restart the Tomcat server.

Configure Ticket Status

When an alarm is cleared in DX NetOps Spectrum, the ticket status in CA Service Desk Manager is updated to "Closed" status by default. You can change the status of the ticket in a DX NetOps Spectrum configuration file.

CA Service Desk tickets are created when an alarm is raised in DX NetOps Spectrum, and when it is cleared, Service Desk tickets for alarms that are cleared are set to the status that is defined in the file 'service-desk-config.xml'. If nothing is defined in that configuration file, the default status, “Closed” (CL), is used.

WARNING
Be sure to verify the code of the status that you want to set. For example, RE is the Code for the status “Resolved”; CL is the code for the status “Closed”. If you specify an incorrect code, the CA Service Desk tickets are not updated. They remain open, even after the corresponding alarm is cleared in DX NetOps Spectrum.

Follow these steps:

1. Log in to the OneClick server.
2. Open the following file in a text editor:
   `<$SPECROOT>/custom/svdsk/config/service-desk-config.xml`

   NOTE
   This file is created after you have configured your OneClick server for integration with CA Service Desk Manager.
3. Perform a search for the “ticket-status” tag.
4. If “ticket-status” is not found, add the following tag:
   `<ticket-status>RE</ticket-status>`

   NOTE
   RE is the Code for the Resolved status in CA Service Desk.
5. If the <ticket-status /> tag is present, replace it with the following tag:
   `<ticket-status>RE</ticket-status>`
6. Save the service-desk-config.xml file.
7. Navigate to the OneClick Administration pages.
8. Click the Service Desk Configuration link from the left panel of the Administration page.
   The Service Desk Configuration administration page opens.
9. Click Save.
   The changes to the XML can now take effect. When an alarm is cleared in DX NetOps Spectrum, the ticket status in CA Service Desk Manager is updated to "Resolved" status.

   NOTE
   You can instruct DX NetOps Spectrum to clear the alarm when you update the corresponding ticket status to “Resolved” in CA Service Desk Manager. For more information, see Example: Using Custom Keywords for CA Service Desk Notifications.

Reset Ticket Status to Default Settings

If you have customized the settings that determine the ticket status of CA Service Desk tickets, you can revert these changes. To reset ticket status to the out-of-the-box setting, edit the same configuration file that you used to select a custom status.

1. Follow these steps:
2. Log in to the OneClick server.
3. Open the following file in a text editor:
   `$SPECROOT/custom/svdsk/config/service-desk-config.xml`
4. Perform a search for the “ticket-status” tag.
5. Replace the complete tag (<ticket-status>RE</ticket-status>) with the following tag:
   `<ticket-status />.`
6. Save the service-desk-config.xml file.
7. Navigate to the OneClick Administration pages.
8. Click the Service Desk Configuration link from the left panel of the Administration page.
   The Service Desk Configuration administration page opens.
9. Click Save.
   The changes to the XML can now take effect. Ticket settings are restored to their defaults.

Configure Ticket Summary

When a ticket is created in CA Service Desk Manager for an alarm in DX NetOps Spectrum, the Originating Event or Cause Code text in the Summary field of the ticket is populated automatically. You can customize the text that is used to populate the Summary field by modifying a DX NetOps Spectrum configuration file.

When an alarm is raised in DX NetOps Spectrum, a ticket is created in CA Service Desk Manager. The Summary field of the ticket is populated with the Originating Event text or Cause Code that is defined in the 'service-desk-config.xml' file.

> **WARNING**
> If nothing is configured for this parameter, or if an incorrect attribute is supplied, the Summary field is not updated. CA Service Desk Manager supplies the default Description text in the Summary field.

Follow these steps:

1. Log in to the OneClick server.
2. Open the following file in a text editor:
   ```
   $SPECROOT/custom/svdsk/config/service-desk-config.xml
   ```
   > **NOTE**
   > This file is created after you have configured your OneClick server for integration with CA Service Desk Manager.
3. Perform a search for the “ticket-summary” tag.
4. If “ticket-summary” is not found, add *one* of the following tags:
   - Originating Event :
     ```
     <ticket-summary>0x1296e</ticket-summary>
     ```
   - Cause Code :
     ```
     <ticket-summary>0x11f50</ticket-summary>
     ```
     > **NOTE**
     > Only the Originating Event or Cause code text in the Summary field of the CA Service Desk ticket can be customized. The above identifiers include the corresponding required attribute IDs.
5. If "ticket-summary" is found, replace the existing tag with one of the tags that are supplied in the previous step.
6. Save the service-desk-config.xml file.
7. Navigate to the OneClick Administration pages.
8. Click the Service Desk Configuration link from the left panel of the Administration page.
   The Service Desk Configuration administration page opens.
9. Click Save.
   The changes to the XML can now take effect. The Summary field of each CA Service Desk ticket that is initiated by a DX NetOps Spectrum alert is populated with the Originating Event text or Cause Code that you specified.

Reset Ticket Summary to Default Settings

If you have customized the settings that determine the summary text that appears in CA Service Desk tickets, you can revert these changes. To reset ticket summary to the out-of-the-box setting, edit the same configuration file that you used to select a custom summary.

1. Follow these steps:
2. Log in to the OneClick server.
3. Open the following file in a text editor:
   ```
   $SPECROOT/custom/svdsk/config/service-desk-config.xml
   ```
4. Perform a search for the “ticket-summary” tag.
5. Replace the complete tag with the following tag:
   ```
   < ticket-summary />
   ```

6. Save the file.
7. Navigate to the OneClick Administration pages.
8. Click the Service Desk Configuration link from the left panel of the Administration page.
   The Service Desk Configuration administration page opens.
9. Click Save.
   The changes to the XML can now take effect. Ticket settings are restored to their defaults.

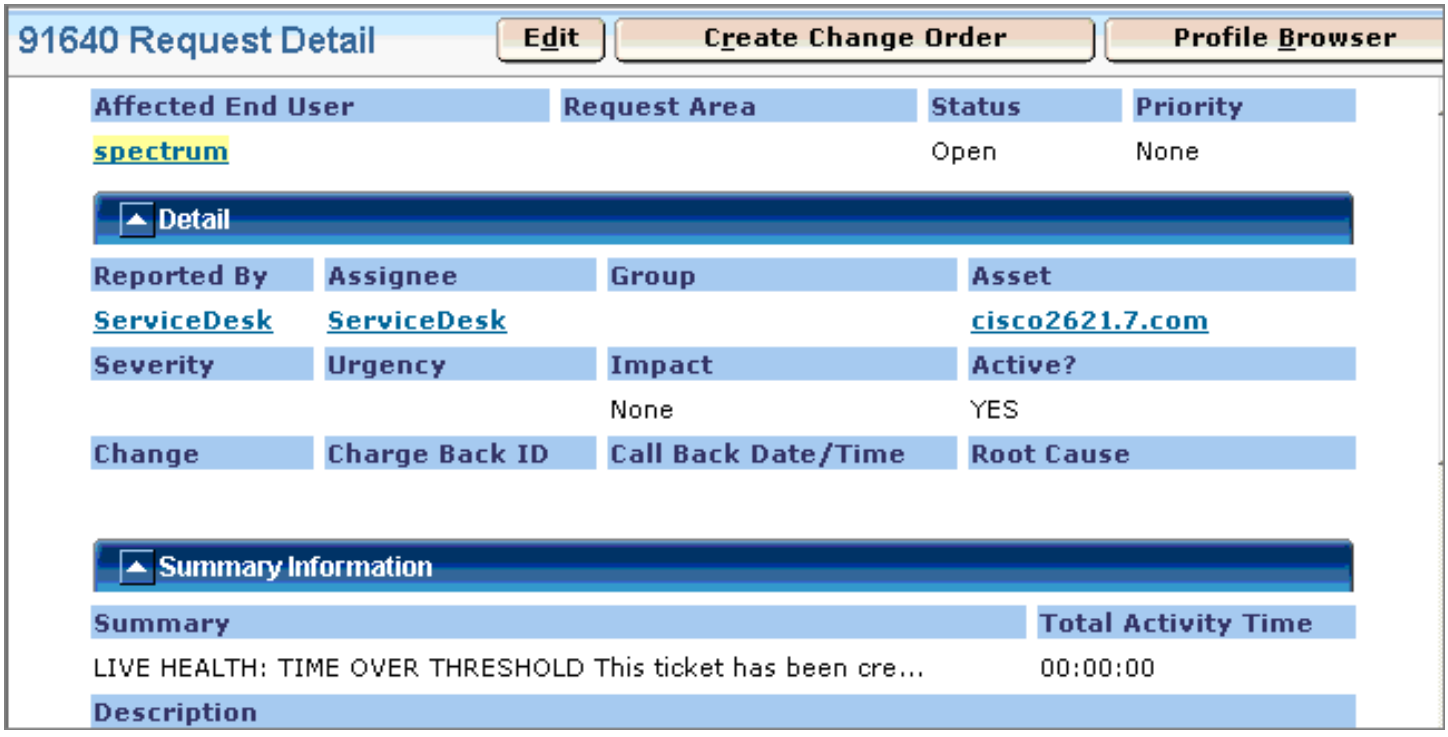
About Asset Assignment

You can configure the DX NetOps Spectrum and CA Service Desk Manager integration to assign an asset to a ticket submitted from OneClick. Automatically assigning assets to a service ticket helps CA Service Desk Manager users to work efficiently. Through a single click in CA Service Desk Manager, these users can view details about the device responsible for submitting the ticket, such as device attributes and a list of other tickets that are submitted for the same device. Assign an asset to the ticket so that the CA Service Desk Manager user can see that multiple trouble tickets are open for the same device.

When this option is enabled, only DX NetOps Spectrum device model types (0x1004b) or a port of a DX NetOps Spectrum device model type assigns assets to trouble tickets. Assets are assigned to a DX NetOps Spectrum device model type only when it, or one of its ports, submits a trouble ticket. DX NetOps Spectrum does not attempt to find or create an asset for a DX NetOps Spectrum device model before submitting a trouble ticket.

NOTE
You can still submit trouble tickets for other DX NetOps Spectrum model types, but no asset is assigned to them.

When OneClick submits a trouble ticket with an assigned asset, a CA Service Desk Manager user sees the Asset field that is populated with a link in the information about the trouble ticket, as shown:



When you click the linked device in the Asset field, details about the asset appear.

Assigning Assets in CA Service Desk Manager

This section describes asset assignment in CA Service Desk Manager. If CA Service Desk Manager is configured to run in ITIL mode, substitute the word “asset” with “configuration item” or “CI” throughout this section.

How Assets are Added to CA Service Desk Tickets

Assign an asset to a trouble ticket, which the DX NetOps Spectrum submits. Once the asset assignment is enabled, device details are accessible from the CA Service Desk trouble tickets that are submitted by DX NetOps Spectrum. The details that are provided after creating a trouble ticket vary, depending on the information available in DX NetOps Spectrum. Determine how the assets are added to trouble tickets to understand what to expect in the CA Service Desk tickets. If necessary, troubleshoot communication issues between CA Service Desk Manager and DX NetOps Spectrum.

Assets are added to CA Service Desk tickets according to the following workflow:

1. An alarm that is generated by a device model submits a trouble ticket to CA Service Desk Manager.
2. The ServiceDesk_Asset_ID attribute of the DX NetOps Spectrum device model is read.
3. If the ServiceDesk_Asset_ID attribute is not set for the DX NetOps Spectrum device model, a web service call to CA Service Desk is made to search for an asset that matches the device model.
   - If an asset is found, its identifier is returned to DX NetOps Spectrum and is written to the ServiceDesk_Asset_ID attribute of the device model.
   - If no match is found in CA Service Desk Manager, an asset that represents the DX NetOps Spectrum device model is created in CA Service Desk Manager. The identifier of the asset is returned to DX NetOps Spectrum and written to the ServiceDesk_Asset_ID attribute of the device model. As a result, future alarms on the model do not require additional web service calls to locate the asset.
4. The trouble ticket is created in CA Service Desk Manager using the asset identifier. This identifier is used in the future when creating trouble tickets for the same device.

Assign Assets in CA Service Desk Tickets

Assign the assets in the CA Service Desk tickets that OneClick creates. Once the asset assignment is enabled, device details are accessible from the CA Service Desk trouble tickets that DX NetOps Spectrum submits. Automatically assigning assets to a service ticket helps CA Service Desk Manager users perform efficient troubleshooting.

Follow these steps:

1. Navigate to the OneClick Administration pages:
   ```
   http://<oc> Web server/spectrum/admin/index.jsp
   ```
2. Click the Service Desk Configuration link from the left panel of the Administration pages.
   The Service Desk Configuration administration page opens.
3. Select the Enabled option in the Assign Assets/Configuration Items field.
4. Click Save.
   The following message appears:
   ```
   Successfully saved configuration to the service-desk-config.xml file.
   ```
   Assets are assigned with the CA Service Desk tickets that are submitted from DX NetOps Spectrum.

How Asset Details are Created in CA Service Desk Manager

Once the asset assignment is enabled, device details are accessible from the CA Service Desk trouble tickets submitted by DX NetOps Spectrum. The details provided upon creating a trouble ticket vary, depending on the information available in DX NetOps Spectrum. Knowing how asset information is gathered before adding them to trouble tickets can help you understand what to expect in the CA Service Desk tickets.

The process for creating asset details in CA Service Desk Manager can be customized. However, the following process explains the default method for locating and creating asset details in CA Service Desk Manager:

1. To locate the device details, DX NetOps Spectrum searches for the Model_Name of the device model, MAC_Address, and sysName attributes. It matches them to the name of the CA Service Desk asset, mac_address, and system_name attributes, respectively.

   NOTE
   If a device model attribute that is defined in the search has no value, it is excluded from the asset query.
2. To create an asset in CA Service Desk Manager for a DX NetOps Spectrum device model, DX NetOps Spectrum and CA Service Desk Manager perform the following steps:
   – DX NetOps Spectrum writes the Model_Name of the device model, Network_Address, MAC_Address, Serial_Number, and sysName attributes to the name of the CA Service Desk asset, alarm_id, mac_address, serial_number, and system_name fields, respectively.
   – CA Service Desk Manager uses "Discovered Hardware" for the asset class and "Device asset" for the asset description.

   NOTE
   If the model attribute defined in mapping has no value, the corresponding asset field is assigned an empty (blank) value.

Clear the Asset ID from All DX NetOps Spectrum Models

Clear out the ServiceDesk_Asset_ID attribute (0x12db9) for each device model. You can then search for and recreate assets in CA Service Desk Manager. For example, if you switch CA Service Desk Manager databases, these values must be repopulated to enable the integration with DX NetOps Spectrum. Clear this attribute by using the Attribute Editor in DX NetOps Spectrum or by using the DX NetOps Spectrum Command Line Interface (CLI). Using the CLI lets you create scripts to automate this procedure.

Follow these steps:

1. Connect to the CLI.
2. Run the following command on each device model that has the attribute set:

   ```
   update mh=<device model handle> attr=0x12db9,val=
   ```

   The ServiceDesk_Asset_ID attribute is cleared.

   NOTE

   For more information about the CLI, see the Command Line Interface section.

How to Customize Asset Assignment

By editing the asset mapping file, you can customize how CA Service Desk Manager assets from OneClick are found and created. Customization can help CA Service Desk Manager users to troubleshoot issues efficiently.

To change the attribute mapping between DX NetOps Spectrum models and CA Service Desk Manager assets, perform the following tasks:

1. Copy the service-desk-asset-mapping.xml and service-desk-asset-mapping.xsd files from *$SPECROOT*/tomcat/webapps/spectrum/WEB-INF/svdsk/config to *$SPECROOT/custom/svdsk/config.*
2. Modify the copy of the service-desk-asset-mapping.xml file, located in *$SPECROOT/custom/svdsk/config.*
   The XML file includes <asset> elements. An <asset> element defines the asset mapping for a DX NetOps Spectrum model type that is defined in the mtype_h attribute of the element. Each <asset> element has a Default child element and multiple <constant> and <mapping> children.

3. Apply your mapping changes.

Edit the Asset Mapping XML File

To change the attribute mapping between DX NetOps Spectrum models and CA Service Desk Manager assets, edit the service-desk-asset-mapping.xml file. Editing the file changes how asset information is found and which information about each asset is provided to CA Service Desk Manager.

Follow these steps:

1. Open the service-desk-asset-mapping.xml file in a text editor.
2. Locate the mtype_h attribute for the asset information you want to modify.

   NOTE
   Only DX NetOps Spectrum device model types assign assets to trouble tickets, and the mtype_h attribute for the device model type is "0x1004b."
3. Create an asset query by modifying the Default parameters.
4. Define the asset mapping for the asset creation. Modify the <constant> and <mapping> attributes of the selected asset.
   Note: When creating an asset, the name and class attributes are always required. Additionally, specify any other asset attributes that are stored in the "nr Object" in CA Service Desk Manager. For a complete list of attributes that are defined in the "nr Object," see the CA Service Desk Manager section.
   The information to be recorded in the CA Service Desk trouble ticket is defined.
5. Save the file.
   Your asset mapping file edits are complete.

   NOTE
   Your changes do not go into effect immediately. Apply the changes in DX NetOps Spectrum after your modifications are complete.

Customize Asset Search and Assignment

The service-desk-asset-mapping.xml file is used to customize how asset attributes are mapped between DX NetOps Spectrum models and CA Service Desk assets. You can troubleshoot issues with the help of this customization.

The XML file is located in the *$SPECROOT*/tomcat/webapps/spectrum/WEB-INF/svdsk/config folder of any OneClick server. This file includes <asset> elements. Each <asset> element has a Default child element and multiple <constant> and <mapping> children. The following sections describe the XML syntax, Elements, and Notes that are required to customize asset search and assignment.

XML Syntax

The XML file has the following basic syntax:

```
- <asset mtype_h="asset_ID">
  - <search>
    - <and>
      - <equals>
        <sd-attribute>SD_name</sd-attribute>
        <model-attribute>SPEC_name_attribute</model-attribute>
        </equals>
      - <equals>
        <sd-attribute>SD_name2</sd-attribute>
        <model-attribute>SPEC_name_attribute2</model-attribute>
        </equals>
      </and>
    </search>
```

```
 - <constant>
  <sd-attribute>constant</sd-attribute>
  <value>constant_value</value>
  </constant>
- <mapping>
  <sd-attribute>mapping_name</sd-attribute>
  <model-attribute>mapping_name_attribute</model-attribute>
  </mapping>
</asset>
```

Elements

The XML file syntax includes the following elements:

- **<asset mtype_h="*asset_ID*">**
  Defines the asset mapping for a DX NetOps Spectrum model type that is defined in the mtype_h attribute (*asset_ID*) of an element. The only supported <asset> element is for the device model type, which is "0x1004b." This element includes the following child elements:
  - Default
  - <constant>
  - <mapping>

  Example: <asset mtype_h="0x1004b">
- **Default**
  Defines the query to locate an asset in CA Service Desk for the DX NetOps Spectrum model. In this element you can define and, or, and equals logic to your asset query by embedding the <and>, <or>, and <equals> child elements respectively. The Default element can contain multiple child elements. Their hierarchy determines the order of operations and placing parenthesis around logical elements when required.
  - **<and>**
    Indicates that this attribute is required when searching for an asset match between CA Service Desk Manager and DX NetOps Spectrum. The <and> element appears between the child elements of the Default element.
  - **<or>**
    Indicates that this attribute is optional when searching for an asset match between CA Service Desk Manager and DX NetOps Spectrum. The <or> element appears between the child elements of the Default element.
  - **<equals>**
    Defines the CA Service Desk Manager and DX NetOps Spectrum attribute mapping for your search. Each <equals> relationship that you define must include the following child elements:
    - <sd-attribute>*SD_name*</sd-attribute> -- Defines that asset attribute (*SD_name*) for which the query searches. You can use any asset attribute that is defined in the "nr Object" in CA Service Desk Manager for your asset query.
    - <model-attribute>*SPEC_name_attribute*</model-attribute> -- Defines the model attribute (*SPEC_name_attribute*) text to match when searching.

      NOTE
      If a model attribute is not set, the parameter is not used in the query. You can verify the complete list of *nr Object* attributes that is available. For more information, see the CA Service Desk Manager section.
- **<constant>**
  Assigns a specified value (*constant_value*) to the asset attribute (*constant*) when creating an asset, regardless of the attribute values of the model. You can define multiple <constant> rules for the asset creation. Each <constant> element that you define must include the following child elements:
  - <sd-attribute>*constant*</sd-attribute>
  - <value>*constant_value*</value>
- **<mapping>**

Assigns the value of the model specified attribute (*mapping_name_attribute*) to the specified asset attribute (*mapping_name*) when creating an asset. You can define multiple <mapping> rules for asset creation, but they must appear after all <constant> rules. Each <mapping> element includes the following child elements:

- <sd-attribute>*mapping_name*</sd-attribute>
- <model-attribute>*mapping_name_attribute*</model-attribute>

Notes

When creating an asset, the name and class attributes are always required. In addition, you can specify any other asset attributes that are stored in the "nr Object" in CA Service Desk Manager. For example, you can include the following CA Service Desk attributes in the <sd-attribute> element:

- **class**
  (Required) Determines the asset class in CA Service Desk Manager. The asset class must exist before creating an asset.
- **name**
  (Required) Defines the asset name.
- **description**
  Sets the Notes section text.
- **alarm_id**
  Defines the IP address of the asset.
- **mac_address**
  Defines the MAC address of the asset.
- **serial_number**
  Defines the serial number of the asset.
- **system_name**
  Defines the hostname of the asset.

OneClick does not create objects in CA Service Desk tables besides the nr Object. Therefore, certain attributes that are references to other objects (such as the vendor) must be created manually in CA Service Desk Manager. The object identifier is then used to assign each attribute an asset mapping. For a complete list of nr Object attributes, see the CA Service Desk Manager section.

NOTE
You can use DX NetOps Spectrum search criteria to identify the existing asset. If a search fails to find the asset with the given search criteria, it results in a "No match found" message. A new asset ID is created based on the specified parameters. However, if you change the properties, such as host name, serial number, MAC address, DNS name, or asset label, DX NetOps Spectrum does not create a new asset ID. For more information, see Asset Matching Logic and About Asset Assignment.

Example: Create a Custom Asset Query

This example shows how to locate an asset in CA Service Desk Manager that has a name attribute matching the model name, or an alarm_id attribute matching the model network address (IP address) and a mac_address attribute that matches the model MAC address. The logic here can be represented in the following logical statement:

```
(name='<MODEL_NAME>') OR
(
(alarm_id='<NETWORK_ADDRESS>') AND
(mac_address='<MAC_ADDRESS>')
)
```

Given that the <MODEL_NAME>, <NETWORK_ADDRESS>, and <MAC_ADDRESS> model attributes are 0x1006e, 0x1027f, and 0x110df respectively, modify the Default element for the asset as follows:

```
<search>
  <or>
```

```
    <equals>
      <sd-attribute>name</sd-attribute>
      <model-attribute>0x1006e</model-attribute>
    </equals>
    <and>
      <equals>
        <sd-attribute>alarm_id</sd-attribute>
        <model-attribute>0x1027f</model-attribute>
      </equals>
      <equals>
        <sd-attribute>mac_address</sd-attribute>
        <model-attribute>0x110df</model-attribute>
      </equals>
    </and
  </or>
</search>
```

Example: Create a Custom Attribute Mapping for Asset Creation

In this example, you want all device model types in DX NetOps Spectrum to assign the model attributes MODEL_NAME and MAC_ADDRESS to asset attribute names and a mac_address, respectively. You also want to assign each asset description to read "Device modeled by SPECTRUM OneClick." And you want the class to be "SPECTRUM Device" (previously created manually in CA Service Desk Manager and defined as cr:9).

The following code shows how to configure these parameters by defining two <constant> and two <mapping> elements to the device model asset mapping. Assume that the model attributes for MODEL_NAME and MAC_ADDRESS are 0x1006e and 0x110df, respectively:

```
<asset mtype_h="0x1004b">
  ...
  <constant>
    <sd-attribute>description</sd-attribute>
    <value>Device modeled by SPECTRUM <oc></value>
  </constant>
  <constant>
    <sd-attribute>class</sd-attribute>
    <value>cr:9</value>
  </constant>
  <mapping>
    <sd-attribute>name</sd-attribute>
    <model-attribute>0x1006e</model-attribute>
  </mapping>
  <mapping>
    <sd-attribute>mac_address</sd-attribute>
    <model-attribute>0x110df</model-attribute>
  </mapping>
</asset>
```

Asset Reporting Customization

When integrating CA Service Desk Manager and DX NetOps Spectrum, you can modify the behavior of finding and creating the CA Service Desk Manager assets. You can modify this behavior when creating a trouble ticket from OneClick. This customization is done by changing the attribute mapping between DX NetOps Spectrum models and CA Service Desk Manager assets.

Customizing the asset reporting lets you prioritize the information that is used to identify a device. You can determine which information to record within CA Service Desk Manager. Customization can enhance the efficiency and reporting capabilities of individual CA Service Desk Manager users.

Apply Asset Mapping Changes

When you modify the asset mapping file, your changes do not immediately take effect when you save the file. Apply the changes in DX NetOps Spectrum after your file modifications are complete. Restarting the OneClick clients is not required.

Follow these steps:

1. Navigate to the OneClick Administration pages:
   `http://<oc> Web server/spectrum/admin/index.jsp`
2. Click the Service Desk Configuration link from the left panel of the Administration pages.
   The Service Desk Configuration administration page opens.
3. Click the Reload Asset/CI Mapping button.
4. Click Save.
   The following message appears:
   `Successfully saved configuration to the service-desk-config.xml file.`
   Your asset mapping changes are now applied.

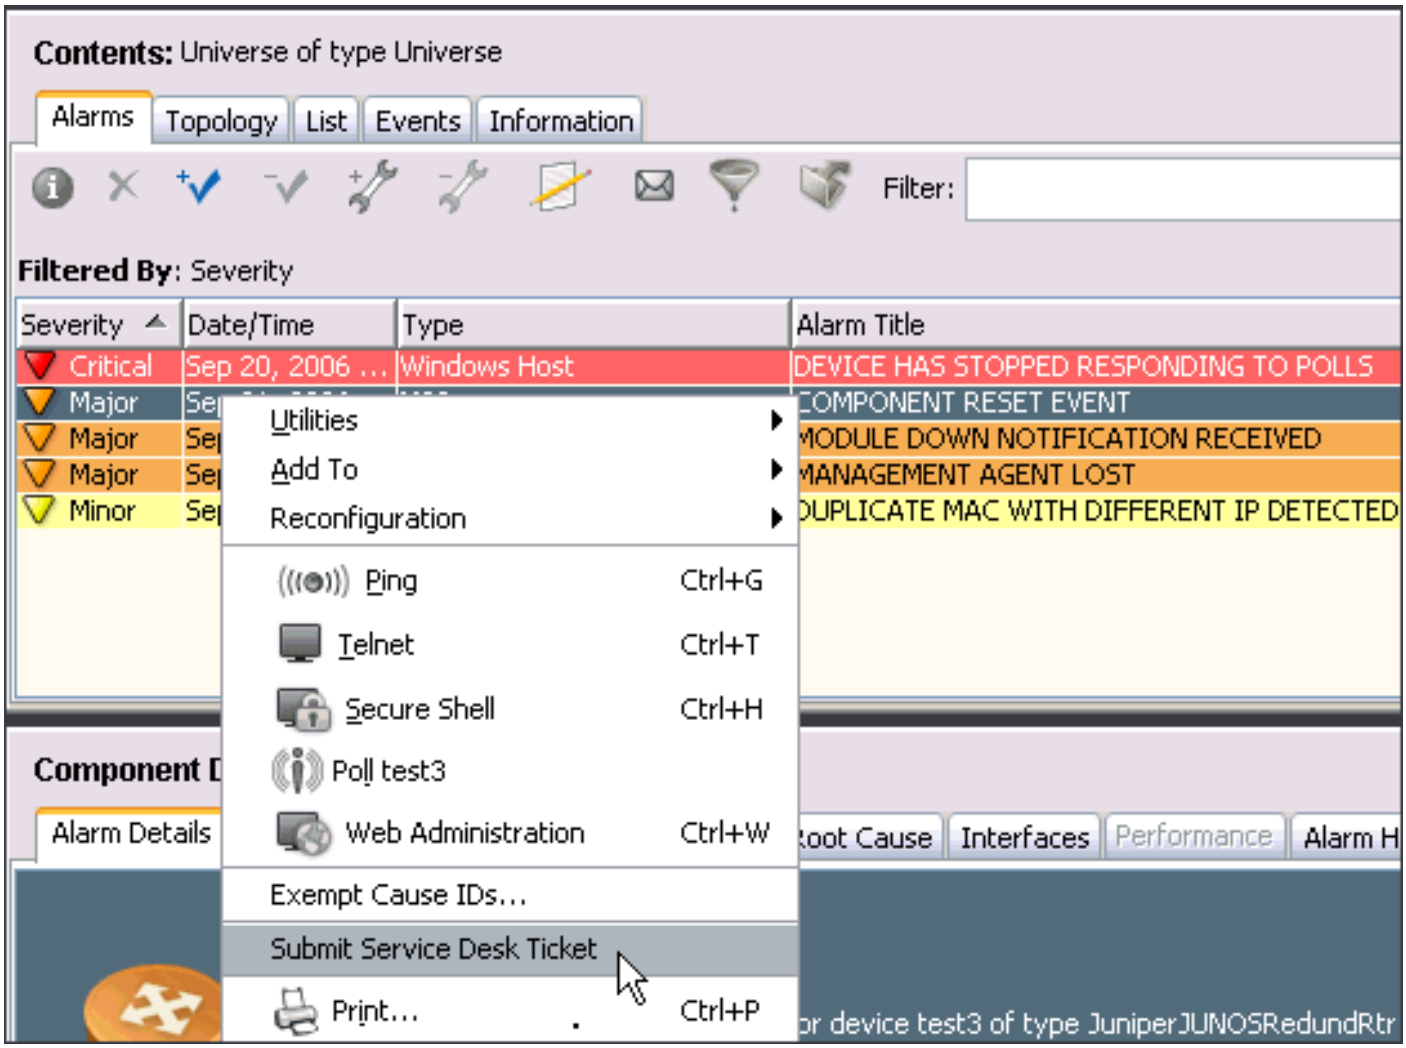
Using the Integration

Submit CA Service Desk Tickets from the OneClick Console Manually

You can manually create a CA Service Desk ticket from OneClick.

Follow these steps:

1. In the OneClick Console, right-click an alarm that you want to submit to CA Service Desk.
2. Select Submit Service Desk Ticket, as shown in the following figure. The ticket is sent to CA Service Desk Manager. The alarm is updated with the Service Desk Trouble Ticket ID. The ID provides a link from the DX NetOps Spectrum alarm back to the ticket in CA Service Desk Manager.



NOTE
After an alarm is submitted to CA Service Desk Manager, right-click the alarm. Select “Service Desk Ticket Information” to view the ticket details.

View CA Service Desk Tickets from the OneClick Console

After a CA Service Desk ticket is created for a DX NetOps Spectrum alarm, you can open the ticket in CA Service Desk Manager from within OneClick. Alarms that are associated with CA Service Desk Manager trouble tickets contain a trouble ticket ID link. Once an alarm has been submitted to CA Service Desk Manager, you can view detailed information about the ticket in OneClick.

Follow these steps:

1. In the OneClick Console, right-click an alarm that has an associated CA Service Desk ticket.
2. Select Service Desk Ticket Information. The Service Desk Request Detail window opens for that ticket ID.

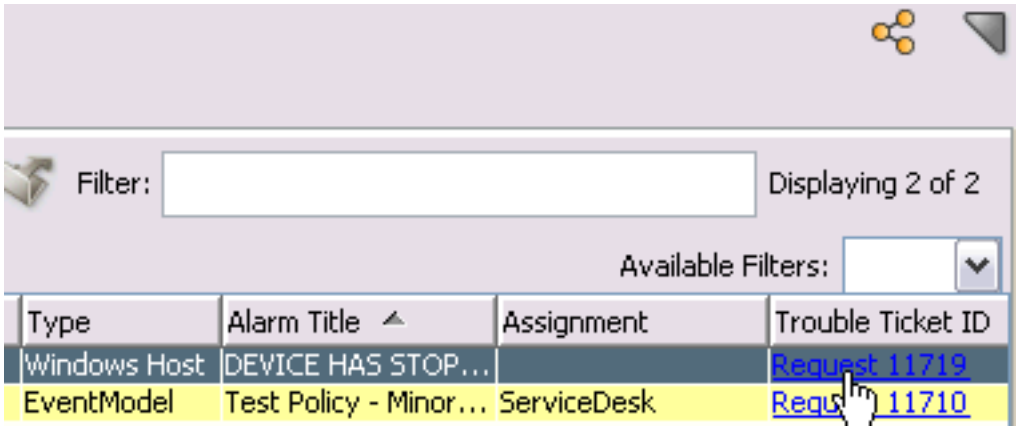
You can also view CA Service Desk tickets by adding the Trouble Ticket ID column to the OneClick Alarms tab view.

Follow these steps:

1. In the OneClick Console, locate an alarm with an existing CA Service Desk ticket.

2. Configure the OneClick client to display the Trouble Ticket ID column in the Alarms tab view as follows:
   a. Right-click the top of any column in the Alarms tab to launch the Table Preferences dialog.
   b. In the Columns tab of the dialog, select Trouble Ticket ID.
   c. Click OK.

   NOTE
   For more information about customizing columns, see Using OneClick.
3. Click the Trouble Ticket ID of the alarm in which you are interested.



The Service Desk Request Detail window opens for that ticket ID.

Using SANM with CA Service Desk Manager

This section provides instructions for configuring and using Alarm Notification Manager (SANM) with the and CA Service Desk Manager integration**.**

NOTE

This section assumes basic knowledge of the use of the AlarmNotifier and SANM functionality. For more information about SANM, see the Alarm Notification Manager section.

CA Service Desk Manager and SANM Overview

The Alarm Notification Manager (*SANM*) is a component that enhances the functionality of alarm-processing applications. You can take advantage of the SANM alarm filtering capabilities to configure the alarms that create CA Service Desk Manager trouble tickets. To enable this feature, deploy special Alarm Notifier scripts that create, clear, and update CA Service Desk Manager tickets. The following scripts let you customize alarm parameters:

- ServiceDeskSetScript
- ServiceDeskClearScript
- ServiceDeskUpdateScript

Best Practices for Automatic Trouble Ticket Creation Using OneClick or SANM

When deploying the CA Service Desk Manager integration, an important best practice is to configure alarm creation using only *one* of the following methods:

- Use the Selected Alarm Types filter in OneClick. To configure the Selected Alarm Types filter on the Service Desk Configuration Administration page to create alarms, take the following steps:
  a. Verify that the Alarm Notifier integration component for CA Service Desk Manager (SDNotifier) is not enabled.

b. Follow the instructions to select alarm types for which to create alarms.

- Configure the CA Service Desk Manager integration Alarm Notifier component and SANM to generate alarms. Take the following steps:
  a. Verify that the Selected Alarm Types filter of the Service Desk Configuration Administration page is set to NONE.
  b. Configure the SANM CA Service Desk integration component to generate CA Service Desk trouble tickets by completing these tasks:
     a. Configure the Alarm Notifier Integration component for CA Service Desk Manager.
     b. Configure SANM to create CA Service Desk tickets.

     WARNING
     When using SANM to generate trouble tickets, first set the Selected Alarm Types parameter on the Service Desk Configuration Administration page to NONE. Be sure to save the change.

If the and CA Service Desk Manager integration is configured to generate alarms using both of these methods, the integration can create unwanted, redundant trouble tickets.

Configuring the AlarmNotifier Integration Component for CA Service Desk Manager

The DX NetOps Spectrum and CA Service Desk Manager integration includes the Alarm Notification Manager support files that are required to configure the SANM functionality. These files are saved in the <*$SPECROOT*>/Notifier/ and <*$SPECROOT*>/Notifier/sd_notifier/ directories.

Follow these steps:

1. Copy the <*$SPECROOT*>/Notifier/AlarmNotifier.exe file to the <*$SPECROOT*>/Notifier/sd_notifier/ directory, renaming the file as <*$SPECROOT*>/Notifier/sd_notifier/SDNotifier.exe.

   NOTE
   The executable files that are referenced in this procedure (for example, SDNotifier) do not have an extension on Linux systems.
2. Copy the <*$SPECROOT*>/Notifier/.alarmrc file to the <*$SPECROOT*>/Notifier/sd_notifier/directory as .alarmrc.
3. In the <*$SPECROOT*>/Notifier/sd_notifier/.alarmrc file, modify the Set script, Clear script, and Update script entries to point to the CA Service Desk-specific scripts found in <*$SPECROOT*>/Notifier/sd_notifier. The actual scripts are named ServiceDeskSetScript, ServiceDeskClearScript, and ServiceDeskUpdateScript.

   NOTE
   Use caution and look for relative pathnames to these scripts. Verify that the pathnames point to the correct directory.
4. In the <*$SPECROOT*>/Notifier/sd_notifier/.alarmrc file, change the application name entry to 'SDNotifier'.
5. Run <*$SPECROOT*>/Notifier/sd_notifier/ServiceDeskIntegrationSetup.exe.
6. Run SDNotifier.exe.
7. Launch the SANM Policy Manager.
8. Create a policy that uses your preferred filters. For more information, see Alarm Notification Manager .
9. Create an application that is named "SDNotifier", and apply the policy to your application.

Configure SANM to Create CA Service Desk Tickets

A few more steps are required to support the SANM functionality in the DX NetOps Spectrum and CA Service Desk Manager integration. Configure SANM to create tickets in CA Service Desk Manager. You can add and modify alarm policies and filters in OneClick.

Follow these steps:

1. Start an instance of AlarmNotifier and verify that it is using the ServiceDeskSetScript.

2. Apply a filter policy to your AlarmNotifier instance.

   NOTE

   Note: Whenever an alarm matches the applied filter, a Service Desk ticket is created.

   For information about applying a filter policy, see Alarm Notification Manager (SANM) .

Provide CA Service Desk Ticket Request Number in SDNotifier Output

You can configure the CA Service Desk Manager integration to provide the CA Service Desk ticket request number in the SDNotifier output. Edit the .alarmrc file and the ServiceDeskUpdateScript to include more instructions.

Follow these steps:

1. Navigate to the sd_notifier directory.
2. Edit the .alarmrc file to add the following new lines:

```
EXTRA_ATTRS_AS_ENVVARS=0x12022
UPDATE_ATTRS=0x12022
```

3. Add the following lines to the ServiceDeskUpdateScript:
   On Windows:

```
ServiceDesk_Request=$SANM_0X12022
echo "ServceDesk_Request:
echo $SANM_0X12022 | cut -f3 -d'>'
```

   On Linux:

```
ServiceDesk_Request=$SANM_0x12022
echo "ServceDesk_Request:
echo $SANM_0x12022 | cut -f3 -d'>'
```

Example: CA Service Desk Ticket Request Number in SDNotifier Output

The following Ticket Request Number is a sample of successful output:

```
Alarm Notification from SPECTRUM
Alarm UPDATED:
Date:              11/10/2006
Time:              11:24:16
DeviceType:        6G306-06
Mtype:             6G3xx
ModelName:         1.2.4.5
AlarmID:           16600
ServiceDesk_Request:
Request 283</a
Severity:          MINOR
ProbableCauseID:   1030a
RepairPerson:
AlarmStatus:
SpectroSERVER:     ratchet.ca.com
Landscape:         0x1e00000
ModelHandle:       0x1e0004d
ModelTypeHandle:   0x3d20001
IPAddress:         1.2.4.5
SecurityString:
AlarmState:        NEW
Acknowledged:      FALSE
UserClearable:     TRUE
```

```
Location:          6C107
AlarmAge:          0
NotificationData:

ProbableCause:     No Associated Text

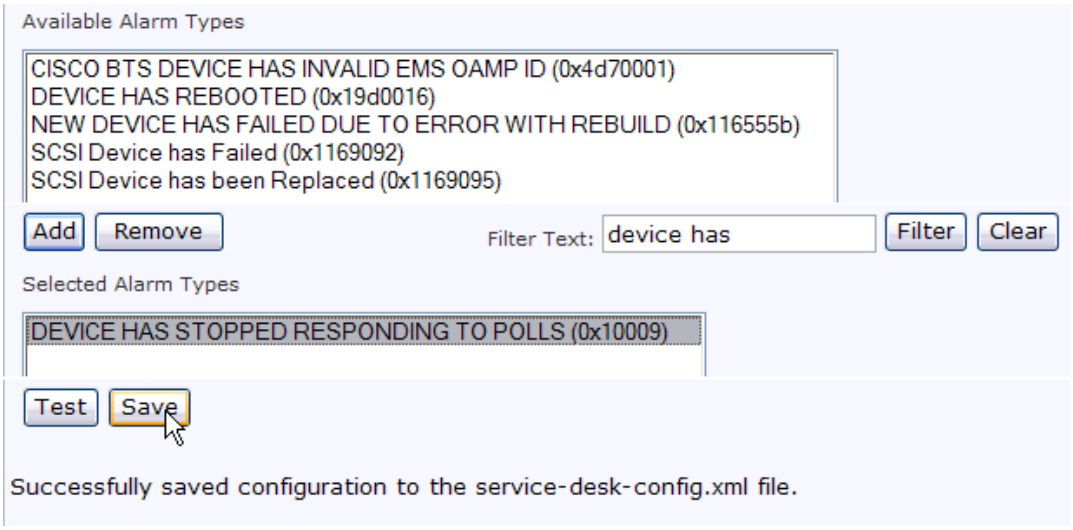
EventMessage:      No Associated Event Message
```

References

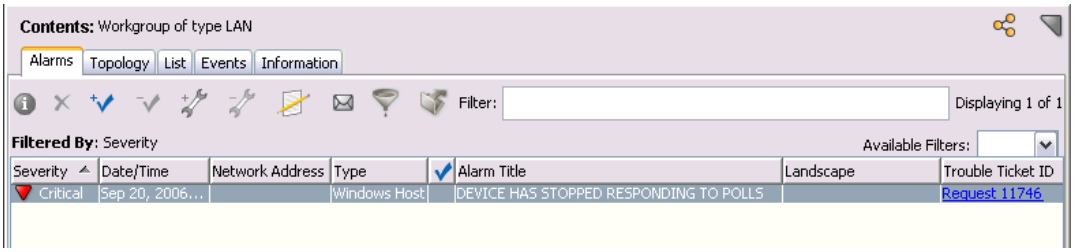
Example Create CA Service Desk Tickets Automatically for a Single Alarm Type

This section describes a simple example of how to configure the integration to create tickets automatically.

The following figure shows the DX NetOps Spectrum alarm type DEVICE HAS STOPPED RESPONDING TO POLLS (0x10009) has been added to the Selected Alarm Types list from the Available Alarm Types list and that this configuration change has been saved:

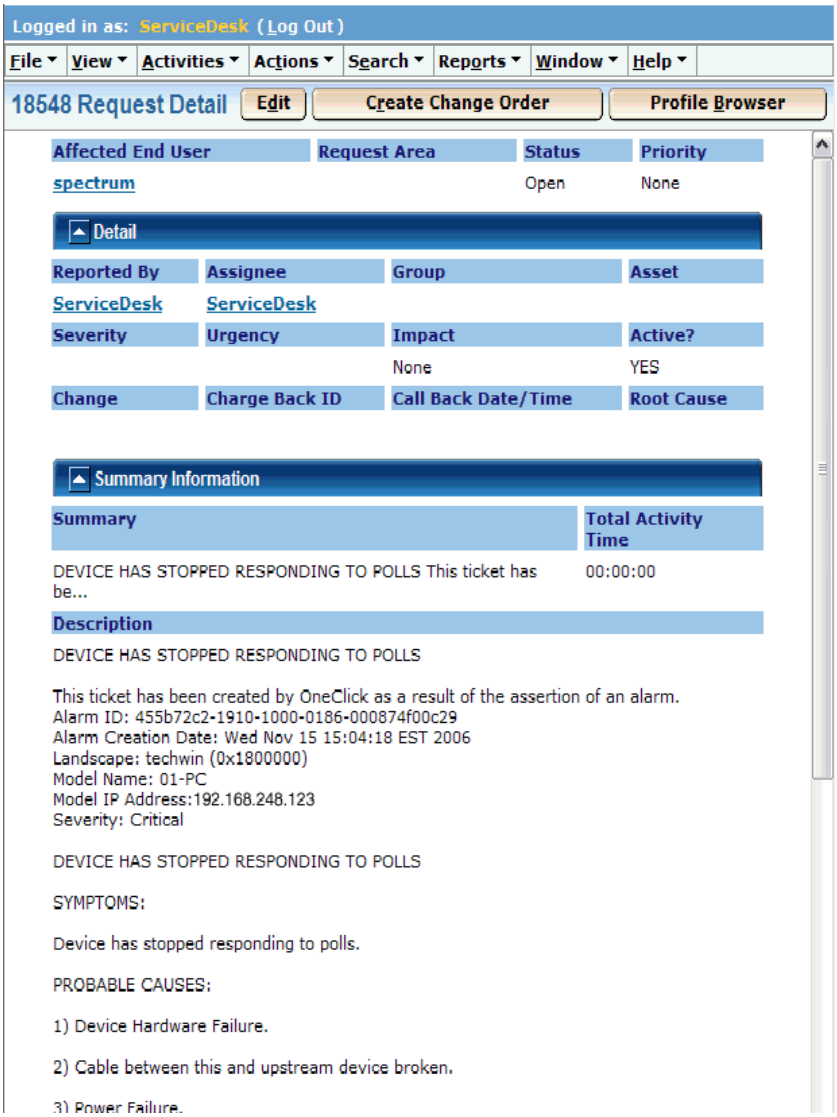


In this example, DX NetOps Spectrum alarms of type DEVICE HAS STOPPED RESPONDING TO POLLS (0x10009) generate corresponding CA Service Desk tickets. The following figure shows an instance of a DX NetOps Spectrum alarm of type 0x1009. The Trouble Ticket ID column contains a link to the CA Service Desk ticket that was automatically created for this alarm.



Click the Trouble Ticket ID link to open the web login page for your CA Service Desk Manager server in a browser.

After you log in to your CA Service Desk Manager server, the Service Desk Request Detail page for the OneClick ticket opens, as shown:



Example Using Custom Keywords for CA Service Desk Notifications

You can customize the keywords that CA Service Desk Manager uses for notifications of ticket actions. Custom keywords must be configured both in CA Service Desk Manager and in DX NetOps Spectrum. The following example explains how to configure both CA Service Desk Manager and DX NetOps Spectrum to use “Fixed” as the custom keyword for the ticket closed action.

Follow these steps:

1. From the CA Service Desk Manager server home page, select the Administration tab.
2. Expand the Notifications folder, and select Activity Notifications.
   The Activity Notification List opens.
3. Select the Close activity.
   The Close Activity Notification Detail dialog opens.
4. Click Edit.

5. Take the following actions:
   a. Click the Notification Rules tab and then click the name of the notification rule that is being used by the transfer activity.
   b. Click the message template that is used by the transfer activity, and click Edit.
6. In the Notification Message title field, change the assignment information from (for example):

   ```
   Request @{call_req_id.ref_num} Closed
   ```

   to

   ```
   Request @{call_req_id.ref_num} Fixed
   ```

   Fixed
   Is the keyword that you want to use for the ticket closed action.

   NOTE
   Do not remove the information in the 'Description: @{call_req_id.description}' field. DX NetOps Spectrum uses this information to associate alarms in DX NetOps Spectrum with the CA Service Desk ticket. Without this information, alarms are not cleared in DX NetOps Spectrum when a CA Service Desk ticket is closed.
7. Click Save in the Close Update Activity Notification window.
8. Close the Close Activity Notification Detail window.
9. Log in to your CA Service Desk Manager server host computer and navigate to the <*Service_Desk_Installation_directory*>/bin directory.
10. Change the Close keyword in DX NetOps Spectrum using one of the following methods:
   – Run the <*Service_Desk_Installation_directory*>/bin/OneClickIntegrationSetup(.exe) configuration program and enter *Fixed* at the Cloase keyword prompt.
   – Manually edit the value for the Close keyword in the <*Service_Desk_Installation_directory*>/bin/oc-integration.cfg configuration file to reflect the *Fixed* keyword for the close action.

   WARNING
   If the keywords that are configured in the DX NetOps Spectrum integration for the Close and/or Transfer actions do not match the keywords set in the CA Service Desk Notification Message Title for those actions, closing or transferring CA Service Desk tickets that are associated with DX NetOps Spectrum alarms does not clear or assign (respectively) the alarm to a troubleshooter in DX NetOps Spectrum.

Troubleshooting with Service Desk

Troubleshoot the Ticket Creation Rules

Sometimes CA Service Desk tickets generated by DX NetOps Spectrum assign the problem type and affected end user, or both. Tools in DX NetOps Spectrum can help you identify problems with ticket creation and correct them.

Ticket rules must be loaded through the CA Service Desk Integration page or by a Tomcat restart. Then the object that manages the ticket rules displays the actual rules that are loaded in memory in the proper order.

Follow these steps:

1. Navigate to the OneClick Administration Debugging Page.
2. Select Context Factory as the option on the left menu.
3. Select **com.aprisma.sd.ServiceDeskTicketConfig**

You can also see how the rules are analyzed and examine the actual web service call that is made to CA Service Desk Manager when a ticket is created. Set the CA Service Desk Integration debugging level to MAX. This debugging level lets you see whether a rule with a higher priority is being unexpectedly applied to your ticket. You can also determine whether the actual web service call results in the expected problem type and affected end-user values.

Troubleshooting Redundant Trouble Ticket Issues

Symptom:

We are seeing two CA Service Desk trouble tickets that are generated for each alarm in OneClick.

Solution:

Duplicate tickets indicate a misconfiguration of the DX NetOps Spectrum and CA Service Desk Manager integration. You probably configured the alarm generation using both the OneClick Selected Alarm Types filter and a SANM policy.

If both OneClick and SANM are configured to generate alarms, one of the trouble tickets has a ticket number that matches the Trouble Ticket ID attribute of the associated alarm in DX NetOps Spectrum. The ticket number of the redundant trouble ticket does not match the ticket number of the Trouble Ticket ID attribute of any alarm in DX NetOps Spectrum.

Even though the redundant trouble ticket does not appear to be associated with a particular alarm, closing it clears the alarm that created it. For the steps to ensure that duplicate tickets are not created by SANM and OneClick, see Best Practices for Automatic Trouble Ticket Creation.

Service Desk Tickets Not Created After Switching Servers

Symptom:

I recently switched my DX NetOps Spectrum and CA Service Desk Manager integration to use a new CA Service Desk Manager server. I restarted Tomcat, but now DX NetOps Spectrum is unable to create tickets in CA Service Desk Manager. The error in my tomcat log is as follows:

```
Oct 15, 2007 1:24:24 PM (AlarmNotifier) (SDIntegration) - SDAlarmHandler -
received alarm SET
Oct 15, 2007 1:24:24 PM (AlarmNotifier) (SDIntegration) - SDAlarmHandler -
attempting to create ticket for alarm 4713a247-0167-1000-0183-0080102af61e
Oct 15, 2007 1:24:24 PM (AlarmNotifier) (SDIntegration) - SDSetAction -
gathering info to create ticket for alarm 4713a247-0167-1000-0183-0080102af61e
Oct 15, 2007 1:24:24 PM (AlarmNotifier) (SDIntegration) - ServiceDesk_Asset_ID
attribute found in <sp>: nr:2929BAB6C548A34FA64FB06A5811A414
Oct 15, 2007 1:24:31 PM - Error occurred while attempting to create a ticket in
Service Desk. Internal err with update_lrel with handle
nr:2929BAB6C548A34FA64FB06A5811A414: NOT FOUND
```

When I try to submit an alarm manually, a "creation failed" message appears. Why can I not create a CA Service Desk ticket from DX NetOps Spectrum?

Solution:

If you enable Assign Assets in OneClick, and then switch to a new CA Service Desk Manager server, verify that the new server uses the same database as the old server. If you switch to a server that uses a different database, CA Service Desk Manager cannot create the ticket. The reason is that the DX NetOps Spectrum model in the original database is aware of the assets that were created for it in CA Service Desk Manager. The new database does not have information about that asset, causing an error when CA Service Desk Manager attempts to assign the asset from the DX NetOps Spectrum alarm.

To continue assigning assets after you switch to a new CA Service Desk Manager database, take one of the following actions:

- Configure the new CA Service Desk Manager server to use the original database.
- Manually clear the ServiceDesk_Asset_ID fields of all the DX NetOps Spectrum models.

Integration with Service Desk

In this release, DX NetOps Spectrum enables integration with third-party service desks (apart from the existing CA Service Desk Manager integration), by adopting an enhanced integration framework acting as an intermediary between DX NetOps Spectrum and the Service Desk(s) which is part of the DX NetOps Spectrum install package. The installation is part of the Spectrum install and the default Integration Parameters are auto-configured, when you enable this integration.

WARNING

We recommend using this integration capability only for fresh installations of DX NetOps Spectrum.

You can select and configure the Service Desk application as well as enable the integration with DX NetOps Spectrum from the OneClick Administration Pages.

For more information, see Select Service Desk and enable integration on the DX NetOps Spectrum OneClick Server.

The new integration enables better communication between the operations center and the service desk, helping automate an efficient workflow process, reduce mean-time-to-resolution, and, lower overall management costs. This integration provides automated and real-time updates as problems are triaged and resolved. We get real-time visibility into the current status of problem conditions. This integration framework also supports policy-based automated alarm ticket submission, and on-demand ticket submission from the DX NetOps Spectrum OneClick.

By default, DX NetOps Spectrum uses polling mechanism to get the ticket update (Assignee and Status) information from the configured Service Desk, based on your configuration in **OneClick Administration** Page > **Service Desk Configuration Integration Parameters** section > **Polling** field.

NOTE

You can configure notifications to OneClick from ServiceNow. See Configuring OneClick notifications from ServiceNow.

WARNING

The enhanced integration framework for integrating DX NetOps Spectrum with Third-party Service Desk applications is not supported on Solaris Operating System.

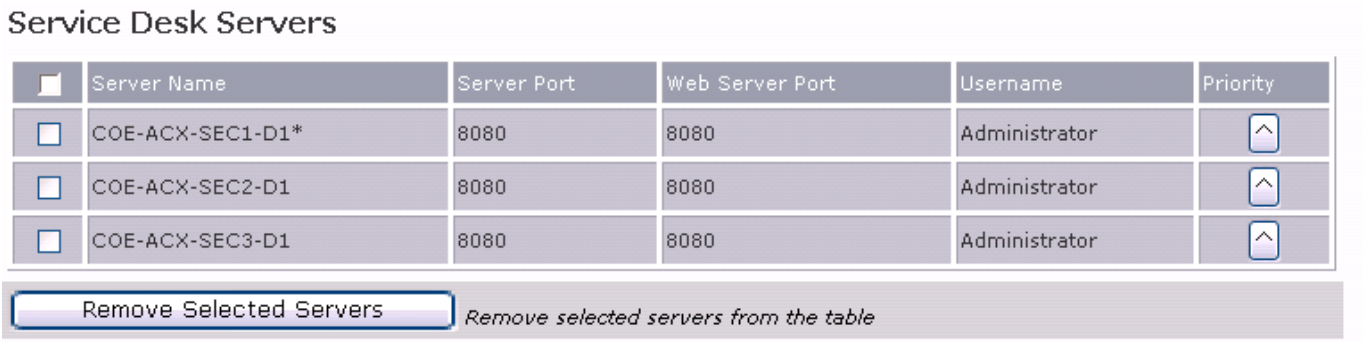
10.3 allows you to integrate with the following Service Desk applications, in addition to CA Service Desk Manager:

- BMC Remedy ITSM
- ServiceAide
- HP ServiceManager
- ServiceNow

WARNING

You cannot configure any other Service Desk application if you have already integrated CA Service Desk Manager with DX NetOps Spectrum on the same OneClick Server.

NOTE
If you have already integrated DX NetOps Spectrum with CA Service Desk Manager, you need to disable the integration and remove the entries, from the OneClick Administration Page > Service Desk Configuration > Service Desk Servers table, as displayed below.



Currently, the integration supports incident creation, update and assignment from both the Service Desk interface as well as the DX NetOps Spectrum OneClick Console.
The following features are supported:

- Incident Creation / Submit Service Desk Ticket
- Launch in Context for Service Desk ticket created in Spectrum
- Incident Assignment (Add/Update Assignee)
- Close / Resolve Incident / Tickets. (Reflects immediately on DX NetOps Spectrum, fetches the data from the Service Desk based on polling interval)

Reproduce-*-

Installing and Configuring the Integrations

To install and configure the DX NetOps Spectrum and Service Desk applications/ MDRs integration successfully, complete the following procedures:

1. Verify integration system requirements for OneClick and Service Desk servers.
2. Select Service Desk and enable integration on the DX NetOps Spectrum OneClick Server
3. Configuring the Service Desk/ MDR Application server.

Verify integration system requirements for OneClick and Service Desk servers.

Before you begin, verify that your DX NetOps Spectrum and Service Desk/ Incident Manager servers meet the following requirements:

- **DX NetOps Spectrum OneClick server software** -- CA Spectrum 10.3. For system requirements, see System Requirements for Installing DX NetOps Spectrum.
- **Service Desk software** – For the list of supported Service Desk/ MDR software and compatible versions, see the following table:

Service Desk / Incident Management Application	Supported Version(s)
BMC Remedy ITSM	8.1, 9.1
ServiceAide	Goldfish
HP ServiceManager	9.32
ServiceNow	See Integration Compatibility

- **Supported platform / Operating Systems**

WARNING

The enhanced integration framework for integrating DX NetOps Spectrum with Third-party Service Desk applications is not supported on Solaris Operating System.

- Ensure that during Service Desk/MDR configuration, User/Troubleshooter/ Assignee should exist on both applications for the assign option to work from both ends.

NOTE

This integration will support only AdoptOpenJDK 8u212 or higher versions of Java.

WARNING

The DX NetOps Spectrum integration with Third-party Service desk(s) is configured and enabled from the DX NetOps Spectrum OneClick Administration> Service Desk Configuration Page.
The following section specifies any special considerations/ exceptions that are applicable for configuring the integration on the Service Desk server side.

Configuring the Service Desk/ MDR Application server

The enhanced integration framework which acts as the intermediary between DX NetOps Spectrum and Service Desk(s) is part of the DX NetOps Spectrum installation package, and installs the required components and configuration during installation. However, for the following Service Desk applications, there are certain considerations and exceptions, which you need to consider:

HP Service Manager

To open an HP Service Manager ticket URL from DX NetOps Spectrum (Launch-In-Context feature), you will need to update/make certain configuration changes on the server where HP Service Manager is deployed/installed.

To launch the HP Service Manager ticket URL from DX NetOps Spectrum; follow these steps:

1. On the machine where HP Service Manager is deployed, stop the Tomcat server.
2. Navigate to the following location *:\apache-tomcat-7.0.67\webapps\webtier-9.32\WEB-INF*
3. Open the ***web.xml*** file.
4. In the web.xml file, do one of the following:
   - Search for the 'querySecurity' parameter and if the parameter exists ensure that the <parameter-value> = false.
   - If the parameter does not exist, follow these steps to add the parameter:

```
<init-param>
      <param-name>querySecurity</param-name>
      <param-value>false</param-value>
    </init-param>
```

5. Save the web.xml file
6. Restart the Tomcat server.

BMC Remedy ITSM

To enable the communication between DX NetOps Spectrum and BMC Remedy ITSM, copy the SDK jar files from the BMC Remedy System to the DX NetOps Spectrum library.

The integration user needs to have the privileges for the following roles in the BMC Remedy ITSM > Roles list:

License Type: Fixed
Application Permission: Incident Master, Incident User

Follow these steps:

1. In the machine where BMC Remedy ITSM is installed, navigate to:
   `\\BMC Software\ARSystem\Arserver\api\lib`
2. Copy the following SDK jar files:
   `arapi8*.jar`
   `arutil81*.jar`
3. Get the following jar file from the location where BMC Remedy is installed or you can download it from the internet.
   `log4j*.jar`
4. Save all the jar files in the following location:
   `\\win32app\Spectrum\tomcat\webapps\ca-nim-sm\WEB-INF\lib`
5. Restart the Tomcat server.

WARNING
Ensure that you copy the specified BMC Remedy SDK jar files and log4j*.jar file to the DX NetOps Spectrum Library before you execute any DX NetOps Spectrum operation on BMC remedy.

NOTE

- If BMC ITSM is configured with an IP address instead of its Host name, the ticket open/launch in context feature is not supported by BMC Remedy.
- It is recommended for the BMC Remedy server to be on the domain as the DX NetOps Spectrum OneClick Server for better response time.

ServiceAide

DX NetOps Spectrum alarms automatically create incident tickets in the ServiceAide (formerly known as CA Cloud Service Management). Operators can also manually create an incident ticket from an alarm in the OneClick Console. When an incident ticket is closed in ServiceAide, the corresponding alarm in DX NetOps Spectrum is also cleared if you enabled Polling in the Service Desk Configuration page - Integration Parameters.

In order for this integration to work, you must configure a Web Services user account in ServiceAide.

Follow these steps:

1. Create an account in either https://csm3.serviceaide.com or https://csmstaging.serviceaide.com
2. Set a password and a role for the new account you created.
3. Check if you can successfully log in to the ServiceAide web page.
4. In the OneClick Administration - Service Desk Configuration, supply the information and click on the Test button.
5. Click the Add/Modify Server button to add the Service Desk Server Name in the table. You can click on the Save button now, or in the next step.
6. Enable the Service Desk Integration, select the alarm types for which you would like Service Desk tickets created and click on the Save button.
   When you select the Enable option, the Integration Parameters will show up. Enable the Polling if you want to clear the alarm in DX NetOps Spectrum side when the ticket is closed.
7. Once a new alarm is asserted, the Service Desk ticket is created. Click on the Trouble Ticket ID URL for the Ticket details.

WARNING

In ServiceAide, you cannot have a user with the user name 'administrator' as the system user in ServiceAide is 'administrator'.

ServiceNow

You have to select and configure ServiceNow from the OneClick Administration Server > Service Desk Configuration to enable the integration.

The default integration behavior is that DX NetOps Spectrum polls ServiceNow to get the ticket update (Assignee and Status) information from the configured ServiceNow instance.
If you wish to enable OneClick (push) notifications to DX NetOps Spectrum from ServiceNow, refer to the Configuring OneClick Notifications for ServiceNow section.

The integration module makes calls to fetch data from ServiceNow for the properties of an incident on the following tables:

- sys_db_object
- sys_dictionary
- incident
- task
- sys_journal_field

Please ensure that the user which is used in the integration has the privileges to access these tables and fetch data from these tables.

The integration user also needs to have the privileges for the following roles in the ServiceNow > Roles list:

- soap
- soap_create
- soap_delete
- soap_ecc
- soap_query
- soap_query_update
- soap_script
- soap_update
- web_service_admin
- odbc
- midserver
- catalog_admin
- u_journal_entry_user

> **NOTE**
> Additionally, the integration user must have the read & write privileges for the roles which are assigned in the ACLs of the tables sys_db_object, sys_dictionary, incident, task, and sys_journal_field. Contact the ServiceNow administrator to know roles defined in ACLs.

Once the integration user has access to these tables.

Please click the Save button on the ServiceDesk Integration page in DX NetOps Spectrum OneClick Administration.

> **NOTE**
>
> If you have already enabled the integration prior to enabling access to the tables and roles listed above, you will need to restart the Tomcat server.

Configuring the OneClick Server for Service Desk Integration

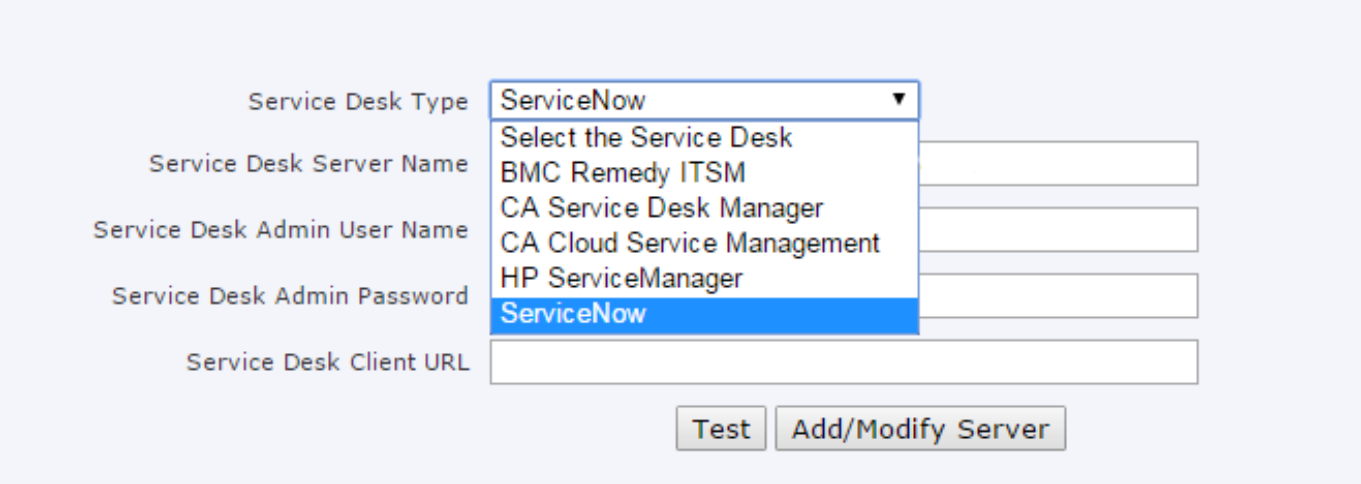
WARNING

The following instructions are applicable for configuring all the Service Desk applications that are supported by DX NetOps Spectrum (including CA Service Desk Manager).

Select Service Desk and enable integration on the DX NetOps Spectrum OneClick Server

To configure the Service Desk integration with Spectrum, follow these steps:

1. Navigate to the **OneClick Administration pages** > **Administration> Service Desk Configuration.**
2. Select the Service Desk you want to integrate with DX NetOps Spectrum, from the **Service Desk Type** field.



3. Configure OneClick to connect to a Service Desk server by entering valid values for the following fields:

   NOTE

   Based on the Service Desk you are integrating the fields may vary, please specify the values applicable for your selected Service Desk.

   - **Service Desk Server Name**
     The host name of the Service Desk Manager server.
   - **Service Desk Server Port**
     The HTTP port of the Service Desk Port. DX NetOps Spectrum uses this port to create Service Desk tickets.
   - **Service Desk Web Server Port**
     The HTTP port of the Service Desk Web Server. This port is used when launching the Service Desk interface from OneClick.
   - **Service Desk Admin Username**
     The user name of the Service Desk server administrator.
   - **Service Desk Admin Password**
     The password of the CA Service Desk Manager server administrator.
   - **Service Desk Client URL** The URL to access the Service Desk web client.
   - **Service Desk Protocol**
     The network access protocol used by the Service Desk
4. Click Test to verify the connection between the Service Desk server and DX NetOps Spectrum OneClick server. A successful test displays a relevant confirmation message.

   NOTE

   The settings are not saved until you click Save.

NOTE

We recommend that you do not add multiple Service Desk applications/ servers.
At any point in time, DX NetOps Spectrum can be integrated with only one Service Desk/ Incident Management application which is enabled in the GUI from the OneClick Admin > Service Desk Configuration > Select Service Desk Type field.

5. Supply values for the following additional fields:

- **SSL Support**
  SSL Support is used in the case of CA Service Desk. If the CA Service Desk is running in 'https' mode, use this option to connect with it using this option.
- **Specify Reported By Field**Select Yes to include the submitting user in the Reported By field when you manually submit Request, Incident and Problem tickets.

NOTE

The user you specify in the **Reported By** the field needs to be an existing user in the Service Desk application, you have configured. If the specified user does not exist in Service Desk application ticket creation and ticket assignment from DX NetOps Spectrum will fail.

- **Assign Assets/Configuration Items**
- **Reload Asset/CI Mapping**
- **Reload Ticket Rules**

NOTE

The above fields (**Assign Assets/Configuration Items**/ **Reload Asset/CI Mapping**/ **Reload Ticket Rules**) are currently not supported in this integration.

- **Service Desk Integration** Select the Enabled option to allow DX NetOps Spectrum to communicate with the specified Service Desk server.

NOTE

The **Integration Parameters** field(s) are displayed only after you enable the Service Desk Integration in the previous option.

Integration Parameters

An enhanced integration framework acting as an intermediary between DX NetOps Spectrum and the Service Desk(s) is part of the CA Spectrum 10.2 install package. The framework installation is part of the Spectrum install and the default Integration Parameters are auto-configured, when you enable this integration. We recommend using this integration capability only for fresh installations of DX NetOps Spectrum.

The Integration Parameters section displays default values for the following fields:

WARNING

It is recommended to use the default values that are displayed in the **Integration Parameter** fields. The Integration Parameter fields are used by the enhanced framework to enable communication between DX NetOps Spectrum and the Service Desk application you are integrating with.

- **Integration Access Protocol**
  Specifies the Access Protocol of the NIM server. This value is the same as the OneClick Server protocol as NIM is deployed on the same machine.
- **Integration Host**
  Specifies the Integration Hostname (Hostname of the machine where the Integration Server is deployed.)

This is the hostname where the OneClick server is deployed. By default, it will be the localhost as the NIM is deployed on the same machine.

- **Integration Port**
  Specifies the Port number for Integration Host
- **Integration Username**
  Specifies the user name (Default is nimadmin)
- **Integration Password**
  Specifies the password of the integration user (Default is nimadmin)
- **Polling**
  By default, Polling is disabled.
  Enabling polling fetches the ticket update (Assignee and Status) information from the configured Service Desk.
  Select the Enabled option to enable polling.

  NOTE

  Time should be in sync for One Click with all Service Desk. Time zones can be different, however, if the time (of the Service Desk Server and Spectrum OneClick server) is not in sync, polling will not work.
- **Polling Interval**
  Specifies how frequently DX NetOps Spectrum queries the configured Service Desk server for updates. If you modify this value, the new polling interval takes effect at the next polling cycle.
  This field specifies the polling interval in seconds. The default value is 300 (seconds). You can configure this field to a value of your choice (in seconds).
- **Status To Check**Specifies the ticket **status to check** from the Service Desk ticket.
  DX NetOps Spectrum looks for the tickets in the configured Service Desk application with the following status': Resolved and Closed. If the ticket status is Resolved or Closed, the corresponding alarms will be cleared from the list of alarms in DX NetOps Spectrum, based on the polling interval defined.
  This feature applies only to alarms that are clearable in DX NetOps Spectrum, and does not apply to non-clearable alarms.

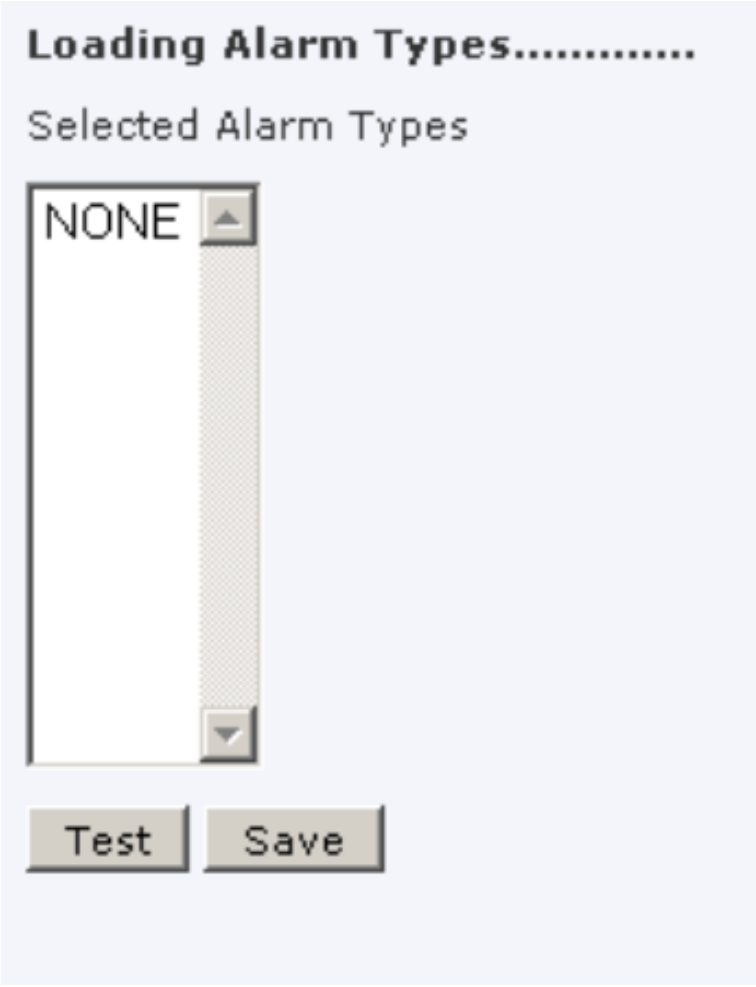
Select Alarm Types to create Service Desk Tickets

Configure the DX NetOps Spectrum and Service Desk integration to create CA Service Desk trouble tickets when DX NetOps Spectrum generates alarms of certain types that you specify.

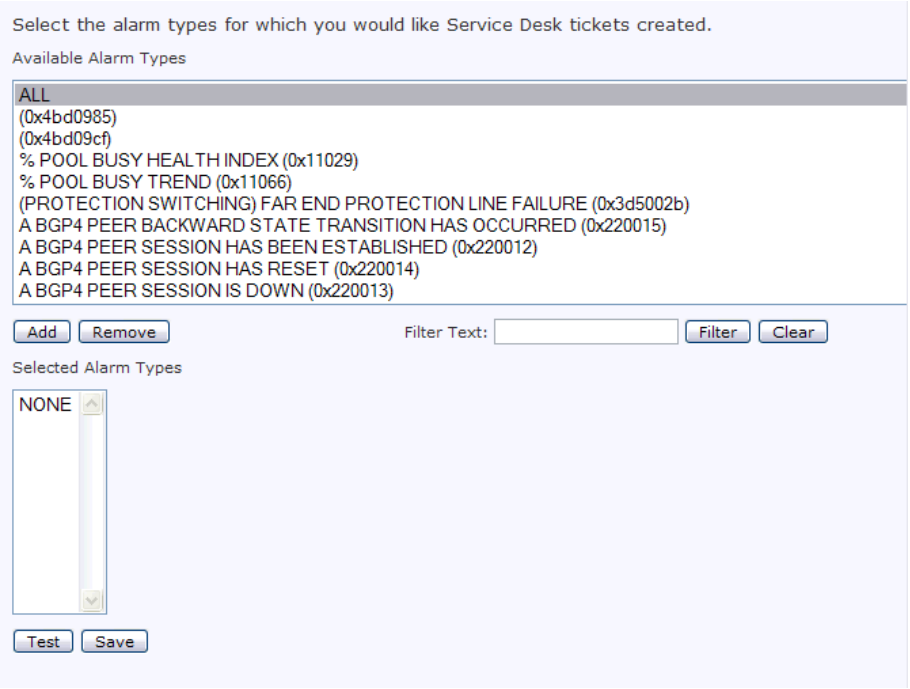
NOTE

Automatic ticket creation is an optional feature. Operators can instead create all tickets manually. By default, the integration does not automatically create tickets for any DX NetOps Spectrum alarms.

1. From the **Available Alarm Types** field, select the alarm types for which you would like Service Desk tickets created. The first time that you open the Service Desk Configuration administration page and anytime the cache timeout (one hour) of the page expires, the “Loading Alarm Types” message is displayed as shown in the following image:



The available alarm types are displayed in the Available Alarm Types section of the Service Desk Configuration administration page:



2. In the Available Alarm Types section, select the alarms for which you want OneClick to create Service Desk tickets, and click Add.

   NOTE
   A delay can occur the first time you add alarm types. The delay occurs when all of the probable cause files are loaded for display in the Available Alarm Types section of the Service Desk Configuration administration page.
3. To generate Service Desk tickets for all DX NetOps Spectrum alarms, select ALL from the Available Alarm Types list, and click Add.

   NOTE
   o select an individual alarm type, enter some text from the desired alarm type into the Filter Text field and click Filter.

   NOTE

   After selecting the alarms, click the Test button to see if your selection is successful. Relevant Confirmation / Error messages are displayed.
4. Click Save.
   A relevant confirmation message appears.

   NOTE

   Click the Save button after modifying the list of selected alarms to ensure that your changes will take effect.

Configuring OneClick Notifications for ServiceNow using MID Server

Overview

ServiceNow can send notifications to OneClick when a ticket that is associated with OneClick alarm changes. These notifications update the alarm that is associated with a ticket in OneClick to reflect changes to the ticket. The ServiceNow integration can be configured to generate an automatic Ticket Closed notification that causes OneClick to clear the associated alarm when a ticket is closed. Similarly, when a ticket has been transferred, a Ticket Transfer notification causes OneClick to update the troubleshooter information for the associated alarm.

> **NOTE**
>
> OneClick only clears an associated alarm when a ticket is closed/resolved in ServiceNow if the alarm is user-clearable.

These notifications use "keywords" which must match keywords that are set in the integration for OneClick. Keywords are case-sensitive.
By default, the keyword for the close action is "Closed", and the keyword for the transfer action is "Transfer" (in both ServiceNow and the DX NetOps Spectrum integration setup). These keywords can be customized in ServiceNow and in the DX NetOps Spectrum integration setup.

Configure ServiceNow to push notifications to OneClick

Follow these steps:

Before you configure ServiceNow and DX NetOps Spectrum to communicate with each other, download and install the integration components on your MID application server. The Management, Instrumentation, and Discovery (MID) Server is a Java server that facilitates communication and movement of data between the ServiceNow platform and external applications, data sources, and services.

Download and Install Integration Components on the MID Server

1. Download and install the MID server from ServiceNow (on the same server where DX NetOps Spectrum is installed or a different server). The Management, Instrumentation, and Discovery (MID) Server is a Java server that facilitates communication and movement of data between the ServiceNow platform and external applications, data sources, and services.
   Refer ServiceNow documentation for Installing MID
   > **NOTE**
   > Please keep handy the name you assign to the MID server during installation and configuration, for use during Creating Business Rules.
2. Download and install integration components from the OneClick Server in the MID server installation directory.
   You can download the integration components on the same machine where the MID agent is installed.
   To achieve this use one of the following methods, depending on your operating systems.
   > **WARNING**
   > Please ensure that **Polling** is disabled from the **OneClick Admin Pages**> **Service Desk Configuration**> **Integration Parameters** before you initiate the OneClick notifications from ServiceNow..
3. Navigate to your ServiceNow server instance and create the following Business Rules:
   - **Update**
   - **Clear**

   For more information, see Creating Business Rules. This example describes creating Business Rules for the Update and Close actions after you have completed and enabled the integration.
   > **NOTE**
   > Please refer ServiceNow™ documentation for information on:
   >
   > - Business Rules
   > - Creating a Business Rule

MID Server and OneClick Web Server Use Different Operating Systems

Perform the following steps when your ServiceNow MID server uses a different operating system than the OneClick web server:

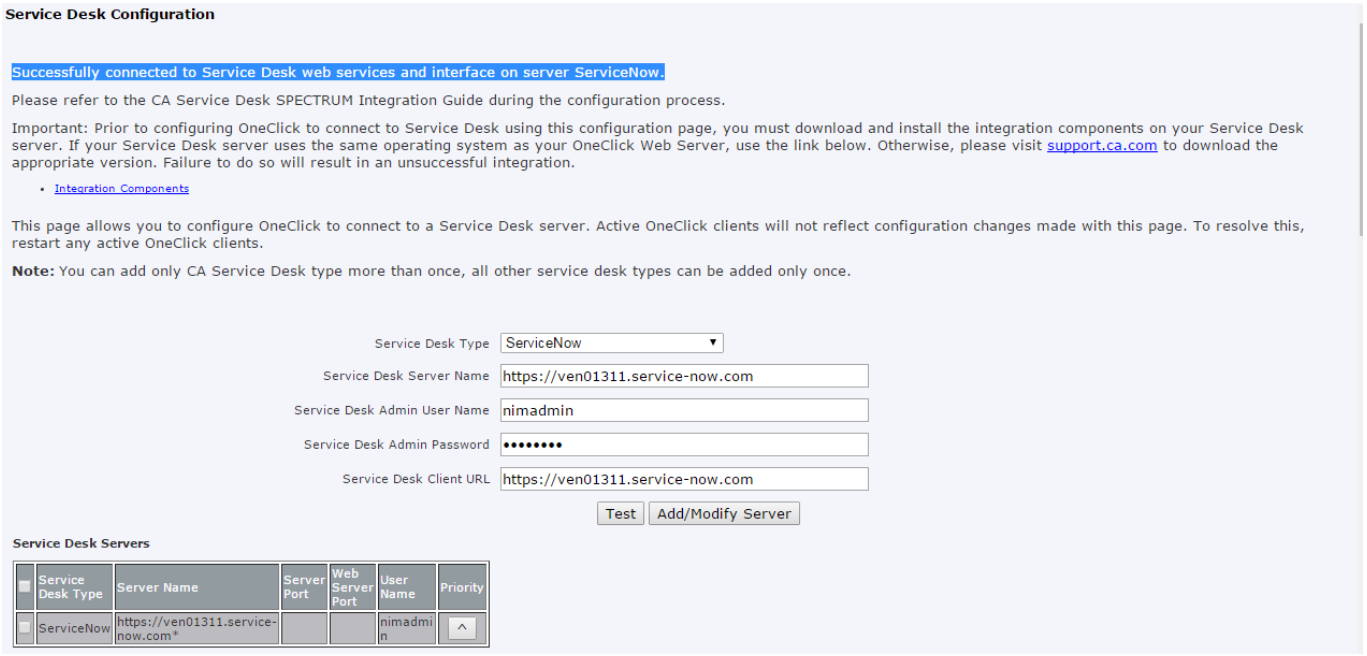
1. Visit the Support website to locate a version of the integration components that are appropriate for your MID server.
2. Download and save the appropriate version of the integration components for your operating system to the following directory on your MID server:
   ```
   MID Server_Installation_directory
   ```
3. After you have saved the integration components to your MID server, follow the instructions for installing and configuring the integration components using the same operating system, beginning with Step 5.

MID server and OneClick Web Server Use the Same Operating System

Download the integration components from the OneClick web server and install them on the MID server.

Follow these steps:

1. From your Service Desk server, navigate to the OneClick Administration pages.
   ```
   http://OneClick Web server/spectrum/admin/index.jsp
   ```
2. Click the Service Desk Configuration link in the left panel of the Administration page.
   The Service Desk Configuration administration page opens in the right panel, as shown:



1. Click the Integration Components link to download the oc_components.exe file. This self-extracting archive file contains the executable programs to configure the Service Desk server.
2. Save the oc_components.exe file to the directory on your MID server:
   ```
   MID Server_Installation_directory
   ```
3. Log in to your MID server host computer and navigate to the *MID_Server_Installation* directory.
4. Locate the oc_components.exe file you downloaded.
5. **Linux:** Run the following command to make the oc_components.exe file executable:
   ```
   chmod 755 oc_components.exe
   ```
   Windows: Do not edit the permissions of the downloaded file for the file to be executable.

6. Run the oc_components.exe file.
   The OneClickIntegrationSetup(.exe) file is extracted to the <*MID Server_Installation_directory*> directory.
7. Run the MID Server_*Installation_directory*/OneClickIntegrationSetup(.exe) configuration program. At each prompt, enter the requested information and press Enter to continue. The following table describes each prompt and the required information:

OneClick Integration Setup Prompt	**Description**
OneClick Server name?>	Enter the hostname of your OneClick Web server.
OneClick Server port?>	Enter the port of the OneClick Web server.
OneClick Homepage path [default="spectrum"]?>	If your OneClick home page URL uses the default value of http://<*oc*> *Web server*/spectrum, press Enter to accept it. Otherwise, enter the correct home page path portion of the OneClick home page URL at this prompt. This home page path value is <path>, as in the example http://*OneClick Web server*>/*path*. The default value in OneClick is “spectrum.”
Username?>	Enter the username of the OneClick Administrator. This name is the DX NetOps Spectrum "super user" who installed the OneClick Web server.
Password?>	Enter the password of the OneClick Administrator.
Confirm password?>	Re-type the password of the OneClick Administrator and press Enter.
Enable logging? [yes|no]>	Type *yes* to enable logging or type *no* to disable logging and press Enter. We recommend enabling logging only when you are troubleshooting an integration problem. An active integration can create a large log file. When logging is enabled, the integration creates a file named oc-notification.log in the *Service_Desk_Installation_directory*/bin directory. When enabled, logging writes information about Service Desk notifications to this log file. Information is logged each time the DX NetOps Spectrum notification occurs and includes the type of activity and whether or not it was a success. In the case of a failed notification, this log file may contain a possible solution such as an invalid port or that the OneClick web server is unavailable.
Enable SSL? [yes|no]>	Type *yes* to enable SSL or type *no* to disable SSL and press Enter. To enable SSL in DX NetOps Spectrum Tomcat, install OneClick and see Administrating. To enable SSL in CA Service Desk Tomcat, see Service Desk Administration.
Path to the JRE root installation directory?>	Type the JRE root installation directory path and press Enter. Specify the JRE root installation directory so that appending "bin/java - version" becomes a successful command. Java 2 Runtime Environment (JRE) version 1.8.0 or later is required.
Close keyword [default="Closed"]?>	To use default values press Enter at the prompt without specifying a keyword. Leave the line blank and press Enter.
Transfer keyword [default="Transfer"]?>	To use default values press Enter at the prompt without specifying a keyword. Leave the line blank and press Enter.

The OneClick Integration Setup program creates a file named NotifyOneClick(.bat or .sh, depending on the operating system), in the *MID Server_Installation_directory*.

> **NOTE**
> To reconfigure this information later, run the OneClickIntegrationSetup program again or manually edit values in the M*ID Server_Installation_directory*/oc-integration.cfg configuration file. Any changes that are made to this file take effect immediately. No additional restart is required.

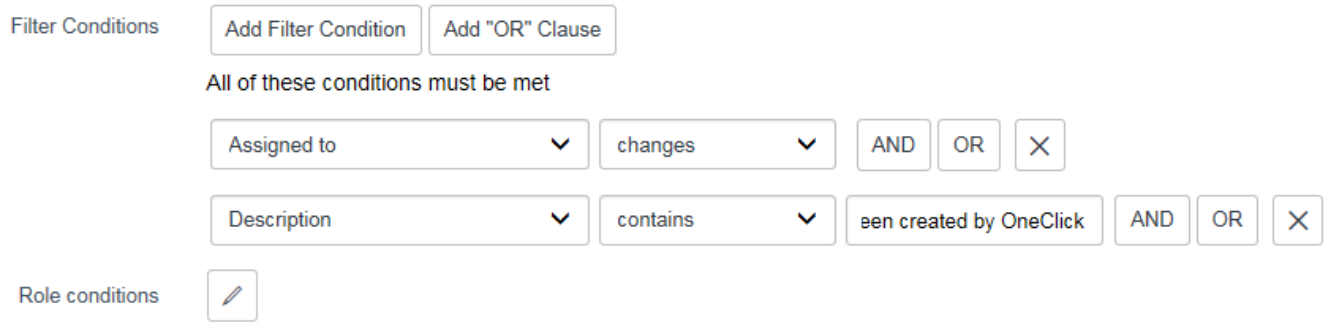
Creating Business Rules

1. Navigate to **Business Rules** (under **System Definition** tab) and click **New** to create a new rule.
2. Provide a relevant name to the Business Rule, for e.g. 'Update'.

3. Select **“Incident”** from the **Table** drop down.
4. Check **“Active”** and **“Advanced”** check box(es).
5. In the **When to run** section, do the following:
   a. Select “after” from the **When** drop down
   b. Enter 100” in the the **Order** field for update rule.
   c. Check the **“Update”** checkbox.
   d. Add filter conditions.
   For **Update** rule :

Assigned to + Changes AND Description + contains + **“This ticket has been created by OneClick”**.

The following image displays how Filter Conditions show up for this Business Rule in ServiceNow



Update Business Rules

In In the **Advanced** section at the bottom of the page give the below script for **Update** by changing the relevant details.

See comments in the script below:

```
function onBefore(current, previous) {
 //This function will be automatically called when this rule is processed.
myFunction();}
 //Update
function myFunction() {
 //Set the path of the OCNotify.jar
 var jarLocation = "C:\\MID_Server\\OCNotify.jar";//OCNotifier.jar"; \\example: "C:\\Users\\abcuser\\Desktop\
\OCNotifier.jar";
 //change the name of the spectrum_mid to be the name of your midserver you specified during mid server
 configuration/installation
 var midHost = "mid.server.spectrum_mid";
 var ecc = new GlideRecord('ecc_queue');
 ecc.initialize();
 ecc.agent = midHost;
 ecc.topic = "Command";
 ecc.queue = "output";
 var description = current.description;
 var re = new RegExp("Alarm ID: ((\\w+)(-\\w+){4})");
 var expResult = re.exec(description);
 var assignee = current.assigned_to.getDisplayValue();
```

```
 var cmd = "java -jar " + jarLocation + " " + "update " + expResult [1] + " " + encodeURI(assignee);
 ecc.payload='<parameters><parameter name="name" value="'+cmd+'"/></parameters>';
 ecc.insert();
}
```

Update Script for New York Version

Use the following script for the New York version.

```
(function executeRule(current, previous) {
//This function will be automatically called when this rule is processed.
myFunction();
})(current, previous);
 //Update
function myFunction() {
 gs.log('in function'+current.number);
 //Set the path of the OCNotify.jar
 var jarLocation = "D:\\SNMidServer\\MidServer01\\agent\\OCNotify.jar";
 //change the name of the MidServer01 to be the name of your midserver you specified during mid server
 configuration/installatio
 var midHost = "mid.server.MidServer01";
 var ecc = new GlideRecord('ecc_queue');
 ecc.initialize();
 ecc.agent = midHost;
 ecc.topic = "Command";
 ecc.queue = "output";
 var description = current.description;
 var re = new RegExp("Alarm ID: ((\\w+)(-\\w+){4})");
 var expResult = re.exec(description);
 var assignee = current.assigned_to.getDisplayValue();
 var cmd = "java -jar " + jarLocation + " " + "update " + expResult [1] + " " + encodeURI(assignee);
 gs.log('in function cmd' +cmd);
 ecc.payload='<parameters><parameter name="name" value="'+cmd+'"/></parameters>';
 gs.log('in function payload' + ecc.payload);
 ecc.insert();
 gs.log('in function inserted');
}
```

Close Business Rules

For creating the **Close** rule, follow the steps mentioned for Creating Business Rules,

In step 5 b. enter “200” as the value in the **Order** field, and in step 5d. add the following filter conditions for **Close** rule:

State + is + Closed AND

Description + Contains + **“This ticket has been created by OneClick”** AND

State + Changes

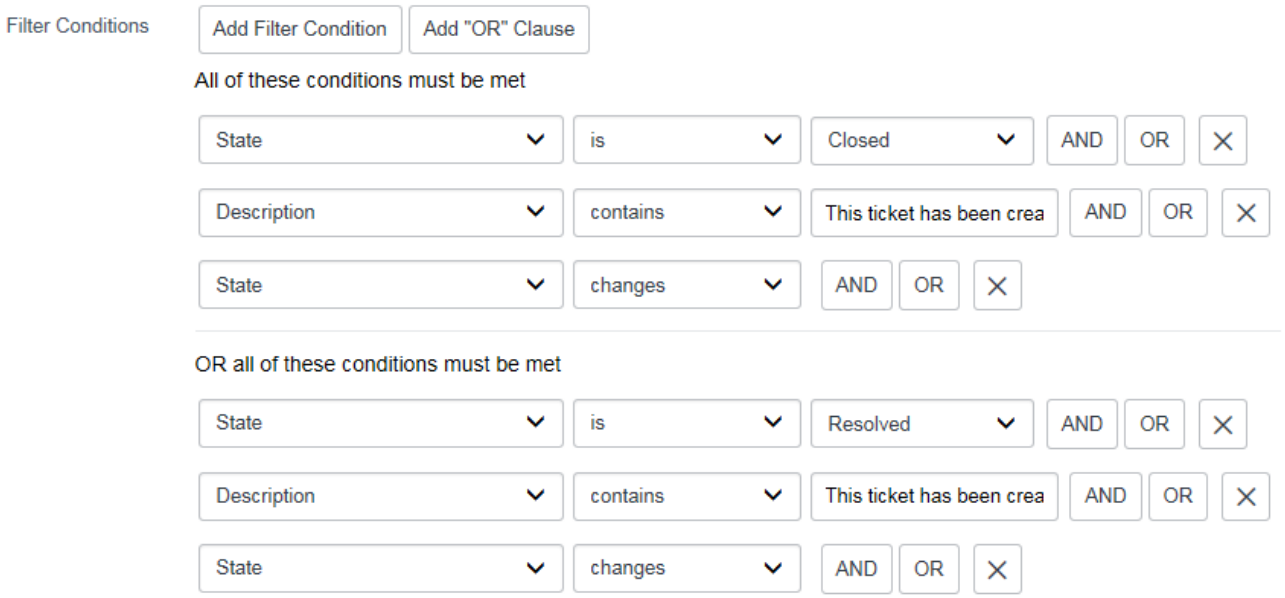
Click ‘Add “OR” Clause’ button and add another filter as:

State + is + Resolved AND

Description + Contains + “**This ticket has been created by OneClick**” AND

State + Changes

The following image displays how Filter Conditions show up for this Business Rule in ServiceNow



In the **Advanced** section at the bottom of the page give the below script for Close by changing the relevant details. See comments in the script, below

```
function onBefore(current, previous) {
 //This function will be automatically called when this rule is processed.
 myFunction();}
//Clear
function myFunction()
{
 //Set the path of the OCNotify.jar
 var jarLocation = "C:\\MID_server\\OCNotify.jar";
 //change the name of the spectrum_mid to be the name of your midserver you specified
 during mid server configuration/installation
 var midHost = "mid.server.spectrum_mid";
 var ecc = new GlideRecord('ecc_queue');
 ecc.initialize();
 ecc.agent = midHost;
 ecc.topic = "Command";
 ecc.queue = "output";
 var description = current.description;
 var re = new RegExp("Alarm ID: ((\\w+)(-\\w+){4})");
 var expResult = re.exec(description);
 var status = current.state.getDisplayValue();
 var cmd = "java -jar " + jarLocation + " " + "clear " + expResult [1] + " " +
 encodeURI(status);
 ecc.payload='<parameters><parameter name="name" value="'+cmd+'"/></parameters>';
```

```
 ecc.insert();
}
```

Clsoe Script for New York Version

Use the following script for the New York version.

```
(function executeRule(current, previous) {
 //This function will be automatically called when this rule is processed.
myFunction();
})(current, previous);
//Clear
function myFunction()
{
 //Set the path of the OCNotify.jar
 var jarLocation = "D:\\SNMidServer\\MidServer01\\agent\\OCNotify.jar";
 //change the name of the MidServer01 to be the name of your midserver you specified during mid server
 configuration/installation
 var midHost = "mid.server.MidServer01";
 var ecc = new GlideRecord('ecc_queue');
 ecc.initialize();
 ecc.agent = midHost;
 ecc.topic = "Command";
 ecc.queue = "output";
 var description = current.description;
 var re = new RegExp("Alarm ID: ((\\w+)(-\\w+){4})");
 var expResult = re.exec(description);
 var status = current.state.getDisplayValue();
 var cmd = "java -jar " + jarLocation + " " + "clear " + expResult [1] + " " + encodeURI(status);
 ecc.payload='<parameters><parameter name="name" value="'+cmd+'"/></parameters>';
 ecc.insert();
}
```

The setup is now complete.
For updates made to tickets in ServiceNow, you should see the changes being reflected in the associated alarms in OneClick Console, after the changes made to the ticket are completed on the ServiceNow side .

> **NOTE**
>
> To disable OneClick notifications from ServiceNow to OneClick, go to the Business Rule, clear the **“Active”** checkbox for both the Business Rules (Update and Clear) and click **Save.**

Alarm Fields, REST Examples and Attribute Mapping

DX NetOps Spectrum Alarm Fields

By default, the enhanced integration framework for integrating DX NetOps Spectrumwith the third-party Service Desk applications uses a polling mechanism to communicate with all the Service Desks.

The following DX NetOps Spectrum Alarm Model fields data is passed to Service Desks to create an incident.

- Summary
- reportedByUserID
- Severity
- Alarm_Status
- assetID
- TroubleShooter
- Creation_Date
- ModifiedTime
- affectedEndUserID
- resolution

Mapping Alarm Model Fields to Incident Fields

The following REST API returns mappings of the above-mentioned DX NetOps Spectrumalarm model fields to the incident fields:

URL	**Sample**: http://<serverhost>:<serverport>/ca-nim-sm/api/v2/config/integration/caspectrum/mapping/incident
Method	**GET**
Request Body	**None**
Headers	**Authorization**: Basic bmltYWRtaW46bmltYWRtaW4=
	Accept: application/json
	Content-type: application/json

Response

```
 [
  {
    "NIMField": "reportedByUserID",
    "MDRField": "reportedByUserID",
    "Description": "UserName or ID of the user who reported the
 Incident"
},
  {
   "NIMField": "name",
    "MDRField": "summary",
    "Description": "short description of the Incident"
},
  {
   "NIMField": "severity",
    "MDRField": "severity",
    "Description": "Severity of the Incident"
  },
  {
    "NIMField": "description",
    "MDRField": "description",
    "Description": "Description of the Incident"
  },
  {
    "NIMField": "status",
    "MDRField": "alarmStatus",
    "Description": "Status of the Incident"
  },
  {
    "NIMField": "affectedCIID",
    "MDRField": "assetID",
    "Description": "CI on which Incident is created"
  },
  {
    "NIMField": "assigneeUserID",
    "MDRField": "troubleShooter",
    "Description": "User to which the incident is assigned"
  },
  {
    "NIMField": "creationTimeStamp",
    "MDRField": "creationDate",
    "Description": "Time at which the incident is created/
opened"
  },
  {
    "NIMField": "updatedTimeStamp",
    "MDRField": "modifiedTime",
    "Description": "Last updated time stamp for the incident"
  },
```

```
  {
    "NIMField": "affectedEndUserID",
    "MDRField": "affectedEndUserID",
    "Description": "UserName or ID of the user impacted by the
 Incident"
```

Mapping Incident Fields and Service Desk Incident

To view field mappings between integration incident and Service Desk incident, use the below REST API:

URL	**Generic**:http://<serverhost>:<serverport>/ca-nim-sm/api/<version>/config/integration/<mdrName>/mapping/<ciName> **Sample**: *http://<Spectrum_OC_Host>:<OC_Port> /ca-nim-sm/api/v2/config/integration/<service_desk_id>/mapping/incident*
Method	**GET**
Request Body	**None**
Headers	**Authorization**: Basic bmltYWRtaW46bmltYWRtaW4=
	Accept: application/json
	Content-type: application/json
Example	To see mappings between normalized incident and ServiceNow incident fields, following REST API should be invoked – *http://<serverhost>:<serverport>/ca-nim-sm/api/v2/config/integration/<service_desk_id>/mapping/incident*

Verifying or Looking at Log Levels

This REST API is used to get log levels of the integration components.

URL	**Generic**: http://<serverhost>:<serverport>/ca-nim-sm/api/<version>/Loglevel **Sample**: http://<SPECTRUM_OC_HOST>:<OC_PORT>/ca-nim-sm/api/v2/Loglevel
Method	**GET**
Request Body	**None**
Headers	**Authorization**: Basic bmltYWRtaW46bmltYWRtaW4=
	Accept: application/json
	Content-type: application/json

Response

```
[
  {
    "name": "root",
    "level": "INFO"
  },
  {
    "name": "cacsm",
    "level": "INFO"
  },
  {
    "name": "omodule",
    "level": "INFO"
  },
  {
    "name": "oapi",
    "level": "INFO"
  },
  {
    "name": "resources",
    "level": "INFO"
  },
  {
    "name": "model",
    "level": "INFO"
  },
  {
    "name": "HPServiceManager",
    "level": "INFO"
  },
  {
    "name": "common",
    "level": "INFO"
  },
  {
    "name": "configuration",
    "level": "INFO"

Enable Loglevel in Integration Component to Debug

The following REST API is used to set the log level for the given integration component.

URL	**Generic**: http://<serverhost>:<serverport>/ca-nim-sm/api/<version>/Loglevel/<name> **Sample**: http://<SPECTRUM_OC_HOST>:<OC_PORT>/ca-nim-sm/api/v2/Loglevel/common
Method	**PUT**
Request Body	**None**
Headers	**Authorization**: Basic bmltYWRtaW46bmltYWRtaW4=
	Accept: application/json
	Content-type: application/json

Payload	<pre>{
	"name": "common",
	"level": "DEBUG"
	}</pre>

Response	<pre>{
	"name": "common",
	"level": "DEBUG"
	}</pre>

Encoded/ Plain User Password Using REST API in 10.4.2.1

URL	http://<serverhost>:<serverport>/spectrum/restful/model/modelhandle?attr=0x11f9a&val=<encodedpassword>
Method	PUT
Request Body	None
Header	application/xml
Example	http://<serverhost>:<serverport>/spectrum/restful/model/0x1200077c?attr=0x11f9a&val=9D.1.0.25.43.1.0.6.0.0.0.20.0.0.0.66.53.dc.e9.54.65.03.de.c7.1e.3c.9c.10.a8.de.0f.72.5e.25.f0.18.07.d3.0d.df.e2.1c.fe.26.79.c4.80

Attribute Mapping

The following table displays the attribute mappings between DX NetOps Spectrum(Alarms and Incidents) and the supported Service Desk applications.

Any updates made to these attributes from either DX NetOps Spectrumor the configured Service Desk will be updated and reflect in the other, based on the polling/ OneClick notification mechanism you configure.

NOTE

The OneClick notification through the push mechanism is enabled/supported only for ServiceNow. By default, DX NetOps Spectrumpolls the Service Desk servers for updates.

Alarm Field Name	Incident Field Name	MDR FIELD NAMES	MDR FIELD NAMES	MDR FIELD NAMES	MDR FIELD NAMES
		CACSM	**ServiceNow**	**HPSM**	**BMC Remedy ITSM**
reportedByUserID	reportedByUserID	RequesterID	opened_by		Submitter
Summary	name	Description	short_description	Title	Description
Severity	severity	Severity	severity		
description	description	DescriptionLong	description	Description	Detailed Description

Alarm_Status	status	TicketStatus	state	Status	Status
assetID	affectedCIID	RelatedCI	cmdb_ci	AffectedCI	
Troubleshooter	assigneeUserID	AssignedContactID	assigned_to	Assignee	Assignee Login ID
Creation_Date	creationTimeStamp	CreationTimeStamp	opened_at	OpenTime	Submit Date
ModifiedTime	updatedTimeStamp	LastModTimeStamp	sys_updated_on	UpdatedTime	Last Modiied Date
affectednEnduserID	affectednEnduserID	RequestedForID	caller_id	TicketOwner	
resolution	resolution	Resolution	close_notes	Solution	Resolution

Customize DX NetOps Spectrum to CA NIM Field Mapping

From 10.4.1, you can create a ticket with five more DX NetOps Spectrum attributes (either Alarm or Model) in the ticketing system using the CA Normalized Integration Management (NIM) custom attributes. You can map DX NetOps Spectrum attributes to NIM custom attributes and populate the same in the ticketing system.

Before adding a new attribute mapping, copy the nim-mappings-config.xml file from the `<SPECROOT>\WEB-INF\svdsk\config` directory to the `<SPECROOT>\custom\svdsk\config` directory.

Prerequisites:

- Ensure that you maintain a unique mapping; that is, one DX NetOps Spectrum attribute to one NIM Field.
- Avoid duplicate entries in either DX NetOps Spectrum attribute or NIM Field.
- A maximum of five custom mappings are supported, which is a limitation in NIM.
- Ensure that the NIM custom fields are mapped to the corresponding Service Desk fields in the NIM Customization page to populate the DX NetOps Spectrum attributes to the ticketing system.

The following are the custom fields in CA NIM:

- customField1
- customField2
- customField3
- customField4
- customField5

Sample Configuration for Reference:

The below example shows the customization of the DX NetOps Spectrum attribute to the CA NIM Field Mapping attributes to the ticketing system.

```
<custom-mappings>

<incident>
----
---
<!--
##### Attribute Custom Mapping Support #####
Below example describes - Spectrum Model Name (0x1006e) mapped to NIM customField1 - Spectrum Alarm Symptom
 Count(0x12a06) mapped to NIM customField2
Please make sure maintain unique mappings,i.e. 1 Spectrum Attribute to 1 NIM Field.
There should not be duplicate entries in either Spectrum Attribute or NIM Field.
Maximum 5 custom mappings are supported, which is current limitation in NIM
Please make sure the NIM custom field mapped to the corresponding Service Desk field in the NIM Customization
 page to populate the spectrum attributes to the ticketing system.
      -->
```

```
<attribute-mappings>
   <Mapping>
      <model-attribute>0x1006e</model-attribute>
      <NIMField>customField1</NIMField>
    </Mapping>
    <Mapping>
      <alarm-attribute>0x12a06</alarm-attribute>
      <NIMField>customField2</NIMField>
   </Mapping>
</attribute-mappings>
</incident>
</custom-mappings
```

Troubleshooting Service Desk Integrations (other than CA Service Desk Manager)

Service Desk connection is not successful

Symptom: Service Desk connection is not successful /callback to DX NetOps Spectrum is not working/ticket creation is not successful.

Workaround: Follow these steps

- Verify that the direct login via the browser with respective Service Desk is working.
- To ensure that the integration component is up and running, check if the following url is accessible or not:
  `http://<OC_HOST>:<OC_PORT>/ca-nim-sm/ui/login.jsp`
- Verify the logs (after log level change to MAX) for the payload that DX NetOps Spectrum is sending to NIM and make sure that the values that are mapped correctly.
  To see the mappings refer: Attribute Mapping

  NOTE

  If the Service Desk application is down, logs will be updated in DX NetOps Spectrum > Tomcat logs.

To enable NIM logging run an API call on OneClick server for the following:

- Get Loglevels
- Update Loglevels

For more information refer to the REST APIs example section.

Select the following options to enable the log level to MAX in DX NetOps Spectrum.

- NIM Polling Services - enables the callback logging when we enable polling
- NIM Rest Services - enables the logging and can find the payload that is being sent to NIM

.

Unable to Integrate ServiceNow, get an error - Please check the configuration for ServiceNow(ServiceNow)

Symptom: While integrating DX NetOps Spectrum with Servicenow, we get an error - **Unable to Integrate ServiceNow, get an error - Please check the configuration for ServiceNow(ServiceNow)**

Cause: We get this error if there is a Proxy configured for the browsers. At this point of time, we do not support proxy configuration for this integration.

Workaround:
You need to have a direct connection to the Servicenow servers for the integration to work. This is being considered as an enhancement in the future releases

Integration with Layer7 SiteMinder

Overview

The DX NetOps Spectrum and CA SiteMinder® the integration lets OneClick use CA SiteMinder® Single Sign-On security management capabilities to authenticate DX NetOps Spectrum users. The integration also supports users of applications such as CA Portal and CA eHealth Reports that are integrated with DX NetOps Spectrum

This release of DX NetOps Spectrum, integrates with CA SiteMinder® 12.52 SP01.

OneClick users experience single sign-on in the integrated application environment as follows:

- Users are not prompted for login credentials when they start the OneClick Console from the OneClick home page.
- Users who are logged in to the CA Portal can start the OneClick Console without having to explicitly log in to OneClick.

About DX NetOps Spectrum User Models

Before users can access OneClick in a single sign-on environment, they must have corresponding DX NetOps Spectrum user models. The administrator creates a model for each user in DX NetOps Spectrum.

For more information, see OneClick Administration section.

How OneClick Is Integrated with Layer7 SiteMinder

Complete the following procedures to integrate DX NetOps Spectrum OneClick with CA SiteMinder®:

1. Configure the required OneClick web server parameters on the SiteMinder Policy Server.
2. Register the OneClick web server as a trusted host with Policy Server from the OneClick Administration Pages.

See also:
Configure OneClick Web Server Settings
Disable or Re-enable the Integration
Troubleshooting the Integration Related Issues

Configure OneClick Web Server Parameters in Policy Server

This section describes procedures for setting up the following DX NetOps Spectrum OneClick integration components in Policy Server:

> **NOTE**
> See the Layer7 SiteMinder help if you require more information on Policy Server concepts, components and User Directory creation.

Access the SiteMinder Administration Window

The Administration window is the user interface to the SiteMinder Policy Server.

Follow these steps:

1. Access the Single Sign On web page using the site minder url provided by a administrator: **https://<HOSTNAME>:18443/iam/siteminder/adminui**
2. The Administration Login window opens. Log In as a Policy Server administrator for the domain specified in the Main Policy Server web page address using the credentials provided by the administrator.
   The Administration window opens.

Create a DX NetOps Spectrum OneClick Host Configuration Object

When you create a DX NetOps Spectrum OneClick web server host configuration object, you specify the parameters the DX NetOps Spectrum OneClick web server host uses when it connects to the SiteMinder Policy Server.

Follow these steps:

1. Go to the **Infrastructure > Host >Host Configuration Objects**.
2. Select **Create Host Configuration object**
3. Select Create a new object and type **Host Configuration** and click **OK**.
4. The Site Minder Create Host Configuration window opens. Type '**spectrum_oneclick_server**' in the name of the **Host Configuration Object** field.
5. Under the Configuration Values Section type '**Hostname**'.
6. Enter **44441** as the port value (for all ports) and click **Submit**.

   NOTE

   You can ignore the default parameter values.

   The host configuration object is now created.

Create a DX NetOps Spectrum OneClick Custom Agent Type

The DX NetOps Spectrum OneClick custom agent type defines the actions that can be performed by the DX NetOps Spectrum OneClick custom agent.

NOTE

Verify that the View, Agent Types option is selected.

Follow these steps:

1. Go to **Infrastructure > Agent >AgentTypes**.
2. Select **Create Agent Type**.
   The SiteMinder Agent Type Window opens.
3. Type '**Spectrum OneClick Custom Agent'** in the **Name** field.
4. Define an action by Clicking **Create** in the Agent Type Definition tab.
5. The New Agent Action box opens.Type '**Authenticate**' and Click **Submit**.
   The action name appears in the Actions List.
   The new agent type is now created.

Create a DX NetOps Spectrum OneClick Custom Agent

The DX NetOps Spectrum OneClick custom agent enforces the Policy Server actions on the OneClick web server.

Follow these steps:

1. Go to **Infrastructure > Agents.**
2. Select **Create Agent.**
   The SiteMinder Agent Windows opens. Select Create a new object of type Agent and click **OK**.

3. In the **Name** field, type ‘s**pectrum oneclick custom agent**’. This field specifies the the name of the web agent.
4. You can select either ‘**CA Single Sign On**’ or ‘**RADIUS**’ as the **Agent Type Settings**.
5. You can select the **Agent Type** from the list of the CA Single Sign On or Radius Vendors depending on the Agent style. If you have selected ‘s**pectrum oneclick custom agent**’ in the Agent Type settings then select **'Spectrum OneClick Custom Agent'** from the Agent Type List.
6. Ensure that the **'Support 4.x agents'** option is not selected. This field specifies the IsAgent4x attribute for this Agent instance.
7. Click **Submit**.
   The new agent is now created.

Create Domain

To create a domain, follow these steps:

1. Go to **Policy>Domain>Domains**
2. Select **Create Domain**. The Create Domain window opens.
3. Type ‘**spectrumdomain**’ in the **Name** field. This field specifies the name of the policy domain.
4. The Global Policy Apply box is to be kept checked.
5. To create the **User Directory**, select **Create** and see the SiteMinder User Directory section for details. If the User Directory is already created, then click on the **Add/Remove** button, select the directory and add to the selected list on the right. Click **OK**.
6. Click **Submit**.
   The domain is now created.

Create a DX NetOps Spectrum OneClick Realm

The DX NetOps Spectrum OneClick realm specifies the resources on the OneClick web server that are protected and that require single sign-on authentication to be accessed.

When deploying Single Sign-On for DX NetOps Spectrum OneClick and applications with which it is integrated, the DX NetOps Spectrum OneClick realm and the other application realms should be included in the same domain object. Also, the domain object user store should include users who require access to OneClick.

Follow these steps:

1. Got to **Policies>Domain>Realms**
2. Select **Create Realm**.
   The SiteMinder Create Realm: Select Domain window opens.
3. Select the Domain Name and click **Next**.
4. The Define Realm window opens.
5. Type ‘**spectrum_oneclick’** in the Name field and ‘spectrum’ in the Description field.
6. Select the **Agent** from List of Agents and click **OK**.
7. Type **‘/spectrum/’** in the Resource Filter field. This field specifies the path of the resource filter. The filed functions as a root for locating resources.
8. Select the **'Protected'** option in the Default Resource Protection section.
9. Select the authentication scheme which protects the realm. You can set it to Basic, HTML forms, proxy UI.
10. To create Rules, see Create Rules section.
11. Click **Finish**.
    The realm is now created.

Create Rules

To create rules, follow these steps:

1. Go to **Policies>Domain>Rules**
2. Select **Create Rules**. The Create Rules: Select Domain window opens.
3. Select the already existing Domain which was created and click **Next**.
   If the Domain is not created, see the Create Domain section.
4. The Create Rule: Select Realm window opens.
5. Select the existing Realm and click **Next**. If the Realm is not created, see the Create Realm section.
6. The Create Rule: Define Realm window opens.
7. Enter '**spectrumrule'** in the name field. This field specifies the name of the rule.
8. Select **Authenticate**, in the Action section.
9. Click **Finish**.
   The rules are now created.

Create Domain Policies

To create domain policies, follow these steps:

1. Go to **Policies>Domain>Domain Policies**
2. Select **Create Policy**. The **Create Policy: Select Domain** window opens.
3. Select the existing Domain name and click **Next**. The **Create Policy:General** window opens.
4. Enter '**spectrumpolicy**' in the **Name** field. This field specifies the name of the policy.
5. Click **Next**.The **Create Policy:Users** window opens.
6. Under the User Directories section, select **Add All** and click **Next**. The **Create Policy: Rules** window opens.
7. Select the existing Rule and click **Next**. The **Create Policy: Expression** window opens.
8. Click **Finish**.
   The domain policies are now created.

Configure OneClick Web Server Host Registration Settings

This section includes configuration procedures for setting up log on authentication by CA SiteMinder® for users who access OneClick.

Register the OneClick Web Server with the CA SiteMinder® Policy Server

This section describes how to register DX NetOps Spectrum OneClick Web Server as a trusted host in the Policy Server. The term *trusted host* refers to the webserver host.

When you register the webserver host, initialization parameters that enable the host to connect to the Policy Server are saved to a local configuration file, SmHost.conf. Once the host connects to the Policy Server, the host uses the settings that are specified in the corresponding host configuration object in Policy Server.

Follow these steps:

1. Access the OneClick home page.
2. Click Administration.
   The Administration Pages open.
3. Click Single Sign-On Configuration.
   The Single Sign-On Configuration page opens.
4. Select the SITEMINDER option.
   The SITEMINDER Configuration form opens.

5. Specify the following registration settings in the OneClick Host Registration section:
   - **Policy Server IP Address**
     Specifies the IP address of the Policy Server where you configured the OneClick host configuration object.
   - **Policy Server Port**
     Specifies the Policy Server port number.
     Default: 44441
   - **Policy Server Admin Username**
     Specifies the username of the CA SiteMinder® administrator with privileges in the domain.
   - **Policy Server Admin Password**
     Specifies the administrator password.
   - **Trusted Host Name**
     Specifies the fully qualified domain name of the OneClick web server host.
   - **Host Configuration Object**
     Specifies the OneClick web server host object that is configured on the Policy Server (spectrum_oneclick_server).
     The OneClick host configuration should look like the following:

6. Click Register.

Initialization parameters specified in the registration are saved to the SmHost.conf file. A new form with the “Successfully registered with the Policy Server” message opens. The form includes configuration panels where you can specify additional OneClick registration settings for the Policy Server.

Configure OneClick Web Server Settings

After you have registered the OneClick Web Server host with Policy Server, you can set additional parameters:

- In the Policy Server Settings panel, you can specify backup Policy Servers that have been set up for failover and the maximum amount of time (in seconds) the DX NetOps Spectrum OneClick Web Server waits before it drops a connection request from an unresponsive Policy Server.
- In the OneClick Agent Settings panel, specify the OneClick web server agent and cookie domain parameters. You can also instruct the webserver agent to check IP addresses in cookies so that it can reject unauthorized web server requests if the IP address that is stored in a cookie does not match the IP address of the requester.
- In the Authentication Logging panel, you can specify whether to log authentication information to the Tomcat log file or another log file. You can also disable logging.
- In the DX NetOps Spectrum Authentication Failover panel, you can specify whether to allow OneClick authentication when Single Sign-On authentication fails because the Policy Server cannot be reached. This means that DX NetOps Spectrum users would be able to log on to OneClick as they normally would without a single sign-on.

These settings do not take effect until you save the settings and enable the integration.

The following sections describe the configuration panels and OneClick registration settings in more detail.

Policy Server Settings

The Policy Server Settings panel is available on the OneClick Administration, Single Sign-On Configuration page in the SITEMINDER Configuration form. This form is available after you have successfully registered the OneClick Web Server host with the Policy Server. For more information, see Register the OneClick Web Server with the SiteMinder Policy Server.

In the Policy Server Settings panel, you can specify one or more backup Policy Servers that have been configured for failover. The OneClick Web Server attempts to connect to a backup Policy Server if it detects that the primary Policy Server that is specified in the Registration form is down.

The following shows the Policy Server Settings panel:

You can also specify the timeout interval for connection requests by the OneClick web server to the Policy Server. Set an interval in the Policy Server Settings form. The OneClick web server drops the request if the Policy Server does not respond within the interval. The default interval is 60 seconds. Increase the interval if your connection requests result in frequent drops in high-data traffic or network slowdowns.

NOTE
The OneClick web server does not attempt to connect to a backup server after a request drop because a connection failure alone does not necessarily indicate that the primary server is down.

Follow these steps:

1. To add a backup server, enter the IP address and a port number for the backup server if it differs from the default port, 44441, and click Add.

The backup server and port number are added to the Policy Servers box.

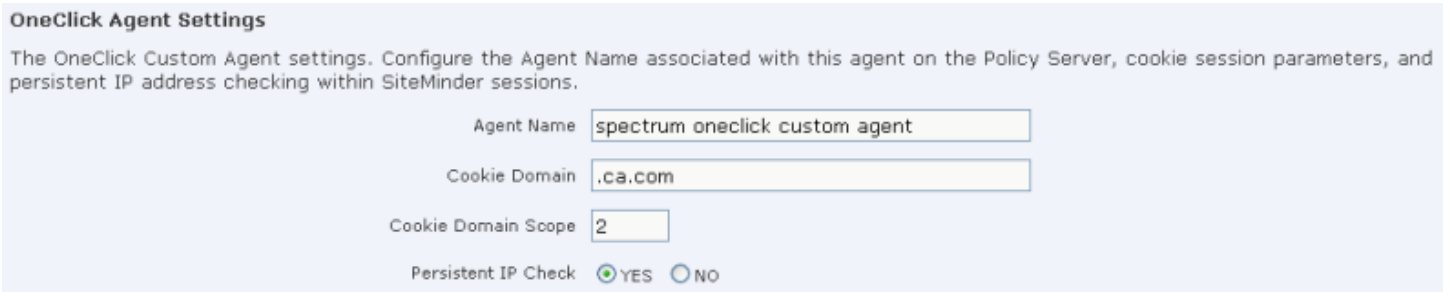
2. To remove a backup, select the server entry in the Policy Servers box, and click Remove.
   The backup entry is removed from the Policy Servers box.
3. To modify the Request Timeout interval, enter a new interval value.
4. Specify whether the Policy Server skips validation of the session IP. Validation if the IP address of the session is changed by a reverse proxy.

Configure OneClick Agent Settings

The OneClick Agent Settings panel is available on the OneClick Administration, Single Sign-On Configuration page in the SITEMINDER Configuration form. This form is available after you have successfully registered the OneClick Web Server host with the Policy Server. For more information, see Register the OneClick Web Server with the SiteMinder Policy Server.

In the OneClick Agent Settings panel, you can specify web agent configuration settings for this trusted host (the OneClick webserver).

The following image displays the OneClick Agent Settings panel:



Follow these steps:

1. From the Single Sign-On Configuration page, navigate to the OneClick Agent Settings panel and configure the following settings:
   - **Agent Name**
     Indicates the name of the DX NetOps Spectrum OneClick custom agent that is created in Policy Server.
   - **Cookie Domain**
     Indicates the cookie domain for the OneClick web server agent. Use the following format for the domain value:

     ```
     .your_company.com
     ```

     NOTE
     If you are trying to inter-operate between CA eHealth and DX NetOps Spectrum using CA EEM or CA SiteMinder®, a second-level domain or greater is required for the cookie domain.

     Cookies are restricted to a certain domain level for security reasons. According to "RFC 2901" and "RFC 2965", cookies cannot be set to a top-level domain (such as .com, .org, .gov). A minimum of the second-level domain is required. For more information, consult the RFC documentation.
     If a domain name ends with a two-letter country code, a minimum of a third-level domain is required. A cookie that is set to a second-level domain is visible at all of its third-level domains. However, a cookie that is set to a third-level domain is not visible at its parent second-level domain or at other subdomains. If no domain name is specified when a cookie is written, the cookie domain attribute defaults to the domain name where the application resides.
   - **Cookie Domain Scope**
     Indicates a cookie domain scope value. The scope determines the number of sections, which are separated by periods, that make up the domain name. Consider the following example:

- Scope = 0, the most specific scope for a given host. (*Not supported in this release.*)
- Scope = 2, .your_company.com
- Scope = 3, your_division.your_company.com

NOTE
A scope value of 1 is not allowed by the HTTP specification.

Default: 2

– **Persistent IP Check**
Enables (Yes) or disables (No) the agent to verify that a single sign-on session token originates from an IP address that differs from the IP address where it is created. If the agent detects a mismatch, it denies the session request.

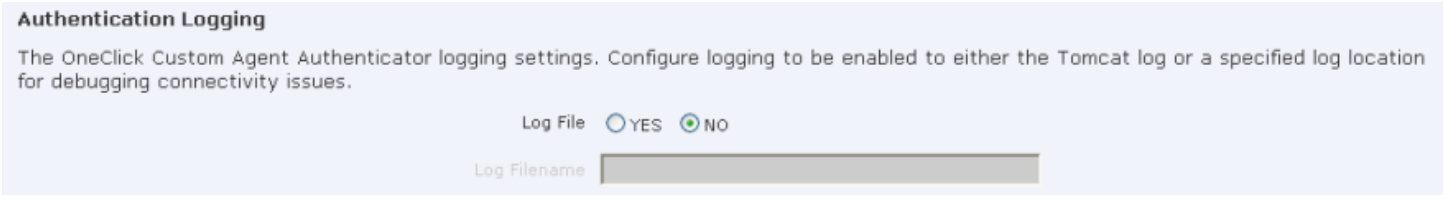
2. Click OK.
OneClick agent settings are configured.

Configure Authentication Logging

The Authentication Logging panel is available on the OneClick Administration, Single Sign-On Configuration page in the SITEMINDER Configuration form. This form is available after you have successfully registered the OneClick Web Server host with the Policy Server. For more information, see Register the OneClick Web Server with the SiteMinder Policy Server.

In the Authentication Logging panel, you can enable verbose logging of authentication and authorization activities for all authentication requests. By default, log files are written to the Tomcat log file (stdout.log on Windows, Catalina.out on Linux). However, you can specify another file and location. Log files include information that can help you troubleshoot authentication and authorization problems. For example, the log indicates whether a user was authenticated properly in the Policy Server and whether a user had the appropriate role associated with a DX NetOps Spectrum user model for the OneClick application.

The following shows the Authentication Logging panel:



NOTE
Because of the large amount of information that is written to the log file, only enable verbose logging as required for troubleshooting purposes. Do not leave it enabled for an extended period of time.

Follow these steps:

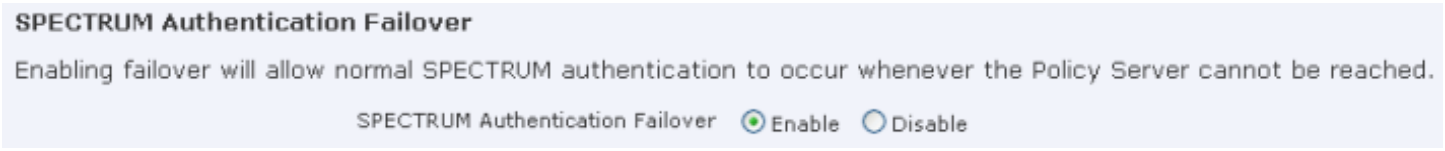
1. To enable logging to the Tomcat log, select YES.
2. To enable logging to a specific file (not the Tomcat log), select YES and enter the full log file path and the log file name in the Log Filename box.
3. To disable logging, select NO (default).

DX NetOps Spectrum Authentication Failover

The DX NetOps Spectrum Authentication Failover panel is available on the OneClick Administration, Single Sign-On Configuration page in the SITEMINDER Configuration form. This form is available after you have successfully registered the OneClick Web Server host with the Policy Server. For more information, see Register the OneClick Web Server with the SiteMinder Policy Server.

In the DX NetOps Spectrum Authentication Failover panel, you can specify whether users are able to log on to OneClick as they normally would (without Single Sign-On) if the OneClick Web Server connection to the Policy Server fails. Do not enable failover if your organization prefers for personnel to access OneClick only through Single Sign-On.

The following shows the DX NetOps Spectrum Authentication Failover panel:



NOTE
DX NetOps Spectrum user passwords may differ from those used by Policy Server to authenticate those users.

To enable authentication failover, select Enable.

User logon requests are authenticated by DX NetOps Spectrum if Single Sign-On fails. Users who have logged on to OneClick through Single Sign-On are prompted to provide DX NetOps Spectrum logon credentials when authentication failover occurs. Conversely, when a connection to the Policy Server is established, those users are prompted for Single Sign-On login credentials.

To disable authentication failover, select Disable (default).

User logon requests are not authenticated by DX NetOps Spectrum if Single Sign-On fails.

Test and Save the Integration

Options to test and save the integration configuration settings are available in OneClick. In OneClick Administration, a Single Sign-On Configuration page is included in the SITEMINDER Configuration form. This form is available after you have successfully registered the OneClick Web Server host with the Policy Server. For more information, see Register the OneClick Web Server with the CA SiteMinder® Policy Server.

Execute an integration test after you have set integration parameters and before you save and enable the integration. The test determines whether you configured the connection parameters correctly and the test username and test password match an entry in the domain. If the test fails, you can reconfigure parameters and re-test. After you have successfully tested the settings, you can save them, automatically enabling the integration.

The following shows the Test and Save options at the bottom of the SITEMINDER Configuration form:

Test the integration settings from OneClick Administration.

Follow these steps:

1. Enter a username and password from the Policy Server domain user directory in the Test Username box and Test Password field. CA SiteMinder® administrators manage the user directory and provide the password for Single Sign-On authentication.

   NOTE
   The username in the Policy Server user directory must match the username created in the applications (DX NetOps Spectrum, CA eHealth) that the user plans to access.
2. Click Test.

If the test is successful, the following message appears:
"Successfully established connection with the Policy Server"

You can also save the integration settings.

Follow these steps:

1. Click Save to save the integration settings.
   You are prompted to restart Tomcat.
2. Click OK to restart Tomcat to apply the configuration.
   SiteMinder single sign-on integration in OneClick is enabled.

Disable or Re-enable the Integration

When you initially configure the CA SiteMinder® integration settings, you automatically enable the integration upon saving. You can also disable and re-enable the integration if necessary. When you disable the integration, users are authenticated by the integrated applications that they access from OneClick.

Disable the CA SiteMinder® integration on the Single Sign-On Configuration page in OneClick Administration.

Follow these steps:

1. Select 'No Single Sign-On' and click Save.
   You are prompted to restart Tomcat.
2. Click OK to restart Tomcat and disable the CA SiteMinder® integration.

When the integration is disabled, you can re-enable it.

Follow these steps:

1. On the OneClick Administration, Single Sign-On Configuration page, select the SITEMINDER option.
   The SITEMINDER Configuration form opens.
2. Verify that the existing settings are correct and click Save.
   You are prompted to restart Tomcat.
3. Click OK to restart Tomcat and apply the CA SiteMinder® integration configuration.

Troubleshooting the Integration Related Issues

This section provides solutions to problems you may encounter with the integration. If you cannot find a solution in this section to your particular problem or you need additional assistance, contact Technical Support.

Debugging Options

OneClick provides multiple debugging options that can help you pinpoint problems with the integration.

- Users cannot log in to the OneClick home page.
  You can enable logging of authentication activities to the Tomcat log (stdout.log on Windows, catalina.out on Linux) using the Authentication Logging option in Single Sign-On Configuration. Authentication logging indicates whether Policy Server is denying a user access to DX NetOps Spectrum OneClick or if the user role is not being retrieved from DX NetOps Spectrum.
- The OneClick web server cannot connect to Policy Server during a single sign-on configuration.

You can enable logging of information about integration parameters to the Tomcat log (stdout.log on Windows, catalina.out on Linux) by enabling the Web Server Debug Page (Runtime)/Single Sign-On Integration option available from the Debugging link on the Administration page.

- Particular users cannot access the OneClick Console from the OneClick home page without being prompted for credentials.
  You can enable the Debug Console for Single Sign-On in the OneClick Console. It provides information about single sign-on token recognition. You can also enable this option directly in the oneclick.jnlp file.

How to disable the EEM integration with Spectrum

Perform the following steps to disable EEM and Spectrum integration:

1. Have all users log out from OneClick.
2. Shut down tomcat on the OneClick server.
3. On the OneClick web server, in the **$SPECROOT/custom/ directory** rename the SSO directory to sso.bak.
4. Edit the web.xml in the directory **$SPECROOT/tomcat/webapps/spectrum/WEB-INF** as follows**:**
   a. Change the following parameters:
   ```
   <login-config>
   <auth-method> EXTERNALSSO </auth-method>
   <realm-name>SPECTRUM</realm-name>
   </login-config>
   ```
   to:
   ```
   <login-config>
   <auth-method> BASIC </auth-method>
   <realm-name>SPECTRUM</realm-name>
   </login-config>
   ```
   b. Comment this entry out that should show at the top of the file:
   ```
   <listener>
   <listener-class>com.aprisma.tomcat.authenticator.ExternalSSOAuth</listener -class>
   </listener>
   ```
   to make it:
   ```
   <!--
   <listener>
   <listener-class>com.aprisma.tomcat.authenticator.ExternalSSOAuth</listener-class>
   </listener>
   -->
   ```
5. Save the changes that are made to the **$SPECROOT/tomcat/webapps/spectrum/WEB-INF/web.xml file.**
6. Go to the **$SPECROOT/tomcat/conf/context.xml** file and add the following:
   ```
   <Valve className="org.apache.catalina.authenticator.BasicAuthenticator"
    changeSessionIdOnAuthentication="false" /></Context>
   ```
   and comment out the following:
   ```
   <Valve
    className="com.aprisma.tomcat.authenticator.ExternalSSOAuth"changeSessionIdOnAuthentication=
   ></Context>
   ```
   So that it looks like:
   ```
   <!--
   ```

```
<Valve
 className="com.aprisma.tomcat.authenticator.ExternalSSOAuth"changeSessionIdOnAuthentication=
></Context>
-->
```

7. Save the file changes to the **$SPECROOT/tomcat/conf/context.xml** file.
8. Start the OneClick Tomcat web server and attempt to log in with a non-ldap account.

Re-Registering the OneClick Web Server

In some troubleshooting scenarios (current registration is invalid, for example), you may have to remove the current registration and re-register the OneClick web server with the CA SiteMinder® Policy Server.

Follow these steps:

1. Stop Tomcat.
2. Remove the Trusted Host Name for the server from the Policy Server.

   NOTE
   For more information, see the Policy Server Help.
3. Remove the *$SPECROOT*/custom/sso directory.
4. Specify DX NetOps Spectrum OneClick Authentication in the web.xml file.
5. Restart Tomcat.
   Register the webserver.

Specific Problems and Solutions

Specific Problems and Solutions

This section describes specific problems with DX NetOps Spectrum SiteMinder integration and recommended procedures for solving the problems.

Host Registration Fails

Valid on Linux and Windows

Symptom:

When you test the registration, an error message indicates that the OneClick Web Server was unable to connect to the Policy Server.

When you test the registration, an error message indicates that the OneClick Web Server was able to connect to the Policy Server, but the login credentials were invalid.

Solution:

If you received an “Invalid credentials” message, make sure the username and the password you specified in Single Sign-on Configuration are correctly configured in CA SiteMinder®. Consult the SiteMinder/Policy Server administrator for assistance.

If you received an “Unable to connect” message, verify that the Policy Server is up and running and then check settings in Single Sign-on Configuration and Policy Server.

Single Sign-on Configuration:

- Verify that the Policy Server IP Address and Policy Server Port settings are correct.
- Verify that the Policy Server Admin Username and Policy Server Admin Password settings are correct. Also, verify that the credentials provide administrative privileges.

Policy Server:

- Verify that the DX NetOps Spectrum OneClick host configuration object has been correctly created on the Policy Server.
- Verify that the name you specified in Single Sign-On Configuration for the Trusted Host Name setting is not a duplicate of a name that is already included as a Trusted Host in the Policy Server. If it is a duplicate, use another name or delete the name in Policy Server and retry the registration.

Authentication Server (Policy Server) Cannot Be Contacted

Valid on Linux and Windows

Symptom:

An error message states that the authentication server cannot be contacted when a user attempts to invoke the OneClick Console.

Solution:

- Verify that the Policy Server is up and running.
- If the message mentions that the user failed to authorize, do the following:
  - On the Single Sign-On Configuration page, set Log File to “YES” and Save.
  - Look at the Tomcat log after the user attempts to log on. The log indicates whether the Policy Server is denying the user or if the user role is not being retrieved from DX NetOps Spectrum.

Prompted for DX NetOps Spectrum Logon Credentials When Invoking OneClick Console

Valid on Linux and Windows

Symptom:

Even though the integration is enabled, the user is prompted for a DX NetOps Spectrum username and password when attempting to start the OneClick Console from the OneClick home page.

Solution:

An error might have occurred in the communication of Single Sign-On parameters to OneClick from the webserver. To display how Single Sign-On information is being transferred, enable OneClick to display the java debug console.

Follow these steps:

1. Edit the JNLP file (located at *$SPECROOT*/tomcat/webapps/spectrum/oneclick.jnlp).
2. Find the following line:
   ```
   <!--<argument>-debug Poller=on</argument> -->
   ```
3. Add the following line below it:
   ```
   <argument>-debug SSOConsoleDebug=on</argument>
   ```
4. Launch into the OneClick Console with the java debug console displayed.
   If you detect that the -ssoToken parameter is not being passed or it does not have a value associated with it, there is a problem with how your Single Sign-On cookies are being written. Make sure your cookie settings (located in the OneClick Agent Settings area of the Single Sign-On Configuration administration page) coincide with how you are accessing your OneClick web server.

Example: Incorrect Cookie Setting Causes Authentication Problem

The following is an example of an incorrect cookie setting that would produce the authentication problem:

- In the OneClick Agent Settings page, the cookie domain is set to ".ca.com" and the cookie scope is set to "2". This means that cookies will be written to.ca.com in the browser.
- You access your web server using http://someuser/spectrum in your URL. This violates the cookie settings because "someuser" is out of scope with the.ca.com domain. Instead, you should use http://someuser.ca.com/spectrum to access your web server.

Cannot Access the Disable Integration Option in Single Sign-On Configuration

Valid on Linux and Windows

Symptom:

You cannot access the Single Sign-On Configuration page and disable the integration.

Solution:

The OneClick access authorization method is specified in the web.xml file. You can disable the integration (and restore standard DX NetOps Spectrum login access) by editing the <auth-method> element in the file.

Application Web Agents Ignore OneClick Single Sign-On Tokens

The OneClick implementation of CA SiteMinder® uses its own customized agent, rather than an installed web server agent, to communicate with the SiteMinder policy server. If you are sharing single sign-on tokens between OneClick and installed web agents of other applications, you may need to modify the agent configuration of each installed web agent to recognize, or not ignore, OneClick agent tokens.

Set the following web agent parameter from NO to YES for the other applications:

```
AcceptTPCookie=YES
```

Integration with DX APM

> **NOTE**
>
> Starting from the 10.3 release, the **Spectrum SNMP Trap** plugin is deprecated and will not be shipped with DX NetOps Spectrum. However, you can use the **SNMP Alert Action** plugin of DX APM for the trap generation between DX NetOps Spectrum and DX APM.
>
> The **Spectrum SNMP Trap** plugin of DX NetOps Spectrum and **SNMP Alert Action** feature of DX APM both are used for the same purpose (for trap generation). Since, the **SNMP Alert Action** feature of DX APM has more enhanced functionality, we recommend you to use the **SNMP Alert Action** in DX APM for the trap generation.
>
> To configure the SNMP Alert Action plugin, see the Create and Configure Notification Actions section. To migrate from **Spectrum SNMP Trap** to **SNMP Alert action**, see Migrate from Spectrum SNMP Trap to SNMP Alert Action of DX APM.

Integration Prerequisites

Beginning with version 9.1 of DX Application Performance Management (DX APM), the name "Wily" was dropped from the CA Wily Introscope® product. This section retains the name where it helps to clarify compatibility with previous versions of DX APM.

For DX NetOps Spectrum and DX APM integration information, see the Integration Compatibility page.

How the Integration Works

DX Application Performance Management (DX APM) consists of an Enterprise Manager and one or more CA Introscope agents. Introscope agents are installed on servers running Java virtual machines (JVMs). The agents deliver information about numerous metrics, such as servlet response time and report metrics, to the Enterprise Manager.

Enterprise Manager uses a Management Module to organize and report on the metric data provided by an agent. By configuring thresholds on reported metrics, Enterprise Manager creates an alert when a threshold is violated and clears the alert when the threshold is no longer violated. Introscope agents are polled every 60 seconds to determine whether a threshold has been violated or whether a violated threshold has been cleared. An alert is created when a threshold event occurs.

DX NetOps Spectrum models the CA Introscope infrastructure using two model types, the IntroscopeAdmin model and the WilyAgent model.

- The IntroscopeAdmin model represents one Enterprise Manager.
- The WilyAgent model represents an application container (JVM or CLR). When you initiate a Discovery, or when a Discovery is initiated when you restart Tomcat, DX NetOps Spectrum requests a list of application containers from the Enterprise Manager and models them as WilyAgent models.

When CA Introscope generates an alert, data about the metric and its threshold is forwarded to DX NetOps Spectrum. An alarm is generated on a WilyAgent model. If the alert is cleared, DX NetOps Spectrum is notified and clears the associated alarm.

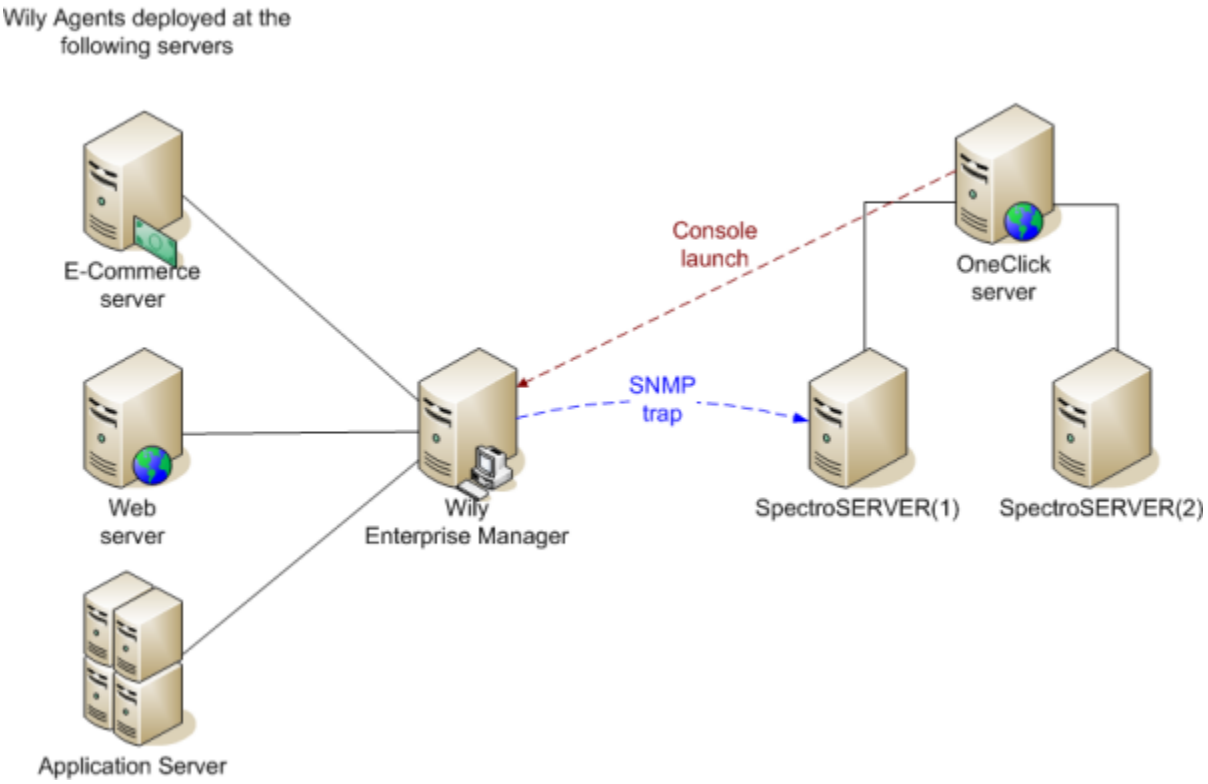
The DX NetOps Spectrum integration with DX APM also actively monitors the inventory of application containers on an Enterprise Manager.

- When an Enterprise Manager starts to monitor a new application container, DX NetOps Spectrum is notified and automatically creates a WilyAgent model to represent the application container.
- When an Enterprise Manager no longer monitors a discovered application container, DX NetOps Spectrum generates an alarm on the corresponding WilyAgent model.

> **NOTE**
> If you move an Introscope agent from one Enterprise Manager to another, a new IntroscopeAgent model is created and associated with the IntroscopeAdmin model. That model represents the Enterprise Manager to which the agent was moved. This activity results in two identical IntroscopeAgent models associated with two distinct IntroscopeAdmin models. Destroy the original IntroscopeAgent model so that the new IntroscopeAgent model receives all subsequent events.

Integration Architecture

The following diagram depicts the architecture of the DX APM and DX NetOps Spectrum integration, and identifies the direction of data transfers.



Integration Considerations

Review the following considerations:

- The integration combines web services with trap notifications:
  - A traditional axis 1.4 polling web service that provides inventory information, such as the Management Module, the agent, alert definitions, alerts, and Management Module/Agent pairs that help determine the DX NetOps Spectrum model. DX NetOps Spectrum uses only the agent information.
  - A bi-directional subscription web service, introscope-wssdk-consumer, uses the Apache Muse framework, which is deployed inside *$SPECROOT*/ tomcat/webapps. The introscope-wssdk-consumer web service listens for and processes asynchronous updates from CA Introscope.
- Trap notifications require the installation of a trap generation plugin on the CA Introscope Enterprise Manager.
- All communication between DX NetOps Spectrum and CA Introscope passes through the Tomcat web server for agent inventory.
- The integration can be enabled on only one server.
- In a distributed SpectroSERVER environment, designate a OneClick server as the integration server.

Maintenance Mode

You can put WilyAgent models into maintenance mode. However, the status of a WilyAgent model is dependent on event updates that the Enterprise Manager sends through SNMP traps. Therefore, before putting WilyAgent models into maintenance mode, consider the following:

- If the WilyAgent model is in an alarm state, and the Enterprise Manager posts an alarm clear update during maintenance mode, the model remains in an alarm state when it comes out of maintenance.
- If the WilyAgent model is in a normal state, and its counterpart on the Enterprise Manager enters an alarm state during maintenance mode, the model remains in a normal state when it comes out of maintenance.

How to Integrate with DX APM

Contents

The following sections describe the process of installing and configuring the integration of DX APM and DX NetOps Spectrum:

Install the Trap Generation Plugin on the Enterprise Manager

> **NOTE**
>
> Starting from the 10.3 release, the **Spectrum SNMP Trap** is deprecated and will not be shipped with DX NetOps Spectrum. However, you can use the **SNMP Alert Action** plugin of DX APM for the trap generation between DX NetOps Spectrum and DX APM.
>
> The **Spectrum SNMP Trap** plugin of DX NetOps Spectrum and **SNMP Alert Action** feature of DX APM is used for the same purpose (for trap generation). Since, the **SNMP Alert Action** feature of DX APM has more enhanced functionality, we recommend you to use the **SNMP Alert Action** in DX APM for the trap generation.
>
> To configure the SNMP Alert Action plugin, see the Create and Configure Notification Actions section. To migrate from **Spectrum SNMP Trap** to **SNMP Alert action**, see Migrate from Spectrum SNMP Trap to SNMP Alert Action of DX APM.

Create and Configure Notification Actions

Contents

> **NOTE**
>
> Starting from the 10.3 release, the **Spectrum SNMP Trap** is deprecated and is not shipped with the installer. However, you can use the **SNMP Alert Action** plugin of DX APM for the trap generation between and DX APM.
>
> The **Spectrum SNMP Trap** plugin of and **SNMP Alert Action** feature of DX APM both is used for the same purpose (for trap generation). Since, the **SNMP Alert Action** feature of DX APM has more enhanced functionality, we recommend you to use the **SNMP Alert Action** in DX APM for the trap generation.
>
> To migrate from **Spectrum SNMP Trap** to **SNMP Alert action**, see Migrate from Spectrum SNMP Trap to SNMP Alert Action of DX APM.

Use the DX APM Workstation to create and configure notification actions for the alert that forwards data to . Configure the SNMP Alert Action Plugin of DX APM allows the APM Catalyst Connector to get Introscope alert data and supply it to DX NetOps Spectrum.

Create SNMP Alert Action

Follow these steps:

1. Open the DX APM Management Module Editor.
2. Select **Elements**, **New Action**, **New SNMP Alert Action**.
3. Provide a name for the new action and select the Management Module that contains the alert that forwards data to .
4. Click OK.
   The new SNMP alert action gets created.
5. Select the **Active** checkbox to activate the action.

6. Complete the details for **SNMP Destination** and **Introscope** in the **SNMP Trap Configuration** panel:
   SNMP Destination:
   - **Host IP**. The IP address of the SpectroSERVER.
   - **Trap Port**. The port number of the SNMP trap for the SpectroSERVER. The default value is '162'.
   - **Community**. the SNMP community string for the SpectroSERVER. The default value is 'public.'

   Introscope:
   - **EM/MOM Host IP**. The IP address of an Enterprise Manager or the MOM Enterprise Manager in a cluster environment.
     - Only IPv4 is supported.
     - The Host IP address must be set to the same as the Enterprise Manager IP address.
   - **WebView Protocol**. The port number of the Enterprise Manager WebView. Select one of the following protocols:
     - Http
     - Https
   - **WebView Host IP**. The IP address of the Enterprise Manager WebView.
   - **WebView Port**. The port number of the Enterprise Manager WebView. The default value is '8080'.
   - **Management Module**. The name of the Management Module that contains the alert that forwards data to . This is the same Management Module that you selected in step 3.
   - **Dashboard Name**. The name of the dashboard for the Alarm/Event launches back.
   - **Domain Name**. The domain name (or Superdomain name) that corresponds with the dashboard name that you specified.
7. Click **Apply**.
   The trap action is configured.
8. Click **Test** to verify the communication between the Enterprise Manager and the APM connector.
   The SNMP action alert configuration is set.

For more detailed configuration details, see the Create an SNMP Alert Action section in the DX APM documentation.

Alerts that are associated with the trap actions must have their 'Notify by Individual Metric' check box selected. You can create Management Modules and Dashboards and Alerts. For more information, see the CA Introscope documentation.

Migrate from Spectrum SNMP Trap to SNMP Alert Action of DX APM

If you are already using the the **Spectrum SNMP Trap** plugin for trap generation, you can migrate to **SNMP Alert Action** of DX APM using the following steps:

1. Login to DX APM.
2. Navigate to **Workstatiion**, **Management Module**.
3. Select the management module that you want to edit.
4. Expand the **Alerts** of selected management module.
5. Select the alert for which you want to assign the SNMP Alert Action. The right side window displays, the **Configuration** and **Settings** details.
6. Select the Spectrum SNMP Trap action that is already applied to the selected alert. Click **Remove**.
7. Click **Add** to assign the **SNMP Alert Action** for the selected alert. The **Choose Action** window appears. This window allows you to either to choose an already created SNMP Alert Action or create a new action using the **New Action** button. For creating new SNMP Alert Action, see the Create SNMP Alert Action section.
8. Choose an SNMP Alert Action from the list of actions.
9. Click **Choose**. The SNMP alert action is associated with the selected alert.

NOTE

For further help regarding the migration contact the DX APM Support team.

Configure Web Services on the Enterprise Manager

You can configure web services on the Enterprise Manager. For more information, see DX APM Introscope Web Services .

Designate the Integration Server and Enable the Integration

Designate an OneClick Tomcat server as the integration server host. You can designate the server you use to access OneClick or you can designate a headless server, which is dedicated to processing DX APM data. You can designate any OneClick Tomcat server within the distributed environment. Therefore, select a server that can accommodate the extra load of the DX APM data.

Important: The DX APM integration becomes disabled when you designate a headless server as the integration server host and then stop and restart an OneClick Tomcat server that is not the integration server host. In such a situation, re-enable the integration.

You designate the integration server and enable the integration at the same time.

Follow these steps:

1. Select Administration from the OneClick home page.
   The OneClick Administration page opens.
2. Select APM Integration Configuration from the left panel.
   The APM Configuration page opens.
3. Complete the fields as follows:
   - **Integration Server Host Name**. The integration server hostname.
   - **Integration Server Port**. The port number for the integration server.
4. Select Enabled in the APM Introscope Integration field.
5. Click Save.
   The Successfully saved configuration message appears.

   NOTE
   You can disable the integration at any time.

Follow these steps:

1. Select Administration from the OneClick home page.
   The OneClick Administration page opens.
2. Select APM Integration Configuration from the left panel.
   The APM Configuration page opens.
3. Select Disabled in the APM Introscope Integration field.
4. Click Save.
   The Successfully saved configuration message appears.

   NOTE
   Disabling the integration disables all IntroscopeAdmin models in a Distributed SpectroSERVER (DSS) environment. DX NetOps Spectrum requires a single IntroscopeAdmin model modeling a single Enterprise Manager in a DSS environment.

Create IntroscopeAdmin Models

After you enable the integration, create an IntroscopeAdmin model to represent the connection to an Enterprise Manager. The Enterprise Manager can be modeled in any landscape in a Distributed SpectroSERVER environment.

NOTE
You can create an IntroscopeAdmin model in each landscape in a distributed SpectroSERVER environment to monitor a singular Enterprise Manager. However, only a single IntroscopeAdmin model can monitor a single Enterprise Manager in a distributed SpectroSERVER environment. Disabling the integration disables all IntroscopeAdmin models.

Follow these steps:

1. Select the Universe subview from the OneClick Navigation panel and select the Topology tab from the Contents panel.
   The OneClick Topology view is displayed in the Contents panel.
2. Click the Model by Type icon

   The Select Model Type dialog opens.
3. Select IntroscopeAdmin from the list, and then click OK.
   The 'Create Model of Type IntroscopeAdmin' dialog opens.
4. Enter the unique Model name and network IP address of the Introscope host system, and then click OK.
   The IntroscopeAdmin model is created.

Discover Introscope Agents

The final step in the configuration process is for DX NetOps Spectrum to discover the Introscope agents that are configured to send information to DX NetOps Spectrum.

Follow these steps in DX APM:

The Spectrum Discovery process for the integration finds and creates the Management Modules as DX APM Agent models in Spectrum. If there are no Management Modules present in DX APM EM, the discovery process completes successfully but no DX APM Agent models are created in DX NetOps Spectrum.

1. Add the following parameter in the 'IntroscopeEnterpriseManager.properties' file, which is located in the '<EM_Home>/config' directory to add the Management Modules in DX APM EM.
   'introscope.alerts.extension.managementmodules.enable=ALL'

   NOTE

   - If the parameter exists, change its value to 'ALL'.
   - The value 'ALL' must be in all capital letters else it is not acknowledged.
2. Restart the EM.

Follow these steps in DX NetOps Spectrum:

1. Select the Universe subview from the OneClick Navigation panel and select the IntroscopeAdmin model.
   Information about the IntroscopeAdmin model is displayed in the Contents panel.
2. Click the Information tab.
   IntroscopeAdmin configurations and information are displayed.
3. Expand the Introscope Integration Administration node.
   Integration configurations are displayed.
4. Verify the settings.
   To change a setting, click the 'set' link next to the setting, enter the appropriate information in the field, and press Enter.
5. When your settings are correct, click Discover Agents.
   The Introscope agents are discovered, and the Discovery status is displayed in the Status window.

Alarms, Events, and Application Statistics

View Introscope Alarms and Events

You can view Introscope alarms and events in OneClick.

NOTE
For more information, see Modeling and Managing Your IT Infrastructure .

Follow these steps:

1. Launch OneClick.
2. Expand the Universe subview in the Navigation panel, and select the IntroscopeAdmin model.
   Information about the IntroscopeAdmin model is displayed in the Contents panel.
3. Click the Alarms tab to display alarms or click the Events tab to display events.
   Introscope alarms or events are displayed in the Contents panel. Information about the agent that caused the event or alarm is displayed in the Component Detail panel when you select an alarm or event in the Contents panel.
4. (*Optional*) Launch the Introscope Dashboard to view more information about the alert in the DX APM interface:
   a. Select an alarm.
   b. Click the URL on the Alarm Detail tab.
      The Introscope Dashboard launches.

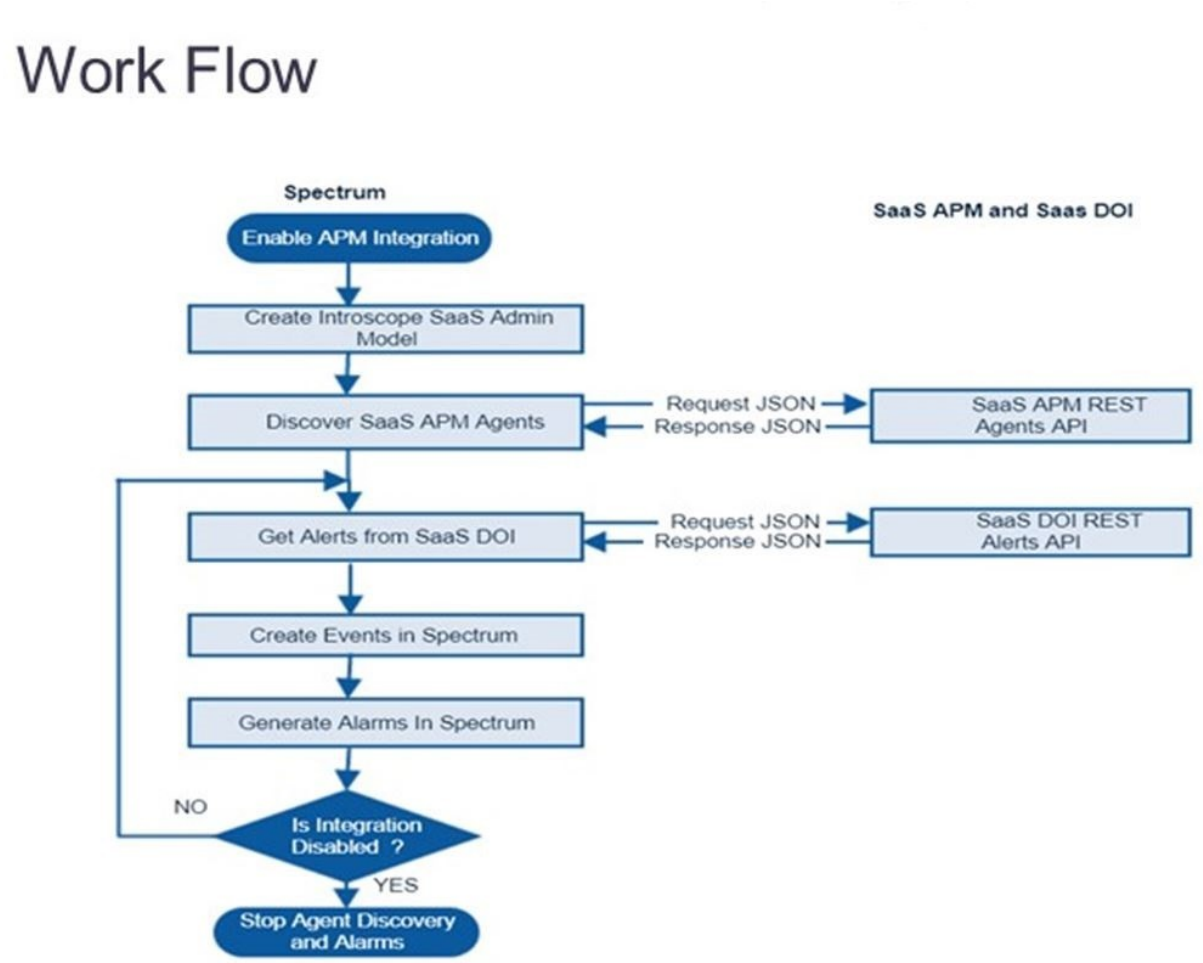
Support for DX NetOps Spectrum Integration with APM SaaS and DXI

About the Integration

With Spectrum 10.3.1, users can now leverage the new APM SaaS integration! The CA APM (SaaS) integration is available through the CA Digital Experience Insights (DXI) platform. With this integration, users can now, discover models/agents from APM SaaS, and get APM alerts via SaaS DOI. APM and (Digital Operational Intelligence) DOI are part of SaaS-enabled DXI. The Spectrum with APM SaaS and DXI platform enabled solution, address key challenges for customers such as managing APM agents in SaaS, discovering APM, inventory/models from SaaS, and fetching the APM alerts from SaaS.

How the Integration works

Following is the screenshot of the APM SaaS integration works:

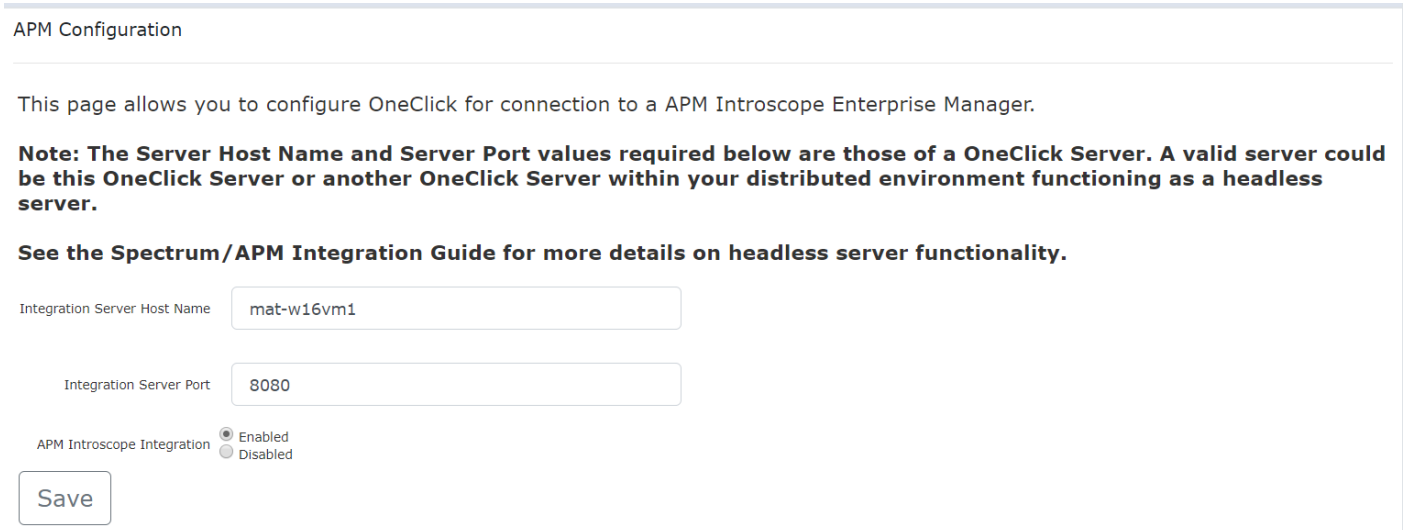


Generate APM SaaS Security Token

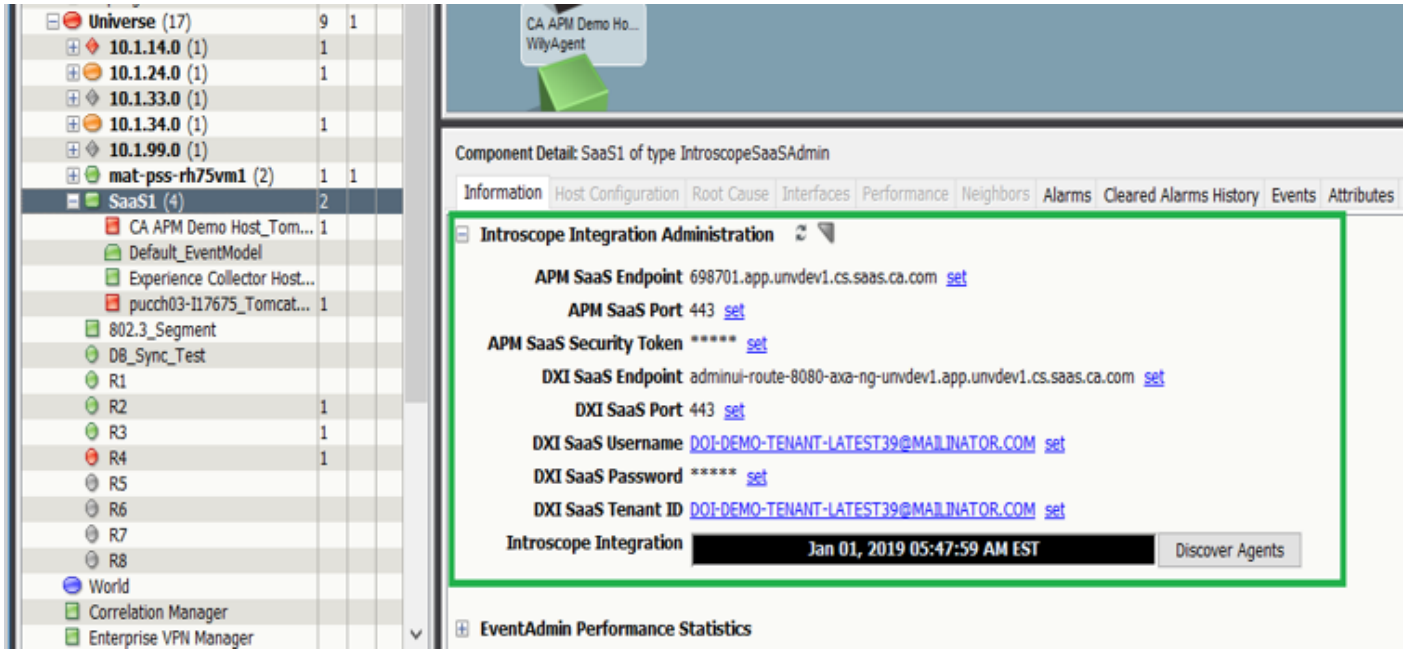
A security token is a randomly generated text string and is roughly equivalent to a text password. This token gives the API access to the APM Web Service. Connect the Enterprise Manager to Command Center. Generate a security token in Team Center. For instructions to generate the token, see the Generate a Security System Token in Team Center section in the CA APM documentation.

Spectrum and APM SaaS Configuration

1. Ensure that the DX NetOps Spectrum and CA APM integration is enabled. Enable the integration from the **OneClick Administration** page. Only after enabling the APM integration you find the configFile **apm-saas-config.xml** created and at **$SPECROOT\custom\wily\config** .This file allows you to configure the polling interval and throttle count values. By default, the value for the polling interval is configured as a maximum of 60 seconds and a minimum value of 15 seconds. For the throttle count, the maximum value is 500.
   For instructions, see Designate the Integration Server and Enable the Integration.



2. Create IntroscopeSaaSAdmin Model from the Topology with details of the APM SaaS Endpoint and the DXI SaaS Endpoint.
   For instructions, see the *Create IntroscopeSaaSAdmin Model* section on this page.



3. From the Introscope Integration Administration window, discover the Introscope Agents and provide details such as the:
   - APM SaaS Security token
   - Port
   - DXI SaaS Port
   - Username
   - Password
   - Tenant ID

   NOTE
   For instructions, see the *Discover Introscope Agents* section on this page.

Create IntroscopeSaaSAdmin Model

After you enable the integration, create an IntroscopesaasAdmin model to represent the connection to an Enterprise Manager. The Enterprise Manager can be modeled in any landscape in a Distributed SpectroSERVER environment.

> **NOTE**
>
> You can create an IntroscopeSaaSAdmin model in each landscape in a distributed SpectroSERVER environment to monitor a singular Enterprise Manager. However, only a single IntroscopeSaaSAdmin model can monitor a single Enterprise Manager in a distributed SpectroSERVER environment. Disabling the integration disables all IntroscopeSaaSAdmin models.

Follow these steps:

1. Select the **Universe** subview from the OneClick **Navigation** panel and select the **Topology** tab from the **Contents** panel.
   The OneClick Topology view is displayed in the **Contents** panel.
2. Select the Model by Type icon

   
3. Select **IntroscopeSaaSAdmin** from the list, and then select **OK.**
   The 'Create Model of Type IntroscopeSaaSAdmin' dialog opens.
4. Enter the unique Model name.
5. Provide APM SaaS Endpoint and DXI SaaS Endpoint details then select **OK**.
   The IntroscopeSaaSAdmin model is created.

Discover Introscope Agents

Follow these steps in DX NetOps Spectrum to discover the Introscope agents.

1. Select the **Universe** subview from the OneClick **Navigation** panel and select the **IntroscopeSaaSAdmin** model.
   Information about the IntroscopeSaaSAdmin model is displayed in the **Contents** panel.
2. Select the **Information** tab in the **Component Detail** panel.
   IntroscopeSaaSAdmin configuration is displayed.
3. Expand the Introscope Integration Administration node and verify the following settings:
   - Protocol (introduced in 10.4.2.1)
     Supports both HTTP and HTTPS (Default).
   - APM SaaS Endpoint
   - APM SaaS Port – (default-443)
   - APM SaaS Security Token
   - DXI SaaS Endpoint
   - DXI SaaS Port – (default-443)
   - DXI SaaS User Name - User name that is used for DXI login
   - DXI SaaS Password - User password that is used for DXI login
   - DXI SaaS Tenant ID - Provide DXI SaaS Tenant Name used to fetch alarms
4. To change a setting, select the **Set** link next to the setting, enter the appropriate information in the field, and press **Enter**.
5. Select **Discover Agents**. If there is no alarm/error on the model "IntroscopeSaaSAdmin" then the configuration is complete.
   The Introscope agents are discovered and modeled in DX NetOps Spectrum.

How the Sync Works

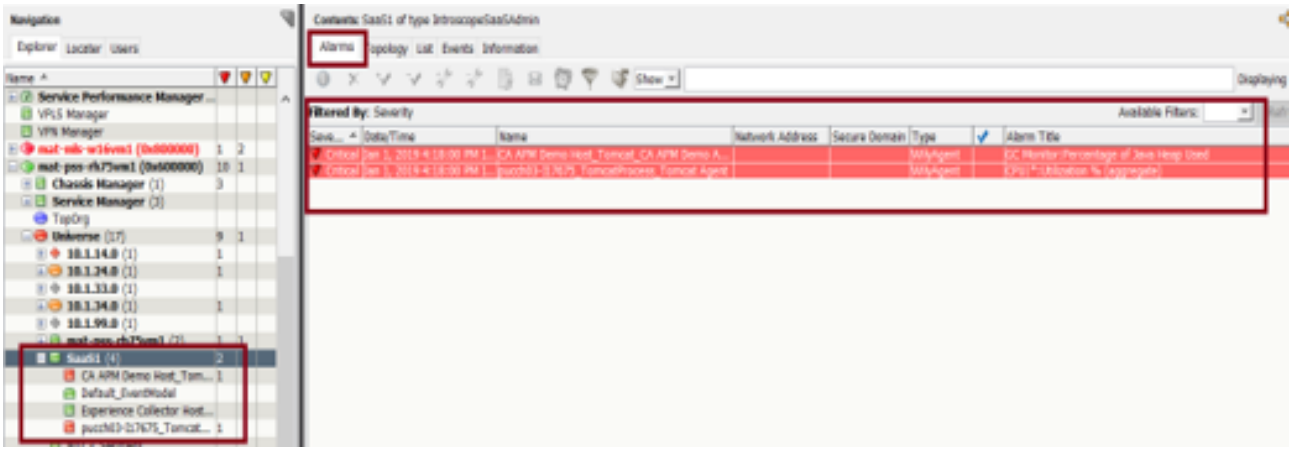
Once the APM Inventory sync and the Alert sync start, you can see the APM Inventory/Models/Agents under the model type 'IntroscopeSaaSAdmin'. If there are any APM alerts that are raised, those can be seen on the models. To perform a full sync for alerts select the Discover Agent under the Information tab in the OneClick. You can also run the discover agents on demand and OneClick server startup. Incremental Sync, that are APM alerts based on the polling interval is specified in the **apm-saas-config.xml** and is applicable for only alerts sync and not the inventory sync.

View Introscope Alarms and Events

You can view Introscope alarms and events in Spectrum OneClick, follow these steps:

1. Launch the OneClick.
2. Expand the **Universe** subview in the **Navigation** panel, and select the **IntroscopeSaaSAdmin** model. Information about the IntroscopeSaaSAdmin model is displayed in the **Contents** panel.
3. Select the **Alarms** tab to display alarms or select the **Events** tab to display events. The CA Introscope alarms or events are displayed in the **Contents** panel. Information about the agent that caused the event or alarm is displayed in the **Component Detail** panel when you select an alarm or event in the **Contents** panel.

Following is the screenshot of Alarms being generated in the IntroscopeSaaSAdmin model:



Troubleshooting

For the following error messages these are the recommended actions you need to take as a Spectrum user:

1. Error Message while running discovery 'Unable to contact APM Endpoint' The recommended action, if you cannot communicate to APM SaaS Endpoint is to verify the configuration for the Endpoint, Security Token, and the Port.
2. Error Message 'Unable to contact DXI Endpoint' The recommended action if you cannot communicate to DXI SaaS Endpoint is to verify the configuration for the Endpoint, Tenant ID, Username, Password, and the Port.

Troubleshooting Tips

Consider or check the following for potential issues:

- “Discover Agents” button is disabled
- Alarms that are created on the APM inventory model and IntroscopeSaaSAdmin model that is related to the connection lost.
- Alerts not syncing into Spectrum from APM/DOI

To trace and correct faults in the system:

- Ensure that APM integration is enabled in the OneClick Administration page
- Check for the tomcat log for connection loss and see the recommended action under the Troubleshooting section.
- If the alerts are not generated in APM, then verify the same in the APM configuration.
- If alerts do not pass in DOI, then verify the same in the APM/DOI configuration.
- If alerts do not pass in Spectrum, then enable the APM Integration debug logs and verify in the tomcat logs whether Alerts are actually coming from APM/DOI.

Common Access Card Authentication

Within secure environments, the use of a single point of entry is required for easy access management. Without a single point of entry, administrators of secure environments must manage several programs with different security levels and requirements in addition to user access. Common Access Cards (CACs) provide a single point of entry by requiring the use of the CAC for access to all controlled resources.

The following topics are covered under this section:

How CACs Work

Each CAC contains certificates that are issued by certificate authorities. A managing authority, such as the ActivIdentity® ActivClient®, controls access to the CAC certificates. Managing authorities prevent the certificates that are contained within the CACs from being used outside of the CAC without first verifying the CAC owner.

The managing authority verifies the card owner by prompting the user of the CAC for a Personal Identification Number (PIN). If the PIN is verified, the managing authority allows access to the CAC Certificates.

The presentation of a CAC Certificate, however, is not sufficient to gain access to a resource. The CAC Certificate must first be checked for both authenticity and validity.

Certificate authenticity is checked by building a certificate path from the CAC Certificate through any intermediate certificates to a trusted root certificate. A chain of trust thus links the user certificate to the trusted root certificate. If this chain is properly built, the certificate is authentic. Certificate authorities provide intermediate and root certificates to administrators for this purpose.

Once a certificate is verified as authentic, validity checks are required. Certificate authorities can revoke CAC Certificates. Revocation invalidates the certificate, which renders the CAC that holds the certificate useless. This verification can be accomplished in *one* of the following two ways:

- Certificate Revocation Lists (CRLs) are the most common way to verify that a CAC is valid and are the industry standard.
  CRLs are flat files that contain the serial numbers of revoked certificates. They become outdated frequently because of constant additions. As a result, they expire at predetermined times and must be refreshed. CRLs also consume a great deal of memory and must be placed on the local file system. Generally administrators choose this option when they have no access to an OCSP server/responder.
- Online Certificate Status Protocol (OCSP) eliminates the load times of CRLs by abstracting the information that is stored within them into a database.
  An OCSP server accepts requests to verify certificates. OCSP servers and responders are rarely outdated because administrators can revoke a certificate at any time. OCSP can be placed on a separate server from DX NetOps Spectrum.

Once a certificate has been verified as both authentic and valid, the CAC can be accepted.

How CAC Authentication Works

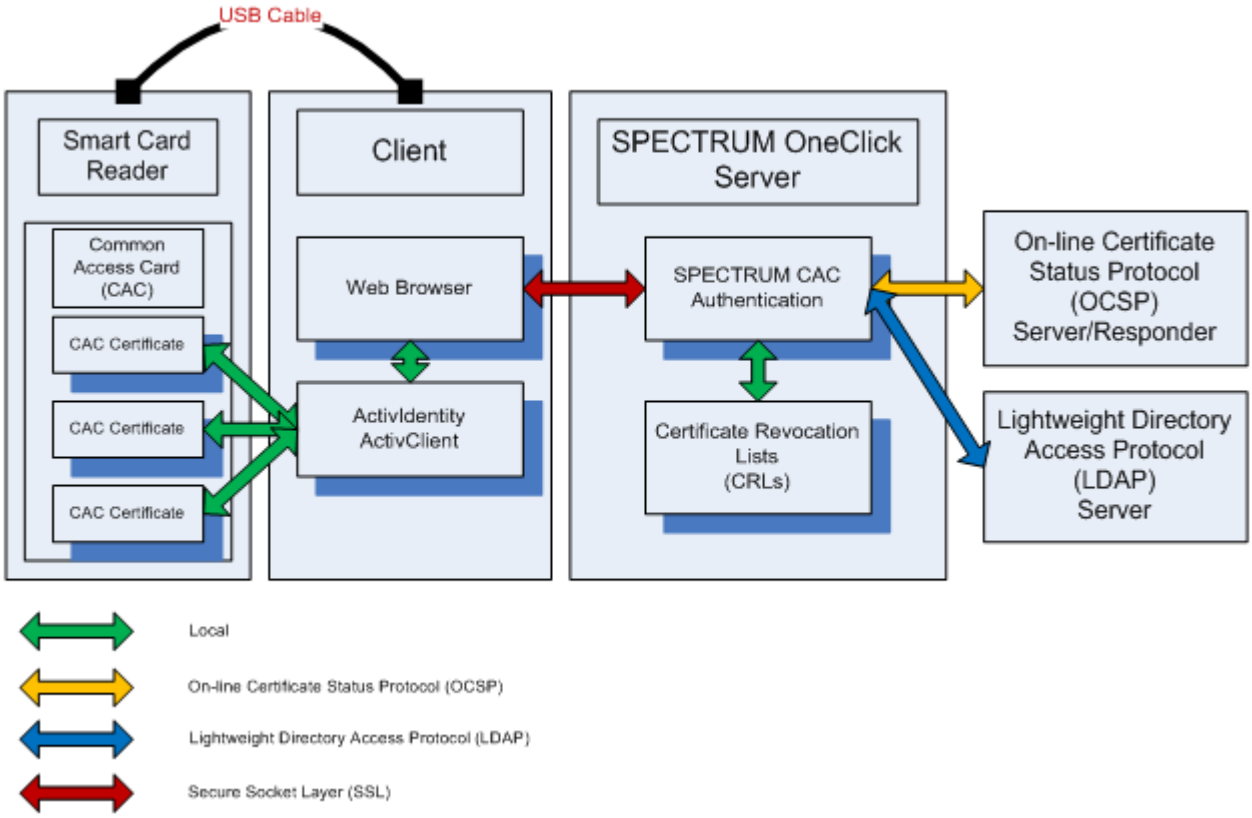
DX NetOps Spectrum CAC Authentication works by leveraging SSL, the Java PKIX Library, and any middleware that exposes PKSC11 to provide a complete CAC authentication solution.

> **NOTE**
> ActivIdentity ActivClient is an example of middleware that exposes PKSC11. We use this client to illustrate the DX NetOps Spectrum CAC authentication solution throughout this section.

As part of SSL negotiation (if SSL is configured), clients that are connecting to the OneClick web server with ActivIdentity ActivClient installed have their CAC Certificates made available for authenticating automatically. Each user provides a CAC PIN to ActivIdentity. Once the PIN is verified, ActiveIdentity releases the CAC Certificate to the OneClick server. DX NetOps Spectrum CAC Authentication verifies that the uploaded CAC Certificate is authentic and valid. Verification consists of building a certificate path and validating the certificate against either Certificate Revocation Lists (CRLs) or an Online Certificate Status Protocol (OCSP) Server.

SSL negotiation is now complete. If LDAP for CAC has been configured, the directory is queried using a unique identifier that is derived from the CAC Certificate. The unique identifier acts as a key to acquire a username to enable login. If LDAP is not used, the user is prompted for a username and password to log in to DX NetOps Spectrum.

The following image shows the architecture for DX NetOps Spectrum CAC Authentication.



Supported Platforms

DX NetOps Spectrum CAC Authentication is available on the OneClick client for the Microsoft Windows and Red Hat Enterprise Linux platforms that DX NetOps Spectrum supports. DX NetOps Spectrum CAC Authentication can be configured on the OneClick server for all DX NetOps Spectrum-supported platforms.

NOTE
DX NetOps Spectrum CAC Authentication for the OneClick client on the Oracle Solaris platform is not supported. If you require CAC Authentication on Solaris, contact CA Support to open a product Enhancement Request.

The following list displays the tested combinations of OneClick client on Windows and the OneClick servers running on Windows and Red Hat Enterprise Linux platforms:

OneClick Clients: See System Requirements for Windows page.	**OneClick Servers:** See System Requirements for Windows page.
Middleware on Windows: HID Global ActivIdentity® ActivClient® 6.2 and 7.0	**Java Runtime Environment (JRE) versions:** JRE 1.6 and 1.7
Web Browser: Microsoft Internet Explorer version 8.0	

NOTE
The table summarizes the platform combinations that we tested. Our testing was constrained by our available resources. Other combinations might also be supported. For more information, contact CA Support.

How to Configure SSL and CAC Authentication

NOTE
The command-line actions that you perform during this process must be executed using the installation owner account. This account owns the DX NetOps Spectrum files.

To configure DX NetOps Spectrum for SSL and CAC Authentication, use the following process:

1. Gather and record the appropriate security certificate information.
2. Verify that ActivIdentity ActivClient™, or other middleware that can expose PKSC11, has been installed on any client that will access OneClick.

   NOTE
   For specific information about installing middleware, see the instructions for the middleware product.
3. Install DX NetOps Spectrum on your server and then reboot.

   NOTE
   For more information about installing DX NetOps Spectrum, see the Fresh Install section.
4. Add DX NetOps Spectrum users.
5. Add Intermediate and Root certificates to DX NetOps Spectrum.
6. Configure the secure socket on the OneClick server.
7. Configure CAC Authentication from the OneClick client.
8. Enable DX NetOps Spectrum CAC Authentication.
9. Verify that CAC is functional. Log in to the CAC Authentication web page and launch the OneClick Console on Windows.
10. (Optional) Configure Linux clients.

Gather Security Certificates and Information

Before you can start setting up DX NetOps Spectrum CAC Authentication, verify that you have the appropriate security certificates and security information readily available to you. Start by gathering the required certificate and security information.

Follow these steps:

1. Import the certificate for the OneClick server as follows:
   - (Optional) Generate a self-signed certificate for the OneClick server if you do not already have one.
   - (Optional) Import an existing self-signed certificate for the OneClick server.
   - (Optional) Import an existing private key and certificate for the OneClick server.
2. Gather root and intermediate certificates for the CACs.
3. Determine the method that you plan to use for CAC verification. Record the information that is indicated for your selection as appropriate:
   - **OCSP AIA**
     Retrieves the parameters of the OCSP server from the certificate on the Common Access Card from the “AIA extension” of the certificate. The OCSP responder certificate is required.
   - **OCSP Server**
     Uses a URL to access the OCSP server and a certificate for the specified server. The OCSP responder certificate and the OCSP responder URL are required.
   - **CRL Directory**
     Uses a path to the directory which contains CRL files. The full path to the directory containing CRLs is required.
   - **CRL URL**
     Specifies a list, separated by spaces, of full URLs to the CRL files that are provided by the webserver. The full URL to each CRL is required.
   - **CRL Distribution Point**
     Specifies that DX NetOps Spectrum retrieves the information about the web location of the CRL files from the certificate itself.

     NOTE
     For more information about these options, see How CACs Work.
4. (Optional) If you are using Lightweight Directory Access Protocol (LDAP), collect the following information:
   - Hostname
   - Port
   - Base distinguished name
   - User distinguished name
   - User password
   - EDIPI attribute name
   - LDAP server certificate (if you plan to enable SSL)
   - Field name to map ID to
   - Field from which to extract the DX NetOps Spectrum Username
   - **For mapping from the certificate to LDAP:**
   - Decide whether ID information on the card certificate (EDIPI or another type of the ID) will come from the subject, alternative name, or rfc822 name.
   - Create a parsing rule to extract ID information from the card.

Generate a Self-Signed Certificate

If you do not already have a certificate, generate a self-signed certificate on the OneClick server.

Follow these steps:

1. Open a command prompt/shell and change the directory to: <*SPECROOT*>/Java/bin.
2. Run the "keytool" program with the following arguments:
   ```
   -genkey -alias tomcatssl -keyalg RSA -keystore <SPECROOT>/custom/keystore/cacerts
   ```
3. Enter **changeit** for the -keystore password.

NOTE
The word 'changeit' is the default password for the keystore.

4. Complete the fields. The following fields are not self-explanatory:
   - **First+Last name**
     Specifies the fully qualified domain name of your OneClick server. For example, "myhostname.mydomain".
   - **Organizational Unit**
     Specifies your company division. For example, Spectrum Engineering.
   - **Organization**
     Specifies the company name. For example, CA Inc.
5. Verify that your information is correct, and type 'yes' to accept.
6. Press Enter to use the same password as the keystore.

Import an Existing Self-Signed Certificate for the OneClick Server

If you already have a certificate, you must import it for DX NetOps Spectrum CAC Authentication.

To import the existing certificate for DX NetOps Spectrum CAC Authentication

1. Change the directory to: <SPECROOT>/Java/bin.
2. Run the following command:
   ```
   ./keytool -importcert -alias tomcatssl -file cert_file -keystore <SPECROOT>/custom/keystore/cacerts
   ```
   - ***cert_file***
     Specifies the existing OneClick certificate file.
3. Type **changeit** for the keystore password.
4. Press Enter to use the same password as the keystore.

Import an Existing Private Key and Certificate for the OneClick Server

WARNING
This procedure destroys your existing cacerts keystore and creates a new one with your private key and certificate. At present, you cannot force a private key into an existing keystore. This procedure is the only way to create a new keystore with a preexisting private key.

Follow these steps:

1. Gather the private key and the certificate files.
2. Change the directory to a temporary directory.
3. Execute the following command:
   ```
   openssl pkcs12 -export -inkey <private_key_file> -in <server_cert_file> -out mycert.pfx -name "default"
   ```
4. Change to the following directory:
   <SPECROOT>/Java/bin
5. Execute the following command:
   ```
   keytool -importkeystore -srckeystore <path_to_mycert.pfx> -srcstoretype pkcs12
   -destkeystore <SPECROOT>/custom/keystore/cacerts -srcalias default -destalias
   tomcatssl -destkeypass changeit
   ```
   Your private key and server certificate are now stored in the keystore, which is located in the following directory: <*SPECROOT*>/custom/keystore/cacerts

Add Users

You can add DX NetOps Spectrum users from the DX NetOps Spectrum Control Panel.

NOTE
For more information, see the OneClick Administration section.

Follow these steps:

1. Open the DX NetOps Spectrum Control Panel using *one* of the following methods depending on the platform you are using:
   - Linux: /usr/SPECTRUM/bin/SCP
   - Windows: Start, Program Files, CA, DX NetOps Spectrum Control Panel.
2. Click Start SpectroSERVER.
   The SpectroSERVER starts.
3. Select Control, Users from the main menu.
   The Users dialog opens.
4. Click Create to create the desired user.
   The Create dialog opens.
5. Type the user's name in the User Name field.

   NOTE
   If you are using LDAP, user names in DX NetOps Spectrum must exactly match those in LDAP.
6. Type a password in the New Password and Confirm New Password fields.

   NOTE
   This password is only used if LDAP is not enabled.
7. Click OK.
   The Create dialog closes.
8. Click Close.
   The DX NetOps Spectrum user is created.

Add Intermediate and Root Certificates

Use the SSL Certificates administration page to load root and intermediate certificate authority certificates for the CACs.

NOTE
For more information, see the OneClick Administration section.

Follow these steps:

1. Click Administration in the OneClick home page.
   The Administration Pages open.
2. Click SSL Certificates in the left side panel.
   The SSL Certificates page opens.
3. Load the root or intermediate certificate authority Certificates for the CACs in the 'File with Certificate' field.
4. Enter an appropriate alias name of your choice.
5. Click Save.

   NOTE
   Restarting the OneClick server is not required after you load each separate certificate. You can wait until you have loaded all of the desired certificates.
6. Repeat Steps 3-5 for every certificate you want to load.
7. (Optional) Load the Online Certificate Status Protocol (OCSP) Responder Certificate if you are using (OCSP).

   NOTE
   Record the name of the certificate alias that is associated with this certificate. The alias name is a requirement for a later step.
8. (Optional) Load the LDAP certificate if you are using SSL to connect to the LDAP server.

9. Click Restart OneClick Server after you have loaded all of the appropriate certificates.

How to perform key functions:

1. Go to $SPECTRUM/Java/bin and run ./keytool.exe -help Key and Certificate Management Tool and run the following commands to perform any specific function:

```
-certreq Generates a certificate request
-changealias Changes an entry's alias
-delete Deletes an entry
-exportcert Exports certificate
-genkeypair Generates a key pair
-genseckey Generates a secret key
-gencert Generates certificate from a certificate request
-importcert Imports a certificate or a certificate chain
-importpass Imports a password
-importkeystore Imports one or all entries from another keystore
-keypasswd Changes the key password of an entry -list Lists entries in a keystore
-printcert Prints the content of a certificate
-printcertreq Prints the content of a certificate request
-printcrl Prints the content of a CRL file
-storepasswd Changes the store password of a keystore
```

NOTE

Refer to Configure the Secure Socket on the OneClick Server page on how to use the keytool!

Configure the Secure Socket on the OneClick Server

As a final step in configuring the OneClick web server for SSL, configure the secure socket on the OneClick web server host.

Follow these steps:

1. Shut down the OneClick web server:
   - **Linux**
     As root: <*$SPECROOT*>/tomcat/bin/stopTomcat.sh
   - **Windows**
     Enter the following command from a command prompt:
     ```
     C:\> net stop spectrumtomcat
     ```
2. Open <*$SPECROOT*>/tomcat/conf/server.xml in a text editor.
3. Locate the following section in the server.xml file:

```
<!-- Define a SSL Coyote HTTP/1.1 Connector on port 443 -->
    <!--
    <Connector
           port="443" minProcessors="5" maxProcessors="75"
           enableLookups="true" disableUploadTimeout="true"
           acceptCount="100" debug="0" scheme="https" secure="true"
           clientAuth="false" sslProtocol="TLS"
           keystoreFile="<SPECROOT>/custom/keystore/cacerts"
           keystorePass="changeit">
     </Connector>
```

```
-->
```

By default the <Connector> element in the section is commented out. Uncomment this section and change clientAuth="false" to clientAuth="true".

NOTE
The preceding XML fragment is Windows-specific. This example specifies 443 as the default port where the OneClick web server listens for SSL communications. You can omit the port from the URL for accessing the OneClick home page:

```
https://<fully_qualified_host_name>/spectrum
```

On a UNIX-based installation, the OneClick web server is not run as root, and the default port is 8443 (it must be greater than 1024).

4. Specify the port number in the web browser when you enter the URL to access the OneClick home page:
   ```
   https://<fully_qualified_host_name>:8443/spectrum
   ```
5. Remove the comments around the Connector definition. Make the definition active by deleting the “<!--” and “-->” tags that surround this section.
6. Replace <*$SPECROOT*> with the actual path as follows:
   - **Linux**
     /usr/SPECTRUM
   - **Windows**
     C:/win32app/SPECTRUM
7. Change clientAuth to “true”.

   NOTE
   Changing this setting to "true" is a key component of the DX NetOps Spectrum Common Access Card solution. You can configure DX NetOps Spectrum for SSL without ClientAuth. However, this parameter must be set to "true" to enable DX NetOps Spectrum Common Access Card authentication. For more information, see OneClick Administration section.
8. Save and close the server.xml file.
9. Start the OneClick web server using one of the following commands, depending on the platform you are using:

   - **Linux**
     As root:
     <*$SPECROOT*>/tomcat/bin/startTomcat.sh
   - **Windows**
     From a command prompt:
     ```
     C:\> net start spectrumtomcat
     ```

The secure socket is now configured.

Configure CAC Authentication on the OneClick Client

After configuring DX NetOps Spectrum for SSL, configure CAC Authentication on the OneClick client. You can set up CAC Authentication by entering all of the relevant security information you have gathered.

Follow these steps:

1. Log in to the OneClick client that has ActivIdentity ActivClient installed.
2. Open the OneClick Administration pages using the SSL port as follows:
   - For Linux, type **https://your_hostname:8443/**
   - For Windows, type **https://your_hostname/**
3. Provide your CAC Certificate.

NOTE
The CAC certificate that you provide here is used to verify that the CAC Configuration is valid.

4. **(Optional)** Accept the OneClick Server Certificate if prompted.
5. Enter the installation owner user name and password when prompted.

   NOTE
   If you have not changed the password for the installation owner, it is *spectrum*.

   The OneClick home page opens.
6. Click Administration.
   The Administration Pages open.
7. Click CAC Configuration in the left side panel.
   The CAC Configuration page opens.

   NOTE
   If you do not see a full web page here with options available, you did not use the SSL port. Repeat Steps 1 through 6.

Setting Up the eHealth Integration with CAC Enabled

You can set up the CAC Integration with DX NetOps Spectrum using the following steps:

- Disable **TLS 1.2** in Java Console (this is to be able to launch JNLP applications) on **Windows client** system, where the card-reader is attached.
- Stop Spectrum Tomcat and eHealth httpd and SCARVES
  - **SPEC:** $SPECROOT/tomcat/bin/stopTomcat.sh
  - **EH:** $NH_HOME/bin/nhHttpd stop
  - **EH (AS ROOT):** $NH_HOME/bin/nhSmartCard.sh stop
- **SPEC:** cd $SPECROOT/CERTS/certs
- **SPEC:** sftp nhuser@<EH Machine Name>
  - cd **<path_to_EH_home>/**web/httpd/conf/cacerts
  - put SpectrumRootCA.crt
  - bye
- **EH:** Import the Spectrum certificates into the eHealth trust stores
  - cd $NH_HOME/bin
  - ./nhSmartCard.sh trust -import -storepass 123456 -alias SpectrumRootCA -file $NH_HOME/web/httpd/conf/cacerts/SpectrumRootCA.crt
  - ./nhWebProtocol -mode https -hostname <EH FDQN> -strongCipher -disableSSLv2 -enableSCAuth -SCCAdir $NH_HOME/web/httpd/conf/cacerts -SCCAsvrFile $NH_HOME/web/httpd/conf/myDaemonCert3.pem -SCServerIPs "<EH FDQN>:8888" -certificate $NH_HOME/CERTS/<HOSTNAME>.crt -key $NH_HOME/CERTS/<HOSTNAME>.key -intermediate $NH_HOME/web/httpd/conf/myDaemonCert3.pem –fips
- – $NH_HOME/bin/nhHttpd start
  - **AS ROOT:** $NH_HOME/bin/nhSmartCard.sh start
  - Verify you can still log into eHealth with CAC.
- **SPEC:** Import the eHealth certificates into the Spectrum OneClick trust store
  - Stop tomcat
    - $SPECROOT/tomcat/bin/stopTomcat.sh
  - cd $SPECROOT/CERTS
  - sftp nhuser@<EH HOSTNAME>

  - cd $NH_HOME/web/httpd/conf
  - get myDaemonCert3.pem eHealth.pem
  - bye
- $SPECROOT/Java/bin/keytool -import -alias EH_CAC -file eHealth.pem -keystore $SPECROOT/custom/keystore/cacerts -storepass changeit
- Edit $SPECROOT/lib/SDPM/partslist/**TOMCAT.idb** and add the following command like parameters to tomcat (applies for LINUX Spectrum 9.4.0 and earlier versions)
- su
- chmod –R a+rwx $SPECROOT/lib/SDPM
- Edit $SPECROOT/tomcat/bin/**catalina.sh** and add the following command like parameters to tomcat JAVA_OPT variable (applies for LINUX Spectrum 9.4.0 and earlier versions):
  - -Djavax.net.ssl.keyStore=$SPECROOT/custom/keystore/cacerts
  - -Djavax.net.ssl.keyStorePassword=changeit

  Example for Spectrum 9.4.2 and later : **catalina.sh** change

```
# This needs to be done after setclasspath.sh as it sets the JAVA_OPTS as well
if [ "$HOST" = "SunOS" ]; then
JAVA_OPTS="-DOneClick -Xmx1024M -XX:PermSize=128M -XX:MaxPermSize=128M -XX:+HeapDumpOnOu
tOfMemoryError -server -Djava.awt.headless=true -Djavax.net.ssl.trustStore=$SPECROOT/cus
tom/keystore/cacerts -Dfile.encoding=UTF-8 -Dcom.sun.management.jmxremote -Dorg.apache.c
oyote.USE_CUSTOM_STATUS_MSG_IN_HEADER=true -Djavax.net.ssl.keyStore=$SPECROOT/custom/key
store/cacerts -Djavax.net.ssl.keyStorePassword=changeit"
else
JAVA_OPTS="-DOneClick -Djava.compiler=NONE -Xmx1024M -XX:PermSize=128M -XX:MaxPermSize=1
28M -XX:+HeapDumpOnOutOfMemoryError -server -Djava.awt.headless=true -Djavax.net.ssl.tru
stStore=$SPECROOT/custom/keystore/cacerts -Dfile.encoding=UTF-8 -Dcom.sun.management.jmx
remote -Dorg.apache.coyote.USE_CUSTOM_STATUS_MSG_IN_HEADER=true -Djavax.net.ssl.keyStore
=$SPECROOT/custom/keystore/cacerts -Djavax.net.ssl.keyStorePassword=changeit"
fi
```

- Edit $SPECROOT/tomcat/bin/**OneClickService.conf** and add the following command like parameters to the end of file (applies for LINUX Spectrum 9.4.0 and earlier versions):
  - jvm_opt=-Djavax.net.ssl.keyStore=C:/win32app/Spectrum/custom/keystore/cacerts
  - jvm_opt=-Djavax.net.ssl.keyStorePassword=changeit
- Start tomcat
  - $SPECROOT/tomcat/bin/startTomcat.sh
- Attempt to configure the eHealth integration from the OneClick Administration page.

CAC Configuration Page

Use the CAC Configuration page to configure OneClick to use Common Access Cards (CAC) for authentication.

- **Choose CAC Option**
  Specifies whether to enable or disable the CAC authentication solution.
  - **Disable CAC**
    Disables CAC authentication.
  - **Enable CAC**
    Enables CAC authentication.

The Trusted Keystore section contains the following fields:

- **Trusted Keystore password**
  Specifies the password to use for accessing the Trusted Keystore: **changeit**.
- **Re-enter Trusted Keystore password**
  Confirms the password for accessing the Trusted Keystore.

The Revocation System section specifies how you want DX NetOps Spectrum to determine whether a CAC has been revoked. Select *one* of the following options:

- **Enable OCSP AIA**
  Instructs DX NetOps Spectrum to retrieve the parameters of the OCSP server from the certificate on the Common Access Card from the “AIA extension” of the certificate.
- **Enable OCSP Server**
  Specifies that the user must provide a URL to access OCSP server and a certificate for this server.
- **Enable CRL Directory**
  Specifies that a path to the directory that contains CRL files is required.
- **Enable CRL URL**
  Specifies a list, separated by spaces, of full URLs to the CRL files that the web server provides.
- **Enable CRL Distribution Point**

Specifies that DX NetOps Spectrum retrieves the information about the web location of the CRL files from the certificate itself.

The OCSP AIA Connectivity section appears when you select Enable OCSP AIA in the Revocation System section. This section contains the following option:

- **Test OCSP AIA**
  Verifies that OCSP AIA is working properly.

The OCSP Server Connectivity section appears when you select Enable OCSP Server in the Revocation System section. This section contains the following options:

- **OCSP Server URL**
  Specifies the complete URL for accessing the OCSP Responder. The complete URL is used because many OCSP Responders are servlets running on a larger OCSP server.
- **OCSP Server Certificate Alias**
  Specifies the certificate for the specified OCSP server.
- **Test OSCAP Server**
  Tests the connection to the OCSP server based on the credentials that you entered.

The Certificate Relocation Lists appears when you select Enable CRL Directory or Enable CRL URL in the Revocation System section. It contains the following settings, depending on the CRL option that you selected:

- **CRL Directory**
  Specifies the full path to the directory that contains the CRL files for verifying user certificates.
- **CRL URL**
  Specifies a list of full URLs, separated by spaces, to the CRL files that the web server provides.
- **Test CRL Availability**
  Attempts to load the CRLs in the specified directory.

The LDAP Username Lookup section contains the following settings:

- **Enable LDAP**
  Enables LDAP.
- **LDAP Server Hostname**
  Specifies the host name of an LDAP server that contains users that correspond to user certificates.
- **LDAP Server Port**
  Specifies the port number for accessing the LDAP server.
- **Enable SSL**
  Enables secure connecting to the LDAP server using SSL.

  NOTE
  Load the LDAP server certificate if you enable SSL.
- **LDAP Base DN**
  Specifies the LDAP base distinguished name.
- **LDAP User DN**
  Specifies the distinguished name (DN) of the user that is used to query the LDAP server.
- **LDAP User Password**
  Specifies the password of the user that is used to query the LDAP server.
- **Re-enter LDAP User Password**
  Confirms the LDAP user password.
- **Certificate's EDIPI Field**
  Specifies the source for user ID information. Select *one* of the following options, which describe the format in which EDIPI is stored in the CAC certificate:

- Subject
- SubjectUniqueId
- AltName.otherName
- AltName.rfc882Name

- **EDIPI Extraction Rule**
  Specifies the rule to use to extract EDIPI from the CAC certificate field.
  Type: Java regular expression
  Example: The default value for this field is as follows:

```
"CN=\w*\.\w*\.(\d+),";
```

  This string defines a rule that matches a string that resembles the following example:

```
CN=aaaa.bbbbbb.1233454,xxxxxxxxxxxxxxxx
```

  - Literal “CN=”
  - Any word (possibly empty) \w*
  - Literal “.”
  - Any word (possibly empty) \w*
  - Literal “.”
  - Integer number (non-empty) \d+
  - Literal “,”
  - Anything can follow.

    NOTE
    Regex *capturing group* must be defined in the regular expression. DX NetOps Spectrum uses the first defined group in the expression to extract unique user ID information. More information about capturing groups is available on the Internet.

- **LDAP EDIPI Attribute Name**
  Specifies the name of the LDAP field that is used to store EDIPI (or other unique identifier) information.
- **LDAP Username Attribute Name**
  Specifies the name of the LDAP field that is used to store DX NetOps Spectrum user name information.
- **LDAP Referral Setting**
  Specifies how OneClick handles LDAP referrals.
  - **follow**
    (Default) Instructs OneClick to automatically follow any referrals.
  - **throw**
    Instructs OneClick to throw an exception for each referral. The request is likely to fail with an "Unprocessed Continuation Reference(s)" error.
  - **ignore**
    Instructs OneClick to ignore referrals. The request is likely to fail with an "Unprocessed Continuation Reference(s)" error.

    NOTE
    LDAP Referral Setting is hidden by default on the CAC Configuration page. To display this field and change its value, see Modify LDAP Referral Setting.
- **Test LDAP Server**
  Attempts to connect to the LDAP server using the credentials that you supplied.

Modify LDAP Referral Setting

The LDAP Referral Setting specifies how OneClick handles LDAP referrals. When an LDAP server cannot locate a requested object, the server returns a referral to the client. The referral directs the request to another server to locate the object. By default, OneClick automatically follows referrals to obtain the requested information.

You can also specify to ignore referrals or to throw an exception for each referral. The LDAP Referral Setting is hidden by default on the CAC Configuration page. To modify its value, change the configuration file to display the field.

Follow these steps:

1. Open <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/cac/cac-config.jsp in a text editor.
2. Uncomment the LDAP Referral Setting display code:
   a. Add "-->" after <!-- BEGIN HIDDEN REFERRAL SETTING SECTION
   b. Add "<!--" before END HIDDEN REFERRAL SETTING SECTION -->
3. Save and close the file.
4. Refresh the CAC Configuration page.
   The LDAP Referral Setting field appears.
5. Select a value from the LDAP Referral Setting drop-down list, and click Save.
   The new LDAP Referral Setting takes effect.

Enable CAC Authentication

After you have configured DX NetOps Spectrum CAC Authentication on the OneClick server and have finished setting up security, you can enable it from the CAC Authentication page.

Follow these steps:

1. Click Administration in the OneClick home page.
   The Administration Pages open.
2. Click CAC Configuration in the left panel.
   The CAC Configuration page opens.
3. Click Enable CAC.
   The available configuration options for enabling CAC are displayed.
4. Enter the Keystore password in the Keystore password fields.

   NOTE
   If you have not changed the Keystore password, it is *changeit*.
5. Select one of the following options in the Revocation System section. These options specify how DX NetOps Spectrum determines whether a CAC has been revoked. Complete the resulting fields:
   - **Enable OCSP AIA**
     Instructs DX NetOps Spectrum to retrieve the parameters of the OCSP server from the certificate on the Common Access Card from the “AIA extension” of the certificate.
   - **Enable OCSP Server**
     Specifies that the user must provide a URL to access the OCSP server and a certificate for this server.
   - **Enable CRL Directory**
     Specifies that a path to the directory that contains CRL files must be specified.
   - **Enable CRL URL**
     Specifies a list, separated by spaces, of full URLs to the CRL files that are provided by the webserver.
   - **Enable CRL Distribution Point**
     Specifies that DX NetOps Spectrum retrieves the information about the location of the CRL files from the certificate itself.

   The CAC Configuration page changes to display the fields that relate to the option that you selected. For more information, see CAC Configuration Page.

6. (Optional) If you are using LDAP, select the Enable LDAP checkbox, and complete the fields as described in CAC Configuration Page.
7. Click the individual test buttons to test your information.
8. Click Save to save your selections.
   A full test of your CAC configuration options runs. If the test is successful, the CAC information is saved, and the OneClick server restarts. If you are using CRLs, they are loaded immediately after the restart. Depending on the number of CRLs and their size, this process can take several minutes. During this time, attempts to access the server using a web browser do not always provide feedback.
9. (Optional) Track the progress of the load operation by viewing one of the following logs:
   – *$SPECROOT*/tomcat/logs/catalina.out for Linux
   – *$SPECROOT*/tomcat/logs/stdout.log for Windows

Configure Linux Clients

If any users are accessing DX NetOps Spectrum from Linux clients, configure those clients for DX NetOps Spectrum CAC Authentication.

Follow these steps:

1. Run mkoctar script on the OneClick server by doing the following:
   1. Set the environment variable SPECROOT to the SPECTRUM root directory.
   2. Navigate to <*$SPECROOT*>/tomcat/webapps/spectrum/
   3. Run the following command:
      ./mkoctar - servercert <*oneclick_certificate_alias*> -cert <*root_alias*> -cert <*int_alias_1*> -cert <*int_alias_2*>
   4. **- servercert <oneclick_certificate_alias>**
      a. Specifies the alias for the OneClick web server certificates. If you created a self-signed certificate, the OneClick certificate alias is "tomcatssl".
   5. **-cert <root_alias>**
      a. Specifies the alias for the root certificate, as defined in Add Intermediate and Root Certificates to DX NetOps Spectrum.
   6. **-cert <int_alias_1>**
      a. Specifies the alias for the first intermediate certificate, as defined in Add Intermediate and Root Certificates to DX NetOps Spectrum.
   7. **-cert <int_alias_2>**
      a. Specifies the alias for the second intermediate certificate, as defined in Add Intermediate and Root Certificates to DX NetOps Spectrum.
   8. (Optional) Run the following command if you see a Permission Denied error:
      chmod +x mkoctar
   9. (Optional) Run the following command to view additional options:
      ./mkoctar -h

   This command produces the file "oc.tar" in the same directory. You can now copy oc.tar to a temporary directory on Linux clients that will access OneClick.
2. On the Linux client, extract oc.tar as follows:
   a. **Note:** For performance and security reasons, extract this file to a local disk, not to a network drive.
   b. Run the following command:
      tar xvf oc.tar
   c. Edit the line in card.config.Linux that begins with "library=". Change it to point to the ActivIdentity pkcs library. For example, change it to the following line:
      ```
      library = /usr/local/ActivIdentity/ActivClient/lib/libacpkcs211.so
      ```

d. Run the runoc script to launch OneClick. Take *one* of the following steps:

- LDAP: Run the following command:
  ./runoc
- Non-LDAP: Run the following command:
  ./runoc - noldap

When it is first run, runoc installs a JRE in the current directory.

NOTE
Users are always prompted for their CAC Personal Identification Number (PIN). If you are not using LDAP, users are also prompted for their user name and password.

Working with CAC Authentication

Once DX NetOps Spectrum CAC Authentication is enabled, the only visible change to the user interface is the new CAC Configuration page in the OneClick Administration pages.

Non-SSL access is completely disabled after DX NetOps Spectrum CAC Authentication has been enabled. Any attempts to access the server from a non-secured port will cause a redirection to the SSL port.

Memory Consumption Using CAC Authentication with CRLs

A single CRL can hold more than half a million revoked certificate serial numbers. Some environments require 20 or more CRLs to cover all potential user certificates. Loading this much data consumes a great deal of time and memory. For example, a set of CRLs that is approximately 100 MB on disk consumes about 1.5 GB of memory and takes several minutes to process.

Take this increased memory consumption into account when you decide where to install OneClick. An easy way to calculate the memory consumption is to take the total size of your CRLs and multiply by 15. One MB of CRLs consumes 15 MB of memory, and 50 MB consumes 750 MB of memory. If your total exceeds 400 MB, consider increasing the amount of memory that is available to OneClick. If your total exceeds 500 MB, OneClick typically requires increased memory to function.

WARNING
If your total CRL memory requirement exceeds 1 GB, do not run DX NetOps Spectrum CAC Authentication with CRLs on a Windows server.

The steps to take to increase the amount of memory that is available to the OneClick server are described in Configure OneClick Web Server Memory Settings.

To alleviate the time impact on end-users, CRLs are loaded while OneClick is initializing. Users of OneClick do not experience significant delays once OneClick is running. You can track the progress of the CRL load operation by viewing the OneClick log file at one of the following locations:

- **Linux**
  `<SPECROOT>/tomcat/logs/catalina.out`
- **Windows**
  `<SPECROOT>\tomcat\logs\stdout.log`

Configure OneClick Web Server Memory Settings

By default, the OneClick web server needs 4 GB dedicated to OneClick Web Server. If the OneClick web server is using more than 75 percent of its configured maximum memory, consider increasing the maximum memory value.

NOTE
The actual memory requirement depends on your OneClick server environment and usage, like configuration and number of managed devices.

- Default: 4 GB
- For production environments: minimum of 8 GB
- For OneClick integrations: minimum of 16 GB
  (for example, integration with CAPM, UIM, ServiceDesk, VNA and so on)

If the webserver runs out of memory, an OutOfMemory error appears in the following log files:

- tomcat/logs/stdout.log (for Windows)
- tomcat/logs/catalina.out (for Linux).

You can change the memory allocations on the Web Server Memory Administration page. We recommend allocating 50% to 75% of the available OS memory to the tomcat process. For example, if you have 32GB then, set tomcat memory to 16GB or 24GB. The steps in this procedure are an optional method for addressing out-of-memory issues.

NOTE
Restart the OneClick web server for these changes to take effect.

Follow these steps:

1. Verify the OneClick web server memory usage:
   a. Click Administration in the OneClick home page.
      The Administration Pages open.
   b. Click Web Server Memory in the left panel.
      The Web Server Memory page opens.
   c. Check the OneClick Server Memory Usage field to verify if memory usage is greater than 75 percent of the configured maximum.
2. Configure the maximum OneClick web server memory usage:
   a. In the Maximum Memory the Server Can Use (In MB) field, enter the new value.
      NOTE
      Do not set the maximum memory to a value larger than the available memory for the system.
   b. Click Save.
      A dialog prompts you to commit your changes and restart the OneClick web server.
   c. Click OK.
      Your changes are saved, and the OneClick web server is restarted.

Changes to Access Security

If any part of the CAC certificate verification process fails, the user cannot be granted access. Allowing a user to log in without a validated CAC would defeat the purpose of enabling CAC Authentication.

If LDAP is up, but a user name is not returned properly or the returned user name is not in DX NetOps Spectrum, the user cannot be granted access. This is because user access is still controlled by DX NetOps Spectrum, and allowing someone who has a valid CAC but an invalid user name to log in as anyone is not secure.

Troubleshooting CAC Authentication

This section includes troubleshooting tips to solve the specified problems while you use CAC authentication.

Java Heap Size and OutOfMemory Errors

Symptom:

I am seeing errors such as "Java Heap Size" and "OutofMemory" when I use DX NetOps Spectrum CAC Authentication with CRLs.

Solution:

The memory of your OneClick server is set too low. Complete the following procedure to avoid seeing these errors.

1. Remove a few CRLs from your CRL directory.
2. Restart the OneClick server.
3. Increase the amount of memory available on the server as described in Configure OneClick Web Server Memory Settings.
4. Try using DX NetOps Spectrum CAC Authentication again.

> **NOTE**
> If you continue to get this error, you may not have enough memory to run DX NetOps Spectrum CAC Authentication with CRLs.

OneClick Client Locks Up After Authentication

Platform: Linux only

Symptom:

I am using CAC authentication for my OneClick clients, which I launch on a Linux server. After I invoke the runoc script, the client fails soon after startup. The OneClick client locks up and becomes unusable. Sometimes, I see a certificate error. I am forced to exit the application. After a few attempts, the client starts and runs as expected.

Solution:

This situation occurs when the SSL connection between the OneClick client and the Tomcat server times out before the SSL handshake has completed.

To resolve this issue, increase the timeout period that is set on the client and on the Tomcat server. On Linux, clients use a script (runoc) to launch OneClick. You can modify the -ssltimeout parameter in this script so that SSL has more time to complete the handshake. The longer timeout lets the handshake complete while the connection is still established.

First, reconfigure the server to use a five-minute connection timeout.

Follow these steps:

1. Navigate to *$TOMCAT_ROOT*/conf/
2. Open the file server.xml for editing, using your preferred text editor.
3. Locate the SSL Connector element in the file.
4. Change the connectionTimeout parameter to use a value equivalent to five minutes in milliseconds:

```
connectionTimeout="300000"
```

> **NOTE**
> The server setting is in milliseconds.

5. Restart the OneClick server so that the change takes effect.

Now launch the OneClick client using the new -ssltimeout parameter.

Follow these steps:

1. Navigate to the directory from which you launch the runoc script on the OneClick client. For example, /opt/CA_OC.
2. Invoke the runoc script, using the -ssl timeout parameter. For example, enter the following command:

```
./runoc  - ssltimeout <value>
```

In this example, use a value of 300 (the equivalent of five minutes in seconds).

NOTE
The client setting is in seconds.

The OneClick client now has a five-minute timeout setting, which matches the timeout that you set on the tomcat server.

Poor OneClick Client Performance

Platform: Windows

Symptom:

The OneClick clients take a long time to start up. Once the clients have started, users experience long wait times for the user interface to react to mouse clicks and navigation tasks. They are so slow that we can hardly use them.

Solution:

This behavior results from the default setting for the "javaws.reuseConnections" Java System property, which is "false". In previous versions of DX NetOps Spectrum, the default value was "true". A change was made to facilitate out-of-the-box connectivity for users with web proxies or load balancers in their environment. Without reusing connections, SSL certificate verification is performed for every request from the client to the server. This work is expensive, in terms of round-trip times.

Change the value of the "javaws.reuseConnections" Java Runtime System property to "true".

To change the property setting, edit the oneclick.jnlp file.

Follow these steps:

1. Navigate to the following directory:
   ```
   <$SPECROOT>/tomcat/webapps/spectrum/
   ```
2. Open the oneclick.jnlp file for editing using your preferred text editor.
3. Add the following line, immediately below the "<resources>" line:
   ```
   <property name="javaws.reuseConnections" value="true"/>
   ```
4. Restart all open OneClick clients.

Poor OneClick Client Performance

Platform: Linux

Symptom:

The OneClick clients take a long time to start up. Once the clients have started, users experience long wait times for the user interface to react to mouse clicks and navigation tasks. They are so slow that we can hardly use them.

Solution:

This behavior results from the default setting for the "javaws.reuseConnections" Java Runtime System property, which is "false". In previous versions of DX NetOps Spectrum, the default value was "true". A change was made to facilitate out-of-the-box connectivity for users with web proxies or load balancers in their environment. Without reusing connections, SSL certificate verification is performed for every request from client to server. This work is expensive, in terms of round-trip times.

Change the value of the "javaws.reuseConnections" Java runtime property from "false" to "true".

To change the property setting for Linux clients, edit the runoc script.

Follow these steps:

1. Navigate to the directory where you installed the runoc script.
2. Add "-Djavaws.reuseConnections=true" to the last line of the script as follows:
   ```
   $JRE_HOME/bin/java -Djavaws.reuseConnections=true -classpath
   ```
3. Save the script.
4. Restart all open OneClick clients.

OneClick console does not launch Start Console

Platform: Windows

Symptom:

After enabling CAC, the ‘Start Console’ is not lauched from the OneClick console.

Solution:

This behavior results from the setting of ‘Use TLS 1.2’ in Java Control Panel.

Before opening the OneClick console, you must disable the ‘Use TLS 1.2’ option from ‘Advanced Security Settings’ in Java Control Panel.

Follow these steps:

1. Open the command prompt.
2. Type the following command to launch the Java Control Panel:
   ```
   javaws -viewer
   ```
3. Click the ‘Advanced’ tab.
4. Navigate to ‘Advanced Security Settings’ section and disable the ‘Use TLS 1.2’ option.
5. Click ‘Ok’ to save the changes.

Unable to Build Certificate Path

Symptom:

I am seeing the error "Unable to Build Certificate Path".

Solution:

This error occurs when SSL is set up, but the option for Client Authentication is not set to “true”. In this case when someone attempts to access a OneClick server with DX NetOps Spectrum CAC Authentication, they do not present a CAC certificate ahead of time. As a result, DX NetOps Spectrum CAC Authentication attempts to build a certificate path, but no certificates are available.

Refer to Configure the Secure Socket on the OneClick Server. Verify that you have set clientAuth to “true”, and restart the OneClick server.

Unable to Determine Certificate Status

Symptom:

I am seeing the error "Unable to Determine Certificate Status".

Solution:

This error is usually presented when CRLs have expired. Acquire new CRLs from the Certificate Authority and replace the old CRLs. Then restart the OneClick server.

Certificate Has Been Revoked

Symptom:

I am seeing the error "Certificate Has Been Revoked".

Solution:

This error indicates that the CAC Certificate has been revoked. The revocation occurred either by an entry in a CRL or because the OCSP Responder has indicated that the certificate is no longer valid.

Microsoft MOM and SCOM

This section describes how to integrate Microsoft® Operations Manager (MOM) and Microsoft® System Center Operations Manager (SCOM) with DX NetOps Spectrum.

- **MOM Connector**: A DX NetOps Spectrum executable that enables alert forwarding from Operations Manager to DX NetOps Spectrum.
- **SCOM Connector:** A DX NetOps Spectrum executable that enables alert forwarding from System Center Operations Manager to DX NetOps Spectrum.

> **NOTE**
>
> The DX NetOps Spectrum MOM and SCOM connectors are compatible with Microsoft® Operations Manager 2005 and Microsoft® System Center Operations Manager (SCOM) 2012, respectively.

MOM/SCOM Connector Comparison

Both the MOM Connector and the SCOM Connector support the following functionality:

- Extracting alerts from Microsoft Operations Manager or System Center Operations Manager and creating alarms on the appropriate system models in DX NetOps Spectrum.
- Supporting drill-down from DX NetOps Spectrum alarms. You can configure DX NetOps Spectrum alarms to display a URL that calls up the appropriate alert in the MOM or SCOM web console.
- Bidirectional alert/alarm clearing.
- Bidirectional alert/alarm acknowledgment.

The MOM Connector and the SCOM Connector have the following differences:

- Alert/alarm acknowledgments: The connectors handle acknowledgments differently.

System Center Operations Manager does not support a resolution state for acknowledging an alert. Therefore, you must create one manually. You can then configure the SCOM Connector to use the new resolution state to synchronize acknowledgments of alerts and alarms. System Center Operations Manager does not provide acknowledgment synchronization by default.

For more information, see Create an Acknowledged Resolution State.

By default, Microsoft Operations Manager 2005 provides an acknowledgment resolution state and acknowledgment synchronization.

- Deployment options: The SCOM Connector can be deployed to almost any Windows host in your environment. But the MOM Connector must run on the MOM server.
- The MOM Connector is not fully supported in a DSS environment. For more information, see MOM Connector in a DSS Environment.

Some versions of the SCOM connector are not fully supported in a DSS environment. The extra configuration is required to support distributed deployments. For more information, see SCOM Connector in a DSS Environment.

- Distinct configuration files: The MOM configuration file is named ".momrc". The SCOM configuration file is named ".scomrc." For more information, see Install the MOM Connector or Install the SCOM Connector.

Install and Run the MOM Connector

This section assumes the following:

- You have an installed and configured Microsoft Operations Manager 2005 Management Server.
- You are integrating your MOM environment with DX NetOps Spectrum network management software.

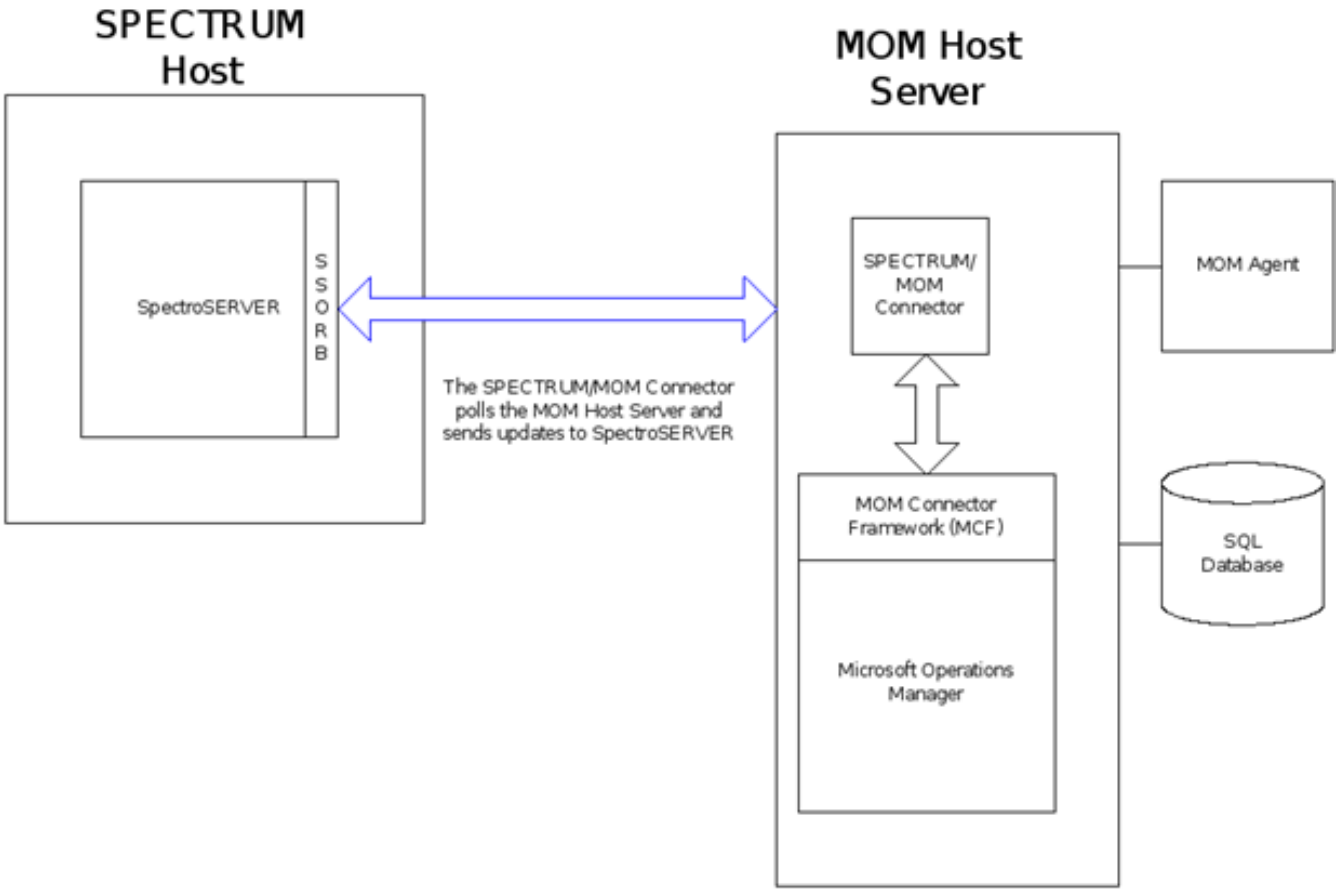
MOM Connector is an application that synchronizes alarm data between DX NetOps Spectrum and Microsoft Operations Manager. The MOM Connector uses the DX NetOps Spectrum SSORB CORBA API to interface with DX NetOps Spectrum. It uses the MOM Connector Framework (MCF) to interface with Microsoft Operations Manager.
You can monitor and respond to MOM-generated alert conditions by creating DX NetOps Spectrum events and alarms. You can also monitor the status of the MOM agents managed by the MOM application using DX NetOps Spectrum.
The MOM Connector performs the following tasks:

- Creates DX NetOps Spectrum alarms when alerts are generated in MOM.
- Clears DX NetOps Spectrum alarms when the resolution state of the corresponding MOM alert is set to "Resolved" (and the reverse).
- Acknowledges a DX NetOps Spectrum alarm when the resolution state of the corresponding MOM alert is set to "Acknowledged."

WARNING

The MOM connector is not fully supported in a DSS environment. For more information, see MOM Connector in a DSS Environment.

The following diagram illustrates the DX NetOps Spectrum/MOM architecture.



MOM Connector and Fault Tolerant Environments

If you are deploying a fault-tolerant environment with the MOM Connector running, you must restart the MOM Connector after fault tolerance has been set up. Restart the connector because the connector only checks the landscape map once to find a backup SpectroSERVER, typically during initialization or startup. After the MOM Connector has finished initializing, it does not check again to find a backup SpectroSERVER unless it is restarted.

MOM Connector in a DSS Environment

When the MOM Connector is deployed in a Distributed SpectroSERVER (DSS) environment, Microsoft Operations Manager only forwards alerts to a single connector. The connector must be configured to connect to the SpectroSERVER that is managing the same set of servers and hosts as the Microsoft Operations Manager server.
When the Microsoft server connects to a connector on the main location server (MLS), only models that are present on the MLS have corresponding DX NetOps Spectrum alarms created for Microsoft Operations Manager alerts. Any Microsoft Operations Manager alerts that are forwarded to the MLS are not subsequently forwarded to other location servers in the DSS environment. Therefore, the alarms are not raised on models in the other SpectroSERVERs in the environment.

MOM Connector Software Requirements

Verify the following prerequisites before you install the connector software:

- v9.2 or later.
- Microsoft Operations Manager 2005 (the only version that the DX NetOps Spectrum MOM Connector supports).
- The PATH environment variable on the Microsoft Operations Manager server is updated to include the path to the Microsoft .NET Framework.

Add the .NET Framework Path

You must add the path to the Microsoft .NET Framework to the PATH environment variable on the server running MOM. Verify that you have met the following prerequisites before adding the .NET path:

- The Microsoft .NET Framework, Version 1.1 is installed on the MOM Server Host.
  See the documentation provided with the Microsoft Operations Manager 2005 software or the relevant support website for the most accurate requirements.
- You know the path to the .NET Framework software.

Follow these steps:

1. Open the Windows Control Panel.
2. Double-click the System icon.
   The System Properties dialog opens.
3. Click the Advanced tab.
4. Click Environment Variables.
5. Select the Path variable in the System variables table and click Edit.
6. Add the .NET Framework path to the end of the value and click OK.
   Your changes are saved.

Install the MOM Connector

The following procedure describes how to install the MOM Connector software.

> **NOTE**
> In a Distributed SpectroSERVER (DSS) environment, the connector must be configured to connect to the SpectroSERVER that is managing the same set of servers and hosts as the Microsoft Operations Manager server. For more information, see MOM Connector in a DSS Environment.

Follow these steps:

1. Copy the <*$SPECROOT*>/MOMConnector directory to the MOM Server Host.

   > **NOTE**
   > Once you install the DX NetOps Spectrum MOM Connector on the MOM Server Host, you cannot move the directory; select a stable destination directory. For example: C:\Program Files\MOMConnector.
2. On the MOM Server Host, rename the file momrc.example to .momrc.
3. Open the .momrc file with a text editor.
4. Change the ssHost entry to the name of the SpectroSERVER Host. For example, ssHost=MOM01.
5. Execute the following command from the MOMConnector directory on the MOM Server Host:

   ```
   SpectrumMomConnector.exe --install
   ```

   This command sets up the required registry entries used by the MOM Connector and installs the MOM Connector as a Windows Service.
6. In the Windows Control Panel select Administrative Tools, Services.
   The Services dialog opens.
7. Double-click the Spectrum MOM Connector service.

8. Click the Log On tab and select the 'This account' option.
9. Choose a valid DX NetOps Spectrum user account, for example, Administrator.
10. Type and confirm the password for the account.
11. Click OK.
    The MOM Connector is now installed.

Add the MOM Host Server to the Host Security on SpectroSERVER

You must add the MOM Host Server name to the Server List on your SpectroSERVER to allow the servers to communicate.

Follow these steps:

1. Open the Spectrum Control Panel.
2. Select Configure, Host Security.
   The Host Security dialog opens.
3. Enter the MOM Host Server name in the text box under Server List.
4. Click Add.
   The MOM Host Server name is added to the Server List.
5. Click OK.
   Your changes are saved and the Host Security dialog closes.

Run the MOM Connector

Use the following procedure to run the MOM Connector.

Follow these steps:

1. Open the Windows Control Panel and select Administrative Tools, Services.
   The Windows Services dialog opens.
2. Select the Spectrum MOM Connector service.
3. Select Start from the Action menu.
   The MOM Connector service starts.

Verify that the MOM Connector is Running Properly

Verify that the MOM Connector is running from the Microsoft Operations Manager Administrator Console.

Follow these steps:

1. Open the MOM Administrator Console.
2. From the tree in the left pane, click Console Root, Microsoft Operations Manager (hostname), Administration, Product Connectors.
3. Verify that ‘SPECTRUM_Connector’ appears in the right pane.

Viewing MOM Alarms

When the MOM Connector receives alerts, it generates events based on the content of the alert. DX NetOps Spectrum then determines whether to generate an alarm.

After an alarm is generated, right-click the device model and select Alarm Details. You can view the cause of the alarm and the events that generated the alarm in the Alarm Details tab.

For information about sending MOM alerts to the MOM Connector, see Configure MOM Event Rules for Alert Forwarding.

Uninstall the MOM Connector

You can uninstall the MOM Connector if necessary.

Follow these steps:

1. Select Start, Control Panel, Administrative Tools, Services.
   The Services window opens.
2. Right-click the Spectrum MOM Connector service and select Stop.
3. Execute the following command from the MOMConnector directory on the host server:
   ```
   SpectrumMOMConnector.exe --remove
   ```
   The MOM Connector no longer appears in the Windows Services dialog. The connector is removed from the list of Product Connectors in the MOM Administrator Console.

MOM Connector Remains in Windows Services after Uninstallation

Symptom:

After I uninstalled the MOM Connector, the Connector remains in the Windows services dialog. The MOM Connector service is listed as Disabled. I refreshed the Windows services dialog, but the service remains in the list.

Solution:

When the MOM Connector service is in a 'Disabled' state, you cannot reinstall it.

Restart Windows. The Services dialog releases the handle. When you call up the Services dialog, the service is removed. You can now reinstall the MOM Connector.

Configure the MOM Connector

Configure MOM Event Rules for Alert Forwarding

An Event Rule specifies how a condition must be met for MOM to generate alerts to the DX NetOps Spectrum/MOM Connector. If the condition is met, an alert is generated. For an alert to be sent to the DX NetOps Spectrum/MOM Connector, the event resolution state must be set to SPECTRUM_Connector.

> **NOTE**
> See the Microsoft Operations Manager documentation for additional information about event processing rules that generate alerts.

Use the following procedure to create a new event rule that sends alerts that the rule generate to the SPECTRUM_Connector.

Follow these steps:

1. In Microsoft Operations Manager, select Console Root, Microsoft Operations Manager (hostname), Management Packs.
2. Select Rule Groups, Microsoft Operations Manager, Operations Manager 2005, Agent, Event Rules.
3. Right-click Event Rules and select Create Event Rule.
   The Select Event Rule Type dialog opens.
4. Select “Alert on or Respond to Event (Event)” as the rule type, and click Next.
   The Event Rules Properties - Event Provider dialog opens
5. Select “System” from the list box as the data provider and click Next.
   The Event Rules Properties - Criteria dialog opens
6. Click Next to proceed.

The Event Rules Properties - Schedule dialog opens.
7. Click Next to proceed.
   The Event Rules Properties - Event Provider dialog opens.
8. Click Next to proceed.
   The Event Rules Properties - Alert dialog opens.
9. Select Generate alert.
10. Select SPECTRUM_Connector from the Resolution state list box.
11. Click Next.
    The Event Rule Properties - Alert Suppression dialog opens.
12. Clear the option to 'Suppress duplicate alerts,' and click Next.
    The Responses dialog opens.
13. Click Next to proceed.
    The Event Rule Properties - Knowledge Base dialog opens.
14. Click Next to proceed.
    The Event Rule Properties - General dialog opens.
15. Enter a name for the event rule in the Rule Name field, and click Finish.

NOTE
If alerts are not forwarded to DX NetOps Spectrum immediately, the MOM server is updating. Wait a few minutes, and check again for alerts.

Configure Alert Rules to Modify Alerts Generated by MOM Event Rules

By default, alerts created by MOM event rules are not forwarded to the MOM Connector because their resolution state is set to something other than SPECTRUM_Connector. Instead of changing your MOM event rules, you can create an alert rule to forward alerts to DX NetOps Spectrum. You can create an alert rule that modifies alerts created by event rules so that they are forwarded to DX NetOps Spectrum.

Follow these steps:

1. In the MOM administrator console, create an Alert Rule with your specified criteria. Be sure that the Rule Group containing your Alert Rule is associated with the correct Computer Groups.
2. In the new alert rule's properties, in the Responses tab, click Add, and select Launch a script.
   The Launch Script dialog opens.
3. In the Launch a Script dialog, create a new script. The language should be set to VBScript. Use the following format:

```
Option Explicit
Sub Main()
 Dim myAlert
 'change resolution state
 Set myAlert = ScriptContext.Alert
 myAlert.ResolutionState = 211
End Sub
```

NOTE
The scripts set myAlert.ResolutionState to 211, which is the default value for the connectorID parameter. If you have modified the connectorID value in the .momrc file, you will need to change the value used to define myAlert.ResolutionState in the scripts to the connectorID value specified in the .momrc file.

4. Once you have entered the script source, click Next.
5. Click Finish.

NOTE
The script does not require any parameters.

6. In the Alert Rule Properties dialog, click OK.

7. Right-click Console Root and select Microsoft Operations Manager (<*host_name*>), Management Packs node.
8. Select Commit Configuration Change from the menu.
   It can take several minutes for the MOM system to update. When the update is complete, you see alerts that are forwarded to DX NetOps Spectrum.

Create Models for MOM Agents

Model each of the MOM agent hosts on your network so that you can view them in the Topology tab. When you model a MOM agent, DX NetOps Spectrum selects the host device model type that most accurately represents each MOM agent.

Follow these steps:

1. Click the Topology tab.
2. Click the Create a new model by IP icon in the toolbar.
   The Create Model by IP Address dialog opens.
3. Enter the Network Address, Community Name, and Agent Port for DX NetOps Spectrum to use to communicate with MOM agents.
4. Click OK.
   DX NetOps Spectrum creates a model that represents the host device with the specified IP address.

   NOTE
   If the model is not created successfully, verify that the information you entered in Step 3 is correct.
5. Select the new model in the Topology tab.
   The new model information is displayed in the Component Detail panel Information view.
6. Click 'set' next to the label displaying the IP address to the right of the model icon, and type the host name of the MOM agent host.
   This value is case-insensitive.
7. Press Enter to set the name.
   The MOM Connector uses one of the MOM alert properties to identify which model should receive the DX NetOps Spectrum event that is generated.
8. Repeat Step 1 through Step 7 for each MOM agent host in your network.

Install and Run the SCOM Connector

NOTE

10.3 supports SCOM 2016 and 2012 R2 Standard.

The SCOM connector is a Windows service that synchronizes alarm data between DX NetOps Spectrum and Microsoft System Center Operations Manager. The SCOM connector uses the DX NetOps Spectrum SSORB (CORBA) API to communicate with DX NetOps Spectrum and it uses the Operations Manager Connector Framework (OMCF) API to communicate with System Center Operations Manager.

WARNING
The SCOM connector versions are available to support multiple versions of System Center Operations Manager. With version 2012, Microsoft introduced some architectural changes that eliminated the Root Management Server (RMS). Therefore, your deployment differs fundamentally based on your version of Microsoft SCOM.

The SCOM connector synchronizes System Center Operations Manager alerts with DX NetOps Spectrum events and alarms. It provides bidirectional alert/alarm clearing and bidirectional alert/alarm acknowledgment. Thus, if you clear or acknowledge a System Center Operations Manager-related alarm in DX NetOps Spectrum, the corresponding alert is cleared or acknowledged in System Center Operations Manager, and the reverse.

WARNING
The SCOM connector is not fully supported in a DSS environment.

In DX NetOps Spectrum you can monitor and respond to System Center Operations Manager-generated alert conditions by generating DX NetOps Spectrum events and alarms. You can also monitor the status of the System Center Operations Manager agents that are managed by the Microsoft application using DX NetOps Spectrum.

The SCOM connector performs the following tasks:

- Creates DX NetOps Spectrum alarms in response to alerts that are generated in System Center Operations Manager.
- Clears DX NetOps Spectrum alarms when the resolution state of the corresponding System Center Operations Manager alert is set to "Closed" (and the reverse).
- Acknowledges a DX NetOps Spectrum alarm when the resolution state of the corresponding System Center Operations Manager alert is set to "Acknowledged."

> **NOTE**
> By default, the SCOM connector does not include a resolution state for acknowledging an alert; you must create it. For more information about creating this resolution state, see Create an Acknowledged Resolution State.

Installing and Configuring the SCOM Manager

The supported operating system is Windows 2016 and 2012R2.

> **NOTE**
> DX NetOps Spectrum 10.4.2 has not been validated on Windows Server 2012. However, Broadcom will support any DX NetOps Spectrum product issues, if found. We reserve the right to have you upgrade to Windows Server 2016 (or later) if deemed necessary.

Prerequisites

Following are the prerequisites to install SCOM Manager:

1. Install CGI and Microsoft .NET FrameWork v.4.1 or above.
2. IIS should be installed and all ISS services are to be installed.
3. Enable IIS and CGI configuration.
4. Install reporter.exe.
5. Add the machine to the domain.
6. Install SQL 2014 SP1 with the default instance.
7. Ensure whether all the SQL 2014 SP1 services have been started.

Configuring

1. Navigate to the '**Operations Manager Set up - Configuration'** window.
2. Select either one of the installation options:
   - Create the first management server in a new management group: This option is best suited for first-time installation.
   - Add a management server to an existing management group: This option is best suited for those who want to add another management group on top of an existing one.
3. To create a management group for the first time, specify the management group name as SCOM2016.
   The 'Configure Operational Database' window appears.
4. Provide the SQL Server name and the instance name.
   The 'Configure Data Warehouse Database' window appears.
5. Verify the database name and the port. Ensure that you have sufficient permissions on the database instance.
   The 'SQL Server for reporting instances' window appears. This window is to configure report services and web console.
6. Select Next.
   The 'Specify a website for use with the web console' window appears.
7. Select the default website and select Next.

The 'Authentication Mode for Web Console' window appears.

8. Select 'Use Mixed Authentication' and select Next.
   The 'Configure Operations Manager accounts' window appears.
9. Select the 'Management server action account' option for 'Local System' and then select the 'System Center Configuration' option for 'Local System'.
10. Enter the credentials for the 'Data Reader account' and the 'Data Writer account', select Next.
    The 'Microsoft Window' appears.
11. Turn off the Microsoft updates, by enabling the 'Off' radio button and select Next.
    The 'Setup is complete' window appears.
12. Once the setup is completed, refer to the Microsoft support site, to update the product key for SCOM.

Installing

To Install SCOM connector:

1. Copy the SCOM folder from the SpectroSERVER machine. By default it is at 'C:\win32app\Spectrum$'
2. Install the SCOM connector from the command prompt. Refer to the section on Installing SCOM connector for more information.
3. After installing the SCOM connector, refer to the section on SCOM Configuration for Spectrum Manager.
4. Subscribe the SCOM connector with the SCOM Manager to receive alerts from the SCOM Manager to Spectrum Manager.

SCOM Connector Versions

Changes to the SCOM connector in CA Spectrum 10.3 enable integration with Microsoft System Center Operations Manager 2016 and 2012.

Previous versions of Microsoft SCOM used a Root Management Server (RMS), which represented a single point of failure. With SCOM 2012, this server has been eliminated. As a result, CA has changed the SCOM connector architecture for deployment with SCOM 2012.

Previous versions of the connector were deployed with one SCOM connector on the RMS. Because alerts from all SCOM servers were propagated to the RMS, one DX NetOps Spectrum SCOM connector could send all SCOM alerts to DX NetOps Spectrum.

With no RMS running in the Microsoft SCOM environment, you must deploy a connector on each SCOM management server from which you want to collect alerts.

DX NetOps Spectrum architecture dictates that each connector can only be associated with a single landscape. Therefore, all DX NetOps Spectrum landscapes must reflect the devices that each management server is managing. Otherwise, the alerts are mapped under the VNM model.

The SCOM connector version for SCOM 2012 does not support new SCOM functionality, such as fault tolerance.

SCOM Connector Software Requirements

- Microsoft System Center Operations Manager 2016 or Microsoft System Center Operations Manager 2012. Comparable support is available for both versions of SCOM. New functionality that is introduced in Microsoft System Center Operations Manager 2012 is not supported. However, the SCOM connector for Microsoft System Center Operations Manager 2016 and 2012, offers better support for DSS deployments.
- Microsoft .NET Framework 3.0 or later. This software must be installed on the SCOM connector Host.

WARNING
On Windows 2012 Server, the .NET Framework v3.5 is required. If v4.0 of the .NET Framework is installed, the connector application fails. Be aware that .NET v4.0 is installed on this platform by default.

- Microsoft SCOM uses the SpectrumSCOMConnector.exe file to communicate with DX NetOps Spectrum. You must have vcredist_x86 (VS2008) for SpectrumSCOMConnector.exe to work properly.

SCOM Connector and Fault Tolerant Environments

If you are deploying the SCOM connector in a fault-tolerant environment, restart the connector after you set up fault tolerance. The SCOM connector only checks the landscape map once to find a backup SpectroSERVER. Typically this check is performed during initialization or at startup. After the SCOM connector has completed the initialization, it does not check again for a backup SpectroSERVER unless you restart it.

SCOM Connector in a DSS Environment

When the SCOM connector is deployed in a Distributed SpectroSERVER (DSS) environment, System Center Operations Manager only forwards alerts to a single connector. The connector must be configured to connect to the SpectroSERVER that is managing the same set of servers and hosts as the System Center Operations Manager server.

When the Microsoft server connects to a connector on the main location server (MLS), only models that are present on the MLS have corresponding DX NetOps Spectrum alarms that are created for System Center Operations Manager alerts. Any System Center Operations Manager alerts that are forwarded to the MLS are not subsequently forwarded to other location servers in the DSS environment. Therefore, the alarms are not raised on models in the other SpectroSERVERs in the environment.

For Microsoft System Center Operations Manager 2012R2

Microsoft System Center Operations Manager 2012 no longer uses a Root Management Server (RMS). Instead, each SCOM Management Server is a peer with other Management Servers in its own management group.

Deploy multiple SCOM connectors to support SCOM 2012 in a DSS environment. Each connector must be subscribed to single SCOM Management Server and must be configured to connect to a single SpectroSERVER in the DSS environment. The connector must be configured to connect to the SpectroSERVER that is managing the same set of servers and hosts as the SCOM Management Server. With this configuration, the connector supports a DSS configuration.

Update the .scomrc file on each connector to include the hostname of each Management Server (RMS) in the "scomHost" field.

Before Installing the SCOM Connector

The topics in this section assume the following:

- You have installed and configured a Microsoft System Center Operations Manager (SCOM) Management Server.
- You are integrating your System Center Operations Manager environment with DX NetOps Spectrum network management software.
- You are aware of basic deployment differences between versions of the connector.
  Versions of System Center Operations Manager prior to version 2012 and version 2012 and later have fundamental architectural differences. For more information, see SCOM Connector Versions.

Before installing the SCOM Connector, verify the following:

User Access

The user account under which the SCOM Connector will run must have access to both DX NetOps Spectrum and Microsoft System Center Operations Manager.

- In DX NetOps Spectrum, use the Users tab in the OneClick Console to create a DX NetOps Spectrum user model for the SCOM Connector user. The user model should be an administrator user but not necessarily a super user account.

  WARNING
  The user model must already exist in DX NetOps Spectrum before you install the SCOM Connector.
- In Microsoft System Center Operations Manager, verify that the connector user is a member of the Administrator User Role. By default, the Administrator User Role in SCOM contains the local Administrator user group as a User Role Member. Therefore, to give the user access to SCOM, you can add the user to the local Administrator user group using the Windows Computer Management dialog.

Host Access

If the SCOM Connector is running on a host other than the SpectroSERVER host, add the SCOM Connector host to the SpectroSERVER host security. You can add the host by using SCP or by editing the *<$SPECROOT>*/.hostrc file.

For more information, see Add the SCOM Host Server to the Host Security on SpectroSERVER.

Communication Ports

Firewalls must be configured to allow traffic to pass on certain ports:

- On the remote SpectroSERVER host, the connector tries to reach the Naming Service on Port 14006 by default.

  NOTE
  We recommend verifying firewall configuration to enable connections to the required SSORB communication ports. For more information, see the Distributed SpectroSERVER Administration section.
- On the remote SCOM host, the connector tries to reach the Connector Framework on Port 5724 by default. Verify that Port 5724 is open between the SCOM Connector and the Connector Framework on the RMS.
- By default, the CORBA API listens for communications from the connector on Port 14001.
- SpectroSERVER for TCP/CORBA uses port 14002.
- LocServ on SpectroSERVER for TCP/CORBA uses port 14004.
- You can set a different connector listening port in a configuration file. For more information, see Configure Connector Communication Settings.

Acknowledged Resolution State

To enable bidirectional alert/alarm acknowledgment, you must create a custom resolution state within SCOM. The new resolution state is used to represent an alert that has been “Acknowledged.”

Host Names and Model Names

The host name of the SCOM alert must match the DX NetOps Spectrum model name for the integration to operate properly. Case is not considered. If the host name that arrives in DX NetOps Spectrum in an SCOM alert does not match the DX NetOps Spectrum model name to which it applies, the alarm is not raised or cleared. Synchronization of host

names for SCOM alerts and model names in DX NetOps Spectrum must be maintained for the integration to operate properly.

When creating model names in DX NetOps Spectrum, consider establishing an internal policy such as setting the sysName for SNMP agents to the host name or fully qualified domain name (FQDN) for consistency. Use the Model Naming Order setting in the SpectroSERVER Control subview for the VNM model to control how models are named.

NOTE
Additional documentation discusses the Model Naming Order setting and the SpectroSERVER Control Subview. For more information, see the Modeling and Managing Your IT Infrastructure section.

Install the SCOM Connector

The following procedure describes how to install the SCOM Connector software.

NOTE
In a Distributed SpectroSERVER (DSS) environment, the connector must be configured to connect to the SpectroSERVER that is managing the same set of servers and hosts as the System Center Operations Manager server. For more information, see SCOM Connector in a DSS Environment.

Follow these steps:

1. Copy the <*$SPECROOT*>/SCOMConnector directory to the server where you plan to deploy the SCOM Connector.
   WARNING
   Once you install the SCOM Connector on the server host, you cannot move the directory. Select a stable destination directory. For example, select C:\Program Files\SCOMConnector.
2. On the host server, rename the file "scomrc.example" to ".scomrc".
3. Open the .scomrc file with a text editor and modify the parameters as needed.
   NOTE
   The .scomrc file contains descriptions of each of the available parameters.
   a. Specify the ssHost and scomHost parameters if the connector is remote from one or both of the management systems. For example, if the SCOM Connector is installed on the SCOM host and the SpectroSERVER is on a different host, specify a value for the ssHost parameter to enable the connector to reach DX NetOps Spectrum.
   b. Specify the scomAckResolutionState parameter to enable bidirectional alarm/alert acknowledgment. The value of this parameter is the numeric identifier of the 'Acknowledged' resolution state in System Center Operations Manager.
      NOTE
      To enable bidirectional alarm/alert acknowledgment, create an Acknowledged resolution state. For more information, see Create an Acknowledged Resolution State.
   c. Set the scomWebHost parameter to point the Alert URL in DX NetOps Spectrum events to a SCOM web server. This parameter lets you specify a different server than the SCOM server.
      This value defaults to scomHost. If either scomWebHost nor scomHost is set, this value defaults to localhost.
   d. (Optional) Specify the web URL port that is used to access the SCOM web console. For SCOM 2012, the default port is 80 and for SCOM 2016 the default port is 1433.
   e. (Optional) For SCOM 2012, specify the web console application name of the SCOM web console, where applicable. For example, type http://SERVER_NAME: Port/OperationsManager. The default is OperationsManager.
4. Execute the following command from the SCOMConnector directory on the host server:
   ```
   SpectrumSCOMConnector.exe --install
   ```
   This command sets up the required registry entries for the SCOM Connector and installs the SCOM Connector as a Windows Service.
5. In the Windows Control Panel, select Administrative Tools, Services.
   The Services dialog opens.
6. Double-click the Spectrum SCOM Connector service.

7. Select the login tab, and select ‘This account’.
8. Select a user account for the connector to run under, such as Administrator. Select a valid DX NetOps Spectrum user.
9. Type and confirm the password for the account.
10. Select OK to accept your changes.
    The SCOM Connector is now installed.

Add the SCOM Host Server to the Host Security on SpectroSERVER

Add the SCOM Connector host name to the Server List on your SpectroSERVER to enable the servers to communicate.

Follow these steps:

1. Open the DX NetOps Spectrum Control Panel.
2. Select Configure, Host Security.
   The Host Security dialog opens.
3. Type the SCOM Connector host name in the text box under Server List.
4. Click Add.
   The SCOM Connector host name is added to the Server List.
5. Click OK.
   Your changes are saved and the Host Security dialog closes.

> **NOTE**
> You can also add the SCOM Connector host to the host security on the SpectroSERVER by editing the <*$SPECROOT*>/.hostrc file.

Configure Connector Communication Settings

You can set the SCOM Connector listening port in a configuration file. Setting a static port is a recommended best practice. When the connector instead selects a random listening port, intervening firewalls can disrupt communications among components in a distributed environment. The configuration file (.corbarc) must be present in the <*SCOMCONNECTOR*> folder on the server where the SCOM Connector is installed.

Follow these steps:

1. On the host server, navigate to the directory where you have copied the SCOM Connector folder.
2. Rename the corbarc.example file to '.corbarc'.
3. Open the .corbarc file using your preferred text editor.
4. Change the variable (indicated by italics) in the following line to match the hostname in your environment:
   ```
   vbroker.se.iiop_tp.proxyHost= <hostname of the server where the Connector is installed>
   ```
5. Change the variable (indicated by italics) in the following line to match the port that you want to configure as the static listening port for the connector:
   ```
   vbroker.se.iiop_tp.scm.iiop_tp.listener.port=<port number>
   ```

   > **WARNING**
   >
   > - The default port is 14001. This port must be open between the connector and the SpectroSERVER.
   > - If the connector is installed on a machine where Spectrum is running, configure the connector listening port to the port that Spectrum is not using.
   >
   > Execute netstat –a | grep 14001 to check whether the 14001 port is in use.
6. Save the .corbarc file.
7. When you have started the connector with the above changes applied, verify the change by issuing the following commands:

```
netstat -ano | grep <SCOM Connector pid>
```

The information that is returned verifies whether the connector is using the listener port that you specified in the .corbarc file.

Start the SCOM Connector

The following procedure describes how to run the DX NetOps Spectrum/SCOM Connector.

Follow these steps:

1. Open Windows Control Panel and select Administrative Tools, Services.
   The Windows Services dialog opens.
2. Select the Spectrum SCOM Connector service.
3. Select Start from the Action menu to start the service.
   The SCOM Connector starts running.

Verify that the SCOM Connector is Running Properly

You can use SCOM Administration to verify that the SCOM Connector is running.

Follow these steps:

1. Open the SCOM Operations Console.
2. Change to the Administration context in the console.
3. From the tree in the left pane, expand Administration and select Product Connectors.
4. Verify that 'SPECTRUM Connector' appears in the right pane.

Viewing SCOM Alarms

When the SCOM Connector receives alerts, it generates events based on the content of the alert. DX NetOps Spectrum then determines whether to generate an alarm.

> **NOTE**
> The host name of the SCOM alert must match the DX NetOps Spectrum model name (except for case) for the integration to operate properly. For more information, see Host Names and Model Names.

After an alarm is generated, right-click the device model and select Alarm Details. You can view the cause of the alarm and the events that generated the alarm in the Alarm Details tab.

See Set Up SCOM Connector Subscriptions for information about sending SCOM alerts to the SCOM Connector.

Uninstall the SCOM Connector

The following procedure describes how to uninstall the SCOM Connector.

To uninstall the SCOM Connector

1. Select Start, Control Panel, Administrative Tools, Services.
   The Services window opens.
2. Right-click the Spectrum SCOM Connector service and select Stop.
3. Execute the following command from the SCOMConnector directory on the host machine:
   ```
   SpectrumSCOMConnector.exe --remove
   ```
   The SCOM Connector no longer appears in the Windows Services dialog and is removed from the list of Product Connectors in the SCOM Operations Console.

Configure the SCOM Connector

Set Up SCOM Connector Subscriptions

Set up a connector subscription in System Center Operations Manager. The subscription lets the SCOM Connector forward alerts to DX NetOps Spectrum.

Follow these steps:

1. After you have started the SCOM Connector for the first time, you will see DX NetOps Spectrum Connector that is listed as a Product Connector in the SCOM Operations Console. Right-click DX NetOps Spectrum Connector in the Operations Console and click Properties.
   The Product Connector Properties dialog opens.
2. Click Add in the Subscription section to create a new connector subscription.
   The Product Connector Subscription Wizard opens.
3. Enter a subscription name and a description in the General page and click Next.
4. Select the groups whose alerts you want forwarded to DX NetOps Spectrum in the Groups page and click Next.
5. Select the targets whose alerts you want forwarded to DX NetOps Spectrum in the Targets page and click Next.
6. Select the appropriate criteria for the alerts that are forwarded to DX NetOps Spectrum in the Criteria page.
7. Click Create.
   The SCOM Connector subscription is created.

Create Models for SCOM Agents

You can model each of the SCOM agent hosts on your network so that you can view them in the Topology tab. When you model an agent, DX NetOps Spectrum selects the host device model type that most accurately represents each agent.

Follow these steps:

1. Log in to OneClick.
2. In the Landscapes area, select Universe Node.
3. Click the Topology Tab in the Contents Panel.
4. Click the Create a New Model by IP icon in the toolbar.
   The Create Model by IP Address dialog opens.
5. Enter the Network Address, Community Name, and Agent Port for DX NetOps Spectrum to use to communicate with SCOM agents.
6. Click OK.
   DX NetOps Spectrum creates a model that represents the host device with the specified IP address.

   NOTE
   If the model is not created successfully, verify that the information that you entered previously is correct.
7. Select the new model in the Topology tab.
   The new model information is displayed in the Component Detail panel Information view.
8. Change the name of the model to the host name of the server that hosts the Operations Manager agent, as follows:
   1. Select *Set* next to the label displaying the IP address to the right of the model icon in the Information view.
   2. Enter the *host name of the SCOM agent* host. This value is case-insensitive.
   3. Select *Enter* to set the name.
9. The SCOM Connector uses one of the System Center Operations Manager alert properties to identify the model that receives the DX NetOps Spectrum event that is generated.
10. Repeat the previous steps for each agent host on your network.

For more information, see Modeling and Managing Your IT Infrastructure section.

Create an Acknowledged Resolution State

By default, the SCOM Connector does not include a resolution state for acknowledging an alert. Instead, you must create one. Once you have created the resolution state in SCOM, the Connector can be configured to use that resolution state to synchronize the acknowledgment of alerts and alarms. By default, however, the SCOM Connector does not provide acknowledgment synchronization.

Follow these steps:

1. On the SCOM host, open the SCOM Operations Console.
2. In the Operations Console, select Administration, Settings.
3. Right-click Alerts in the central table.
4. In the Alert Resolution States tab, click New.
5. Type a name for the new resolution state, and select a Unique ID.

> **NOTE**
> This Unique ID is used to configure the scomAckResolutionState parameter in the .scomrc file.

Troubleshoot the SCOM Connector

SCOM Alerts Not Synchronized with DX NetOps Spectrum Alarms

Symptom:

When a System Center Operations Manager alert arrives in DX NetOps Spectrum, the appropriate DX NetOps Spectrum alarm is not raised or cleared.

Solution:

The host name of the System Center Operations Manager alert must match the DX NetOps Spectrum model name (except for case) for the integration to operate properly. If the host name that arrives in DX NetOps Spectrum in an SCOM alert does not match the DX NetOps Spectrum model name for which it applies, the alarm is not raised or cleared. Synchronization of host names for SCOM alerts and model names in DX NetOps Spectrum must be maintained for the integration to operate properly.

> **WARNING**
> If you have applied any hotfixes to your DX NetOps Spectrum environment, make sure that you have also upgraded the SCOM Connector. The installed DX NetOps Spectrum and SCOM Connector versions must be the same for the integration to operate properly.

Alert States Not Updated

Symptom:

I have installed the SCOM Connector and I have configured the integration. I have even followed the steps in Create an Acknowledged Resolution State. The System Center Operations Manager alerts are coming through as alarms in DX NetOps Spectrum. However, when I acknowledge or unacknowledge an alarm in DX NetOps Spectrum, the resolution state does not update in SCOM. I eventually concluded that the SCOM Connector uses a random listening port each time it is restarted.

Solution:

To resolve the issue with alert states that are not updated on multiple servers, first check your firewall settings. Ports 14006 and 14001 (or the port that is set in the .corbarc file, if applicable) must be open between the SpectroSERVER and the SCOM Connector to enable bidirectional communication between these components.

The SCOM Connector uses listening port 14001 by default to receive communications from the CORBA API. If that port is in use, you can set another port in a CORBA configuration file. Edit the .corbarc file to include the listening port that you want to use.

SpectroSERVER for TCP/CORBA uses port 14002 and LocServ on SpectroSERVER for TCP/CORBA uses port 14004.

> **NOTE**
> If the connector is installed on a machine where Spectrum is running, configure the connector SCOM listening port to the port that Spectrum is not using.
>
> Execute netstat - a | grep 14001 to check whether the 14001 port is in use.

We have included an example of this file to guide you in configuring the applicable parameters. For more information, see the Configure Connector Communication Settings section.

SCOM Connector Loses Ownership of of Alerts After Reinstallation

Symptom:

If you uninstall and then reinstall the SCOM Connector, the Connector can lose ownership of SCOM Connector alerts.

Solution:

Manually forward the alerts again to the newly installed SCOM Connector.

SCOM Connector Remains in the Windows Services Dialog after Uninstallation

Symptom:

After I uninstalled the SCOM Connector, the Connector service remains in the Windows services dialog. The SCOM Connector service is listed as being in the “Disabled” state. Refreshing the Windows services dialog does not remove the SCOM Connector from the list.

Solution:

When the SCOM Connector is in this state, you cannot reinstall it. Restart the server. After Windows restarts, the Services dialog releases the handle and the service is removed. You can now reinstall the SCOM Connector.

SCOM Connector not available for Spectrum on Linux

Symptom:

How can the Spectrum SCOM Connector be installed to monitor SCOM environments when the Spectrum Server is only available on Linux.

The Spectrum SCOM Connector binaries only exists for Windows Platforms.

Solution:

1. Check the Spectrum License in $SPECROOT/Install-Tools/LOGS/<SpectrumRelease>/summary* file and make sure the entry "Microsoft MOM Connector" exists.
2. Check the $SPECROOT/Install-Tools/.history file for the current release and patch level of Spectrum.
3. A standalone SCOMConnector package is not available. So if the Spectrum Windows installer is available, the $SPECROOT/SCOMConnector can be extracted to the SCOM Windows System based on the extraction key or a Support Issue can be opened with the .history information to request a Zip Archive for the Windows System of the $SPECROOT/SCOMConnector directory.
4. The Spectrum SCOM Connector has to be run on the SCOM Server or on another Windows Server that has the .NET framework 3.0 installed.

Launch the Web Console

Launch the Web Console from the OneClick Console

The DX NetOps Spectrum integration with MOM and SCOM lets you launch the applicable Web Console from the OneClick Console.

To launch the MOM Web console from OneClick

1. Select any DX NetOps Spectrum model that has an associated MOM-based alarm.
2. Click the Alarms tab in the Contents panel.
3. Click the Alarm Details tab in the Component Detail panel.
4. Click the omAlertURL at the bottom of the window to display alarm details.

> **NOTE**
> A hyperlink is not shown for alarms that lack an associated URL.

To launch the SCOM Web console from OneClick

1. Select any DX NetOps Spectrum model that has an associated MOM- or SCOM-based alarm.
2. Click the Alarms tab in the Contents panel.
3. Click the Alarm Details tab in the Component Detail panel.
   The Web Context URL provides a link labeled, “Click here to launch.”

Configure the SCOM Connector to Provide HTTPS URLs

SCOM supports HTTPS for the web console. You can configure the SCOM Connector to provide HTTPS URLs.

Follow these steps:

1. Open the .scomrc file with a text editor.
2. Specify the scomWebPrefix parameter with a value of https, as follows:
   ```
   scomWebPrefix = https
   ```
3. Save the .scomrc file.
4. Restart the SCOM Connector.
   Your changes are applied.

Change the OneClick Web Context URL

You can change the context URL for launching the MOM Web Console from OneClick. This procedure requires a working knowledge of XML and HTML. Although this procedure applies to both MOM and SCOM, it uses MOM as an example.

> **NOTE**
> You can preserve the customized XML that is created in this procedure from being overwritten during a DX NetOps Spectrum or OneClick upgrade or a reinstallation. For more information, see the OneClick Customization section.

Follow these steps:

1. In the OneClick installation directory (<*$SPECROOT*>), navigate to the following location:
   <*$SPECROOT*>/tomcat/webapps/spectrum/WEB-INF/alarm/config
2. Open the column-alarmwebcontexturl-config.xml file for editing.
3. Modify the text between the <html> and </html> tags to display an alternate hyperlink in OneClick. For example, replace the existing text to display a hyperlink in OneClick that reads, "Launch MOM Web Console".
   Replace this text:
   ```
   "<html>Click <a href='" + (String)value() + "'>here</a> to launch</html>"
   ```

With the following text:

```
"<html><a href='" + (String)value() + "'>Launch MOM Web Console</a></html>"
```

Events

This chapter shows the DX NetOps Spectrum events that are generated based on alerts received from MOM- or SCOM-managed hosts. The tables in this chapter contain the following information:

- **DX NetOps Spectrum Event**
  The DX NetOps Spectrum event created based on a MOM or SCOM alert.
- **Event Code**
  The DX NetOps Spectrum event code for the event.
- **Event Action**
  The processing that is performed on the event based on the instructions in the event disposition file. For example, raise an alarm, clear an alarm, or check for a frequent problem.
- **Alarm Code**
  The alarm code generated or cleared by the event.
- **Alarm Severity**
  The severity of the alarm generated.

Supported MOM Connector DX NetOps Spectrum Events

The following table lists the DX NetOps Spectrum events supported by the MOM Connector.

DX NetOps Spectrum Event	Event Code	Event Action	Alarm Code	Alarm Severity
Success	0x3e0000a	N/A	N/A	N/A
Information	0x3e0000b	N/A	N/A	N/A
Warning	0x3e0000c	Alarm Generated	0x3e0000c	Minor
Error	0x3e0000d	Alarm Generated	0x3e0000d	Major
Critical Error	0x3e0000e	Alarm Generated	0x3e0000e	Critical
Security Breach	0x3e0000f	Alarm Generated	0x3e0000f	Critical
Service Not Available	0x3e00010	Alarm Generated	0x3e00010	Critical

Supported SCOM Connector DX NetOps Spectrum Events

The following table lists the DX NetOps Spectrum events supported by the SCOM Connector.

DX NetOps Spectrum Event	Event Code	Event Action	Alarm Code	Alarm Severity
Information	0x3e00012	N/A	N/A	N/A
Warning	0x3e00013	Alarm Generated	0x3e00011	Minor
Error	0x3e00014	Alarm Generated	0x3e00012	Critical

Nortel Preside MDM

Nortel Preside Multiservice Data Manager (MDM) is an element management system (EMS) for managing faults, configuration, accounting, performance, and security of Nortel's telecommunications network and devices.

NOTE
For details about Nortel MDM operation and concepts, see the Nortel product documentation.

The MDMConnector integrates Nortel Preside MDM telecommunication networks and devices with DX NetOps Spectrum Telco EMS Manager. MDMConnector runs on the same machine as the MDM application. Nortel Preside MDM uses a node to represent any managed element, including devices, ports, cards, shelves, and so on. Links, which are a physical or logical connection between two nodes, are also supported. When you discover and model a network managed by MDM, the MDMConnector queries the MDM Network Modeling server for nodes and links and forwards them to DX NetOps Spectrum. MDMConnector also registers with the MDM Alarm and Status server for events and forwards them to DX NetOps Spectrum. MDMConnector periodically checks the status of MDM and reports it to DX NetOps Spectrum along with its own status through the heartbeat mechanism.

Installing and Configuring MDMConnector

Install the MDMConnector Files

The MDMConnector executable and all associated configuration files are installed on the SpectroSERVER host machine in the TelcoEMSManager directory. The files are bundled into the MDMConnector.tar file, which you must copy to the MDM Server host machine.

To copy and install the MDMConnector files

1. Copy the MDMConnector.tar file to a new, empty directory on the MDM Server host machine.
2. From the directory on the MDM server host, run the following command:

   ```
   $ tar xvf MDMConnector.tar
   ```

   The following files appear in the directory:
   - MDMConnector
   - MDMConnector.cfg
   - MDMConnector.lst
   - MDMConnector.sh
   - libtelcohelper.so.1
   - libssorbconvert.so.1
   - libVPapi.so.1
   - libcosnm_r.so
   - libssorb.so.1
   - libssorbutil.so.1
   - libGlobl.so.1
   - libtelcocorba.so.1
   - liborb_r.so
   - libvport_r.so
   - libPort.so.1

MDMConnector Configuration

You can configure MDMConnector with the MDMConnector.cfg configuration file. This file is in the same directory as the MDMConnector binary. All parameters should be specified in the 'name = value' format. MDMConnector runs with default

values if the configuration file is not present or if parameters are missing. The following lists the configuration parameters with their default values:

- **SPECTRO_SERVER**
  Specifies the name of the machine where the SpectroSERVER is running.
  Default: localhost
- **TRACE_FILE**
  Specifies the file name of the log file.
  Default: MDMConnector.log
- **TRACE_LEVEL**
  Specifies the trace level for the log messages. The possible values are:
  0 = No messages are logged
  1 = Only error messages are logged
  2 = Detail log for debugging
  Default: 0
- **SPEC_FILE**
  Specifies the file specifying the discovery criteria. MDMConnector discovers components from MDM based on contents of this file.
  Default: MDMConnector.lst
- **EMS_ID**
  Specifies the EMS identifier. This should be unique for every EMS (MDM server) that DX NetOps Spectrum monitors.
  Default: MDM_*<local machine>*
- **EMS_VENDOR**
  Specifies the vendor name for managed components.
  Default: CA
- **TYPES_DIR**
  Specifies the name of the directory where MDM stores the .ltdf and .mtdf files which contain information about different component types. The default value is the current directory.
- **MDM_USER**
  Specifies the MDM username used for registering with MDM.
  Default: mdpadmin
- **MDM_ALARM_FORMAT**
  Specifies the alarm format used while displaying MDM alarms. The possible values are:
  – 0 = EPI_ALARM_TERSE_FORMAT
  – 1 = EPI_ALARM_NORMAL_FORMAT
  – 2 = EPI_ALARM_FULL_FORMAT
  Default: EPI_ALARM_FULL_FORMAT
- **OSAGENT_PORT**
  Specifies the ORB Agent Port to connect to the SpectroSERVER.
  Default: 14008

Discovery Specification File

You can specify a list of nodes and links to discover in the discovery specification file. The default discovery specification file is the MDMConnector.lst file. The MDMConnector.lst file has four sections:

- **node**
  Specifies the list of nodes you want to discover. 'All' discovers all the nodes.
- **nodeTypeId**
  Specifies the list of node types that you want to discover.
- **link**

Specifies the list of links to discover. 'All' discovers all the links.

- **linkTypeId**
  Specifies the list of link types to discover. All the links of the specified types will be discovered.

Start the MDMConnector

You must start the MDMConnector as the same user account that started MDM.

To start MDMConnector

1. Log in to the MDM server machine as the MDM user.
2. Change to the directory where the MDMConnector files are installed on the MDM server.
3. Enter the following command:

```
$ ./MDMConnector.sh
```

Discovery and Modeling for MDMConnector

Discover MDM Equipment

Discovery is the process in which DX NetOps Spectrum communicates with all installed Nortel Preside MDMConnectors and directs them to collect information about the Nortel MDM nodes. Each MDMConnector then communicates with its associated Nortel Preside MDM server and retrieves the desired network and device information. The MDMConnector then sends the discovery data back to DX NetOps Spectrum to be modeled in the database. DX NetOps Spectrum's Telco EMS Manager can discover any or all managed elements and links in a Nortel Preside MDM.

To perform a discovery of all desired MDM equipment

1. Navigate to the Telco EMS Manager application in OneClick by expanding the desired landscape icon in the Navigation panel, and then selecting Telco EMS Manager.
2. In the Information tab of the Component Detail panel, expand the Configuration subview to display Telco Discovery.
3. Click Discover.
   The Discovery process begins; any discovered MDM nodes are added to the landscape.

MDM Modeling

DX NetOps Spectrum stores all the Nortel Preside MDM equipment data in the SpectroSERVER's modeling database.

Nortel Preside MDM uses a node to represent any managed element, including devices, ports, cards, shelves, and so on. Links, which are a physical or logical connection between two nodes, are also supported. For this reason, DX NetOps Spectrum uses two different model types to model any node or link in a Nortel Preside MDM: TelcoEMSManagedElement (0x4fd0001) and TelcoEMSManagedLink (0x4fd0003).

> **NOTE**
> Dynamic models are created inside the Nortel Preside MDM only when a problem exists on a Static model and an alarm needs to be created. When there are no remaining alarms on a Dynamic model, it may be destroyed by the Nortel Preside MDM. Static models are persistent within the Nortel Preside MDM until the model is no longer being managed by the Nortel Preside MDM. To maintain event and alarm history when a Dynamic model is destroyed within a Nortel Preside MDM, the Dynamic model is not automatically destroyed in DX NetOps Spectrum.

A TelcoEMSManagedElement or TelcoEMSManagedLink model can be copied and pasted anywhere in the DX NetOps Spectrum network topology views (Universe, World, or TopOrg). This lets you arrange your network containment based on your organization needs. DX NetOps Spectrum associates TelcoEMSManagedElement models appropriately to reflect the hierarchical relationship of managed elements (device-> board-> port-> logical port) in MDM.

TelcoEMSManagedElement Model Type Attributes

The following list describes the TelcoEMSManagedElement model type attributes.

- **EmsID**
  The name of the Nortel Preside MDMConnector or Nortel Preside MDM station where TelcoEMSManagedElement is located.
  Attribute ID: 0x4fd0003
- **EmsComponentId**
  The unique name that identifies the TelcoEMSManagedElement in the associated Nortel Preside MDM and within DX NetOps Spectrum.
  Attribute ID: 0x4fd0000
- **EmsElementDescr**
  The description given to this element inside the Nortel Preside MDM.
  Attribute ID: 0x4fd0004
- **EmsElementType**
  The type given to this element inside the Nortel Preside MDM.
  Attribute ID: 0x4fd0005
- **EmsVendor**
  The vendor of this element inside the Nortel Preside MDM.
  Attribute ID: 0x4fd0007
- **EmsPersistence**
  The persistence type of this element, either Static or Dynamic.
  Attribute ID: 0x4fd0008

TelcoEMSManagedLink Model Type Attributes

The following list describes the TelcoEMSManagedElement model type attributes.

- **EmsId**
  The name of the Nortel Preside MDMConnector or Nortel Preside MDM station where TelcoEMSManagedLink is located.
  Attribute ID: 0x4fd0003
- **EmsComponentId**
  The unique name that identifies this TelcoEMSManagedLink in the associated Nortel Preside MDM and within DX NetOps Spectrum.
  Attribute ID: 0x4fd0000
- **EmsLinkDescr**
  The description given to this link inside the Nortel Preside MDM.
  Attribute ID: 0x4fd0004
- **EmsLinkType**
  The type given to this link inside the Nortel Preside MDM.
  Attribute ID: 0x4fd0005
- **EmsPersistence**
  The persistence type of this link, either Static or Dynamic.
  Attribute ID: 0x4fd0008

Accessing Nortel Preside MDM within OneClick

This chapter describes how to use Nortel Preside MDM with OneClick. In particular, it describes how you can access and work with Nortel Preside MDM using the various OneClick components.

Navigation Panel

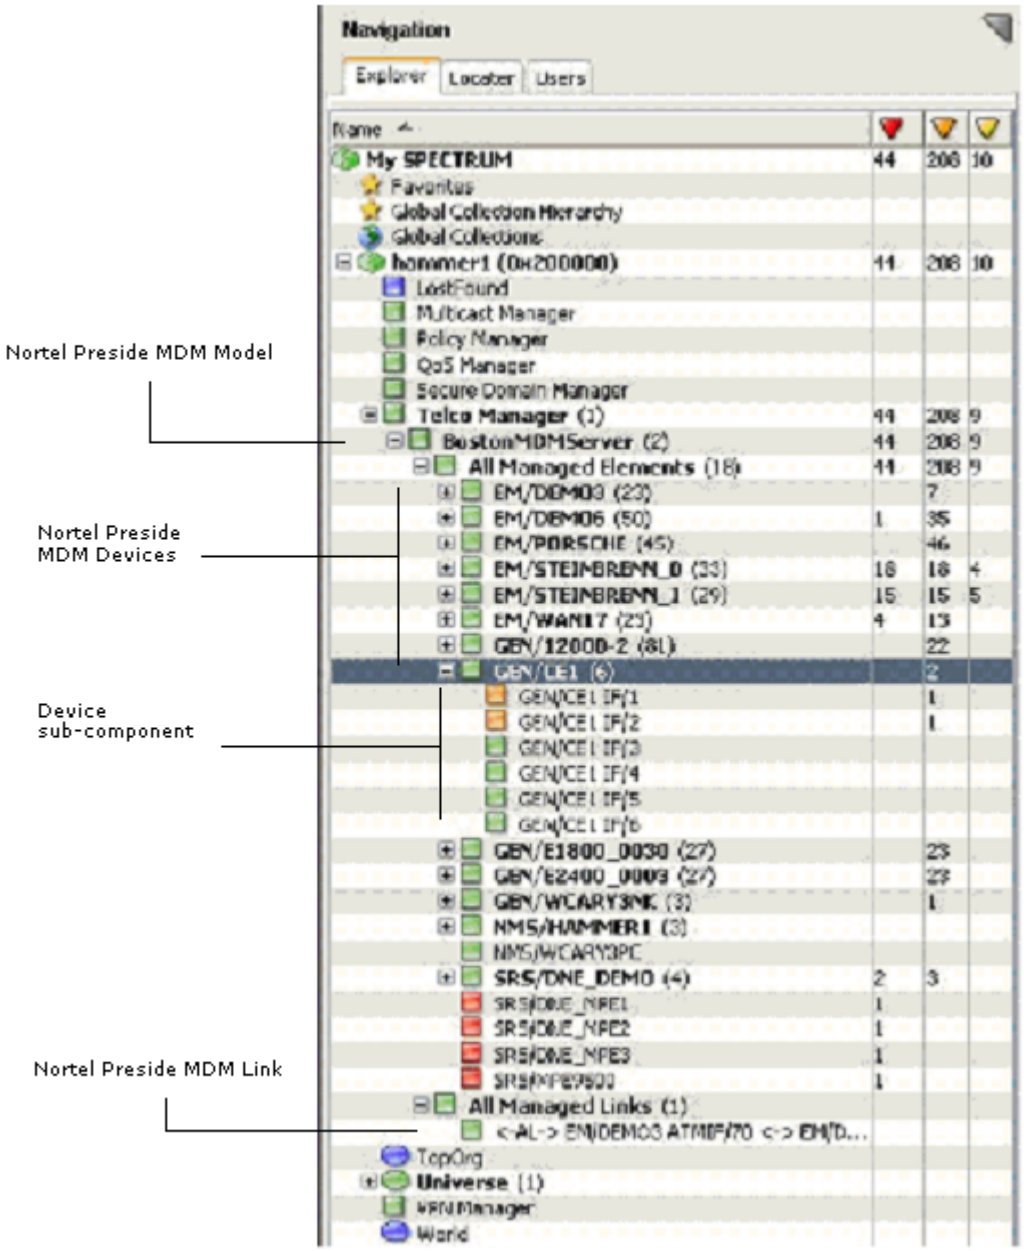
In the Explorer tab of the OneClick Navigation panel, expand the desired landscape to display the Telco EMS Manager application. Every Nortel Preside MDMConnector that connects successfully with DX NetOps Spectrum is represented by its corresponding model. Expand the Telco EMS Manager model to display all Nortel Preside MDM models connected with DX NetOps Spectrum.

All TelcoEMSManagedElement and TelcoEMSManagedLink models managed in DX NetOps Spectrum appear inside the All Managed Elements or All Managed Links model within the Nortel Preside MDM model.

The All Managed Elements model contains all device models connected to a Nortel Preside MDM model. Expand the desired device model to display its sub-components.

The All Managed Links model contains a list of all links managed by the selected Nortel Preside MDM. Expand the desired link to display its sub-links.

The following image displays an expanded view of the Telco EMS Manager and its elements.



Contents Panel

The information displayed in the Contents panel is determined by the model or element selected in the Navigation panel and the tab selected in the Contents panel. The following sections discuss the different tabs in the Contents panel.

- **Alarms tab**
  When you select any Nortel Preside MDM model in the Navigation panel, the Alarms tab displays all alarms on the selected model and its sub-components.
- **List tab**
  The List tab displays all immediate sub-components of the model selected in the Navigation panel. Depending on the type of models displayed in the List tab, different information appears in the columns.
- **Topology tab**

The Topology tab is disabled for all Nortel Preside MDM-related models because they do not have their own topology. Any TelcoEMSManagedElement or TelcoEMSManagedLink model can, however, be copied and pasted into any of the DX NetOps Spectrum network topology views (Universe, World, or TopOrg). This lets you arrange your network containment as desired.

Component Detail Panel

The information displayed in the Component Detail panel depends on which model or element is selected in the Navigation panel and in the Contents panel. When you select a model in the Alarms tab or the List tab of the Contents panel, the Component Detail panel displays information about the selected model.

> **NOTE**
> To view the Component Detail of a container model that has children (such as the Telco EMS Manager model or a Nortel Preside MDM model), you must select the List tab in the Contents panel and press the Control (Ctrl) key to deselect all models listed. This lets OneClick display the container model's information in the Component Detail panel.

Information Tab

The Information tab displays the configuration options for different elements as follows:

- **Telco EMS Manager Model**
  The Information tab for the Telco EMS Manager model contains the following sections:
  - **General Information**
    Displays the basic DX NetOps Spectrum information about the model.
  - **Configuration**
    Starts a new Telco Discovery.
  - **Telco EMS List**
    Displays a list of the Nortel Preside MDMs that are currently connected with this landscape.
- **Nortel Preside MDM Model**
  The Information tab for the Nortel Preside MDM model contains the following sections:
  - **General Information**
    Displays the basic DX NetOps Spectrum information about the model.
  - **Telco Sub-Component List**
    Shows the following Telco model grouping containers:
    - All Managed Elements
    - All Managed Links
- **All Managed Elements/All Managed Links**
  When you select the All Managed Elements or All Managed Links grouping container, the Information tab contains the following sections:
  - **General Information**
    Displays the basic DX NetOps Spectrum information about the model.
  - **Telco Sub-Component List**
    Shows all of the top-level models such as devices or links.
- **TelcoEMSManagedElement**
  The Information tab for the TelcoEMSManagedElement model contains the following sections:
  - **Telco Managed Element Information**
    Displays the EMS-specific information describing the model.
  - **General Information**
    Displays the basic DX NetOps Spectrum information about the model.
  - **Telco Sub-Component List**

Shows all the TelcoEMSManagedElement models that are sub-components of the selected model such as cards, slots, ports, and so on.

- **TelcoEMSManagedLink**
  The Information tab of the TelcoEMSManagedLink model contains the following sections:
  - **Telco Managed Link Information**
    Displays the EMS-specific information describing the model.
  - **General Information**
    Displays the basic DX NetOps Spectrum information about the model.
  - **Telco Sub-Component List**
    Shows all the TelcoEMSManagedLink models that are sub-components of the selected model such as logical links.
  - **Connected Telco Managed Element List**
    Displays the two TelcoEMSManagedElement models connected by the selected link model.

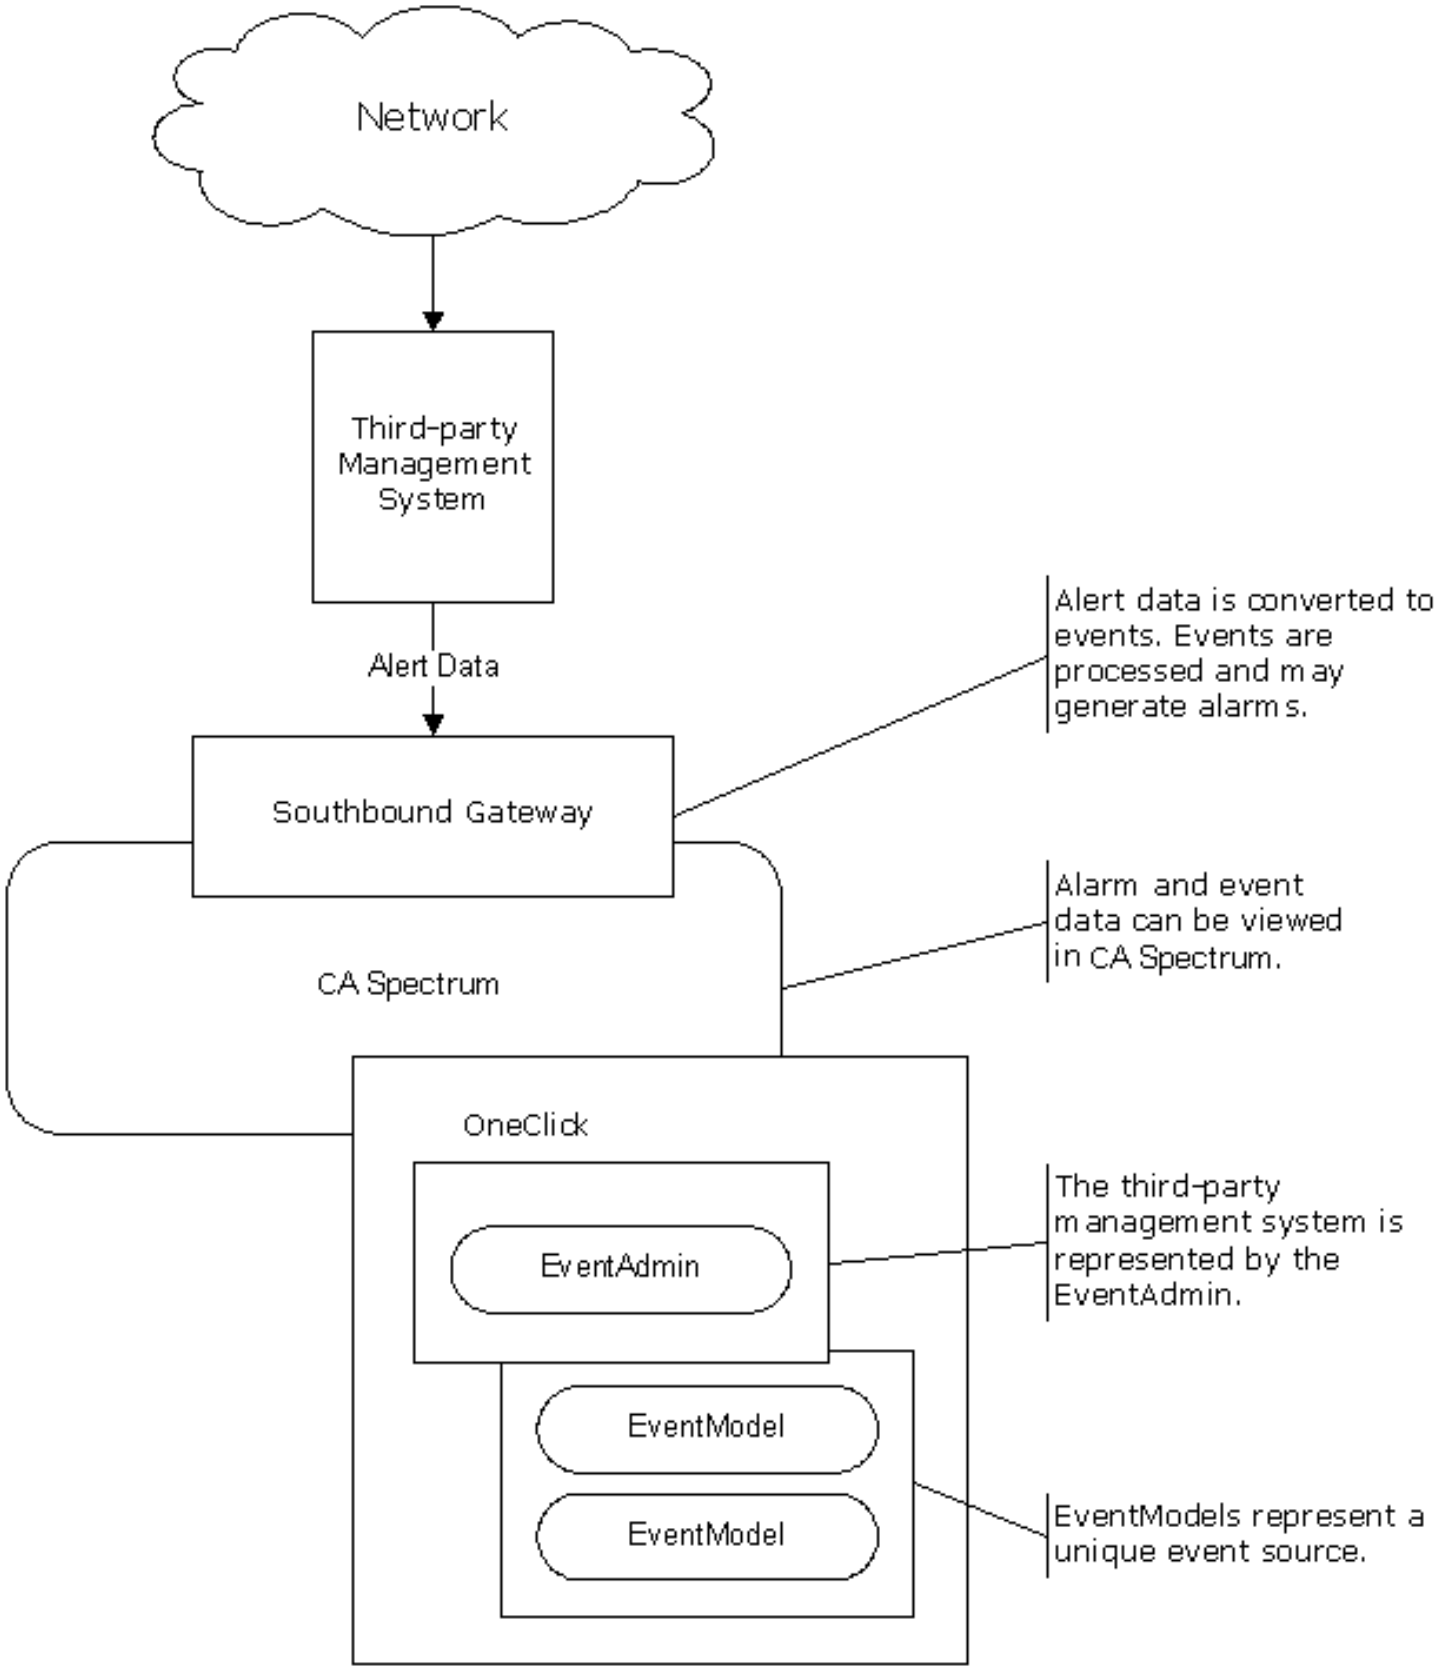
Southbound Gateway Toolkit

Centralize Network Management with Southbound Gateway

The Southbound Gateway integration point accepts alert data from third-party sources. Often these sources are other network management applications that specialize in monitoring a specific aspect of a computing environment. Using Southbound Gateway, you can centralize network management, letting DX NetOps Spectrum capture and display data from other systems. Alert data is organized into DX NetOps Spectrum event and alarm data for display in OneClick.

Southbound Gateway can be used with any incoming alert data stream format. It provides a simple, non-programmatic integration point for systems that generate SNMP traps. It is also very useful for managing non-SNMP environments. The Southbound Gateway import tool accepts XML-formatted alert data for integration with systems that cannot generate SNMP traps. A Document Type Definition (DTD) is provided to specify the XML elements used in this file. Model types that represent the external management system and its components are built into DX NetOps Spectrum, eliminating the need to generate or derive new model types. The EventAdmin model type represents a third-party system that sends alerts to DX NetOps Spectrum. The EventAdmin can contain one or more EventModels. These EventModels represent a unique event source within the network management system. To deploy the Southbound Gateway toolkit, you configure alert, event, and alarm support for these model types. When the integration is complete, you can monitor events and alarms from this third-party system using OneClick.

The following diagram illustrates the components of a Southbound Gateway integration and shows how these components work together to process third-party alert data.



Network
Third-party Management System
Alert Data
Southbound Gateway
CA Spectrum
OneClick
EventAdmin
EventModel
EventModel
Alert data is converted to events. Events are processed and may generate alarms.
Alarm and event data can be viewed in CA Spectrum.
The third-party management system is represented by the EventAdmin.
EventModels represent a unique event source.

Prerequisites for Developers

Before you use Southbound Gateway, verify that you have met the following requirements:

- Significant exposure to DX NetOps Spectrum
- Familiarity with the Getting Started section and with the underlying concepts of DX NetOps Spectrum
- A basic knowledge of MIBs and SNMP
- Detailed knowledge of the system you are integrating
- (For non-SNMP integrations) Working knowledge of XML, C++, or Java
- Ability to use UNIX or Windows operating systems to navigate the file system, copy and delete files, and create and edit text files

Southbound Gateway Architecture

Southbound Gateway Model Types

An EventAdmin model type represents a third-party system sending alerts to DX NetOps Spectrum. Each instantiated EventAdmin model represents an individual instance of a running external management application. Specific events from the third-party system are sent to the EventAdmin model. The EventAdmin model receives these events and transfers the event data to EventModels or device models depending on how the integration has been configured. Alarms can be created from this event data.

The EventModel is a model type that represents a unique source of event data on the system managed by the EventAdmin model application. A given EventAdmin model can contain one or many instantiated EventModels. Each event received through the Southbound Gateway contains information that uniquely identifies the source of that event. The EventAdmin model receives the event, finds the unique event source, and passes the event to the target model that represents the unique source. If the integration has been configured to use a unique identifier to map events exclusively to EventModels and no EventModel exists for the source, an EventModel model is automatically created to represent it. All new EventModel models are placed in the corresponding EventAdmin container model. You can cut or copy EventModel models from an EventAdmin container model and paste them into other types of container models in the Topology, Location, or Organizational view. You can cut or copy the EventAdmin model and paste it into the Topology, Location, or Organizational view. You can also place EventModels into maintenance mode as required.

Southbound Gateway Model Type Support Files

Support files supply information to the EventAdmin and EventModel models. Work with the following support files to create a Southbound Gateway integration:

- **AlertMap file:** If the alert source sends SNMP traps, create a text file to add data to the EventAdmin AlertMap file. DX NetOps Spectrum can then receive and parse the SNMP traps and convert them to DX NetOps Spectrum events.
- **XML file:** If the alert source does not send SNMP traps, create an XML file to send events to DX NetOps Spectrum. The syntax of the XML file must follow the Document Type Definition (DTD) provided with this toolkit. You can find a sample XML file named sbgw_event_sample.xml in the SS-Tools/GSADEMO directory. The Southbound Gateway import tool imports the data from the XML file into DX NetOps Spectrum.
- **EventDisp file:** Create these text files to add data to the EventDisp files that the EventAdmin and EventModel use. These additions define how the events are processed.
- **Event Format file:** Create Event Format files to provide additional, optional, or textual information and formatting for each event.
- **Probable Cause file:** Create Probable Cause files to give textual information about each alarm you create.

These support files organize the data into an event, process the event, and display event information. If the alert is SNMP-based, it is sent to the AlertMap file. If the data is non-SNMP based, it can be formatted into an XML file and processed by the Southbound Gateway import tool.

In both cases, the data is mapped from the alert to the DX NetOps Spectrum event. Variable data from the event is formatted, and a unique event source identifier is defined using the Southbound Gateway Event Data Template. The event is then passed to the EventAdmin model. The EventAdmin model checks its EventDisp file to verify that it is registered to receive this event. If the event is present in the EventDisp file, the EventAdmin examines the event to find the unique ID. The variable information sent with the event is mapped to determine a unique event source. Based on this unique identifier, the EventAdmin forwards the event to the appropriate EventModel. If this model does not yet exist, it is automatically created.

When the EventModel receives the event, it uses its EventDisp file to determine what to do with the event. The event can be logged, mapped to an alarm, used to clear an alarm, or used with other events to create an alarm. The EventModel uses the Event Format and Probable Cause files to display information about the event or alarm in the various Event and Alarm views or applications.

Host Model Types

DX NetOps Spectrum has several host model types that have the same functionality as the EventAdmin model type. These include Host_Compaq, Host_Dell, Host_IBMDirector, Host_Sun, and Host_systemEDGE. You can use any one of these host model types instead of the EventAdmin model type to represent the third-party system.

If you use one of these model types, all the integration instructions in this section are still applicable. However, modify the AlertMap and EventDisp support files for the model type that you have selected. These files are located in the following directory:

```
<$SPECROOT>/SS/CsVendor/Ctron_Gen_HOST/<model_type>
```

- ***<model_type>***
  Indicates the host model type that you have selected.

Once you have configured the integration, use the setup instructions in the topic titled Use a Host Model Type Instead of the EventAdmin Model Type.

> **NOTE**
> If you use a host model type instead of the EventAdmin model type, you cannot distribute the integration.

The Flow of Data through the Southbound Gateway

The following diagram illustrates how data flows from the third-party system into DX NetOps Spectrum through the Southbound Gateway:

Third-party Application

Southbound Gateway Integration

How to Create a Southbound Gateway Integration

Your primary job as the Southbound Gateway integrator is to create data for the support files that provide information to the EventAdmin and EventModel models representing the third-party system.

Integration steps include:

1. Configuring the third-party system to send alert data to DX NetOps Spectrum.
2. Mapping SNMP trap data to a DX NetOps Spectrum event if the third-party system can send SNMP traps.
3. Mapping non-SNMP alert data to a DX NetOps Spectrum event if the third-party system sends alerts that are not SNMP-based.
4. Controlling events and alarm creation by creating data for EventDisp files.
5. Defining the presentation format of events with Event Format files. These files provide event information to DX NetOps Spectrum applications.
6. Adding value to alarms by creating Probable Cause files. These files provide alarm information to DX NetOps Spectrum applications.

Configuring the Third-Party System

The methodology to configure a third-party system to send alert data to the Southbound Gateway depends on the functionality of the individual system.

If the third-party system can send SNMP traps to DX NetOps Spectrum, configure it to send them. The application must send the trap data to the hostname and port where the SpectroSERVER is running and listening. By default, DX NetOps Spectrum listens at the standard SNMP trap port 162. You can modify this default by changing the snmp_trap_port parameter in the DX NetOps Spectrum .vnmrc file located in the SS directory. Once Southbound Gateway receives the alert data, this data must be mapped to a DX NetOps Spectrum event in an AlertMap file.

If the third-party system is sending non-SNMP alerts, format the alert data using XML. Import the data into DX NetOps Spectrum using the sbgwimport tool.

In both cases, Southbound Gateway selects the appropriate EventAdmin model to receive alert data. The IP address of the host computer that sends the data determines the target model. The IP address of the host computer should match the IP address that was used to create the EventAdmin model.

About Integrating Alert Data from a Third-Party System in a Secure Domain

Consider the following before you integrate alert data from a third-party system in a secure domain:

- Set the SecureDomainAddress attribute (0x12d83) of the EventAdmin model to the IP address of the SSDC for the domain that includes the third-party system.
- When an EventModel is created, its secure domain context is set to the secure domain context of the EventAdmin that created it.
- EventAdmin forwards events only to EventModels or device models that have the same secure domain context.
- By default, Southbound Gateway models only forward events to target models when the Southbound Gateway model and the target model have the same secure domain address. Or they forward events if the Southbound Gateway model and the target model are both directly managed (the secure domain address is 0.0.0.0). Set the SBGW_Ignore_Secure_Domain_Address attribute (0x3dc001d) of the Southbound Gateway model to TRUE to forward events to all matching models, regardless of their secure domain addresses.

If you want to forward events to remote models, we recommend using a *single* Southbound Gateway model to forward events to each remote target model. If multiple Southbound Gateway models forward events,

all of the Southbound Gateway models must have the same secure domain IP address. In addition, the SBGW_Ignore_Secure_Domain_Address attribute (0x3dc001d) must be set to the same value. DX NetOps Spectrum does not store all the information about a remote model locally, nor does it search for updated information about that remote model when a new Southbound Gateway model forwards events.

Remote target models are found using the settings on the Southbound Gateway model. Each Southbound Gateway model finds a remote target model from a cache of models, by name or targets IP address. It can find a remote target even if the secure domain address does not match the address of the Southbound Gateway model.

About Host Agents and Southbound Gateway

Southbound Gateway can forward syslog messages that are received as traps from the log monitoring agents. Agents such as CA Unicenter NSM Agent, CA SystemEDGE Agent, or iAgent are supported. The messages are forwarded to the originating device if it can be determined. The forwarding algorithm inspects the trap message for an IP address or hostname to determine the actual source. If a hostname is found, DX NetOps Spectrum attempts to resolve the hostname to an IP address and locate the associated model.

For performance reasons, the Southbound Gateway caches resolved and unresolved hostnames for approximately six hours. Therefore, if you want to use newly created name service entries whose name was cached as an unsuccessful lookup in the Southbound Gateway you must either restart DX NetOps Spectrum or wait for six hours.

Southbound Gateway log matching algorithm is a set of waterfall heuristics that make a best-effort attempt to recognize and parse the inbound trap. While DX NetOps Spectrum supports over 10,000 known Cisco messages, you can set up your own.

Southbound Gateway has debugging capabilities to assist you in resolving ParseMap and translation errors. You can enable this debugging by sending the action 0x3dc0001 to the Agent model. Output appears in the DX NetOps Spectrum Control Panel and is written to the VNM.OUT file.

NOTE

For more information about working with log monitoring agents in DX NetOps Spectrum, see the Host System Resources Management section.

Map SNMP Trap Data to a DX NetOps Spectrum Event

If a third-party system is configured to send SNMP traps to DX NetOps Spectrum, map these traps to DX NetOps Spectrum events in an AlertMap file. To map traps, create data to be added to an existing AlertMap file. This data specifies the trap, the event it is mapped to, and the variable-bindings from the trap. Understand the components of an SNMP trap to map the SNMP trap data in an AlertMap file.

NOTE
DX NetOps Spectrum supports the reception and processing of SNMPv2 format traps and InformRequests as defined by RFC 2576. For more information about how to refer to SNMPv2 traps in the AlertMap file, see the Event Configuration User *section.*

For DX NetOps Spectrum to use trap information from a third-party system, associate the trap with a specific DX NetOps Spectrum event in an AlertMap file. The AlertMap file has three main functions:

- Indicates the SNMP traps that are received from the third-party system.
- Indicates the event code to be generated for a given trap.
- Maps the trap variable bindings to DX NetOps Spectrum event variable IDs.

The AlertMap file that is provided for Southbound Gateway is located in the following directory:

```
$SPECROOT/SS/CsVendor/gen_app_gw/EventAdmin
```

Do not modify the existing AlertMap file directly. The AlertMap file that is located in the specified directory can contain mapping information for pre-existing integrations. Create a text file that contains the alert map data to be added to this AlertMap file. When you distribute the Southbound Gateway integration, include the Southbound Gateway installation script that is provided with the toolkit. This script recreates the AlertMap file, which is based on the text files that are supplied by all Southbound Gateway integrations. For more information, see the Event Configuration User *section.*

Use the following convention to rename the test file that you created for AlertMap data:

```
indexfilename.amp
```

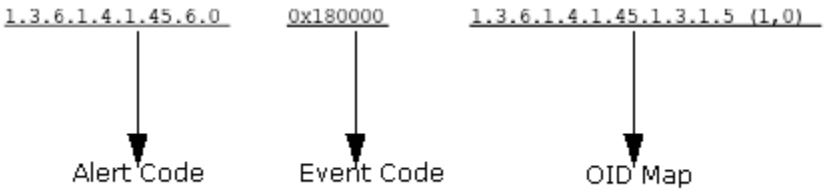
- **indexfilename**
  Specifies the name of the index file that you create when using the DX NetOps Spectrum Extension Integration toolkit to distribute this Southbound Gateway integration.

AlertMap File Syntax

Each trap mapped to a DX NetOps Spectrum event must have an entry in the AlertMap file. Each entry in the AlertMap file has three components:

- The alert code
- The event code
- The OID map

Example AlertMap file entry:



Alert Code

The alert code consists of several pieces of information from the trap: the Enterprise OID string, the generic trap identifier, and the specific trap code.

- **1.3.6.1.4.1.45:** Enterprise OID indicating, in this case, a Synoptics device.
- **6:** The Generic Trap Identifier, in this case the 6 indicates an enterprise-specific trap.
- **0:** Specific Trap Code indicating the specific enterprise trap.

Event Code

> **NOTE**
> To complete this process, a CA Developer ID is required. For further information about obtaining a Developer ID, see the Concepts *section.*

The event code is a hexadecimal number composed of the Developer ID and a number that uniquely identifies this particular event. The Developer ID makes up the first half of the event code. The second half of the event code is a unique number. Generate and manage this unique number to ensure that an event code for your Developer ID is never repeated.

If the event code is 0, this alert is ignored.

The OID Map

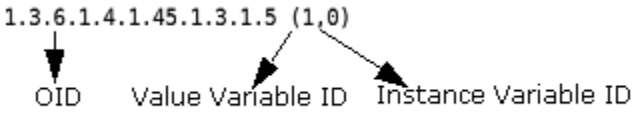
A trap can include one or more pieces of variable information, known as variable bindings. Each variable binding represents a piece of information about the trap. You can map these bindings to enable DX NetOps Spectrum to use this information.

The variable-bindings and their mappings in DX NetOps Spectrum are specified in the OID map section of the alert map entry. A single alert map entry can have multiple associated OID maps, which indicates that multiple variable bindings were sent with the SNMP trap. Separate these OID maps using the '\' character and a new line as shown in the following example:

```
1.3.6.1.4.1.52.6.271 0x1060f 1.3.6.1.4.1.52.1.2.1.9.2.1.2(3,4)\
                             1.3.6.1.4.1.52.1.2.1.1.24(5,6)\
                             1.3.6.1.4.1.52.1.2.2.3.1.1(1,2)
```

The OID map can be broken down into three parts:

- The OID
- The value variable ID
- The instance variable ID



The OID identifies the specific variable that is sent with the trap. For example, the previous OID references the s3ChassisPsStatus variable in the Synoptics Trap MIB.

The value variable ID stores the value of the variable sent in the variable binding. The instance variable ID stores the instance portion of the OID. If your variable binding identifies a particular object from a table variable within the trap MIB, it likely includes an instance ID.

Determine the integer values for the value variable ID and the instance variable ID by referring to the Southbound Gateway Event Data Template. The values that you select depend on the content from the variable binding. The following section outlines the Event Data Template and how to select the appropriate number, depending on the content of the variable binding.

Map Non-SNMP Alert Data to a DX NetOps Spectrum Event

Two approaches are available to map non-SNMP alert data to a DX NetOps Spectrum event. The first method is to use XML to create DX NetOps Spectrum events. We recommend this method, which is efficient and easy to implement.

You can also programmatically send events to DX NetOps Spectrum. This method requires a more in-depth understanding of the DX NetOps Spectrum application programming interfaces.

Use XML to Create DX NetOps Spectrum Events

Southbound Gateway provides the sbgwimport tool to create DX NetOps Spectrum events based on data from an XML file. You mark up the data in the alert using the XML elements provided in the Southbound Gateway DTD file, .sbgwimport.dtd. Once you have created the XML file, run the sbgwimport tool. The tool creates events from the data in the XML file and sends them to the EventAdmin model that represents the third-party system. Southbound Gateway identifies the EventAdmin model that represents the third-party system based on the IP address of the host running the sbgwimport tool. If an EventAdmin model to represent the third-party system does not yet exist, a new EventAdmin model is automatically created.

NOTE
Working knowledge of XML and how a DTD functions is required to use this tool.

Create an XML File to Format the Alert Data

Southbound Gateway provides the .sbgwimport.dtd file located in the SS-Tools directory. The DTD defines the elements that can be used to create the XML input file. Two elements are defined in the DTD: the Import element and the Event element.

The Import element is the root element. XML syntax rules specify that the root element is the outermost element and denotes the beginning and end of the XML file. Therefore, the Import element surrounds the rest of the XML elements in the input file. It has one child element, the Event element. Any number of Event elements can exist within the Import element.

Attributes

The Event element is used to format alert data using a series of attributes. These attributes define the event that is sent to DX NetOps Spectrum. All of these attributes correspond to specific fields in the Event Data Template, except for the eventType and eventAdminName attributes. The attributes that correspond to the Event Data Template takes on the event variable ID specified in the Event Data Template. The event variable ID can then be used in an Event Format file. The following list defines all the available attributes.

- **eventType**
  Event Data Template Variable ID: N/A
  Required attribute. The value for this attribute should be the hexadecimal event code assigned to the event. The event code is a hexadecimal number composed of the Developer ID and a number uniquely identifying this particular event. Your Developer ID makes up the first half of the event code. The second half of the event code is simply a unique number. Generate and manage this unique number to help ensure that an event code for your Developer ID is never repeated.
- **uniqueId1- uniqueId6**
  Event Data Template Variable ID: 1-6
- **targetName**
  Event Data Template Variable ID: 7

  NOTE
  You can use the attribute targetNameIgnoreCase if you do not want DX NetOps Spectrum to consider the case when matching the attribute's value to the model name.
- **targetAddress**
  Event Data Template Variable ID: 8
- **eventModelName**
  Event Data Template Variable ID: 10
- **eventAdminName**
  Event Data Template Variable ID: N/A
  Only used if an EventAdmin model representing the system sending the events does not yet exist. If this EventAdmin model does not exist, DX NetOps Spectrum creates an EventAdmin model and uses the value of this attribute as the model name.
  If this value is not specified when a new EventAdmin model is created, *EventAdmin_<HostName>* is used as the model name, where *<HostName>* is the name of the host computer running the sbgwimport tool.
  If an EventAdmin model exists, DX NetOps Spectrum ignores the value for the eventAdminName attribute. After you run the sbgwimport tool, a message indicates that the value for the eventAdminName attribute was not used because an EventAdmin model exists for this system.
- **networkAddress**
  Event Data Template Variable ID: 13
- **macAddress**
  Event Data Template Variable ID: 14
- **Manufacturer**
  Event Data Template Variable ID: 15

This attribute can be set with the manufacturer of the alert source. If defined, the value of this attribute can be referenced in the Event Format file.

- **targetNameIgnoreCase**
  Event Data Template Variable ID: 16
- **userDefined_101- userDefined_120**
  Event Data Template Variable ID: 101-120
  These attributes can be used to define user-specific data. If defined, each of these values can be referenced in the Event Format file. More user-defined attributes can be added to the DTD if they are necessary for the integration. They must use an integer value > 120.

Sample Alert Data XML File

The following is a sample XML file that creates three events:

```
<?xml version="1.0" standalone="no"?>
<!DOCTYPE Import SYSTEM ".sbgwimport.dtd">
<Import>
   <Event eventType = "0x3c80000" uniqueId1 = "xyzLocation"
    uniqueId2 = "abcPortNumber" eventAdminName = "MyTestAdmin"
    modelClass = "Router"
    userDefined_101 = "Test Application Name" />
   <Event eventType = "0x3c80004" uniqueId1 = "xyzLocation"
    uniqueId2 = "defPortNumber"
    eventAdminName = "MyTestAdmin" />
   <Event eventType = "0x3c80004" targetAddress = "10.253.29.1"
    eventAdminName = "MyTestAdmin" />
</Import>
```

The first event has an event code of 0x3c80000 defined by the eventType attribute. The attributes of uniqueId1 and uniqueId2 are used to identify the source of this event. These attributes are concatenated together to create xyzLocation_abcPortNumber as the unique identifier for the alert source. The EventAdmin model to receive the event is named MyTestAdmin. The device that sends the event is identified as a router using the modelClass attribute. The user_Defined_101 attribute is used to send data that is not described by one of the other fields.

The second event has an event code of 0x3c80004. The attributes ‘uniqueId1’ and ‘uniqueId2’ identify the source of this event. These attributes are concatenated to create ‘xyzLocation_defPortNumber_ClientID0x56FF’ as the unique alert source identifier. The EventAdmin model to receive the event is named ‘MyTestAdmin.’

The third event also has an event code of 0x3c80004. The attribute targetAddress directs the event to a pre-existing DX NetOps Spectrum device model with an IP address of 10.253.29.1. The EventAdmin model to receive the event is named ‘MyTestAdmin.’

Run the sbgwimport Tool

Once you have created the XML file, you are ready to run the sbgwimport tool.

> **NOTE**
> You can run the sbgwimport tool from the third-party host because Southbound Gateway identifies the EventAdmin model that represents the third-party system based on the IP address of the host computer that runs the import tool. To run the import tool from the third-party host, move the tool and all of its support files to that host. For instructions, see the Distributed SpectroSERVER Administrator section.

To run the import tool, use the following syntax:

```
sbgwimport  - vnm v_name inputfile
```

- **v_name**

Specifies the name of the DX NetOps Spectrum server.

- **inputfile**
  Specifies the name of the XML file.

  NOTE
  Under some circumstances, such as on Linux, the sbgwimport tool returns the localhost address (127.0.0.1) instead of the actual IP address. In this event, specify the IP address that the import tool uses to identify the desired EventAdmin model.

To run the sbgwimport tool using a specific IP address, use the following syntax:

```
sbgwimport -vnm v_name input_file -localIP IP address
```

- **IP address**
  Specifies the IP address.

Using CORBA to Create Events

You can use the CORBA API to create and send events into DX NetOps Spectrum. Use a very small portion of the functionality of this API to connect to the appropriate EventAdmin model, format the event data from the third-party system, and then send this data in an event to the EventAdmin model. The sample code to send events to an EventAdmin model is available in the SS-Tools/GSADEMO directory. Open the file named SBGWImport.java.

You can use the command-line interface (CLI) to generate these events; however, for performance reasons, we recommend that you use the CORBA API. This toolkit only provides examples using the SSORB interface.

The Event Data Template

The Southbound Gateway Event Data Template defines alert variable data. This template is used with both SNMP and non-SNMP integrations. For SNMP integrations, the Event Data Template variable IDs are used in the AlertMap file to select the appropriate number for the value variable and instance variable IDs.

Selecting the correct Event Data Template variable ID values is important because they enable essential functions of the Southbound Gateway integration. The values that you select determine how a target model for the incoming event is identified. You can control whether a new EventModel is created to handle an incoming event. You can also select variable ID values, which specify whether to use a network address or model name as the event target search criterion. You can then map events to any type of model, including devices or ports. Other values let the variable data serve as attribute values for the EventModel where the event is sent. All variables can be referenced in the Event Format files. A zero value for either the value variable or instance variable IDs indicates that the value is not stored.

The Event Data Template shows the name, type, and description of each variable ID that the Southbound Gateway mechanism supports. When selecting values for the value variable ID for an integration, choose appropriate variable IDs that describe the content of the value of the variable binding. Where applicable, the instance variable ID is stored as one of the unique identifier fields.

Specify one of the following variable ID values to identify a target model:

- One of the Unique ID variables (1-6)
- Target Name (7) or Target Name Case Insensitive (16)
- Target Address (8)

Event Data Template Fields

The following table describes the fields in the Event Data Template. Each event must contain the required vardata items to be processed by the Southbound Gateway.

NOTE
If the event received does not conform to the Event Data Template, an event with an ID 0x03dc0000 is generated against the EventAdmin model.

Variable ID	Name	Type	Description	Required/ Optional
1	Unique ID 1	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	
2	Unique ID 2	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	
3	Unique ID 3	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	
4	Unique ID 4	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	

5	Unique ID 5	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: `<1>_<2>_<3>_<4>_ <5>_<6>` in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	
6	Unique ID 6	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to six variable data items (one to six). The final unique identifier string is composed as follows: `<1>_<2>_<3>_<4>_ <5>_<6>` in that exact order. If one of the components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found one is created. Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.	NA
7	Target Name	String	This field lets you specify a target model by model name. An EventModel is not created if a target model is not found using a Target Name event variable. However, if event variable 7 (Target Name) or event variable 16 (Target Name Case Insensitive) is used with the 'unique id' event variable (1-6), the unique id field is used to identify the model.	
8	Target Address	Octet/Text String	This field lets you specify a target model by IP address. Use this field if you want to send the event to a model other than an EventModel.	
9	Reserved for future CA use			
10	EventModel Name	String/Integer	This field provides the ability to assign a model name that is different than the unique identifier. If this data is not provided, the composite unique identifier becomes the model name.	Optional
11	Model Class	Integer	Populates the Model Class attribute of the target EventModel with the value specified in this event variable.	Optional
12	Reserved for future CA use			
13	Network Address	Octet/Text String	Populates the Network Address attribute of the target EventModel with the value specified in this event variable.	Optional
14	MAC Address	Octet/Text String	Populates the MAC Address attribute of the target EventModel with the value specified in this event variable.	Optional
15	Manufacturer	String	Populates the Manufacturer attribute of the target EventModel with the value specified in this event variable.	Optional
16	Target Name Case Insensitive	String	This field lets you specify a target model by model name. An EventModel is not created if a target model is not found using a Target Name Case Insensitive event variable. However, if event variable 7 (Target Name) or event variable 16 (Target Name Case Insensitive) is used with the 'unique id' event variable (1-6), the unique id field is used to identify the model.	
17-99	Reserved for future CA use			

Any other variable ID greater than or equal to 100.	Any Data	Any Type	This data is forwarded to the EventModel model unchanged. The data type and data are preserved. This data can be viewed within an event message.	Optional

Variable ID Fields 1-6

The EventModel unique identifier is composed of the first six fields within the Event Data Template. Southbound Gateway integrations often require more than one piece of data to identify the source of an alert. The Event Data Template provides a way to create an EventModel unique identifier that is composed of the elements from up to six different fields. The EventModel unique identifier is composed as follows:

```
<1>_<2>_<3>_<4>_<5>_<6>
```

For example, a location and port number can be used to represent a router as the EventModel unique identifier. The router's location would be put in Event Data Template field 1 and the port number would be put in Event Data Template field 2. The EventModel unique identifier would then appear as follows: Location_PortNumber.

Variable ID Field 7 (Target Name)

This field lets you specify the model name of the model you would like the event data to be sent to. For example, if you specify the model name *MyRouter* in the Target Name field, Southbound Gateway searches the existing models to find a model with this model name. If this model is found, Southbound Gateway sends the event data to this model for processing.

> **WARNING**
> If no model is found, an EventModel is not created.

This field has the same functionality as Variable ID Field 16 (Target Name Case Insensitive), except that it is case sensitive. If this field had the value MyRouter, and DX NetOps Spectrum had two models, one named MyRouter and one named myrouter, MyRouter would receive the event and myrouter would not. If instead you used the Target Name defined in field 16, both models (MyRouter and myrouter) would receive the event. If for some reason you used both of these fields (7 and 16) and each had the value MyRouter, the model with the model name MyRouter would receive two events (sent as a result of field 7 and 16) and the model with the model name myrouter would receive one event (sent as a result of field 16).

If you specify both a unique ID (using a combination of fields 1 through 6) and a Target Name (using fields 7 or 16), Southbound Gateway sends the event to both the EventModel specified by the unique ID and the model specified by the Target Name.

If you specify a unique ID, a Target Name using fields 7 or 16, and a Target Address, and if the Target Name and Target Address are for different models, the Southbound Gateway sends the event to all three models.

If the Target Name is not found, the EventAdmin model generates an Event that indicates that DX NetOps Spectrum has no models with the name <Target Name>. If a unique ID has also been specified, the event is sent to an EventModel.

If you specify a Target Name using fields 7 or 16 and a Target Address and one or both is not found, the appropriate error message is generated, and the event is not sent to any model. If a unique ID has also been specified, the event is sent to an EventModel.

Variable ID Field 8 (Target Address)

This field lets you specify the IP address of the model you would like the event data to be sent to. Use this field if you want to send data to a model other than the EventModel. For example, if you specify the IP address 10.253.97.2 in the Target

Address field, Southbound Gateway searches the existing models to find a model with this IP address. If Southbound Gateway finds this model, it sends the event data to this model for processing.

If you specify both a unique ID, using a combination of fields 1 through 6, and a Target Address, Southbound Gateway sends the event to both the EventModel specified by the unique ID and the model specified by the Target Address.

If you specify a unique ID, a Target Name, and a Target Address, and the Target Name and Target Address are for different models, the Southbound Gateway sends the event to all three models.

If the Target Address is not found, the EventAdmin model generates an event that indicates that DX NetOps Spectrum has no models with the network address <Target Address>. If a unique ID has also been specified, the event is sent to an EventModel.

If you specify a Target Name and a Target Address and one or both is not found, the appropriate error message is generated, and the event is not sent to any model. If a unique ID has also been specified, the event is sent to an EventModel.

Variable ID Field 10 (EventModel Name)

This is an optional name that can be given to the EventModel model. If supplied, it appears beneath the EventModel icon in the OneClick topology views. If you define an EventModel prefix when creating the EventAdmin model, the EventModel name is concatenated onto the EventModel prefix, separated by an underscore. If you do not define the EventModel prefix and the EventModel name is defined, the EventModel name becomes the model name. If the EventModel Name is not provided within Field 10, the unique identifier is used as the EventModel model name.

Variable ID Field 11 (Model Class)

If provided, this variable indicates the value with which to populate the model class attribute on the EventModel. The model class defines the type of device the model represents. The entry in Field 11 should be an integer that identifies the model class. A list of model classes and their respective integer identifiers can be found in the Getting Started section.

Variable ID Field 13 (Network Address)

If provided, this variable indicates the value with which to populate the network address attribute on the EventModel.

Variable ID Field 14 (MAC Address)

If provided, this variable indicates the value with which to populate the MAC address attribute on the EventModel.

Variable ID Field 15 (Manufacturer)

If provided, this variable indicates the value with which to populate the manufacturer attribute on the EventModel.

Variable ID Field 16 (Target Name Case Insensitive)

This field lets you specify the model name of the model where the event data is sent. This field has the same functionality as Variable ID Field 7 (Target Name), except that this field is case-insensitive.

Other Variable IDs (Any Additional Data)

Any other integration-specific data can be placed in any DX NetOps Spectrum variable ID greater than or equal to 100. This data is not set as attributes on the EventModel model, but is viewable from within the Event Format file.

The following list shows additional data that can be captured for display in an event message:

- application name: 100
- server name: 101
- event status: 102
- ticket status: 103
- ticket type: 104
- comments: 105

Control Events and Alarm Creation

EventDisp files define how events are processed. When alert information has been converted to an event, DX NetOps Spectrum identifies the model that the event has occurred in and then locates the EventDisp file that is associated with that model's model type. DX NetOps Spectrum searches the file for the appropriate event code and carries out the action specified for that event code.

Because there are two different model types that play a part in handling events for Southbound Gateway, create data for two different EventDisp files. There is one EventDisp file for the EventAdmin model type that defines how the EventAdmin models process the event and there is another EventDisp file for the EventModel model type that defines how the EventModel models process the event.

The EventAdmin EventDisp file is located in the following DX NetOps Spectrum directory:

```
<$SPECROOT>/SS/CSVendor/gen_app_gw/EventAdmin
```

The EventModel EventDisp file is located in the following DX NetOps Spectrum directory:

```
<$SPECROOT>SS/CSVendor/gen_app_gw
```

Do not modify the existing EventDisp files directly. The EventDisp files currently located in these directories can contain information for pre-existing integrations. Instead, create text files containing the EventDisp data that should be added to each of the files. When you distribute the Southbound Gateway integration, you include the Southbound Gateway installation script provided with the toolkit, which recreates each of the EventDisp files based on the text files supplied by all installed Southbound Gateway integrations.

The text files that you create for your EventDisp data must each use the following naming convention. This gives you two files with the same name. We recommended that you manage these files by keeping them in separate directories while you are working with them.

```
<indexfilename>.evd
```

- ***<indexfilename>***
  Specifies the name of the index file that you create when using the DX NetOps Spectrum Extension Integration toolkit to distribute this Southbound Gateway integration.

EventAdmin EventDisp File

The purpose of the EventAdmin EventDisp file is to define what events are received from the external alert/trap source. To do this, the EventDisp file must list the event codes of the events that are received. These event codes are defined in the AlertMap file, or in the XML import file.

NOTE
This EventDisp file must list those events that are forwarded to other DX NetOps Spectrum models through the use of Target Name or Target Address, and events that are forwarded to EventModel models.

For example, an EventDisp file expecting to receive three events with the codes 0x03dc003, 0x03dc004, and 0x03dc005 would have the following content:

```
0x03dc003
0x03dc004
0x03dc005
```

You can define more options for the event within this EventDisp file but it is not recommended. The intention of this file is to indicate what events the EventAdmin model should process. Once the EventAdmin receives the event, it forwards the event to the proper EventModel. It is at the EventModel level where further definition of the event processing takes place.

NOTE
This file is not optional. If your integration sends an event code that is not referenced in the EventAdmin EventDisp file, DX NetOps Spectrum simply drops that event, which prevents it from being forwarded to the appropriate EventModel model.

EventModel EventDisp File

Although the EventDisp for the EventModel is not required, it is highly recommended. In the EventAdmin EventDisp file, all the events that the EventAdmin could receive are listed. At the EventModel level you define how these events are processed. In addition to receiving events, EventDisp files can define a number of event behaviors and characteristics including:

- If the event should be logged
- The severity of the event
- If the event should clear an alarm
- If the event should generate an alarm
- If the alarm generated can be cleared by a user
- The severity of any alarm to be generated
- The probable cause of any alarm to be generated
- The event or series of events that should generate another event

Using the EventCondition Event Rule, you can create an event disposition entry that allows events to be created conditionally based on the value of variable bindings from a trap or based on the value of DX NetOps Spectrum attributes. This can be useful if the third-party application sending traps to DX NetOps Spectrum through the Southbound Gateway sends only one trap OID. This trap may have different meanings based on the value of one or more variable bindings. Using the EventCondition rule, you can generate different events depending on the value of these variable bindings. See the Event Configuration for complete information about the EventConditon Event Rule.

In general, if you are forwarding events to a model other than an EventModel model, you define the instructions for event processing in the EventModel's EventDisp file. This EventDisp file processes events for all appropriate model types. However, if you are using the EventCondition Event Rule as outlined in the previous paragraph, you can create this entry in the model type EventDisp file for the model to which you are forwarding events. This forces the condition parsing work to be done by that model type rather than by the EventModel.

Event Configuration provides reference information about EventDisp files. See the syntax instructions in this section when creating your EventDisp syntax.

Presentation Format of Events

Event format files determine the contents of an event message when the event is displayed in OneClick. Each event has a separate event format file. Event messages appear in the Events tab and the Alarm Details tab in OneClick.

Each event that requires a corresponding event message must have an associated event format file. Keep in mind that most of the information a user receives about an event or alarm is through the message text that is affiliated with that alarm or event. The index file that you create for distribution unpacks the event format files into the correct location (SG-Support/CsEvFormat) on the user's SpectroSERVER.

Unlike the AlertMap and EventDisp files, the data in the text files is not added to other files. Therefore, it is important to use the naming convention outlined in this section to identify your Event Format files.

The event format file must be named as Eventxxxxxxxx where xxxxxxxx equals the event code given to the event in the AlertMap file and listed in the EventDisp file. The event code must be written in a hexadecimal format with a full eight digits, including leading zeros.

The event format file can contain plain text, but can also contain variables that reference specifics about the instance of the individual event. For information about possible variable references, see the Event Configuration section.

The following is an example of the event format file:

```
{d "%w- %d %m-, %Y - %T"} - ASX DS3 LOS DETECTED - This trap indicates that the specified DS3 port has
 detected incoming LOS (Loss of Signal) Alarm. - Model Name: {m};
PortName: {S 1},
PortBoard: {I 2},
PortModule: {I 3},
PortNumber: {I 4}.
(event [{e}])
```

In this example, {d "%w- %d %m-, %Y - %T"} places the date and time into the event message, m inserts the model name, and e inserts the event code. The other variables reference values from variable bindings and their corresponding data types, S for string and I for integer.

Use the variable IDs that you have used from the Event Data Template to construct any type of message; however, verify that the variables in the message are the correct data type.

Add Value to Alarms

Alarms that are generated as a result of the EventDisp file usually contain a probable cause as part of the alarm message. The text of this probable cause is defined in the Probable Cause file associated with the alarm. Create a separate Probable Cause file for each of the alarms that you generate. Each Probable Cause file contains a textual explanation of the cause of the alarm with optional advice about the likely cause and common troubleshooting steps. The index file that you create for installation unpacks the Probable Cause files into the correct location (SG-Support/CsPCause) on the user's SpectroSERVER. Unlike the AlertMap and EventDisp files, the data in the text files are not added to other files. Therefore, it is important to use the following naming convention to identify your Probable Cause files.

Each Probable Cause file must be named Probxxxxxxxx where xxxxxxxx is the event code that generated the alarm through the EventDisp file. Write the event code in hexadecimal format with a full eight digits, including leading zeros.

The Probable Cause file contains text only. The first line states the cause of the alarm in uppercase letters. Following the cause are three separate sections, each with a title in uppercase letters: SYMPTOMS, PROBABLE CAUSES, and RECOMMENDED ACTIONS. Under each of these titles, list the appropriate data.

If there are multiple symptoms, probable causes, or recommended actions, format the data under those categories as a numbered list.

The following is an example of a Probable Cause file showing the appropriate syntax:

```
ALL DEVICE CONNECTIONS ARE UNREACHABLE
SYMPTOMS:
The VNM is unable to contact this device because all of the devices that this one is connected to are
 unreachable.
PROBABLE CAUSES:
1) A router connected to this device has gone down.
2) A network cable has become unplugged.
RECOMMENDED ACTIONS:
1) Check the status of the devices that this one is connected to for problems.
2) Check for a loose or unplugged network cable.
```

Distributing a Southbound Gateway Integration

After creating the proper files to support your Southbound Gateway integration, the next step is to package the files for distribution to other DX NetOps Spectrum users.

To do this, you use some of the tools in the DX NetOps Spectrum Extension Integration toolkit. This toolkit provides the ability to create a package of files called a VCD (Virtual CD-ROM) that the DX NetOps Spectrum installer opens and expands. This package of files can include a number of different components; at a minimum, yours includes the Southbound Gateway installation script, an index file, a Part Description file, and the support files you have created.

The Installation Script

The Southbound Gateway installation script is a pre-built script included with the Southbound Gateway toolkit. It is named MergeVendorFiles.cus and is located in the SS-Tools/GSADEMO directory. This script is responsible for taking your EventDisp and AlertMap data contained in the text files you created in the integration process, and recreating the existing AlertMap and EventDisp files to include that data. Add the following line to all Southbound Gateway index files to verify that the installation script is included with your integration.

```
file: SS cus /<$SPECROOT>/SS-Tools/GSADEMO/MergeVendorFiles.cus ? ?
```

The Part Description File

The part description file is a text file that contains a brief synopsis of the integration being installed. The user can view the text in this file during the install process. Pay close attention to the directory structure outlined in the Sample Index File. For the integration to work properly, the support files must be correctly placed on the computer.

Create an Index File

The index file maps all the files included in the VCD indicates the files needed for installation, where these files are located on your computer, and where the files should be unpacked on the customer's computer. For a description of the possible syntax for an index file, see the Extension Integration (SEI) Developer Reference section. The syntax outlined in Sample Index File describes a typical Southbound Gateway integration installation. In your index file, include references to the following files:

- Southbound Gateway Installation Script
- AlertMap file (if applicable)
- Part Description file
- EventDisp files
- Event Format files
- Probable Cause files

Create your index file using your preferred text editor and then save the index file in the SG-Tools directory. The naming convention for the index file is as follows:

```
3P-<ABCxxxx>.i
```

- **3P**
  Specifies a third-party integration.
- ***<ABC>***
  Specifies the first three letters of your developer name.
- ***<xxxx>***
  Specifies any four-digit integer that uniquely identifies this index file from any other index file you have created.

Sample Index File

The following sample index file shows the components of an integration that includes the Southbound Gateway installation script, a Part Description file, an Event Format file, a Probable Cause file, two EventDisp files, and an AlertMap file. At install time, all files are unpacked into their proper directory and the installer program runs the Southbound Gateway installation script.

```
level: 1
mm:     CA Spectrum Southbound Gateway Integration Demonstration
irev:   06.50.00.000
rev: 6.5
pprep:  Sample
vend:   gen_app_gw
file: SS cus /SpectrumRootDirectoryName/SS-Tools/GSADEMO/MergeVendorFiles.cus ? ?

file:   SG other ? ../../SG-Support/CsEvFormat/Event03e50000 ? ?
file:   SG other ? ../../SG-Support/CsPCause/Prob03e50000 ? ?
file:         SS vfile ? ../SS/CsVendor/gen_app_gw/components/3P-ABC0001.evd SS/CsVendor/gen_app_gw/components
 3P-ABC0001.evd
file:         SS vfile ? ../SS/CsVendor/gen_app_gw/EventAdmin/components/3P- ABC0001.evd SS/CsVendor/
gen_app_gw/EventAdmin/components 3P-ABC0001.evd
file:   SS vfile ? ../../SS/CsVendor/gen_app_gw/EventAdmin/AM_components/3P-ABC0001.amp ? 3P-ABC0001.amp
```

The index file can be divided into the following two portions:

- The first portion is the extension module description entries. These entries include specific information about the integration, such as name and release level. For more information, see the Extension Integration (SEI) Developer Reference section.
- The second portion of the index file contains the file distribution entries. These entries specify the files that can be included with the installation. The first line in this section has the following syntax:

  ```
  file: SS cus /SpectrumRootDirectoryName/SS-Tools/GSADEMO/MergeVendorFiles.cus ? ?
  ```

Include this line in all the index files that are created to distribute a Southbound Gateway integration. This line is responsible for activating the Southbound Gateway installation script. The rest of the index file references the Event Format file, the Probable Cause file, the two EventDisp files, and the AlertMap file for this particular installation. For more information, see Extension Integration (SEI) Developer Reference section.

mkmm and mkcd

To complete the package, run the mkmm and the mkcd tool. See the Extension Integration (SEI) Developer Reference section for more information.

Using a Southbound Gateway Integration

DX NetOps Spectrum provides different model types that represent components of a third-party system, the EventAdmin, and the EventModel. These model types work together to manage alert information sent to DX NetOps Spectrum. A unique EventAdmin exists for each instance of a third-party system managed by DX NetOps Spectrum. The EventAdmin is a container model type and includes models of the type EventModel. EventModels represent unique sources of event information that a third-party system manages. The EventAdmin receives an event from the third-party system and dispatches it to an EventModel.

When you represent this system within DX NetOps Spectrum, you are representing the management application, not the host computer that the application is running on. To manage this host computer, create a separate model of the appropriate model type.

For both SNMP and non-SNMP integrations, the EventAdmin's network address is stored in the attribute named trapIPAddress, instead of in the usual NetworkAddress attribute. This prevents the EventAdmin from interfering with another DX NetOps Spectrum model that is managing the device containing that network address, that is, the model that is managing the host computer.

Create an EventAdmin Model

Before attempting to represent your third-party system within DX NetOps Spectrum, verify that the management application is running. Once the application is running properly, the first step is to model the application in DX NetOps Spectrum using the EventAdmin model type. In most situations, you add the EventAdmin icon into the same topology view as the VNM icon.

You can define several attributes when you create this model. Most of these attributes carry over to become attributes of EventModel models created for this EventAdmin. There are several applications within DX NetOps Spectrum that display the EventModel models' attributes, events, and alarms. To make this information as useful as possible, it is a good idea to provide as much information as you can about those EventAdmin and EventModel models.

To create the EventAdmin model

1. From the Topology tab that you want to create the model in, click the Create new model by type button.
   The Select Model Type dialog appears.
2. In the Containers tab, click EventAdmin.
3. Click OK.
   The Create Model of Type EventAdmin dialog appears.
4. Configure the following parameters:
   - **Name**
     Optional. Defines the EventAdmin's model name. This model name appears in the field at the top of the EventAdmin icon.
   - **Network Address**
     Required for all integrations that are based on SNMP traps. Specifies the network address of the event source's host computer. If you are unsure if your third-party application sends SNMP traps, consult with the documentation for that product.
   - **Security String**
     (Optional) Defines who can view and edit this model.
   - **Manager Name**
     When this attribute is set on the EventAdmin, all EventModels contained within this EventAdmin also have this attribute. If the name of the third-party application does not appear on this list, select Default from the drop-down list.
   - **EventModel Prefix**

This field is prepended to the EventModel Name for all the EventModels contained by this EventAdmin. This helps ensure that there are consistent naming prefixes for all EventModels associated with a particular EventAdmin. It is also useful for sorting and filtering.

5. After you enter the appropriate information into these fields, click OK.
   This generates an EventAdmin model. A default EventModel is also created and is contained in the EventAdmin model. This model is used for fault tolerance functionality.

   NOTE
   You can configure the EventAdmin model to forward events to models on remote landscapes by setting the SBG_AlertForwardingEnabled (0x3dc000c) attribute for the EventAdmin model to TRUE.

EventAdmin Model Status

Once you have instantiated an EventAdmin model, its status becomes green (Normal) even if there are not yet any EventModel models associated with it. This status changes to reflect alarms asserted on the EventAdmin model.

NOTE
DX NetOps Spectrum does not monitor the status of the application that the EventAdmin represents, so the status of the model does not represent the state of the third-party application, nor does it represent the state of the third-party application's host computer.

Move an EventAdmin Model

An EventAdmin model can be cut or copied and then pasted into other topologies as needed.

The following is a list of containers that an EventAdmin can be placed in:

- Universe:
  - Broadband_Net
  - LAN
  - Network
  - Universe
  - WAN
  - GnChasCont
  - LAN_802_3
  - LAN_802_5
  - FDDI
- World:
  - Panel
  - Rack
  - Room
  - Site
- TopOrg:
  - Org_Owns
  - Service_Owns

You move an EventAdmin model in the same way you would move any other model. However, it is not possible for an EventAdmin model to contain another container model. The EventAdmin model can only contain EventModel models.

To move an EventAdmin model

1. Open the topology view that contains the EventAdmin model that you want to move.
2. Right-click the model that you would like to move and select Copy or Cut.

3. Go to topology view where you want to place the EventAdmin model, right-click and select Paste.
   You have now successfully moved the model.

   NOTE
   The EventAdmin model represents the third-party management system and is required for proper operation of the Southbound Gateway integration. If you delete the EventAdmin model to remove support for the third-party system, delete all EventModel models that are associated with the EventAdmin.

View EventAdmin Model Information

You can review details about the EventAdmin model from the tabs in the Contents panel and the Component Detail panel.

You can use the Information tab to review and edit the model name, network address, manager name, and the EventModel prefix of the EventAdmin model.

From the Topology tab, you can navigate to all the EventModels contained by the EventAdmin.The EventAdmin model manages the third-party application and the alerts it sends to DX NetOps Spectrum, the EventAdmin does not manage the host computer that is running the third-party application.

Use a Host Model Type Instead of the EventAdmin Model Type

You can use a DX NetOps Spectrum host model type instead of the EventAdmin model type to represent the third-party system. After making the necessary support file modifications outlined in the previous chapters, you can configure the host model.

To configure the host model

1. Click the create a new model button in the view you want to add the host model to.
   The Select Model Type dialog appears.
2. Choose the appropriate host model type:
   - Host_Dell
   - Host_Compaq
   - Host_IBMDirector
   - Host_Sun
   - Host_systemEDGE

   and click OK.
   The Create Model of Type dialog appears.
3. Fill in the fields appropriately, using the IP address of the third-party server for the Network Address field and then click OK.
   DX NetOps Spectrum creates the model.
4. For EventModels to be created, set the Enable_SouthboundGateway (0x116296e) attribute on the host model to TRUE. Do this using the Attribute Editor.

   NOTE
   For more information about using the Attribute Editor, see the Modeling and Managing Your IT Infrastructure section.
5. Specify where the EventModels created by the host model are to be placed when they are created. They can be placed in any container model available in the Topology view with the exception of any SW_Link, WA_Link, and VNM container models. To specify the appropriate container model, set the host model's EventModelContainerHandle attribute (0x3dc000a) equal to the model handle of the container where you would like the EventModels to be created. Do this using the OneClick Attribute Editor.
   If you would like the EventModels to be placed directly in the Universe view, use the model handle of the Universe view. You can retrieve the model handle of the Universe view by using the Attributes tab in the OneClick Component Detail panel tab to read the model_handle attribute on the Universe model.

The host model is now configured to receive and process traps.

Create an EventModel Model

The EventAdmin that manages the EventModels is created automatically. When an alert is sent from the third-party application into DX NetOps Spectrum, the alert is converted into an event. Each event has a unique ID string. This unique ID string is set up during the integration development process to determine a unique source of alert information within the third-party system. The EventAdmin examines this unique ID and looks for an EventModel with a matching unique ID. If this EventModel exists, the event is sent to that EventModel. If an EventModel with this unique ID string does not exist, the EventModel is automatically created.

NOTE
A default EventModel model is created when the EventAdmin model is created. This is for use in a fault-tolerant environment. EventModel models can also be created using the Modeling Gateway. For more information, see the Modeling Gateway Toolkit section.

EventModel Models

EventModels for a particular EventAdmin are automatically placed in a topology view that can be accessed by drilling down from the EventAdmin. These icons do not show any connectivity with one another because they represent an event source, not necessarily a physical device, or component.

About Moving an EventModel Model

EventModel models can be cut or copied from the EventAdmin container model and pasted into various types of container models within the Topology, Location, or Organizational views.

The following is a list of containers that an EventModel can be placed in:

- Topology view:
  - Broadband_Net
  - LAN
  - Network
  - Universe
  - WAN
  - GnChasCont
  - LAN_802_3
  - LAN_802_5
  - FDDI
- Location view:
  - Panel
  - Rack
  - Room
  - Site
- Organization view:
  - Org_Owns
  - Service_Owns

You move an EventModel model in the same way you would move any other model.

An EventAdmin model cannot contain another container model. The EventAdmin model can only contain EventModel models.

Even if you have moved all the EventModel models out of the EventAdmin model, it is important that you do not delete the EventAdmin model. This model represents the third-party management system and is required for proper operation of the Southbound Gateway integration. Any new EventModel models that are created appear in this EventAdmin model by default.

If you delete the EventAdmin model to remove support for the third-party system, delete all EventModel models associated with the EventAdmin also.

Attributes

The EventModel icon displays the model name and model type. The incoming alert information can assign the model name. If the model name is not assigned, the unique ID string that identifies the EventModel is visible within the Model Name field.

If you defined an EventModel prefix when creating the EventAdmin, this prefix prepends the EventModel name for all the EventModels contained by this EventAdmin. This provides a way to further uniquely identify the EventModel for a particular integration.

If you have chosen a specific Manager Name when creating the EventAdmin, the information is also available to the EventModel.

All these parameters can be changed from the Attributes tab in the Component Detail view of the EventAdmin. If such changes are made, existing EventModels are updated with the new attribute values.

Put an EventModel Model into Maintenance Mode

You can put EventModel models into maintenance mode from the Information tab in the Component Detail view. Putting EventModel models into maintenance mode suspends management traffic to the EventModel model and its components and prevents the generation of any events or alarms on its behalf. When an EventModel is put into maintenance mode, its icon displays a device condition color of brown.

To put an EventModel model into maintenance mode

1. Select the EventModel model you want to put into maintenance mode, click the Information tab in the Component Detail view, and then expand the General Information node.
2. Click set in the In Maintenance field, and then select Yes from the drop-down list.
   The EventModel model is now in maintenance mode; its icon color changes to brown.

Set Up a Fault-Tolerant Environment

Fault tolerance is provided by having more than one SpectroSERVER available for managing a given landscape. If the primary SpectroSERVER fails, the secondary SpectroSERVER takes over.

To set up a fault-tolerant environment with Southbound Gateway

1. Set up the fault-tolerant environment as described in the Distributed SpectroSERVER Administration section.
2. Start the primary SpectroSERVER and then start the management application being integrated through the Southbound Gateway.
   The primary SpectroSERVER creates an EventAdmin model automatically if you have used the sbgwimport tool to create your integration, or if you have used the DX NetOps Spectrum CORBA API and specified programmatically that the EventAdmin be created automatically. Otherwise, the EventAdmin model is not created automatically and creates it on the primary SpectroSERVER.
   A default EventModel model is created automatically once the EventAdmin model is activated.

3. Synchronize the primary and secondary SpectroSERVER databases using the DX NetOps Spectrum Online Backup feature.

   NOTE
   See the Distributed SpectroSERVER Administration section and the Database Management section for instructions.

If the primary SpectroSERVER goes down and the secondary SpectroSERVER takes over, the default EventModel model is used to process incoming events.

When the secondary SpectroSERVER is monitoring the network and events are received by the EventAdmin model, new EventModel models are not created. First, the EventAdmin checks to see if there is an appropriate existing EventModel to send the events to, if not, instead of creating an EventModel, the events are sent to the default EventModel model.

Allowing the secondary SpectroSERVER to create new EventModel models would cause disparate model handle information between the primary and secondary SpectroSERVERs. This would cause the Archive Manager to store the event and statistical information for a single event source in different places, as if the information is actually from different event sources. The default EventModel prevents this from happening.

NOTE
If either the EventAdmin or default EventModel is destroyed on the primary, secondary, or tertiary server, the previous steps must be repeated. Steps 1 to 3 must be repeated if the models are destroyed on the primary SpectroSERVER. Steps 2 to 3 must be repeated if the models are destroyed on the secondary or tertiary SpectroSERVER.

Archive Manager Failure

If events are being sent to the EventAdmin model through the sbgwimport tool, additional fault tolerance has been implemented in case of an Archive Manager failure. If the Archive Manager goes down, alarms triggered by incoming events are created on the default event model. When the Archive Manager is running again, the events are sent to it and can be viewed in the event log.

Southbound Gateway Case Study

This chapter walks you through an integration with typical third-party management software that can send SNMP traps to DX NetOps Spectrum.

The traps sent by this software have been directed to the SpectroSERVER and are received by Southbound Gateway. For the sake of simplicity, this chapter assumes that this application only sends one type of trap to the Southbound Gateway. The trap is an enterprise-specific trap with a number of variable bindings.

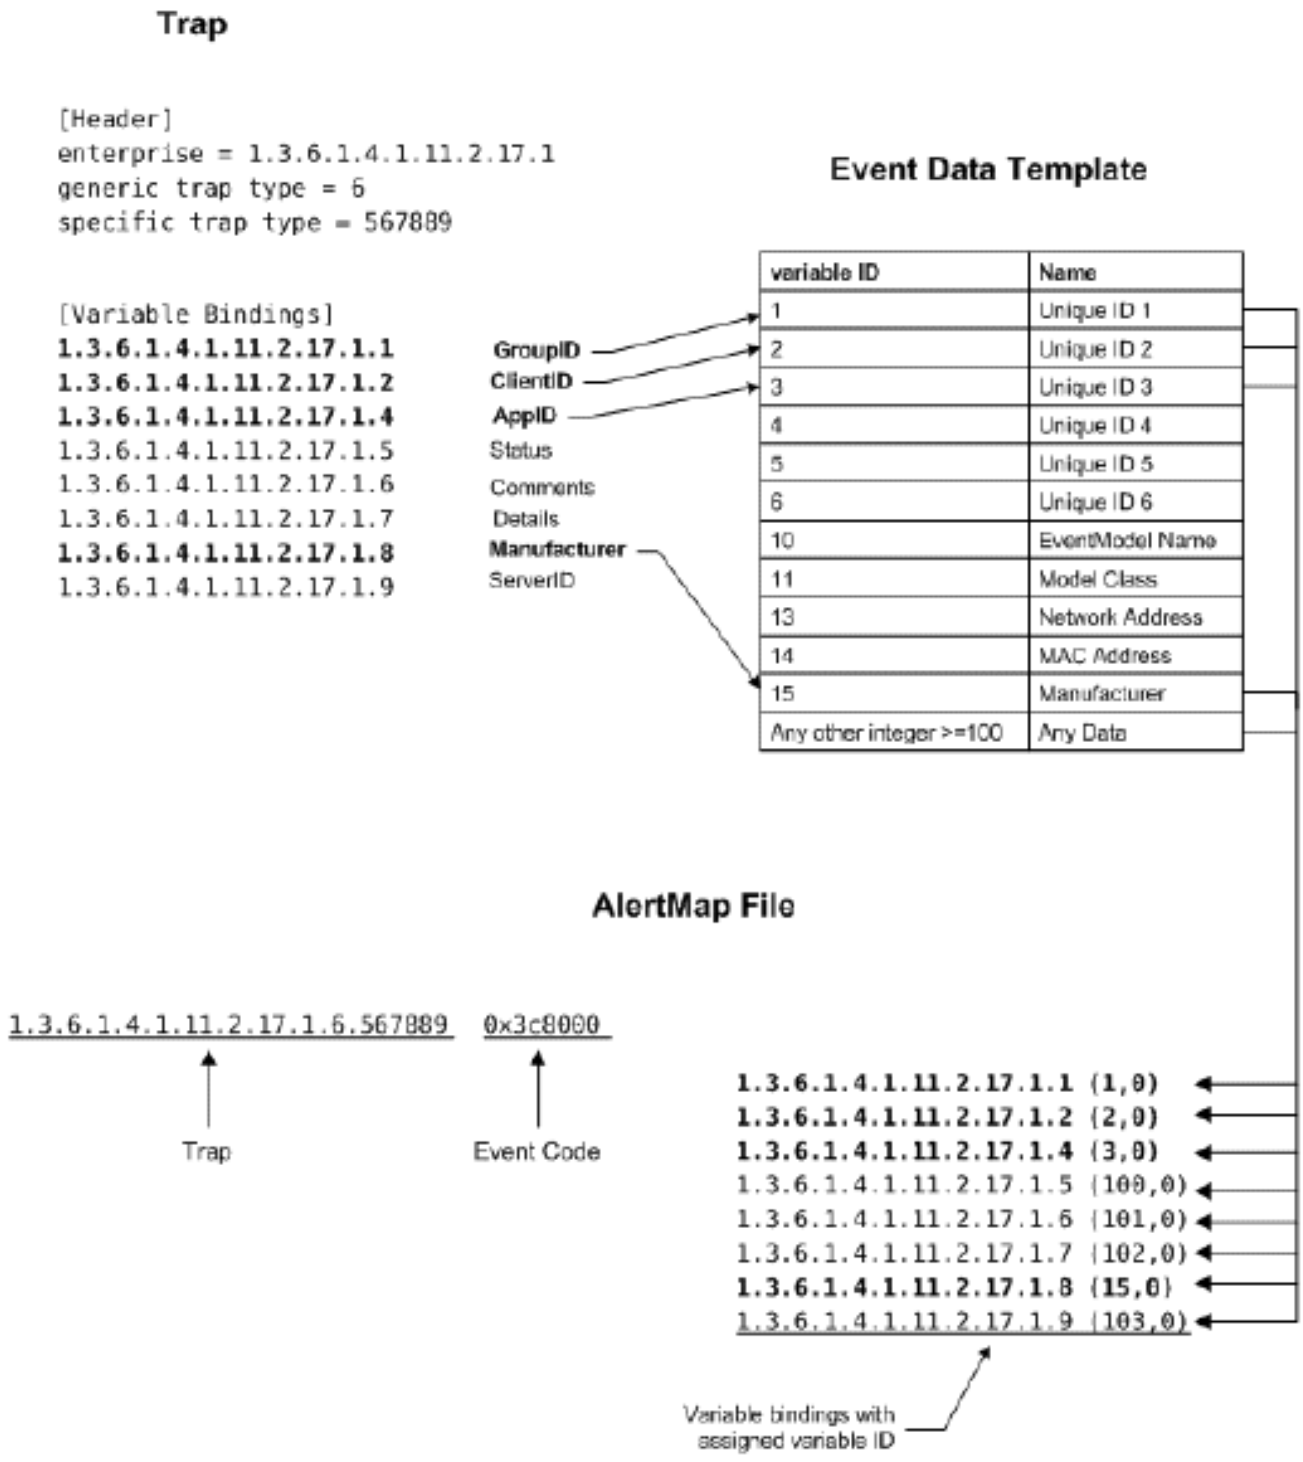
```
[Header]
enterprise = 1.3.6.1.4.1.11.2.17.1
generic trap type = 6
specific trap type = 567889
[Variable Bindings]
1.3.6.1.4.1.11.2.17.1.1
1.3.6.1.4.1.11.2.17.1.2
1.3.6.1.4.1.11.2.17.1.4
1.3.6.1.4.1.11.2.17.1.5
1.3.6.1.4.1.11.2.17.1.6
1.3.6.1.4.1.11.2.17.1.7
1.3.6.1.4.1.11.2.17.1.8
1.3.6.1.4.1.11.2.17.1.9
```

Step 1. The AlertMap File

The trap information must be mapped to an event; therefore, create an alert map entry for this trap. The most important thing to specify is the string that makes up the unique identifier for the EventModel. This unique ID can be comprised of up to six variable bindings using the variable IDs one through six. This data can then be viewed within the event message.

The following example shows the trap being mapped to an event in the AlertMap file. The variable-bindings are being assigned a variable ID from the Event Data Template. All non-bold variable bindings have been mapped to the “Any Data” category of the Event Data Template.

These variable bindings have been given a variable ID that has not been assigned to a specific category in the Event Data Template.



Trap

assigned variable ID

Step 2. The EventAdmin EventDisp File

The following is a sample of the EventAdmin EventDisp file. This EventDisp file lists all the events generated by the third-party system. Listing them here lets them be received by the EventAdmin model.

Example: The EventAdmin EventDisp File

```
0x3c8000
```

The events should be logged at the EventModel level rather than the EventAdmin level. For this reason, the only thing listed in this file is the event code. This syntax indicates that the event should be received, but not logged. After the EventAdmin model receives the event, the EventAdmin model forwards it to the appropriate EventModel model.

Step 3. The EventModel EventDisp File

This EventDisp file gives the event received at the EventModel its properties. This file is optional, but highly recommended. These events are the same as those in the EventAdmin EventDisp file.

Example: The EventModel EventDisp File

```
0x3c8000 E 50 A 1,0x3c8000
```

Clearly this file has more data than the EventAdmin EventDisp file. The E indicates that the event is logged. The event severity is indicated by the number 50; event severity ranges from 1 to 100, 100 being the most severe. The A indicates that the event generates an alarm. The number 1 indicates the severity of the alarm. Valid values for the alarm severity are 1 through 6. The hexadecimal number 0x3c8000 is the alarm code.

There is also an optional ‘S’ flag available for use with EventDisp files which specifies whether an event should be registered for Southbound Gateway processing. It applies to modeltype-specific entries only and only those model types derived from the southbound modeltype fragment. For more information about this flag and the rest of the EventDisp file syntax, see the Event Configuration section.

Step 4. The Event Format File

The Event Format files define the event message seen in both the Events tab and the Alarm Details tab in OneClick.

Example: Event Format File

```
{d "%w- %d%m-, %Y - %T"} - Device {m} of
type {t}
The user's SMTP/POP3 mail transaction
failed with error code 554. The event
code is {e}.
Other information:
Group {S 1}
Client {S 2}
Application {S 3}
Manufacturer: {S 15}
Server: {S 103}
Status: {S 100}
Comments: {S 101}
Details: {S 102}
```

The items in parenthesis indicate that variable value is placed in the event text message. The S indicates the data type (String) and the numeric value is the variable ID assigned in the AlertMap file representing the value that is placed there.

Step 5. The Probable Cause File

The Probable Cause files define the alarm title, symptoms, probable causes, and recommended actions.

Example: Probable Cause File

```
MAIL TRANSACTION ERROR RECEIVED
SYMPTOMS:
The client's attempt to send mail failed.
PROBABLE CAUSES:
1. Network connectivity.
2. The mail server.
RECOMMENDED ACTIONS:
1. Check the network connectivity.
2. Check the mail server operation.
```

Step 6. Package for Distribution

Once you have created all the files necessary for the integration, you need to package these files so that they can be installed on a SpectroSERVER. See the Extension Integration (SEI) Developer Reference section for specific instructions and examples.

Creating a Southbound Gateway Demonstration

Introduction to Creating a Southbound Gateway Integration

This chapter helps you demonstrate the functionality of a Southbound Gateway integration without completing all the steps to create a fully functional integration.

In this demonstration, you are sending a fictitious trap to the EventAdmin model using a trap-generating software. The model receives the trap, translates the trap into a event, creates an EventModel based on the event information and forwards the event to an EventModel model. The event generates an alarm on this EventModel model and the text of the event format and probable cause files is shown in the Alarm tab and the Alarm Details tab in OneClick.

> **WARNING**
> Any changes made directly to AlertMap or EventDisp files are overwritten when a new version of is installed or when an additional Southbound Gateway integration is installed. For this reason, use the steps in this chapter for demonstration purposes only and not as a replacement for the complete integration steps outlined in the chapters of this section.

Step 1. Edit the EventAdmin AlertMap File

To allow the EventAdmin to receive an SNMP trap from a third-party system, the trap must be translated into DX NetOps Spectrum event in the EventAdmin AlertMap file.

To edit the EventAdmin AlertMap file

1. Open the AlertMap file located in the following directory:
   `<$SPECROOT>/custom/Events/gen_app_gw/EventAdmin`
2. Add the following line to the AlertMap file:
   `1.3.6.1.4.1.1850.6.1 0x5990001 1.3.6.1.4.1.1850.1.0.0.1(1,0)`

This line indicates that the trap, 1.3.6.1.4.1.1850.6.1, is translated into event 0x5990001. The value variable ID 1 (indicated in parentheses) shows that the Event Data Template variable of 1 is being used to represent the value of the variable binding, 1.3.6.1.4.1.1850.1.0.0.1. Because the Event Data Template variable 1 is one of the unique identifier values, the value of the variable binding is used as a unique identifier for the event model.

3. Save and exit the AlertMap file.

Step 2. Edit the EventAdmin EventDisp File

For the event created in the AlertMap file to be passed along to the EventModel for processing, add the event code to the EventAdmin EventDisp file.

To edit the EventAdmin EventDisp file

1. Open the EventAdmin EventDisp file located in the following directory:
   ```
   $SPECROOT/custom/Events/gen_app_gw/EventAdmin
   ```
2. Add the following line to this EventDisp file:
   ```
   0x5990001
   ```
3. Save and exit the EventDisp file.

Step 3. Edit the EventModel EventDisp File

For the EventModel model to process the event, create processing instructions in the EventModel model EventDisp file.

To edit the EventModel EventDisp file

1. Open the EventDisp file located in the following directory:
   ```
   <$SPECROOT>/custom/Events/gen_app_gw/EventModel
   ```
2. Add the following line to this file:
   ```
   0x5990001 E 50 A 1, 0x5990001
   ```
   This line indicates that the event should create a minor alarm on the EventAdmin model.

Step 4. Create an Event Format File

The event format file lets users get information about the event in the Events tab in the Component Detail view in OneClick.

To create the event format file for this event

1. Create a text file with the following content:
   ```
   {d "%w- %d %m-, %Y - %T"} - SAMPLE - This is a sample event format file for the Southbound Gateway
    demonstration.
   The event processed is event {e}.
   The variable binding data sent with the trap is: {S 1}.
   ```
2. Save this text file as *Event05990001* in the following directory:
   ```
   <$SPECROOT>/custom/Events/CsEvFormat
   ```
3. Verify that your text editor does not add a file extension to this text file and then close the text file.

Step 5. Create a Probable Cause File

The text of the probable cause file is shown in the Alarm Details tab of the Component Detail view and provides information about the causes and resolutions for the alarm.

To create the probable cause file for this alarm

1. Create a text file with the following content:

```
SAMPLE PROBABLE CAUSE FILE FOR THE SOUTHBOUND GATEWAY DEMONSTRATION
SYMPTOMS:
The symptoms of the problem are listed here
PROBABLE CAUSES:
1) Cause 1.
2) Cause 2.
RECOMMENDED ACTIONS:
1) Action 1.
2) Action 2.
```

2. Save this text file as *Prob05990001_en_US* in the following directory:

```
<$SPECROOT>/custom/Events/CsPCause
```

3. Verify that your text editor does not add a file extension to this text file and then close the text file.

Step 6. Create an EventAdmin Model

Complete this procedure to create an EventAdmin model in the Universe topology for the purposes of this demonstration.

Follow these steps:

1. Click **Create new model by type** in the Topology tab.
   The Select Model Type dialog appears.
2. In the Containers tab, click **EventAdmin**, and then click **OK**.
   The Create Model of Type EventAdmin dialog appears.
3. Configure the following parameters:
   a. Enter Test in the Name field.
   b. Enter the network address of the computer from which you launch the trap in the Network Address field.
      If you are using a trap generation program for the purposes of this demonstration, enter the network address of the computer running the trap generation program.
   c. Leave the Security String field blank.
   d. Leave the Manager Name field as Default.
   e. Leave the EventModel Prefix field blank.
4. Click OK.

The EventAdmin model is now created and appears in the Universe topology.

Step 7. Send the Trap

After you have finished Steps 1 through 6, shut down and restart the SpectroSERVER to activate the changes you have made.

After you have activated your changes, send a trap to the Southbound Gateway to show how this trap is handled. DX NetOps Spectrum accepts an individual SNMP trap packet to a maximum size of 65467 bytes.

You can use a trap generating software such as Trap Generator from Network Computing Technologies to send the trap to the SpectroSERVER. The following procedure uses Trap Generator to illustrate how to send a trap to Southbound Gateway.

> **NOTE**
> The Trap Generator shareware is being used in this example to demonstrate a process, but is not directly supported by CA. For information about downloading, licensing, and using Trap Generator, see the Network Computing Technologies web site: http://www.ncomtech.com/trapgen.html.

To send a trap to Southbound Gateway using Trap Generator

1. If you are using Trap Generator, use the following syntax in your parameter text file:

```
-d <IP Address of SpectroSERVER>:162
-c public
-o 1.3.6.1.4.1.1850
-g 6
-s 1
-v 1.3.6.1.4.1.1850.1.0.0.1 STRING "TestEventModel"
```

2. After you have created this text file, launch the trap by typing:

```
trapgen -f <name of parameter text file>
```

   This syntax directs the trap to port 162 on the SpectroSERVER and defines a variable binding, data type, and value.

Step 8. Show the Results in OneClick

The following process shows the results in OneClick.

The Alert is Received and Translated into a DX NetOps Spectrum Event

When you launch the trap from the trap generation program, the EventAdmin model receives and processes the event.

The Event is Processed by the EventAdmin

When the EventAdmin model processes the event, it uses the variable binding used in Step 1. Edit the EventAdmin AlertMap File as the unique identifier to specify which EventModel to forward the event to. Since this EventModel does not yet exist, a new one is created. To view the EventModel, from the Universe Topology, drill down into the EventAdmin container.

An Alarm is Asserted on the EventModel

In Step 3. Edit the EventModel EventDisp File, an entry was added to the EventModel's EventDisp file to indicate how the event should be processed. This entry indicated that the event should create a minor alarm.

The EventModel model has a status of yellow indicating a minor alarm.

View Data About the Alarm in OneClick

You can view data about the alarm from the Alarm Details tab in OneClick.

To view information about this alarm

1. Select the Event Model in the Explorer tab in the Navigation panel.
2. Click the Events tab in the Contents panel to view the contents of the event format file created in Step 4. Create an Event Format File.
3. Click the Alarms tab in the Contents panel, and then click the Alarm Details tab in the Component Detail view to review the contents of the probable cause file created in Step 5. Create a Probable Cause File.

How to Integrate with DX NetOps Virtual Network Assurance (DX NetOps VNA)

DX NetOps Spectrum and DX NetOps VNA integration lets you access SDN inventory via a single point of integration. The integration uses the DX NetOps VNA Client API (uses WebSocket) to connect to DX NetOps VNA and UDM (Unified Data Model) to access the data.

From 10.4.1, all the SNMP models discovered through DX NetOps VNA are retained in DX NetOps Spectrum in their respective containers after DX NetOps VNA integration is disabled.

WARNING

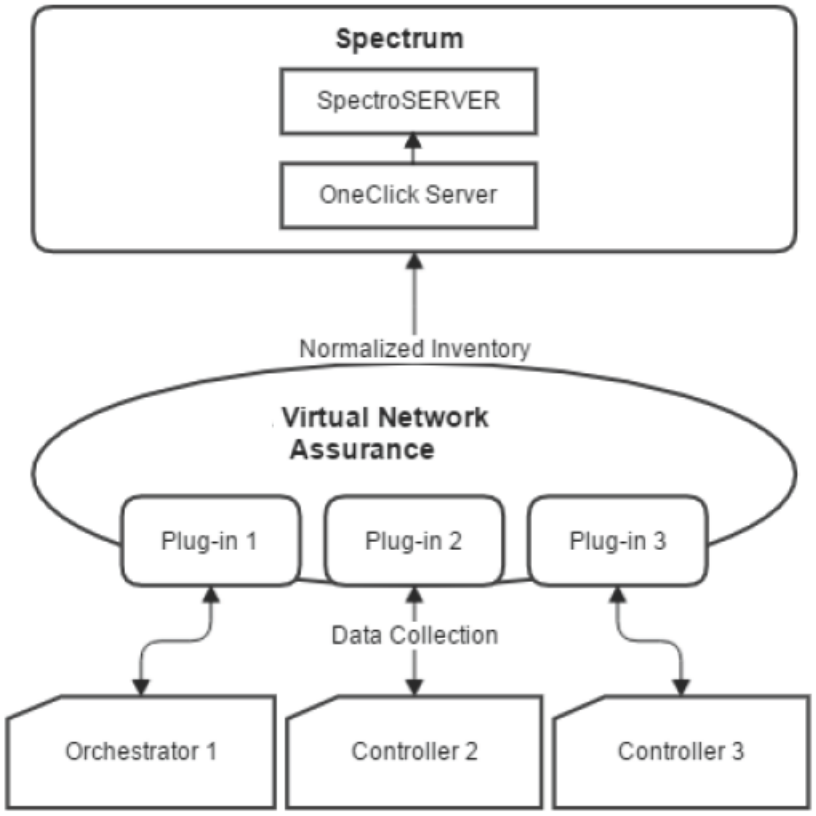
SDN Integration is not supported on Internet Explorer (IE).

The SDN Gateway data source contributes the following item types to DX NetOps Spectrum:

- Topology
- SFC View
- Inventory updates (includes SDN entities and their status information)

The following diagram illustrates DX NetOps Spectrum and DX NetOps Virtual Network Assurance Integration Architecture:

Figure 81: DX NetOps Spectrum and DX NetOps Virtual Network Assurance



Supported DX NetOps Spectrum and DX NetOps VNA version integrations:

For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

Integrating with DX NetOps Virtual Network Assurance

NOTE

From 10.2.3 onwards, SDN Gateway Integration Configuration is now called **DX NetOps VNA Configuration** on the Administration page of the OneClick UI.

NOTE

10.2.3 introduces **Multi-tenancy Support with DX NetOps VNA**. For more information see, DX NetOps VNA Aggregator Integration section**.**

WARNING

SDN Integration is not supported on Internet Explorer (IE).

Integrating DX NetOps Spectrum with DX NetOps VNA allows you to view both virtual network data and traditional physical infrastructure data. The DX NetOps VNA collects data from all your SDN environments and delivers that information to DX NetOps Spectrum. For more information about SDN, see the DX NetOps Virtual Network Assurance documentation.

From 10.4.2.1, you can search the DX VNA models from the **Locator** search. Here is a non-exhaustive list of device models that are searchable:

- All VNA entity models Sdnmanager
  SNMP, slapath, tunnels, interfaces, devices anything, non-SNMP, anything discovered through DX VNA
- Non-SNMP entity models
  VMS, non-SNMP model-able routers/switches not interfaces, nothing granular/ep/epgs
- SNMP models
  SNMP routers, VMS, mdl_create_method : check on this to createmodelbyip, autodisc, createmodelbytype(nonsnmp for vna)
- Entity models per user domain
  Everything under the user domain. SDN_contains_entities relation

Integrating DX NetOps Spectrum with DX NetOps VNA

DX NetOps VNA Standalone and Aggregator Integration

Integration Compatibility Matrix

To know more about version compatibility of other integrated products with DX NetOps Spectrum 10.4.1, see the Integration Compatibility chart.

NOTE

For DX NetOps Spectrum-DX NetOps VNA Integration issues, see the Troubleshooting section.

WARNING

DX NetOps VNA Configuration is not supported on Internet Explorer (IE).

DX NetOps VNA Standalone Integration

To receive the DX NetOps VNA data, you must enable the integration between DX NetOps Spectrum and DX NetOps VNA, which acts as SDN Gateway. You can enable the integration through the OneClick Administration page. Specify the DX Netops VNA configuration information such as the Server Host Name, Server Port, and select a SpectroSERVER to model the inventory from DX NetOps VNA after integration.

Follow these steps:

1. Open the OneClick Administration page.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages appear.

3. Click the DX NetOps VNA Configuration link in the left panel.
   The DX Netops VNA Configuration window appears with the following configuration options:
   - **VNA Server Host Name**
     Specify the IP address/hostname of the DX NetOps VNA Server.
   - **VNA Server Port**
     Specify the server port number of DX NetOps VNA.
   - **Select a SpectroSERVER**
     Specify the SpectroSERVER to be modeled.
4. For **DX NetOps VNA Configuration**s, elect the **Enable** radio button.
5. Click **Test** to verify if the connection is working.
   If the test is successful, ‘Test connection to DX Netops VNA Server was successful’ message appears.
6. Click **Save** and 'Successfully saved configuration to the database' message appears. DX NetOps VNA Configuration is now enabled.

   NOTE
   You cannot change any settings on any other OneClick server other than the integration OneClick server.
7. After saving the configurations, the **Discover** button appears, click on the **Discover** button to allow DX NetOps Spectrum to discover and models devices coming from DX Netops VNA.

   NOTE
   SDN Manager uses community strings from "VNM -> AutoDiscovery Control -> Modeling and Protocol options > SNMP Community Strings" to discover SNMP devices.

   When the DX NetOps Spectrum and DX NetOps VNA Configuration is enabled from the OneClick Administration page, DX NetOps Spectrum receives the data from DX NetOps VNA through the Rest API. Once the data is retrieved from the Rest API, DX Netops VNA hosts are modeled in DX NetOps Spectrum.

   NOTE
   To fetch and update the latest details of the userDomain from DX Netops VNA, **Sync** to remodel devices on the OneClick console by selecting SDN MAnager→ ForceGatewayfullSync→and setting 0x673002c to True. By performing this action a web socket communication towards DX Netops VNA would be restarted.

   NOTE
   Before upgrading to 10.2.3, disable the existing integration between DX NetOps VNA and CA Spectrum.

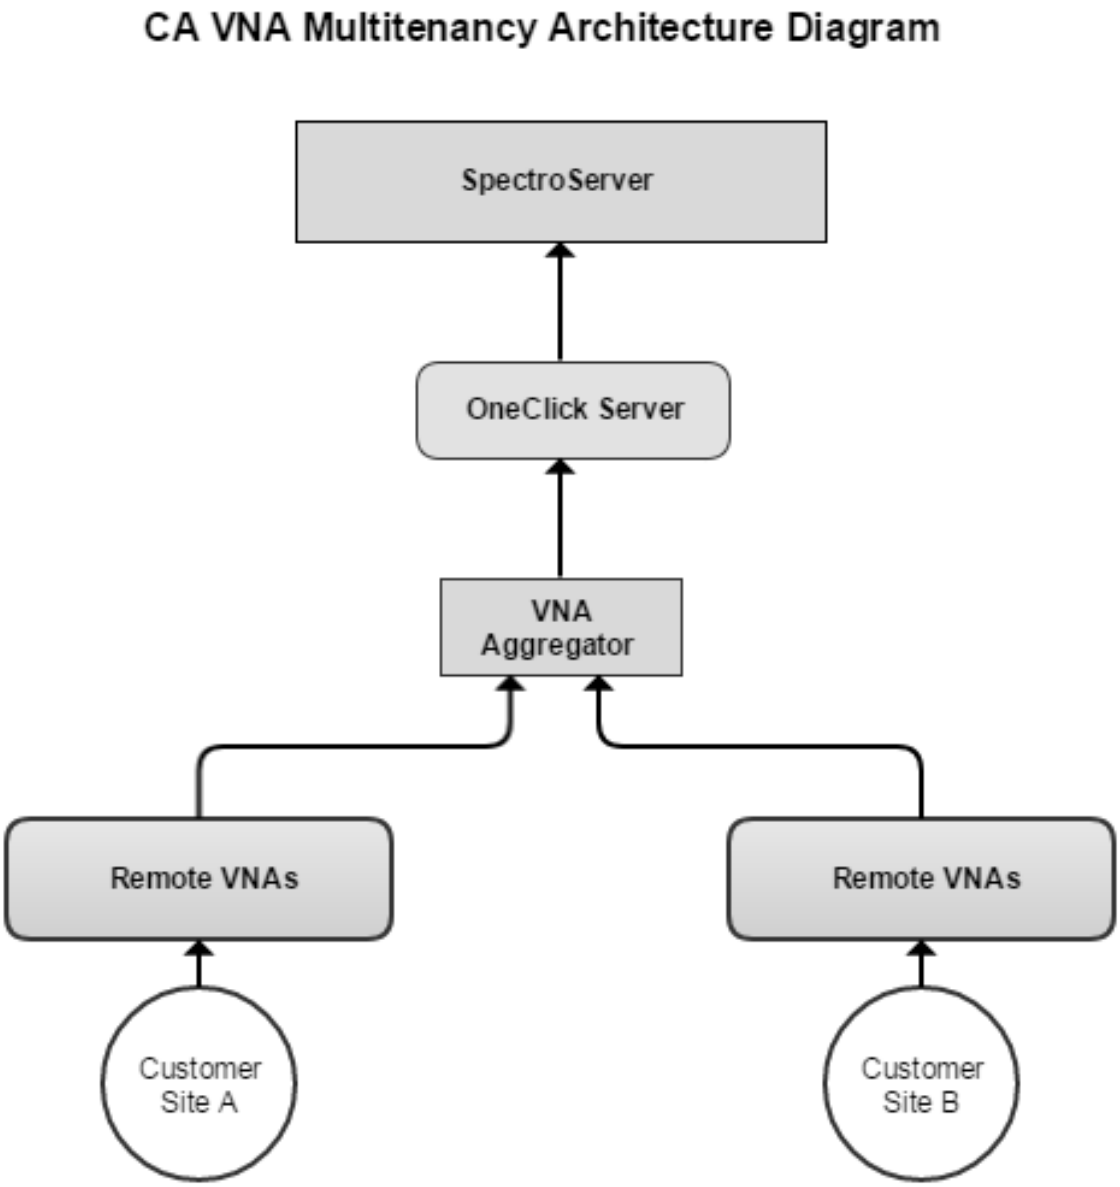
DX NetOps VNA Aggregator Integration

DX NetOps Spectrum 10.2.3 release introduces Multitenancy through VNA aggregator integration that enables modeling of multiple selected domains in any corresponding SpectroSERVER in a DSS environment to effectively manage several devices in your network. Through multitenancy, you can configure multiple domains to the corresponding landscapes and configure both SDN network elements via DX NetOps Virtual Network Assurance and the physical network elements through the Secure Domain Connector (SDC).

To aggregate data from multiple DX NetOps Virtual Network Assurance (VNA) hosts for DX NetOps Spectrum, you can configure and deploy a multi-tenant environment where multiple remote VNAs installed in a remote location/ domain can talk to one aggregator DX NetOps VNA. In this environment, a VNA Aggregator aggregates data from multiple remote VNA hosts and sends the data to DX NetOps Spectrum with unique entity IDs. Refer to the DX NetOps Virtual Network Assurance documentation for more information.

Multitenancy Architecture Diagram is as follows:

Figure 82: DX NetOps VNA Multitenancy Architecture Diagram



Prerequisites:

The prerequisite is to install and integrate all Secure Domain Connectors (from various domains) with SpectroSERVERs so that it would be listed during mapping, although this is not mandatory. This step is optional if the SDN physical elements (SNMP enabled) can be fetched by SpectroSERVER only via Secure Domain Connector.

NOTE

Proper SDC should be selected in case of physical network elements to be modeled.

- It is recommended that the VNA Aggregator and OneClick should reside on the same server, although it is not mandatory.
- The inventory/alarms update should have the DX NetOps Virtual Network Assurance plugin IP with the domain ID.
- It is recommended to not use or reuse an existing standalone VNA as Aggregator VNA. Instead, always use a fresh installed VNA as Aggregator.
- We strongly recommend having a dedicated VNA for Aggregation.
- Do not configure any plugin on Aggregator DX Netops VNA.

DX Netops VNA Configuration

To receive the VNA data, you must enable the integration between DX NetOps Spectrum and DX NetOps VNA, which acts as SDN Gateway. You can enable the integration through a web server from the OneClick Administration page. Specify the VNA configuration information such as the Server Host Name, Server Port, and select a SpectroSERVER to enable the integration.

Follow these steps:

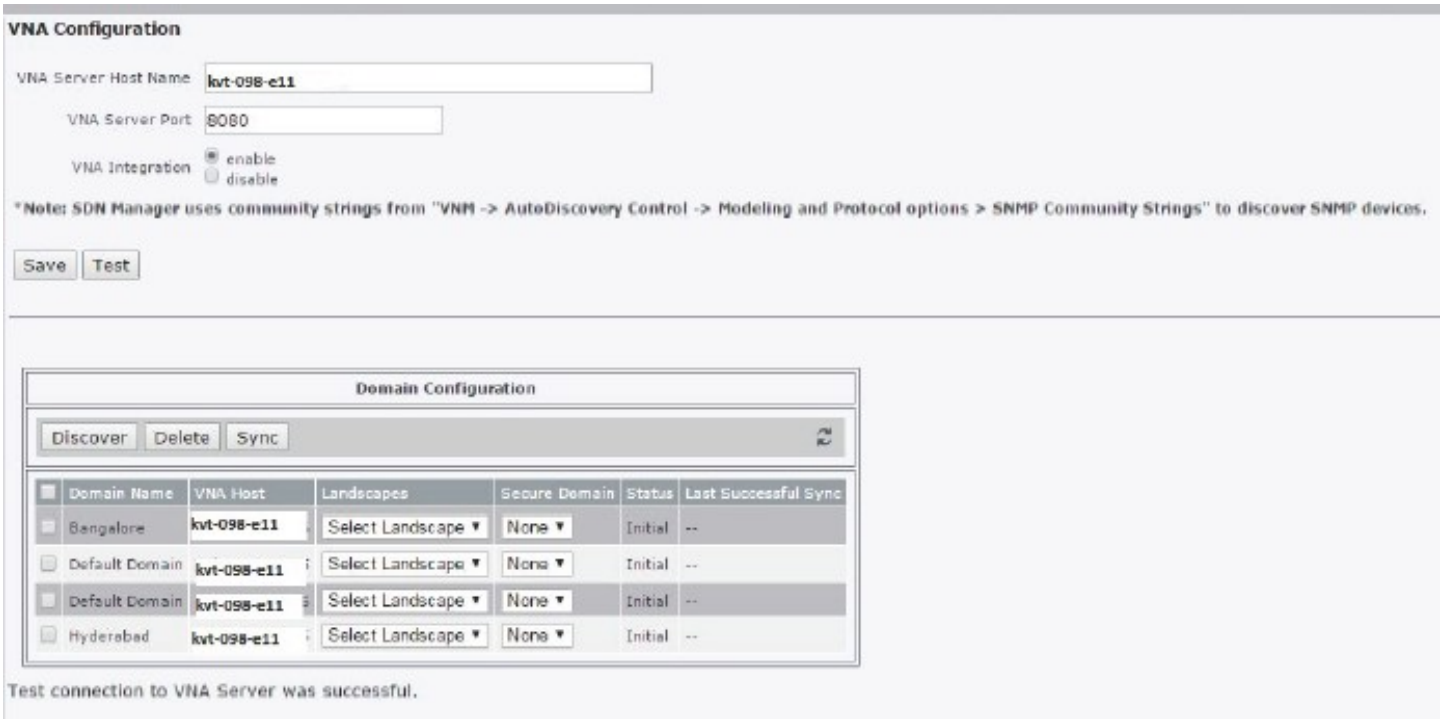
1. Open the OneClick Administration page.
2. Click the Administration tab and select the VNA Configuration from the left panel. The VNA Configuration window appears with the following configuration settings:
   - **VNA Server Host Name:** Indicates the IP address/hostname of the DX NetOps VNA Server.
   - **VNA Server Port:** Indicates the server port number of DX NetOps VNA.
   - **VNA Configuration:** Select the **Enable** radio button.
3. Click **Test** to verify if the connection is working. If test is successful, ‘Test connection to VNA Server was successful’ message appears.
4. Click **Save** and 'Successfully saved configuration to the database' message appears.
   DX NetOps VNA Configuration is now enabled and the **Domain Configuration Table** appears.

   NOTE

   SDN Manager uses community strings from "VNM -> AutoDiscovery Control -> Modeling and Protocol options > SNMP Community Strings" to discover SNMP devices.

Domain Configuration Table

The domain configuration table contains the following fields for modeling of selected domains:



The fields description is as follows:

Domain Name: Displays the selected domains fetched from the VNA server.

VNA Host: Displays the DX Netops VNA Server Hostname where userDomain is present (either DX Netops VNA name or IP address).

Landscapes: This drop-down list displays the list of SpectroSERVERs in a DSS environment. The user has to have one SpectroSERVER selected to model domain entities.

Secure Domain: By default it is None. In case the user has any private network (the network behind firewall) then the user has to have the Secure Domain Collector (SDC) installed and integrated with the SpectroSERVER. Based on SpectroSEVER selection, the SDC list will be changed. The user should ensure to have an appropriate mapping for SDC. domains will not be modeled if there is a mismatch in the SDC selection.

Status: This field displays the status of selected domains modeled in SpectroSERVER, which could be the following:

- **Initial**- Specifies the mapping which is to be done.
- **Discovery in progress** & **Sync in progress** - Specifies the waiting process for an update from VNA or that the modeling is in progress.

  NOTE

  These details are static and not dynamic in nature.
- **Discovered** - Specifies that the modeling is completed.
- **Deleted** - Specifies that the selected user domain and the corresponding models are deleted in the modeling database.

Last Successful Sync: This field displays the time and date of the last successful sync of the specified modeled domains with the VNA server.

The domain configuration table contains the following keys/buttons:

NOTE
Ensure the primary OneClick and the landscape SpectroSERVER is up and running before selecting **Discover**, **Delete** or **Sync** button.

Discover: DX NetOps Spectrum starts communicating with DX NetOps VNA and models the network elements in the corresponding mapped landscape based on the entered details under domains, landscapes, and secure domain fields and generates the status and updates the last successful sync of the existing domains which are modeled. It also starts processing faults (received from VNA) on those elements. In case of physical network elements DX NetOps Spectrum tries to identify, model the network by regular discovery methods and also resolves the connections.

Delete: To delete selected domain(s) and domain elements modeled in a corresponding SpectroSERVER.

Sync: To refresh details such as status updates and the last successful sync of selected user domain models in the modeling database. During the sync, the OneClick server sends request to the aggregator VNA to get the latest updates.

NOTE
By selecting the **Sync** button the user can remodel devices that were deleted. The **Sync** button fetches and updates the latest details of the userDomain from VNA.

WARNING
Use this option only when there are discrepancies in the inventory. Ensure the primary OneClick and the landscape SpectroSERVER is up and running.

Refresh icon: On-demand refresh when a new domain is added or removed at VNA.

Handling DX NetOps Spectrum-DX NetOps VNA On-Demand Sync of Particular Sites Issues

Due to issues in on-demand sync between DX NetOps Spectrum-DX NetOps Virtual Network Assurance of particular sites, DX NetOps Spectrum does not receive the expected data from DX NetOps Virtual Network Assurance.

From 10.4.2, the following new sync statuses are added for on-demand sync of particular sites:

- If a response is not received from DX NetOps Virtual Network Assurance, a new sync status **waiting_for_response** is displayed in DX NetOps Spectrum.
- If the web socket connection is broken between DX NetOps Spectrum and DX NetOps Virtual Network Assurance, a new status **sync_failed** is shown.

Troubleshooting with DX NetOps VNA Integration

'unable to connect to SDN Gateway through webSocket' error message found during DX NetOps Spectrum and DX NetOps VNA integration

Symptom:

The following error message is thrown 'unable to connect to SDN Gateway through webSocket' during DX NetOps Spectrum and DX NetOps VNA integration. Following is the error message log:

```
java.lang.IllegalArgumentException: no such vertex in graph: 1100
at org.jgrapht.graph.AbstractGraph.assertVertexExist(AbstractGraph.java:132)
at org.jgrapht.graph.AbstractBaseGraph.addEdge(AbstractBaseGraph.java:141)
at com.ca.em.sdn.gateway.broker.common.client.SDNClientHelper.lambda$splitUpdate

at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:617)
at java.lang.Thread.run(Thread.java:745)
```

Solution:

Such exceptions occur when the DX NetOps VNA inventory is corrupted. To overcome this issue, reinstall DX NetOps VNA.

Aggregator DX NetOps VNA is sending unwanted Full updates to OneClick

Symptom:

Aggregator DX NetOps VNA is sending unwanted full updates to OneClick. Alarm occurrence count is increased when an integrated DX NetOps VNA is queried from another SDN gateway client. Aggregator DX NetOps VNA should only connect to one OneClick. In case another client connects to the Aggregator DX NetOps VNA, it sends Full updates to all the connected OneClick clients.

Solution:

Ensure only one OneClick is installed with a DX NetOps VNA Aggregator.

Inventory is not modeled or models are duplicated

Symptom:

Inventory is not modeled or models are duplicated.

Solution:

Follow these steps:

1. Run sync on the domain
2. Ensure that the SpectroSERVER and the primary OneClick is up and running.
3. Check the Tomcat logs on the primary OneClick for error messages.

Leaf and spine switches are not getting modeled

Symptom:

Leaf and spine switches are not modeled.

Solution:

DX NetOps Spectrum uses community strings from VNM>AutoDiscovery Control>Modeling and Protocol options→SNMP community string to discover SNMP devices. Follow these steps:

1. Ensure the device SNMP credentials are added.
2. Log into the APIC portal and select **Fabric** on the top bar of the page. Navigate to the **Fabric Policies**> **Pod Policies** > **Policies** > **SNMP** and check for the SNMP policies.

3. Add the SpectroSERVER IP address to the **Client Group Policies** list to discover and model ACI elements in the corresponding SpectroSERVER.

   NOTE

   Upgrade from the previous version is not supported. Users have to disable the existing integration and integrate it again with VNA 3.5.1.

'Site is missing' how to find out if the remote DX NetOps VNA is down from DX NetOps Spectrum?

Symptom:

Remote DX NetOps VNA connection is missing.

Solution:

Follow these steps:

1. You can check the connection status between DX NetOps VNA Aggregator and the remote DX NetOps VNA.
2. Check for DX NetOps VNA troubleshooting in the DX NetOps VNA documentation.

Fault data is missing, how to find out if it is a DX NetOps VNA or a DX NetOps Spectrum issue?

Symptom:

Fault data from APIC faults view is not displayed in the DX NetOps Spectrum alarm console.

Solution:

Follow these steps

1. Check if fault data is supported by DX NetOps VNA. Unsupported faults are not sent to DX NetOps Spectrum by VNA and therefore will not be displayed.
2. Check if fault data is present in the DX NetOps VNA db (MySQL). If fault is not present in the VNA db, it is either unsupported.
3. Enable SDN Gateway debug from the OneClick Admin page.

'Modeling in progress' (an attribute on SDN Manager) stuck for longer time of this?

Symptom:

DX NetOps Spectrum modeling job is stuck or not completed.

Solution:

1. Check whether any exception occurred in the OneClick server logs.
2. If 'Modeling in progress' attribute (SDN_Modelling_inProgress) is true for a longer time, enable the DX NetOps VNA configuration debug log in OneClick web page.
   To enable DX NetOps VNA configuration debug log in OneClick web page:
   a. Go to the Administration page of OneClick > Debugging > Web Server Debug Page (Runtime) > VNA Integration Information > ON radio button> Desired Level=Max > Apply
   b. Administration > Debugging > Web Server Debug Page (Runtime) > VNA Notification Sync > ON > Desired Level=Max > Apply
   c. Collect the OneClick Web Server Logs in windows and Linux
3. Disable SDN_Modelling_inProgress attribute (false) and perform **Sync** action on one of the user domains modeled in that SpectroSERVER.
4. If the problem persists, approach the DX NetOps Spectrum support team by providing the OneClick server logs.

WARNING

To enable debug logs in the DX NetOps VNA server, see DX NetOps VNA documentation.

Monitoring SDN Devices

SDN Manager

After the DX NetOps VNA Configuration is complete, you can see a folder that is named 'SDN Manager' in the Explorer tab of DX NetOps Spectrum. All SDN related entities are listed under the SDN Manager folder. When you execute a discovery in DX NetOps Spectrum, the following SDN entities are available under the SDN folder: In SDN Hierarchy the locations of Models are updated in the SdnContainsModelNameString attribute (0x133e4) If DX NetOps Spectrum need to support new faults from DX NetOps Virtual Network Assurance, those can be updated in the `EventDisp` file in `$SPECROOT/SS/CsVendor/SDN/` location.

- Compute - Contains all Hypervisors
- Fabric - Contains all switches and routers
- Technologies - Lists the technologies that are supported. For example, Cisco ACI, OpenStack, vSphere, and Juniper Contrail.
- Tenants - Contains all tenants (Applications Profiles, Virtual Machines, VRFs, and so on).

In SDN Hierarchy the locations of Models are updated in the SdnContainsModelNameString attribute (0x133e4) If the DX NetOps Spectrum need to support new faults from DX NetOps VNA, those can be updated in the EventDisp file in $SPECROOT/SS/CsVendor/SDN/ location.

Logging DX NetOps VNA Inventory Data

From 10.4.2, a new attribute (`Dump_Inventory`) is introduced to store the DX NetOps VNA inventory data.

NOTE
You must enable the `Dump_Inventory` attribute after you enable integration with DX NetOps Virtual Network Assurance.

When the `Dump_Inventory` attribute is enabled in DX NetOps Virtual Network Assurance integration on the SDN Manager node, a CSV file is stored in `%OC_Tomcat%/logs` directory. The CSV file contains the entityUUID and mh of the DX NetOps Virtual Network Assurance inventory.

Search SDN Models

The Locater tab in OneClick allows you to search the following SDN Models:

- Compute
- SDN Virtual Machines
- NFVs
- Neutron Networks / Subnet
- vSwitches
- Service Function Chains
- Tenants

NOTE

If compute is put in maintenance mode, all the VMs hosted on that compute are automatically moved into maintenance mode by DX NetOps Spectrum.

Monitor Cisco ACI Devices

Cisco Application Centric Infrastructure (ACI) is a fabric, which uses policy model provision by Application Policy Infrastructure Controller (Cisco ACI) for networks, servers, storage, security, and services. The Cisco ACI related plug-in of DX NetOps VNA collects inventory for various items such as ACI Tenants, ACI End Point Groups (EPG), and so on. For more information about how DX NetOps Virtual Network Assurance supports Cisco ACI see the Cisco ACI section in the DX NetOps Virtual Network Assurance documentation.

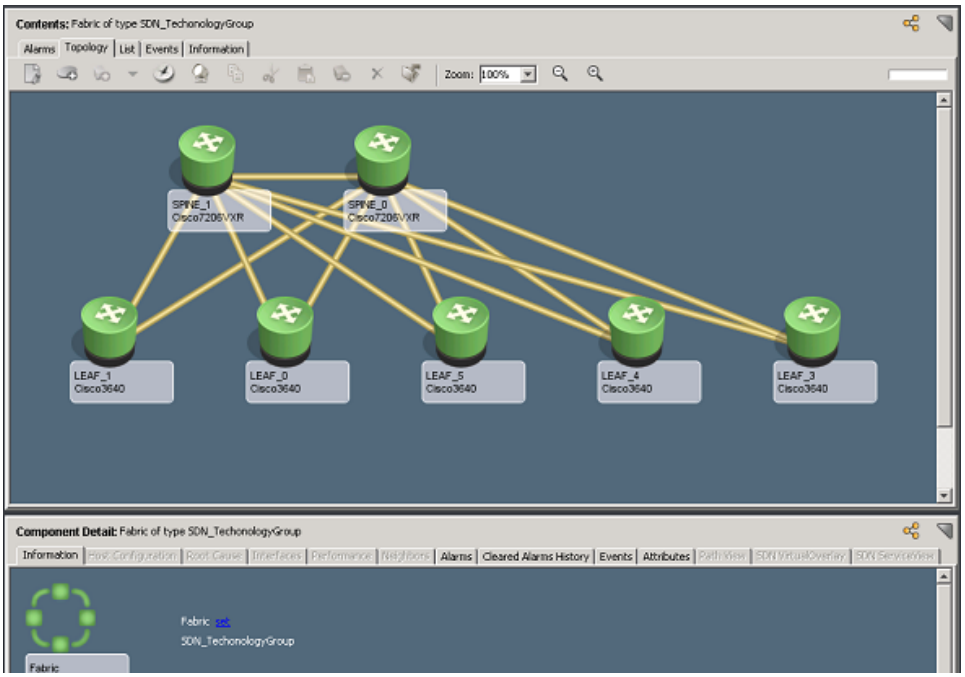
Starting from the 10.2 release, DX NetOps Spectrum supports to discover and model Cisco Application Centric Infrastructure (ACI) fabric devices. DX NetOps Spectrum displays the following Cisco ACI views in OneClick:

- Fabric View
- Contract View
- Application Profile View
- EPG View

Fabric View

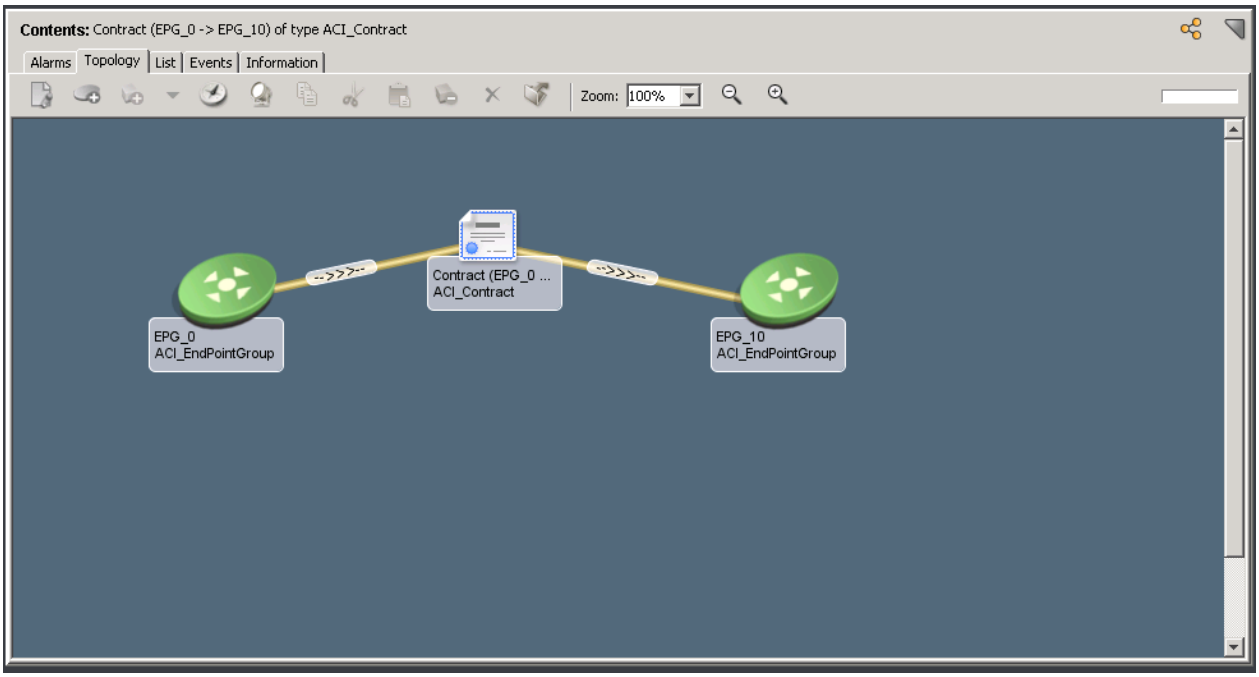
The ACI Fabric View displays the connections between Leaf and Spine switches. After the discovery in DX NetOps Spectrum, you can see all the connections from Leaf to Spine switches.

> **NOTE**
>
> To see the Fabric view of Cisco ACI devices in DX NetOps Spectrum, you must integrate DX NetOps Spectrum with DX NetOps Virtual Network Assurance.



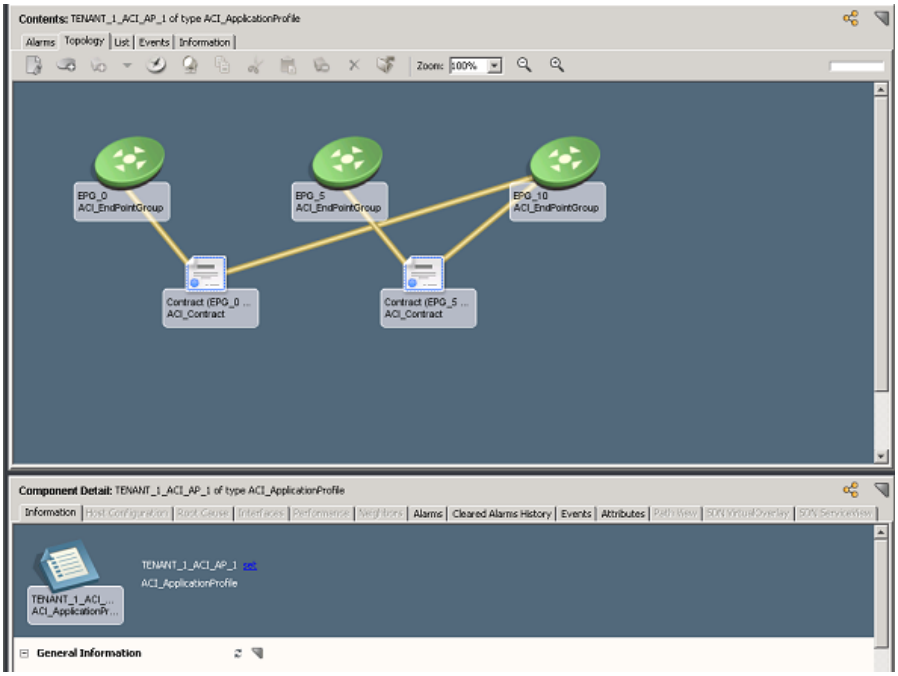
Contract View

The Contract View displays the End Point Groups that are providing and consuming the contracts.



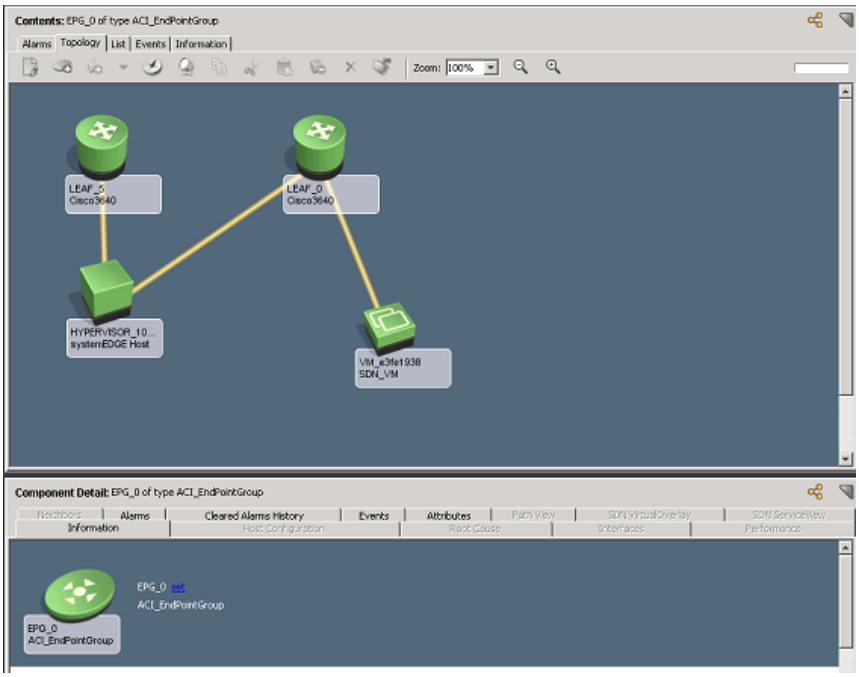
Application Profile View

The Application Profile View displays all the contracts, End Point Groups that are associated with a tenant.



EPG View

The ACI End Point Groups View displays endpoints that are associated with the group and their upstream leaf switch connectivity.



Support for Cisco ACI Faults

Cisco ACI system creates a fault based on specific conditions like component failures or an alarm. Faults are automatically created, escalated, de-escalated, and deleted by the system as specific conditions are detected. DX NetOps Spectrum receives both inventory (managed elements or devices) and Faults on the managed elements or devices from DX NetOps Virtual Network Assurance. For a detailed list of DX NetOps Spectrum supported Cisco ACI faults, refer to the Supported ACI Faults file.

DX NetOps Spectrum asserts the fault to the right entity (managed elements or devices) and displays an alarm in the OneClick alarm view.

NOTE

For entities that are not modeled in DX NetOps Spectrum using DX NetOps VNA, notifications are shown on the site model.

NOTE

Only the events which were created after the DX NetOps VNA plug-in are configured and saved in DX NetOps VNA DB and they are sent to DX NetOps Spectrum.

Correlation of SDN Fabric Devices

The following correlations are supported by Fabric (spine/leaf) Devices.

F1543 - fltFabricNodeInactive

This fault occurs when a leaf or spine node of a fabric domain is down, the ACI sends fault to DX NetOps Virtual Network Assurance and from DX NetOps Virtual Network Assurance, DX NetOps Spectrum receives the fault. Also, generates SNMP fault in DX NetOps Spectrum for that corresponding node. The SNMP faults and ACI faults are correlated and displayed in the DX NetOps Spectrum OneClick Console.

F0532 -fltEthpmIfPortDownInfraEpg

This fault occurs when an interface of leaf or spine node of a fabric domain is down, the ACI sends fault to DX NetOps Virtual Network Assurance and from DX NetOps Virtual Network Assurance, DX NetOps Spectrum receives the fault.

Also, generates SNMP fault in DX NetOps Spectrum for that corresponding node interface. The SNMP fault and ACI fault are correlated and displayed in the DX NetOps Spectrum OneClick console.

F1822: fltEqptcapacityFSPartitionFsPartitionLimitsExceededCritica

This fault occurs when a disk usage of a partition increases beyond its threshold. The ACI sends fault to DX NetOps Virtual Network Assurance and from DX NetOps Virtual Network Assurance, DX NetOps Spectrum receives the fault. Also, generates SNMP fault in DX NetOps Spectrum for that corresponding node. The SNMP fault and ACI fault are correlated and displayed in the DX NetOps Spectrum OneClick console.

In all the above scenarios the correlations are performed between SNMP fault and DX NetOps VNA Fault of Spine/Leaf. The SNMP fault is shown as the root cause and DX NetOps VNA fault is shown as a symptom.

ACI Events

DX NetOps Spectrum processes ACI events that are received from DX NetOps Virtual Network Assurance. By default, all DX NetOps VNA alarms are asserted with event code 0x673000c and event assertion 0x673000b. This event contains event conditions such as fault code and entity ID, which help to generate a corresponding Pcause code.

Steps to check if a fault code is supported by DX NetOps Spectrum:

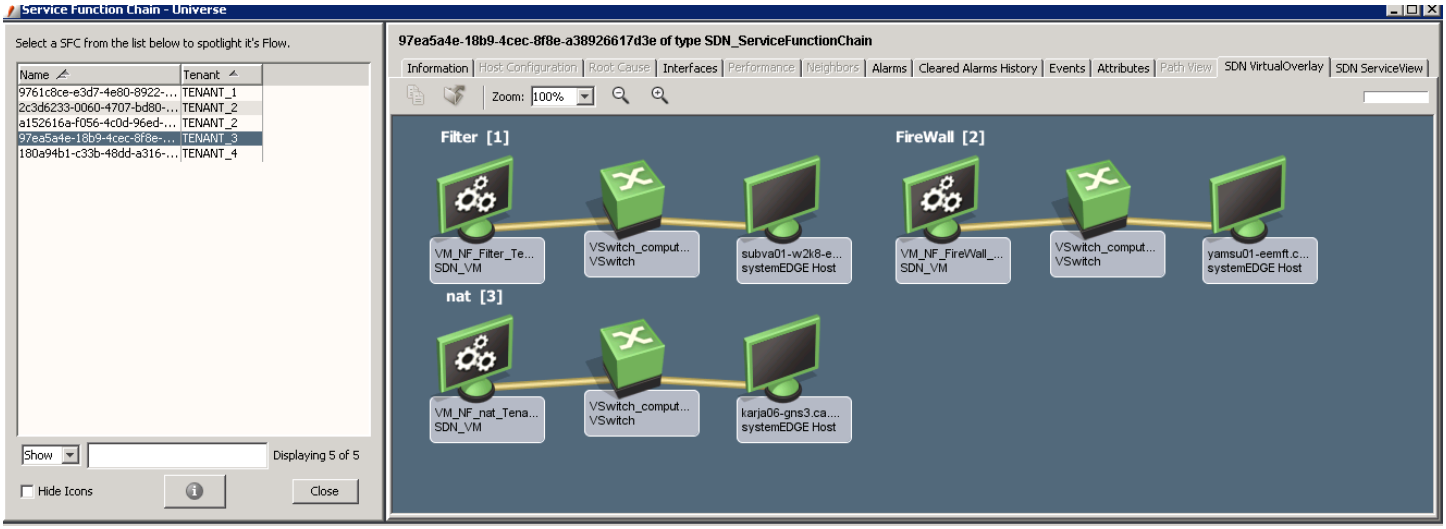
1. Go to Location <$SPECROOT>/SS/CsVendor/SDN
2. Open the SDN EventDisp file in a text editor
3. Search for the fault code in the file. For example, if you want to check fault F0532, search for 0532 in the file.
4. If you find an uncommented entry under CA EventCondition rule, then the fault is supported by DX NetOps Spectrum.
5. If you do not find any entry, then the fault is not supported by DX NetOps Spectrum.

NOTE

Due to the huge number of rules attached to this particular event code 0x673000c, you cannot modify it from the Event configuration Editor. But, you can directly open the event code file in a text editor and modify it.

SDN Virtual Overlay

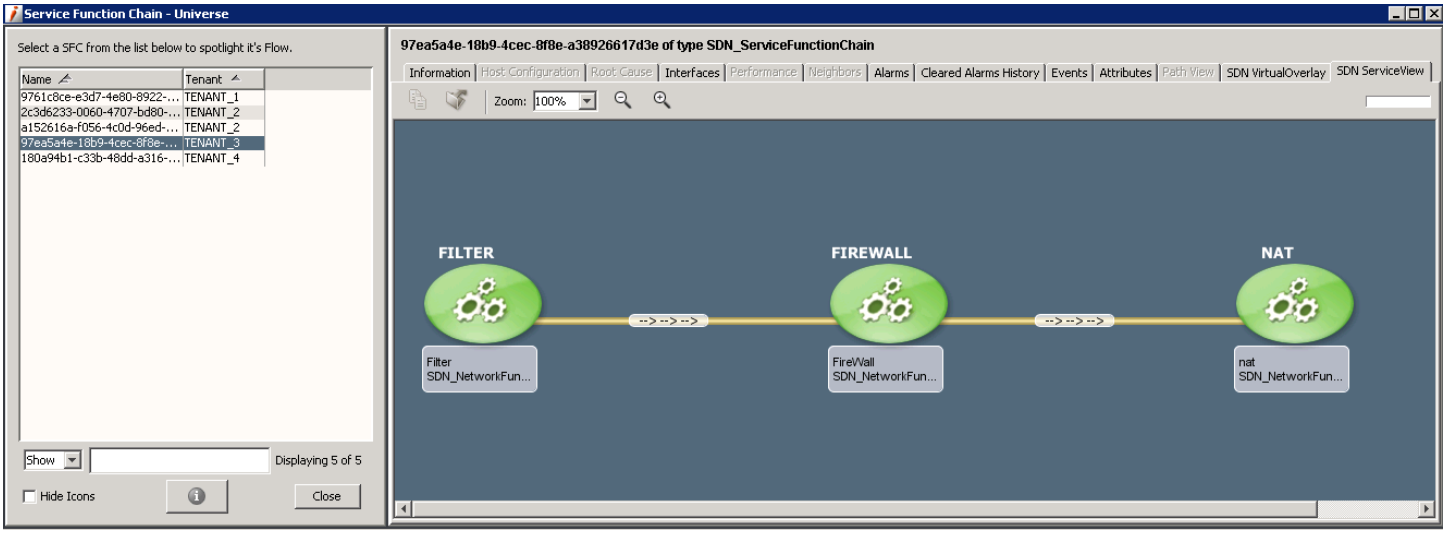
The SDN Virtual Overlay tab shows the network functions that are part of the selected SFC and Compute on which these network functions are hosted.



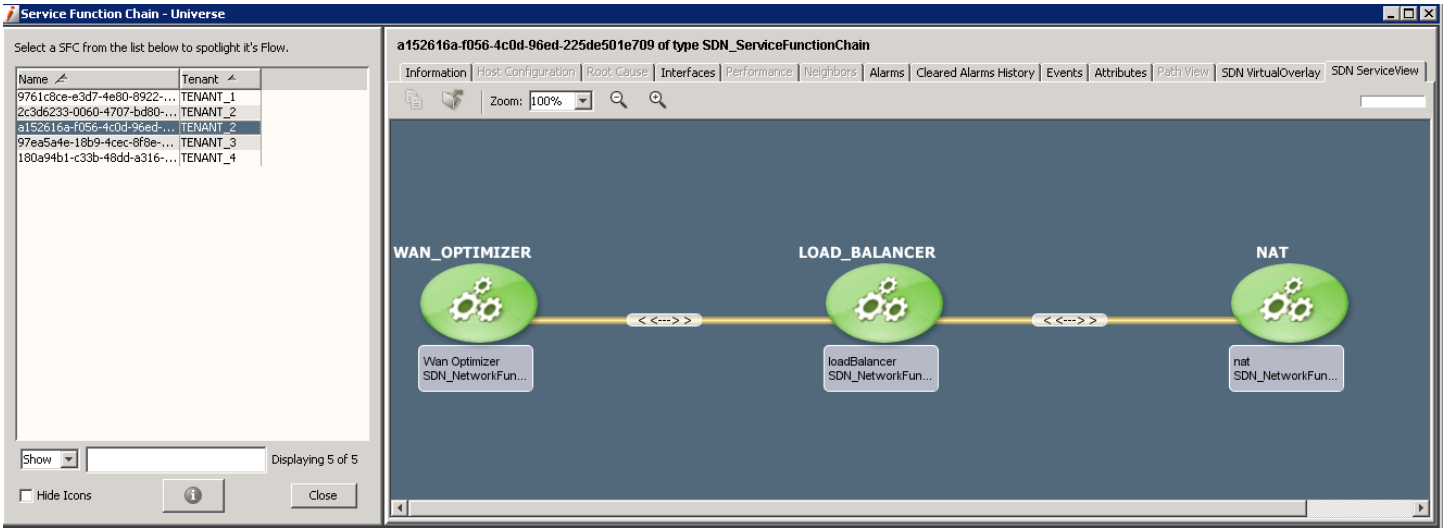
SDN Service View

The SDN Service View tab allows you to view the order of the network functions and direction of the packet flow (unidirectional or bidirectional) for the selected Service Function. The following images show how the Unidirectional and Bidirectional Service View looks like.

Unidirectional Service View:



Bidirectional Service View:



Monitoring VMware vSphere with ACI

DX NetOps Virtual Network Assurance 3.5.1 supports vSphere which communicates to vCenter and gives detailed information about data centers, ESXs and VMs. DX NetOps Spectrum then models all these entities and displays the entire topology from the leaf switches to the VMs, provided the vSphere is integrated with Cisco ACI.

The following are the prerequisites to see the topology:

1. SNMP must be enabled on ESXi Host.
2. DVS should have been created by ACI as part of ACI/VMware integration.
3. Hosts should be connected to Leaf switches.

Following is the topology view:

SDN_VM

NOTE

here is no connectivity between VMs and vswitch/DVS.

ACI and vSphere plugin correlation

Cisco ACI integrates with the VMware vCenter instances to transparently extend the Cisco ACI policy framework to VMware vSphere workloads. Cisco ACI creates a virtual distributed switch (VDS) in VMware vCenter to create a virtual network. From that point onward, Cisco ACI manages all application infrastructure components. The network administrator creates EPGs and pushes them to VMware vCenter as port groups on the DVS. Server administrators can then associate the virtual machines and provision them accordingly.

Viptela IWAN

Viptela is an SD-WAN solution. DX NetOps Virtual Network Assurance collects inventory and performance metrics from Viptela to support SD-WAN monitoring.

The plug-in collects inventory for the following items:

- Sites
- vEdge router
- vEdge interfaces
- Tunnels
- vManage
- vSmart
- Application/SLA Paths

Refer to Device Certifications section for more information about vEdge router, vSmart Controller, vManage, and vBond Orchestrator certifications.

To know more about SD-WAN support for Viptela, refer to the DX NetOps VNA Documentation for Viptela.

Service Function Chain (SFC)

The Service Function Chains that are configured in the SDN environment are displayed in DX NetOps Spectrum.

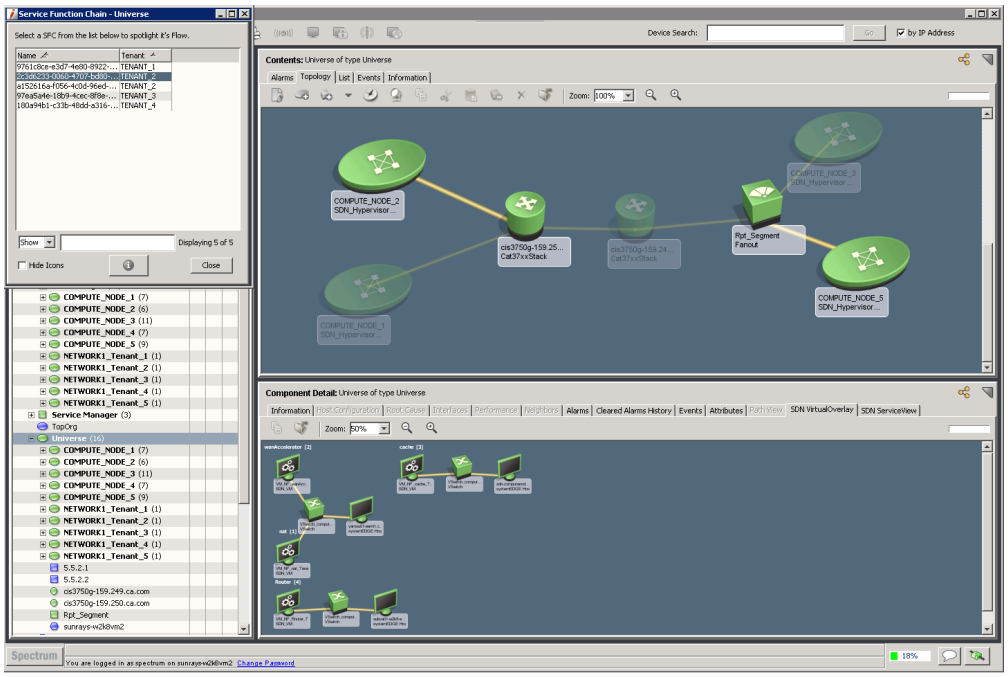
Follow these steps:

1. Open **OneClick**.
2. Expand the desired landscape on the **Explorer** tab and select **Universe**.
   Details about the selected **Universe** appear in the **Contents** panel.
3. Click the **Topology** tab.
4. Click the Spotlight View icon

   ,
   then select **Service Function Chain** from the list.
   The Service Function Chain dialog displays the list of SFCs and tenants that are associated with each SFC.
5. Select a **Service Function** from the list.
   The computer which has VMs associated with the SFC are highlighted in the Universe.

   NOTE
   The SDN Virtual Overlay and SDN Service View tabs in the Component Detail panel are enabled only when you select Universe.



NOTE

You can use the **Hide Icons** option in the **Service Function Chain List** dialog to view only the selected Service and its connections.

NOTE

To view Component details like SDN Service View and SDN Virtual Overlay details for the selected model in the Service Function list, click information the icon on the SFC dialog.

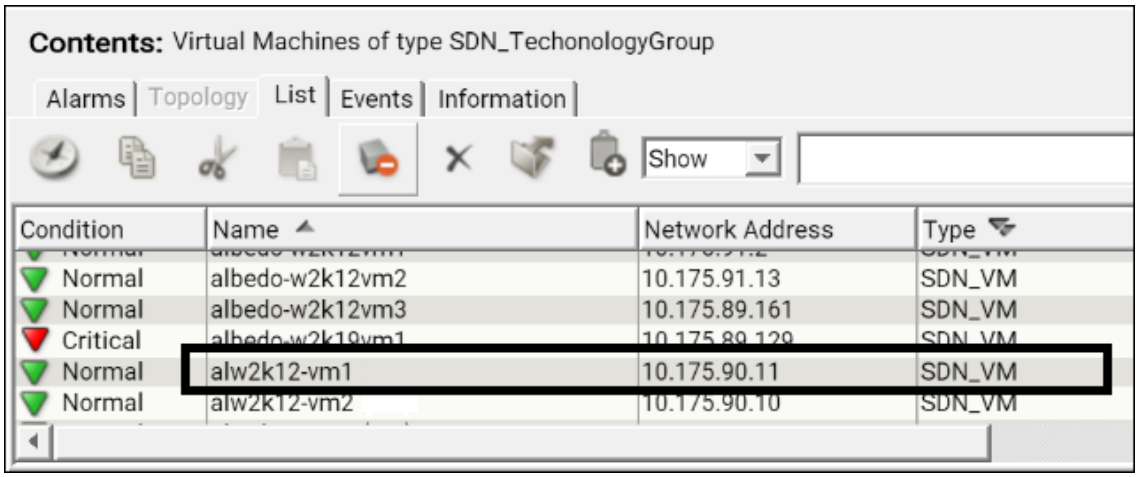
6. The Service Function Chain page integrates service chains into the traditional monitoring environment. The page shows you SDN Virtual Overlay and SDN Service View and also shows the physical and virtual connections of the Compute in the Service Chain.

Upgrade IP Devices to SNMP Devices

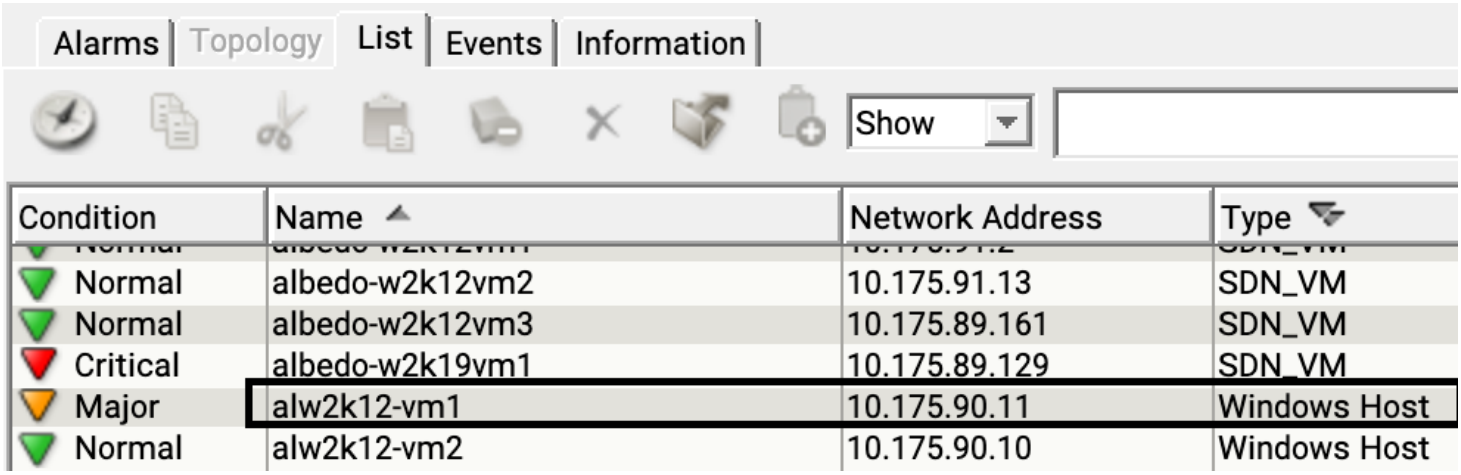
From 10.4.2, you can upgrade your existing IP pingable devices and re-model the devices to support SNMP services. You can search for these SDN IP pingable devices from the Explorer tab in OneClick. You must set the **ApplySNMPCapabilitiestoSDNVMs** attribute to **Yes** to monitor the devices as SNMP devices.

Follow these steps:

1. Select **SDN Manager** in the **Explorer** tab to view the devices.
2. Select **List** view in the **Contents** section.
   You can see a list of all devices.



3. Select **SDN Manager** in the **Explorer** tab.
4. Select **Attributes** tab, in the **Component Detail** section.
5. Search the **ApplySNMPCapabilitiestoSDNVMs** attribute.
6. Right-click the **ApplySNMPCapabilitiestoSDNVMs** attribute and select **Add**.
   The ApplySNMPCapabilitiestoSDNVMs attribute is moved to the right-hand section.
7. Right-click the **ApplySNMPCapabilitiestoSDNVMs** attribute and select **Edit**.
8. In the **Edit SDN Manager** popup, uncheck **No change** and select **Yes**.
9. Select **OK** to apply the change.
   The **Attribute Edit Results** window shows the status.
10. Close the window, on the successful assignment of the attribute.
    DX NetOps Spectrum deletes the existing SDN_VM devices which are SNMP reachable and remodel them as SNMP devices. The **List** view in the **Contents** section shows the new devices. The **Type** column shows the SDN_VM as a corresponding SNMP Model.



Disable SNMP Modeling

From 10.4.2.2, you can disable SNMP model devices from SDN Manager. By default, **Disable SNMP Modeling** option is set to **NO**. If you Enable VNA integration with **Disable SNMP Modeling** option as NO, all the devices which are SNMP reachable get modeled as SNMP model. When DX VNA integration is disabled all DX VNA models except SNMP are deleted.

If you re-enable the integration with DX VNA with the **Disable SNMP Modeling** option as NO, Since SNMP models are already existing, models are reconciled and not duplicated. Enable DX VNA integration with the **Disable SNMP Modeling**

option as YES, devices that are SNMP reachable are modeled as virtual models and duplicate models for the same IP are created (No reconciliation).

> **NOTE**
> Irrespective of **Disable SNMP Modeling** option, SPINE, and LEAF switches are modeled as SNMP only.

Dump OCS DX VNA Inventory Cache

From 10.4.2.2, inventory cache which maps DX VNA entities with DX NetOps Spectrum model handles, will be dumped in the connected OneClick server. A CSV file is generated under tomcat logs.

If No (Default), IP devices from DX VNA integration are modeled through SNMP discover. Devices which are not SNMP reachable, are modeled as a virtual device. If Yes, IP devices from DX VNA integration are modeled as virtual devicæs irrespective of their SNMP reachability. Hence, the overall discovery end modeling time is reduced. Duplicate models may be crested for SNMP devices modeled prior to the DX VNA integration (No reconciliation).

> **NOTE**
> This configuration is ignored for Cisco ACIswitches (SPINE/LEAF) as DX NetOps Spectrum always them to be SNMP enabled.

Follow these steps:

1. Navigate to Locator, SDN Manager, Information tab
2. Select SDN Manager Configuration
3. Select **Dump Now** in the **Dump Inventory** field.

Troubleshooting ACI Faults

How To Enable Debug Logs for ACI Faults in DX NetOps Spectrum

Symptom: I want to see debug logs for ACI Faults in DX NetOps VNA Integration to troubleshoot ACI inventory and faults.

Solution:

Follow these steps:

1. Go to OneClick **Administration** Page.
2. Select **Debugging** option from the menu bar.
3. Select the **Web Server Debug Page (Runtime)** The Debug Controller table appears.
4. Search for **VNA Integration Information** and select the **On** radio button.
5. Search for **VNA Notification Sync** and select the **On** radio button.
6. Go to $SPECROOT/tomcat/logs and check the debug logs for **Notification Registration**, **Historical** and **Live ACI faults** in catalina.out/stdout.log files.

When the DX NetOps VNA Integration is enabled, ACI Historical Faults are not received in OneClick Console

Symptom: When DX NetOps Spectrum is integrated with DX NetOps VNA, I cannot see Historical Faults for ACI in DX NetOps Spectrum OneClick Console.

Solution:

Follow these steps:

1. Enable Debug logs (see "How to enable debug logs" steps mentioned in the above topic)
2. Verify if the DX NetOps VNA database contains Faults.
   To verify follow these steps:

a. Log in to DX NetOps VNA host.
b. Navigate to cd /opt/CA/MySql/bin.
c. Run the following commands:
./mysql -u user -p (user should be Installed user name)
use vna
select * from notifications where notificationType='Alarm';

3. If the VNA database contains faults and those faults are not received in OneClick Console, then verify whether the Web Socket Connection is established between DX NetOps Spectrum and CA VNA.
To verify follow these steps:
a. Go to OneClick **Administration** Page.
b. Go to **VNA Configuration**.
c. Click the **Test** button to check the Web Socket Connection status. You can see 'Test connection to VNA Server was successful' message.
d. Go to $SPECROOT/tomcat/logs and check for connection time out log in catalina.out/stdout.log files.

ACI Live Faults are not received in OneClick Console

Symptom: When DX NetOps Spectrum is integrated with DX NetOps VNA, I cannot see ACI Live Faults in DX NetOps Spectrum OneClick Console.

Solution:

Follow these steps:

1. Verify the VNA database if the faults are received from APIC and also check the fault status.
To verify the DX NetOps VNA database, follow these steps:
a. Log in to DX NetOps VNA host.
b. Navigate to cd /opt/CA/MySql/bin.
c. Run the following commands:
./mysql -u user -p (user should be Installed user name)
use vna
select * from notifications where notificationType='Alarm';
2. If the faults state is shown as 'cleared' then those faults not received in DX NetOps Spectrum OneClick Console.
If the faults state is other than cleared, then verify the catalina.out/stdout.log files in $SPECROOT/tomcat/logs.

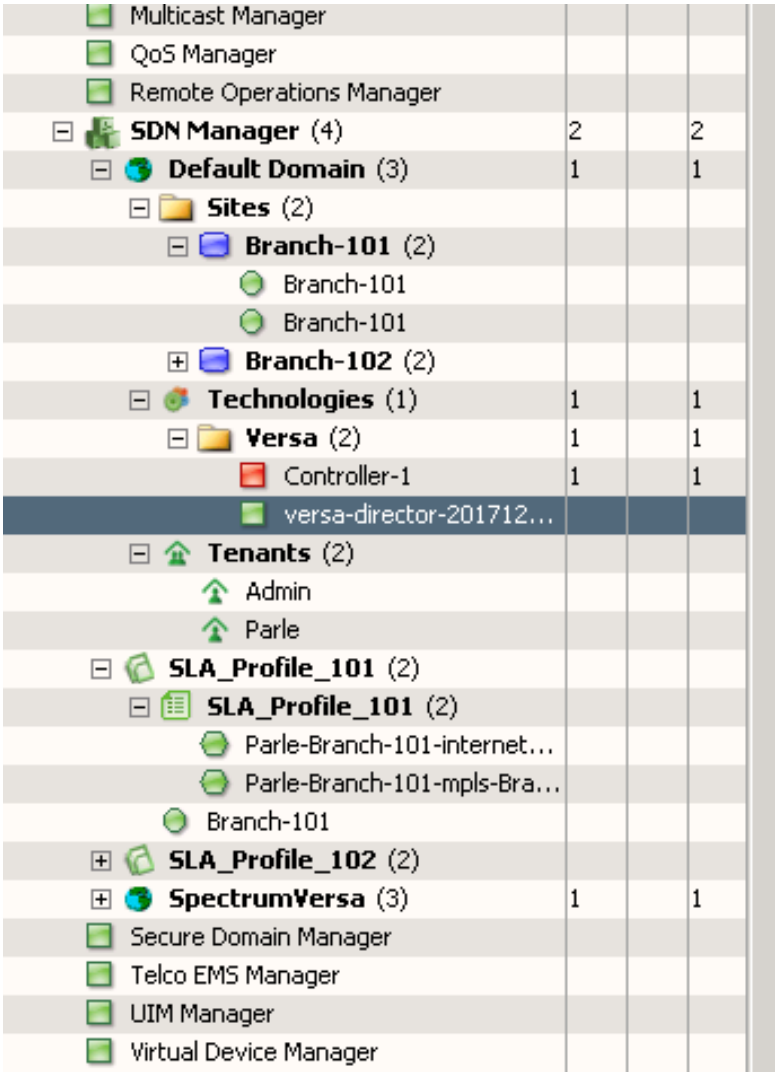
Monitoring SD-WAN for Versa

10.3.1 supports the monitoring of Versa devices through DX NetOps VNA integration. When DX NetOps Spectrum is integrated with DX NetOps VNA (configured with Versa plug-in), DX NetOps Spectrum receives the inventory information of the Versa devices through DX NetOps VNA.

> **NOTE**
> VNA configured with Versa plug-in. acts as an SDN Gateway to collect Versa inventory information and forwards information to DX NetOps Spectrum. Ensure that the DX NetOps VNA must be configured with Versa plug-in.

The DX NetOps Spectrum and DX NetOps VNA integration fetches the following Versa entities inventory information and displays under the SDN Manager hierarchy in OneClick.

- Sites
- Branch Router
- Director
- Controller
- Policy Group



This integration supports Versa entities synchronization. When the DX NetOps Spectrum and DX NetOps VNA integration is enabled, synchronization happens automatically at the scheduled time interval. Additions, deletions, and modifications of Versa entities in a Versa environment are reflected in DX NetOps Spectrum.

Versa Topology

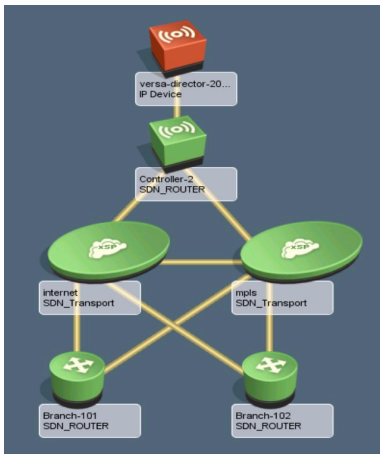
DX NetOps Spectrum displays topology for Versa devices.

Topology for Director

The overlay topology is seen by clicking the director, it displays the devices and how they are connected through the various transports.

Hub-Spoke Topology:

- The Director model connects to the controller models directly.
- Branch routers (BRs) are inter-connected to each other through transports.
  For example, MPLS transport, Internet transport and so on.
- The controller also has a connection towards branch routers through transports - as shown in the following image:



IMPORTANT
Topology is supported only for non-SNMP Versa models created by DX NetOps VNA Integration.

Versa Inventory

You can view the Versa entities such as Branch Router, vBond, Controller, Director in the OneClick console. Logical entities such as Sites and Policy Groups can also be viewed on the OneClick Navigation page. A new container '**VNA Inventory**' is created under the Universe view, this container has the Versa entities. In the Explorer View, **SDN Manager** provides a more detailed hierarchy i.e. ***Domain > Sites > Policy Groups > Policy > branch routers*** , compared to the **VNA Inventory** view, which only displays the hierarchy of branch routers and associated Tunnels.

Reconciling Versa Entity Data in DX NetOps Spectrum

During DX NetOps VNA data synchronization, when a new Versa entity is created in versa, it is reported to DX NetOps Spectrum. DX NetOps Spectrum performs a search to identify if this entity was modeled during DX NetOps Spectrum discovery and modeling. If such an existing model is found, DX NetOps Spectrum reconciles the CA Versa entity information with the existing model, instead of creating a model.

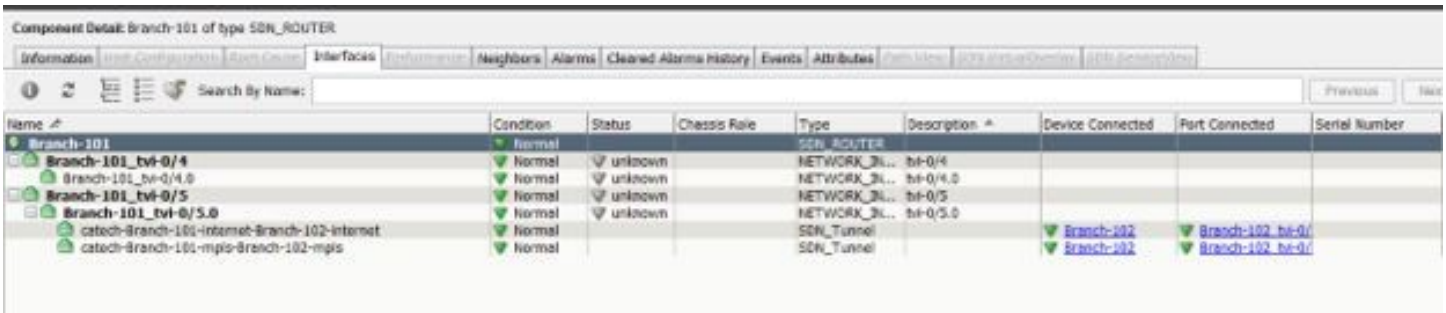
Interfaces Information

As a user, you can see the tunnels that are associated with the interfaces under the **Interfaces** tab.

- Tunnels
- Physical Interfaces
- Transport

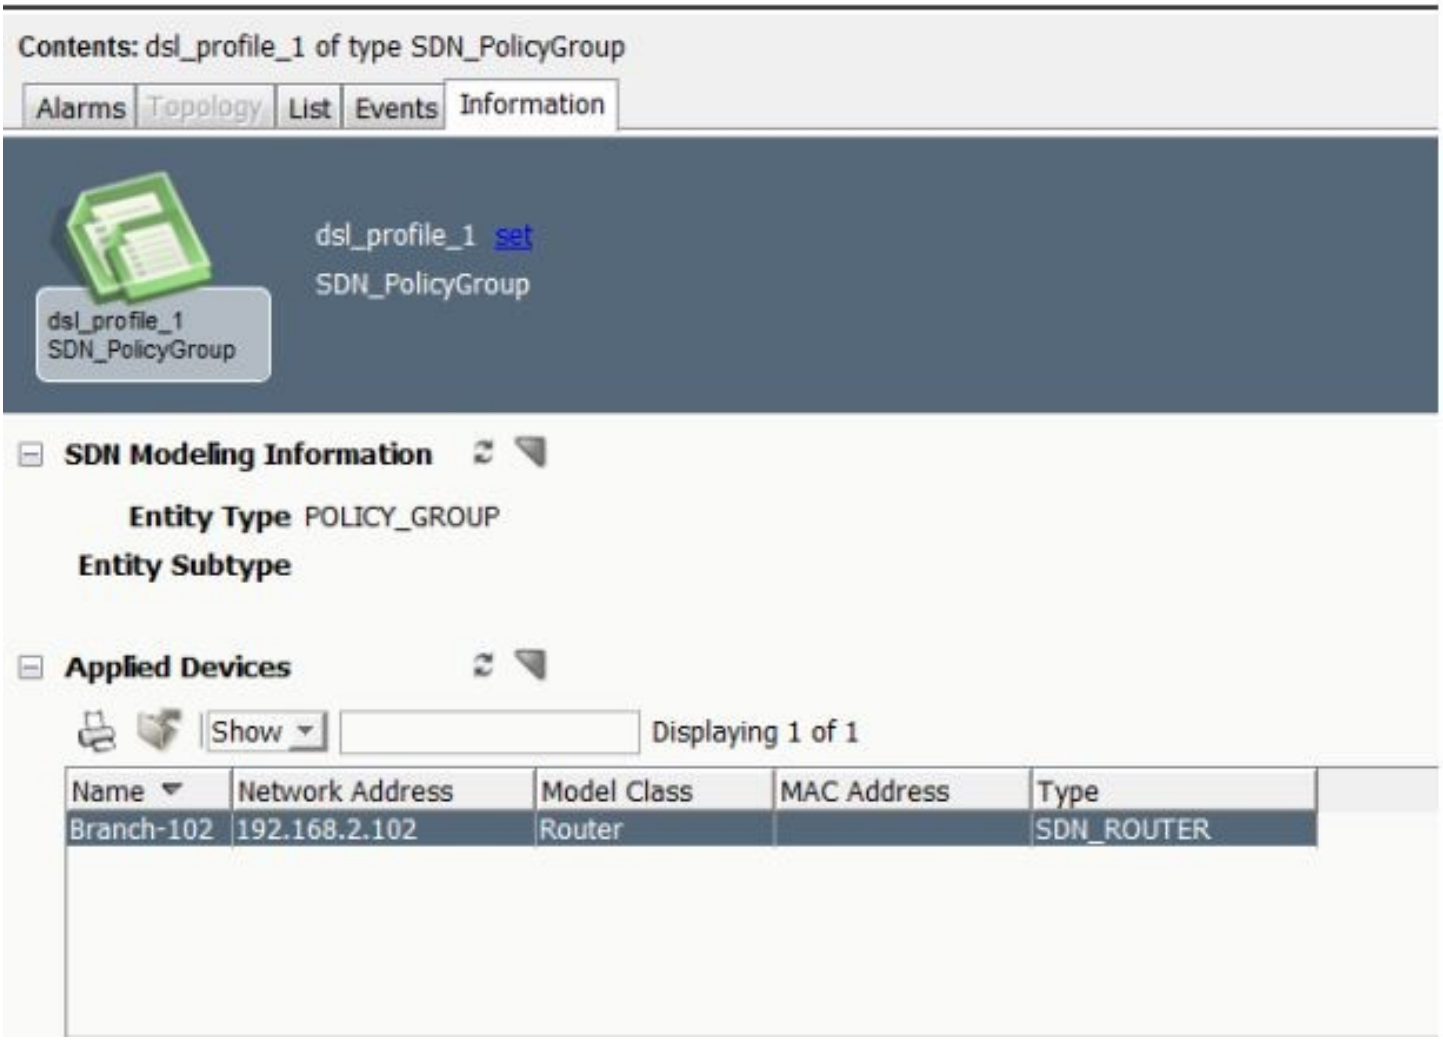
SDN Tunnels associated to Branch Router Interfaces

The Interfaces tab in the Component Details panel shows all the tunnels information which is associated with the selected branch router.



Policy Group

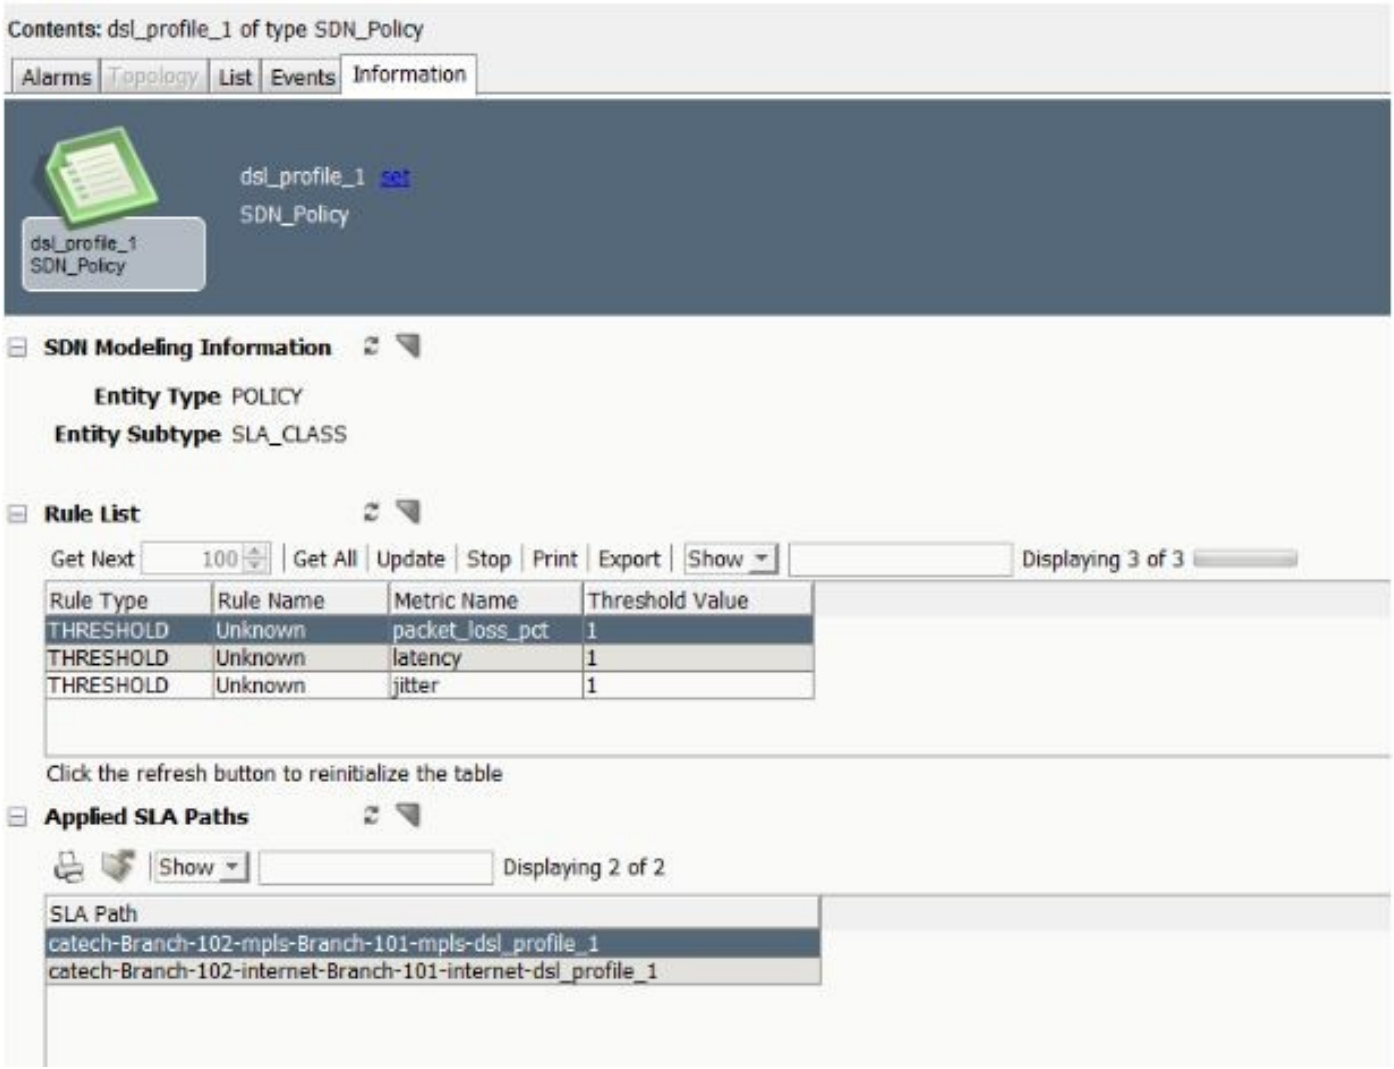
As a user you can see the edge router to which the policy group is applied:



Policies Information

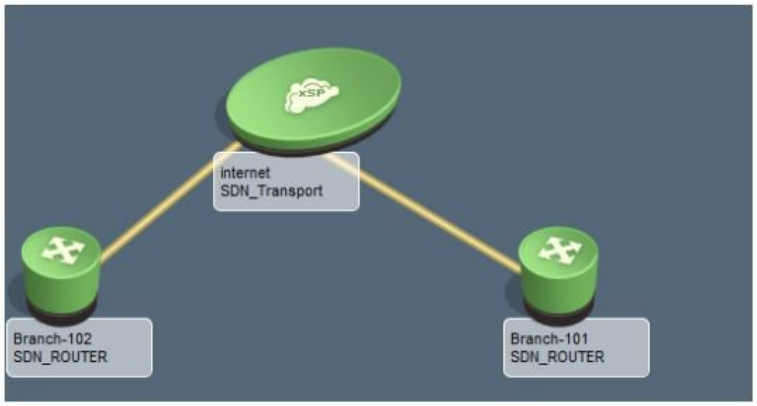
On clicking the policy, as a user, you can see the metrics that are associated with the policy and the SLA paths applied. For branch routers, associated policy and policy group information is displayed in the **Information** tab of the contents panel.

Branch router Policy Information



SLA Path

As a user you can see the edge devices and their transport associated with the SLA path:



Prior to the 10.4.2.2 release, SLA Path used to have the "Topology tab" which displayed the Branch routers connected through Transports. From the 10.4.2.2 release, same connections are shown under the SDN Overlay tab. SLA Path models are not displayed under the SDN Manager hierarchy. You can use the locater search to find SLA Path.

Events Generated in Versa Analytics

The following table provides information about the supported alarm types, threshold values, and the default destination to which the alarms are exported. Following are the events that are generated under Versa analytics and pulled into DX NetOps Spectrum:

Alarm Type	Description	Default Destination
cpu-utilization	Generated when datapath CPU utilization exceeds the configured threshold value.	SNMP, Syslog, analytics
mem-utilization	Generated when datapath memory utilization exceeds the configured threshold value.	SNMP, Syslog, analytics
disk-utilization	Generated when disk utilization exceeds the configured threshold value.	SNMP, Syslog, analytics
org-session-utilization	Generated when the number of sessions of an org exceeds configured number of sessions.	SNMP, Syslog, analytics
device-session-utilization	Generated when the number of sessions exceeds the configured number of sessions for a device/appliance.	SNMP, Syslog, analytics
Interface-down	Generated when an interface (or sub-interface) goes down.	SNMP, Syslog, analytics
uplink-bw-threshold	Generated when current uplink bandwidth exceeds the configured uplink bandwidth of an interface.	SNMP, Syslog, analytics
dnlink-bw-threshold	Generated when current downlink bandwidth exceeds configured uplink bandwidth of an interface.	SNMP, Syslog, analytics
adc-server-down	Generated when the backend server does not respond to ADC monitors for a specified amount of time. Once the server is marked down, it is not considered for load balancing.	SNMP, Syslog, analytics
adc-vservice-down	Generated when all backend servers attached to virtual service are declared down because of monitor health failure. No traffic is served by this virtual service (VIP).	SNMP, Syslog, analytics
cgnat-pool-utilization	Generated when the CGNAT pool exceeds configured threshold value or when the pool is exhausted.	SNMP, Syslog, analytics
snat-pool-utilization	Generated when the SNAT pool exceeds configured threshold value or when the pool is exhausted.	SNMP, Syslog, analytics
ipsec-tunneldown	Generated when IPSEC tunnel with a peer goes down.	SNMP, Syslog, analytics
ipsec-ike-down	Generated when IKE connection that is established with a peer goes down.	SNMP, Syslog, analytics
bgp-nbr-state-change	Generated when BGP between peers goes down or comes back up.	SNMP, Syslog, analytics
vrrp-v3-new-master	Generated when VRRP router transitions to the MASTER state.	SNMP, Syslog, analytics
vrrp-v3-new-backup	Generated when VRRP router transitions to the backup state.	SNMP, Syslog, analytics
vrrp-v3-proto-error	This notification indicates that the VRRP router has encountered protocol error like version mismatch, checksum error, or VRRP group id mismatch.	SNMP, Syslog, analytics
ddos-threshold	Generated when DDOS traffic exceeds the configured aggregate/classified DDOS threshold.	SNMP, Syslog, analytics

zone-protection-flood	Generated when flood traffic exceeds the configured zone protection threshold value.	SNMP, Syslog, analytics
port-scan-flood	Generated when PORT-SCAN from a source to destination exceeds the configured zone protection profile value.	SNMP, Syslog, analytics
sdwan-branch-disconnect	Generated a branch gets disconnected from Controller.	SNMP, Syslog, analytics
sdwan-datapath-down	Generated when all paths between two branches go down.	analytics (From Controller)
dhcp-pool-utilization	Generated when DHCP addresses are exhausted and no more addresses can be allocated from DHCP address pools.	SNMP, Syslog, analytics
software-trial-expired	Versa appliance trial period expired.	SNMP, Syslog, analytics
software-trial-error	Versa appliance trial key tampered.	SNMP, Syslog, analytics
interface-half-duplex	Generated when an interface is detected to be in Half Duplex mode.	SNMP, Syslog, analytics
nexthop-down	Generated when nexthop gateway does not respond to monitors for a specified amount of time. Once nexthop is marked down, routes are withdrawn.	SNMP, Syslog, analytics
monitor-down	Generated when IP destinations that are part of the monitor does not respond to the given type of probe packets for a specified amount of time. Once the monitor is marked down, dependent routes are withdrawn and redistribution policies are recomputed.	SNMP, Syslog, analytics
software-key-about-to-expire	Versa FlexVNF key expires soon. Contact Versa Support to replace it with a new key. For unrestricted usage, ensure Versa FlexVNF is subjugated to Versa Director and there is connectivity between Versa FlexVNF and Versa Director.	SNMP, Syslog, analytics
ha-state-change	Generated when HA state changes from master to slave or vice versa.	SNMP, Syslog, analytics
ha-sync-status	Generated after configuration sync happens between active and standby. Either sync error (or) sync ok are reported.	SNMP, Syslog, analytics

Monitoring SD-WAN for Silver Peak

DX NetOps Virtual Network Assurance (DX NetOps VNA) enables existing infrastructure management solutions to monitor software-defined networking (SDN) and network functions virtualization (NFV). DX VNA reduces the challenge and risk of SDN/NFV deployments by providing extended visibility and sustained reliability for self-service, automated networks. DX NetOps VNA collects data from SDN/NFV controllers and orchestrators and provides that data to subscribers. Each orchestrator or controller requires a plug-in to configure the connection.

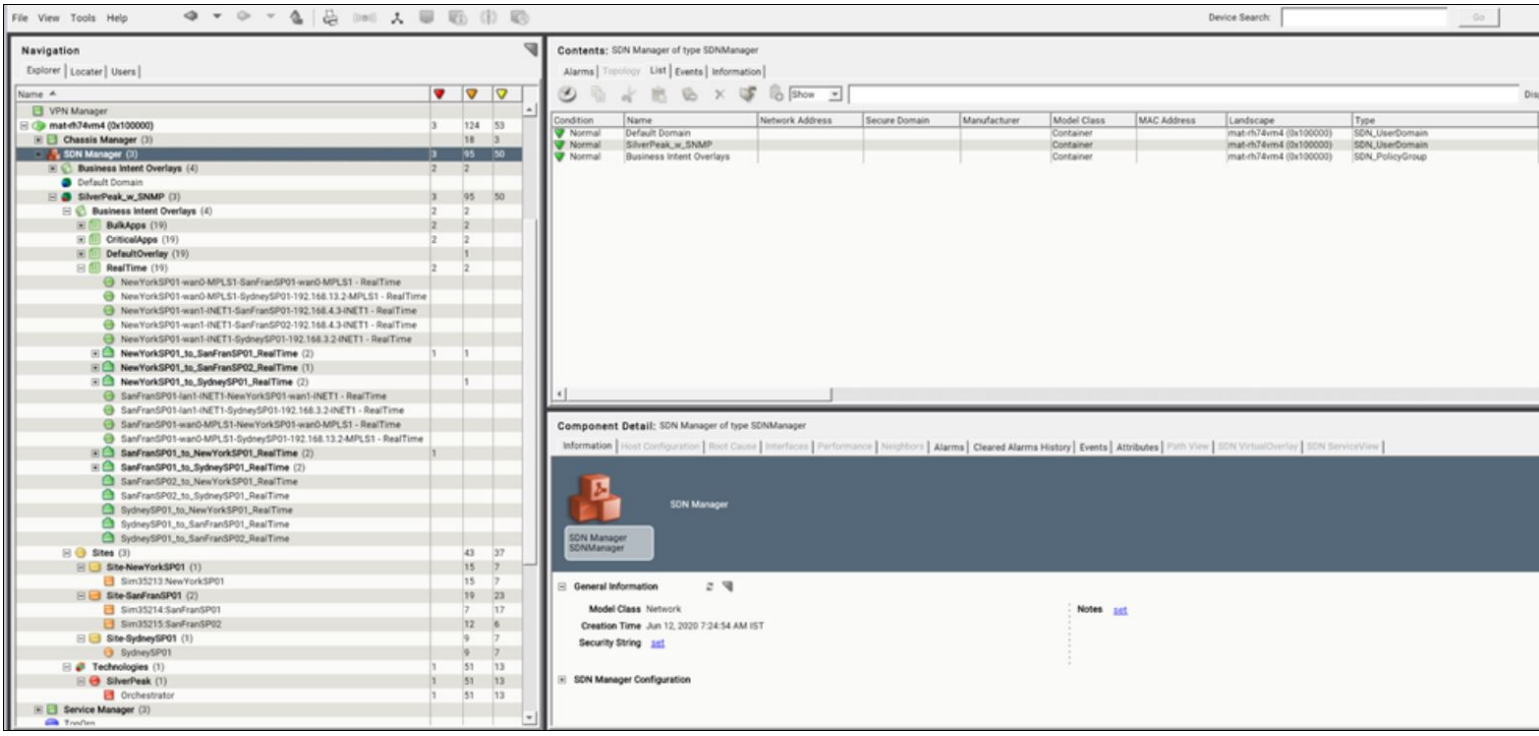
Orchestrator

DX NetOps Spectrum offers the following monitoring capabilities for the Silver Peak SD-WAN:

Inventory:
Orchestrator, Sites, Routers (Edges), SLA Class/Profile, Interfaces, Tunnels, Application/SLA Paths.



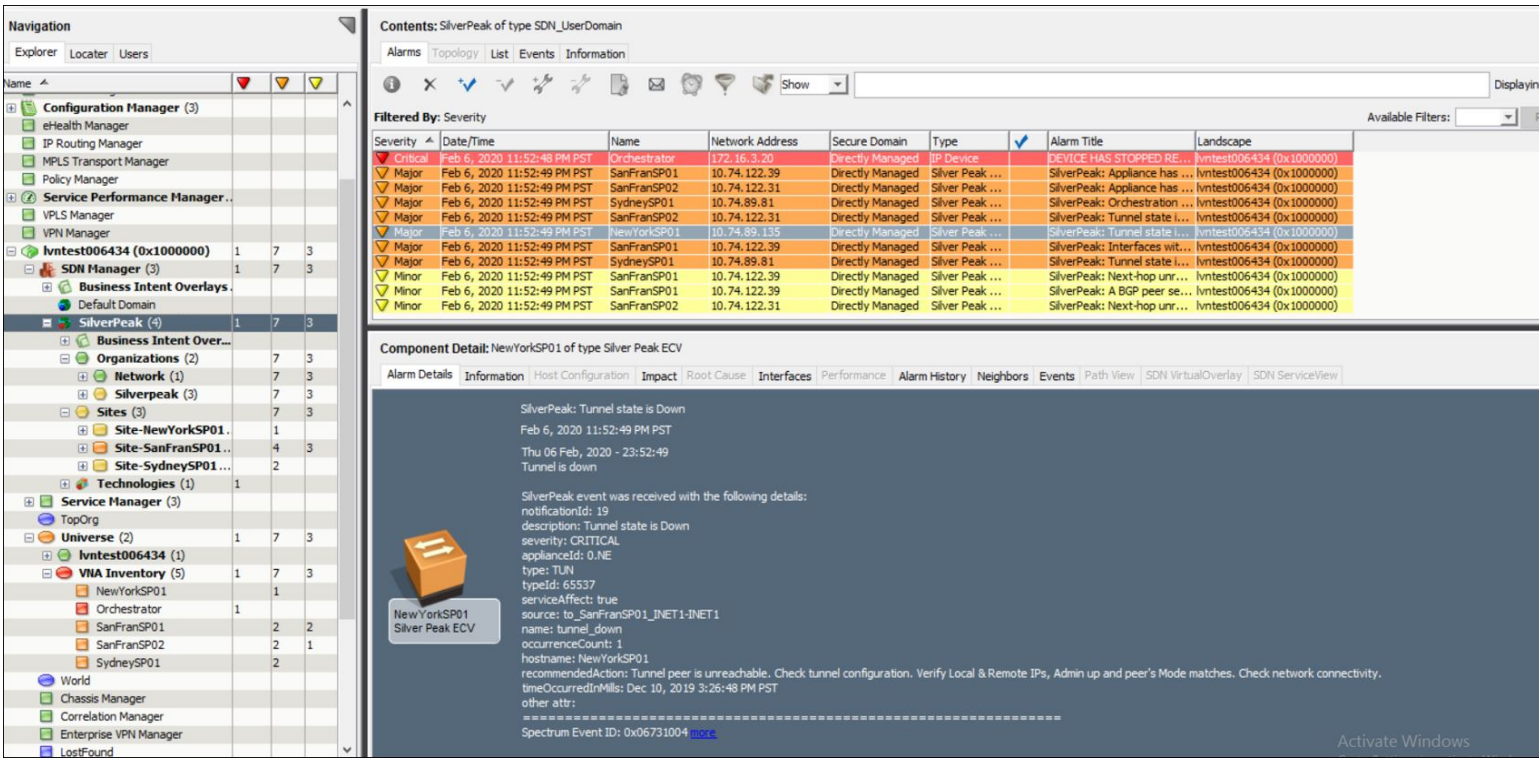
Performance

- Tunnels, SLA Path (Jitter, Latency, Packet Loss).
- SNMP statistics: interfaces, device health, UDP, TCP, SNMP, IP routing, IP/MAC address count, and IPv4 statistics.

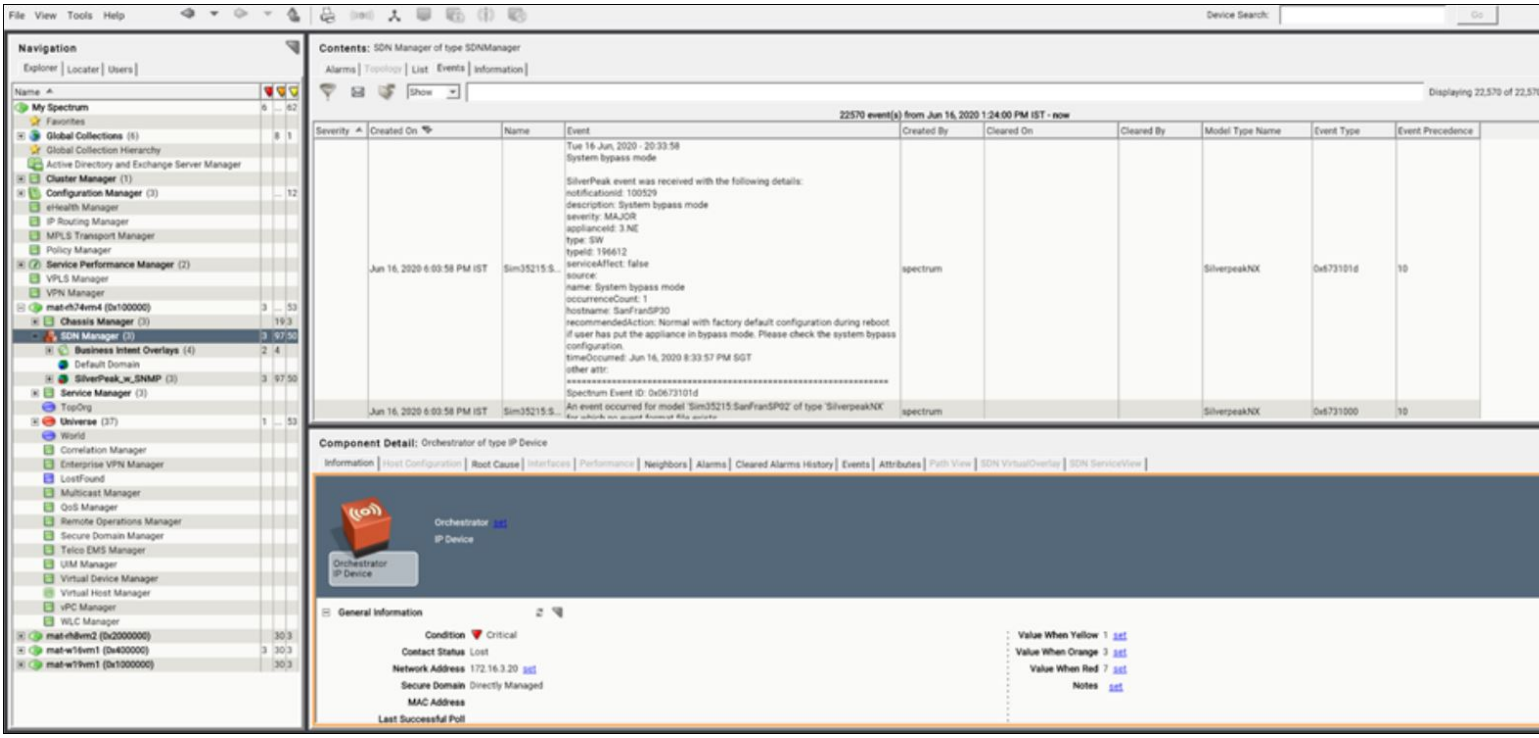
Alarms and Events

Supports over 200+ events for faster resolution of network issues.

Alarm View:



Events View:



Silver Peak SD-WAN Components

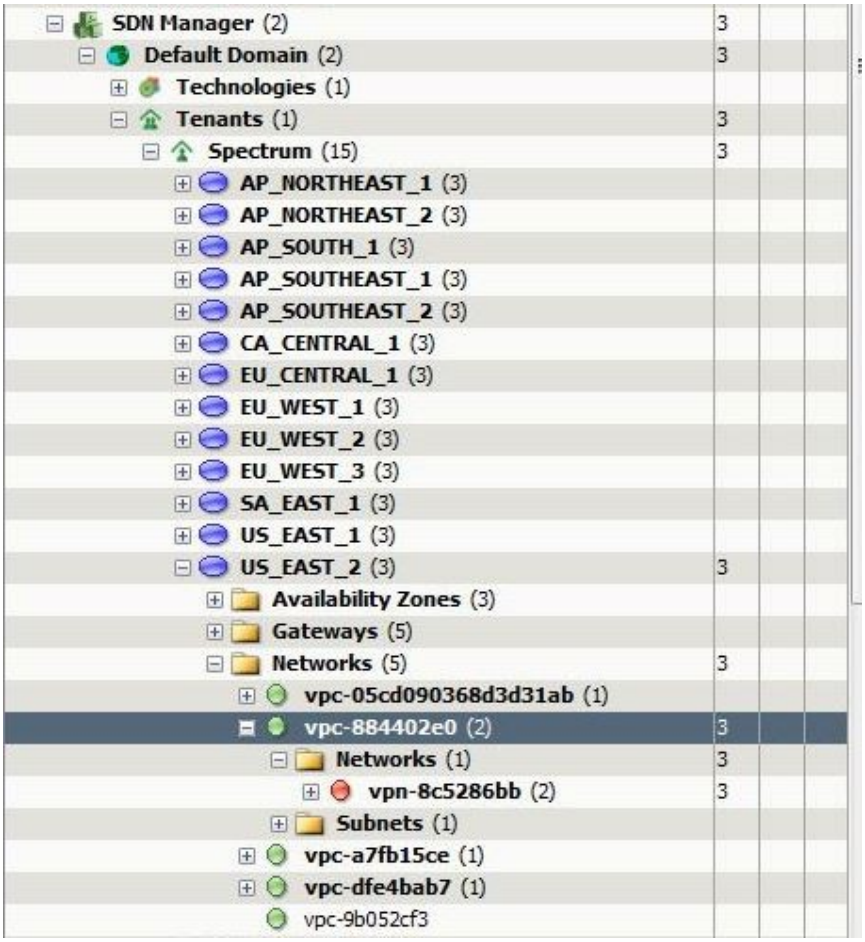
The Silver Peak SD-WAN has the following components.

- **Orchestrator:**
  Orchestrator was formerly called GMS (Global Management Software). An orchestrator is responsible for the management and configuration of Silver Peak EdgeConnect devices and NX/VX appliances. It centrally assigns policies to secure and control all WAN traffic. Orchestrator must connect to Cloud Portal for it to function.
- **EdgeConnect:**
  It can be either a physical or virtual appliances deployed in branch offices to create a secure, virtual network overlay. It is responsible for creating connections and must connect to Cloud Portal.

Support for AWS Network Monitoring

10.3.2 supports AWS Network Monitoring through the AWS VPN tunnel creation and direct connections. DX NetOps Spectrum monitors the tunnels on the VPN connection in the AWS Monitoring Network between the Virtual Private Gateway and the Customer Gateway through DX NetOps VNA notifications. The DX NetOps VNA and DX NetOps VNA integration fetches the following AWS entities inventory information in the given hierarchy and displays the same under the SDN Manager hierarchy in OneClick as shown in the screenshot below.

- Tenants
  - Regions
    - Availability Zones
    - Gateways
      - Internet Gateway
      - VPN Gatetway
      - Customer Gateway
      - NAT Gateway
    - Networks
      - VPC
      - Networks and VPN connection
    - Subnets
      - VMs



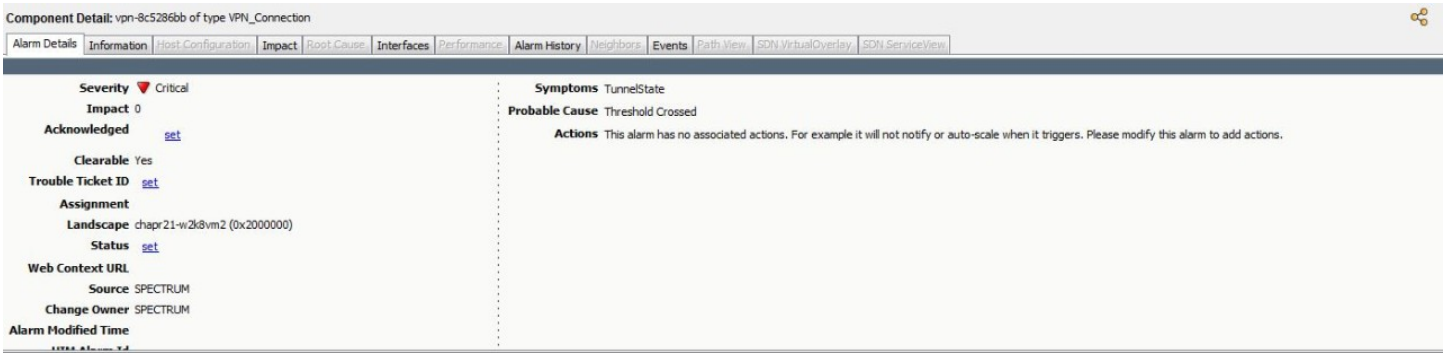
This integration supports AWS entities synchronization. When the DX NetOps Spectrum and DX NetOps VNA integration is enabled, synchronization happens automatically at the scheduled time interval. Additions, deletions, and modifications of AWS entities in a AWS environment are reflected in DX NetOps Spectrum.

Alarms Metrics

Following is the list of Alarm Metrics fetched from the AWS CloudWatch:

Alarm Metrics	Description	Value
TunnelState	Describes the state of the tunnel, for example, as shown below.	0 = down 1= up
TunnelDataIn	This is the bytes received through the VPN tunnel. Each metric data point represents the number of bytes received after the previous data point. The sum statistic to show the total number of bytes received during the period. The metric counts the data after decryption.	Bytes
TunnelDataOut	This is the bytes sent through the VPN tunnel. Each metric data point represents the number of bytes sent after the previous data point. The sum statistic to show the total number of bytes sent during the period. The metric counts the data before decryption.	Bytes

Here is an example of the TunnelState Alarm Metric details appearing in Spectrum, where the value is 0 signifying it is down.



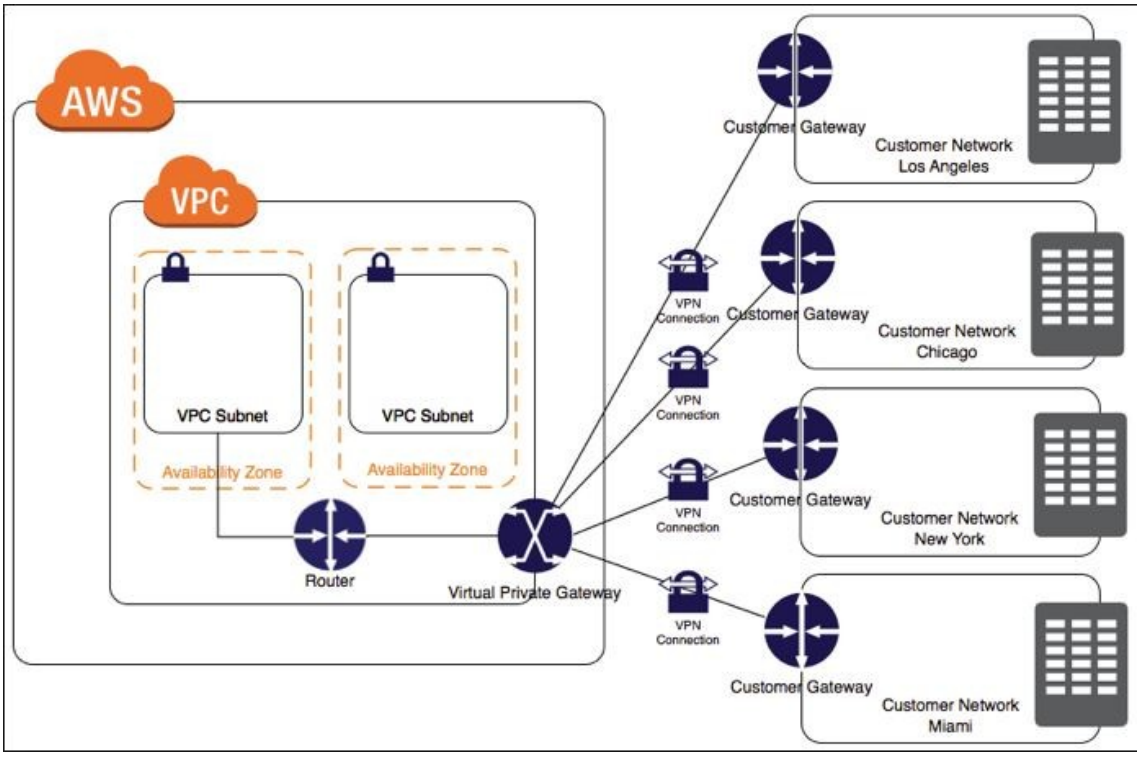
Fault Correlation

Fault correlation in the AWS Network Monitoring occurs between the VPN connection and the tunnels. If the VPN connection is down and the VPN tunnels are down, then the VPN connection is the root cause and the tunnel is the symptom (as shown in the screenshot above).

You can filter the AWS VPC VPN data using the following dimensions:

Dimension	Description
VpnId	The dimension filters the data by the VPN connection.
TunnelIPaddress	The dimension filters the data by the IP address of the tunnel for the virtual private gateway.

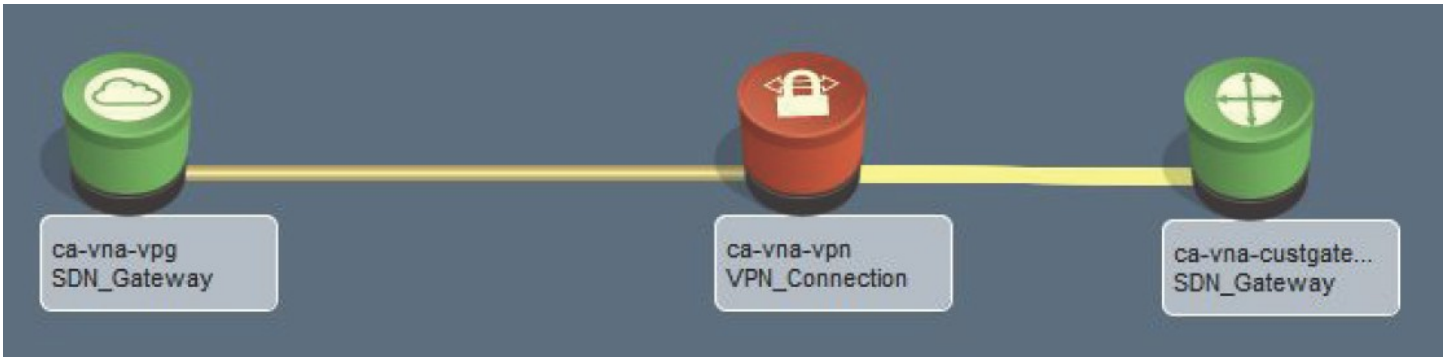
This is the AWS Network Monitoring diagram*



**This image is an intellectual property belonging to Amazon Web Services.*

AWS Monitoring Topology

The following screenshot displays the topology supported by DX NetOps Spectrum to monitor AWS network:



Icons

Following are the icons supported with this release:

Availability Zone

Availability zones (AZs) are isolated locations within data center regions from which public cloud services originate and operate.

VPN Gateway

Technology that provides network connectivity to AWS, is capable of acting as a router that intelligently forwards packets, manages availability between different network paths, and provides Virtual Private Network (VPN) or Software-Defined Wide Area Networking (SD WAN) services.

VPC

A virtual private cloud (VPC) is a virtual network dedicated to your AWS account. It is logically isolated from other virtual networks in the AWS Cloud. You can launch your AWS resources, such as Amazon EC2 instances, into your VPC. A VPC spans all the Availability Zones in the region. After creating a VPC, you can add one or more Subnets in each Availability Zone.

Customer Gateway

A customer gateway is an anchor on the user's side of the connection.

VPN Connection (down)

VPN is a managed client-based VPN service that enables you to securely access your AWS resources in your on-premises network.

Subnet

Subnet is a logical subdivision of an IP network. When you create a subnet, you specify the CIDR block for the subnet, which is a subset of the VPC CIDR block.

VM

Virtual Machine or 'instance'.

Reconciliation of models between VNA and UIM

During DX NetOps VNA data synchronization, when a new entity is created in AWS, it is reported to DX NetOps Spectrum. Spectrum performs a search to identify if this entity was modeled during DX NetOps Spectrum discovery and modeling or not, if it was, then the AWS data is reconciled through UIM, with the existing model, instead of creating a model.

Support for Cisco Meraki

Virtual Network Assurance and CA Spectrum 10.3.2 (or higher) support modeling of Cisco Meraki devices (Cloud Controller and Access Points) and proactive monitoring and managing of wireless networks. The monitoring information is provided by DX NetOps VNA, whereas, DX NetOps Spectrum relies on the inventory data from VNA to monitor and manage Meraki devices. The Access Points are modeled as certified SNMP devices, if they are SNMP- reachable, if not, then they are modeled as Access Point pingable models. To model the Access Points using SNMP, ensure the SNMP community string of the access points is added under the following:

- VNM→AutoDiscovery
- Control→Modeling
- Protocol Options-→SNMP Community Strings

Discovering connections between controller, switches and access points is based on the SNMP data available on the corresponding models, without which DX NetOps Spectrum cannot create any connections, and VNA cannot provide this connectivity information.

Properties of Cloud Controller and Access Points are displayed under the OneClick information tab. The operation status of Cloud Controller and Access Points is monitored based on the VNA inventory updates. Access Point availability is monitored through DX NetOps Spectrum and VNA inventory updates. If Access Point is unreachable from DX NetOps Spectrum (by Poll/Ping) and from VNA (OperationStatus is down), then a device unreachable alarm is asserted on the AP model.

Meraki Cloud controller dashboard exposes APIs to monitor its elements (Cloud Controller, Access Points, Service Appliances, Switches, Routers, and so on). VNA uses APIs to get monitoring data of DX NetOps Spectrum Controller and Access Points. DX NetOps Spectrum is integrated with VNA (using a Meraki plugin) that consume inventory information from VNA to model Meraki devices in the SDN/VNA manager hierarchy.

Following are the entities which are newly supported for Meraki under VNA:

- POLICY
- POLICY_GROUP
- SSID
- WIFI_CONTROLLER
- WIRELESS_NETWORK
- ACCESS_POINT
- MX_ROUTER

These entities are modeled in DX NetOps Spectrum with special model types. Meraki Cloud Controller is auto-modeled as a Wifi_Controller, which is a virtual entity.

The Cloud Controller properties are displayed under OneClick view, which contains:

- General Information, displaying the serial number, MAC, IP address, uptime, system name, location, condition/contact status, etc.
- Wireless Information, displaying the Access Points hardware details.

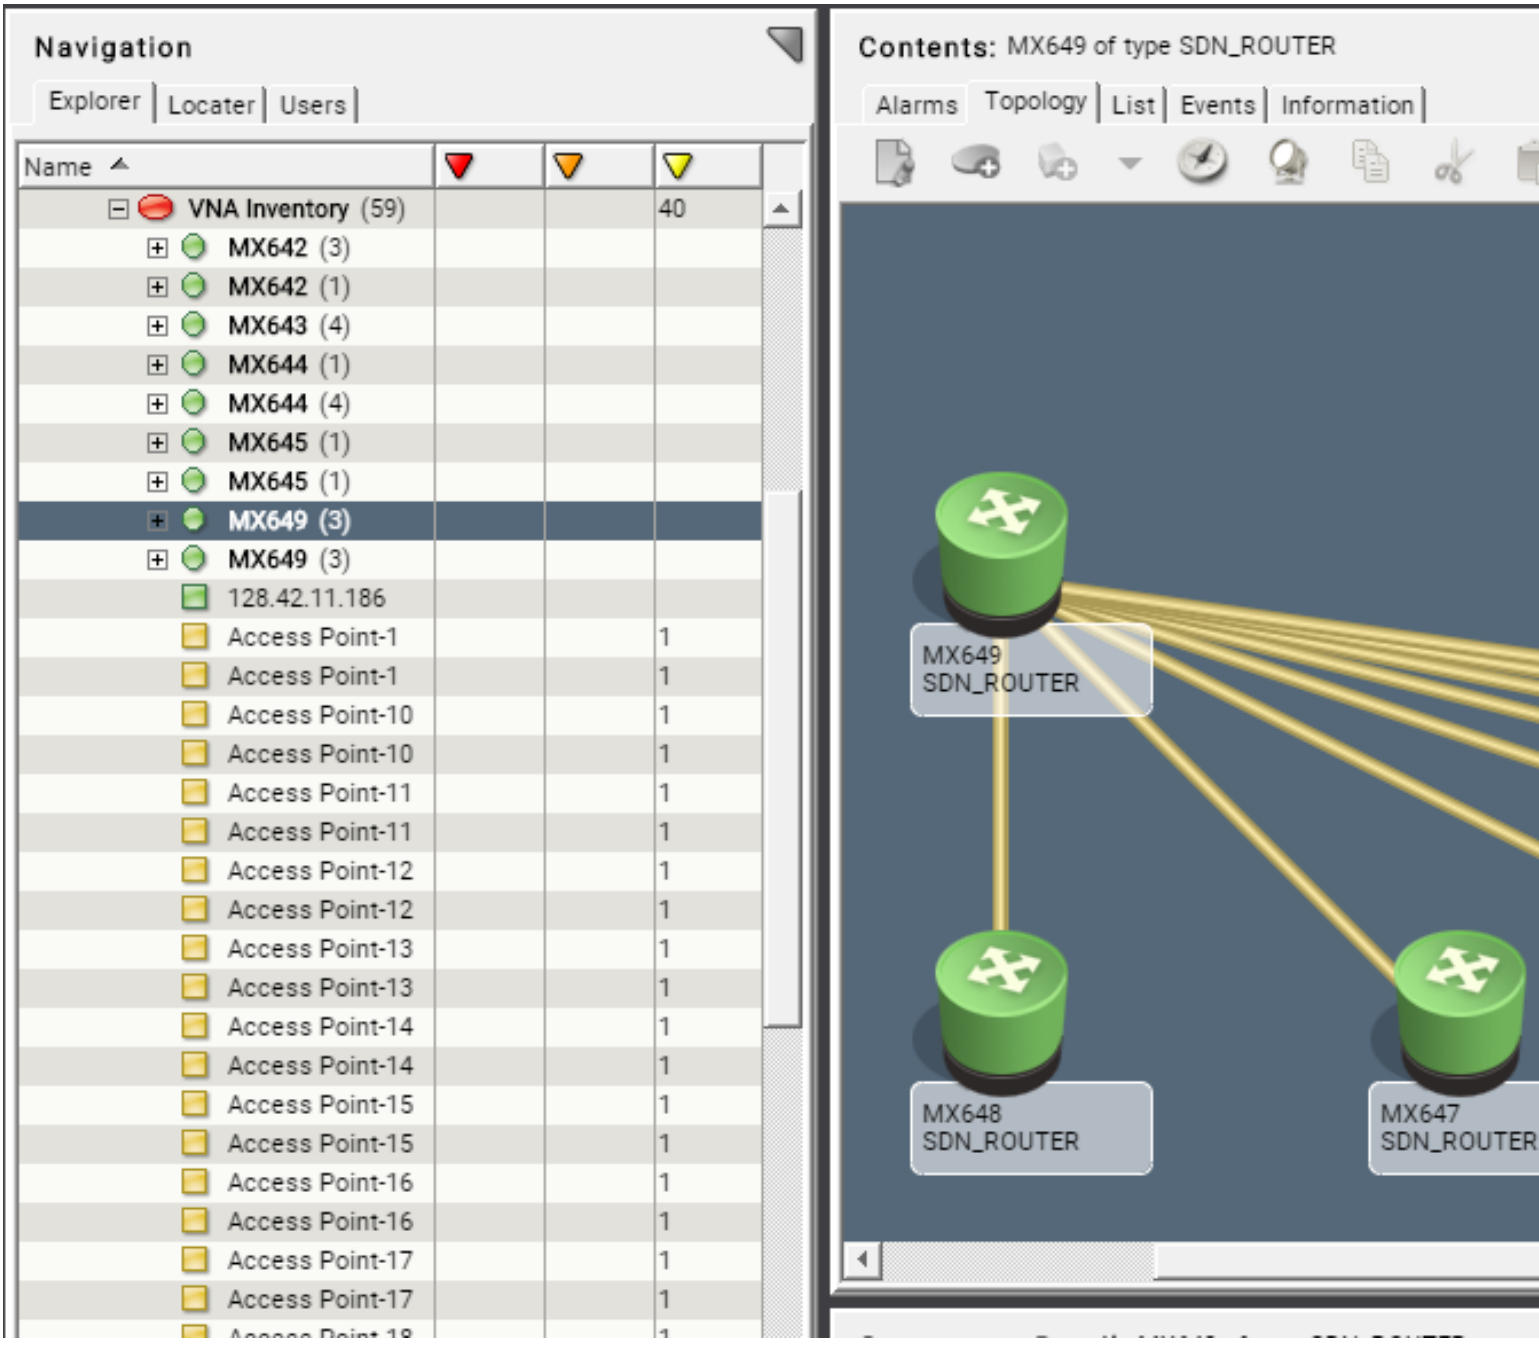
The Access Point properties that are displayed under the OneClick view are:

- General
- Asset Information

Hierarchy and Icons

Following is the hierarchy and icons that are supported with this release:

Organizations>Wireless Networks>Access Points, Appliances (MX Routers), and SSIDs



Organization

A collection of networks that are all part of a single organizational entity.

Access Points

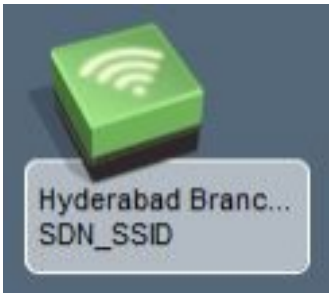
Access points provide deep network insight enabling smarter network management.

MX Router

MX Routers provide powerful routing, switching, security, and services features.

SSIDs

Service Set Identifier (SSID) is a unique identifier that is applied to the Access Point (AP) and the wireless client, allowing them to associate.



Cloud Controller

Cloud Controller is the control framework that allows various Cisco Meraki products to work together seamlessly, including indoor and outdoor wireless access points, switches, security appliances.

Events and Alarm

Events and alarms are raised on Meraki entities using the data that is provided by VNA. Following is the list of Events and Alarms identified:

MX Routers

Event Type	Description	Alarm Severity
events	VPN connectivity change	minor VPN_Connectivity=false
events	VPN connectivity change	Clear VPN_Connectivity=false
events	uplink connectivity change	critical Cellular Connection Down
events	uplink connectivity change	Major
events	uplink connectivity change	Major
events	uplink connectivity change	Clear Cellular Connection Down
events	client DHCP lease	NA
ids-alerts	ids signature matched	NA
ids-alerts	ids signature matched	NA
security_event ids_alerted	ids signature matched	NA
security_event security_filtering_file_scanned	Malicious file blocked by amp	Minor action="block"
security_event security_filtering_disposition_change	File issued retrospective malicious disposition	Clear Minor action="block"

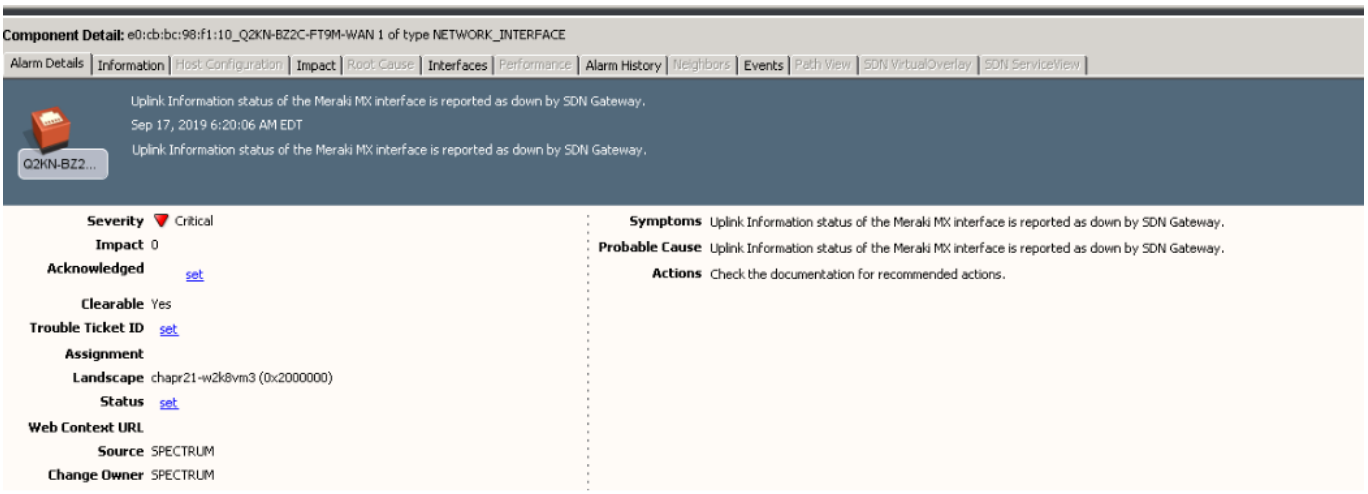
Meraki Dashboard API

The DX NetOps Virtual Network Assurance polls the Meraki Dashboard API. The following REST API returns mappings of above DX NetOps Spectrum alarm model fields to incident fields:

URL	GET /networks/{networkId}/devices/ {serial}/uplink

Response	<pre>[
	{ "interface": "WAN 1",
	"status": "Active",
	"ip": "1.2.3.4",
	"gateway": "1.2.3.5",
	"publicIp": "123.123.123.1",
	"dns": "8.8.8.8, 8.8.4.4",
	"usingStaticIp": false
	}
	]</pre>

In case the status of the uplink interface is down, the Virtual Network Assurance sends an update to DX NetOps Spectrum. Once DX NetOps Spectrum receives an update, it raises an alarm.



Access Points

Event Type	Event Description	Alarms
events	802.11 association	N/A
events	802.11 disassociation	N/A
events	WPA authentication	N/A
events	WPA deauthentication	N/A
events	WPA failed authentication attempt	N/A
events	802.1x failed authentication attempt	N/A
events	802.1x deauthentication	N/A
events	802.1x authentication	N/A
events	splash authentication	N/A
events	wireless packet flood detected	Minor
events	wireless packet flood end	Clear packet flood detected alarm

events	rogue SSID detected	Major

NOTE

There is no overlay topology for Meraki devices. The topology is formed based on the connections that are discovered as part of the regular/legacy SNMP discover connections action in DX NetOps Spectrum.

WARNING
Refer to SNMP Support for Cisco Meraki Solutions for a list of supported Meraki solutions, including wireless appliances and switches.

Monitoring SD-WAN for Viptela

Starting from the 10.3.1 release, DX NetOps Spectrum supports monitoring of Cisco Viptela devices through DX NetOps VNA integration. This functionality allows you to use the SD-WAN solution that is provided by Viptela. SD-WAN stands for Software-Defined Wide Area Networking. It is a combination of Software Defined Networking (SDN) and Wide Area Networking (WAN).

When DX NetOps Spectrum is integrated with DX NetOps VNA (configured with Viptela plug-in), DX NetOps Spectrum receives the inventory information of the Viptela devices through DX NetOps VNA.

NOTE

DX NetOps VNA configured with Viptela plug-in. acts as an SDN Gateway to collect Viptela inventory information and forwards information to DX NetOps Spectrum. Ensure that the DX NetOps VNA must be configured with Viptela plug-in.

The DX NetOps Spectrum and DX NetOps VNA integration fetches the following Viptela entity inventory information and displays under the SDN Manager hierarchy in OneClick.

Supported in 10.4.2 and later releases

- Sites

  NOTE
  Viptela sites map to site groups in the Performance Centre. If desired, you can manage your site groups in the Performance Centre to update a site name.
- vEdge router
- vEdge interfaces
- vManage
- vSmart
- Policy Group

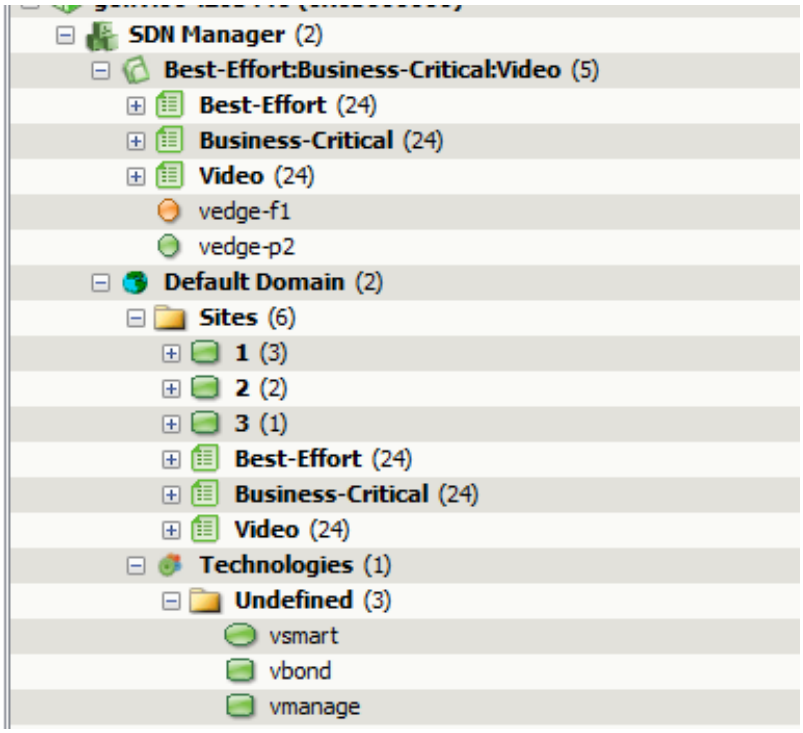
Supported in 10.4.2.2

- Tunnels
- Alarms and events raised on vEdge routers

  NOTE
  DX NetOps Spectrum consumes alarms raised on vEdge routers. For more information, see the Viptela documentation
- Application/SLA Paths
- cEdge router (16.x and 17.x)
- cEdge interfaces (16.x and 17.x)

  NOTE

  - cEdge Interface is available for NetOps 20.2.4 or higher versions.
  - Performance Stats are not supported for cEdge



This integration supports Viptela entity synchronization. When the DX NetOps Spectrum and DX NetOps VNA integration is enabled, synchronization happens automatically at the scheduled time interval that is displayed in the OneClick view. Additions, deletions, and modifications of Viptela entities in DX NetOps VNA are reflected in DX NetOps Spectrum after full synchronization.

Icons for Viptela Devices in Spectrum

The following are the new icons that are created for Viptela devices in DX NetOps Spectrum.

SDN Site

A site is a particular physical location within the Viptela overlay network. Each site is identified by a unique integer, called a site ID. Each Viptela device at a site is identified by the same site ID.

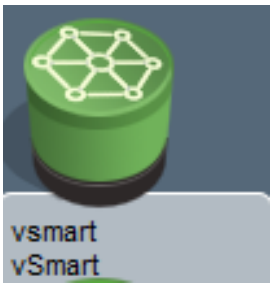
vManage

The vManage is a centralized network management system to maintain all Viptela devices and links in the overlay network. It is a fully manageable centralized portal to run and operate software-defined network (SD-WAN).

vBond

The vBond orchestrator is a software module that authenticates the vSmart controllers and the vEdge routers in the overlay network and coordinates connectivity between them. A Viptela overlay network can have one or more vBond orchestrators. It initiates the bring-up process of every vEdge device, at the first step it creates a secure tunnel with vEdge and informs vSmart and vManage about its parameters like for instance IP address. It has to be fully connected with every device.

vSmart



The vSmart controller establishes a secure DTLS connection to each vEdge router in the network and runs an Overlay Management Protocol (OMP) to share routes, security, and policy information.

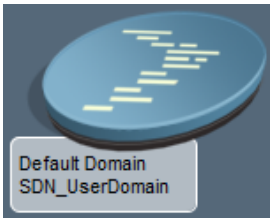
vEdge

vEdge is a router that receives complete control and data policies from the vSmart. It establishes secure IPSec tunnels with others vEdges depending on selected topology.

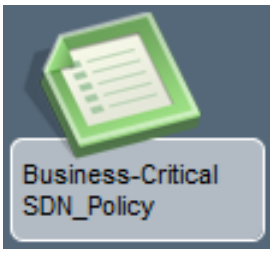
SLA Path

Prior to the 10.4.2.2 release, SLA Path used to have the "Topology tab" which displayed the Branch routers connected through Transports. From the 10.4.2.2 release, the same connections are shown under the SDN Overlay tab. SLA Path models are not displayed under the SDN Manager hierarchy. You can use the locater search to find SLA Path.

Default Domain



SDN Policy and Policy Group



SDN Transport

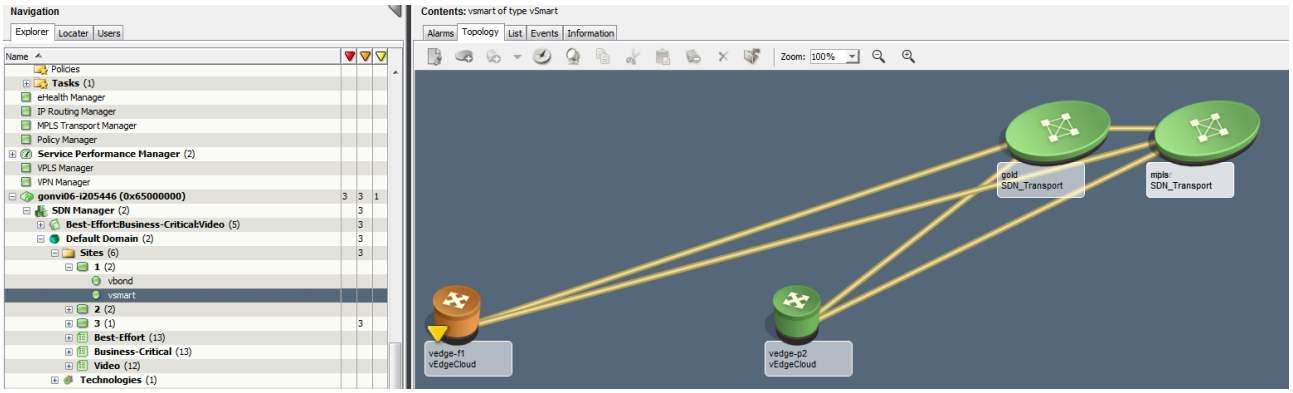
SDN Tunnel

Viptela Topology

DX NetOps Spectrum displays topology for Viptela devices. vSmart, vEdge, and SLA Paths.

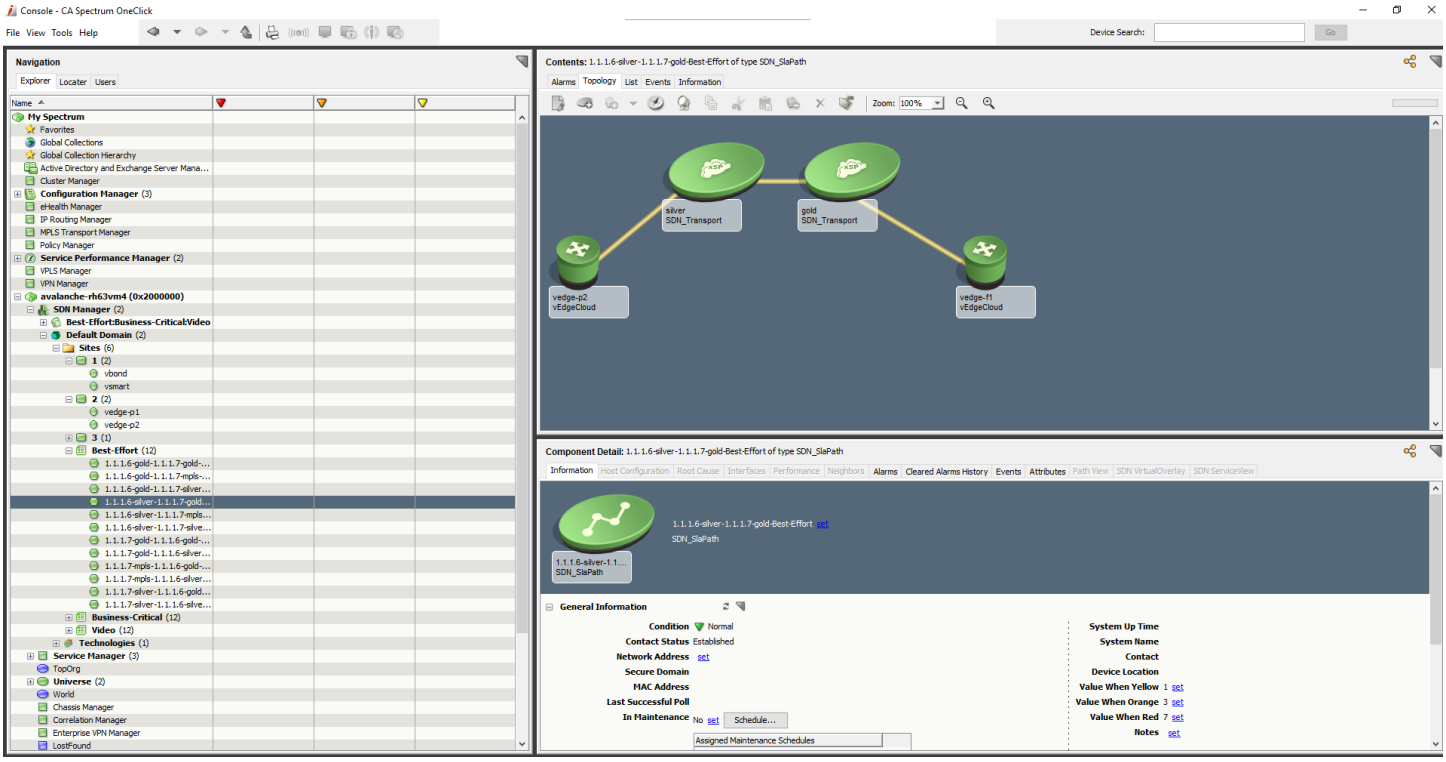
Topology for vSmart

DX NetOps Spectrum displays an Overlay Topology for vSmart, which shows vEdges associated with SDN Transports.



Topology for SLA Paths

The SLA Path topology that is displayed when an SLA path is selected under Policy Group in the Explorer tab. This topology shows the connectivity between vEdge router models, Transport models.



Topology for vEdges

The vEdge topology is displayed when a Policy is selected in the Policy Group under SDN Manager.

Support for Alarms Traps and Events

DX NetOps Spectrum can perform automatic discovery and mapping of a device interface and connections based on the following events and conditions:

- A change in the number of configured interfaces on a device
- When a device sends a LINK up a trap
- When DX NetOps VNA reconfigures a modeled device

Viptela Inventory

You can view the Viptela entities such as vEdge, vBond, vSmart, vManage in the OneClick console. Logical entities such as Sites and Policy Groups can also be viewed on the OneClick Navigation page. A new container '**VNA Inventory**' is created under the Universe view, this container has the Viptela entities. In the Explorer View, **SDN Manager** provides a more detailed hierarchy i.e. ***Domain > Sites > Policy Groups > Policy > vEdges*** , compared to the **VNA Inventory** view, which only displays the hierarchy of vEdges and associated Tunnels.

The vEdge devices are discovered and placed in the VNA Inventory folder under Universe in OneClick. A vEdge device must have a valid security certificate to participate in a Viptela network. You can configure the certificate state from the vManage Certificates administration page.

Viptela Alarms

The Alarms tab in OneClick displays the alarms for Viptela devices. The status of the alarms is fetched from VNA.

DX NetOps Spectrum and DX NetOps VNA integration for Viptela devices management support the alarms that are received from VNA. Alarms with following statuses are supported in DX NetOps Spectrum:

- Alarms with state as 'CREATED'
  When an alarm notification is received from VNA, an event and alarm is generated in DX NetOps Spectrum for the respective alarm with the event code 0x673000c
- Alarms with state as 'CLEARED'
  When an alarm notification is received from VNA, an event and alarm is generated in DX NetOps Spectrum for the respective alarm with the event code 0x673000d

The following Viptela alarms are supported in DX NetOps Spectrum:

Alarm	Description
BFD Between Sites Up	At least one BFD session on a vEdge router between two sites is in the Up state.
BFD Node Up	At least one BFD session for a vEdge router is in the Up state.
BFD Site Up	At least one BFD session on a vEdge router in a site is in the Up state.
BFD TLOC Up	At least one BFD session for a TLOC is in the Up state.
Control Node Up	At least one control connection for a vEdge router is in the Up state.
Control Site Up	At least one control connection from the vManage NMS and the vBond orchestrator in the site is in the Up state.
Control vSmart Up	At least one control connection from a vSmart controller in the overlay network is in the Up state.
Control TLOC Up	At least one control connection for a TLOC is in the Up state.
OMP vSmarts Up	At least one OMP connection from all vSmart controllers in the overlay network is in the Up state.
OMP Node Up	At least one OMP connection for a vEdge router is in the Up state.
OMP Site Up	At least one OMP connection to vSmart controllers from all nodes in the site is in the Up state.
Control vManage Up	At least one control connection from a vManage controller in the overlay network is in the Up state.

OSPF Router Up	All OSPF peering sessions from a particular OSPF router to all its OSPF peers on other vEdge routers are up.
Admin Password Change	The password for the admin that is changed on a router or controller.
Clear Installed Certificate	All certificates on a controller or device, including the public and private keys and the root certificate, have been cleared, and the device has returned to the factory-default state.
Cloned vEdge Detected	A duplicate router that has the same chassis and serial numbers and the same system IP address has been detected.
Cloud onRamp	The Cloud onRamp service was started on a router.
Control vManage Down	All control connections from a vManage NMS are in the Down state.
Default App List Update	The default application and application family lists, which are used in application-aware routing policy, have changed.
Interface Admin State Change	The administrative status of an interface in a controller or router that is changed from up to down (Critical) or down to up (Medium).
Memory Usage	The memory usage on a controller or device has reached a critical level that could impair or shut down functionality, or a medium level that could impair functionality.
New CSR Generated	A controller or router generated a certificate signing request (CSR).

Correlation of DX NetOps Spectrum Alarms to Viptela Alarms

DX NetOps Spectrum tries to correlate alarms that are received from Viptela and creates a root cause alarm in Spectrum. For example, if there is a physical interface down in Viptela, Spectrum receives multiple alarms for different events. DX NetOps Spectrum correlates these alarms from Viptela and creates a Bad Link Detected alarm in Spectrum. Alarms that are received from Viptela are shown as symptomatic alarms and the Spectrum alarm is considered as the root cause.

DX NetOps Spectrum keeps updating/replacing the symptomatic alarms with the latest alarms that are received from Viptela. The root cause alarm remains the same (bad link detected) in Spectrum until all the alarms are cleared from Viptela.

Alarms for SLA Violation

Whenever there is a violation of the defined SLA, DX NetOps Spectrum generates a critical alarm on the vEdge routers for the SLA. The SLA violation alarms in Spectrum helps you to identify the bad policies (which resulted in too many policy violations) and take corrective actions.

Reconciling Viptela Entity Data in DX NetOps Spectrum

During DX NetOps VNA data synchronization, when a new Viptela entity is created in DX NetOps VNA is reported to DX NetOps Spectrum. Spectrum performs a search to identify if this entity was modeled during DX NetOps Spectrum discovery and modeling. If such an existing model is found, DX NetOps Spectrum reconciles the CA Viptela entity information with the existing model, instead of creating a model.

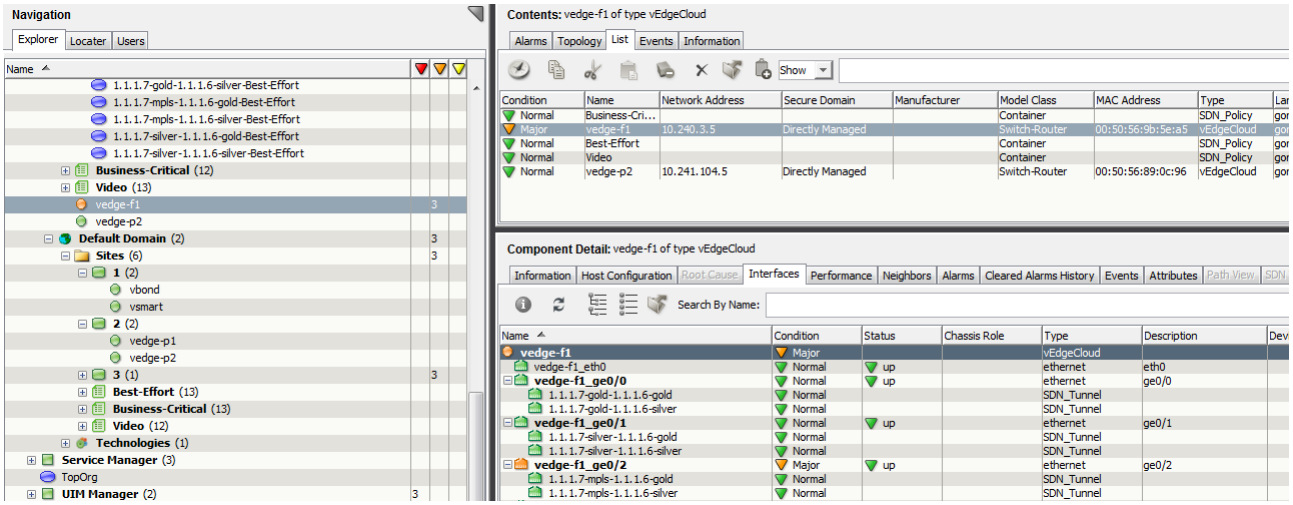
Interfaces Information

DX NetOps Spectrum reads the information of the following Viptela devices from VNA and displays in the OneClick Interfaces tab:

- Tunnels
- Physical Interfaces
- Transport

SDN Tunnels associated with vEdge Interfaces

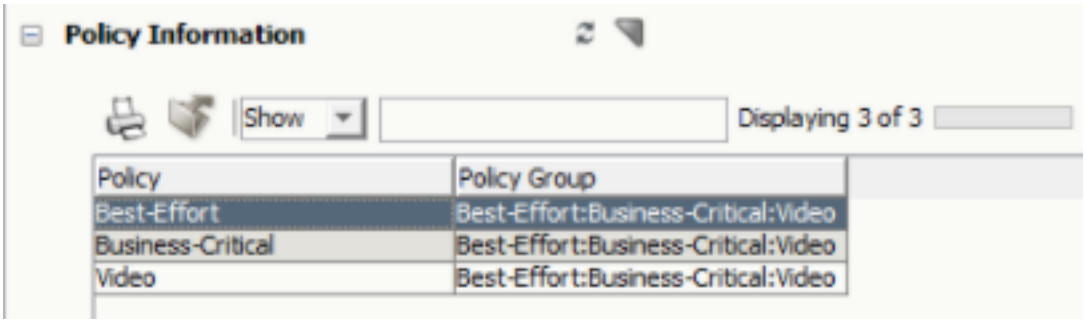
The Interfaces tab in the Component Details panel shows all the tunnels information which is associated with the selected vEdge.



Policies Information

For vEdges, associated policy and policy group information is displayed in the Information tab of the contents panel.

vEdge Policy Information



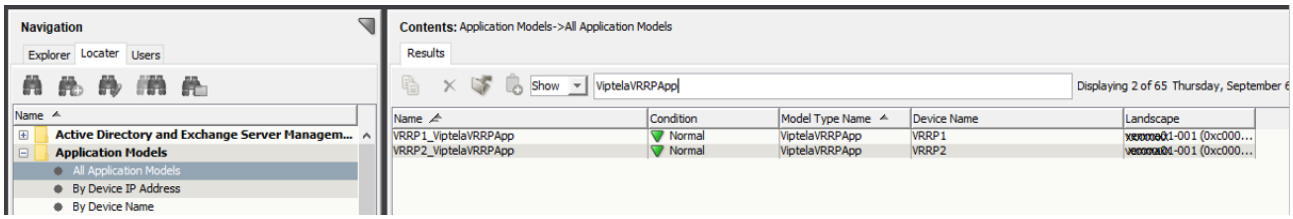
Viptela VRRP Models

Using the search functionality in the Locater tab to find Virtual Router Redundancy Protocol (VRRP) enabled Viptela devices that are available in the DX NetOps Spectrum environment. You can access the Locater search from the Locater tab of the Navigation Panel. The Search results appear in the Results tab of the Contents panel.

Change the State of the ViptelaVRRPMode Attribute

To search VRRP models, follow these steps:

1. Open the DX NetOps Spectrum OneClick Console.
2. From the Navigation Panel, select the Locater tab.
   The Search Options window opens.
3. Expand Application Models, All Application Models.
   The Locater Search results are displayed in the Contents pane.
4. In the Results tab, filter for the ViptelaVRRPApp model.
   The VRRP enabled Viptela devices are displayed.



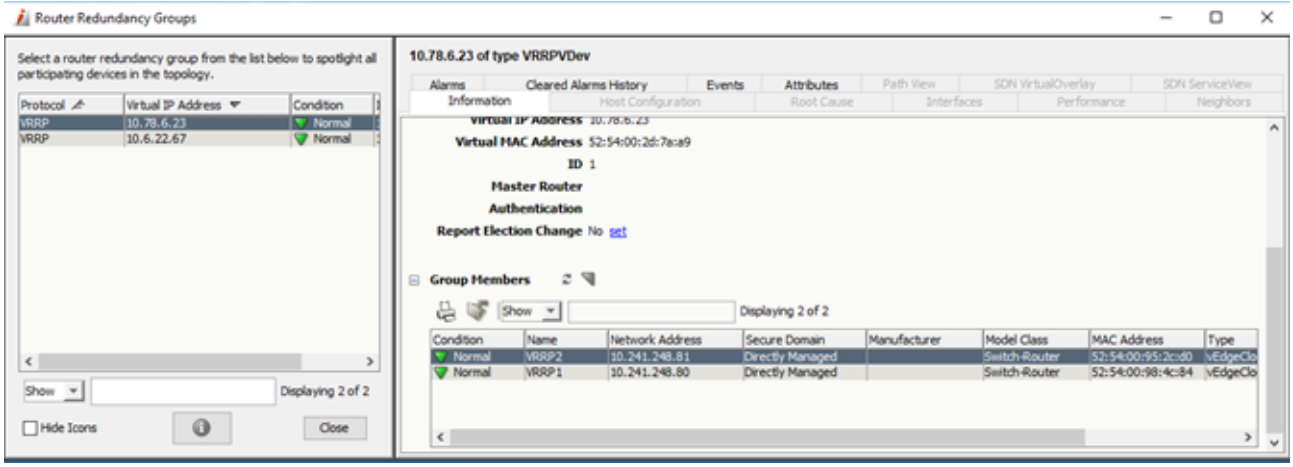
5. Select an App model from the list
6. In the Component Detail panel, select the Attributes tab then search for the ViptelaVRRPMode attribute.
7. Set the attribute value to Active. The default value is Off.
   Repeat the same for remaining similar App models.

Spotlighting Viptela Devices

Spotlighting Viptela Devices in the Topology view helps you isolate and visualize the Viptela model relationships within your network. Use the OneClick Spotlight feature to see all Access Points that are related to a Viptela in the Topology view.

To spotlight Viptela devices, follow these steps:

1. Open OneClick.
2. Expand the desired landscape on the Explorer tab and select Universe.
   Details about the selected Universe appear in the Contents panel.
3. Select the Topology tab.
   The topology of the Universe is displayed.
4. Select the Spotlight View and select Router Redundancy from the list of options.
   The list of Router Redundancy Groups appears.
5. Select a Router Redundancy group from the list to spotlight all participating devices in the topology.



The Group Members view shows the list of devices for the selected Router Redundancy Group.

Network Configuration Manager (NCM) Support for Viptela Devices

After the DX NetOps Spectrum and DX NetOps VNA integration is enabled, during the DX NetOps Spectrum discovery a folder for Viptela is created under the Device Families folder of Configuration Manager. Network Configuration Manager automatically assigns all Viptela devices to the Viptela family.

The Configuration Management process helps in identifying and monitoring configurations of single devices and device families that comprise a network. Using the Network Configuration Manager, you can perform the following tasks for Viptela devices:

- Manage configurations for Viptela devices that are modeled in DX NetOps Spectrum.
- Capture device configurations and store them in the DX NetOps Spectrum database.

Configure Device Family General Settings

The General Configuration subview contains the Configuration Manager settings. Configuration Manager lets you disable tasks for an entire device family. When Configuration Manager is disabled, Network Configuration Manager operations are not performed on any of the devices that are contained by this device family.

Configure Device Family Communication Mode

The Primary Communication Mode determines how Network Configuration Manager interacts with the associated devices. By default, Viptela device family supports 'SSH' communication mode. You need to specify the device username, password, and enable password to contact the devices.

Manually Capture the Viptela Device Configuration

You can manually capture the Viptela device configurations in OneClick. Capturing the device configurations helps to see that any changes occurred in device configurations and helps to store the updated configuration in the database.

Follow these steps:

1. Select the Viptela device in the Explorer tab.
   The device appears in the List tab of the Contents panel.
2. Select the Host Configuration tab in the Component Detail panel.
3. Select the Capture Configuration for Selected Host icon.
   The results of the capture appear. Either a new configuration appears in the list or the last verified time is updated for the current configuration.

Upload Configuration

You can manually upload a configuration file to a Viptela device on your network. When you upload a configuration file, you merge it into the existing configuration file.

Follow these steps:

1. Select the Viptela device in the Explorer tab.
   The device appears in the List tab of the Contents panel.
2. Select a configuration from the Host Configuration tab in the Component Detail panel.
3. Select the Upload Configuration to the Selected Host icon.
   The Upload Configuration window opens.
4. Modify the configuration and select update
5. Perform any of the following optional steps:
   – Edit configuration content as desired.
   – Enter the criteria in the Search field to locate specific lines in the configuration file to change content or to verify content prior to upload.
   – Select Open to import a previously exported configuration file that is saved locally on your system.
   – Select Save As if you want to save and export this configuration file in txt or HTML format.
6. Select Upload to upload the configuration file to the selected device.
   The message “The configuration upload succeeded” appears when the procedure is complete.

   NOTE

   To compare configuration differences, capture the newly uploaded configuration.

Known Anomalies

DX NetOps Spectrum has following known anomalies for supporting Viptela devices:

1. SDN Tunnels do not show the connected device and port unless the vEdge model is reconfigured.
2. SDN Tunnels getting deleted when the physical interface goes down.
3. Overlay topology shows the overlapped transports.

Monitoring SD-WAN for VeloCloud

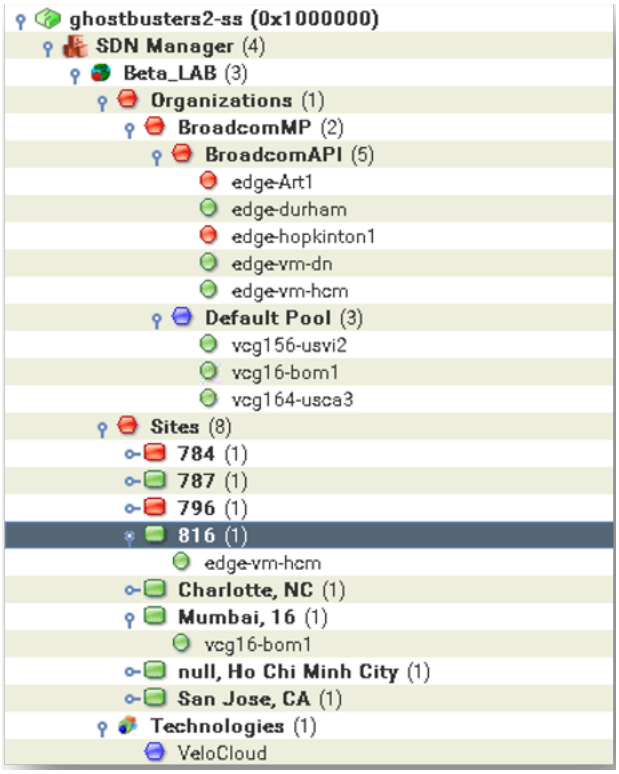
From the 10.4.2.2 / 20.2.5 release, DX NetOps Spectrum supports the monitoring of VeloCloud devices through DX NetOps VNA integration. This functionality allows you to use the SD-WAN solution that is provided by VeloCloud. SD-WAN stands for Software-Defined Wide Area Networking. It is a combination of Software Defined Networking (SDN) and Wide Area Networking (WAN).

When DX NetOps Spectrum is integrated with DX NetOps VNA (configured with VeloCloud plug-in), DX NetOps Spectrum receives the inventory information of the VeloCloud devices through DX NetOps VNA.

> **NOTE**
> DX NetOps VNA configured with VeloCloud plug-in. acts as an SDN Gateway to collect VeloCloud inventory information and forwards information to DX NetOps Spectrum. Ensure that the DX NetOps VNA must be configured with VeloCloud plug-in.

The DX NetOps Spectrum and DX NetOps VNA integration fetches the following VeloCloud entity inventory information and displays under the SDN Manager hierarchy in OneClick:

- Enterprise Proxy
- Enterprise
- Gateway Pool
- Gateway (VCG)
- Site
- Router (VCE)

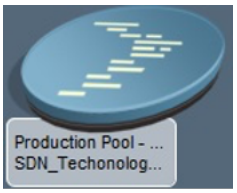


This integration supports VeloCloud entity synchronization. When the DX NetOps Spectrum and DX NetOps VNA integration is enabled, synchronization happens automatically at the scheduled time interval that is displayed in the OneClick view. Additions, deletions, and modifications of VeloCloud entities in DX NetOps VNA are reflected in DX NetOps Spectrum after full synchronization.

Icons for VeloCloud Devices in DX NetOps Spectrum

The following are the icons that are created for VeloCloud devices in DX NetOps Spectrum.

SDN Technology Group



SDN Site

SDN Gateway

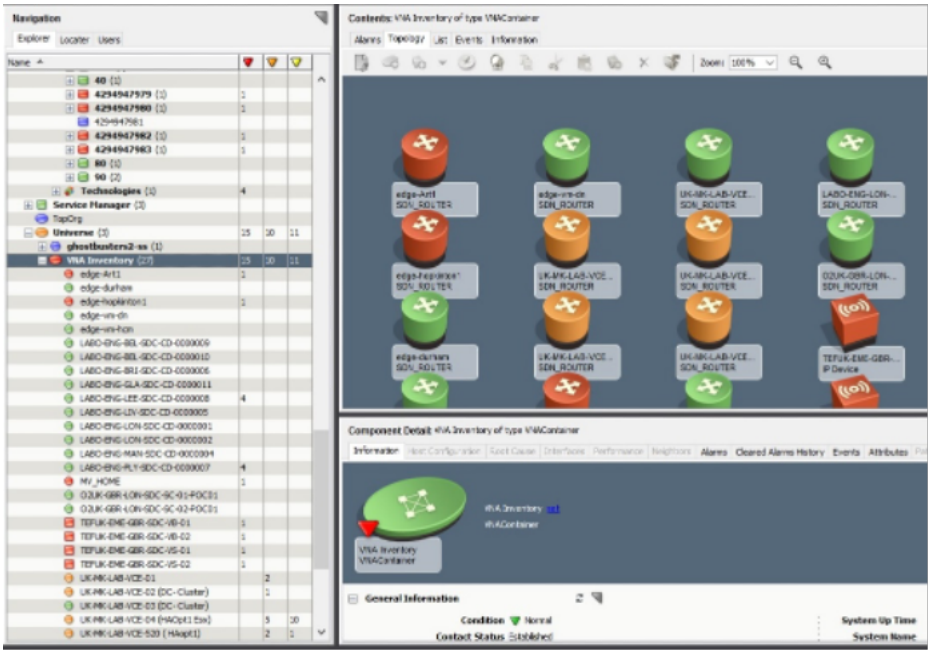
SDN Router

VeloCloud Edge 5X0

VeloCloud Inventory

You can view the VeloCloud entities such as Router, Gateway in the OneClick console. The other entities - Sites, Enterprise Proxy, Enterprise, and Gateway Pool can also be viewed on the OneClick Navigation page.

The Router devices are discovered and placed in the VNA Inventory folder under Universe in OneClick.



VeloCloud Alarms

The Alarms tab in OneClick displays the alarms for VeloCloud devices. The status of the alarms is fetched from DX NetOps VNA. DX NetOps Spectrum and DX NetOps VNA integration for VeloCloud devices management support the alarms that are received from DX NetOps VNA. Alarms with the following statuses are supported in DX NetOps Spectrum:

Alarm	Description
EDGE_DOWN	Edge down
EDGE_UP	Edge up
LINK_DOWN	Link down
LINK_UP	Link up
VPN_TUNNEL_DOWN	VPN tunnel down
EDGE_HA_FAILOVER	HA failed
EDGE_SERVICE_DOWN	Edge service down
GATEWAY_SERVICE_DOWN	Gateway service down
VNF_VM_EVENT	VNF VM event
VNF_VM_DEPLOYED	VNF VM deployed
VNF_VM_POWERED_ON	VNF VM powered on
VNF_VM_POWERED_OFF	VNF VM powered off
VNF_VM_DEPLOYED_AND_POWERED_OFF	VNF VM deployed and powered off
VNF_VM_DELETED	VNF VM deleted
VNF_VM_ERROR	VNF VM error
VNF_INSERTION_EVENT	VNF Insertion event
VNF_INSERTION_ENABLED	VNF Insertion enabled
VNF_INSERTION_DISABLED	VNF Insertion disabled
TEST_ALERT	Test alert
EDGE_CSS_TUNNEL_DOWN	Edge CSS Tunnel down
EDGE_CSS_TUNNEL_UP	Edge CSS Tunnel up
VNF_IMAGE_DOWNLOAD_EVENT	VNF Image download event
VNF_IMAGE_DOWNLOAD_IN_PROGRESS	VNF Image download in progress
VNF_IMAGE_DOWNLOAD_COMPLETED	VNF Image download completed
VNF_IMAGE_DOWNLOAD_FAILED	VNF Image download failed

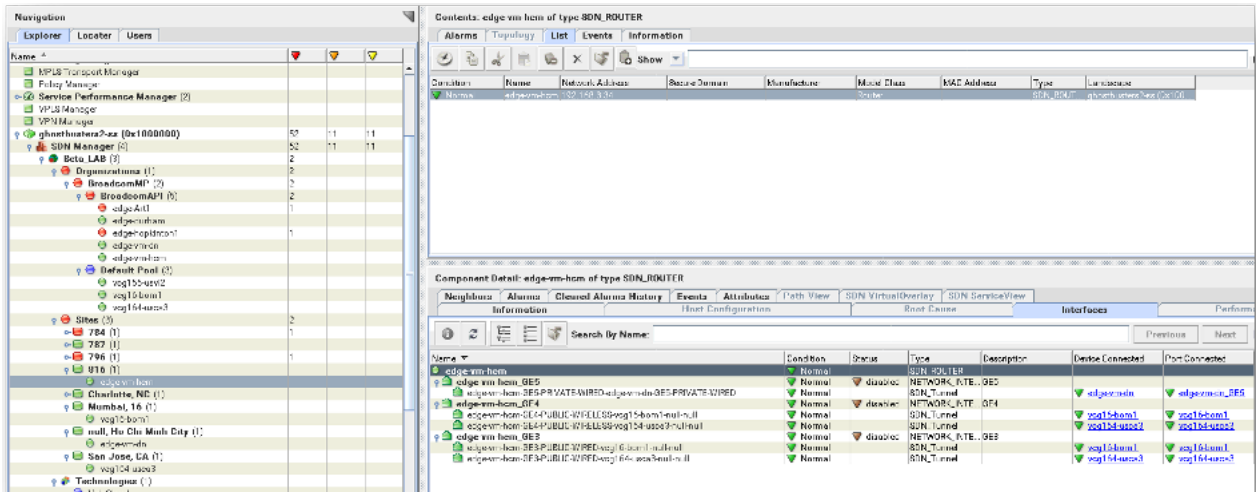
VeloCloud Interface Information

DX NetOps Spectrum reads the information of the following VeloCloud devices from VNA and displays in the OneClick Interfaces tab:

- Physical Interfaces
- Tunnels
- Transport

SDN Tunnels Associated with Router Interfaces

The Interfaces tab in the Component Details panel shows all the tunnels information which is associated with the selected Router.



VMware vSphere Support

DX NetOps Spectrum introduces support for vSphere virtualization through CA VNA 3.5.1, which provides better insights resulting in improved performance. Starting from the 10.2.3 release, the Vmware vSphere plugin collects inventory for the following from the vCenter server:

- Data centers
- Clusters
- Hosts
- Virtual machines
- Host interfaces
- Virtual machine interfaces
- vSphere distributed switches (Created by the Cisco ACI Virtual Machine Manager Domain integration with VMware vSphere)

NOTE

There is no connectivity between VMs and vSwitch/DVS.

The vSphere events in and their details are as follows:

Event	Event Description	Event Code
DrsVmMigratedEvent	This event records a virtual machine migration that was recommended by Distributed Resource Scheduler (DRS)	0x6730162
VmMigratedEvent	This event records a virtual machine migration.	0x6730161
VmFailedMigrateEvent	This event records a failure to migrate a virtual machine.	0x6730160
VmBeingHotMigratedEvent	This event records that a virtual machine is being hot-migrated.	0x673015f
VmBeingMigratedEvent	This event records that a virtual machine is being migrated.	0x673015e

NOTE

The default event is 0x6730011.

Disable the DX NetOps VNA Integration

You can disable the DX NetOps Spectrum and DX NetOps VNA Integration from the OneClick Administration page.

NOTE

You must disable DX NetOps VNA integration from the web server on which the integration is enabled.

Follow these steps:

1. Open the OneClick Administration page.
   The OneClick Administration page opens.
2. Click the Administration tab.
   Links to various OneClick web server configuration pages are displayed.
3. Click the VNA Integration Configuration link in the left panel.
4. To disable the DX NetOps VNA integration, select Disable and click Save.
   The Integration disabled message appears.

NOTE

Wait for the all the DX NetOps VNA Host server models and the folder hierarchy to be cleared from the DX NetOps VNA in the OneClick view after disabling the integration. To validate, search for any DX NetOps VNA Server models, using the search option.

Co-Existence of DX NetOps VNA and Unified Infrastructure Management (UIM) Integration

Overview

DX NetOps Spectrum supports the co-existence of UIM and DX NetOps VNA integration together for the VMware inventory. This enhancement allows you to reconcile vCenter, ESX Host, and Virtual machines as SNMP and Pingable models.

Benefits for this co-existence include:

- Reconciliation of UIM and DX NetOps VNA Host Servers
- Fault Correlation between UIM and DX NetOps VNA alarms
- OneClick Views for reconciled Events & Alarms

Previously, when you integrated DX NetOps VNA to monitor VMware entities in your VMware environment, and if you also integrated UIM Virtualization for the same environment, duplicate entries were created in DX NetOps Spectrum. Starting Spectrum 10.3, you can reconcile the same set of data from different sources. The UIM models are reconciled with VNA models and these results are shown in the Explorer tab.

NOTE

To synchronize UIM alarms with DX NetOps Spectrum, the VM names of UIM should match with the VM names of DX NetOps Spectrum.

VMware Entities Reconciliation

After DX NetOps Spectrum is integrated with UIM and DX NetOps VNA, then the reconciliation of the models occurs, which are part of both UIM and DX NetOps VNA. The reconciled models are moved from Universe to DX NetOps VNA Inventory Container.

For ESX Hosts and VMs, new icons are created during the reconciliation from UIM to VNA.

NOTE

When DX NetOps VNA Integration is disabled, the models which were discovered and reconciled, get deleted as part of the inventory clean-up.

Based on the following scenarios, the reconciliation process has different results.

Integrate UIM first and DX NetOps VNA next

When you integrate UIM first then integrate DX NetOps VNA, you observe the following results:

- ESX Hosts are reconciled and the attributes are auto-filled.
  When you integrate UIM, then ESX Host models get created in DX NetOps Spectrum. After you integrate DX NetOps VNA, reconciliation happens and these ESX Host models will get deleted and recreated under the VNA Inventory container. The VMs under ESX Hosts are moved from the UIM Inventory container to the VNA Inventory container.
- The DataCenter is created in both UIM and VNA inventories and Model Handle is the same in both the inventories.
- In the UIM Manager hierarchy, the UIM vCenter name is changed, to the name of the VNA vCenter.
- Reconciliation of existing UIM logical entities with DX NetOps VNA.
  The DataCenter and Cluster should get reconciled and the UIM models get VNA attributes.
  The following attributes are filled during reconciliation of existed UIM Data Center and Cluster to VNA Cluster and Data Center, ESX Host Server:
  – UIMOrgin
  – VirtulaEntityUniqueId

The following attributes are filled for SDN_VM's when VNA Integration is enabled.
SDNUIM_DATA_SOURCE_CONTEXT
SDNUIM_DESCRIPTION
SDNUIM_INSTANCE_ID
SDNUIM_IP_ADDRESS_LIST
SDNUIM_MAC_ADDRESS_LIST
SDNUIM_MEMORYINGB
SDNUIM_NUMBEROFCORES
SDNUIM_OSTYPE
SDNUIM_OSVERSION
SDNUIM_SOURCEPRODUCTNAME
SDNUIM_BIT_RATE
SDNUIM_STORAGEINGB
SDNUIM_TOPOUPDATE_ACTIVE
SDNUIM_VIRTUALIZATION_ENV
SDNUIM_VM_ID
SDNUIM_VM_NAME
SDNUIM_VNF_NAME

When DX NetOps VNA integration is disabled

When UIM first and DX NetOps VNA next integrated and if you disable the VNA Integration, you observe the following results:

- The inventory gets deleted including the ‘VNA Inventory’ container and the inventory under the ‘SDN Manager’.
- Deletes all reconciled models under the ‘UIM Manager’ and the ‘UIM Inventory’ containers.

Integrate DX NetOps VNA first and UIM next

When you integrate DX NetOps VNA first then integrate UIM, you observe the following results:

- Virtual Entity Unique ID is the as same under DX NetOps VNA and UIM
- UIM inventory of type ‘Cluster’ shows Modeltype_Name as ‘SDN_Cluster’. This entity_type matched with the same in DX NetOps VNA. The DataCenter under UIM and DX NetOps VNA shows Modeltype_Name as SDN_Cluster.
- vCenter name is changed according to the vCenter name in UIM inventory
- The ESX Hosts moves out of UIM Inventory (Universe -> UIM inventory) and displayed directly under the Universe.

When UIM integration is disabled

When both UIM and DX NetOps VNA are integrated, and if you disable the UIM integration, you observe the following results:

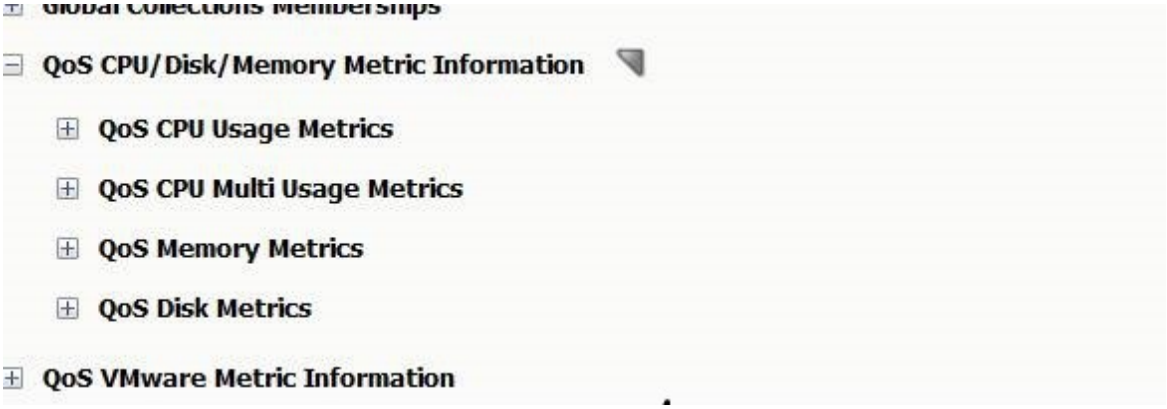
- The UIM inventory is cleaned up from the UIM Inventory folder.
- The UIMEventAdmin folder gets deleted.

OneClick Views

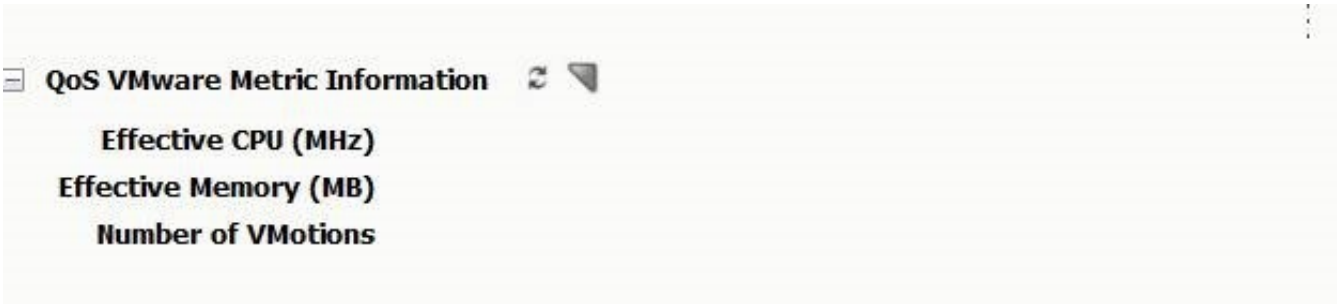
When DX NetOps VNA integrated first and UIM next, OneClick views get reconciled from UIM to DX NetOps VNA on VNA models.

> **NOTE**
>
> No views are reconciled for a Data Center.

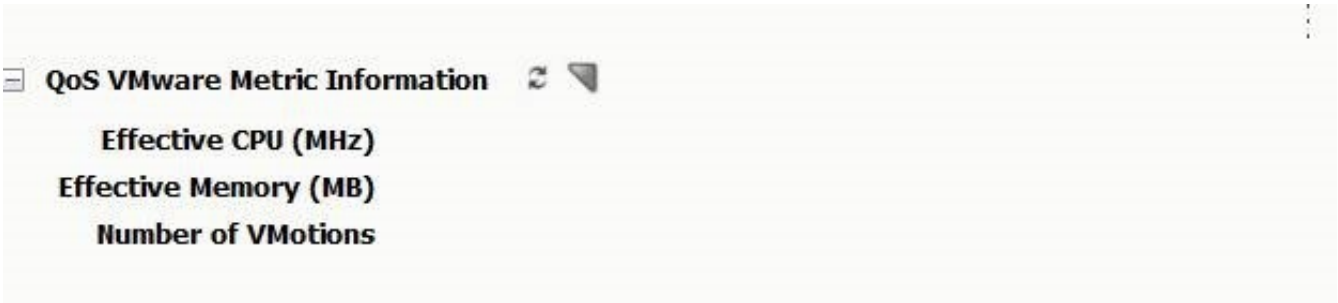
The following OneClick view gets reconciled for ESX Hosts and VMs:



The following OneClick view gets reconciled for a vCenter:



The following OneClick view gets reconciled for a Cluster:



When both the integrations are disabled

When you disable both the UIM and DX NetOps VNA integrations, you observe the following results:

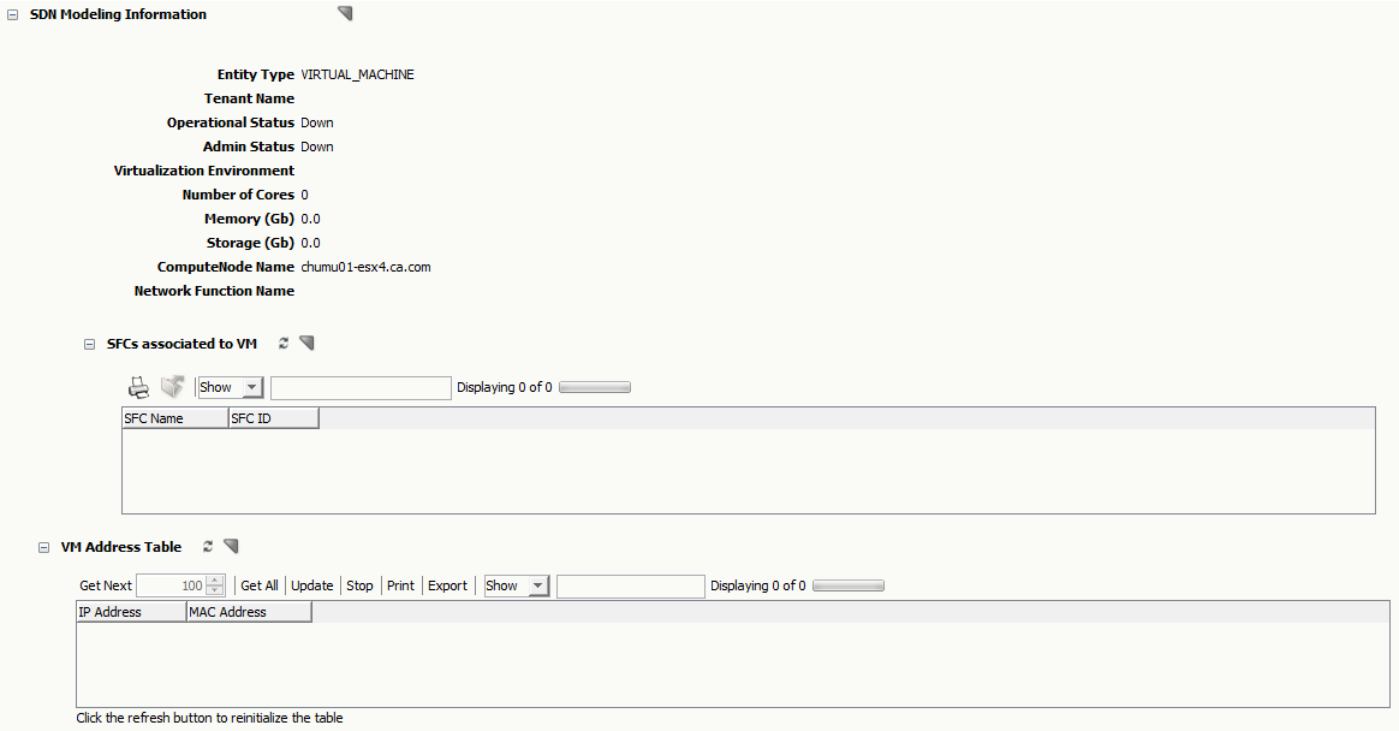
- The VNA Inventory is cleaned-up from SDN Manager.
- The UIM Inventory is cleaned-up from UIM Manager.
- Both VNA Inventory and UIM Inventory containers get deleted from the Universe.
- The existing SNMP Models (such as ACI Leaf, Spine, vCenter or Controller), and Pingable Models (VMs), which were modeled before the integration, are not deleted.

SDN Modeling Information

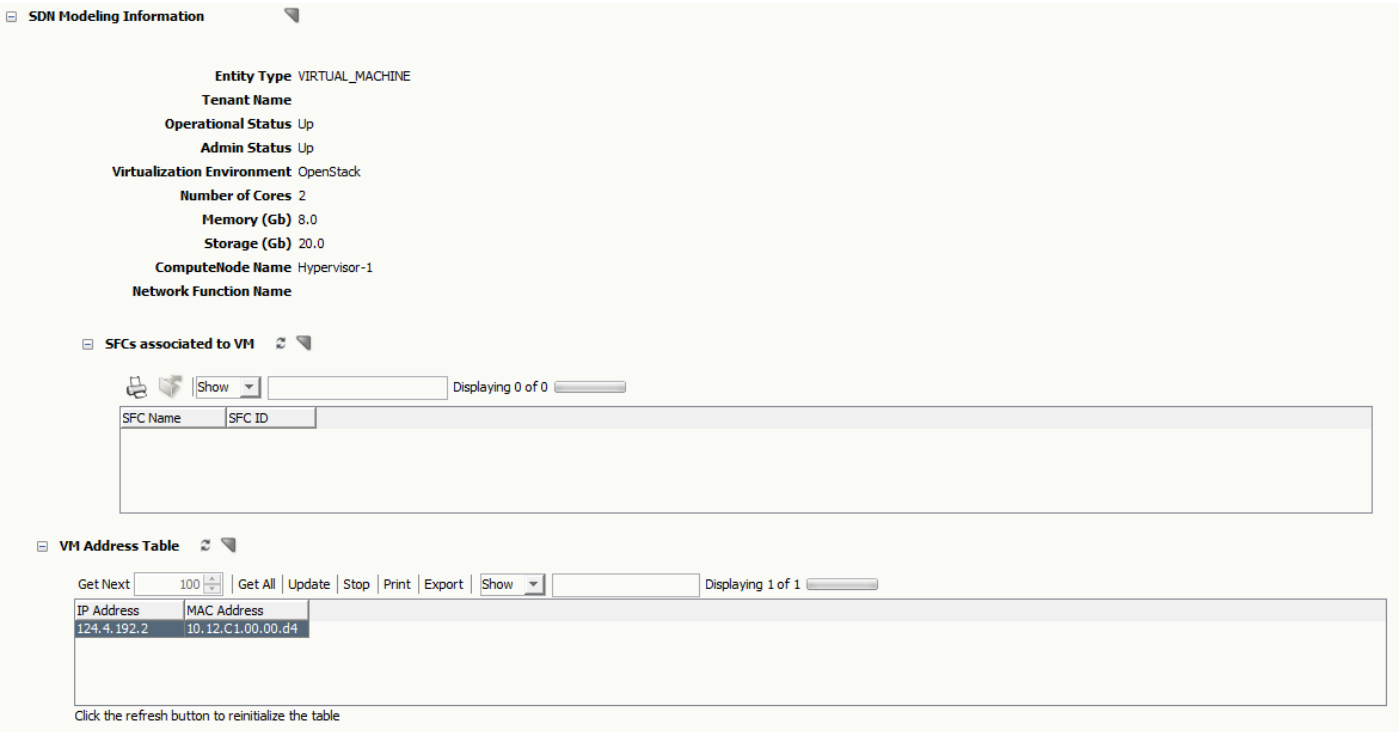
From the OneClick console, you can view the SDN Modeling Information of the Virtual Machine (VM) which is reconciled.

Follow these steps:

1. Open the DX NetOps Spectrum OneClick console.
2. Select **UIM Manager**, **Virtualization, VMware, Cluster, and** select **Resources** from the Navigation panel.
   The **Contents** pane opens.
3. Select the **Information** tab.
4. Expand **SDN Modeling Information**.
   SDN Modeling Information for the selected virtual machine is displayed.
   The following image displays the SDN Modeling Information of a virtual machine, when you integrate UIM first and DX NetOps VNA next.



The following image displays the SDN Modeling Information of a virtual machine, when you integrate DX NetOps VNA first and UIM next.



Launch-in-Context

The Launch-in-Context feature allows you to launch a UIM-UMP device/alarm view, from DX NetOps Spectrum for performance views of the device/alarm, in the given context. The UIM-UMP device view provides detailed information

about the IP elements such as Virtual Center (VC), ESX Hosts, and Virtual Machines (VM). The information (such as disk usage, CPU usage, processor queue length, paging, and memory usage) about the UIM virtual entities is displayed graphically.

If you are launching the UMP view for the first time in a browser, a dialog for user credentials appears. The user credentials dialog does not appear if you are launching the UMP view using the same browser instance.

NOTE

The Launch-in-Context feature is available only for the IP elements. This feature is disabled for logical entities such as Data Centers, ResourcePools, and Clusters.

Follow these steps:

1. In the DX NetOps Spectrum OneClick console, select **UIM Manager**, **Virtualization > VMWare**
2. Navigate to the device details that you want to view.
   A list of all entities under the sub-section that you have selected is displayed.
3. Right-click on one of the IP elements and select **Launch UIM UMP View**.
   The UIM UMP login page opens.
4. Enter the UIM UMP credentials and select 'Login'.
   The UMP view opens with the detailed information about the IP elements.

Analytics

The integration between DX NetOps Spectrum and CA Digital Operational Intelligence (App Experience Analytics) provides you with digital experience insights and helps you quickly determine if an issue with an app is with the infrastructure. You can triage the issue before it impacts the customer experience. This solution provides data-driven, actionable insights that are based on information that is received from different domains, types, and processes through the analytics platform. The DX NetOps Spectrum integration with the Analytics platform leverages the following information from DX NetOps Spectrum to help the user in a proactive resolution of issues:

- Alarms
- Network Configuration Manager - Change events (Disabled by default, enable if required)
- Topology

When you integrate DX NetOps Spectrum with DX Operational Intelligence, your enterprise gains the following benefits:

- Provide a holistic view of the availability of host servers and VMware environment across the network and their performance data for fault management in a single pane of the application.
- End-to-end root cause and impact analysis across network and server elements, extending the DX NetOps Spectrum core capabilities to other infrastructure domains.
- Advance condition correlation between CA UIM and DX NetOps Spectrum helps build robust fault management.
- Alarm management for both fault and performance alarms using either solution

With this integration, IT operators can do the following:

- Know the trends about device availability by groups. The groups can be created for different criteria using global collections.
- View the alarm information that is presented using multiple filters and are available out of the box or with custom filters.
- Use custom attributes to customize the out of the box dashboards.
- Drill down through the dashboards to view detailed information.

Integrate With DX Operation Intelligence

Overview

The integration between DX NetOps Spectrum and DX Operational Intelligence allows you to leverage data from DX NetOps Spectrum and helps to analyze, correlate, and proactively resolve the network issues. The SpectrumDataPublisher is a utility/service in DX NetOps Spectrum that publishes the DX NetOps Spectrum data to the analytics platform.

The 10.4.2 release supports sending Topology inventory and its relations from DX NetOps Spectrum to Topology Analytics Service (TAS) using DX NetOps Spectrum Data Publisher (Spub).

- SpectrumDataPublisher synchronizes DX NetOps Spectrum inventory to the TAS database used by DX OI.
- SpectrumDataPublisher pushes all the DX NetOps Spectrum devices and their relations among the adjacent devices to the TAS database.
- SpectrumDataPublisher converts DX NetOps Spectrum devices into Vertices, and devices relations to Edges before sending them to TAS.

The following data is synchronized from DX NetOps Spectrum to DX Operational Intelligence:

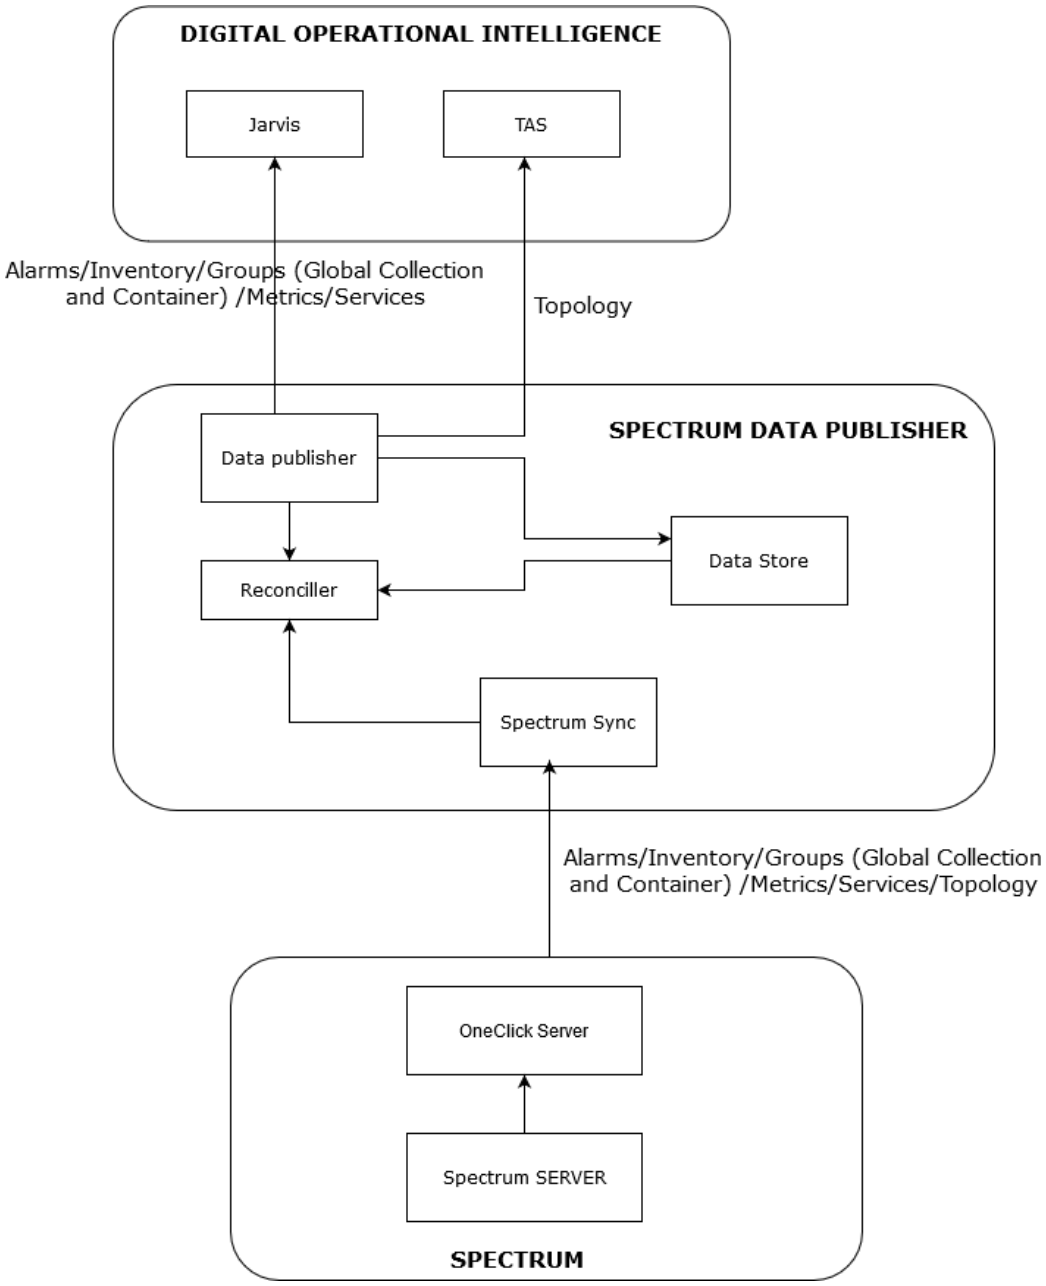
- Alarms

  IMPORTANT
  Reconciliation does not happen when elastic has a large number of alarms. There is a limitation of 10000 alarms from DX OI.
- Network Configuration Manager- Change events (Disabled by default, enable if required)
- Topology

  NOTE
  The following data are not supported from 10.4.2 release as the related data is pushed as part of Topology (TAS Integration):

  - Inventory
  - Groups (Global Collection and Container)
  - VNAInventory (Disabled by default, enable if required)
  - Metrics: Device count and Device availability (based on Model Type and Group)

The following diagram explains how the DX NetOps Spectrum-DX Operational Intelligence integration works:



Compatibility Matrix

For more information about the integration of DX NetOps Spectrum with other CA products, see Integration Compatibility.

Installing the SpectrumDataPublisher

The DX NetOps Spectrum OneClick page allows you to download and install the SpectrumDataPublisher JAR file. The DX NetOps Spectrum Data Publisher version should be the same as the version of the DX NetOps Spectrum.

Follow these steps:

1. Log in to the OneClick WebApp.
2. Navigate to the **OneClick Administration** page.

3. Select the **Analytics Configuration** option from the panel on the left.
   The **Analytics Configuration** page opens in a separate window.
4. Under the **DX NetOps Spectrum Data Publisher** section, select the SpectrumDataPublisher JAR file link to download the installer.
   The SpectrumDataPublisher.jar file is downloaded to the Downloads folder on your computer.
5. Perform one of the following steps:
   – In **Windows:** Double-click on the jar to open the install wizard and enter the **Install Directory**. By default, the path is:
     ```
     C:\win32app\
     ```
     The **DX NetOps Spectrum Data Publisher Install** wizard opens.
   – In **Linux** perform one of the following tasks to start the installation:
     • Execute the following command for silent installation:
       ```
       java -jar SpectrumDataPublisher.jar -i silent -DUSER_INSTALL_DIR="<install directory>"
       ```
       For example:
       ```
       java -jar SpectrumDataPublisher.jar -i silent -DUSER_INSTALL_DIR="/opt"
       ```
     • Execute the following command to export DISPLAY to a Windows Server and start GUI based installation:
       Export DISPLAY=<machine-name>:0 and then run the following command:
       ```
       java -jar SpectrumDataPublisher.jar
       ```
6. Select **Next**.
7. Select Install for the **DX NetOps Spectrum Data Publisher** to be installed.
8. Select **Done** to close the Install wizard.
   After the installation is complete, the SpectrumDataPublisher folder is created in the install folder location.

Configuring the SpectrumDataPublisher

To synchronize data from DX NetOps Spectrum to DX Operational Intelligence, configure the SpectrumDataPublisher.

Follow these steps:

1. Navigate to the DX NetOps Spectrum Data Publisher install location.
2. Open the 'config' folder.
3. Open the ConnectorConfig.xml file, and configure the following:
   a. Enter the DX NetOps Spectrum OneClick host server details in the **<SpectrumConfiguration>** section.
      For example:
      ```
      <SpectrumConfiguration>
             <OneClickServerUrl></OneClickServerUrl> <!-- give OneClickServerUrl. example: http://
      spectrum-123.net:8080/ -->
             <ConfigFile>SpectrumConfig.xml</ConfigFile>
             <WebappLaunchUrl></WebappLaunchUrl> <!-- give webapp url. example: http://
      spectrum-123.net:8080/spectrum/webapp/ -->
      </SpectrumConfiguration>
      ```

      If you want to use the Secure Sockets Layer (SSL) protocol to encrypt communications between OneClick and the SpectrumDataPublisher, you must import the SSL (https) Certificate of DX NetOps Spectrum into SpectrumDataPublisher.

      Launch OneClick Console or WebApp from DX OI Alarms (Introduced in 10.4.2.1)
      When `<WebappLaunchUrl></WebappLaunchUrl>` is empty OneClick console is launched and when you provide the WebApp URL the WebApp is launched.
   b. Enter the DX Operational Intelligence host Jarvis server details in the **<DestinationConfiguration>** section.
      For example:
      ```
      <!-- For CA Digital Operational Intelligence details -->
      ```

```
        <DestinationConfiguration>
            <DestinationType>DOI</DestinationType>
            <DestinationDefaultTenant></DestinationDefaultTenant>
            <DestinationUrl></DestinationUrl> <!-- give Jarvis host url. example: http://
jarvis.doi-123.net:8080/ -->
            <DestinationEntitiesPerPayload>200</DestinationEntitiesPerPayload>
            <ProxyHostForDestination></ProxyHostForDestination>
            <ProxyPortForDestination></ProxyPortForDestination>
            <ConfigFile>DOIConfig.xml</ConfigFile>
            <Alarms>true</Alarms>
            <Ncm>false</Ncm>
            <AlarmReconcileConfiguration> <!-- Clears the stale alarms in DOI during service startup.
 -->
                <Enable>false</Enable>
                <OIUrl></OIUrl> <!-- give OI host url. example:  https://doi.dxi-na1.saas.broadcom.com
 -->
                <BearerToken></BearerToken>
           </AlarmReconcileConfiguration>
        </DestinationConfiguration
```

NOTE

- Set the `<Enable></Enable>` parameter to **true** to clear the stale alarms.
- Use the **AlarmReconcileConfiguration** parameter to clear the stale alarms from the DX OI. Provide the DX OI URL and the bearer token. See Get DX OI Bearer Token Used in Alarm Reconcile Configuration to get the DX OI bearer token.

IMPORTANT

Reconciliation does not happen when elastic has a large number of alarms. There is a limitation of 10000 alarms from DX OI.

If you want to use the Secure Sockets Layer (SSL) protocol to encrypt communications between Jarvis and the SpectrumDataPublisher, you must import SSL (https) Certificate CA Jarvis into SpectrumDataPublisher.

c. Enter the TAS configuration in the **<TasConfiguration>** section:

```
 <TasConfiguration>
        <EnableIntegration>false</EnableIntegration>
        <TasUrl></TasUrl> <!-- give TAS host url. example: http://ngtas.doi-123.net:8080/ -->
        <EnableIncrementalSync>false</EnableIncrementalSync>
        <FullSyncInterval>720</FullSyncInterval> <!-- value in hours -->
        <IncrementalSyncInterval>30</IncrementalSyncInterval> <!-- value in minutes -->
        <FailedPayloadRetry>3</FailedPayloadRetry> <!-- default is 3 times, Set max up to 10 times -->
        <RetryTimeout>10</RetryTimeout> <!-- value in Seconds, each retry will wait for 10 seconds by
default, Set max up to 60 seconds -->
        <StorePath>tas/graph/storeAsync</StorePath>
    </TasConfiguration>
```

NOTE

Enter the **TasUrl** value and set the **EnableIntegration** to true to sync the data.

NOTE

If you want to use the Secure Sockets Layer (SSL) protocol to encrypt communications between TAS and the SpectrumDataPublisher, you must import SSL (https) Certificate to TAS endpoint.

After the configuration is complete, start the SpectrumDataPublisher service.

Start the SpectrumDataPublisher Service

To start the SpectrumDataPublisher service, follow these steps:

1. Perform one of the following step to start the SpectrumDataPublisher service:
   - In Windows, from the command line, run the `run.bat start` command.
   - In Unix, from the console, run the `run.sh start` command.
2. When you run the 'run.bat start' or 'run.sh' for the first time, it asks to create a log in password for SpectrumDataPublisher.

   NOTE
   You need this login password for next time when you run 'run.sh' or 'run.bat start' commands.
3. After creating the login password for SpectrumDataPublisher, it asks for the following login details that must be encrypted/decrypted with the password.

   1. **Enter OneClick username:** DX NetOps Spectrum username
   2. **Enter OneClick password:** DX NetOps Spectrum user password
   3. **Enter TAS Bearer Token:** TAS bearer token
   4. **Enter username for destination proxy -- if applicable:** Enter a proxy server user name
   5. **Enter password for destination proxy -- if applicable:** Enter the password of the proxy server

   The SpectrumDataPublisher service starts.

SpectrumDataPublisher Validation at Service Start

1. The SpectrumDataPublisher validates the user inputs and all the connections at the service startup using the following criteria before starting the service:
2. <SpectrumConfiguration> URL is empty.
3. Both Jarvis Url is empty and TAS integration is disabled, either of one is required to send the data.
4. It runs the test connection validations to all given URLs, and checks for the following errors:
   - SSL Error - This error comes when https configured, and certificates not imported.
   - HTTP 401 - if the authentication fails.
   - HTTP 407 - if proxy details are incorrect.
   - UnknownHost exception - if the provided URL is not valid.

   You can check the SpectrumDataPublisher.log for the exact error description.

Post-installation

- To avoid manual restart of the SpectrumDataPublisher service, change the 'Startup Type' from 'Manual' to 'Automatic'in Windows Services.

Stop the SpectrumDataPublisher service

If you want to stop the SpectrumDataPublisher-service, run the following command
Windows: `run.bat stop (Windows)`
Linux: `run.sh stop (Linux)`

Restart the SpectrumDataPublisher service

If you want to restart the SpectrumDataPublisher-service, run the following command:
Windows: `run.bat restart (Windows)`
Linux: `run.sh restart (Linux)`

NOTE
On Windows machines, the SpectrumDataPublisher-service can be stopped and restarted through the Windows Services Console.

Import SSL (https) Certificate into SpectrumDataPublisher

If you want to use the encrypted communication (https protocol) between DX NetOps SpectrumDataPublisher and integrated products (DX NetOps Spectrum and CA Jarvis server), you must import the SSL/https certificate from the respective products into the SpectrumDataPublisher.

Follow these steps to import the certificate:

1. Ensure that the 'https' certificate is exported and copied to the server where the SpectrumDataPublisher is installed. For export instructions, refer to the notes provided at the end of this section.
2. Perform one of the following steps to download the CA Jarvis Server SSL/HTTPS certificate:
   - Run the following command:
     ```
     openssl s_client -connect Jarvis_Hostname:443  < /dev/null | sed -ne '/-BEGIN CERTIFICATE-/,/-END
      CERTIFICATE-/p' > jarvisServer.cer
     openssl s_client -connect TAS_Endpoint:443  < /dev/null | sed -ne '/-BEGIN CERTIFICATE-/,/-END
      CERTIFICATE-/p' > tas.cer
     ```
     OR
   - Access the Jarvis URL using HTTPS in a browser and save the certificate from site information.
3. Run the following command to import the certificate into the Keystore of SpectrumDataPublisher.
   ```
   keytool -importcert -alias <certificate_alias> -file /<PATH>/<FILENAME.cer> -keystore /<PATH>
   ```
   For example:
   ```
   keytool -importcert -alias tomcatssl -file /SpectrumDataPublisher/OCServer.cer -keystore /
   SpectrumDataPublisher/Security/cacerts
   keytool -importcert -alias jarvisssl -file /SpectrumDataPublisher/jarvisServer.cer -keystore /
   SpectrumDataPublisher/Security/cacerts
   keytool -importcert -alias tas -file /SpectrumDataPublisher/tas.cer -keystore /SpectrumDataPublisher/
   Security/cacerts
   ```

   NOTE
   Ignore the warning about migrating to PKCS12 format.
4. When prompts, provide the Keystore 'changeit' as a password.
5. After the certificate is imported, stop the SpectrumDataPublisher service.
6. Make sure the hostname, port, and protocol details are proper in the /SpectrumDataPublisher/config/ConnectorConfig.xml
7. Start the SpectrumDataPublisher service.

   NOTE
   To export the ssl/https certificate of DX NetOps Spectrum, run the following command from DX NetOps Spectrum Oneclick server:
   ```
   keytool -export -keystore /usr/<PATH> -alias <certificate_alias> -file <FILENAME.cer>
   ```
   For example:
   keytool -export -keystore /usr/Spectrum/custom/keystore/cacerts -alias tomcatssl -file OCServer.cer

Disable SSL Certificate Validation

You can disable the verification to check the validity of certificates. You can disable SSL Certificate Validation in the following scenarios:

- When you do not have the SSL certificates.
- When you get an SSL exception, even after you import the SSL certificates.

Add the following tags in the `ConnectorConfig.xml` file:

```
<DisableSSLHostnameVerifier>true</DisableSSLHostnameVerifier>
<TrustAllX509Certificates>true</TrustAllX509Certificates>
```

Reset the Login Details of SpectrumDataPublisher service

In case you forgot the login password for the SpectrumDataPublisher service, you can reset the same by using the following commands. Note that, when you reset the login details, the stored configuration details are deleted and you should provide the details again in the ConnectorConfig.xml file.
Windows: `run.bat reset (Windows)`
Linux: `run.sh reset (Linux)`

Logging Configuration for SpectrumDataPublisher

You can find the following log files in the SpectrumDataPublisher/logs/ folder:

- The `SpectrumDataPublisher.log` shows the information and error messages of all the syncs.
- The `topology.log` shows the inventory data sent from DX NetOps Spectrum to TAS.
- The `alarm.log` shows the alarm data sent from DX NetOps Spectrum to Jarvis..
- The `ncm.log` shows the NCM data sent from DX NetOps Spectrum to Jarvis.

Note the following points about the logs:

- To set the `SpectrumDataPublisher.log` level change the value of `rootLogger.level` to info, debug, error, or fatal in the log4j2.properties file.
- Set the `logger.topoLogger.level` parameter to **trace** in log4j2.properties to log the topology data. **logger.topoLogger.level=trace**
- Set the `logger.alarmLogger.level` parameter to **trace** in log4j2.properties to log the alarm data. **logger.alarmLogger.level=trace**
- Set the `logger.ncmLogger.level` parameter to **trace** in log4j2.properties to log the NCM data. **logger.ncmLogger.level=trace**
- The maximum size of the log file is 100 MB. When the file reaches the maximum size, a backup file is created. The name of the backup file is SpectrumDataPublisher.log prefixed with a timestamp. The normal logging is continued in the SpectrumDataPublisher.log file.

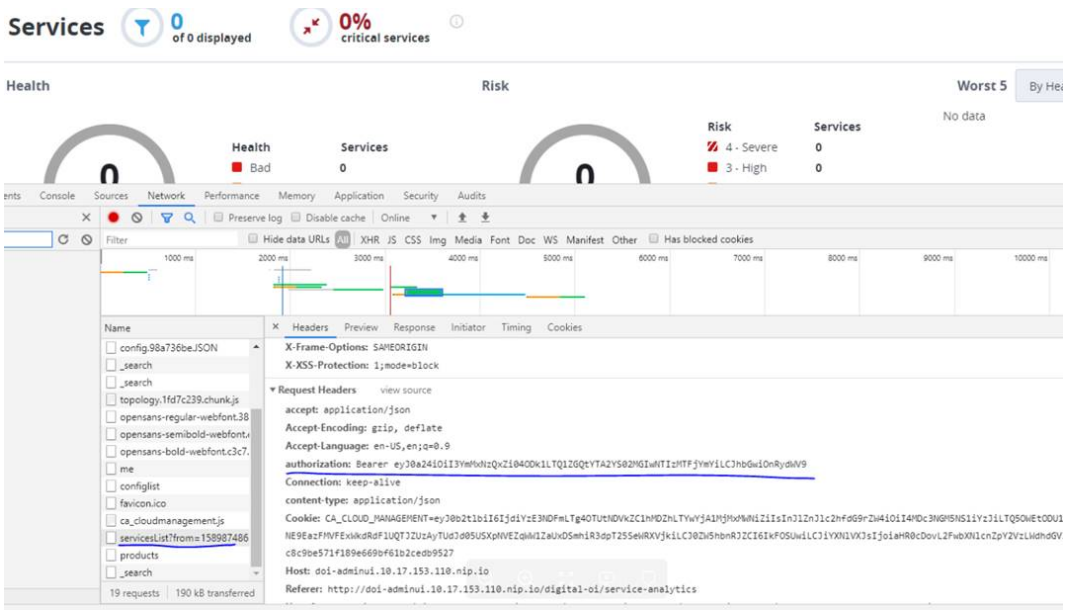
Get DX OI Bearer Token Used in Alarm Reconcile Configuration

You need DX OI bearer token when you configure the SpectrumDataPublisher. Note this bearer token for future use.

> **NOTE**
> The token expires periodically, hence you must fetch the token afresh while starting the service.

Follow these steps:

1. Refresh the DOI page after login.
2. Press CTRL+SHIFT+R on the keyboard.
3. Navigate to the Network.
4. Refresh the page again.
5. Click on any API in the **Network** tab.
6. Scroll down, you can see the authorization: Bearer.



Troubleshooting SpectrumDataPublisher

Troubleshooting information for the problems that are encountered with SpectrumDataPublisher.

DX NetOps Spectrum Data does not sync to DX Operational Intelligence

Symptom:
SpectrumDataPublisher.log shows the exception: com.ca.spectrum.spub.common.ConnectorException. DX NetOps Spectrum Data does not sync to DX Operational Intelligence.

Resolution:
Provide correct details of the Jarvis server under the DestinationConfiguration section of ConnectorConfig.xml and make sure the DestinationHostname is resolved to a valid IP address.

Configure Events Synchronization

After the DX NetOps Spectrum-CA Digital Operational Intelligence integration, configure the following UIM probes to view the analytics dashboards for DX NetOps Spectrum events in the CA Digital Operational Intelligence.

1. Configure the **Log Forwarder (log_forwarder) probe.**
   The log_forwarder probe reads the DX NetOps Spectrum log files and publishes the log file content to a specific UIM queue with subject LOG_ANALYTICS_LOGS. For log_forwarder probe configuration instructions, see the log_forwarder (Log Forwarder) section in the CA Unified Infrastructure Management Probes documentation. The Log Forwarder probe should be present in the SpectroSERVER.
2. Configure the **AXA Log Gateway (axa_log_gateway) probe.** The AXA Log Gateway (axa_log_gateway) probe transfers the log data from the UIM Log Analytics Queue (subject: LOG_ANALYTICS_LOGS) and writes the data to the CA Digital Operational Intelligence (Default: logAnalyticsLogs). For axa_log_gateway probe configuration instructions, see the axa_log_gateway (AXA Log Gateway) section in the DX Unified Infrastructure Management Probes documentation.

Set up the Data Source

You must configure the log data collection source to send log data from DX NetOps Spectrum to CA Digital Operational Intelligence. The Log Forwarder probe collects the log data and sends it to the UIM queue.

In DX NetOps Spectrum, the Archive Manager resource settings allow you to control how historical records are processed. These resources also enable the Archive Manager to communicate with the SpectroSERVER and DDM databases.
Archive Manager resources are defined in the .configrc file, which is located in the $SPECROOT/SS/DDM directory. The resources are listed in the form “resource = resource_value”.

Follow these steps to update the .configrc file:

1. Edit $SPECROOT/SS/DDM/.configrc to add the following attributes:
   - **FLATFILE_EVENTS_FILENAME** - Specifies the file name and location where events log file should be saved.
     Example: FLATFILE_EVENTS_FILENAME=C:\win32app\Spectrum\SS\AXAEventsFile.log
     If you are saving the log file to a different computer or mapped network drive, you need to provide the full path of the computer. Providing only the drive name such as 'z:' is not accepted in the path.
     Example: \\<host name>\shared\AXAEventsFile.lo

     NOTE
     The Log file can be saved only on the local computer and cannot be saved on any SAN/NAS storage.
   - **FLATFILE_EVENTS_MAX_FILESIZE** - Specifies the file size in MB.
     Example: FLATFILE_EVENTS_MAX_FILESIZE=1 (the value 1 represents the file size in MB, each log file should be of 1-MB size and anything more than 1 MB is rotated)
     If the attribute is not added in the .configrc file, then the default max size considered is 100 MB. The maximum size accepted is 2048 MB.
   - **FLATFILE_EVENTS_BACKED_UP_FILECOUNT** - Specifies the count of the number of rotated log files to retain, rest all would be deleted.
     Example: FLATFILE_EVENTS_BACKED_UP_FILECOUNT=5 (the value 5 represents the count of the number of rotated log files to retain, it retain only 5 rotated log files)
     If the attribute value is not configured, then the default number of files that are considered is 10.
2. Edit $SPECROOT/SS/.vnmrc to set the **AXA_EVENT_INTEGRATION_ENABLED** attribute value to true. This attribute populates IPs and Groups of the devices or servers that you want to collect log data from. If the attribute value is not configured, then the IPs and Groups show no data.
   Example: AXA_EVENT_INTEGRATION_ENABLED=tru

   NOTE
   To read the custom events, the events and PCause files should be present in OneClick and SpectroSERVER.
3. Restart the archive manager and SpectroSERVER to start the logging of events.
   a. Stop the SpectroSERVER and the Archive Manager by clicking Stop SpectroSERVER in the DX NetOps Spectrum Control Panel
      Or, you can stop the SpectroSERVER and Archive Manager from the command line by running the "< $SPECROOT>/bin/stopSS.pl" as Spectrum Owner at the command prompt.
   b. Start the SpectroSERVER and the Archive Manager by clicking Start SpectroSERVER in the DX NetOps Spectrum Control Panel
      Or, you can start the SpectroSERVER and Archive Manager from the command line by running the "< $SPECROOT>/bin/startSS.pl" as Spectrum Owner at the command prompt.

Create Profile and Add Filters for Spectrum Events

In the Log Forwarder (log_forwarder) probe, you need to create a profile and define filters (Log Exclude Rules and Log Format Rules) for Spectrum events.

Create Spectrum Events Profile

To monitor the Spectrum events data in CA Digital Operational Intelligence, you need to create a configuration profile in the Log Forwarder (log_forwarder) probe. For the steps to create a profile, see **Create a Profile** section in the log_forwarder AC Configuration page.

Define Filters

In the Log Forwarder (log_forwarder) probe, you can define the following filters:

- Log Exclude Rules - To identify a line or block of input which you want the probe should exclude from monitoring. For the steps to define Log Exclude Rules, see Create Log Excludessection.
- Log Format Rules - To specify a line or block of input which starts with a defined start and end text or expression. For the steps to define Log Exclude Rules see Create Log Format Rules section.

> **NOTE**
> The Log Format Rule for DX NetOps Spectrum events must contain proper Start and End Expressions. For details see Create Log Format Rules section in the Log Forwarder (log_forwarder) probe documentation.

View DX NetOps Spectrum Events Analytics Dashboards in CA Digital Operational Intelligence

After configuring the probes, setting up the data collection source, creating profile and defining filters you can view the Spectrum events log analytics dashboards in CA App Experience Analytics. The Data Studio page in the AXA is a primary user interface for Log Analytics. Data Studio provides out-of-the-box dashboards for the supported log types, full-text search, and ad-hoc data exploration. For more information, see Data Studio.

Programming

This section contains information about using DX NetOps Spectrum to create a custom solution and contains reference material for the developers.

Development API Reference

The Development API is the Common Object Request Broker Architecture (CORBA)-based application program interface (API) to SpectroSERVER. You can also refer to it as the SpectroSERVER Object Request Broker (SSORB) interface or SSORB, because it depends on an object request broker (ORB). This section explains the purpose of the Development API, what it consists of, and what you can do with it.

> **NOTE**
> See the Release Information section for notifications of release-specific changes (if any) to the Development API interface.

Architecture

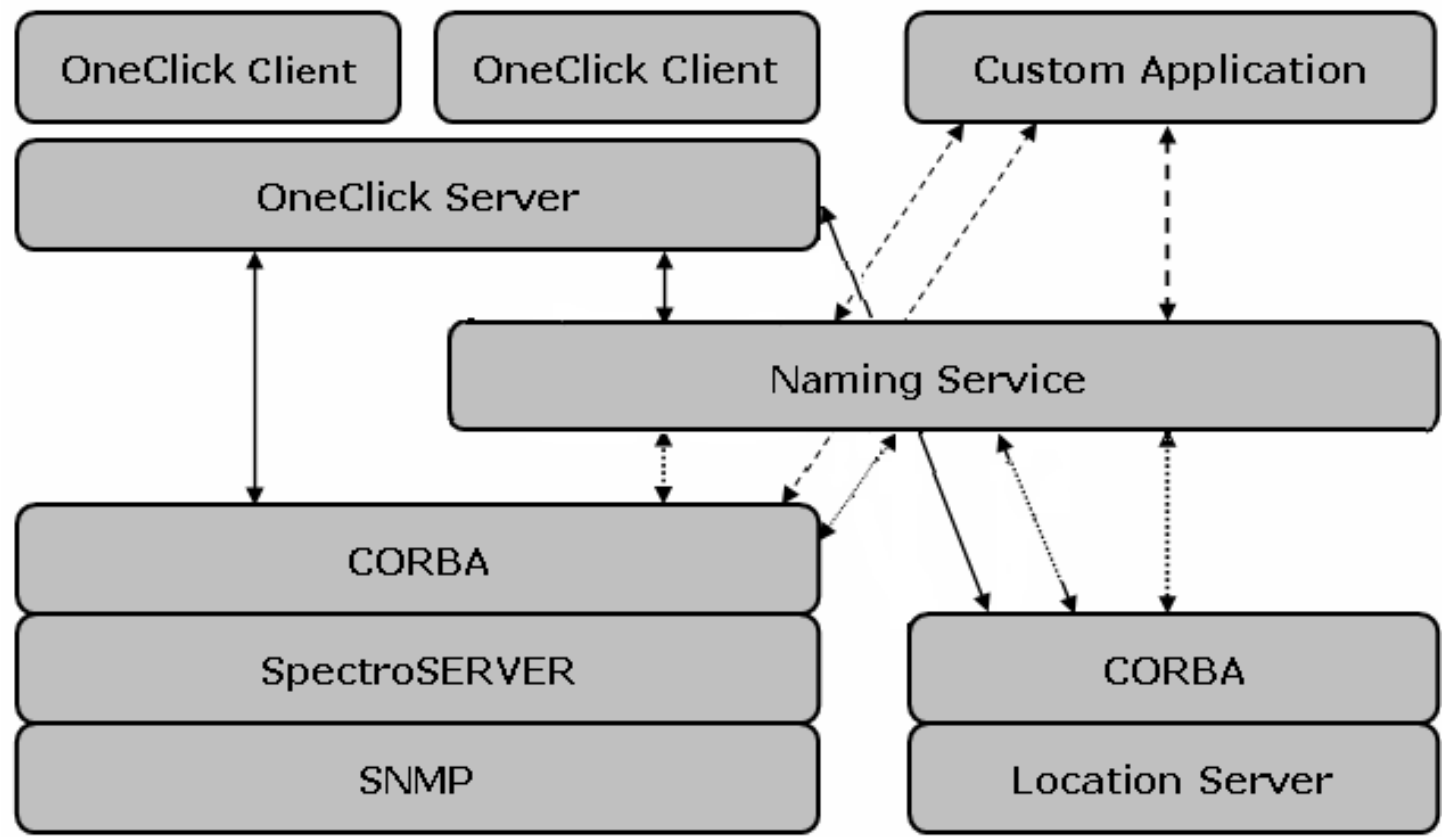
The Development API advertises through the CORBA Naming Service. Advertising through the CORBA naming service facilitates compatibility with other ORBs such as Orbacus and Java that support the standard Naming Service.

Client applications contact the Naming Service to retrieve the list of available services. You can view the list by using the *osfind* tool or the *nsutil* tool for the Naming Service list. Once the client application contacts an advertiser and gets the location of the required service, the client application can contact that service directly. Calls for data retrieval are possible after security checks are cleared.

Native threads handle incoming data requests at the VisiBroker CORBA layer. The requests then queue for SpectroSERVER processing.

The SpectroSERVER takes the first request off the queue and retrieves the required data. The data is attached to the outgoing queue to return to the client application. In the case of asynchronous data or callbacks, the SpectroSERVER maintains an active list of changes and notifies the client application about them. On multi-CPU systems where client applications implement callbacks, this workload is redistributed among native threads, freeing up processing cycles.

The Development API has the following architecture:



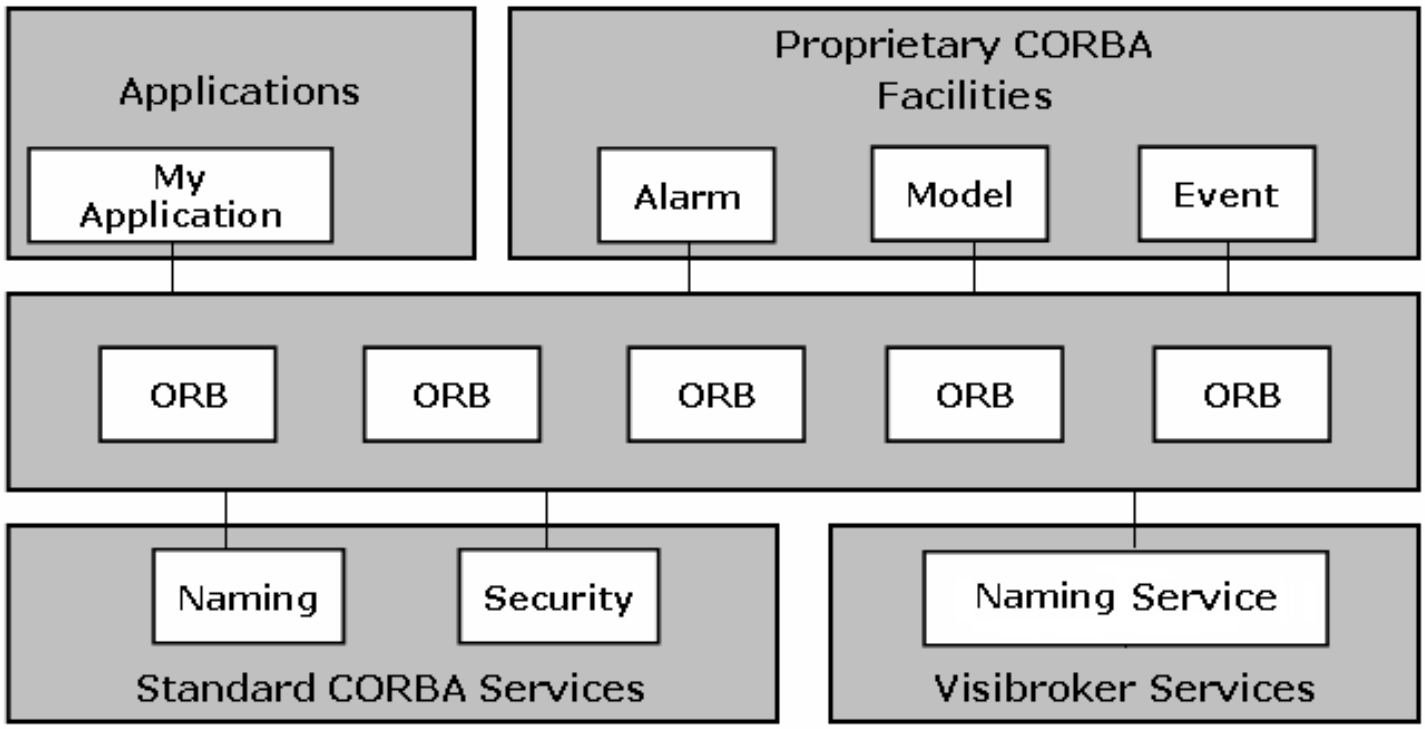
In this architecture, the Location Server, SpectroSERVER, and Archive Manager (not pictured) each have a CORBA interface for data retrieval. The Location Server provides the list of SpectroSERVERs available in the distributed SpectroSERVER domain. SpectroSERVER handles the interfaces to the model domain, alarm domain and type catalog. The Archive Manager handles the event domain.

When the SpectroSERVER, Location Server, or Archive Manager starts up, it advertises its services to the Naming Service.

The CORBA Standard

CORBA is a standard developed by the Object Management Group (OMG) consortium. The CORBA standard is a middleware, a framework that specifies how distributed applications can communicate using an ORB.

The following illustration shows client-server communication through an ORB:



The ORB facilitates communication between software components coded in different languages for different operating systems with different hardware architectures. It enables disparate objects on the network to recognize each other and invoke each other's methods.

The ORB is not a product; it is an implementation of OMG's CORBA standard. The CORBA standard defines the Interface Definition Language (IDL) used to describe the following:

- Interfaces to CORBA objects
- Programming language mappings
- Transport protocols
- High level services like naming and security

The CORBA Mechanism

The CORBA component that facilitates communication between remote applications is the IDL that defines an API. The SPECTRUM Development API consists of an IDL file for each object type. This set of IDL files is usually referred to as the DX NetOps Spectrum IDL.

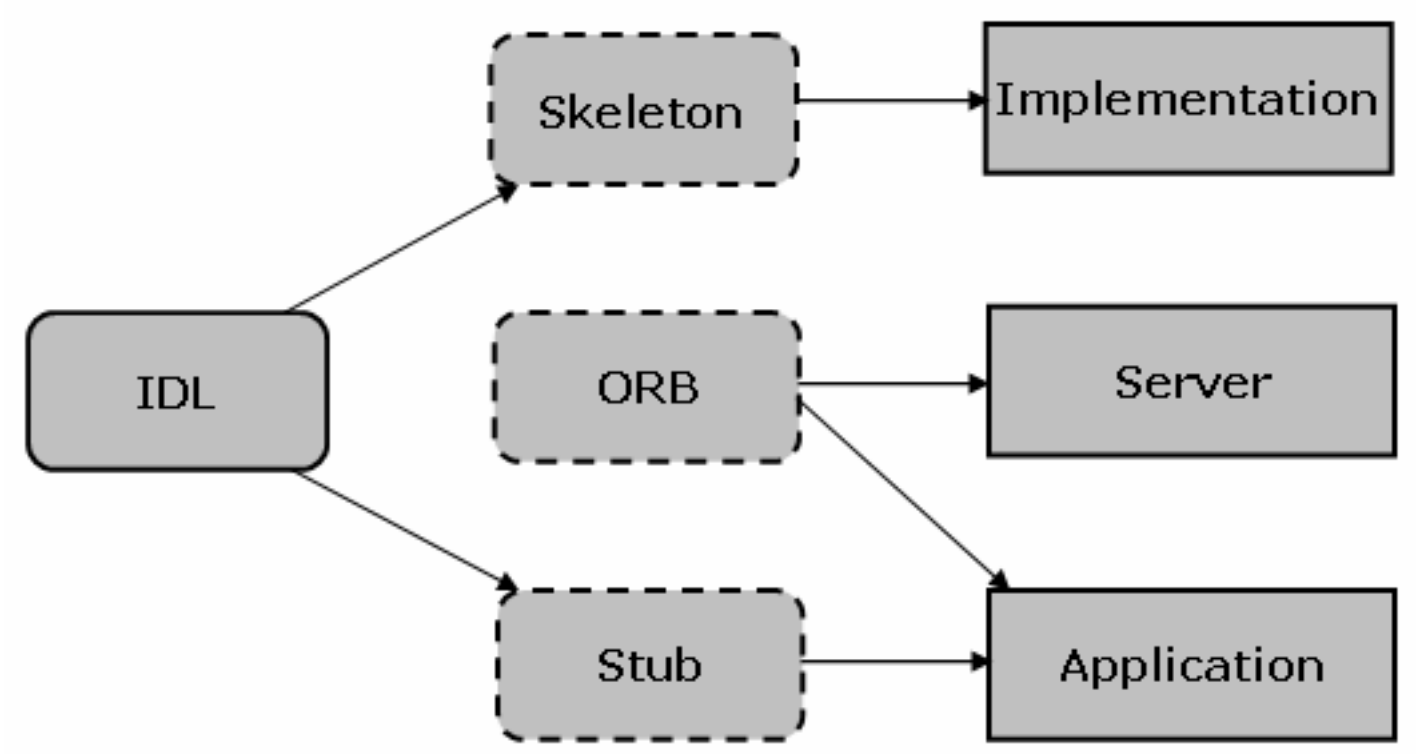
NOTE
The term IDL can also describe an interface.

CORBA defines a language mapping for every programming language. The language mapping describes how an IDL converts into the language-specific API. An IDL compiler implements this mapping by compiling an IDL file into a set of stubs and skeletons. *Stubs* are the methods and objects that an application can use; *skeletons* are empty methods and objects that you fill in to implement a server. The IDL generates stubs and skeletons while a vendor provides the ORB.

A programmer who creates a CORBA service object defines the interface in a CORBA-standard language, namely the IDL. If the IDL is run through the appropriate compilers, it produces both server and client code in standard programming languages. The server code is the skeleton because it represents a basic object as an abstract class from which the programmer derives a class to implement a service. The client code consists of a set of object reference stubs, which need no further coding.

For example, for a C++ mapping, the stubs include the header files used to compile the application and the object library linked to the application.

The application and server should link to the ORB library as shown in the following diagram:



To develop a server, you need to write the IDL and the implementation inside the skeletons. To develop an application, you need to call the stubs.

A program participating in the CORBA framework relies on its local ORB to overcome the communication barriers of language and process location. The program sends requests and gets responses to and from a data pipeline composed of all the ORBs in the system. This network of ORBs is often referred to as the ORB.

Each CORBA service resides on some computer and is implemented as an object coded in a programming language. To make itself available to clients, the object advertises its services through the ORB. A naming service (a standard CORBA service) picks up the advertisements and records the service name and object reference. If a client wants to use the service, it specifies the service name and contacts the naming service through the ORB. It receives the object reference and uses it to access the object's services.

The object reference and its corresponding server object are instances of different classes with the same interface. An object reference, obtained by the client from the naming service, executes on the client. The server object resides on the server. If a client invokes an object reference method, the method uses the ORB to call the corresponding method on the server. This server method fulfills the service request and returns the required data. For the client, the local object reference simulates the server object, but actually, the reference only does remote method invocations to the server.

Why DX NetOps Spectrum Uses CORBA

The Development API uses CORBA to focus on Java application development.

Use of Java in web-based applications is increasing. The SPECTRUM Development API focuses more on Java though it provides the same set of core services to both C++ and Java developers.

CORBA, an open standard, is best suited for Java application development. CORBA helps DX NetOps Spectrum customers write CORBA applications that integrate DX NetOps Spectrum with other CORBA services.

CORBA Sources

OMG publishes CORBA standard sections that cover the architecture and the language-specific mappings of CORBA. These standards are available at http://www.omg.org.

You can also get CORBA information from Borland Software Corporation, the vendor of VisiBroker ORB that DX NetOps Spectrum uses. The documentation is available at http://www.borland.com.

Data Structure Classes

Data structure classes are of two types: parameter and helper.

- **Parameter Class**
  Transfers data. Your client programs instantiate these classes and pass them to interface methods. The methods also return instances of these classes to your programs. Examples include CsCModelPropList, CsCMTypePropList, and CsCAttrValList.
- **Helper Class**
  Builds and unwraps complex parameter class objects.

You can find the Java docs for these classes by clicking the link com.aprisma.spectrum.core.util in the file <*$SPECROOT*>/SDK/docs/SSORB/index.html. Examples include CsCorbaValueHelper and CsCAttrFilterHelper.

Error Reporting

CORBA reports errors through exceptions. Error reporting through exceptions is an all-or-nothing approach because no other result is possible. This approach is not helpful for partial failures, when only a few items of a request fail. Also, it is not optimal to raise an exception for every failure. The CORBA approach is to use exceptions for complete failures and report partial failures with error codes in result lists. Because it is not optimal to search an entire list to see if any item failed, result lists also provide an overall error code to indicate partial failures.

C++ Development on Windows

The following table lists the library and dynamic link libraries necessary for C++ development on Windows. The corresponding directory location is <*$SPECROOT/lib*>.

Library Files	SDK
libGlobl (dll), libssorb (dll), ibssorbutil (dll)	SPECTRUM
orb_r_70 (dll), cosnm_r_70 (dll), vport_r_70 (dll), vdlog_r_70 (dll)	Borland VisiBroker

The following table shows the corresponding header file locations:

Library	Header File Location
libGlobl.dll	<*$SPECROOT*>\SDK\include\GLOBL
libssorb.dll	<*$SPECROOT*>\SDK\include\SSORB\idl
libssorbutil.dll	<*$SPECROOT*>\SDK\include\SSORB\util
cosnm_r_70.dll, orb_r_70.dll, vbsec.dll, vdlog_r_70.dll, vport_r_70.dll	Provided by Borland VisiBroker SDK (Not included in SPECTRUM CORBA toolkit.)

Prerequisites for programming with the Development API

Verify that you have the following in place before you start programming with the Development API:

- Development requirements.
- DX NetOps Spectrum version -- You need r9.*x* or above, with SpectroSERVER and Archive Manager (ArchMgr) running.
- DX NetOps Spectrum access -- If your DX NetOps Spectrum server and client computer are different, the .hostrc file in the DX NetOps Spectrum directory on your DX NetOps Spectrum server should allow the programs on your client to interact with the SpectroSERVER. To facilitate this, open the .hostrc file with a text editor, remove the individual host name if it exists, and add either a plus (+) sign or the name of your client computer, and close the file. You need not shut down and restart any DX NetOps Spectrum processes; they automatically re-read the configuration file within a minute.
- User model -- Verify that DX NetOps Spectrum has a user model with a name that matches the user name you use on your client computer to run the example programs.
- Devices -- Many of the exercises require you to create models or read model attributes. It is helpful to have a few SNMP devices (switches, routers, and so on) running on your network so that you can model them. You can model your own client computer if it is running a supported SNMP agent.
- Work directory -- Create a work directory for the example exercises in the following section. You need to set the CLASSPATH variable pointing to the CORBA JAR files, which are located in <*$SPECROOT*>/lib.

  NOTE
  For CLASSPATH examples, see Java Development Specifics.

If your development environment meets all these criteria, you can compile a program by executing javac <*ProgramName*>.java and run a program by executing java <*ProgramName*>.

Environment Verification

You can perform a test of your development environment once you have verified the following:

- SpectroSERVER and ArchMgr are running on your DX NetOps Spectrum server.
- JDK and DX NetOps Spectrum SDK are present on your client computer.
- DX NetOps Spectrum SDK contains the necessary example programs, jar files, and javadoc files.

The test involves verifying the client-server communication and whether you can compile and run the example programs from the cmdline directory.

To verify that the example programs can communicate with your SpectroSERVER, enter the following:

```
cd SDK/examples/SSORB/DevelopmentAPI
javac GetDomainID.java
java GetDomainID <domainName>
```

Replace <*domainName*> with the Domain Naming System (DNS) or network name of your SpectroSERVER host system. The GetDomainID example should display the landscape handle of your SpectroSERVER.

Version Requirements

The following table lists the version requirements for the various software tools used with the Development API:

Development Tools	Version
Borland VisiBroker SDK	8.5sp1

Windows	Windows Server 2016 Windows Server 2012
Java SDK	1.7.0
Red Hat Enterprise Linux	6, 7
GNU C++	4.1 or 4.4
Java SDK	1.7.0
Java SDK	1.7.0

Java Development Specifics

The following JAR files are necessary for Java development with DX NetOps Spectrum SDK, where *xx* is the version of DX NetOps Spectrum that you are running. For example, if you are running DX NetOps Spectrum r9.3, global*xx*.jar would be global93.jar.

- global*xx*.jar
- ssorb*xx*.jar
- ssorbutil*xx*.jar
- util*xx*.jar
- utilapp*xx*.jar
- utilnet*xx*.jar
- utilsrv*xx*.jar
- vbhelper*xx*.jar
- vbjorb.jar
- bsec.jar
- lm.jar
- cryptojFIPS.jar
- sanct6.jar (Linux only)
- sanctuary.jar (Linux only)

The corresponding directory location is <*$SPECROOT*>/lib, and the JAR file location should be set by the CLASSPATH environment variable.

Example: Setting the CLASSPATH environment variable

The following are examples of setting the CLASSPATH variable for different platforms. Replace the following variables accordingly:

- ***<$SPECROOT>***
  Specify the complete path to your DX NetOps Spectrum installation directory.
- ***xx***
  Specify the version of DX NetOps Spectrum that you are running. For example, if you are running DX NetOps Spectrum r9.3, global*xx*.jar would be global93.jar.
- You can set the CLASSPATH on Windows as follows:

```
CLASSPATH=<$SPECROOT>\lib\globalxx.jar;<$SPECROOT>\lib\ssorbxx.jar;<$SPECROOT>\lib\ssorbutilxx.jar;<
$SPECROOT>\lib\vbhelperxx.jar;<$SPECROOT>\lib\vbjorb.jar;<$SPECROOT>\lib\vbsec.jar;<$SPECROOT>\lib
\utilxx.jar;<$SPECROOT>\lib\utilnetxx.jar;<$SPECROOT>\lib\utilsrvxx.jar;<$SPECROOT>\lib\lm.jar;<$SPECROOT>
\lib\cryptojFIPS.jar;<$SPECROOT>\lib\utilappxx.jar;.;
```

- You can set the CLASSPATH on Linux as follows:

```
CLASSPATH=<$SPECROOT>/lib/globalxx.jar:<$SPECROOT>/lib/ssorbxx.jar:<$SPECROOT>/lib/ssorbutilxx.jar:<
$SPECROOT>/lib/vbhelperxx.jar:<$SPECROOT>/lib/vbjorb.jar:<$SPECROOT>/lib/vbsec.jar:<$SPECROOT>/
lib/utilxx.jar:<$SPECROOT>/lib/utilnetxx.jar:<$SPECROOT>/lib/utilsrvxx.jar:<$SPECROOT>/lib/lm.jar:<
$SPECROOT>\lib\cryptojFIPS.jar:<$SPECROOT>/lib/sanct6.jar:<$SPECROOT>/lib/sanctuary.jar:<$SPECROOT>/lib/
utilappxx.jar:.:
```

C++ Development on Windows

The following table lists the library and dynamic link libraries necessary for C++ development on Windows. The corresponding directory location is <*$SPECROOT/lib*>.

Library Files	SDK
libGlobl.lib libssorb.lib ibssorbutil.lib	DX NetOps Spectrum
orbcore_r.lib cosnm_r_80.lib vport_r_80.lib vdlog_r_80.lib	Borland VisiBroker

The following table shows the corresponding header file locations:

Library	Header File Location
libGlobl.dll	<*$SPECROOT*>\SDK\include\GLOBL
libssorb.dll	<*$SPECROOT*>\SDK\include\SSORB\idl
libssorbutil.dll	<*$SPECROOT*>\SDK\include\SSORB\util
orbcore_r_80.dll cosnm_r_80.dll vport_r_80.dll vdlog_r_80.dll	Provided by Borland VisiBroker SDK (Not included in DX NetOps Spectrum CORBA toolkit.)

C++ Development on Linux

The following table lists the shared objects and libraries necessary for C++ development on Linux. The corresponding directory location is <*$SPECROOT/lib*>.

Library File	SDK
libGlobl (so, so.1) libssorb (so, so.1) libssorbutil (so, so.1) libPort (so, so.1) libVPapi (so, so.1)	DX NetOps Spectrum
liborbcore_r.so libcosnm_r.so libvport_r.so libvdlog_r.so	Borland VisiBroker

The following table shows the corresponding header file locations:

Shared Object/Library File	Header File Location
libGlobl.so	<*$SPECROOT*>/SDK/include/GLOBL
libssorb.so	<*$SPECROOT*>/SDK/include/SSORB/idl
libssorbutil.so	<*$SPECROOT*>/SDK/include/SSORB/util
libPort.so	<*$SPECROOT*>/SDK/include/PORT
libVPapi.so	<*$SPECROOT*>/SDK/include/VPAPI
liborbcore_r (so, so.8.0) libcosnm_r (so, so.8.0) libvport_r (so, so.8.0) libvdlog_r (so, so.8.0)	Provided by Borland VisiBroker SDK (Not included in DX NetOps Spectrum CORBA toolkit.)

Standard Naming Service and VisiBroker ORB

Client applications use the Standard Naming Service, resulting in ORB independence. With ORB independence, the only requirement is that the ORB implement the Standard Naming Service.

ORB Examples

The DX NetOps Spectrum Developer Kit includes CORBA client applications built with ORBs from other vendors that use the standard naming service.

The following table lists the ORBs and directory locations for different development platforms:

ORB	Platform and Development	Directory Location
Mico	Linux, C++	<*$SPECROOT*>/SDK/examples/SSORB/nameserv/cc/mico
Java	Windows Java	<*$SPECROOT*>/SDK/examples/SSORB/nameserv/java/

The DX NetOps Spectrum IDL

The IDL files are the essential part of the SPECTRUM Development API (which also includes the helper classes, examples, and documentation). The IDL files define the interfaces to various DX NetOps Spectrum services (model domain, event domain, and so on) and are available in the following directory:

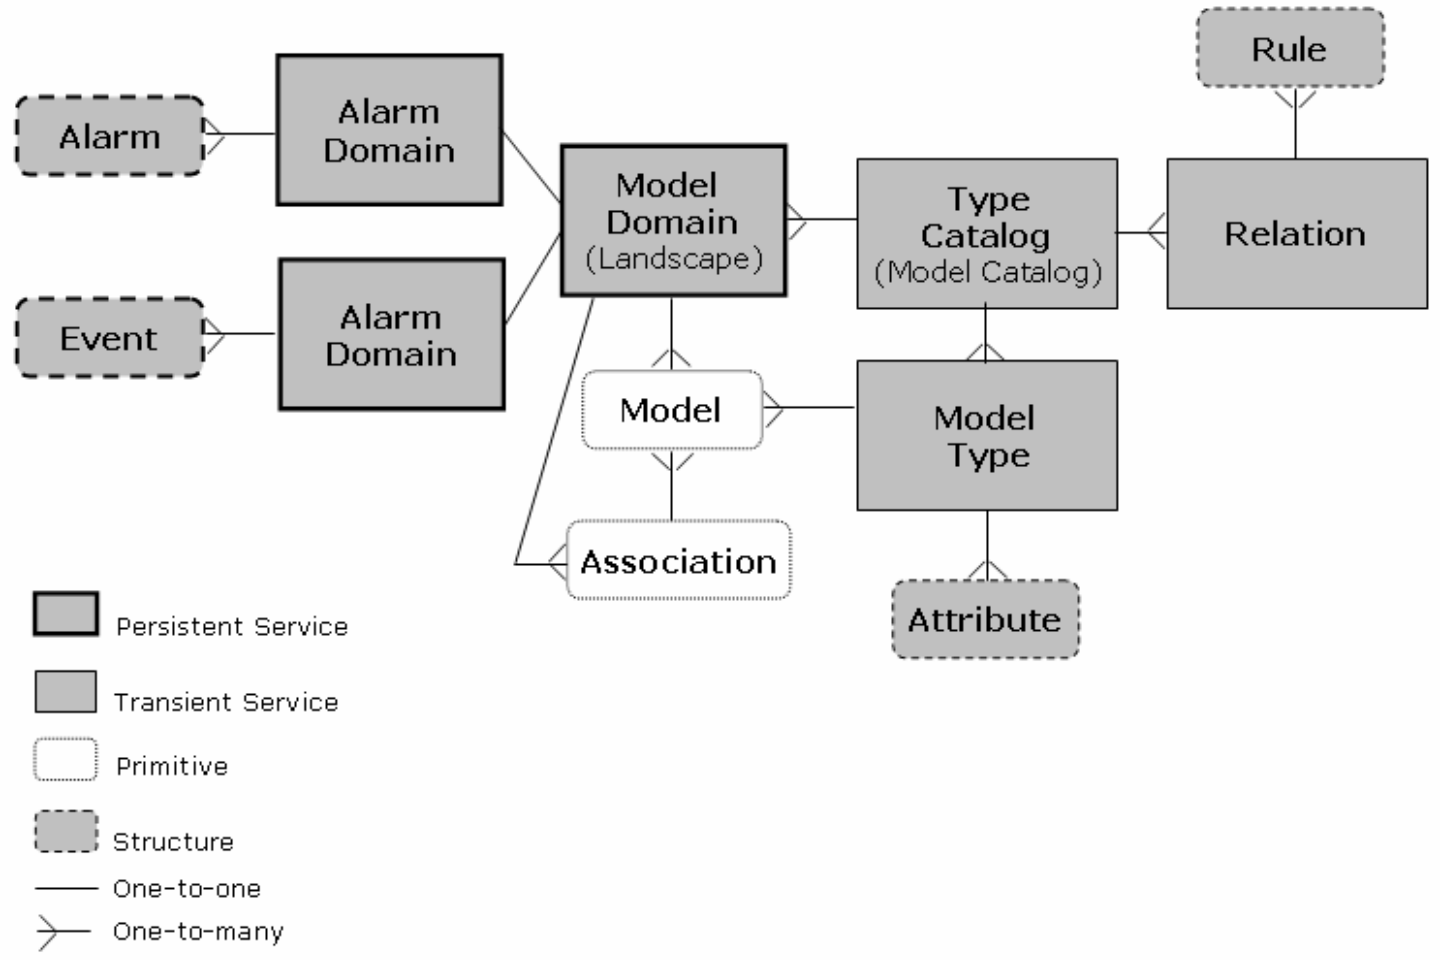
```
<$SPECROOT>/SDK/examples/SSORB/idl
```

WARNING
The DX NetOps Spectrum IDL is proprietary; even two CORBA-compliant platforms cannot collaborate unless they use the same IDL.

The DX NetOps Spectrum IDL is based on SSAPI and IHAPI to keep it close to the concepts familiar to DX NetOps Spectrum legacy application developers. The DX NetOps Spectrum IDL data model is similar to that of earlier toolkits and all of the following continue to exist:

- Models with attributes
- Model types
- Associations between models
- Relations
- Alarms
- Events
- Statistics

The Development API data model is as follows:



The Development API Classes

The SPECTRUM Development API includes interface and data structure classes. Interface classes implement the DX NetOps Spectrum services and data structure classes include parameter, helper, and global classes.

Interface Classes

SpectroSERVER and ArchMgr contain the following classes. You need object references to access these classes.

- **CsCModelDomain**
  Defines the model domain. Each instance of this class contains models and associations of a model domain. Each SpectroSERVER implements a model domain.

This is a persistent CORBA service and the supporting IDL file is cscmodeldomain.idl.

- **CsCTypeCatalog**
  Provides access to a type catalog, which contains model types and relations. All the SpectroSERVERs of a release at a site should have the same type catalog, but differences may occur. Each type catalog has its own instance of this service, with each SpectroSERVER implementing a type catalog.
  This is a transient CORBA service and the supporting IDL file is csctypecatalog.idl.
- **CsCModelType**
  Provides access to a model type and its attributes. A model type is a template for creating and classifying models. Each model type has its own instance of this service.
  This is a transient CORBA service and the supporting IDL file is cscmodeltype.idl.
- **CsCRelation**
  Provides access to a relation and its rules. A relation is a template for creating and classifying associations. Each relation has its own instance of this service.
  This is a transient CORBA service and the supporting IDL file is cscrelation.idl.
- **CsCAlarmDomain**
  Provides access to an alarm domain. An alarm domain contains alarms for models of a model domain. Each alarm domain has its own instance of this service, with each SpectroSERVER implementing one alarm domain.
  This is a persistent CORBA service and the supporting IDL file is cscalarmdomain.idl.
- **CsCEventDomain**
  Provides access to an event domain. An event domain contains events for the models of a model domain. Each event domain has its own instance of this service with each ArchMgr implementing one event domain.
  This is a persistent CORBA service and the supporting IDL file is csceventdomain.idl.

You can find the Java Docs for these classes by opening the file <*$SPECROOT*>/SDK/docs/SSORB/index.html and clicking com.aprisma.spectrum.core.idl in the Packages list. The IDL files for these classes are available in <*$SPECROOT*>/SDK/examples/SSORB/idl.

Additional IDLs

The <*$SPECROOT*>/SDK/examples/SSORB/idl includes the following IDL files but the services they support are not considered CORBA services:

- **cscattribute.idl**
  Defines attribute types and attribute values that other IDLs reuse.
- **cscdeveloper.idl**
  Defines the structures that management module developers use in the type catalog.
- **cscerror.idl**
  Defines the error codes that other IDLs reuse.
- **cscexception.idl**
  Defines the DX NetOps Spectrum exception that other IDLs reuse because most methods raise this exception.

Data Structure Classes

Data structure classes are of two types: parameter and helper.

- **Parameter Class**
  Transfers data. Your client programs instantiate these classes and pass them to interface methods. The methods also return instances of these classes to your programs. Examples include CsCModelPropList, CsCMTypePropList, and CsCAttrValList.
- **Helper Class**
  Builds and unwraps complex parameter class objects.

You can find the Java docs for these classes by clicking the link com.aprisma.spectrum.core.util in the file <*$SPECROOT*>/SDK/docs/SSORB/index.html. Examples include CsCorbaValueHelper and CsCAttrFilterHelper.

Global Classes

Global classes contain standard security and login objects that DX NetOps Spectrum uses. You can find the Java docs for these classes in <*$SPECROOT*>/SDK/examples/SSORB/idl.

Java Development Specifics

The following JAR files are necessary for Java development with DX NetOps Spectrum SDK, where *xx* is the version of DX NetOps Spectrum that you are running. For example, if you are running 10.3, global*xx*.jar would be global103.jar.

- global*xx*.jar
- ssorb*xx*.jar
- ssorbutil*xx*.jar
- util*xx*.jar
- utilapp*xx*.jar
- utilnet*xx*.jar
- utilsrv*xx*.jar
- vbhelper*xx*.jar
- vbjorb.jar
- bsec.jar
- lm.jar
- cryptojFIPS.jar
- sanct6.jar (Linux only)
- sanctuary.jar (Linux only)

The corresponding directory location is <*$SPECROOT*>/lib, and the JAR file location should be set by the CLASSPATH environment variable.

Example: Setting the CLASSPATH environment variable

The following are examples of setting the CLASSPATH variable for different platforms. Replace the following variables accordingly:

<*$SPECROOT*>

Specify the complete path to your DX NetOps Spectrum installation directory.

xx

Specify the version of DX NetOps Spectrum that you are running. For example, if you are running 10.3, global*xx*.jar would be global103.jar.

- You can set the CLASSPATH on Windows as follows:

CLASSPATH=<*$SPECROOT*>\lib\global*xx*.jar;<*$SPECROOT*>\lib\ssorb*xx*.jar;<*$SPECROOT*>\lib
\ssorbutil*xx*.jar;<*$SPECROOT*>\lib\vbhelper*xx*.jar;<*$SPECROOT*>\lib\vbjorb.jar;<*$SPECROOT*>\lib
\vbsec.jar;<*$SPECROOT*>\lib\util*xx*.jar;<*$SPECROOT*>\lib\utilnet*xx*.jar;<*$SPECROOT*>\lib\utilsrv*xx*.jar;<*$SPECROOT*>
\lib\lm.jar;<*$SPECROOT*>\lib\cryptojFIPS.jar;<*$SPECROO*T>\lib\utilapp*xx*.jar;.;

- You can set the CLASSPATH on Linux as follows:

CLASSPATH=<*$SPECROOT*>/lib/global*xx*.jar:<*$SPECROOT*>/lib/ssorb*xx*.jar:<*$SPECROOT*>/lib/
ssorbutil*xx*.jar:<*$SPECROOT*>/lib/vbhelper*xx*.jar:<$SPECROOT>/lib/vbjorb.jar:<*$SPECROOT*>/lib/
vbsec.jar:<*$SPECROOT*>/lib/util*xx*.jar:<*$SPECROOT*>/lib/utilnet*xx*.jar:<*$SPECROOT*>/lib/utilsrv*xx*.jar:<*$SPECROOT*>/
lib/lm.jar:<*$SPECROOT*>\lib\cryptojFIPS.jar:<*$SPECROOT*>/lib/sanct6.jar:<*$SPECROOT*>/lib/
sanctuary.jar:<*$SPECROOT*>/lib/utilapp*xx*.jar:.:

C++ Development on Windows

The following table lists the library and dynamic link libraries necessary for C++ development on Windows. The corresponding directory location is <*$SPECROOT/lib*>.

Library Files	SDK
libGlobl.lib libssorb.lib ibssorbutil.lib	DX NetOps Spectrum
orbcore_r.lib cosnm_r_80.lib vport_r_80.lib vdlog_r_80.lib	Borland VisiBroker

The following table shows the corresponding header file locations:

Library	Header File Location
libGlobl.dll	<*$SPECROOT*>\SDK\include\GLOBL
libssorb.dll	<*$SPECROOT*>\SDK\include\SSORB\idl
libssorbutil.dll	<*$SPECROOT*>\SDK\include\SSORB\util
orbcore_r_80.dll cosnm_r_80.dll vport_r_80.dll vdlog_r_80.dll	Provided by Borland VisiBroker SDK (Not included in DX NetOps Spectrum CORBA toolkit.)

C++ Development on Linux

The following table lists the shared objects and libraries necessary for C++ development on Linux. The corresponding directory location is <*$SPECROOT/lib*>.

Library File	SDK
libGlobl (so, so.1) libssorb (so, so.1) libssorbutil (so, so.1) libPort (so, so.1) libVPapi (so, so.1) libWrappers (so, so.1)	CA Spectrum
liborbcore_r.so libcosnm_r.so libvport_r.so libvdlog_r.so	Borland VisiBroker

The following table shows the corresponding header file locations:

Shared Object/Library File	Header File Location
libGlobl.so	<*$SPECROOT*>/SDK/include/GLOBL
libssorb.so	<*$SPECROOT*>/SDK/include/SSORB/idl
libssorbutil.so	<*$SPECROOT*>/SDK/include/SSORB/util
libPort.so	<*$SPECROOT*>/SDK/include/PORT
libVPapi.so	<*$SPECROOT*>/SDK/include/VPAPI
liborbcore_r (so, so.8.0) libcosnm_r (so, so.8.0) libvport_r (so, so.8.0) libvdlog_r (so, so.8.0)	Provided by Borland VisiBroker SDK (Not included in DX NetOps Spectrum CORBA toolkit.)

Standard Naming Service and VisiBroker ORB

Client applications use the Standard Naming Service, resulting in ORB independence. With ORB independence, the only requirement is that the ORB implement the Standard Naming Service.

ORB Examples

The DX NetOps Spectrum Developer Kit includes CORBA client applications built with ORBs from other vendors that use the standard naming service. The following table lists the ORBs and directory locations for different development platforms:

ORB	Platform and Development	Directory Location
Mico	Linux, C++	<*$SPECROOT*>/SDK/examples/SSORB/nameserv/cc/mico
Java	Windows, Java	<*$SPECROOT*>/SDK/examples/SSORB/nameserv/java/sun

DX NetOps Spectrum IDL

The IDL files are an essential part of SPECTRUM Development API (which also includes the helper classes, examples, and documentation). The IDL files define the interfaces to various DX NetOps Spectrum services (model domain, event domain, and so on) and are available in the following directory:

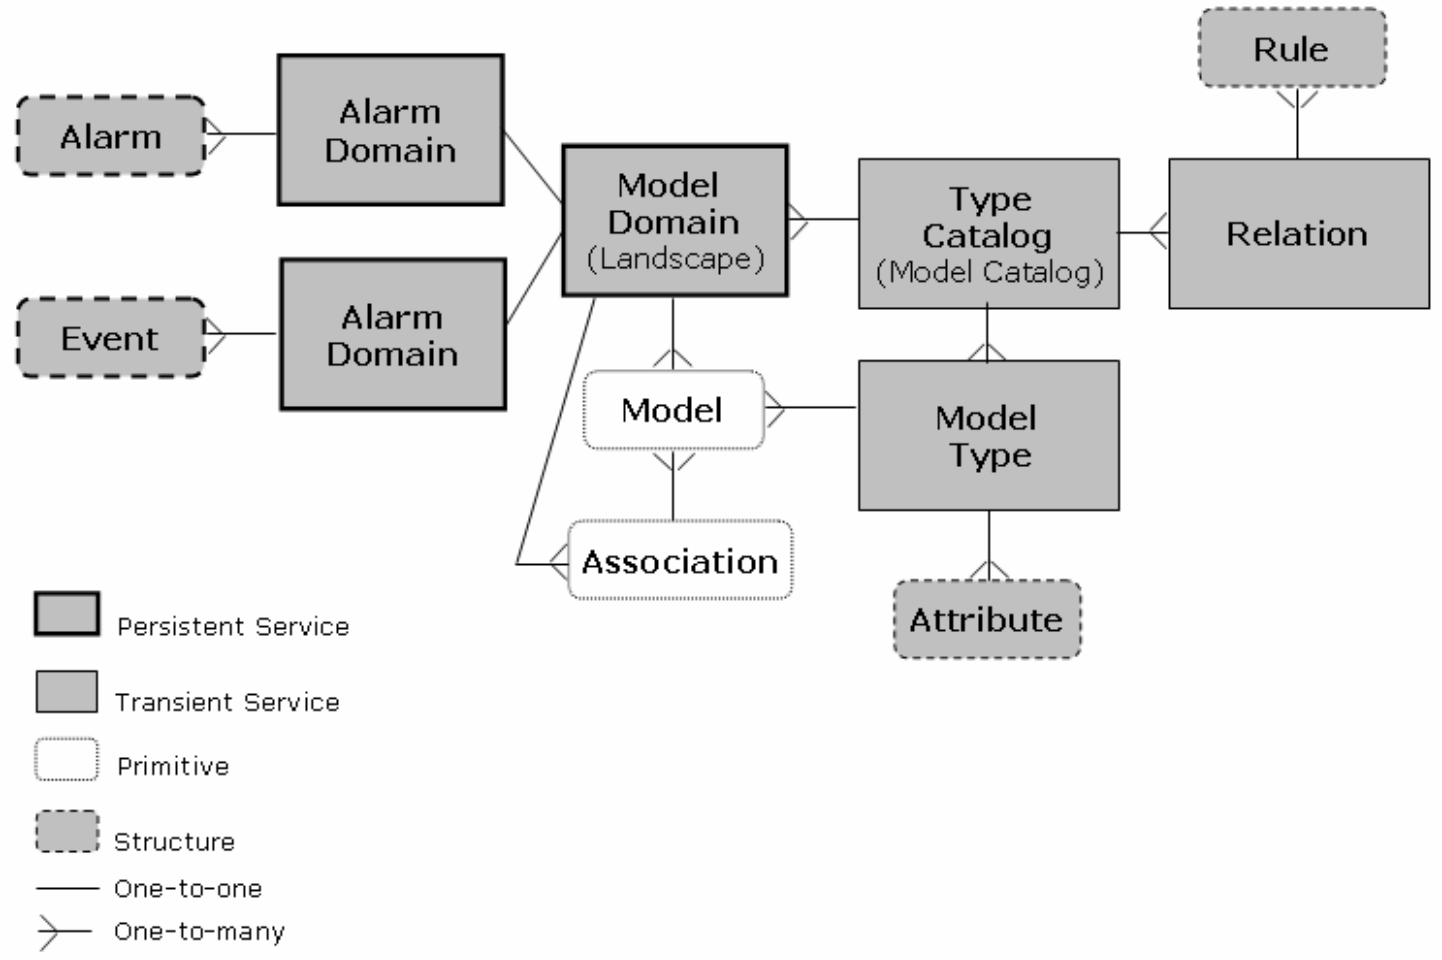
```
<$SPECROOT>/SDK/examples/SSORB/idl
```

> **WARNING**
> DX NetOps Spectrum IDL is proprietary; even two CORBA-compliant platforms cannot collaborate unless they use the same IDL.

DX NetOps Spectrum IDL is based on SSAPI and IHAPI to keep it close to the concepts familiar to DX NetOps Spectrum legacy application developers. The DX NetOps Spectrum IDL data model is similar to that of earlier toolkits and all of the following continue to exist:

- Models with attributes
- Model types
- Associations between models
- Relations
- Alarms
- Events
- Statistics

The Development API data model is as follows:



Development API Classes

The SPECTRUM Development API includes interface and data structure classes. Interface classes implement the DX NetOps Spectrum services and data structure classes include parameter, helper, and global classes.

Interface Classes

SpectroSERVER and ArchMgr contain the following classes. You need object references to access these classes.

- **CsCModelDomain**
  Defines the model domain. Each instance of this class contains models and associations of a model domain. Each SpectroSERVER implements a model domain.

This is a persistent CORBA service and the supporting IDL file is cscmodeldomain.idl.

- **CsCTypeCatalog**
  Provides access to a type catalog, which contains model types and relations. All the SpectroSERVERs of a release at a site should have the same type catalog, but differences may occur. Each type catalog has its own instance of this service, with each SpectroSERVER implementing a type catalog.
  This is a transient CORBA service and the supporting IDL file is csctypecatalog.idl.
- **CsCModelType**
  Provides access to a model type and its attributes. A model type is a template for creating and classifying models. Each model type has its own instance of this service.
  This is a transient CORBA service and the supporting IDL file is cscmodeltype.idl.
- **CsCRelation**
  Provides access to a relation and its rules. A relation is a template for creating and classifying associations. Each relation has its own instance of this service.
  This is a transient CORBA service and the supporting IDL file is cscrelation.idl.
- **CsCAlarmDomain**
  Provides access to an alarm domain. An alarm domain contains alarms for models of a model domain. Each alarm domain has its own instance of this service, with each SpectroSERVER implementing one alarm domain.
  This is a persistent CORBA service and the supporting IDL file is cscalarmdomain.idl.
- **CsCEventDomain**
  Provides access to an event domain. An event domain contains events for the models of a model domain. Each event domain has its own instance of this service with each ArchMgr implementing one event domain.
  This is a persistent CORBA service and the supporting IDL file is csceventdomain.idl.

You can find the Java Docs for these classes by opening the file <*$SPECROOT*>/SDK/docs/SSORB/index.html and clicking com.aprisma.spectrum.core.idl in the Packages list. The IDL files for these classes are available in <*$SPECROOT*>/SDK/examples/SSORB/idl.

Additional IDLs

The <*$SPECROOT*>/SDK/examples/SSORB/idl includes the following IDL files but the services they support are not considered CORBA services:

- **cscattribute.idl**
  Defines attribute types and attribute values that other IDLs reuse.
- **cscdeveloper.idl**
  Defines the structures that management module developers use in the type catalog.
- **cscerror.idl**
  Defines the error codes that other IDLs reuse.
- **cscexception.idl**
  Defines the DX NetOps Spectrum exception that other IDLs reuse because most methods raise this exception.

Data Structure Classes

Data structure classes are of two types: parameter and helper.

- **Parameter Class**
  Transfers data. Your client programs instantiate these classes and pass them to interface methods. The methods also return instances of these classes to your programs. Examples include CsCModelPropList, CsCMTypePropList, and CsCAttrValList.
- **Helper Class**
  Builds and unwraps complex parameter class objects.

You can find the Java docs for these classes by clicking the link com.aprisma.spectrum.core.util in the file <*$SPECROOT*>/SDK/docs/SSORB/index.html. Examples include CsCorbaValueHelper and CsCAttrFilterHelper.

Global Classes

Global classes contain standard security and login objects that DX NetOps Spectrum uses. You can find the Java docs for these classes in <*$SPECROOT*>/SDK/examples/SSORB/idl.

Product-Related Services

The following sections explain how application developers can use DX NetOps Spectrum services.

Security

Security is a major concern because the development API accepts Java applet calls over the web. To continue to provide the same level of security as earlier DX NetOps Spectrum versions, the API includes user passwords. The API also includes helper classes to set the login and maintain a secure connection.

Error Reporting

CORBA reports errors through exceptions. Error reporting through exceptions is an all-or-nothing approach because no other result is possible. This approach is not helpful for partial failures, when only a few items of a request fail. Also, it is not optimal to raise an exception for every failure. The CORBA approach is to use exceptions for complete failures and report partial failures with error codes in result lists. Because it is not optimal to search an entire list to see if any item failed, result lists also provide an overall error code to indicate partial failures.

Documentation and Examples

The SPECTRUM Development API provides a well-commented IDL as the primary source for application developers. You can also use the IDL to create Java doc web pages through Java-generated stubs.

The toolkit also includes working examples and test programs for which Java versions are available in <*$SPECROOT*>/SDK/examples/SSORB/DevelopmentAPI.

Additional VisiBroker Arguments

The *VisiBroker Programmer's Reference* includes additional VisiBroker arguments that the SPECTRUM Development API provides.

> **NOTE**
> For more information, access the following web address: http://info.borland.com/techpubs.

Developer Kit

Access DX NetOps Spectrum Java Documentation

The Development API Java documentation is an important part of the SPECTRUM Development API.

To access the Development API Java documentation

1. Open <*$SPECROOT*>/SDK/docs/SSORB/index.html in your browser and click com.aprisma.spectrum.core.idl under Packages.
   The Interface Summary and Class Summary appear.
2. Click a link under the summaries.
   The interface or class description appears.
3. Scroll past the description.
   The field, constructor, and method summaries appear. Method descriptions appear under Method Summary.

4. Click a method link.
   The Method Detail section appears.

   NOTE
   The code samples are available in <*$SPECROOT*>/SDK/examples/SSORB/DevelopmentAPI.

Java Permissions

You need to set permissions as follows:

- The java.util.PropertyPermission: Set both read and write permissions.
- The java.lang.RuntimePermission: Use setContextClassLoader.

You need to set additional permissions depending on the application you develop. For example, to read a properties file or write to a log file, you need to set the file permission.

Model Domain ID

Each SpectroSERVER in a DX NetOps Spectrum environment has a model domain with a unique ID and name as follows:

- The unique ID is the entity named *landscape handle* in DX NetOps Spectrum terminology.
- The unique name is the DNS or network name of the SpectroSERVER host system.
- The GetDomainID program uses a model domain name to get and display the model domain ID. In doing so, GetDomainID also performs the following functions:
- Bind to a DX NetOps Spectrum CORBA service
- (Optional) Set security

All programs that you write should perform these functions.

Service Binding

CORBA provides a helper object to simplify the binding process for DX NetOps Spectrum. The CORBAHelper class encapsulates a CORBA ORB and provides helper methods for locating and advertising CORBA objects. The purpose of this class is to hide ORB vendor-specific methods of advertising CORBA objects. CORBAHelper is an abstract class; you can obtain a vendor-specific implementation through one of the static methods.

NOTE
You need to import the CORBAHelper class from the com.aprisma.util.corba package.

The CORBAHelper class defines the following properties:

- **LOGIN_USERNAME (user.name)**
  Defines the user name.

  NOTE
  user.name is set in the System Properties at startup, but you can override it in Supplied Properties.
- **LOGIN_APPNAME (CORBAHelper.AppName)**
  Defines the application name.
- **LOGIN_SUBAPPNAME (CORBAHelper.SubAppName)**
  Defines the sub-application name.
- **LOGIN_APPVERSION (CORBAHelper.AppVersion)**
  Defines the version of the application.
- **LOGIN_PASSWORD (CORBAHelper.password)**
  Defines the user password.

NOTE
For all the previous properties, for SSORB communication, the corresponding CsApplicationInfo field is set.

- **LOGIN_CONNECTIONTYPE (CORBAHelper.ConnectionType)**
  Defines the connection type as enumerated in CsApplicationInfo.
- **NAMING_SERVICE_PORT**
  Set this property only if your Naming Service is configured to run on a port other than 14006 (the SPECTRUM default).

An application can set these properties through *System.setProperty* or a Properties object supplied to the init method. The defined values are in parentheses.

Binding Implementation

The following example shows binding implementation. Because a user is not specified, the helper defaults to the user running the program. It also shows the majority of code enclosed in a try catch statement. The methods getObjectImplementation and getModelDomainID throw exceptions if you refer to the Java Docs.

NOTE
Code samples in the later sections of this section leave out the *try* and *catch* statements for brevity, but you must include them in your programs.

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.util.corba.* ;
import java.io.*

public class ExampleBind
{
    public static void main(String[] args)
    {
        try
        {
            //*************************************************
            // Initialize.
            //*************************************************
            String domainName = new String("mySpectroServer");
            // Construct helper
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            if (helper.init(null, null))
            {
                CsCModelDomain md = (CsCModelDomain)
                helper.getObjectImplementation (
                    CsCModelDomain.class, domainName ) ;
                //*********************************************
                //Get the Model Domain ID
                //*********************************************
                int ID = md.getModelDomainID();
                System.out.println("0x" + Integer.toHexString(ID) );
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
```

```
}
```

Binding Implementation with User Specification

The following example shows how to implement binding with user specification.

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.util.corba.* ;
import java.io.*;
public class ExampleBind
{
    public static void main(String[] args)
    {
        try
        {
            //*************************************************
            // Initialize.
            //*************************************************
            String domainName = new String("mySpectroServer");
            // Construct helper
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            Properties props = new Properties () ;
            props.setProperty ( "user.name", "JonDoe" ) ;
            if (helper.init(null, props))
            {
                CsCModelDomain md = (CsCModelDomain)
                helper.getObjectImplementation (
                    CsCModelDomain.class, domainName ) ;
                //*************************************************
                //Get the Model Domain ID
                //*************************************************
                int ID = md.getModelDomainID();
                System.out.println( "0x" + Integer.toHexString(ID) );
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

How To Disable Automatic Reconnect

If connection to a service is lost, reconnecting starts automatically until the connection is regained. Because reconnecting is unnecessary at times, you can turn off the function by passing FALSE as the third parameter to the getObjectImplementation method, as follows:

```
String domainName = new String("mySpectroServer");
// Construct helper
CORBAHelper helper = CORBAHelper.getHelperImpl () ;
Properties props = new Properties () ;
props.setProperty ( "user.name", "JonDoe" ) ;
```

```
if (helper.init(null, props))
{
      CsCModelDomain md = (CsCModelDomain)
        helper.getObjectImplementation (
           CsCModelDomain.class, domainName, FALSE ) ;
}
```

NOTE
You can also disable automatic reconnect by setting java -Dvbroker.orb.cacheDSQuery=false ClientApp.

Security Levels

Each DX NetOps Spectrum CORBA service requires a different level of security. For example, a financial database object might require an encrypted user name and password. A DX NetOps Spectrum model domain requires an unencrypted user name. Security is preset for the user and the host in which the Java application is implemented, but you can change the settings.

If this ORB needs to be set to a user and host other than the default values, the Properties class can be set and passed to *init* as shown in the example Binding Implementation with User Specification.

Type Catalog Interface

The type catalog interface, CsCTypeCatalog, contains information about the Developer IDs, Model Types, Relations, Rules, and Attribute properties. The CsCModelDomain can create models only against the model types that exist in this type catalog. This non-persistent interface does not allow the creation or destruction of new model types, relations, rules, or attributes. But it allows reading of properties for developer information, model types, relations, rules, and attributes and the modification of default values of attributes.

Retrieve the Developer ID Example

You can retrieve the developer ID and prefix from the interface. The getDevProperties method call returns a CsCDevProperties data structure.

NOTE
The Model Type Editor section explains the concept of Developer ID and how to use it with Model Type Editor.

Example: Retrieve a developer ID

The following example shows how to retrieve a developer ID:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.util.corba.* ;
import com.aprisma.spectrum.core.idl.CsCDeveloper.*;
import java.io.*;
public class GetTypeCatalogInfo
{
    public static void main(String[] args)
    {
        try
        {
            //*************************************************
            // Initialize.
            //*************************************************
            String domainName = new String("mySpectroServer");
            // Construct helper
```

```
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            if (helper.init(null, null))
            {
                CsCModelDomain md = (CsCModelDomain)
                helper.getObjectImplementation (
                    CsCModelDomain.class, domainName ) ;
                //*********************************************
                //Get the Retrieve the other Domains
                //*********************************************
                CsCTypeCatalog tc = md.getTypeCatalog();
                CsCDevProperties devprop =
                              tc.getDevProperties(0x210000);
                System.out.println("Name:" + devprop.name );
                System.out.println("Prefix:" + devprop.prefix );
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCDeveloper
  - Classes
    - CsCDevProperties

Model Domain Interface

The CsCModelDomain class provides several methods for creating DX NetOps Spectrum models. These methods are inherited from CsCModelDomainOperations but need to be called from the CsCModelDomain class interface.

User Security

Most client applications you develop using the SPECTRUM Development API use the services of one or more of the following classes:

- **CsCTypeCatalog**
  Provides access to the Modeling Catalog.
- **CsCModelDomain**
  Provides access to the models, associations and attributes.
- **CsCEventDomain**
  Provides access to events.
- **CsCAlarmDomain**
  Provides access to alarms.

CsCModelDomain, CsCEventDomain, and CsCAlarmDomain are persistent interfaces, that is, interfaces that persist across a SpectroSERVER restart. Once the application binds to the ORB and retrieves the interface reference, the reference is valid across SpectroSERVER and ArchMgr restarts.

Obtain interface domain references to these services by first binding to the model domain and invoking the appropriate CsCModelDomain method as follows:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.util.corba.* ;
import java.io.*

public class ExampleBind
{
    public static void main(String[] args)
    {
        try
        {
            //*************************************************
            // Initialize.
            //*************************************************
            String domainName = new String("mySpectroServer");
            // Construct helper
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            if (helper.init(null, null))
            {
                CsCModelDomain md = (CsCModelDomain)
                    helper.getObjectImplementation (
                        CsCModelDomain.class, domainName ) ;
                //*********************************************
                //Get the Retrieve the other Domains
                //*********************************************
                CsCTypeCatalog tc = md.getTypeCatalog();
                CsCEventDomain ed = (CsCEventDomain)
                    helper.getObjectImplementation(
                        CsCEventDomain.class, domainName );
                CsCAlarmDomain ad = md.getAlarmDomain();
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

Model IDs and Model Handles

Model IDs are different from model handles. A model handle is a 32-bit number in which the high order 12 bits make up the landscape and the rest of the 20 bits make up the model ID.

Method calls frequently require model handles. You can make up the handles by joining the landscape and the model ID together.

Device Modeling

Creating a model is different from modeling a device. Creating involves telling DX NetOps Spectrum to create a model that usually represents a simple, unaddressable entity like a container or user. When you model a device, you describe the device (by IP address) to DX NetOps Spectrum, let the server examine the device, and create a set of interrelated models that represent the components and complexities. The previous section explained how to create a network model. The following section explains how to model a device and place it in a network container model.

You can model a device by invoking a single method as follows:

```
CsCModelProperties mp = md. createModelByIP(
ip, // IP address of device.
community, // CsCValue containing the SNMP community string.
5000, // time to wait for ping reply.
3, // retry count
161 // agent SNMP Port
```

The args[i] variables represent command line arguments passed to a dummy program that contains all the code snippets. The parameters in lines 2 through 6 are as follows:

- **ip**
  Defines the IP address of the target device. You can use a helper class to convert an IP address from string format (for example, 192.168.1.81) to int[] form as follows:
  ```
  CsCorbaValueHelper helper = new CsCorbaValueHelper();
  CsCValue ipValue = valueHelper.parseInternetAddressValue(argv[0]);
  byte[] ip = ipValue.internetAddress();
  ```
  NOTE
  The IP address can either be IPv4 or IPv6.
- **community**
  Defines a CsCValue containing the SNMP community string that DX NetOps Spectrum uses to satisfy security requirements when it contacts the device.
- **5000**
  Defines the time (in milliseconds) that DX NetOps Spectrum waits between each attempt to contact the device.
- **3**
  Defines the number of times DX NetOps Spectrum attempts to ping the device before giving up.
- **161**
  Defines the SNMP Agent Port.

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
    - CsCRelation
    - CsCModelType
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCModelPackage
  - Classes
    - CsCModelProperties
- Package com.aprisma.spectrum.core.util
  - Classes

- CsCorbaValueHelper

Model Types

DX NetOps Spectrum model types are related to models in the same way that classes are related to objects in object-oriented programming. Model types are the templates, while models are instances. The following sections show how to explore a model type, that is, retrieve its object reference, its position in the type hierarchy, its attributes, and properties.

Retrieve Model Type Object Reference Example

The following example shows how to retrieve the object reference for a given model type ID:

```
Integer mtypeID = Integer.decode(args[0]);
CsCTypeCatalog tc = md.getTypeCatalog();
CsCModelType mt = tc.getModelType(mtypeID.intValue());
```

The first line gets an mtype ID from the command line. The second line gets an object reference to the type catalog. The third line gets an object reference to the particular model type.

Use the following code to retrieve the object reference for a given model type name:

```
String mtypeName = args[0];
CsCTypeCatalog tc = md.getTypeCatalog();
CsCMTypePropList mtpl = tc.getMTypePropListByName(mtypeName);
```

The first line gets a model type name from the command line. The second line gets an object reference to the type catalog. The third line gets a list of all model types that have the specified name. In most cases, the list contains only one member.

Model Type Hierarchy

Once you have a CsCModelType object reference (mt in the following example), you can use the following methods to determine the model type's base and derived relatives.

```
CsCMTypePropList bmtpl = mt.getBaseMTypePropList();
CsCMTypePropList dmtpl = mt.getDerivedMTypePropList();
```

Model Type Properties

A model type has the following Boolean properties:

- **instantiable**
  Indicates that you can create instances from this model type.
- **underivable**
  Indicates that model types can not be derived from this model type.
- **noDestroy**
  Indicates that you cannot destroy models of this type.
- **unique**
  Indicates that at most one model of this model type can exist.
- **required**
  Indicates that at least one model of this type is required.

How To Read Model Type Properties

Use the following process to read a model type's properties:

1. Obtain a CsCMTypeProperties object to represent a model type. (CsCTypeCatalog and CsCModelType classes have methods to return such an object.)
2. Access the CsCMTypeProperties member variable flags (of type CsCMTypeFlags) that contains a Boolean variable for each property.

Example: Read a model type's properties:

```
Integer mtypeID = Integer.decode(args[0]);
CsCTypeCatalog tc = md.getTypeCatalog();
CsCMTypeProperties mtp = tc.getMTypeProperties
(mtypeID.intValue());
CsCMTypeFlags flags = mtp.flags;
```

The first line gets a model type ID from the command line. The second line gets an object reference to the type catalog. The third and fourth lines get a model type properties object. The fifth line extracts a model type flags object.

Read Model Type Properties Example

The following example shows how to retrieve model type information:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.util.corba.* ;
import com.aprisma.spectrum.core.idl.CsCModelTypePackage.*;
import java.io.*;
public class GetTypeCatalogInfo
{
    public static void main(String[] args)
    {
        Integer mtid = Integer.decode( args[0] );

        try
        {
            //*************************************************
            // Initialize.
            //*************************************************
            String domainName = new String("mySpectroServer");
            // Construct helper
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            if (helper.init(null, null))
            {
                CsCModelDomain md = (CsCModelDomain)
                helper.getObjectImplementation (
                    CsCModelDomain.class, domainName ) ;
                //*********************************************
                //Get the Retrieve the other Domains
                //*********************************************
                CsCTypeCatalog tc = md.getTypeCatalog();
                CsCModelType mt = tc.getModelType( mtid.intValue() );
                CsCMTypeProperties mtprop = mt.getMTypeProperties();
                CsCMTypeFlags mtflags = mtprop.flags;
                System.out.println("Name:" + mtprop.name );
```

```
                System.out.println("Underivable:"
                                   + mtflags.underivable );
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

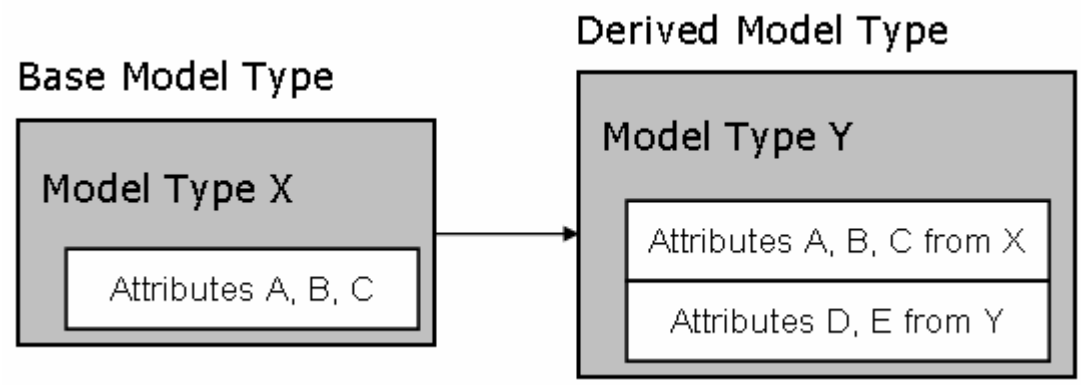
The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
    - CsCModelType
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCModelTypePackage
  - Classes
    - CsCMTypeProperties
    - CsCMTypeFlags

Model Type Attributes

DX NetOps Spectrum model types have attributes associated with them. Attributes describe the model capabilities and reflect internal storage of some data type and external MIB object information. Both basic and derived model types have attributes.

The following illustration shows a base model type and its derived model type:

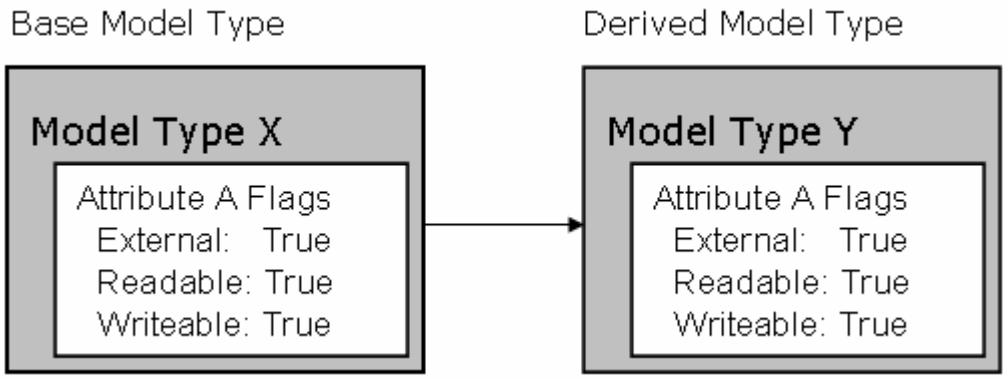


Model type attributes have their own metadata, attribute modifiable properties and attribute non-modifiable properties.

Non-Modifiable Properties

Model type attribute properties remain the same across base and derived model types. That is, the properties cannot be modified for derived model types.

The following illustration shows an example of non-modifiable properties in a base model type and its derived model type:



The non-modifiable properties include the following:

- **external**
  Indicates that the attribute is external to DX NetOps Spectrum and must be obtained through a protocol such as SNMP.
- **readable**
  Indicates that the attribute is readable through an application.
- **writable**
  Indicates that the attribute is writable through an application.
- **shared**
  Indicates that the attribute has only one shared value for all models of a model type.
- **list**
  Indicates that the attribute is a list. The list attributes usually form a column of an attribute table.
- **guaranteed**
  Indicates that the attribute is guaranteed not to be removed by the management module developer.
- **global**
  Reserved for internal use.
- **preserveLegacyValue**
  Indicates that the attribute value in the database is not overwritten by imported database catalog (.e or .xml) files. If you customize model types for your system requirements and set this flag, the changed model type attribute values are preserved if model types are updated by subsequent release versions.

How To Read Attribute Properties

You can read attribute properties as follows:

1. Obtain a CsCAttrProperties object representing a single attribute.
2. Access the Flags member variable (of type CsCAttrFlags) of the CsCAttrProperties class, which contains one Boolean variable for each of these eight characteristics.

Example: Read Attribute Properties

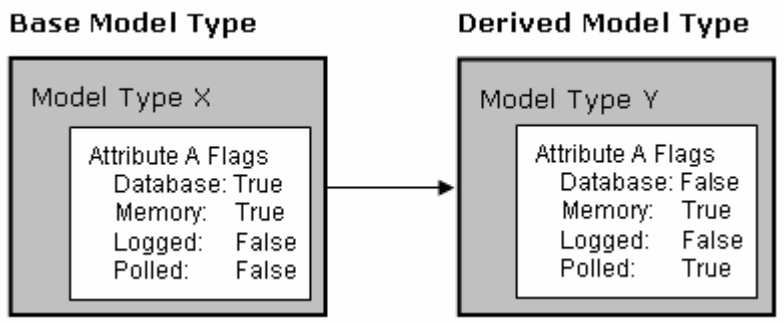
```
Integer attrID = Integer.decode(args[0]);
CsCTypeCatalog tc = md.getTypeCatalog();
CsCAttrProperties ap =
tc.getAttrProperties(attrID.intValue());
CsCAttrFlags flags = ap.flags;
```

The first line gets an attrID from the command line; the second line gets an object reference to the type catalog; the third and fourth lines get an attribute properties object; the fifth line extracts an attribute flags object.

Modifiable Properties

An attribute can have modifiable properties that can be modified at the derived type level. You can also refer to these properties as extended flags.

The following illustration shows an example of modifiable properties in a base model type and its derived model type:



The modifiable properties include the following:

- **polled**
  Indicates that the attribute value is read periodically. The polling interval sets the frequency.
- **logged**
  Indicates that the attribute value is read periodically and saved in the DX NetOps Spectrum statistics log. The logging interval sets the frequency.
- **memory**
  Indicates that, for frequently-read attributes, the attribute value is stored in memory.
- **database**
  Indicates that the attribute value is stored in the database. This is used for attributes that must be preserved between SpectroSERVER restarts.
- **oidPrefix**
  Indicates the first part of the object identifier (OID) in the MIB of an agent that supports a network entity. It is the branch of the MIB tree where a table attribute begins.
- **oidReference**
  Indicates an attribute ID whose value is an OID suffix. This object identifier supplements the OID prefix so as to fully identify the object in the MIB tree. The rows of a table attribute are represented using this value as the suffix. A zero value indicates that the OID reference is not specified for this model type attribute.
- **pollingGroup**
  Indicates the polling group identifier. Attributes of a polling group are polled and logged together. Each model type can have up to 256 polling groups. Each polling group is identified by a number from 0 to 255.
- **pollingInterval**
  Indicates the time, in seconds, after which an attribute value is updated to the latest value.

Model type attribute properties differ from attribute properties as follows:

- Model type attribute properties are not limited to Boolean values.
- Second, they apply to an attribute for a particular model type.

How To Read Model Type Attribute Properties

You can read model type attribute properties as follows:

1. First obtain a CsCModelType object reference representing a single model type.
2. Obtain a CsCMTypeAttrProperties object and access several data members of the object, which comprise the model type attribute properties.

Example: Read Model Type Attribute Properties

```
Integer mtypeID = Integer.decode(args[0]);
Integer attrID = Integer.decode(args[1]);
CsCModelType mt = tc.getModelType(mtypeID.intValue());
CsCMTypeAttrProperties mtap = mt.getMTypeAttrProperties(attrID.intValue());
CsCMTypeAttrFlags flags = mtap.flags;
int[] oidPrefix = mtap.oidPrefix;
int oidReference = mtap.oidReference;
int pollingInterval = mtap.pollingInterval;
int loggingInterval = mtap.loggingInterval;
int pollingGroup = mtap.pollingGroup;
```

The first and second lines get the model type ID and attribute ID from the command line. The third line gets the type catalog object reference. The fifth line gets the model type attribute properties object. The remaining lines access all the fields that comprise the attribute properties.

Retrieve Attribute Properties Example

The following example shows how to retrieve attribute properties:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.util.corba.*;
public class GetAttributeInfo
{
    public static void main( String[] args )
    {
        CsCorbaValueHelper help = new CsCorbaValueHelper();
        Integer attrid = Integer.decode( args[0] );
        Integer mtid = Integer.decode( args[1] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroServer" );

            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );

            md = (CsCModelDomain) helper.getObjectImplementation(
                                CsCModelDomain.class, domainName );

            CsCTypeCatalog tc = md.getTypeCatalog();
            CsCModelType mt = tc.getModelType( mtid.intValue() );
            CsCMTypeAttrProperties mtap = mt.getMTypeAttrProperties(
                  attrid.intValue() );
            CsCMTypeAttrFlags mtaf = mtap.flags;
            System.out.println( "Memory: " + mtaf.memory );
            System.out.println( "Logged: " + mtaf.logged );

            CsCAttrProperties ap = mtap.commonProperties;
            System.out.println( "Name: " + ap.name );
            System.out.println( "Group ID: " + ap.attrGroupID );
```

```
            System.out.println( "Type: " + ap.type.toString() );
            System.out.println( "OID: " +
                  CsCorbaObjectIDHelper.toString( mtap.oidPrefix ) );
            CsCAttrFlags af = ap.flags;
            System.out.println( "Global: " + af.global );
            System.out.println( "Shared: " + af.shared );
            System.out.println( "External: " + af.external );
            System.out.println( "Readable: " + af.readable );
            System.out.println( "Writable: " + af.writable );
        }
        catch (Throwable e)
        {
            System.out.println( e );
        }
    }
}
```

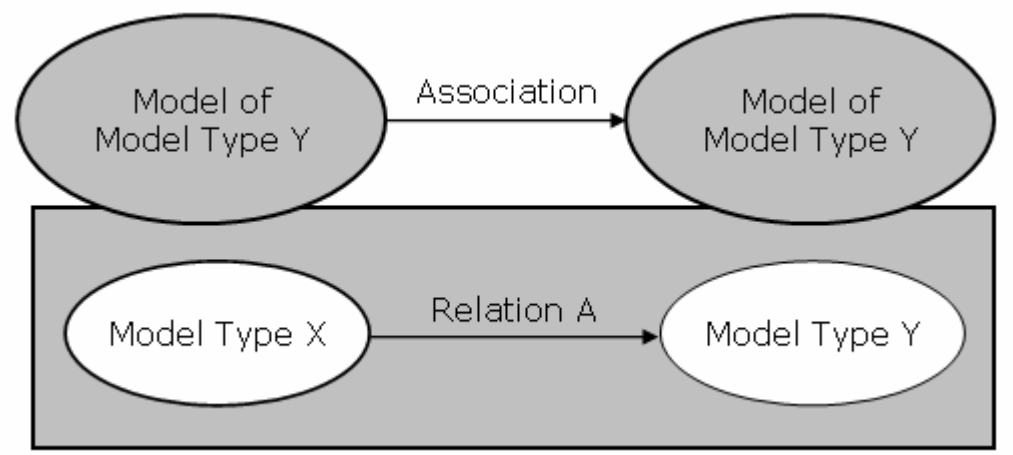
This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
    - CsCModelType
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCMTypeAttrProperties
    - CsCMTypeAttrFlags
    - CsCAttrProperties
    - CsCAttrFlags
    - CsCValueType_e
- Package com.aprisma.spectrum.core.util
  - Classes
    - CsCorbaObjectIDHelper

Model Creation

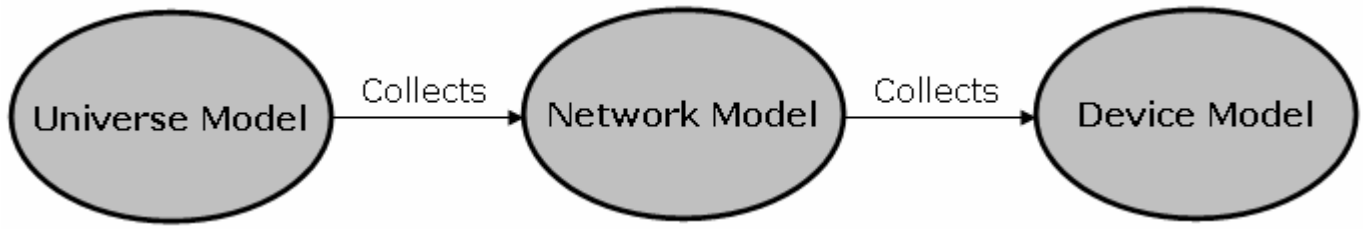
Some methods perform a single task while other methods perform multiple tasks. For example, createModelByID only creates a model. It does not name the model or set attribute values or associate it with another model. However, createModelByIP discovers a network device at the specified IP address and creates a set of models to represent the device. Both creation and association methods require model type IDs and relation IDs as building blocks for the model domain.

The following illustration shows models and associations as instantiations of model types and relations.



To create a container model and collect the model into the Universe view, use the following CsCModelDomain methods: createModelByID and createAssociationByIDs. The first method creates a model of the specified model type and initializes one of the new model's attribute values. Because you want to create a container model, you need to specify a network model type (0x1002e). The second method creates an association between two models. For our purpose, we will specify Collects as the relation (0x10002), the Universe model as the left-hand model and the container as the right-hand model.

The following illustration shows the Collects relation:



NOTE
The new container does not appear in the OneClick topology until the client program invokes the second method.

The following example shows how to invoke CsCModelDomain's Create Model method:

```
Integer mtypeID = Integer.decode(args[0]);
CsCModelProperties mp = md.createModelByID(
mtypeID.intValue());
```

The first and second lines get the model type ID as a primitive data type int. The second line creates the model, specifying the model type ID and returning a CsCModelProperties data class. The createModelByID method does not return the CORBA object, CsCModelType, with the CsCModelProperties. These fields contain null references.

Model Association

The following example shows how to invoke CsCModelDomain's associate model method:

```
int universeID = ...
int myContainerID = ...
int relationID = 0x10002;
md.createAssociationByIDs(relationID,universeID,myContainerID);
```

Lines 1-3 specify the model IDs and relation ID as primitive data types. Line 4 invokes the createAssociationByIDs. This method creates an association between two models in the model domain using a relation. It is important to have container and device models associated in a *collects* association, or else, the model belongs to LostAndFound.

Create and Associate Models Example

The following example shows how to create and associate models:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.* ;
public class CreateModelAndAssocByIP
{
    public static void main(String[] args)
    {
        CsCorbaValueHelper valhelper = new CsCorbaValueHelper();
        byte[] ipAddress = null;
        try
        {
            CsCValue ipValue = valhelper.parseInternetAddress( argv[0] )
            ipAddress = ipValue.internetAddress();
        }
        catch( java.lang.NumberFormatException e)
        { System.out.println(e); }
        Integer relID = Integer.decode(args[1]);
        Integer modeltypeID = Integer.decode(args[2]);
        Integer universeID = Integer.decode(args[3]);
        try
        {
            String domainName = new String("mySpectroSERVER");
            // Bind
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            helper.init(null, null);
            CsCModelDomain md =
                   (CsCModelDomain) helper.getObjectImplementation (
                                CsCModelDomain.class,
                                domainName ) ;
           // Create the Network Models
           CsCModelProperties mpNetwork =
                md.createModelByID(modeltypeID.intValue());
           System.out.println( mpNetwork.modelID );
           // Create the association: Universe "Collects" Network
           md.createAssociationByIDs( relID.intValue(),
                                      universeID.intValue(),
                                      mpNetwork.modelDomainID +
                                      mpNetwork.modelID);
           // Calling this method will return a CsCModelProperties with
           // only the handle value set in the data object
           CsCValue commStrVal = new CsCValue() ;
```

```
            commStrVal.textString( EncodeUtils.convertToBytes( "public" )) ;
                      CsCModelProperties mpDevice = md.createModelByIP( ipAddress,
                                                                        commStrVal,
                                                                        300, 2, 161,
                                                                        avl);
           // Create the association: Network "Collects" Device
            md.createAssociationByIDs( relID.intValue(),
                   mpNetwork.modelDomainID + mpNetwork.modelID,
                   mpNetwork.modelDomainID + mpDevice.modelID );
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

Retrieve a Model Through Association Example

You need to retrieve models through associations for the following reasons:

- To know the port models that exist for a device
- To know the models that exist in a particular container model
- To know how devices are connected to each other.

You can get this information by calling getAssocModelIDList or getAssocModelIDListOfMType. You can make both calls against the model domain.

Example: Retrieve all models collected by the LAN container model

The following example shows how to retrieve all models collected by the LAN container model:

```
int myLANContainer = ...
int relationID = 0x10002; //Collects relation
int[] list = md.getAssocModelIDList(relationID,
myLANContainer,
CsCSide_e.CSC_LEFT_SIDE);
```

NOTE
If you want to narrow down the result set to a particular model type, use getAssocModelIDListOfMType.

The parameters are as follows:

- **myLANContainer**
  Defines the model handle of the container.
- **relation**
  Collects the relation ID.
- **list**
  Defines the int [] of model IDs.
- **CsCSide_e.CSC_LEFT_SIDE**
  Defines the side on which the myLANContainer model handle resides.

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  – Interfaces

    - CsCModelDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCRelationPackage
  - Classes
    - CsCSide_e

The following example shows how to retrieve a model through associations:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCRelationPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.* ;
public class GetModelAssocInfo
{
    public static void main(String[] args)
    {
        Integer relID = Integer.decode(args[0]);
        Integer modelID = Integer.decode(args[1]);
        try
        {
            String domainName = new String("mySpectroSERVER");
            // Bind
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            helper.init(null, null);
            CsCModelDomain md =
                   (CsCModelDomain) helper.getObjectImplementation (
                                  CsCModelDomain.class,
                                  domainName ) ;
            int[] modelIDList = md.getAssocModelIDList(
                   relID.intValue(), modelID.intValue(),
                   CsCSide_e.CSC_LEFT_SIDE);
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

Rules and Relations

You can define rules and relations for DX NetOps Spectrum models.

A *relation* describes the interaction between two models and is expressed as a verb or verb phrase, for example, Contains, Manages, Is_Adjacent_to, and so on.

A *rule* is a statement that applies a relation to two model types. The rule lets models of the two types to be associated through the relation. For example, if there is a relation named Contains, a rule can be Model Type A Contains Model Type B. The left side of the rule statement is referred to as the subject of the rule (Model Type A) and the right side as the object (Model Type B). The role of a model type depends on the side it appears on.

Many relations in the DX NetOps Spectrum knowledge base have one or more metarules that specify which model types can participate in that relation. Model types derived from another model type that is specified in a metarule inherit

the eligibility to participate in that relation. For example, one of the metarules for the Contains relation is LAN Contains Device. If a model type named myLAN is derived from the model type LAN, SpectroSERVER automatically follows the rule myLAN Contains Device.

DX NetOps Spectrum supports the following relation types:

- **One-to-Many:** For example, One LAN Collects Many Devices. Only one LAN can be the parent owner of a device in the topology.
- **Many-to-Many:** For example, Many Ports Connects_To Many Devices.

The cardinality may differ from relation to relation.

NOTE
For a detailed discussion on relations, rules, and metarules, see the Getting Started section.

Relation Handles

Every relation in the DX NetOps Spectrum database has a handle. The following table shows examples of relations and handles:

Relation	Handle
Collects	0x10002
HASPARTS	0x10004
Manages	0x1001f

Retrieve Relation Information Example

The following example shows how to retrieve relation information:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.* ;
import com.aprisma.spectrum.core.util.* ;
import com.aprisma.spectrum.core.idl.CsCException.* ;
import com.aprisma.spectrum.core.idl.CsCError.* ;
import com.aprisma.spectrum.core.idl.CsCRelationPackage.* ;
import com.aprisma.util.corba.* ;
public class GetRelationInfo
{
    public static void main(String[] args)
    {
        CsCModelDomain md = null;
        CsCTypeCatalog tc = null;
        CsCRelProperties relprop = null;
        try
        {
            String domainName = new String("mySpectroServer");
            // Construct helper
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            helper.init(null,null);

            md = (CsCModelDomain) helper.getObjectImplementation (
                        CsCModelDomain.class, domainName);
            tc = md.getTypeCatalog();
```

```
            CsCRelPropList rpl = tc.getAllRelPropList();
            for( int i=0; i < rpl.list.length; i ++)
            {
                relprop = rpl.list[i];
                if(relprop.error == CsCError_e.SUCCESS){
                    System.out.println ("Name        : " +
                                        relprop.name);
                    System.out.println ("Cardinality : " +
                            relprop.cardinality.toString());
                }
            }
        }
        catch (Throwable e) {
            System.out.println(e);
        }
    }
}
```

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
    - CsCRelation
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCRelationPackage
  - Classes
    - CsCRelProperties

Significance of Rules and Metarules

Rules and metarules prevent illogical associations that may cause SpectroSERVER to malfunction. A rule specifies two model types that can participate in a particular relation. The rule also specifies the relative role of each model type by its position (that is, left or right) in the statement. Usually, the model type on the left is the parent in parent-child relationships. A metarule defines that derived model types also take part in that rule.

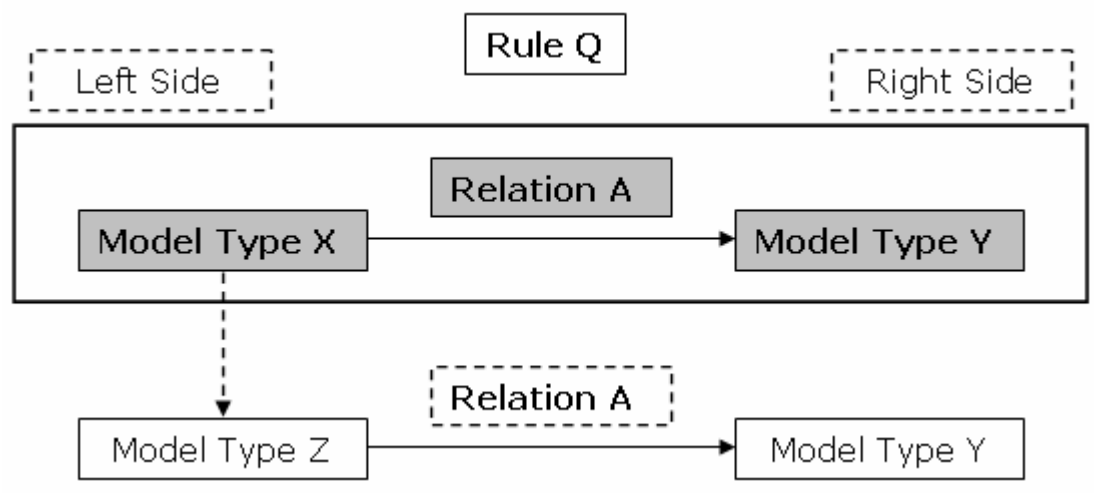
The following table shows the left and right sides of a relation:

Left Side	Relation	Right Side
Universe	Collects	LAN
Port	Connects to	Device
GnSNMPDev	Manages	Manages Apps

For programs that create model associations, check the existing rules to determine the model types that can be associated through a relation.

The getRelMTypePropList method call in the topic Method to Retrieve Rule Information passes the model type and the side (that is, left or right). The *side* parameter is with respect to the model type.

The following illustration shows a rule and its left and right sides:



If the developer is looking for all models of type Y that are on the right side in the rule, model type X is passed. Model type X is on the left.

Retrieve Rule Information Example

The following example shows how to retrieve rule information:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCModelType.*;
import com.aprisma.spectrum.core.idl.CsCModelTypePackage.*;
import com.aprisma.spectrum.core.idl.CsCRelationPackage.*;
import com.aprisma.util.corba.*;
public class GetRuleInfo
{
    public static void main( String[] args )
    {
        Integer relid = Integer.decode( args[0] );
        Integer mtid = Integer.decode( args[1] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String("mySpectroServer");
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );
            CsCTypeCatalog tc = md.getTypeCatalog();
            CsCModelType mt = tc.getModelType( mtid.intValue() );
            CsCRelation rel = tc.getRelation( relid.intValue() );
            CsCMTypePropList mtpl = rel.getRelMTypePropList(
                mt, CsCSide_e.CSC_LEFT_SIDE );
            System.out.println( "Read: " + mtpl.error.toString() );

            for ( int i=0; i<mtpl.list.length; i++ ) {
```

```
                CsCMTypeProperties mtp = mtpl.list[i];
                System.out.println( "ModelTypeName "
                    + new Integer(i).toString() + ": " + mtp.name );
            }

        } catch ( Throwable e ) {
            System.out.println( e );
        }
    }
}
```

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCTypeCatalog
    - CsCRelation
    - CsCModelType
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCModelTypePackage
  - Classes
    - CsCMTypePropList
    - CsCMTypeProperties
- Package com.aprisma.spectrum.core.idl.CsCRelationPackage
  - Classes
    - CsCSide_e

Filters

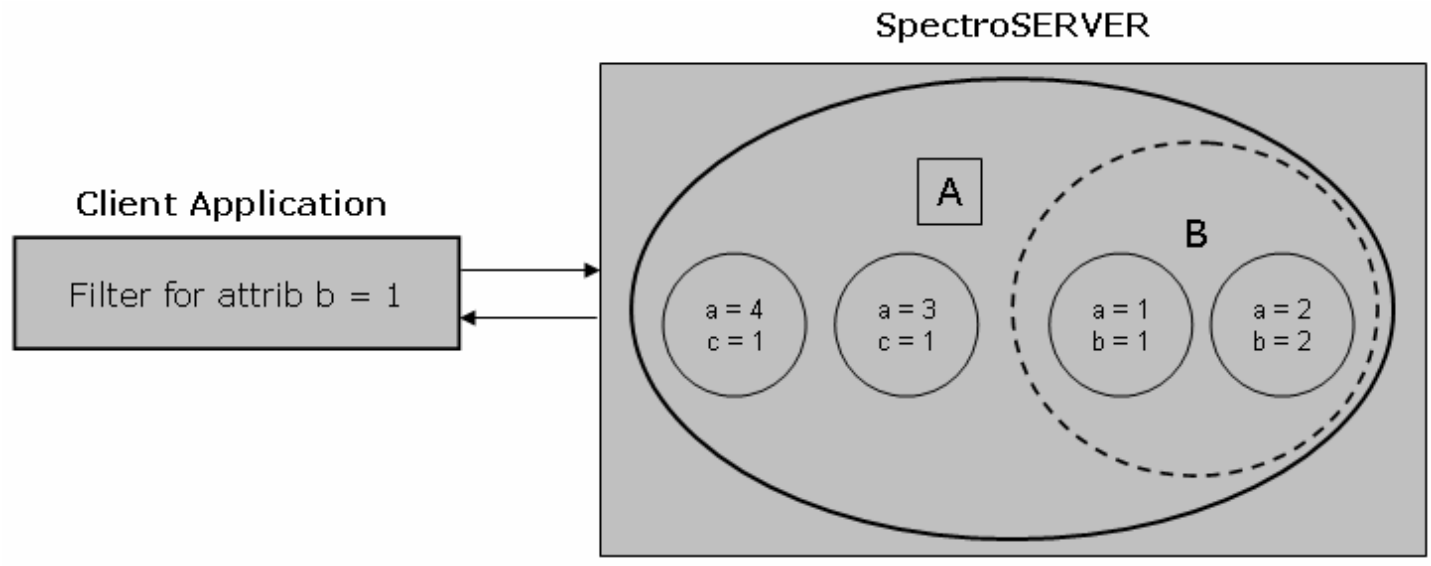
The CsCModelDomain interface provides several techniques to specify the information to be returned in a list. Server-side filtering gives the following benefits:

- Reducing network traffic.
- Removing extraneous data and providing only the necessary information to the client application.

You should ask DX NetOps Spectrum to filter information before sending it to your client application. Using the right attribute as the basis of your filter improves the search performance.

The following illustration shows two sets, A and B. A represents all models, and B represents the subset of models with attribute b. Assume that most customers use attribute a as a filter. The search will work but because attribute A exists for all models; it compares all the models of the database. If attribute B was used, only two models are compared. That is, the comparison time is halved because only half the models are compared.

The following illustration shows the client communicating with the SpectroSERVER using filters:



A DX NetOps Spectrum attribute filter (CsCValue[]) lets you define database search instructions. For example, to obtain a list of all models whose model types derive from the model type Device, you can use a filter as follows:

```
CsCorbaFilterAttrNode node =
CsCorbaAttrFilterHelper.createModelTypeIDNode(
0x10001, // Attribute ID of Model Type Handle
CsCOperator_e.CSC_IS_DERIVED_FROM,
0x1004b ); // Model Type Handle for Device
CsCValue[] filter = node.getFilter();
```

The class CsCorbaAttrFilterHelper is central to this example. You can use methods of this class to build different types of filters, including the createModelTypeIDNode method used in the example. This method takes the following parameters: attribute ID, operator, and model type ID. Once you create the node (lines 1-5), you call the node's getFilter method to create the filter (line 6), which is an array of the following CsCValue objects:

- CSC_OPERATOR = IS_DERIVED_FROM
- CSC_ATTR_VALUE = 0x10001
- CSC_MODEL_TYPE_ID = 0x1004b

An attribute filter contains an operator followed by an attribute ID and a value.

Interfaces that accept attribute filters as parameters require an array of CsCValue objects. Constructing this array is complex because of the order. CsCorbaAttrFilterHelper provides an alternate way of creating attribute filters for CORBA interfaces. This class provides an easy way of creating elementary pieces of the filter and assembling them together. After assembling the filter, you can use the getFilter method to get the final array.

For example, if you want a simple filter for all models with the Model_Name attribute MyName, you can write a filter as follows:

```
CsCorbaFilterNode nameNode =
CsCorbaAttrFilterHelper.createTextStringNode (
0x1006e,
CsCOperator_e.CSC_EQUALS,
"MyName" ) ;
CsCValue [] filter = nameNode.getFilter () ;
```

Here, the method createTextStringNode is called because the attribute of type TextString is compared. The attribute type dictates the call made to the CsCorbaAttrFilterHelper. CsCOperator houses all the logical and text operators that are

used. Because you can use other operators such as CSC_EQUALS_IGNORE_CASE and CSC_HAS_SUBSTRING for Text String attributes, you should consider the available operators before comparing the attribute types.

Complex Attribute Filter

To get all models with model types derived from the Device model type, except models of type Indirect RMON, you can write a filter as follows:

```
CsCorbaFilterAttrNode node1 =
CsCorbaAttrFilterHelper.createModelTypeIDNode(
0x10001, // Attribute ID of Model Type Handle
CsCOperator_e.CSC_IS_DERIVED_FROM,
0x1004b ); // Model Type Handle for Device
CsCorbaFilterAttrNode node2 =
CsCorbaAttrFilterHelper.createModelTypeIDNode(
0x10001, // Attribute ID of Model Type Handle
CsCOperator_e.CSC_DOES_NOT_EQUAL,
0x59001b); // model type ID IndirectRMON
CsCorbaFilterBinaryNode bnode =
CsCorbaAttrFilterHelper.createBinaryNode(
node1,CsCOperator_e.CSC_AND,node2);
CsCValue[] filter = bnode.getFilter();
```

This example creates three nodes as follows:

- Node1 represents all models with model types derived from Device.
- Node2 specifies that model type should not be Indirect RMON.
- The third node, bnode (binary node) is the logical AND of node1 and node2.

The filter array in the example contains the following information:

```
CSC_OPERATOR = AND
CSC_OPERATOR = IS_DERIVED_FROM
CSC_ATTR_VALUE = 0x10001
CSC_MODEL_TYPE_ID = 0x1004b
CSC_OPERATOR = DOES_NOT_EQUAL
CSC_ATTR_VALUE = 0x10001
CSC_MODEL_TYPE_ID = 0x59001b
```

The logical AND appears in the first CsCValue object followed by two triplets representing node1 and node2, respectively.

If you want to augment this filter with another restriction namely, all models of the list must have a Model Class attribute value of 2, you can write this filter as follows:

```
CsCorbaFilterAttrNode node1 =
CsCorbaAttrFilterHelper.createModelTypeIDNode(
SSORBHelper.attrIDMType,
CsCOperator_e.CSC_IS_DERIVED_FROM,
SSORBHelper.mtypeIDDevice);
CsCorbaFilterAttrNode node2 =
CsCorbaAttrFilterHelper.createModelTypeIDNode(
0x10001, // Attribute ID of Model Type Handle
CsCOperator_e.CSC_DOES_NOT_EQUAL,
0x59001b); // model type ID IndirectRMON
CsCorbaFilterBinaryNode bnode =
CsCorbaAttrFilterHelper.createBinaryNode(
```

```
node1,CsCOperator_e.CSC_AND,node2);
CsCValue modelClass = new CsCValue();
modelClass.intValue(2);
node2 = CsCorbaAttrFilterHelper.createAttrValNode(
0x11ee8,
CsCOperator_e.CSC_EQUALS, 2);
bnode = CsCorbaAttrFilterHelper.createBinaryNode(
bnode,CsCOperator_e.CSC_AND,node2);
CsCValue[] filter = bnode.getFilter();
```

NOTE
The attribute specifies whether the model is a bridge, switch, router, brouter, and so on, and a value of 2 specifies switch.

Lines 1-15 are identical to the previous example. The binary node bnode contains information from node1 and node2 and the logical AND operator. Lines 17-23 create a new node specifying Model Class equals 2, reusing the available node2. Lines 25-26 combine bnode and node2 and store the result in bnode again, overwriting the previous information. Line 28 extracts the CsCValue[] array from bnode. The content of the array is as follows:

```
CSC_OPERATOR AND
CSC_OPERATOR AND
CSC_OPERATOR IS_DERIVED_FROM
CSC_ATTR_VALUE 0x10001
CSC_MODEL_TYPE_ID 0x1004b
CSC_OPERATOR DOES_NOT_EQUAL
CSC_ATTR_VALUE 0x10001
CSC_MODEL_TYPE_ID 0x59001b
CSC_OPERATOR EQUALS
CSC_ATTR_VALUE 0x11ee8
CSC_INTEGER 2
```

Lines 3-5 represent one node, and lines 6-8 represent the second. Line 2 represents the logical AND between the two nodes. That is, line 2 makes lines 3-8 into a single node. Lines 9-12 represent the third node. Line 1 represents the logical AND between this node and the single node of lines 3-8.

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCModelPropList
    - CsCModeProperties
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.util
  - Interfaces
    - CsCorbaFilterAttrNode
    - CsCorbaFilterBinaryNode
  - Classes
    - CsCorbaAttrFilterHelper

Search Criteria XML

Use getModelIDListByXmlSearchCriteria() to invoke a search in DX NetOps Spectrum. Any valid search criteria xml in DX NetOps Spectrum can be passed to getModelIDListByXmlSearchCriteria().

NOTE
getModelIDListByXmlSearchCriteria() provides more capabilities than the legacy getModelIDListByAttrFilter(), which only supports a subset of the possible searches.

Use the following procedure to create search criteria xml that can be used with getModelIDListByXmlSearchCriteria().

Follow these steps:

1. Use the OneClick Locater tab to create and save the new search. Custom searches are saved as xml files in the <*SPECROOT$*>/custom/console/config directory.

   NOTE
   For more information about creating searches using the Locater tab, see the Administration section.
2. Use the content of the new search as the xml input to getModelIDListByXmlSearchCriteria(). Make the following minor code modifications:
   - Turn the search criteria into a string or char * data type that is appropriate to the language that you are coding in.
   - Escape any quotes in the code with a backslash (\).

Search Criteria XML

```

```
                                    "      </attribute>\n" +
                                    "    </equals>\n" +
                                    "  </filtered-models>\n" +
                                    "</search-criteria>\n" ;
            CsCValue val = new CsCValue() ;
            val.textString( EncodeUtils.convertToBytes( xmlSearchCriteria )) ;
            int[] modelIDs =
                   md.getModelIDListByXmlSearchCriteria ( val ) ;
            int[] modelIDs =
                    md.getModelIDListByXmlSearchCriteria( xmlSearchCriteria ) ;
            for( int i = 0; i<modelIDs.length; i++ )
            {
                System.out.println( "Model ID: " + modelIDs[i] +
                                   ", mh = 0x" + Integer.toHexString(
domainID + modelIDs[i]) );
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

Attribute Values

DX NetOps Spectrum models are instances of model types. Models and objects contain values of attributes defined in model types.

To read or write a model attribute value, you need to specify a model ID and an attribute ID. After getting a model ID, you need to determine the attributes available for that model.

You can get a model ID as explained in the topics about creating and associating models, retrieving models though associations, and retrieving models though filter searches. You can get the available attributes from one of the following: OneClick Attribute Editor, Model Type Editor, Command Line Interface, the API method to retrieve attribute information. After determining the attributes that can be read, you should know the flags set on them.

Read an Internal Attribute Value Example

The following example shows how to read and display an attribute value for a given model ID:

```
Integer attrID = Integer.decode(args[0]);
int[] attrIDList = new int[1];
attrIDList[0] = attrID.intValue();

int[]modelIDList = md.getModelIDListByXmlSearchCriteria( xmlSearchCriteria ) ;
CsCAttrReadMode_e[] readMode =
   {CsCAttrReadMode_e.CSC_MOST_AVAILABLE};
CsCAttrValListOfModels avlom = md.readAttrValListOfModelsByIDs(
                                    modelIDList,
                                    attrIDList,
                                    readMode );
if( avlom.error == CsCError_e.SUCCESS )
 {
```

```
    for( int i = 0; i < avlom.list.length; i ++ )
    {
       CsCModelAttrValList mavl = avlom.list[i];
       CsCAttrValList avl = mavl.attrValList;
       if( avl.error == CsCError_e.SUCCESS )
       {
         for( int j = 0; j < avl.length; j ++ )
         {
           CsCAttrValue aval = avl.list[j];
           CsCError_e err = aval.error;
           if( err == CsCError_e.SUCCESS )
           {
             CsCValue val = aval.value;
             String name = val.textString();
             System.out.println("Model Name: " + name );
           }
        }
    }
}
```

Lines 1-3 set up an array of attribute IDs. Line 5 retrieves an int array of model IDs from a filter search as explained previously. Line 6 sets up an array of CsCAttrReadMode_e for each attribute requested. Lines 9-12 make a call to the model domain interfaces to read one attribute in MOST_AVAILABLE for an attribute for the list of model IDs found by the search. The method call readAttrValListOfModelsByIDs reads attributes on models and returns the value CsCAttrValListofModels.

The first check is for the overall error code. A check should always look for SUCCESS and not FAILURE because there are many variations of FAILURE. Line 15 constructs a FOR loop to iterate through the array of CsCModelAttrValList classes. Line 19 again checks for SUCCESS before iterating through the CsCAttrValList on line 21. The error code is checked for each CsCAttrValue, and finally the attribute is extracted as a string by calling the method textString on the CsCValue.

Error Codes and CsCValue

You should check for error codes when reading attributes internally or externally. Data classes that pass data contain information about more than one model. If 1 out of 100 models has an error, it permits 99 models to return successfully. Design the code so you can know if only some of the models are successful.

Many classes use CsCValue as a member variable and as an argument in several member methods. A CsCValue object is like an enum because it can hold a variety of objects including the following:

- actionID
- agentID
- alarmID
- attributeID
- attrGroupID
- attrValID
- boolValue
- counterValue
- dateTime
- actionID
- developerID
- enumValue
- eventID
- eventIDList
- gaugeValue
- hiddenValue
- intValue
- ipAddress
- model
- modelID
- modelDomain
- modelDomainID
- eventIDList
- modelType
- modelTypeID
- nullValue
- objectID
- octetString
- operatorValue
- realValue
- relation
- relationID
- taggedOctetString
- textString
- timeTicks

How the Void Constructor Works

To use the class CsCValue, you need to instantiate it through the void constructor.

You can use the void constructor as follows:

1. Create an object with no type or value using the void constructor as follows:
   ```
   CsCValue v = new CsCValue();
   ```
2. Set the object to a particular value type (for example, textString) and value using the appropriate set method as follows:
   ```
   v.textString("Container III");
   ```
3. Use the appropriate get method as follows to extract the value from the object:
   ```
   String name = v.textString();
   ```

Set and *get* are overloaded methods. If you want to determine the type of a particular CsCValue object, enter the following:

```
CsCValueType_e type = v.discriminator();
```

4. To display the type and value of a CsCValue object, use the CsCorbaValueHelper class as follows:

```
CsCorbaValueHelper vh = new CsCorbaValueHelper();
System.out.println(
v.discriminator().toString()
+ " "
+ vh.toStringValue(v));
```

The CsCorbaValueHelper class has a number of methods to deal with CsCValue objects. To learn more about this helper class, click the link com.aprisma.spectrum.core.util on the Java doc page <*$SPECROOT*>/SDK/docs/SSORB/index.html.

Read Modes

CsCAttrReadMode_e provides the following read modes:

- **CSC_MOST_AVAILABLE**
  Reads internally if the memory or db flags are set. If the flags are not set, go external if the attribute has the external flag set.
- **CSC_MOST_CURRENT**
  Reads externally if the external flag is set; otherwise reads internally.
- **CSC_TRY_MOST_CURRENT**
  Reads externally if the external flag is set, else reads internally. If the external read fails, go internal if memory or database flag is set.
- **CSC_SYNC_CURRENT**
  Not used because try latest facilitates the same functionality. If the latest value differs from the memory or database value, it updates the internal values to the latest.

If you are reading an internal attribute, use CSC_MOST_AVAILABLE, and if you are reading externally, read with CSC_MOST_CURRENT. You need to make a decision only if the attribute is external but has memory or database. The direction of read is dictated by whether you need the latest value or the current value is acceptable.

Rules for External Reading

Rules for external reading are as follows:

- Verify that the attribute Dev_Contact_Status is set to 1, that is, Established.
- Verify that the attribute isManaged is set to TRUE.

If these attributes do not have the correct values, your programs may hang because you try to read while the contact was lost. This situation causes the read operation to wait for timeouts and retries. Another reason for the wait can be that the device or port is under maintenance.

Read External Attributes Example

The following example shows how to read external attributes:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.* ;
public class ReadExternalAttribute
```

```
{
    static CsCModelDomain md = null;

    public static void main(String[] args)
    {
        Integer extAttrID = Integer.decode(args[1]);
        Integer modelID = Integer.decode(args[0]);
        int[] modelIDList = new int[1];
        int[] extAttrIDList = new int[1];
        modelIDList[0] = modelID.intValue();
        extAttrIDList[0] = extAttrID.intValue();
        try
        {
            String domainName = new String("mySpectroSERVER");
            // Bind
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            helper.init(null, null);
            md = (CsCModelDomain) helper.getObjectImplementation (
                                  CsCModelDomain.class,
                                  domainName ) ;
            if( okToReadExternal( modelIDList ))
            {
                CsCAttrReadMode_e [] readMode =
                     { CsCAttrReadMode_e.CSC_MOST_CURRENT};
                CsCAttrValListOfModels avlom =
                     md.readAttrValListOfModelsByIDs(
                                        modelIDList,
                                        extAttrIDList,
                                        readMode );
                if( avlom.error == CsCError_e.SUCCESS )
                {
                    for( int i = 0; i < avlom.list.length; i ++ )
                    {
                        CsCModelAttrValList mavl = avlom.list[i];
                        CsCAttrValList avl = mavl.attrValList;
                        if( avl.error == CsCError_e.SUCCESS )
                        {
                            CsCAttrValue aval = avl.list[0];
                            CsCError_e err = aval.error;
                            if( err == CsCError_e.SUCCESS )
                            {
                                CsCValue val = aval.value;
                                System.out.println("Text String: " +
                                    val.textString() );
                            }
                        }
                    }
                }
                else
                {
                    System.out.println("Read was not overall
                       successful");
                }
```

```
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
    public static boolean okToReadExternal(int[] modelIDList)
    {
        boolean ok = false;
        // Dev_Contact_Status 0x110ed
        // isManaged 0x1295d
        int[] okToReadExternAttrs = { 0x110ed, 0x1295d };
        CsCAttrReadMode_e[] readMode = {
            CsCAttrReadMode_e.CSC_MOST_AVAILABLE,
            CsCAttrReadMode_e.CSC_MOST_AVAILABLE};
        try
        {
            CsCAttrValListOfModels avlom =
                 md.readAttrValListOfModelsByIDs(
                     modelIDList,
                     okToReadExternAttrs,
                     readMode);
            if (avlom.error == CsCError_e.SUCCESS)
            {
                if (avlom.list[0].attrValList.list[0].value.intValue()
                     == 1 &&
                    avlom.list[0].attrValList.list[1].value.boolValue()
                     == true)
                {
                    ok = true;
                }
            }
        }
        catch (Throwable e)
        {
            System.out.println(e);
        }
        return ok;
    }
}
```

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes

- CsCAttrReadMode_e
- CsCValueType_e
- CsCValue

Reading Values from an Attribute Table

Reading values from an attribute table is similar to reading a value from a single attribute. The techniques of selecting the right read mode and how to read externally are still valid. But if the tables are large, these techniques can have effects other than increased processing time, such as device performance degradation and increased network traffic.

The API table-read ability is robust and lets you specify ranges (by defining high and low instances) and cap limits on the number of entries that can be retrieved. This improves performance if you are reading only a little data from a table, as shown in the following example:

```
int [] attr = {attrhandle.intValue()};
CsCOIDSpec low = new CsCOIDSpec();
CsCOIDSpec high = new CsCOIDSpec();
int [] lowValue = { 0 };
int [] highValue = { 100 };
low.objectID( lowValue );
high.objectID( highValue );
int length = 23;
CsCModel model = md.getModel( ());
CsCAttrValTable tablevalues = md.readAttrValTable(
modelhandle.intValue(),attr,low, high, length,
CsCAttrReadMode_e.CSC_MOST_CURRENT );
for( int j = 0; j < tablevalues.table.length; j++ )
{
System.out.println(
tablevalues.table[j][0].value.toString());
}
```

The first parameter is an array of attributes that is read. The array should specify attributes that belong to the table, because the instance array bounds may not be the same between different tables.

The second and third parameters specify the low and high ends of the instance range. The range is specified using CsCOIDSpec data parameters for the following reasons:

- Instances can comprise more than one value.
- Usually tables are instanced by a series of values.

The fourth parameter specifies the maximum number of table entries to collect. If the range exceeds the maximum limit, then only the maximum is specified. If the maximum is not met, it returns only the entries found in the table. The fifth parameter follows the single read convention.

In the following example, attribute IDs make up the columns and instances make up the rows. CsCValues make up the body of the array. Error data structures exist for the columns, rows, and values.

> **NOTE**
> Low, high, and limit parameters have wild card ability.

```
CsCModelDomain md = (CsCModelDomain)
helper.getObjectImplementation
 ( CsCModelDomain.class, domainName );
CsCOIDSpec low = new CsCOIDSpec();
CsCOIDSpec high = new CsCOIDSpec();
int length = 0;
```

```
low.noLimit(true);
high.noLimit(true);
int [] attr = {attrid.intValue()};
CsCAttrValTable tablevalues = md.readAttrValTable(
 modelid.intValue(),attr, low, high, length,
 CsCAttrReadMode_e.CSC_MOST_CURRENT);
```

The noLimit method is called on the CsCOIDSpec objects. That sets up the object for wild card capability. For the limit parameter, the wild card capability is set up by setting the limit to zero.

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCAttrReadMode_e
    - CsCValueType_e
    - CsCValue
    - CsCOIDSpec
    - CsCAttrValTable
    - CsCValueError
    - CsCAttrErrorList
    - CsCError_e

Read Table Attributes Example

The following example shows how to read table attributes:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.util.corba.*;
public class ReadTableAttr {
    public static void main( String[] args ) {

        CsCorbaValueHelper help = new CsCorbaValueHelper();
        Integer attrid = Integer.decode( args[0] );
        Integer mid = Integer.decode( args[1] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String("mySpectroSERVER");

            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                 CsCModelDomain.class, domainName );
```

```
            int [] attr = { attrid.intValue() };
            int [] lowValue = { 0 };
            int [] highValue = { 100 };
            CsCOIDSpec low = new CsCOIDSpec();
            CsCOIDSpec high = new CsCOIDSpec();
            int length = 10;
            low.objectID( lowValue );
            high.objectID( highValue );
            CsCAttrValTable tableValues = md.readAttrValTable(
                mid.intValue(), attr, low, high, length,
                CsCAttrReadMode_e.CSC_MOST_CURRENT );
            CsCAttrErrorList ael = tableValues.columnIndexList;
            for ( int i=0; i < ael.list.length; i++ )
            {
                System.out.println( "AEL len: " + ael.list.length );
                CsCOIDError[] vea = tableValues.rowIndexList;
                System.out.println( "VEA len: " + vea.length );
                for ( int j=0; j < vea.length; j++ )
                {
                    CsCValue attrval = tableValues.table[j][i].value;
                    System.out.println( i + ":" + j + " " +
                       attrval.textString() );
                }
            }
        }
        catch (Throwable e)
        {
            System.out.println( e );
        }
    }
}
```

Writing an Attribute Value and Table Values

The principles of reading an attribute also apply to writing attributes, except for the read modes. If an attribute is both external and memory or database, you need to write to both. Verify the attribute Dev_Contact_Status and isManaged before writing externally. Verify if the SNMP community string of the model has write privileges or writing externally fails.

The following example shows how to write a model's attribute value:

```
CsCValue val = new CsCValue();
val.textString(args[2] );
CsCAttrValue attrVal = new CsCAttrValue( attrID.intValue(),
     val, CsCError_e.SUCCESS );
CsCAttrValue[] attrValArray = new CsCAttrValue[1];
attrValArray[0] = attrVal;
CsCAttrValList writeValList = new CsCAttrValList( attrValArray,
     CsCError_e.SUCCESS );
CsCAttrErrorListOfModels aelom = md.writeAttrValListOfModelsByIDs(
     modelIDList,
     writeValList );
```

To write an attribute, you need to create a CsCAttrValList containing the attributes and values. Line 1 begins the construction of CsCAttrValList by creating a CsCValue. Line 2 assigns a test string value to CsCValue. Lines 3-5 create a CsCAttrValue passing the attribute ID, the CsCValue, and the error code SUCCESS. Line 6 is an array of one for CsCAttrValue, and line 7 assigns the CsCAttrValue to the array. Lines 8 and 9 construct the CsCAttrValList with the array and an error code of SUCCESS.

You can also construct CsCAttrValList as follows:

Read the value returned in a CsCAttrValList.

1. Set a value to CsCValue and pass it to the method writeAttrValListOfModelsByIDs.

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCModelPackage
  - Classes
    - CsCAttrErrorListOfModels
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCAttrReadMode_e
    - CsCValueType_e
    - CsCValue
- Package com.aprisma.spectrum.core.util
  - Classes
    - CsCorbaValueHelper

Write Attributes Example

The following example shows how to write attributes:

```
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.* ;
public class WriteModelInfo
{
    public static void main(String[] args)
    {
        Integer attrID = Integer.decode(args[1]);
        Integer modelID = Integer.decode(args[0]);
        int[] modelIDList = new int[1];
        int[] attrIDList = new int[1];
        modelIDList[0] = modelID.intValue();
        try
        {
            String domainName = new String("mySpectroSERVER");
            // Bind
```

```
            CORBAHelper helper = CORBAHelper.getHelperImpl () ;
            helper.init(null, null);
            CsCModelDomain md =
                   (CsCModelDomain) helper.getObjectImplementation (
                                  CsCModelDomain.class,
                                  domainName ) ;
            // Create CsCValue
            CsCValue val = new CsCValue();
            val.textString(args[2] );
            // Create Attr value
            CsCAttrValue attrVal = new CsCAttrValue( attrID.intValue(),
                                                     val,
                                                     CsCError_e.SUCCESS );
            // Construct a CsCAttrValue array
            CsCAttrValue[] attrValArray = new CsCAttrValue[1];
            attrValArray[0] = attrVal;
            CsCAttrValList writeValList =
                 new CsCAttrValList( attrValArray,
                                     CsCError_e.SUCCESS );
            CsCAttrErrorListOfModels aelom =
                md.writeAttrValListOfModelsByIDs( modelIDList,
                                                  writeValList );
            if( aelom.error == CsCError_e.SUCCESS )
            {
                System.out.println("Read was overall successful");
            }
            else
            {
                System.out.println("Read was not overall successful");
            }
        }
        catch(Throwable e)
        {
            System.out.println(e);
        }
    }
}
```

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes

- CsCAttrReadMode_e
- CsCValueType_e
- CsCValue
- CsCOIDSpec
- CsCAttrValTable
- CsCValueError
- CsCAttrErrorList
- CsCError_e

Build a CsC Attribute Value Table Example

Building a CsCAttrValTable for writing table attributes is similar to building a single value.

Example: Build a CsC attribute value table

The following example shows how to build a CsC attribute value table:

```
int size = 5;
CsCValueError[][] table = new CsCValueError[size][1];
CsCOIDError[] rowindexlist = new CsCOIDError[size];
CsCValue value;
for(int i = 0; i < size; ++i )
{
 int[] oidsuffix = new int[1];
 oidsuffix[0] = i;
 rowindexlist[i] = new CsCOIDError( oidsuffix,CsCError_e.SUCCESS);
 value = new CsCValue();
 value.textString("Hello");
 table[i][0] = new CsCValueError( value, CsCError_e.SUCCESS );
}
CsCAttrError[] attrlist = new CsCAttrError[1];
attrlist[0] = new CsCAttrError( attrid.intValue(),
    CsCError_e.SUCCESS);
CsCAttrErrorList columnindexlist = new CsCAttrErrorList( attrlist,
    CsCError_e.SUCCESS);
CsCAttrValTable attrvaltable = new CsCAttrValTable( table,
    rowindexlist, columnindexlist, CsCError_e.SUCCESS);
```

Line 1 sets the table size. Only one table attribute is set. Line 2 constructs a two-dimensional array of CsCValueError that forms the body of the CsCAttrValTable. Line 3 constructs a CsCOIDError array of size 5 for the five entries that are updated in the table. Line 5 sets up a For loop to iterate through the creation of the individual CsCValues. Lines 7, 8, and 9 set the rowindexlist array with the OID suffix and error code SUCCESS. Lines 10, 11, and 12 construct a CsCValue, assign the text string value of Hello, and assign it to the table array as a CsCValueError.

Lines 14-18 set up the attribute ID to write to. First, a CsCAttrError array of size one is constructed. Next, the first element is assigned a CsCAttrError with attribute and error code SUCCESS. Lines 19 and 20 read the constructed values to construct the CsCAttrValTable.

Write Table Attributes Example

The following example shows how to write table attributes:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
```

```
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class WriteTableAttr
{
    public static void main( String[] args )
    {
        Integer attrid = Integer.decode( args[0] );
        Integer mid = Integer.decode( args[1] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroSERVER" );
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );

            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );
            int size = 3;
            CsCValueError[][] table = new CsCValueError[size][1];
            CsCOIDError[] rowindexlist = new CsCOIDError[size];
            CsCValue value;
            for ( int i=0; i < size; i++ )
            {
                int [] oidsuffix = new int[1];
                value = new CsCValue();
                value.textString( "Hello" );
                table[i][0] = new CsCValueError( value,
                                    CsCError_e.SUCCESS );
                oidsuffix[0] = i + 1;
                rowindexlist[i] = new CsCOIDError( oidsuffix,
                                    CsCError_e.SUCCESS );
            }
            CsCAttrError[] attrlist = new CsCAttrError[1];
            attrlist[0] = new CsCAttrError( attrid.intValue(),
                                   CsCError_e.SUCCESS );
            CsCAttrErrorList columnindexlist = new CsCAttrErrorList(
                  attrlist, CsCError_e.SUCCESS );
            CsCAttrValTable attrvaltable = new CsCAttrValTable( table,
                  rowindexlist, columnindexlist, CsCError_e.SUCCESS );
            CsCAttrErrorTable aet = md.writeAttrValTable(
                  mid.intValue(), attrvaltable );
        } catch ( Throwable e  )
        {
            System.out.println( e );
        }
    }
}
```

If you want to clear all entries of an internal attribute list, you cannot write an empty CsCAttrValTable because the writeAttrValTable method adds supplemental entries. Existing entries are updated and new entries added.

One of the methods to clear a list is as follows:

```
int[] attr = { 0xffff0021 };
md.clearListAttrs(mid.intValue(),attr);
```

Event Management

In addition to DX NetOps Spectrum, network managers often rely on third-party products to manage special functions. For example, a third-party product monitors firewalls and another watches the network traffic. These products gather information, filter data, and send events to DX NetOps Spectrum, which correlates, stores, and displays the events, and promotes them to alarms.

The following example shows how to use the API interface to create and manage events:

```
Integer modelID = Integer.decode( args[0] );
Integer eventCode = Integer.decode( args[1] );
int severity = 3;
CsCValue svalue = new CsCValue();
svalue.gaugeValue(severity);
CsCAttrValue sav = new CsCAttrValue(
    CsCorbaEventHelper.SEVERITY,
    svalue,
    CsCError_e.SUCCESS);
CsCAttrValue[] ava = new CsCAttrValue[]{sav};
CsCAttrValList avl = new CsCAttrValList( ava,
    CsCError_e.SUCCESS);
byte[] eventid = md.createEvent( modelID.intValue(),
    eventCode.intValue(), avl );
System.out.println("Event ID:" +
    CsCorbaEventHelper.toString( eventide ));
```

In the preceding example, an event is generated for a model through the CsCModelDomain interface. Lines 1 and 2 decode the model ID and event code. Lines 4-12 create a CsCValue of value 3 to assign as the severity of the event being created. On lines 13-14, the CsCorbaEventHelper is called to print the event ID to text string format. The toString method on the next line displays the event ID, which uniquely identifies the event among all the event domains in the installation. An example of an event ID is 3a63543c-0026-1000-00d9-0080108d4051.

This class contains all attributes from which you can retrieve the following values:

- Creation_Date
- Creator
- EventID
- Event_Type
- Model_Handle
- Model_Name
- Model_Type
- Model_Type_Name
- Severity and Type_Attributes

The class also contains helper methods for converting data such as the event ID into text format. CsCEventDomain provides access to events of a model domain. An event is a record of a situation in a monitored entity such as a router or an application. You can create a history of the entire network by storing a series of events from multiple entities. You can use the history to track down a problem in a monitored entity or a problem caused by the interaction of multiple monitored entities.

A client or DX NetOps Spectrum creates events but DX NetOps Spectrum receives them. Most events are distributed to clients and stored in a database. Events that DX NetOps Spectrum uses internally are not available to clients. CsCEventDomain provides a client interface to retrieve events from the database and receive events.

Every event contains a type and an identifier. Each new situation that occurs in a network creates a new event type. Two examples are *link up* and *link down* event types. An event identifier (CsCEventID) uniquely identifies events independent of the model domain in which it is created. By default, only this basic information is passed to a client.

Each event contains additional information stored in an attribute value error list. An attribute ID identifies the additional information which is sent to a client upon request.

The following section lists the event attributes and their descriptions:

- **Event ID**
  Uniquely identifies an event independent of the model domain in which the event is created.
  Type: CsCEventID
  Attribute ID: 0x11fbc
- **Event Type**
  Indicates the nature of the situation for which an event is created. Event types are 32-bit identifiers. The top 16 bits identify the developer, and the bottom 16 bits are allocated by the management module developer to distinguish each event type the developer creates. Event types are defined as part of management modules and are always contained in each event.
  Type: Integer
  Attribute ID: 0x11fb8
- **Creator**
  The name of the user that created the event. DX NetOps Spectrum creates this attribute when creating an event.
  Type: Text String
  Attribute ID: 0x11fb9
- **Creation Date/Time**
  The date and time of recording the event.
  Type: CsCDateTime
  Attribute ID: 0x11f4e
- **Severity**
  Defines the event severity. A higher severity event needs more attention by the network administrator or represents a bigger failure. Allowed values are 0 through 100, with 100 being the highest severity. Event severity is assigned by a management module and can be changed by users. Every event has a severity associated with it.
  Type: Integer
  Attribute ID: 0x11fb5
- **Model ID**
  The model ID for which the event was created.
  Type: Model ID
  Attribute ID: 0x11f53
- **Model Name**
  The name of the model.
  Type: Text String
  Attribute ID: 0x1006e
- **Model Type**
  The type of the model for which the event was created.
  Type: CsCMType
  Attribute ID: 0x10001
- **Model Type Name**
  Type: Text String
  Attribute ID: 0x10000

The name of the model type.

- **Type Attributes**
  Type: Boolean
  Attribute ID: 0x11fba
  Events may have event-specific attributes. You can use event-specific attributes to construct event messages from event format files. You can use this attribute to specify that the client wants DX NetOps Spectrum to send all event-specific attributes with each event.
- **Model ID**
  The ID of the model for which the event is created.
  Type: Integer
  Attribute ID: 0x129aa
- **Domain ID**
  The ID of the domain for which the event is created.
  Type: Integer
  Attribute ID: 0x129ac

Create Events Example

The following example shows how to create events:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class CreateEvent
{
    public static void main( String[] args )
    {
        Integer modelID = Integer.decode( args[0] );
        Integer eventCode = Integer.decode( args[1] );
        CsCModelDomain md = null;

        try
        {
            String domainName = new String( "mySpectroSERVER" );

            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );

            md = (CsCModelDomain) helper.getObjectImplementation(
                 CsCModelDomain.class, domainName );
            int severity = 7;
            CsCValue svalue = new CsCValue();
            svalue.gaugeValue( severity );
            CsCAttrValue sav = new CsCAttrValue(
                 CsCorbaEventHelper.SEVERITY,
                 svalue, CsCError_e.SUCCESS );
            CsCAttrValue[] ava = new CsCAttrValue[]{sav};
            CsCAttrValList avl = new CsCAttrValList( ava,
                 CsCError_e.SUCCESS );
```

```
            byte[] eventid = md.createEvent( modelID.intValue(),
                 eventCode.intValue(), avl );
        } catch ( Throwable e ) {
            System.out.println( e );
        }
    }
}
```

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCEventDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCEventDomainPackage
  - Classes
    - CsCEvent
- Package com.aprisma.spectrum.core.util
  - Classes
    - CsCorbaEventHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCAttrValList
    - CsCAttrValue
    - CsCValue
- Package com.aprisma.spectrum.core.idl.CsCError
  - Classes
    - CsCError_e

Event Retrieval

You can retrieve events by defining search filters. First, retrieve the CsCEventDomain interface and then construct a filter type to define the event result set returned. Filters can specify a time range, particular model, event types, or a combination of criteria.

Calling the method getEventListByAttrFilter returns events to a client. The first parameter is the filter. The second parameter specifies the attributes to be returned for every event found by the filter. If a response to a request cannot be returned as one result set, CsCError::LIMIT_REACHED is returned as the error. You should call getNextEventListByAttrFilter to get the remaining events. The search limit is 10,000 records. You should pass the requestID to getNextEventListByAttrFilter to request the next group of events associated with this request. This requestID is invalid five minutes after it is returned or when all events have been returned to the client.

Retrieve Events by Type Example

The following example shows how to retrieve events by type:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCEventDomainPackage.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
```

```
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class RetrieveEvent
{
    public static void main( String[] args )
    {
        Integer modelID = Integer.decode( args[0] );
        Integer eventCode = Integer.decode( args[1] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroSERVER" );
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );

            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );
            CsCEventDomain ed = (CsCEventDomain)
                helper.getObjectImplementation(
                    CsCEventDomain.class, domainName );
            CsCorbaFilterAttrNode node =
                CsCorbaAttrFilterHelper.createGaugeValueNode(
                    CsCorbaEventHelper.EVENT_TYPE,
                    CsCOperator_e.CSC_EQUALS, eventCode.intValue());
            CsCValue[] filter = node.getFilter();
            int[] attrIDs = new int[4];
            attrIDs[0] = CsCorbaEventHelper.CREATOR;
            attrIDs[1] = CsCorbaEventHelper.MODEL_NAME;
            attrIDs[2] = CsCorbaEventHelper.MODEL_TYPE_NAME;
            attrIDs[3] = CsCorbaEventHelper.TYPE_ATTRIBUTES;
            org.omg.CORBA.IntHolder requestID =
                new org.omg.CORBA.IntHolder();
            CsCEventList el = ed.getEventListByAttrFilter(filter,
                attrIDs, requestID);
            System.out.println("Overall:" + el.error.toString());
            if (el.error == CsCError_e.SUCCESS ||
                el.error == CsCError_e.LIMIT_REACHED )
            {
                printEventInfo( el );
                if (el.error == CsCError_e.LIMIT_REACHED)
                {
                    el = ed.getNextEventListByAttrFilter(
                        requestID.value);
                    printEventInfo(el);
                }
            }
        } catch ( Throwable e ) {
            System.out.println( e );
        }
    }
    public static void printEventInfo( CsCEventList el )
    {
```

```
        for (int i = 0; i < el.list.length; i++)
        {
            CsCEvent event = el.list[i];
            CsCAttrValList avl = event.attrValList;
            System.out.println("EventCode:" + event.type);
            for (int j = 0; j < avl.list.length; j++)
            {
                CsCAttrValue av = avl.list[j];
                System.out.println("AttrID:" + av.attributeID);
                CsCValue val = av.value;
                System.out.println("AttrVal:" + val.toString());
            }
        }
    }
}
```

The previous example requires the following objects and methods:

Alarms in Development API

The SPECTRUM Development API creates alarms through the event creation process. When an event is created, it is mapped to an entry in the EventDisp files found in a subdirectory of *$SPECROOT*/SS/CsVendor.

For example, the EventDisp file for the mtype 0x1c8000a resides in the *$SPECROOT*/SS/CsVendor/Ctron_SSAH directory and resembles the following file:

```
0x00010306 E 30
0x00010307 E 30
0x00010308 E 50 A 1,0x010308
0x00010309 E C 0x010308
0x0001030a E 50 A 1,0x01030a
```

```
0x0001030b E 50 A 1,0x01030b
0x021b070a E 50
0x021b070b E 50 A 1,0x021b070b
0x021b070c E 50
0x021b070d E 50
0x000d01a0 E 50 A 1,0x0d01a0
0x000d01a1 E 50 A 1,0x0d01a1
0x000d01a2 E 50 A 1,0x0d01a2
0x000d01a3 E 50 A 1,0x0d01a3
0x000d0351 E 50 A 1,0x0d0351
0x000d0001 E 50 A 1,0x0d0001
0x000d0002 E 50 A 1,0x0d0002
0x00830000 E 30
0x00830001 E 30
0x00830002 E 30
0x003c0002 E 50 A 1,0x003c0002
0x000d2afb E 30
```

The numbers in the left column are event codes. Code E tells DX NetOps Spectrum to log the event; Code C tells DX NetOps Spectrum to clear the event; Code A tells DX NetOps Spectrum to generate an alarm; 1 specifies the severity of the alarm. The numbers in the right column indicate the probable cause to display with the alarm.

CsCAlarmDomain provides access to alarms of a model domain. Alarms indicate a situation, in a monitored entity such as a router or application, that requires the attention of product operators. The alarm priority suggests an order in which to address the situations.

The DX NetOps Spectrum alarm system delivers only the most important alarms to clients. You can do this task in two ways such as, deliver only what a client requests, or prioritize the alarm delivery. Only the basic information like the alarm ID, cause, priority, and severity is shipped with alarms by default. If desired, clients must specify additional characteristics, which are defined by attribute IDs that are sent with each alarm.

To prioritize alarm delivery, clients specify prioritized alarm filters. The filters define which alarms are shipped to the client. Prioritizing the filters lets DX NetOps Spectrum generate only high-priority alarms. For example, prioritization is useful in situations where some alarms are delayed due to a high volume of alarm updates. The priority that is assigned to an alarm depends on the priority alarm filters of all the clients that receive the alarm.

The client should use the interface in a way that minimizes the amount of data that is sent to the client, while clarifying the priority of client alarm requests.

Alarm Attributes

DX NetOps Spectrum offers two categories of attributes, Alarm and Model. Alarm attributes exist only within the context of an alarm. Model attributes are stored with models. Clients can select the attributes to include with alarms. For example, you can configure alarms to include the model name and troubleshooter name. Model name is a model attribute and troubleshooter name is an alarm attribute. Letting clients select model attributes for each alarm minimizes the need for clients to query DX NetOps Spectrum for additional data when a new alarm is received.

Verify the following alarm attributes and their descriptions:

- **Acknowledged**
  (Read/Write) Indicates the state of the alarm acknowledgment, that is, whether the user has seen the alarm.
  Type: Boolean
  Attribute ID: 0x11f4d
- **Alarm ID**
  (Read Only) Uniquely identifies the alarm independent of the model domain where the alarm was created. This attribute is automatically sent with every alarm.

Type: CsCAlarmID
Attribute ID: 0x11f9c

- **Alarm Status**
  (Read/Write) Conveys information about the alarm. Status always indicates whether repair is complete.
  Type: string
  Attribute ID: 0x11f4f
- **Alarm Cause**
  (Read Only) Identifies the alarm cause and the nature of the situation for which an alarm is created. This attribute is automatically sent with every alarm so applications need not explicitly request for it.
  Type: CsCCauseID
  Attribute ID: 0x11f50
- **Alarm Source**
  (Read Only) An enumerated value that indicates the alarm source. Currently, the following values are supported.
  – **0**
  Specifies that the alarm is current.
  – **1**
  Specifies that the alarm is residual; it exists from a previous run of the SpectroSERVER.
  Type: enum
  Attribute ID: 0x11fc4
- **Cleared by Name**
  (Read Only) Specifies the user name that cleared the alarm through the API. This attribute is not present when an alarm is created but is added prior to removal.
  Type: string
  Attribute ID: 0x11f51
- **Creation Date**
  (Read Only) The time and date of the alarm creation.
  Type: CsCDateTime
  Attribute ID: 0x11f4e
- **Event ID List**
  (Read/Write) Specifies the list of events that are associated with the alarm. Include the events that caused the alarm to be generated.
  Type: CsCEventIDList
  Attribute ID: 0x11f52
- **Model ID**
  (Read Only) Identifies the model with the situation reported by the alarm.
  Type: Model ID
  Attribute ID: 0x11f53
- **Occurrences**
  (Read Only) Contains the number of occurrences of the alarm. The count is updated when the situation that asserted the alarm recurs through a trap, event, or IH. This attribute is initialized to 1 as the initial alarm is the first occurrence.
  Type: unsigned long (gauge)
  Attribute ID: 0x11fc5
- **Last Occurrence Date**
  (Read Only) Indicates the time and date when the alarm last occurred.
  Type: CsCDateTime
  Attribute ID: 0x1321a
- **Primary Alarm**
  (Read Only) Indicates whether the alarm is a primary alarm. Primary alarms are the highest priority for a model. A model can have more than one primary alarm at a time.
  Type: Boolean

Attribute ID: 0x11f54

- **Resolved**
  (Read Only) Indicates whether the alarm is resolved internally by DX NetOps Spectrum.
  Type: Boolean
  Attribute ID: 0x11f55
- **Severity**
  (Read Only) Indicates the alarm severity. This attribute is automatically sent with every alarm so applications need not explicitly request for it.
  Type: CsCAlarmSeverity
  Attribute ID: 0x11f56
- **Troubleshooter**
  (Read/Write) Specifies the name of the troubleshooter that is assigned to repair the alarm.
  Type: string
  Attribute ID: 0x11f57

  NOTE
  When this attribute is written, the troubleshooter model attribute is updated accordingly, if the name corresponds to a valid troubleshooter model for the user.
- **Troubleshooter Model**
  (Read/Write) Identifies the model of the troubleshooter that is assigned to repair the alarm.
  Type: CsCModel
  Attribute ID: 0x11fc6

  NOTE
  When this attribute is written, the troubleshooter name attribute is updated accordingly. However, if the model is not valid or is not associated with a user, the write fails and returns the error ATTR_BAD_VALUE.
- **Trouble Ticket ID**
  (Read/Write) Contains the ID of the trouble ticket that is associated with the alarm.
  Type: string
  Attribute ID: 0x12022
- **User Clearable**
  (Read Only) Indicates whether a client can clear the alarm. This attribute is provided to let client applications indicate to users that the alarm is not clearable. A client cannot control whether an alarm can be cleared.
  Type: Boolean
  Attribute ID: 0x11f9b
- **Model ID**
  (Read Only) Identifies the ID of the model with the situation reported by the alarm.
  Type: integer
  Attribute ID: 0x129aa
- **Model Type ID**
  (Read Only) Specifies the ID of the model type.
  Type: integer
  Attribute ID: 0x129ab

Retrieving an alarm is similar to retrieving an event. Retrieve events by defining search filters for alarms. First, retrieve the CsCAlarmDomain interface and then construct a filter to define the alarm result set. Filters can specify a time range, a particular model, alarm type, or a combination of criteria. You can use all attributes that are listed here for the filter. The CsCorbaAlarmHelper class defines all alarm attributes. In addition, the helper class can convert alarm ID from byte array to text string and text string to byte array. Alarm IDs are unique like event IDs and have long formats.

Retrieve Alarms by Model ID Example

The following example shows how to retrieve alarms by model ID:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;

            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );
            CsCorbaFilterAttrNode node =
                CsCorbaAttrFilterHelper.createModelIDNode(
                        CsCorbaAlarmHelper.MODEL_HANDLE,
                        CsCOperator_e.CSC_EQUALS, modelID.intValue() );
            CsCValue[] filter = node.getFilter();
            int[] attrIDs = new int[2];
            attrIDs[0] = CsCorbaAlarmHelper.CREATION_DATE;
            attrIDs[1] = CsCorbaAlarmHelper.MODEL_HANDLE;

            CsCAlarmDomain ad = md.getAlarmDomain();
            CsCAlarmList al = ad.getAlarmListByAttrFilter( filter,
                attrIDs );
            System.out.println( "Status:" + al.error.toString() );
            for ( int i=0; i < al.list.length; i++ ) {
                CsCAlarm alarm = al.list[i];
                System.out.println( "Priority:" + alarm.priority );
                System.out.println( "Severity:" + alarm.severity );

                CsCAttrValList avl = alarm.attrValList;
                System.out.println( "CreationDate: " +
                    avl.list[0].value.toString() );
                System.out.println( "ModelHandle: " +
                    avl.list[1].value.toString() );
            }
        } catch ( Throwable e ) {
            System.out.println( e );
        }
    }
}
```

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCAlarmDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAlarmDomainPackage
  - Classes
    - CsCAlarm
    - CsCAlarmList
- Package com.aprisma.spectrum.core.util
  - Interfaces
    - CsCorbaFilterAttrNode
  - Classes
    - CsCorbaAlarmHelper
    - CsCorbaAttrFilterHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCAttrValList
    - CsCAttrValue
    - CsCValue
- Package com.aprisma.spectrum.core.idl.CsCError
  - Classes
    - CsCError_e

Updating and Clearing Alarms

You can update alarm attributes as you update model attributes. The following example shows how to update the trouble ticket ID through a trouble ticketing system. You can also use other attributes such as Trouble_Shooter and Resolved for automation of alarms.

```
byte[][] alarms = new byte[][]{alarm.alarmID};

CsCValue val = new CsCValue();
val.textString("123123");
CsCAttrValue attrVal = new
    CsCAttrValue(CsCorbaAlarmHelper.TROUBLE_TICKET_ID, val,
    CsCError_e.SUCCESS);
CsCAttrValue[] attrValArray = new CsCAttrValue[1];
attrValArray[0] = attrVal;
CsCAttrValList writeValList = new CsCAttrValList(attrValArray,
    CsCError_e.SUCCESS);
try
{
    ad.writeAttrValListOfAlarms(alarms, writeValList);
}
catch (Throwable e)
{
    System.out.println(e);
```

```
}
```

Line 1 takes the Alarm ID byte array and assigns the value to a two-dimensional array if there are multiple alarms to be updated at once. Lines 3-10 construct a CsCAttrValList for setting TROUBLE_TICKET_ID. Line 14 makes the call to write the attribute value.

You can clear alarms automatically through events and EventDisp files. You can also use the following API to clear alarms:

```
try
{
ad.clearAlarm(alarm.alarmID);
}
catch (Throwable e)
{
System.out.println(e);
}
```

Watches using the Dev API

You can register with DX NetOps Spectrum for asynchronous notification of events, such as the following:

- Model creation and deletion
- Attribute value changes
- Event and statistic creation
- Alarm updates

A client application obtains references to objects on the server and uses these stubs to make remote method invocations to the objects. To register for asynchronous notification, the client itself instantiates a watch object and passes a reference to the server instructing it to call a method in the object if a specified condition occurs. If the specified condition occurs, the server calls the method in the client's watch object and notifies the client.

If you are writing a client application that is notified when the value of a particular attribute in the DX NetOps Spectrum knowledge base changes, you should first design an attribute value change class, for example, AttrValCallback. The client program instantiates the class and passes an object reference (and the attribute ID to watch) to DX NetOps Spectrum. If the attribute value changes, DX NetOps Spectrum calls the attrValsChanged method in your AttrValCallback class.

The important factors in changing attribute values include the following:

- For DX NetOps Spectrum to detect a change in the attribute, the memory flag must be set. If not set, the attribute change mechanism does not work because DX NetOps Spectrum does not retain the last known value for comparison.
- For external attributes, you should set the polled flag. Without the mechanism to poll every given period externally, DX NetOps Spectrum never detects a change until some other program reads the attribute.

How To Set Up a Watch

Setting up a watch involves the following steps:

1. Create a class file for the callback and extend it from the desired callback class.
2. Create a main class that instantiates the callback class and passes it to the respective domain.

The following table lists the available callback classes and their domains:

Monitor	Extend Callback Class	Domain
Attribute Value Changes	CsCAttrValWatchCBPOA	Model Domain
Model Creation/Destroy	CsCModelWatchCBPOA	Model Domain
Model Association Changes	CsCAssocModelWatchCBPOA	Model Domain
Event Creation	CsCEventWatchCBPOA	Event Domain
Alarm Creation/Change/ Clear	CsCAlarmWatchCBPOA	Alarm Domain

Watch Attribute Changes for a Model ID Example

The following example shows how to watch attribute changes for a given model ID:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.* ;
import com.aprisma.spectrum.core.util.* ;
import com.aprisma.util.corba.* ;
import com.aprisma.spectrum.core.idl.CsCAttribute.* ;
import com.aprisma.spectrum.core.idl.CsCModelPackage.* ;
public class WatchAttrValue
{
    public static void main(String[] args)
    {
        try
        {
            String domainName =  new String("mySpectroSERVER");
            CORBAHelper hlp = CORBAHelper.getHelperImpl();
            hlp.init(null, null);
            CsCModelDomain md = (CsCModelDomain)
               hlp.getObjectImplementation
                   (CsCModelDomain.class, domainName);

            AttrValCallback callback = new AttrValCallback();
            //decode model ID
            int[] modelIDs = {Integer.decode(args[0]).intValue()};
            int[] attrs = {0x1006e}; //model name
            CsCAttrReadMode_e[] readModes =
                {CsCAttrReadMode_e.CSC_MOST_AVAILABLE};
            CsCAttrValWatchCB cb =
                CsCAttrValWatchCBHelper.narrow(
                    hlp.servant_to_reference( callback ) );
            CsCAttrValListOfModels avlm =
                md.startWatchAttrValsOfModelsByIDs(modelIDs,
                    attrs, readModes, cb);
            System.out.println("Watching started.." +
              " Press Enter to exit");
            System.in.read();
            md.stopWatchAttrValsOfModelsByIDs(cb, attrs, modelIDs);
        }
        catch (Throwable e)
        {
            System.out.println(e);
```

```
        }
    }
}

Watch Model Creation and Deletion Example

If a model is deleted, you can retrieve only the model ID. If you need more information, you should make a repository keyed on model ID.

The following example shows how to watch model creation and deletion:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class WatchModel
{
    public static void main( String[] args )
    {
        Integer mtypeID = Integer.decode( args[0] );
        int[] mtypeIDs = { mtypeID };
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroSERVER" );
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );

            ModelCallback callback = new ModelCallback();
            CsCModelWatchCB cb =
            CsCModelWatchCBHelper.narrow(
                helper.servant_to_reference(callback));
            md.startWatchModelsByTypeIDs(mtypeIDs, cb);
            System.out.println( "Press Enter to exit" );
            System.in.read();
            md.stopWatchModelsByTypeIDs(mtypeIDs, cb);
        }
        catch (Throwable e)
        {
            System.out.println( e );
        }
    }
}
import java.io.*;

Watch Model Association Changes Example

The following example shows how to watch model association changes:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCRelationPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class WatchAssocModel
{
    public static void main( String[] args )
    {
        Integer modelID = Integer.decode( args[0] );
        int[] modelIDs = { modelID };
```

```
        int relationID = 0x10002;
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroSERVER" );
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );

            AssocModelCallback callback = new AssocModelCallback();
            CsCAssocModelWatchCB cb =
            CsCAssocModelWatchCBHelper.narrow(
                helper.servant_to_reference(callback));
            md.startWatchAssocModelsOfModels(relationID,modelIDs,
                CsCSide_e.CSC_RIGHT_SIDE, cb);
            System.out.println( "Press Enter to exit" );
            System.in.read();
            md.stopWatchAssocModelsOfModelsByIDs(cb, modelIDs);
        }
        catch (Throwable e)
        {
            System.out.println( e );
        }
    }
}

import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCModelPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class AssocModelCallback extends CsCAssocModelWatchCBPOA
{
    public void associatedModelsAdded(CsCAssocModelPropList ampl)
    {
        System.out.println( "Overall: " + ampl.error.toString() );
        System.out.println( "Added Assoc: " + ampl.relationID);
        System.out.println( " For Model:  " + ampl.withModel.modelID);
        System.out.println( " On Side:    " +
                                          ampl.withSide.toString());

        }
    }
    public void eventAttrValsUpdated( CsCEventList el )
    {
        System.out.println( "Overall: " + el.error.toString() );
        for ( int i=0; i < el.list.length; i++ )
        {
            CsCEvent event = el.list[i];
            CsCAttrValList avl = event.attrValList;
            System.out.println( "EventCode: " + event.type );
            for ( int j=0; j < avl.list.length; j++ )
            {
                CsCAttrValue av = avl.list[j];
                System.out.println( "AttrID: " + av.attributeID );
                CsCValue val = av.value;
                System.out.println( "AttrVal: " + val.toString() );
            }
        }
    }
}
```

The previous example passes a model filter and an attribute list to be returned by the callback. The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCEventWatchCBPOA
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCEventDomainPackage
  - Classes
    - CsCEvent
- Package com.aprisma.spectrum.core.util
  - Interface
    - CsCorbaFilterAttrNode
  - Classes
    - CsCorbaAttrFilterHelper
    - CsCorbaEventHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  - Classes
    - CsCAttrValList
    - CsCAttrValue
    - CsCValue
- Package com.aprisma.spectrum.core.idl.CsCError
  - Classes
    - CsCError_e

Watch Alarm Creation, Clearing, and Attribute Updates Example

The following example shows how to watch alarm creation, attribute updates, and clearing:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCAlarmDomainPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class WatchAlarms
{
    public static void main( String[] args )
    {
        Integer modelID = Integer.decode( args[0] );
        CsCModelDomain md = null;
        try
        {
            String domainName = new String( "mySpectroSERVER" );
            CORBAHelper helper = CORBAHelper.getHelperImpl();
            helper.init( null, null );
            md = (CsCModelDomain) helper.getObjectImplementation(
                CsCModelDomain.class, domainName );
            CsCAlarmDomain ad = md.getAlarmDomain();
            CsCorbaFilterAttrNode node =
                CsCorbaAttrFilterHelper.createModelIDNode(
                        CsCorbaAlarmHelper.MODEL_HANDLE,
                        CsCOperator_e.CSC_EQUALS, modelID.intValue() );
            CsCValue[] filter = node.getFilter();
            int[] attrIDs = new int[1];
            attrIDs[0] = CsCorbaAlarmHelper.CREATION_DATE;
            AlarmCallback callback = new AlarmCallback();
            CsCAlarmWatchCB cb =
                   CsCAlarmWatchCBHelper.narrow(
                        helper.servant_to_reference(callback));
            ad.startWatchAlarms( filter, attrIDs, cb );
            System.out.println( "Press Enter to exit" );
            System.in.read();
            ad.stopWatchAlarms( cb );
        }
        catch (Throwable e)
        {
            System.out.println( e );
        }
    }
}
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCAttribute.*;
import com.aprisma.spectrum.core.idl.CsCAlarmDomainPackage.*;
```

```
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class AlarmCallback extends CsCAlarmWatchCBPOA
{
    public void alarmsUpdated( CsCAlarmUpdate au )
    {
        CsCAlarmList addlist = au.addList;
        CsCAttrValListOfAlarms changelist = au.changeList;

        System.out.println( "addList len:" + addlist.list.length +
                    " changeList len:" +
                    changelist.list.length );

        for ( int i=0; i < addlist.list.length; i++ ) {
            CsCAlarm alarm = addlist.list[i];
            System.out.println( "Added AlarmID:" +
                    CsCorbaAlarmHelper.toString( alarm.alarmID ) );
                        System.out.println("Value: " +
                           alarm.attrValList.list[0].value );
                        System.out.println("Value: " +
                           alarm.attrValList.list[1].value );
        }
        for ( int j=0; j < changelist.list.length; j++ ) {
            System.out.println( "Changed AlarmID:" +
                    CsCorbaAlarmHelper.toString(
                       changelist.list[j].alarmID ) );
        }
        for (int k = 0; k < au.removeList.length; k++)
        {
            System.out.println("Removed AlarmID:" +
                    CsCorbaAlarmHelper.toString(au.removeList[k]));
        }
    }
}
```

The previous example passes a model filter and an attribute list to be returned by the callback to the startWatch method. In the AlarmCallback class where DX NetOps Spectrum notifies this class, alarms are of three types: newly created, updated, and removed.

The previous example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
    - CsCAlarmDomain
  - Classes
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCAlarmDomainPackage
  - Classes

    - CsCAlarm
    - CsCAlarmList
    - CsCAlarmUpdate
    - CsCAttrValListOfAlarms
- Package com.aprisma.spectrum.core.util
  – Interfaces
    - CsCorbaFilterAttrNode
  – Classes
    - CsCorbaAlarmHelper
    - CsCorbaAttrFilterHelper
- Package com.aprisma.spectrum.core.idl.CsCAttribute
  – Classes
    - CsCAttrValList
    - CsCAttrValue
    - CsCValue
- Package com.aprisma.spectrum.core.idl.CsCError
  – Classes
    - CsCError_e

Miscellaneous Considerations

Distributed Environments

Use the following checklist to verify that the required files and configuration are present when running a client from another workstation:

- User creation in the SpectroSERVER
- Appropriate .hostrc permissions
- Hostname resolution from either DNS or /etc/hosts
- Access control lists on any router between the client and server
- Firewall-blocking ports

> **NOTE**
> For more information about setting up a distributed SpectroSERVER environment, see Distributed SpectroSERVER Administration .

Location Service Interface

To get a list of SpectroSERVERs in a distributed environment, you can use the interface CsCLocServMapInt. The Location Service advertises on this interface and only one call is available to retrieve the SpectroSERVER list. Once the CsCModelDomain interface reference is retrieved, the isPrimary method is called to determine if the interface is primary or secondary.

> **NOTE**
> Calling the isPrimary method is one way of knowing whether the SpectroSERVER is the primary or secondary in a fault-tolerant environment.

Binding to Multiple Domains Example

The following example shows the method for multiple domain binding:

```
import java.io.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.spectrum.core.idl.CsCModelDomainPackage.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.util.corba.*;
public class GetDomainList
{
    public static void main(String[] args)
    {
        CsCorbaValueHelper help = new CsCorbaValueHelper();
        CsCLocServMapInt locserv;
        CORBAHelper helper = null;
        String[] domainnames = { "" };
        CsCModelDomain[] md;
        helper = CORBAHelper.getHelperImpl();
        try
        {
            String domainName = new String("mySpectroSERVER");
            helper.init(null, null);
            locserv = (CsCLocServMapInt)helper.getObjectImplementation(
                CsCLocServMapInt.class, domainName);
            domainnames = locserv.getModelDomainNameList();
        }
        catch (Throwable e)
        {
            System.out.println(e);
        }
        md = new CsCModelDomain[domainnames.length];
        for (int i = 0; i < domainnames.length; i++)
        {
            try
            {
                md[i] =
                   (CsCModelDomain)helper.getObjectImplementation(
                   CsCModelDomain.class, domainnames[i]);
                System.out.println("Name:" + domainnames[i]);
                System.out.println("Is Primary: " + md[i].isPrimary());
            }
            catch (Throwable e)
            {
                System.out.println(e);
            }
        }
    }
}
```

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl

  - Interfaces
    - CsCLocServMapInt
    - CsCModelDomain
  - Classes
    - CsCLocServMapIntHelper
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCError
  - Classes
    - CsCError_e

Status Monitoring of CORBA Interface

Server bouncing may cause non-persistent interfaces and watch reference to be lost except for persistent interfaces like ModelDomain, AlarmDomain and EventDomain. CORBAObjectMonitor provides the facility to know if a domain is lost and contact is reestablished. When the CORBAObjectMonitor, located in utilsrvXX.jar, is instantiated, it binds to the domain through the application user.

Monitoring the CORBA interface status involves the following components:

- CORBAObjectMonitor to poll the domain.
- CORBAObjectMonitorListener to react to a contact change that the CORBAObjectMonitor detected.

CORBAObjectMonitor adds the listener to the CORBAObjectMonitorListener methods to get invoked. CORBAObjectMonitorListener has the following methods:

- connectionError
- connectionEstablished
- connectionLost
- successfullyPolled

This example requires the following objects and methods:

- Package com.aprisma.spectrum.core.idl
  - Interfaces
    - CsCModelDomain
  - Classes
    - CsCModelWatchCBImplBase
    - CsCModelDomainHelper
- Package com.aprisma.spectrum.core.idl.CsCError
  - Classes
    - CsCError_e
- Package com.aprisma.util.corba
  - Interfaces
    - CORBAObjectMonitorListener
  - Classes
    - CORBAObjectMonitor

How CORBA Interface Status Is Monitored

Monitoring the CORBA interface involves the following process:

1. The PersistentWatcher class implements the CORBAObjectMonitorListener.

2. The constructor makes a call to get the required domain (in this case, CsCModelDomain) and sets that reference to a variable. The CORBAObjectMonitor is created. The arguments passed are the service name, the service type, and the polling interval in milliseconds.
3. A call is made to connect on the monitor that obtains the object implementation. If the connection is already established, the object is returned. If not, the connection is attempted again if tryToConnect is set to True.
4. If the connection is good, add the listener and start polling.
5. If you invoke startPolling(), a check is made against the CORBA object to see if it still exists. If it exists, the successfullyPolled method is called. If not, the connection is retried.
6. If the connection is successful, connectionEstablished method is called. If the connection attempt fails, the connectionLost or connectionError is called depending on the problem.

   NOTE
   For fault-tolerant environments, if the primary fails, the CORBAObjectMonitor attempts to monitor the secondary. If successful, the connectionEstablished method is called. If the monitor object cannot connect to the secondary, connectionLost or connectionError is called.

   The following CORBAObjectMonitorListener methods require notification:
   - **successfullyPolled**
     Indicates the listener method called when connection is successfully polled.
   - **connectionEstablished**
     Indicates the listener method called when connection is successful.
   - **connectionLost**
     Indicates the listener method called when connection is not successful and the problem lies in the CORBA framework.
   - **connectionError**
     Indicates the listener method called when connection is not successful and the problem lies outside the CORBA framework.
7. The final call in the constructor sets up the model watch. For each trigger on the listener, an action is performed. For the connection lost and connection error, a message prints informing the user that connection is down. For the connection established, the model watch is reestablished.

Monitor CORBA Interface Status Example

The following example shows how to monitor an interface:

```
import java.io.*;
public class PersistentWatcherApp
{
    public static void main( String[] args )
    {
        String serverName = new String( "mySpectroSERVER" );
        String userName = new String( "user" );
        Integer mtID = Integer.decode( args[0] );
        PersistentWatcher pw = new PersistentWatcher( serverName,
            userName, mtID.intValue() );
    }
}
import java.util.*;
import com.aprisma.spectrum.core.idl.CsCError.*;
import com.aprisma.spectrum.core.idl.*;
import com.aprisma.spectrum.core.util.*;
import com.aprisma.spectrum.core.idl.CsCException.*;
import com.aprisma.util.corba.*;
```

```
/**
 *  This class implements the CORBAObjectMonitorListener but is also
 * responsible for connecting to the server and establishing the
 * watching of the Model Domain.
 */
public class PersistentWatcher implements CORBAObjectMonitorListener
{
    int mt_id;
    // Objects needed throughout the program
    CsCModelDomain modelDomain = null;
    CORBAObjectMonitor monitor = null;

    /**
        Constructs the PersistentWatcher
     */
    public PersistentWatcher( String servername, String username,
                              int modelTypeid)

    {
        this.mt_id = modelTypeid;
        getServerModelDomain( servername, username );

        // Setup CORBA Monitor
        monitor = new CORBAObjectMonitor ( servername,
                                           CsCModelDomain.class,
                                           20000); // 20 seconds
        // Check to see if the monitor has a connection if start the
        // setup the model watch and start to monitor
        if ( monitor.connect ( true ) != null )
        {
            monitor.addListener( this );
            monitor.startPolling();
            setupModelWatch();
            System.out.println("Press Enter to exit");
            try
            {
                System.in.read();
            }
            catch ( Exception e )
            {
                System.out.println( e );
            }
        }
        else
        {
            System.out.println("Monitor could not connect." +
                               "Not Watching");
        }
    }

    /**
        This method is responsible obtaining the SERVER's model domain.
```

```
 */
private void getServerModelDomain( String server, String username )
{
    try
    {
        CORBAHelper helper = CORBAHelper.getHelperImpl() ;
        helper.init(null,null);
        modelDomain =
          (CsCModelDomain) helper.getObjectImplementation (
               CsCModelDomain.class, server);
    }
    catch ( Throwable e )
    {
        System.out.println ( "Could not find server");
        System.out.println ( e ) ;
    }
}
/**
    This method is responsible creating the model watch on
    the model domain.
 */
 private void setupModelWatch()
 {
    try
    {
        int[] mtypeIDs = { mt_id };

        ModelCallback callback = new ModelCallback();
        CsCModelWatchCB cb =
        CsCModelWatchCBHelper.narrow(
            helper.servant_to_reference(callback));
        modelDomain.startWatchModelsByTypeIDs(mtypeIDs, cb);
    }
    catch ( Exception e )
    {
        System.out.println ( "Could not find server");
        System.out.println ( e ) ;
    }
 }
/**
    Interface CORBAObjectMonitorListener
    This method is Invoked when the connection has been lost.

 */
 public void connectionLost ( String objectName,
                              Class idlInterfaceClass )
 {
     System.out.println ("Watch and Connection Lost");
 }
/**
    Interface CORBAObjectMonitorListener
    This method is Invoked when a connection fails for some reason
    other than object
```

```
 */
 public void connectionError ( String objectName, Class
        idlInterfaceClass, Throwable e )
 {
      System.out.println ("Error");
 }

/**
    Interface CORBAObjectMonitorListener
    This method is Invoked when the connection has been
    established.
 */
 public boolean connectionEstablished (
                                  org.omg.CORBA.Object object,
                                    String objectName,
                                    Class idlInterfaceClass )
 {
     setupModelWatch();
     System.out.println ( "Re-established Watch and Connection");
     return true;
 }
/**
    Interface CORBAObjectMonitorListener
    This method is Invoked when the object is polled successfully.
 */
 public void successfullyPolled( org.omg.CORBA.Object object,
                                    String objectName,
                                    Class idlInterfaceClass )
 {
      System.out.println ( "Successful Poll" );
 }
```

Fault-Tolerant Environments

Do not write or update secondary servers in a fault-tolerant environment. You can pull data from the servers to know the client application status. We recommend that all data be updated from primary to secondary through online backup.

When switching from primary to secondary, the Naming Service should receive new advertisements from the secondary seamlessly. To check whether you are on the primary or secondary, call the isPrimary method from CSCModelDomain. You can also determine a switch through the CORBA Object Monitor.

In a fault-tolerant environment, the best way to get a service object from SpectroSERVER is using following API from CORBAHelper class:

```
/**
 * Obtains the implementation for the given object name.
 *
 * @param IDLClass the class of the object as defined in the IDL.
 * @param objectName the name of the object's implementation
 * @return the implementation object or an exception on failure.
 */
public org.omg.CORBA.Object getObjectImplementation(
                      Class IDLClass, String objectName )
                                    throws Throwable
```

The method gets the object from the correct server (primary or secondary). Internally, it gets the domain hierarchy map from the Location Server first, then try to get the object from domain hierarchy hosts, and return the object found.

You can also use following methods to get service object but need to specify the primary/secondary host name of the SpectroSERVER:

```
/**
 * Obtains the implementation for the given object name.
 *
 * @param IDLClass the class of the object as defined in the IDL.
 * @param objectName the name of the object's implementation
 * @param host the host to connect to.
 * @param enableReconnect determines whether to automatically
 *                        re-connect if the current connection is broken.
 *                        The implementation may not support this
 *                        option.
 * @return the implementation object or an exception on failure.
 */
public org.omg.CORBA.Object getObjectImplementation(
                      Class IDLClass, String objectName, String host,
                      boolean enableReconnect )
                                throws Throwable ;
```

For example, to get service object from secondary, the host should be the host name of the secondary.

There is another method that you can specify host names of both primary and secondary, and it will return the object from the correct server:

```
public org.omg.CORBA.Object getObjectImplementation(
                      Class IDLClass, String objectName, String[] hostList,
                      boolean enableReconnect )
                                throws Throwable ;
```

Here is an example to get domain ID without worrying about if the service is from primary or secondary:

```
try
{
     String domainName = "myLandscape";

    // Construct helper
    CORBAHelper helper = CORBAHelper.getHelperImpl();
    if ( helper.init(null, null) )
    {
        CsCModelDomain md = (CsCModelDomain)
        helper.getObjectImplementation(
                   CsCModelDomain.class, domainName );

        int id = md.getModelDomainID();
        System.out.println( "0x" + Integer.toHexString(id) );
    }
}
catch(Throwable e)
{
    e.printStackTrace();
}
```

Performance Issues

You can improve application performance by updating old method calls to the new method calls. All examples in this document use the new calls. Old method calls use large data objects that increase the interface load when they pass through IP packets. The new method calls minimize the data size by using the basic types and improve the speed.

The two main factors in API performance are speed and memory usage. To improve the speed, consider the following:

- How many models are involved?
- What calls are you making against the models? Are the calls identical?
- If you are reading or writing data, how many attributes are involved?
- Are you repeating any methods? If so, can you replace them with a single call using a list of model IDs?
- Is it necessary to read or write all the data?
- Can you group all the attribute reads and writes?
- If you are searching, is the search too broad?

If you have a list of model IDs that need to have an attribute written to, pass the complete list instead of iterating through each ID with a separate call.

To improve the memory usage, do not group too much work together. A large model group request can result in a large memory increase on the SpectroSERVER side. For example, if you are reading a route table, do not read the entire table at one time. Break up the read requests by using the CsCOIDSpec class and set a range. You cannot pass more than 500 models at a time.

> **NOTE**
> If you continue to experience performance issues after following these recommendations, contact CA Support.

Client Application Debugging

Use the following code to enable detailed debugging of a client application:

```
Properties props = new Properties () ;
props.put("ORBwarn", "2");
CORBAHelper helper = CORBAHelper.getHelperImpl();
helper.init(null, props);
CsCModelDomain md = (CsCModelDomain)
helper.getObjectImplementation
(CsCModelDomain.class, "myWorkstation" );
```

Extension Integration (SEI) Developer Reference

About the DX NetOps Spectrum Extension Integration Developer Toolkit (SEI Toolkit)

The DX NetOps Spectrum Extension Integration Developer Toolkit (SEI Toolkit) lets you organize and package DX NetOps Spectrum extension modules for installation and integration into other DX NetOps Spectrum hosts. An *extension module* is any set of software that extends the capabilities of the DX NetOps Spectrum product. There are three basic types of extension modules:

- **Core Components**
  Provide standard DX NetOps Spectrum functionality. CA is the exclusive developer of core components.
- **Management Modules**
  Extend DX NetOps Spectrum to manage various network devices. Although CA provides management modules for a large number of common network devices, it cannot possibly provide management modules for all of the new network devices that appear on the market almost daily. For this reason, DX NetOps Spectrum value-added resellers

(VARs) and device hardware manufacturers often develop and sell management modules that provide DX NetOps Spectrum management for network devices not included in CA's standard management module suite.

- **External Applications**
  Work in conjunction with DX NetOps Spectrum to enhance its usability. Though it is possible for you to develop external DX NetOps Spectrum applications, it is rarely done.

This section focuses primarily on the applications of the SEI Toolkit in the development of management modules. The SEI Toolkit is a Level 1 toolkit and a part of a suite of developer toolkits provided by CA to facilitate the development and distribution of DX NetOps Spectrum management modules. In the context of management module development, you can use the SEI Toolkit to do the following:

- Test the packaging and installation of newly developed management modules.
- Propagate management modules from one DX NetOps Spectrum host to others.
- Package management modules for installation on outside DX NetOps Spectrum hosts. For example, you develop management modules for new network devices, and then you use the SEI toolkit to package these management modules for sale and distribution to your customers. The customers can then install the packaged management modules onto existing DX NetOps Spectrum hosts to allow DX NetOps Spectrum to manage the new network devices.

  NOTE
  CA does not certify or support management modules unless they are distributed using the SEI Toolkit.

SEI Toolkit Goals

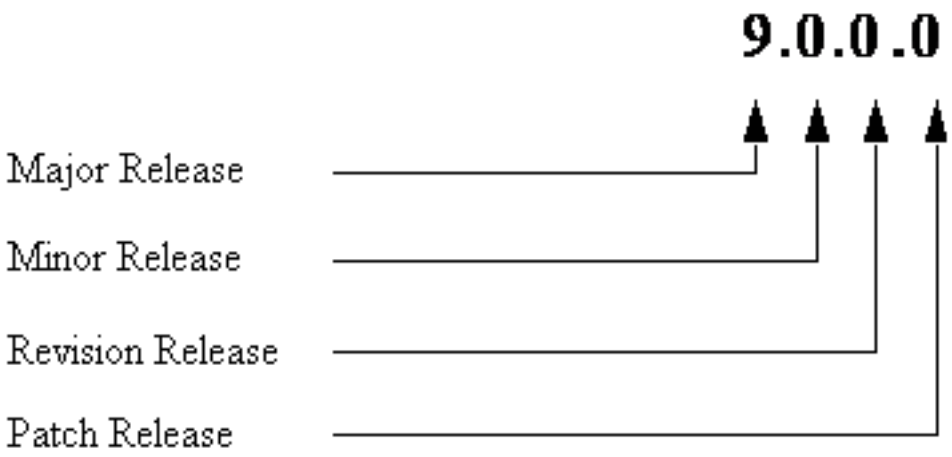
The primary goal of the SEI Toolkit is to provide you with the tools to distribute management modules for integration with DX NetOps Spectrum products. The SEI Toolkit tools and interfaces are standardized to ensure smooth integration of management modules from several different developers onto a single DX NetOps Spectrum host. By providing customers with a standard mechanism for installing and integrating DX NetOps Spectrum management modules, the SEI Toolkit accomplishes the following:

- **Reduces time to market:** Less time is needed to develop and test management module software and test its compatibility with software from CA and other developers.
- **Facilitates integration of components:** Since all CA development partners use the same tools to produce DX NetOps Spectrum management modules, these management modules are less likely to cause installation or integration compatibility problems for customers when used individually or together.
- **Reduces the investment required for developing DX NetOps Spectrum extension modules:** This follows not only from the reduction in time-to-market and a decrease in compatibility issues, but also because the software and expertise used to produce an extension module can be applied to multiple products, across multiple platforms and multiple releases.
- **Increases the value of DX NetOps Spectrum extension modules to customers:** Customers benefit from interoperable products from different developers. Whether they buy extension modules off the shelf or develop their own, customers know that these extension modules will work together.

In general, all of the DX NetOps Spectrum developer toolkits are designed to place minimal constraints on development environments. They are intended to integrate into existing environments, thereby providing maximum advantage in the development of DX NetOps Spectrum-compatible products.

Version Control

The DX NetOps Spectrum numbering scheme for version control consists of four numeric fields:



- **Major Release:** Increments to the number in this field represent major changes in the product's design, functionality, or user interface.
- **Minor Release:** Minor releases are scheduled product upgrades that provide new or enhanced features but do not represent functionality changes as significant as those involved in a major release.
- **Revision Release:** This field is incremented for subsequent revisions to a release and is reset to zero for each new major or minor release.
- **Patch Release:** This field -- previously used for internal tracking of individual builds under a particular revision and not usually visible to the customer -- assumes special importance to the extension developer. The value of this field must be zero for the first release of a management module or application. In addition, it must be incremented to some higher value (not necessarily sequentially) for each successive release of the same module or application.

SEI Toolkit Versioning

The versioning of the SEI Toolkit is tied to the versioning of the DX NetOps Spectrum enterprise management product. Consequently, management modules and applications produced using the SEI Toolkit must follow a similar convention to that described in the preceding section. The actual numbers used can and will be different, but the numbering format must use the same approach in order for the products to be integrated with DX NetOps Spectrum.

SEI Toolkit Architecture

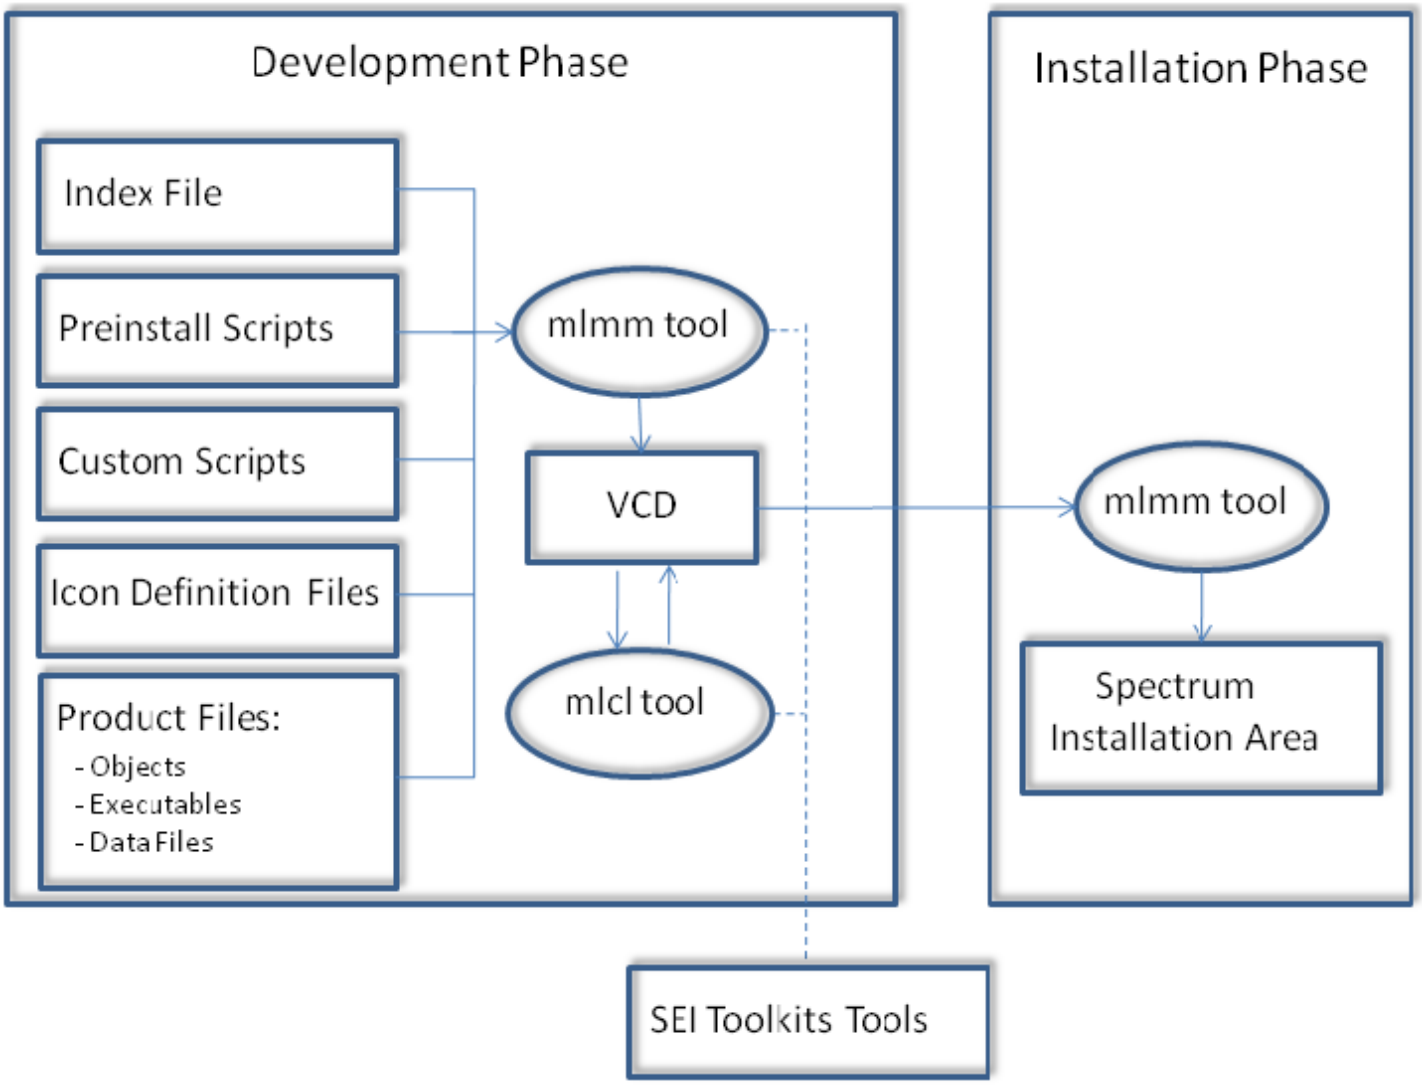
About Extension Modules

The overall process of creating a new DX NetOps Spectrum extension module involves three phases:

- **Development/Customization:** Development and testing of a new extension module is done using the Model Type Editor. The mmship utility can be used to create the index file necessary for the manufacturing process.
- **Manufacturing:** The SEI Toolkit tools mkmm and mkcd are used to manufacture the final product of the development phase.
- **Installation:** Installation and integration of the finished extension module into the DX NetOps Spectrum product is accomplished by the Install program, residing on the DX NetOps Spectrum host.

The tools covered in this document are mmship, mkmm and mkcd, which assemble the applicable files for a given module or application into a VCD.

The following diagram provides an overview of this manufacturing process and the follow-on activity of actually installing the VCD contents onto a host system.



Overview of the Development Phase

The development phase involves the following general steps:

1. Design and develop the files that are to be shipped and installed as part of the extension module. CA provides a Level 1 Toolkit and a CORBA Toolkit to aid in developing new extension modules.

   NOTE
   For more information about management module development, see the Certifications section. For more information about general DX NetOps Spectrum functionality and integration points, see the DX NetOps Spectrum Modeling Concepts section and the SpectroSERVER and DX NetOps Spectrum Databases Overview section.
2. Prepare the module for integration by creating an index file and auxiliary files that describe the module. The index file includes descriptive information about the extension module and lists the files to be shipped and installed as part of the module. For Level 1 management modules, the mmship utility does much of the work of creating an index file.

Additional auxiliary files include part description files, preinstall scripts, and custom scripts, which may be used to customize the installation of the extension module. They also include icon definition files, which simplify creation of icons during installation.

3. Edit the setup initialization files to insert your product name into the installation instructions.
4. Use the mkmm tool and the index files to create a virtual CD-ROM (VCD) or to add the extension module to the VCD. A single invocation of mkmm may be used to add several extension modules to the VCD.
5. Use the mkcd tool to add version identification to the VCD, making it possible to install the extension module software from the VCD into an existing DX NetOps Spectrum installation area.
   The VCD can then be installed from a disk, downloaded over the Internet and installed, or written to a physical CD-ROM and installed from that medium.

Installation Phase

Integration of an extension module on a VCD into an existing DX NetOps Spectrum installation host is accomplished by installing the VCD on that host. This is done by executing one of the following installation tools placed on the VCD when it is created:

- Windows setupnt.exe
- Linux installer

Both of these tools can be invoked either by a command line or using icons.

Beyond these tools, the VCD contains very little of its own installation support software. Instead, the installation process reuses the installation support software that already exists in the host system's DX NetOps Spectrum installation area, placed there when DX NetOps Spectrum was originally installed.

Use Cases for the SEI Toolkit

Common Customizations

You can use the SEI Toolkit in the context of developing the following:

- A DX NetOps Spectrum management module developed using the Level 1 Toolkit and the CORBA Toolkit. This is the most common scenario where VARs use the SEI Toolkit.
- A customized OneClick application.
- A DX NetOps Spectrum external application.

The following is the high-level process to follow:

1. Do one or more of the following depending on your requirements:
   – **Create the management module:** Use the Model Type Editor to create a model type that represents the new device in the SpectroSERVER database. You can also use the Model Type Editor to create a database export file, which you can then use to import the new model type into other DX NetOps Spectrum databases.

     NOTE
     For information about using the Model Type Editor, see the Model Type Editor section.

     Customize the various files in your new management module until the module represents and manages the new network device to your satisfaction. Two common customizations are creating application model types for the device to support the functionality of a MIB and adding support for alerts, events, and alarms.
   – **Create the customized OneClick application:** Using mmship and applicable toolkits, customize OneClick by creating custom views, searches, tables, and menus.

NOTE
For more information about customizing OneClick, see the OneClick Customization section.

– **Create the external application:** Using mmship and applicable toolkits, develop the shippable files for the external application.

NOTE
For more information about developing shippable files, see the Certifications section.

2. Once your new management module, customized OneClick application, or external application performs as desired, create the following auxiliary files needed for the distribution process:
   – An index file
   – A part description file

   While you can create these files entirely by hand using a text editor, doing so using the mmship tool provided with the SEI Toolkit simplifies the process. If you use mmship to generate the files, you should use a text editor to check the generated files for accuracy and completeness, and to make any necessary changes or customizations.
   If you are creating a new management module, be aware that mmship does not include file: entries in the index file for any object files you may have added using the CORBA Toolkit. If you are creating a customized OneClick application, be aware that mmship does not include file: entries in the index file for any XML files you may have added to define your OneClick customizations. In either case, you must use a text editor to add the necessary file: entries to the index file.
   If you are creating a new management module or customized OneClick application, specify an index file level of 1 in the index file. If you are creating an external application, specify an index file level of 2.
3. Edit the setup initialization files to insert your product name into the installation instructions.
4. Use the mkmm tool to add the management module, customized OneClick application, or external application to a VCD.
   If the VCD does not exist, mkmm will create it. If the VCD already exists, mkmm lets you add any number of additional modules or applications to it. Several for Linux and/or Windows can be added to a single VCD.
5. Use the mkcd tool to do the following:
   – Check the integrity of the VCD.
   – Add a version number to the VCD so that it can be installed.
6. Perform final testing of the management module, customized OneClick application, or external application by installing it into an existing DX NetOps Spectrum installation area from the finished VCD. If testing fails, modify the source files as necessary and then rebuild the VCD.
7. Distribute the VCD to customers or local developers. The VCD can be:
   – Installed directly from disk.
   – Installed from a mounted file system.
   – Downloaded from the Web and installed.
   – Committed to physical CD-ROM and installed from that medium

   CA does not provide hardware or software for distributing VCDs using the Web or physical CD-ROM, but these features are available from various third parties.

Types of VCDs

Shippable files fall into two categories:

- **Platform-specific shippable files.** A file is platform-specific if it cannot be installed and used successfully on all supported platforms (Windows and Linux). An example of a platform-specific file is an object file. Since Windows

object files cannot be linked on Linux or vice versa, separate versions of the same object file must be shipped for each platform.

- **Platform-neutral shippable files.** A file is platform-neutral if it can be installed successfully on all supported platforms. An example of a platform-neutral shippable file is a text file. Since text files have the same format on Windows and Linux, the same text file can be shipped once and installed and used successfully on any platform.

VCDs fall into the following categories:

- **Multi-platform VCD.** A multi-platform VCD contains platform-specific shippable files for one or more platforms. As an example, a multi-platform VCD can contain platform-specific shippable files for Windows and Linux. Platform-specific shippable files are kept in the following folders on the VCD:
  - (Windows) nt folder
  - (Linux) linux folder

  When the VCD is installed on a specific platform, files from the appropriate platform-specific folder are installed.
- **Single-platform VCD.** A single-platform VCD is just a multi-platform VCD containing platform-specific shippable files for only one platform. For example, a single-platform VCD for Windows is a multi-platform VCD having an nt area but no `sunos5` or `linux` areas. When the VCD is installed on Windows, therefore, files from the nt area are installed, but the VCD cannot be installed on Linux.
- **Platform-neutral VCD.** A platform-neutral VCD is a VCD that contains only platform-neutral shippable files. These platform-neutral files are kept in any area of the VCD. When installed on any platform (Windows and Linux), files from any area are installed.

The sections that follow describe the scenarios that represent recommended methods for creating multi-platform, single-platform, and platform-neutral VCDs. The scenarios assume the following:

- The necessary shippable files and index files have been created for each platform type that you intend to include on the VCD.
- The shippable files and index files have been made available on the machines on which you intend to create the VCD. This is typically done by copying the shippable files or creating a remote file system.
- The SEI Toolkit has been installed and made available on the machine on which you intend to create the VCD.

Creating a Single-Platform VCD

In this scenario, assume that you have created the shippable files and an index file within a DX NetOps Spectrum directory on a Windows host, and you want to create a single-platform VCD by running mkmm on that host.

1. Change to the directory containing the index file.
2. Run the following command as a single-line entry:

```
<$SPECROOT>/INSDK/mkmm <indexFile> vcd=<vcdDirectory>
```

Because mkmm is running on a Windows host in this case, the program responds to this environment by adding Windows shippable files to the VCD. This results in the creation of a single-platform Windows VCD, and the VCD will not be installable on a Linux platform.

NOTE
mkcd must be invoked on the VCD to make it installable. This is done by running the following command on any platform:

```
<$SPECROOT>/INSDK/mkcd -f <vcdDirectory> <vcdVersion>
```

Example: Create a Multi-Platform VCD (Method 1)

In the following scenario, assume that you have created the shippable files and an index file within a DX NetOps Spectrum directory on a Windows host and on a Linux host, and you want to create a multi-platform VCD that will install on any of these platforms. To accomplish this, you must run mkmm once on each platform-specific host.

On the Windows host, create a single-platform Windows VCD by doing the following:

1. Navigate to the directory containing the Windows index file.
2. Run the following command as a single-line entry:
   ```
   <$SPECROOT>/INSDK/mkmm <WindowsIndexFile> vcd=<vcdDirectory>
   ```

On the Linux host, copy or mount the multi-platform VCD.

1. Still on the Linux host, add the Linux shippable files to the VCD:
   1. Change to the directory containing the Linux index file.
   2. Run the following command as a single-line entry:
      ```
      <$SPECROOT>/INSDK/mkmm <LinuxIndexFile> vcd=<vcdDirectory>
      ```

   The resulting VCD is now capable of being installed on any of the platforms.

   NOTE
   mkcd must be invoked on the VCD to make it installable. This is done by running the following command on any platform:

```
<$SPECROOT>/INSDK/mkcd -f <vcdDirectory> <vcdVersion>
```

Example: Create a Multi-Platform VCD (Method 2)

In the following scenario, assume that you have created the shippable files and an index file within a DX NetOps Spectrum directory on a Windows host and on a Linux host. You want to make a multi-platform VCD that will install on any of these platforms, and you want to use a single host -- in this scenario, the Windows host -- for the production of the multi-platform VCD.

1. On the Windows host, create a single-platform Windows VCD by doing the following:
   a. Navigate to the directory containing the Windows index file.
   b. Run the following command as a single-line entry:
      ```
      <$SPECROOT>/INSDK/mkmm <WindowsIndexFile> vcd=<vcdDirectory>
      ```

      NOTE
      Verify that any directories specified in the index file are accessible by the Windows host.
2. While still on the Windows host, mount the Linux DX NetOps Spectrum area.
3. Add the Linux shippable files to the VCD:
   a. Change to the directory containing the Linux index file.
   b. Run the following command as a single-line entry:
      ```
      <$SPECROOT>/INSDK/mkmm plat=linux <LinuxIndexFile> vcd=<vcdDirectory>
      ```

   The resulting VCD is a multi-platform VCD that is installable on any of the platforms.

   NOTE
   mkcd must be invoked on the VCD to make it installable. This is done by running the following command on any platform:

```
<$SPECROOT>/INSDK/mkcd -f <vcdDirectory> <vcdVersion>
```

Example: Platform-Neutral VCD

In this scenario, assume you have created shippable files and an index file within a DX NetOps Spectrum directory on a Windows host. The shippable files are all platform-neutral, so they can be safely installed on Windows or Linux. Similarly, the index file contains no platform-specific entries (plat=<platform> modifiers), so the same set of files can be shipped for any platform. You want to run mkmm on a single host to create a platform-neutral VCD.

Assume that you are creating the VCD on a Windows host.

1. On the Windows host, navigate to the directory containing the Windows index file.
2. Run the following command as a single-line entry:

   ```
   <$SPECROOT>/INSDK/mkmm any=yes <WindowsIndexFile> vcd=<vcdDirectory>
   ```

   The any=yes flag causes mkmm to create a platform-neutral VCD. Bear in mind that mkmm will fail if you subsequently attempt to add platform-specific shippable files to this VCD.

   NOTE
   mkcd must be invoked on the VCD to make it installable. This is done by running the following command on any platform:

```
<$SPECROOT>/INSDK/mkcd -f <vcdDirectory> <vcdVersion>
```

Creating Index Files

About Index Files

After using the Level 1 Toolkit or the CORBA Toolkit to create a new extension module, a developer will typically proceed to write an index file for the extension module. The index file describes the extension module, describes its relationships to other extension modules, and lists the files that are installed as part of the extension module.

The purpose of writing the index file is to allow the extension module to be added to a VCD. Once on the VCD, the extension module can then be installed from the VCD and integrated into any compatible DX NetOps Spectrum installation area. You use the mkmm and mkcd tools to create the VCD, to add the extension module to the VCD, and to prepare the VCD for installation, but you must create the index file before you can use these tools.

If your extension module is a management module developed using the Level 1 Toolkit or the CORBA Toolkit, you can run the mmship tool to do much of the work of creating the index file for the extension module.

Create an Index File Using mmship

You can use the mmship tool to create index files and auxiliary files for newly developed management modules. mmship uses the following syntax:

```
mmship -s <scriptfilename>
```

- ***<scriptfilename>***
  Is the name of the script file that mmship generates. This script file records your progress using mmship. If you need to stop the tool for any reason, you can use this file to pick up where you left off.

To create an index file using the mmship tool

1. Navigate to the <*$SPECROOT*>/SS-Tools directory.
2. Enter the mmship command using the syntax described at the beginning of this section.
3. You are asked a series of questions concerning the management module. Answer each question and press Enter to continue. A basic overview of each question:
   a. *Please enter the management module version number:*
      Enter a valid version number and press Enter.
   b. *Please enter your vendor name as assigned by CA.*
      Enter your vendor name, and press Enter.
   c. *Please enter your 4-character vendor ID as assigned by CA.*
      Enter your developer ID, and press Enter. The alpha characters in your developer ID is entered in capitals.

NOTE
For more information on developer IDs, see the SpectroSERVER and DX NetOps Spectrum Databases Overview section.

d. *You are now creating a new part <partnumber>. Please enter a short paragraph which will identify the function of part <partnumber> to the user during installation. End the description with a blank line.*
Enter your description. Be sure that the last line in your description is a blank line. Press Enter twice.

e. *You are now adding the representative MM to part <partnumber>. This MM contains the descriptive information for part <partnumber>. What model type are you shipping in the representative MM?*
Enter the model type name, and press Enter.

f. *Does this Management Module include database import files?*
If you have used the Model Type Editor to export files that are used with this model type, enter Yes; otherwise, enter No. Press Enter. For more information about exporting model types to a catalog file (a .e file that can also be imported), see the Model Type Editor section.

g. *Please enter the name of a database import file relative to the DX NetOps Spectrum installation directory.*
Enter the name and path of the .e file that you have exported using the Model Type Editor.

h. *Do you want to include more database import files.*
Enter Yes or No, and press Enter.

i. *Please enter the Base Mode type for <modeltypename>.*
Enter the appropriate base model type name, and press Enter.

j. *Do you want to add another MM to part <partnumber>?*
Answer Yes if you would like to include more model types, or enter No if you are finished.

k. *Do you want to add another part number?*
Enter Yes if you want to create another installable part number, or enter No if you are finished.

mmship has now created the appropriate index files and part description files. They can be found in the *<$SPECROOT>*/SS-Tools directory.

NOTE
If mmship is not applicable to your situation, you can use a text editor to construct an index file for your extension module.

General Index File Syntax

The following general syntax rules apply to DX NetOps Spectrum index files:

- Each index file entry consists of zero or more fields of visible characters, which may be group-separated by one or more spaces or tabs. Spaces and tabs may also appear at the beginning or end of an index file entry.
- Index file entries are newline-delimited (that is, one entry per line, terminated either by a newline character or end of file). There is no mechanism for continuing an index file entry across more than one line. There is no preset limit on the length of an index file entry.
- The following characters are legal in an index file:

Character	ASCII Code
Visible character	33 (!) through 126 (~)
Space	32
Tab	9
Newline (Linefeed)	10
Carriage Return	13 (^M)
Formfeed	12 (^L)

- Each line of an index file consists of an index file entry and can conclude with an optional comment. If a comment is included, the comment begins at the first pound sign (#) in the line and extends to the next newline or end of file. If an index file entry has no fields, the entire line is considered a comment line. Otherwise, the first field of an index file entry must be a valid index file label, as identified in Index File Entry Definitions. Any other index file entry is illegal and will cause mkmm to fail while processing the index file.

Environment Variables

Environment variables of the form $VAR, ${VAR}, or $(VAR) may appear in index files, where VAR is a standard shell variable name (one or more alphanumerics and underscores, not beginning with a digit).

When mkmm processes an index file, embedded environment variables are expanded to their values, as exported in the invoking shell. Therefore, it is necessary to set and export any environment variables used in an index file prior to invoking mkmm to process that index file. For example, if the environment variable $VNUM is set to the value “1.1” and exported before mkmm is invoked, the index file line:

```
mm: Acme Router Version $VNUM
```

is expanded to:

```
mm: Acme Router Version 1.1
```

Environment variables having special meaning to a particular shell (for example, $_, $PATH, $CWD, $HOME, and so on) are not guaranteed to expand to expected values. Environment variables not of the form $VAR, ${VAR}, or $(VAR), (for example, $$, $!, $?, $0, $1, and so on) are not expanded. Avoid using these sorts of environment variables in index files.

Escaping Special Characters

The pound sign (#) and the dollar sign ($) have special meaning within an index file. These characters must be escaped to take on their literal value within an index file entry.

Pound Sign (#)

The occurrence of a pound sign (#) in an index file always denotes the beginning of a comment. The pound sign and any subsequent characters on the line are ignored when mkmm processes the index file. To prevent interpretation of the pound sign as the beginning of a comment, replace the pound sign with the environment variable ${PS}, which mkmm will expand to a literal pound sign.

For example, the index file line:

```
mm: Acme Router #2 Management Module
```

is interpreted by mkmm as the entry “mm: Acme Router” followed by the comment “#2 Management Module”, whereas the line:

```
mm: Acme Router ${PS}2 Management Module
```

is expanded to:

```
mm: Acme Router #2 Management Module
```

Dollar Sign ($)

The dollar sign in the context of $VAR, ${VAR}, or $(VAR) denotes the beginning of an environment variable. When mkmm processes the index file, environment variables are expanded, and the delimiting dollar sign is lost. To prevent interpretation of a dollar sign as part of an environment variable, replace the sign with the environment variable ${DS}, which mkmm expands to a literal dollar sign.

If the environment variable $VNUM is set to the value “1.1” and exported before mkmm is invoked, the index file line:

```
mm: Acme Router Version $VNUM
```

expands to:

```
mm: Acme Router Version 1.1
```

whereas the entry:

```
mm: Acme Router Version ${DS}VNUM
```

expands to:

```
mm: Acme Router Version $VNUM
```

The above example also illustrates the use of the ${VAR} or $(VAR) forms of an environment variable to separate environment variable names from text that immediately follows. For instance, in the index file line:

```
mm: Acme Router Version $VNUM
```

the environment variable $VNUM is expanded, while in the index file line:

```
mm: Acme Router Version ${V}NUM
```

the environment variable ${V} is expanded and NUM keeps its literal value.

Index File Platform Names

Distribution and installation of CA Spectrum 10.3 extension modules are supported on the following platforms (operating systems). Whenever referring to these platforms within index files, use the platform names shown in the following table:

DX NetOps Spectrum Platform Name	Release Level	Platform Name in Index Files	Platform Name in VCD Area
Windows	Microsoft Windows Server 2012 and 2016	intel	nt
Linux	Red Hat Enterprise Linux 6.x and 7.x	linux	linux

The index file platform names refer to the operating systems, not to any specific hardware architectures.

Index File Entry Definitions

Each entry in an index file must contain an index file label followed by an appropriate number of data fields. The label generally indicates the meaning and purpose of the entry, and each entry must conform to the syntax associated with its label.

The index file entries within each category are identified in the shaded block at the beginning of the discussion. For each entry, this discussion gives the entry syntax, a brief example, the entry description, and applicable conventions.

Extension Module Description Entries

Extension module description entries describe the extension module associated with the index file. Each extension module description entry should appear exactly once in each index file. If an extension module index file does not contain

an extension module description entry or contains more than one such entry, mkmm will generate an error and will not add the extension module to the VCD.

irev Entry

Syntax:

irev: <*version*>

Example:

irev: 09.00.00.000

Description:

A single irev: entry is required in every index file.

The irev: entry provides <*version*>, the machine-friendly version number of the extension module. The <*version*> identification is a replica of the DX NetOps Spectrum version control number except that the number value is translated to the format “dd.dd.dd.ddd” where each “d” is a decimal digit. For example, the 09.00.00.000 value shown in the example in this section is what mmship would produce if the user typed in 9.0.0.0 when mmship asked for the version number of the module being developed.

The main use of the irev: entry is to identify any instance of extension module version downgrading during installation. Extension module version downgrading occurs when an older version of an extension module (that is, one with a lower-valued patch release number as the final numerical value) is installed into an area that already contains a newer version of that same extension module. Normally, version downgrading is undesirable, and the DX NetOps Spectrum installation program will flag that situation, preventing you from installing the older version on top of the newer one.

Install detects a downgraded extension module by comparing the irev: version numbers of the previously installed extension module with the one being installed. If the previously installed extension module has a larger irev: version number, an older version of the extension module is being installed over a newer version, and a downgrade is reported for that extension module.

Another important consideration is that the value of the final number (the ddd field, referenced elsewhere as the Patch Release number) must be zero (000) for the initial version of any module. A Patch Release value of zero thus identifies the module as being the original installation. Each successive revision of the same module must have a higher number value, but the increase does not have to be an incremental value with each successive release.

level Entry

Syntax:

level: <*level*>

- **Example:**
  level: 1
- **Description:**
  The level: entry specifies the level of the extension module. The extension module level indicates how software in the extension module is related to DX NetOps Spectrum (SpectroSERVER and/or OneClick). The <level> designation must be one of the following three number values:

0

The software in the extension module is a required part of DX NetOps Spectrum, either for SpectroSERVER and/or OneClick. A level 0 extension module is often referred to as a DX NetOps Spectrum core module. The right to develop and ship level 0 extension modules is reserved to CA alone.

1
The software in the extension module is an optional part of DX NetOps Spectrum. A level 1 extension module is often referred to as a management module, typically containing software that helps DX NetOps Spectrum manage a particular device or class of devices. While CA develops and ships a wide variety of level 1 extension modules, many others are developed by DX NetOps Spectrum users for their own management needs, or by VARs for resale to other DX NetOps Spectrum users.

2
The software in the extension module is not part of DX NetOps Spectrum (although it may work in conjunction with DX NetOps Spectrum). A level 2 extension module is often referred to as an external application or toolkit, and it typically contains a standalone tool or demo for use in the DX NetOps Spectrum environment. Most level 2 extension modules are developed at CA.

Install uses the extension module level value to select extension modules for installation. In addition, the extension module level also affects the way in which files in an extension module are processed during installation. Since level 0 and level 1 extension modules are considered part of DX NetOps Spectrum (SpectroSERVER or OneClick), files shipped in level 0 and level 1 extension modules undergo special processing during installation to integrate them into DX NetOps Spectrum. In contrast, level 2 extension modules are not considered part of DX NetOps Spectrum, so files contained in level 2 extension modules are not integrated into DX NetOps Spectrum during installation.

Do not confuse extension module levels with toolkit levels. CA provides two toolkits for creating and customizing extension modules: the Level 1 Toolkit and the CORBA Toolkit. The Level 1 toolkit can be used by any DX NetOps Spectrum user, but the CORBA Toolkit requires advanced programming knowledge and familiarity with C++. The extension modules that are developed using either of these toolkits are always optional extension modules (level 1 management modules) regardless of whether they were developed using the Level 1 Toolkit or the CORBA Toolkit. Therefore, when shipping extension modules developed using either of these toolkits, always use level: 1 in the index file.

mm Entry

Syntax:

mm: <*name*>

Example:

mm: Adco Controller

Description:

The mm: entry specifies a descriptive name for the extension module.

- ***<name>***
  May consist of a single word or several words but should be kept to a maximum of 30 characters, including spaces, in order to be visible on the screen when displayed as part of a message. <*name*> should be descriptive -- that is, “UPS_Monitor” is preferable to “M4423R-XXX-01.”
  Install displays the <*name*> identification on the installation summary.

rev Entry

Syntax:

rev: <*version*>

Example:

rev: 9.0.2.0

Description:

This value must comply with the following rules.

- <*version*> must be a single alphanumeric field with no spaces allowed (for example, 9.0.0.000).
- Maximum length of <version> is 15 characters.
- With the exception of the fact that mkmm requires this entry, rev: is not used in the distribution and installation utilities. Its presence in the index file serves to identify the extension module version for software maintenance purposes.

vend Entry

Syntax:

vend: <*vendor*>

Example:

vend: CA

Description:

The vend: entry specifies the CA-assigned developer name of the vendor creating the extension module.

- <*vendor*> must be a single-word text string.
- With the exception of the fact that mkmm requires this entry, vend: is not used in the distribution and installation utilities. Its presence in the index file serves to identify the extension module developer for software maintenance purposes.

Extension Module Relation Entries

Extension module relation entries describe relationships between the extension module associated with the index file and other extension modules.

pprep Entry

Syntax:

pprep: <*ppname*> <*mmname*> <*mmname*> …

Example:

pprep: SA-CSI1000

Description:

The pprep: entry specifies that the index file contains the representative extension module of a purchasable part named <*ppname*>, which will inherit its attributes (name, version numbers, and so on) from its representative extension module.

A *purchasable part* can be a single extension module or a group of extension modules that are purchased and installed together as a unit, with the unit having a single purchasable part name (<*ppname*>) for the entire package. If the purchasable part is a group of extension modules, <*ppname*> is the name of the primary module and the subsequent <*mmname*> fields list the additional extension modules that are included in the purchasable part. All names must be unique.

As an example, suppose the index file JOE.i contains the following entries:

```
mm:   JoeCorp Router Management Module
rev:   6.0rev3
pprep:  SM-103701 JIM JILL
```

The pprep: entry defines purchasable part SM-103701. Purchasable part SM-103701 contains the representative extension module JOE and the additional extension modules JIM and JILL, which are defined in index files JIM.i and JILL.i, respectively.

An extension module may represent at most one purchasable part. Therefore, a given index file can contain at most one pprep: entry. The mkmm tool will flag multiple pprep: entries in an index file.

A purchasable part must have a unique representative extension module. Therefore, each purchasable part must have a pprep: entry in exactly one index file. To enforce this, the mkcd tool will flag multiple pprep: entries for a purchasable part, establishing an error condition.

Each purchasable part must have a part description file, which is distributed via a file: Install mmdesc entry. Therefore, if an index file contains a pprep: entry, it must also contain a file: Install mmdesc entry.

Extension modules that do not include either a pprep: or a pp: entry in the index file for that module are known as orphan parts. You can work with these extension modules for testing purposes if you do not have all the applicable parts, but you must provide one or the other of these index file entries before distributing the final VCD for installation.

pp Entry

Syntax:

pp: <*ppname*> <*mmname*> <*mmname*> …

Example:

pp: SA-CSI1000

Description:

The pp: entry specifies that this index file contains an extension module which belongs to the purchasable part named <*ppname*>. The subsequent <*mmname*> fields (if any) list additional extension modules that are included in purchasable part <*ppname*>. The <*ppname*> and <*mmname*> values can be anything that the developer wishes except that they must be unique. They can include standard alphanumeric characters, underscore characters, and hyphen characters.

The pp: entry is similar to the pprep: entry except that it does not establish the current extension module as the representative of the purchasable part <*ppname*>. The pp: entry merely adds the current extension module and the extension modules given by <*mmname*> arguments to the purchasable part <*ppname*>. The representative extension module of the purchasable part is established by the pprep: entry in the current index file or in some other index file.

Extension modules that do not include either a pp: or a pprep: entry in the index file for that module are known as orphan parts. You can work with these extension modules for testing purposes if you do not have all the applicable parts, but you must provide one or the other of these entries before distributing the final VCD for installation.

comp Entry

Contents

Syntax:

comp: <*mmname*>

Example:

comp: CHASSIS-MIMS

Description:

The comp: entry lets developers identify distribution dependencies between two or more extension modules. A distribution dependency exists when the successful distribution and installation of an extension module requires distribution and

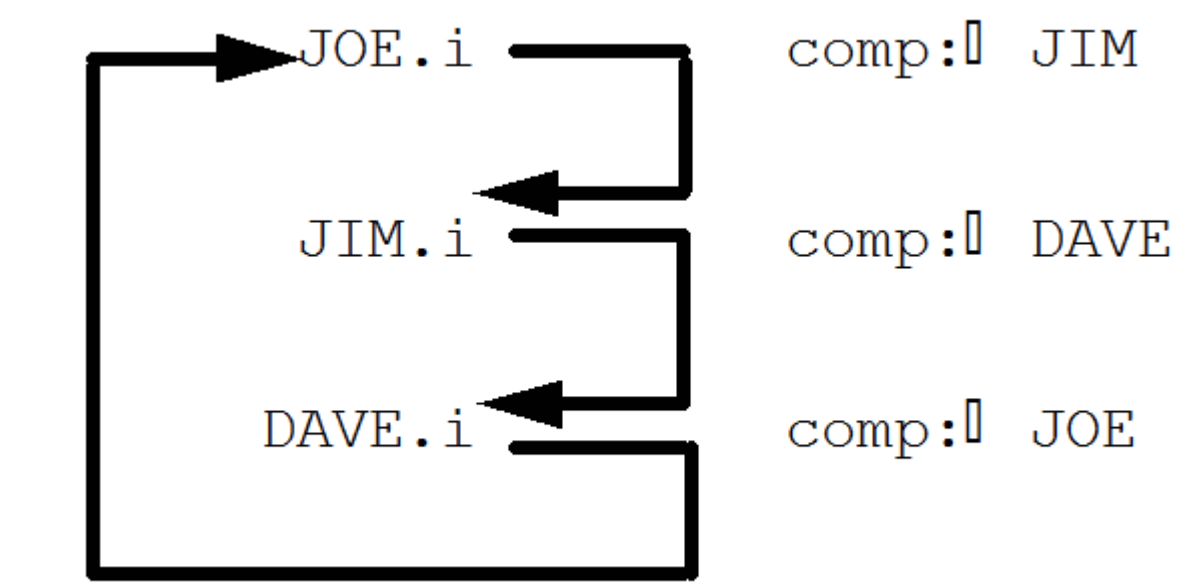
installation of some other extension module. For example, a comp: dependency is commonly used to ensure that if a management module for a derived model type is distributed on a VCD, then the management module for its base model type is also distributed on the same VCD. The dependency also ensures installation of the management module for the derived model type from the VCD will trigger installation of the management module for the base model type.

The comp: entry indicates that the extension module associated with the index file has a distribution dependency on the extension module identified by <*mmname*>. For example, a comp: JIM entry in the index file JOE.i indicates that extension module JOE has a distribution dependency on extension module JIM.

comp: allows only one dependency to be defined at a time. You can establish multiple dependencies by providing a sequence of comp: statements, each on its own line.

The mkcd tool enforces comp: dependencies. If extension module JOE has a comp: dependency on extension module JIM, and JOE is included on a VCD without JIM, by default mkcd will report the unresolved dependency and will not finish the VCD.

comp: dependencies may be circular. For example, assume the following lines in the index files for extension modules JOE, JIM, and DAVE:



These dependencies guarantee that JIM, DAVE, and JOE will be distributed and installed together.

comp: cannot be used to establish a dependency between extension modules of different levels. If this is done, mkcd will generate a warning message and ignore the dependency. (The distribution dependencies between extension modules of different levels is inferred from the levels, and explicit comp: dependencies are unnecessary.)

File Distribution Entries

File distribution entries are used to specify files to be included in an extension module, or to modify the way these extension module files are distributed or installed.

attr Entry

Syntax:

attr: <*file*> [mode=<*mode*>] [uid=root]

Example:

attr: SS/SpectroSERVER mode=4777 uid=root

Description:

The attr: entry lets you change the accessibility of a file, effective following completion of installation.

Normally, after installation, installed files have the mode with which they were extracted from the VCD or created in the installation area, and they are “owned” by the installation owner as specified using the DX NetOps Spectrum installation. However, there are times when it is desirable to override these default permissions or ownerships for specific files. The attr: entry can be used to accomplish this.

In the attr: entry, <*file*> is a file name specified relative to the installation root directory, and <mode> is a UNIX chmod-style mode modifier. At the end of the installation, the mode modifier is applied to the specified file, as if a “chmod <*mode*> <*file*>” UNIX command had been executed. If the “uid=root” flag is also present in the attr: entry, <*file*> is given root ownership.

> **NOTE**
> You can use file: and attr: entries to enforce mode and ownership of installed files.

cus_dep Entry

Syntax:

cus_dep: <*mmname*>

Example:

cus_dep: CHASSIS-MIMS

Description:

The cus_dep: entry lets developers identify custom script dependencies between two or more extension modules. A custom script dependency exists when the custom script of an extension module requires another custom script to be run first.

For example, a cus_dep: dependency is used by the DX NetOps Spectrum installation program to ensure that the mysql custom script runs before the Report Manager or Archive Manager custom scripts run. This sets up mysql before the other extension module.

deflt Entry

The following syntax layout folds the line in order to show the entire contents of the simulated text within the limits of the available page width. However, in an actual index file, your deflt: entry must be entered as a single line, and you cannot use a backslash to continue an entry across more than one line.

- **Syntax:**
  deflt: <*prod*> <*type*> <*defname*> <*value*> [plat=<*plat*>][prot=yes]
  [req=yes]
- **Example:**
  deflt: SS xtn sdir /usr/swd/bin plat=sun4c
- **Description:**
  The deflt: entry associates a default value with a product and file type. These default values then become expanded within subsequent file: or head: entries that have matching product and file types.
  deflt: entries are the only entries that may appear in the data files mkmm.sys and mkmm.loc. These deflt: entries establish the standard default values applied by mkmm to file: and head: entries in all index files.

In index files, deflt: entries are used to override the standard default values defined in mkmm.sys and mkmm.loc. The defaults set by a “deflt: <*prod*> <*type*> …” entry in an index file apply to all subsequent file: and head: entries with the same <*prod*> and <*type*> fields as the deflt: entry, until the end of the index file or until another deflt: entry with the same <*prod*> and <*type*> fields is encountered.
<*prod*> File Product
<*type*> File type
<*prod*> and <*type*> take on any combination of values legal for the <*prod*> and <*type*> fields of the file: entry.
The entry “deflt: <*prod*> <*type*>…” specifies a default source or target directory value to be applied to subsequent file: and head: entries having the same <*prod*> and <*type*> fields.

- ***<defname>***
  Specifies the name of the default being assigned and may take on one or the other of the following two values:
- **sdir**
  Set the <*sdir*> default source directory.
- **tdir**
  Set the <*tdir*> default target directory.
- ***<value>***
  If <defname> = sdir, <value> may be an absolute or relative path name. If <*defname*> = tdir, <*value*> must be a path name that is relative to the current directory when installation is invoked. You can set <*value*> to the “?” variable to recover the system default value.
- **plat=<*plat*>**
  This optional flag must occur after the <*value*> field. It specifies that the deflt: entry is to be processed only on platform <*plat*>. Multiple plat=<*name*> flags may be given to specify that the deflt: entry can be processed on those platforms.
- **plat!=<*plat*>**
  This optional field must occur after the <*value*> field. It specifies that the deflt: entry is not to be processed on platform <*plat*>. For example, to set the default only for Linux, you would specify plat!=intel. Multiple plat=<*name*> flags may be given to specify that the deflt: entry will not be processed on those platforms.

The plat=plat and plat!=plat flags are mutually exclusive; they cannot be used together in the same deflt: entry. If neither plat=<*plat*> nor plat!=<*plat*> is used, the deflt: entry is processed on all platforms.
The prot=yes and req=yes options shown in the syntax example, both of which must occur after the <*value*> field if used, are intended for use only in the mkmm.sys data file. The prot=yes field specifies that files of prod <*prod*> and type <*type*> shipped using subsequent file: entries should be checksum-protected at installation time.
The req=yes field specifies that the deflt: entry cannot be overridden by subsequent deflt: entries. VAR extension module developers should not use these options in their index files.

The “?” fields in the following file: example (and elsewhere in these entry descriptions) will be replaced by system default values for these identifications during processing by mkmm.

file Entry

The following syntax layout (and examples) folds the line in order to show the entire contents of the simulated text within the limits of the available page width. In an actual index file, however, a file: entry must be entered as a single line, and you cannot use a backslash to continue an entry across more than one line.

- **Syntax:**
  file: <*prod*> <*type*> <*sdir*> <*sname*> <*tdir*> <*tname*> [mode=<*mode*>]
  [uid=root] [prot=yes] [plat=<*plat*>]
- **Examples:**
  file: OC file ? company.png tomcat/webapps/CA Spectrum/images/
  Background ?
  file: SS,OC evformat ? CsEvFormat/Event00821000 ? ?

file: OC file source hitv-app-config.xml tomcat/webapps/CA Spectrum/WEB-INF/devman/config/contrib ?

- **Description:**
  The file: entry specifies that a shippable file is to be included in an extension module. When mkmm adds the extension module to a VCD, it attempts to locate the file and add it to a VCD record for the management module (except for a few special types of files which are added to the installation support files of the VCD). mkmm looks for the shippable file <*sdir*>/<*sname*>. If mkmm finds that file, it adds the file to the VCD record so that it will later be installed as <*tdir*>/<*tname*> relative to the DX NetOps Spectrum installation directory; otherwise mkmm fails.
  The file: entry gives the extension module developer precise control over the locations of installed files without having to relocate source files.On the Windows platform, if mkmm is unable to locate the source file <*sdir*>/<*sname*>, it attempts to locate <*sdir*>/<*sname*> with various common extensions (by default, .exe, .cmd, and .bat). If mkmm finds such a file, it adds the file to the VCD so that it will be installed as <*tdir*>/<*tname*> with the same extension. This reduces the need to include multiple file: entries to ship executable files on both Windows and UNIX platforms.
  In the file: entry, the <*prod*>, <*type*>, <*sdir*>, <*sname*>, <*tdir*>, and <*tname*> fields are required, while the remaining fields are optional:
  - ***<prod>***
    File product
  - ***<type>***
    File type

  The <*prod*> and <*type*> fields, respectively, identify the product and file type associated with the file being distributed. The mkmm tool uses <*prod*> and <*type*> to help determine default directories for locating and installing the file (see the associated <*sdir*> and <*tdir*> discussions that follow). Install uses <*prod*> and <*type*> to decide what standard processing to apply to the file during installation.
  The developer must exercise some care in selecting the <*prod*> and <*type*> designations, as this combination in effect determines how Install will process the information in the <*sdir*><*sname*> file to create the <*tdir*><*tname*> file on the target system.
- ***<sdir>***
  <*sdir*> is the source directory of the file to be distributed. <*sdir*> may be an absolute path name, a relative path name (relative to the directory where mkmm is invoked), or the “?” variable. If the “?” variable is used, this causes mkmm to supply a system default value, which either is a standard default value depending on <*prod*> and <*type*>, or else is a default value defined in a previous deflt: command. When the file is in the same working area, the usual practice is to enter a period (.) as the source directory designation.
- ***<sname>***
  <*sname*> is the source name of the file to be distributed; this file will have all of the entries that need to go into the target file (<*tname*>) that will be created by Install in accordance with the process applicable to the <*prod*><*type*> combination, as previously noted. <*sname*> must be an explicitly relative path name or file base name (relative to <*sdir*>) and should be unique; developers should individualize such files by appending the developer name or the model type name either as a prefix or an affix. If <*sname*> is expressed as the “?” variable, however, mkmm will fail.
- ***<tdir>***
  <*tdir*> is the target directory of the file when it is installed. <*tdir*> may be either a relative path name (relative to the installation root directory) or the “?” variable. If <*tdir*> is the “?” variable, mkmm supplies a default value. This value is either a standard default value, depending on <*prod*> and <*type*>, or a default value defined in a previous deflt: command. For detailed information on system defaults for <*tdir*>, examine the mkmm.sys entries. In general, you should not ship to specific directories, but instead use the deflt: directories as defined by the SEI toolkit.
- ***<tname>***
  <*tname*> is the target name of the file when it is installed. <*tname*> may be any of a relative path name, or a file basename (relative to <*tdir*>), or the “?” variable. If <*tdir*> is the “?” variable, mkmm defaults that field to the value of the applicable <*type*> for the given <*prod*>, as determined by <*sname*>.
- **mode=<*mode*>**
  This optional field must occur after the <*tname*> field. <*mode*> must be a legal argument to the POSIX “chmod” command (for example, “mode=644,” “mode=a+x,” or “mode=-w”). This option is used to alter the access permissions of the installed target file. The determination of the installed file permissions is done as follows:

  - On Linux, the target file is added to the VCD with the same permissions as the source file. At installation time, when the target file is extracted, a umask of 022 is applied, turning off write and execute permissions for group and other. Then, if the file: entry for the file includes a mode=<*mode*> option, “chmod <*mode*>” is performed on the file.
  - On Windows, the target file is added to the VCD with full control access for the DX NetOps Spectrum Users group and with its readonly permission matching that of the source file. At installation time, the target file is extracted with these permissions. Then, if the file: entry for the file includes a mode=<*mode*> option, it is applied as follows: If “chmod <*mode*>” specifies to turn on (off) UNIX user write permission, readonly permission of the target file is turned off (on).
- **uid=root**
  This optional field must occur after the <*tname*> field. This option is used to alter the ownership of the installed target file. On Windows the ownership of the installed file is unaffected (all installed target files belong to the DX NetOps Spectrum Users group).
- **prot=yes**
  This optional field must occur after the <*tname*> field. It specifies that at installation time, checksum protection should be used to save the previously installed version of this file if it contains user edits.
  The prot=yes option is intended for use only in CA-produced index files. VAR extension module developers should not use this option.
- **plat=<*plat*>**
  This optional field must occur after the <*tname*> field. This option specifies that the file: entry is to be processed only on the platform designated by the <*plat*> field.
  Since the code setup allows multiple plat=<*name*> flags to be given in sequence on the same line, the presence of multiple entries allows the file: entry to be processed on multiple, specified platforms. However, since the same capability exists if no plat=<*name*> is given, the preferred approach would be to not include this optional field when the file: entry is to be applicable for all platforms (Windows and Linux).
- **plat!=<*plat*>**
  If used, this optional field must occur after the <*tname*> field. This flag specifies that the file: entry is to be processed only on platforms other than the one designated by the <*plat*> field.
  plat=plat and plat!=plat flags cannot be used together in the same file: entry. If neither plat=plat nor plat!=plat is used, the file: entry is processed on every platform.

fdir Entry

The following syntax layout folds the line in order to show the entire contents of the simulated text within the limits of the available page width. However, in an actual index file, your fdir: entry must be entered as a single line, and you cannot use a backslash to continue an entry across more than one line.

- **Syntax:**
  fdir: <*prod*> <*type*> <*sdir*> <*snamepat*> <*tdir*> <*tname*>
  [mode=<mode>] [uid=root] [prot=yes] [plat=<plat>]
- **Example:**
  fdir: OC file source/devman \.xml$ tomcat/webapps/spectrum/WEB-INF/devman ?
- **Description:**
  The fdir: entry specifies that mkmm should traverse a directory, locating all files having base names (filenames less any extension suffixes) that match a specified pattern, and generate file: entries to ship all matching files found.
  The fdir: entry is useful for shipping all files of a given type (identifiable by base name) within a specified directory, where the directory structure of the shipped files should correspond to the directory structure of the files in the development area.
  In the fdir: entry, the <*prod*>, <*type*>, <*sdir*>, <*snamepat*>, <*tdir*>, and <*tname*> fields are required, while the remaining fields are optional.
  When mkmm processes an fdir: entry, it traverses the <*sdir*> directory looking for files to include in the extension module. Whenever it finds a file having a base name that matches the pattern <*snamepat*>, it effectively generates a file: entry to ship the matching file. The <*sname*> and field of each generated file: entry is the name of a matched file relative to <*sdir*>. The <*tname*> field of each file: entry is ? regardless of the <*tname*> specified in the fdir: entry. All

other fields of the generated file: entries -- including the <*prod*>, <*type*>, <*sdir*>, <*tdir*>, and flag fields -- are the same as the corresponding fields of the file: entry.
The <*snamepat*> pattern field must be a regular expression, as used by the Perl programming language (similar to the regular expressions used by the UNIX grep command). <*snamepat*> is used to match the base names of files encountered during traversal of the <*sdir*> directory, not their path names relative to <*sdir*>.
While this document does not describe the complete syntax of Perl-style regular expressions, the following table shows how files are matched by specific <*snamepat*> patterns, thereby indicating how to compose most fdir: entries:

<snamepat>	**Matches files whose base name …**
\.xml$	Ends with extension .xml
^[a-z]	Begins with a lower case letter
^Makefile$	Is “Makefile”
file	Contains the substring “file”
.	Includes all files in the directory

head Entry

The following syntax layout folds the line in order to show the entire contents of the simulated text within the limits of the available page width. However, in an actual index file, your head: entry must be entered as a single line, and you cannot use a backslash to continue an entry across more than one line.

- **Syntax:**
  head: <*prod*> <*type*> <*sdir*> <sname> <*tdir*> <*tname*> [plat=<plat>]
  [mode=<mode>]
- **Description:**
  The head: entry should be avoided in VAR-developed index files.
  The head: entry specifies that a file should be added to the installation support files on the VCD. Except for its label, the syntax and usage of the head: entry is precisely the same as that of the file: entry.
  Any file: entry with <*prod*> = Install or <*type*> = mmdesc, preinst, or cus is interpreted as a head: entry, and mkmm adds the file to the installation support files on the VCD.

obsbackup Entry

Syntax:

obsbackup: <*prod*> <*type*> <*sdir*> <*sname*> <*tdir*> <*tname*>
[mode=<*mode*>] [uid=root] [prot=yes] [plat=<*plat*>]

> **NOTE**
> The syntax parameters for this entry are the same as those for the file entry.

Example:

obsbackup: SS vfile ? ? SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap

Description:

The obsbackup entry indicates that the specified file is to be obsoleted by the installation. A backup copy of the file will be created in the <*$SPECROOT*>/Install-Tools/LOGS/<version_date>/SavedFiles directory. The backup will include the path to the original file.

For example, if the <*$SPECROOT*>/SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap file were to be obsoleted, the following backup file would be created: <*$SPECROOT*>/Install-Tools/LOGS/<version_date>/SavedFiles/SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap.

obschkbackup Entry

The syntax parameters for this entry are the same as those for the file entry.

- **Syntax:**
  obschkbackup: <*prod*> <type> <*sdir*> <*sname*> <*tdir*> <*tname*>
  [mode=<*mode*>] [uid=root] [prot=yes] [plat=<*plat*>]
- **Example:**
  obschkbackup: SS vfile ? ? SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap
- **Description:**
  The obschkbackup entry indicates that the specified file is to be obsoleted by the installation. If the file has been previously customized in some way, a backup copy of the file will be created in the <*$SPECROOT*>/Install-Tools/LOGS/<version_date>/SavedFiles directory. The backup will include the path to the original file.
  For example, if a DX NetOps Spectrum upgrade were to obsolete the <*$SPECROOT*>/SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap file, and the obschkbackup entry had been used to specify that the file must be backed up if it had ever been customized, the DX NetOps Spectrum installation program would use a checksum value to determine if the file had ever been customized. If the file had been customized, the following backup file would be created: <*$SPECROOT*>/Install-Tools/LOGS/<version_date>/SavedFiles/SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap.

obsdir Entry

Syntax:

obsdir: <*prod*> <*type*> ? ? <*dest dir*> ?

Example:

obsdir: SS vfile ? ? SS/CsVendor/Nortel_Carrier/Passport74xx ?

Description:

The obsdir directive will recursively remove all contained files and subdirectories within the <*dest dir*> directory.

obsnobackup Entry

Syntax:

obsnobackup: <*prod*> <*type*> <*sdir*> <*sname*> <*tdir*> <*tname*>
[mode=<*mode*>] [uid=root] [prot=yes] [plat=<*plat*>]

> **NOTE**
> The syntax parameters for this entry are the same as those for the file entry.

Example:

obsnobackup: SS vfile ? ? SS/CsVendor/Ctron_MMAC_Pls/9G426_02 AlertMap

Description:

The obsnobackup entry indicates that the specfied file is to be obsoleted by the installation, and a backup copy should not be made.

CA-Reserved Entries

The entry labels info: and mtype: are reserved for use by CA and should not be used in VAR-developed index files.

CA-reserved entries are restricted for use by CA and are subject to undocumented changes. Unauthorized use of these CA reserved entries in a VAR-developed index file can jeopardize the extension module installation or the behavior of the installed product.

Orphan Extension Modules

At installation time, all purchasable parts are selected for installation. If an extension module on the VCD does not belong to any purchasable part on the VCD, the module will not be installed.

For example, the extension module JOE would be an orphan under either of the following conditions:

- JOE is not included as a part of itself, that is, the index file JOE.i does not include any pp: or pprep: entries
- None of the other extension modules on the VCD include JOE as a part, that is, none of them have index files that include either a pp: entry or a pprep: entry mentioning JOE

The mkcd tool detects orphan extension modules on a VCD. By default, mkcd will fail if orphan extension modules are detected.

Before distributing a VCD to a customer, make sure that the VCD does not contain any orphan parts. You can do this by adding pp: and/or pprep: entries to the applicable index files to ensure that all extension modules on the VCD belong to some part on that VCD.

Example Index File

The following example presents an index file for a fictitious DX NetOps Spectrum management module. The intent of this example is to clarify the use of index file entries that are commonly used in development of the management module index files.

The scenario for this example is that the Jill Corporation sells a line of network hub devices, for which it provides DX NetOps Spectrum management support. As a DX NetOps Spectrum VAR, the Jill Corporation received the software developer name of JillCorp and hexadecimal Developer ID 2f7 from CA.

Jill Corporation has already developed the model type Hub_Jill, generic management of its line of hub devices, which is distributed and sold as part of the Hub_Jill management module. Jill Corporation recently added the new Jill 700 hub to its line, and it wants to develop the new DX NetOps Spectrum management module Hub_Jill700 for the Jill 700 hub, to be packaged and sold with the hub hardware.

To accomplish this task, a developer at Jill Corporation used CA Model Type Editor to derive a new model type Hub_Jill700 for the Jill 700 hub from the base model type Hub_Jill and created the database import file Jill700.e for the new Hub_Jill700 model type. This developer also used the Level 1 Toolkit and the CORBA Toolkit to create the other DX NetOps Spectrum support files that are required to manage the Jill 700 hub. On the development host, the DX NetOps Spectrum support files for the Jill 700 hub reside in a DX NetOps Spectrum installation area in the /usr/devarea/spectrum directory.

The complete set of DX NetOps Spectrum support files for the Jill 700 hub relative to /usr/devarea/DX NetOps Spectrum is:

- A part description file
  Hub_Jill700.mmd
- A SpectroSERVER database import file
  SS/db/Jill700.e
- A SpectroSERVER Event Disposition file
  SS/CsVendor/JillCorp/EventDisp
- A SpectroSERVER Alert Map file
  SS/CsVendor/JillCorp/Hub_Jill700/AlertMap
- A OneClick app-config file
  tomcat/webapps/spectrum/WEB-INF/devman/config/contrib/

jill700-app-config.xml

- Several OneClick customization xml files
  tomcat/webapps/spectrum/WEB-INF/devman/config/
  view-jill700-devicedetails-config.xml
  tomcat/webapps/spectrum/WEB-INF/devman/config/
  privileges-jill700-config.xml
  tomcat/webapps/spectrum/WEB-INF/devman/config/
  table-jill700-sessions-config.xml
  tomcat/webapps/spectrum/WEB-INF/devman/config/
  search-jill700-criteria.xml

The developer must now package these files into the new Hub_Jill700 management module. The ultimate object is to add this management module to a VCD so that it can be distributed to customers and installed into their DX NetOps Spectrum areas.

The first task is to create an index file for Hub_Jill700. The index file must have the same name as the management module, and, therefore, it is named Hub_Jill700.i. We assume Hub_Jill700.i is created in the DX NetOps Spectrum installation directory /usr/devarea/spectrum. The developer has the option of writing the index file manually or using the mmship tool to generate the index file and then editing the resulting file. For the purposes of this example, assume that the developer has chosen to write the index file from scratch.

When the developer has finished editing Hub_Jill700.i, its contents are as follows (with line numbers included to allow for easy reference):

```
1. mm: Jill 700 Hub Management Module
2. rev: 1.0
3. irev: 01.00.00.000
4. level: 1
5.
6. vend: JillCorp
7. pprep: 3M-02F7-1001 Hub_Jill
8. file: Install mmdesc ? Hub_Jill700.mmd ? ?
9.
10. deflt: SS db sdir $SPECROOT/SS/db
11. file:  SS db ? Jill700.e ? ?
12.
13. deflt: SS vfile sdir $SPECROOT/SS
14. file:  SS vfile ? CsVendor/JillCorp/EventDisp ? ?
15. file:  SS vfile ? CsVendor/JillCorp/Hub_Jill700/AlertMap ? ?
16.

30. file:   OC file ? config/table-jill700-sessions-config.xml ? ?
```

```
31. file:   OC file ? config/search-jill700-criteria.xml ? ?
```

Let us analyze this index file.

The name of the index file is Hub_Jill700.i, indicating that it is the index file for the Hub_Jill700 management module.

The first five lines of Hub_Jill700.i describe the Hub_Jill700 management module.

- Line 1 says that the descriptive name of the Hub_Jill700 management module is “Jill 700 Hub Management Module.” The Install program displays this name on the installation summary. Line 2 says that the descriptive version of the Hub_Jill700 management module is 1.0.
- Line 3 says that the internal version of the Hub_Jill700 management module is 01.00.00.000. (The internal version must have the format dd.dd.dd.ddd where each d is a decimal digit.) During installation, this number is used to detect installation of an older version Hub_Jill700 over a newer version (such an occurrence can be named as downgrading, and it should only be done with the consent of the installing user). If Jill Corporation elects to update and re-release the Hub_Jill700 management module in the future, the “patch release” segment (the final ddd value) of this number must have a higher value than zero (for example, 01.00.00.001 or 01.01.00.123). This indicates that the re-released management module is newer than the original release.

  NOTE
  The “Patch Release” value (the final ddd segment of the number) must be higher than any preceding version of a given module to avoid being flagged as downgrading with this value starting over again at zero whenever any of the preceding number segments become incremented.
- Line 4 says that the extension module level of Hub_Jill700 is 1. This indicates that Hub_Jill700 is an optional extension of the DX NetOps Spectrum product that is, a management module (as opposed to a required DX NetOps Spectrum core component or an independent external application).
- Line 6 says that the developer of Hub_Jill700 is JillCorp. This is the CA-assigned developer name for Jill Corporation.

Lines 7 and 8 are both part description entries:

- Line 7 says that the management module Hub_Jill700 represents a part that is named 3M-02F7-1001. The 3M-02F7-1001 part includes the physical Hub_Jill700 and the additional management module Hub_Jill (which includes the base model type for Hub_Jill700).
- Line 8 ships a part description file for part 3M-02F7-1001. This file is required but not used during install.
  Line 8 gives us a first chance to see how the file: entry works. The line reads as follows:

  ```
  file:   Install mmdesc ? Hub_Jill700.mmd ? ?
  ```

  The file: label indicates that a shippable file is being included in the management module.
  The next two fields (Install mmdesc) give the product and the type of the shippable file. The file product Install indicates that the file is used during installation of the management module. The file type mmdesc says that the file is a management module part description file.
  The next two fields (? Hub_Jill700.mmd) specify the location of the source for the part description file (the file we eventually intend to place on the VCD). The source directory field is ?, which indicates that the default value can be used. The default source directory for part description files is “.” (as specified by the following deflt: entry in the mkmm.sys file that is shipped with the SEI Toolkit):

  ```
  deflt:   Install mmdesc sdir .
  ```

  The source name of the part description file is given explicitly as Hub_Jill700.mmd. Keep the source directory and name together, so that the location of the source for the part description file is ./Hub_Jill700.mmd. Since this is a relative path, it is taken relative to the directory containing the index file, which in this case is /usr/devarea/spectrum. Putting it all together, the source for the part description file is /usr/devarea/spectrum/Hub_Jill700.mmd.
  The last two fields (? ?) specify where the part description file should be installed from the VCD. Since the target directory field is ?, the Install program uses the default target directory for part description files. This default directory is Install-Tools/MMD, as specified by the following deflt: entry in the mkmm.sys file:

  ```
  deflt:   Install mmdesc tdir Install-Tools/MMD req=yes
  ```

The req=yes option that is shown in this example is intended for use only in the mkmm.sys data file. Since Install-Tools/MMD is the only acceptable target directory for installing part description files, the req=y flag prevents Install-Tools/MMD from being overridden by other deflt: entries in mkmm.loc or the index file. VAR extension module developers should not use this req=yes option in their index or mkmm.loc files.

Since the target name is also ?, we use the default target file name, which is always the same as the source file name -- in this case, Hub_Jill700.mmd. So, the part description file installs as Install-Tools/MMD/Hub_Jill700.mmd relative to the DX NetOps Spectrum installation directory.

- The deflt: entry on line 10 and the other deflt: entries that follow it set up the default source directories and target directories for the various other types of files that are being included in the management module. Look at Line 10 as a representative case with the following syntax:

  ```
  deflt:  SS db sdir $SPECROOT/SS/db
  ```

  $SPECROOT is an environment variable, which is expanded first to its exported value. In a Level 1 DX NetOps Spectrum development environment, $SPECROOT is set to the DX NetOps Spectrum installation directory, in this case, /usr/devarea/spectrum. So the deflt: entry becomes:

  ```
  deflt:  SS db sdir /usr/devarea/spectrum/SS/db
  ```

  The deflt: label itself indicates that we are setting a default attribute for shippable files.
  The next two fields (SS db) indicate that we are setting the default attribute for shippable files with product SS and file type db. These are SpectroSERVER database import files.
  The next field (sdir) indicates that the default attribute we are setting is the default source directory.
  The last field (<*$SPECROOT*>/SS/db) is the default value being set. This entry thus sets the default source directory for SpectroSERVER database files to /usr/devarea/spectrum/SS/db. This default source directory applies to any subsequent “file: SS db” entries in the index.
- The file: entry on line 11 and the other file: entries that follow it describe the shippable files in the management module. Look at line 11 as a representative case, which reads with the following syntax:

  ```
  file:   SS db ? Jill700.e ? ?
  ```

  The file: label indicates that a shippable file is being included in the management module.
  The next two fields (SS db) give the product and the type of the shippable file. The file product SS indicates that the file is part of the SpectroSERVER product. The file type db says that the file is a SpectroSERVER database import file.
  The next two fields (? Jill700.e) specify the location of the source for the SpectroSERVER database import file. The source directory field is ?, indicating that we can use the default source directory for import files.
  As previously discussed, on line 10, the default source directory is set to <*$SPECROOT*>/SS/db, which becomes /usr/devarea/spectrum/SS/db. The source name of the part description file is given explicitly as Jill700.e. Putting the source directory and name together, the source location of the part description file is /usr/devarea/spectrum/SS/db/Jill700.e.
  The last two fields (? ?) specify where the database import file should be installed from the VCD. The target directory ? indicates that we can use the default target directory for database import files; that default target directory is SS/db (as set in mkmm.sys). Since the target file name is also ?, we use the default target file name, which is always the same as the source file name, in this case, Jill700.e. So, the part description file can be installed as SS/db/Jill700.e relative to the spectrum installation directory.

  NOTE
  You must place all the custom defined events, Pcause, and event table files of the Index file under the $*SPECROOT*\custom directory.

Creating VCDs

Special Requirements on Windows

When using the SEI Toolkit tools on the Windows platform, some special considerations apply:

- On the Windows platform, the proper behavior of tools in the SEI Toolkit requires prior installation of CYGWIN32 UNIX support software. This will not be a problem, normally, as the required software is shipped with DX NetOps Spectrum

and is installed prior to installing DX NetOps Spectrum. However, be aware that interim removal or modification of the installed CYGWIN32 software can result in failure of SEI Toolkit tools (as well as other DX NetOps Spectrum software).
- On the Windows platform, it is necessary to run SEI Toolkit tools within a CYGWIN32 Bash Shell (bash) environment. You must also keep this requirement in mind when invoking SEI Toolkit tools from Makefiles or other build management tools.

Editing Setup Initialization Files

In order for your product name to appear during the installation of the VCD, you must edit the following setup initialization files in the <*$SPECROOT*>/INSDK/CD directory:

- (Windows) setupnt.ini
- (Linux) setuplin.ini

In each file, replace the words YOUR_PRODUCT _NAME_HERE with the name of your product, and then save and close the file.

If you did not make the edits described above and have already created a VCD, to correct this problem, you can replace the words YOUR_PRODUCT_NAME_HERE in the following files:

- <*VCD*>/setupnt.ini
- <*VCD*>/setuplin.ini

Create a VCD Using mkmm

You can use the mkmm tool to create a VCD and/or add one or more extension modules to a VCD.

System Environment

The mkmm utility must reside in its originally installed location in the <*$SPECROOT*>/INSDK directory, and it must be invoked from the directory containing the index files to be processed.

Syntax

The following syntax layout folds the line in order to show the entire contents of the sample text within the limits of the available page width. In actual use, however, your mkmm command-line entry must be entered as a single line:

```
mkmm [exts=<extlist>] [any=y/n] [vcd=<vcddir>] <indexFile>
<indexFile> ...
```

Description

The mkmm tool uses an extension module index file to add an extension module to a VCD. This involves transferring the descriptive information and shippable files for the extension module to the VCD. If the VCD does not yet exist, mkmm creates the VCD. The VCD may be used to install the VCD into an existing DX NetOps Spectrum installation area. You can use a single invocation of mkmm to add several extension modules to a single VCD.

The mkmm tool is located in the <*$SPECROOT*>/INSDK directory. The straight-forward use of mkmm is simply to run it as a command, using as its arguments the names of the index files to be added to the VCD. Use of the optional arguments allows great flexibility.

If mkmm is invoked with no options, it prints a usage summary identifying the required syntax and inputs, as follows:

```
Error: No arguments specified.
Usage: mkmm [options] [indexFile] [indexFile] ...
options:
    exts=<extlist>      Specify filename extensions   default: ".exe,,.cmd,.bat"
```

```
    any=(y|n)           Create platform-neutral VCD   default: n
    vcd=<vcdDirectory>  VCD directory                 default: ./vcd

required:
    indexFile           Index file
```

The VCD created by the mkmm tool cannot be installed immediately. Instead, you must first use the mkcd tool to add a version number to the VCD.

Environment Variables

Any environment variable included explicitly in an index file must be exported before mkmm can be invoked. Also, if an index file uses a default value that references an environment variable, the referenced environment variable must be exported before invoking mkmm.

mkmm sometimes uses the $VCD environment variable to determine the location of the VCD. For details, see the discussion of the vcd=<*vcddir*> entry in the next section on command line options.

Input Files

mkmm uses the following input files:

- **index files**
  For each extension module specified by its index file, mkmm reads the index file, <moduleName>.i.
- **shippable files**
  The mkmm tool reads each shippable file mentioned in the file: and head: entries of each index file it processes.
- **mkmm.sys**
- **mkmm.loc**
  The mkmm tool reads the mkmm.sys and mkmm.loc data files to determine the set of file types legal in DX NetOps Spectrum extension module index files. The tool also reads the default characteristics (including source and target directories, and so on) associated with those file types.

Command Line Options

The following options are available for the mkmm tool; note that some can be used in combination, while others are mutually exclusive.

- **any=n**
  (Default) Allows the extension modules being added to the VCD to be installed from the VCD only on the current DX NetOps Spectrum platform.
  This option should be used with non-portable extension modules, that is, extension modules that contain shippable files that are not portable across all supported DX NetOps Spectrum platforms (such as executables or object files). To distribute a non-portable extension module on multiple platforms, it is necessary to install the SEI Toolkit and run mkmm on each platform.
- **any=y**
  Allows platform-neutral extension modules being added to the VCD to be installed from the VCD on any supported DX NetOps Spectrum platform.
  This option should be used with portable extension modules, that is, extension modules containing only shippable files which are portable across all supported DX NetOps Spectrum platforms.
  If this option is used to ship a non-portable extension module, installation failure or product failure will result.
- **exts=<*extlist*>**
  Use the <extlist> list of filename extensions when looking for shippable files. By default, <extlist> is “,.exe,.cmd,.bat.” Using filename extension lists helps make index files more portable between platforms.
- ***<indexFile>***

Adds extension module <indexFile> to the VCD. <indexFile> may be the name of an extension module (for example, JOE) or its index file (for example, JOE.i) Either of these would cause mkmm to read the index file <indexFile>.i and add extension module <indexFile> to the VCD.
You can add several extension modules to the VCD by including several <indexFile> options on the mkmm command line.

- **vcd=<*vcddir*>**
  Adds the extension modules to the VCD in directory <vcddir>.
  If this option is omitted, mkmm obtains the VCD directory from the export environment variable, $VCD. If $VCD is not set and exported, mkmm uses the VCD directory, ./vcd. If there is no VCD in the VCD directory, mkmm creates a new VCD.

Output Files

The mkmm tool creates the following files:

- **error files**
  Any errors generated by mkmm while adding extension module <*mmname*> to the VCD are saved in the files <*mmname*>.err files.
- **warning files**
  Any warnings generated by mkmm while adding extension module <*mmname*> to the VCD are saved in the <*mmname*>.warn files.
- **VCD**
  The mkmm tool creates a VCD area if there is none and adds extension module files to the VCD area if it already exists.

Exit Status

If mkmm is able to successfully add the extension modules to the VCD for all index files specified on its command line, it returns with exit status 0; otherwise it returns with exit status 1.

Create a VCD for a Distributed Installation

To allow the VCD to be installed in a distributed SpectroSERVER environment, copy the sdic directory in <*$SPECROOT*>/Install-Tools and paste it into the <*$VCD*> directory:

```
cp -r <$SPECROOT>/Install-Tools/sdic <$VCD>/sdic
```

Perform the copy on each platform on which you want to run a distributed installation.

If you are working in the Windows environment, complete these additional steps

1. Create a dummy text file using a text editor. This text file should not contain any information.
2. Replace the cygdist.tgz in the <*$VCD*>/sdic directory with a new gzipped tar file of the same name. This new file should only contain the dummy text file.
   ```
   <$SPECROOT>/Install-Tools/newtar czvf cygdist.tgz <dummy_text_filename>
   ```
   WARNING
   Do not ship CA's cygdist.tgz file. It will cause installation problems.
3. Place cygdist.tgz in the <*$VCD*>/sdic directory. When this file is unpacked during the installation process, it will be placed in the <*$SPECROOT*>/NT-Tools/SRE directory and be used instead of the archive of the distribution of Cygwin shipped with DX NetOps Spectrum.
4. Copy the userconf.exe file from a Windows DX NetOps Spectrum installation area running the same version of DX NetOps Spectrum for which you are creating the VCD. Put this file in the <*$VCD*>/nt directory.
   ```
   cp <$SPECROOT>/Install-Tools/userconf.exe $VCD/nt
   ```

Platform-Neutral Extension Modules

A *platform-neutral extension module* is an extension module that can be installed without change on any supported DX NetOps Spectrum platform. You can add such platform-neutral extension modules to a VCD by using the mkmm “any=y” option. Management modules created by the use of the Level 1 Toolkit typically are platform-neutral extension modules.

If mkmm is running on Windows, for example, the mkmm any=y option causes mkmm to process the index file as a platform-neutral index file. This means that the extension module will be added to the any (platform-neutral) area of the VCD and hence that the extension module can later be installed from the VCD onto any supported DX NetOps Spectrum platform. If the index file contains any platform-specific entries (entries with plat=<*platform*> modifiers), mkmm will fail.

You can use this mkmm any=y option only if every shippable file in the extension module is portable with respect to all supported DX NetOps Spectrum platforms -- that is, the extension module cannot contain any files with formats specific to a given platform (such as object files or completed executables). Furthermore, a VCD cannot contain both platform-neutral and platform-dependent extension modules at the same time, so you should not add a platform-neutral extension module to a VCD unless you intend all extension modules on that VCD to be platform-neutral.

mkmm.sys and mkmm.loc

The mkmm tool uses two data files, mkmm.sys and mkmm.loc, to define the set of file types that may legally be used in file: and head: entries in index files, as well as the standard default characteristics (including source directory, target directory, and so on) associated with each file type. Through proper use of these files, extension module developers can customize the default behavior of mkmm when processing file: and head: entries. Specifically, extension module developers can change the standard default source directories associated with any given file type.

CA ships the mkmm.sys file with the SEI Toolkit, providing default values consistent with proper installation of the DX NetOps Spectrum product. The extension module developer should never remove or modify this file to change the default settings. Removal or improper modification of mkmm.sys can cause mkmm failure or result in production of VCDs that install shippable files to incorrect locations. Moreover, future upgrades of the SEI Toolkit will overwrite mkmm.sys, undoing any interim modifications.

Customization of these default values can be accomplished by modifying the mkmm.loc file, which does not ship with the SEI Toolkit. Instead, the extension module developer can create mkmm.loc (either directly or initially as a copy of mkmm.sys) and then edit it manually to customize the standard default values used by mkmm. Upgrades of the SEI Toolkit will not affect the contents of mkmm.loc, letting those changed values remain in effect.

Both mkmm.sys and mkmm.loc should reside in the same directory in which the mkmm tool resides, namely, the <*$SPECROOT*>/INSDK directory.

When processing an index file, mkmm goes through the following steps:

1. Process mkmm.sys.
   The mkmm.sys file is in index file format and contains deflt: entries for each file type that may legally be used in an index file. It should contain no other entries. These deflt: entries establish the standard default values (source directory, target directory, and checksum protection status) associated with each file type that may legally be used in an index file.
2. Process mkmm.loc (if present).
   The mkmm.loc file also is in index file format and contains only deflt: entries. Since mkmm processes the mkmm.loc entries after the mkmm.sys entries, any same-application deflt: entries in mkmm.loc override the standard default values set by the deflt: entries in mkmm.sys. This arrangement thus lets the developer customize standard default values associated with file types by adding the desired override commands to the mkmm.loc file.
3. Process the index file.
   The standard default values for the various file types defined in mkmm.sys and mkmm.loc now apply to the index file. The deflt: entries in the index file may be used to override these default values, however. The deflt: entries in mkmm.sys and mkmm.loc apply to all index files processed by mkmm, whereas deflt: entries in a given index file apply only to that index file.

The following example illustrates how you can use mkmm.loc to customize standard default values processed by mkmm.

As shipped, the mkmm.sys file contains the following deflt: entries:

```
deflt: Install mmdesc sdir .
deflt: Install mmdesc tdir Install-Tools/MMD req=yes
```

Note that designations of product “Install” and file type “mmdesc” (that is, “Install mmdesc” files, pertaining to Install description files for management modules), as shown in the preceding entries, are legal in DX NetOps Spectrum extension modules.

The standard default source directory (sdir) of “Install mmdesc” files is “.” -- meaning that mkmm, by default, looks for “Install mmdesc” files in the “.” directory (that is, in the same directory in which mkmm was invoked).

The standard default target directory (tdir) is “Install-Tools/MMD” -- meaning that mkmm, by default, adds “Install mmdesc” to the VCD so that Install subsequently can extract the included files from the VCD into the Install-Tools/MMD directory (relative to the DX NetOps Spectrum installation directory).

> **WARNING**
> The req=yes option shown in this example is intended for use only in the mkmm.sys data file. The req=yes flag prevents the standard default target directory (tdir) of “Install mmdesc” files from being overridden by later deflt: entries in mkmm.loc or the index file. VAR extension module developers should not use this req=yes option in their index or mkmm.loc files.

Now, suppose that the source for “Install mmdesc” files at a particular development site were kept in the /user/devarea/install directory. At that site, it would be convenient to arrange for mkmm to look for “Install mmdesc” files in that location. To get this to happen, the developer could add the following entry to mkmm.loc:deflt: SG stdmenu sdir /user/devarea/install.

This entry then would override the “deflt: Install mmdesc sdir .” entry in mkmm.sys, redefining the standard default source directory for “Install mmdesc” files to /user/devarea/install. This new default identification would now apply whenever mkmm is used to process any index file.

Source File Extension Handling in mkmm

This section applies primarily to developers of extension modules for the Windows platform.

There are several file naming conventions that differ between UNIX and Windows file systems. The most notable is that certain types of files on Windows platforms, such as executable files and batch files, require specific filename extensions (for example, .bat, .com, .cmd, .exe, .ksh, and so on), whereas this typically is not the case on UNIX systems.

These differences can cause inconveniences in the index files for multi-platform extension modules that ship on both UNIX-based and Windows platforms. For instance, a compiled executable called mytool on UNIX-based would be called mytool.exe on Windows. In an extension module index file prepared for shipping such an executable, therefore, there would apparently need to be two separate file: entries, one for UNIX platforms and one for Windows platforms, as follows:

```
file: SS exe ? mytool ? ? plat!=intel
file: SS exe ? mytool.exe ? ? plat=intel
```

However, this solution is unsatisfactory, because it potentially requires a lot of duplicated entries in the index files. An alternative solution would be to use a ${EXE} environment variable, set to the null string on UNIX and to “.exe” on Windows. To illustrate, consider the following single index file entry:

```
file: SS exe ? mytool${EXE} ? ? plat=intel
```

This entry would suffice to ship the file on Linux and Windows platforms. Deciding exactly which files need an extension would still be a chore when many files were involved, however.

To alleviate this burden for the extension module developer, the mkmm tool automatically checks for standard file name extensions when processing file: and head: entries.

For example, suppose you were using mkmm to add an extension module to a VCD. Suppose further that the extension module index file contained the following entry:

```
file: SS exe ? mytool ? ?
```

When mkmm processed this entry, it would look for the source file mytool with a number of standard extensions. The default list of extensions is:

- No extension
- .exe
- .cmd
- .bat

Accordingly, mkmm would look first for source file mytool, then mytool.exe, then mytool.cmd, and finally mytool.bat. on a Linux platform then, it would find and ship mytool, whereas on a Windows platform, where mytool does not exist, mkmm would find and ship mytool.exe. Therefore, this single file: entry works without change on either UNIX or Windows.

In the rare case that it may be necessary, the list of extensions used by mkmm when processing file: or head: entries can be changed by using the exts=<*extlist*> option, where <*extlist*> is a comma-separated list of extensions to be checked. For instance, consider the following command:

```
mkmm exts=,.exe,.com DCNET.i
```

This command instructs mkmm to check first for no extension (because there is nothing in <*extlist*> before the first comma), then for an .exe extension, and finally for a .com extension when processing file: and head: entries in index file DCNET.i.

If mkmm exhausts the extension list without finding the source file, it will use the source file name with no extension. This means that mkmm would not find the source file and therefore would fail.

Finishing and Versioning a VCD Using mkcd

You can use the mkcd tool to add version identification to the VCD, making it possible to install the extension module software from the VCD into an existing DX NetOps Spectrum installation area.

System Environment

The mkcd utility must reside in its originally installed location (the INSDK directory in the DX NetOps Spectrum installation area) but is invoked from the same directory in which the mkmm-output files are kept.

Syntax

```
mkcd [-f] [-t complete] <vcddir> <version>
```

or:

```
mkcd -h
```

Description

A VCD created by the mkmm tool cannot be installed immediately, Instead, the mkcd tool must first be used to add a version number to the VCD. The mkcd tool performs the following functions:

- Checks dependencies between purchasable parts and extension modules on the VCD and reports inconsistencies and errors.
- Adds a version number to the VCD, which makes the VCD installable.
- “Finishes” the VCD, locking the VCD against addition of further extension modules via mkmm, as well as preparing the VCD for customer installation.

If mkcd is invoked with no options, it prints a usage summary identifying the required syntax and inputs, as follows:

```
Usage: mkcd [-fh] <vcdDirectory> <vcdVersion>
-f: Finish VCD (prevents future MM additions)
-h: Help (display this message)
```

Command Line Options

The following options are available for the mkcd tool:

- **-h**
  Displays a help message that illustrates usage syntax requirements. This same result occurs if you enter mkcd with no options.

  NOTE
  You cannot use the -h option with other options listed below, as it takes precedence and overrides all other options.
- **-t**
  (Default) Specifies that the VCD contains a complete DX NetOps Spectrum distribution.
  When this option is in effect, mkcd assumes that unresolved extension module dependencies will not be satisfied at installation time, and it fails if it detects unresolved dependencies.Developers using the SEI Toolkit to distribute extension modules should never use the -t complete option when creating a VCD via mkcd.
- **-f**
  Instructs mkcd to “finish” the VCD. This locks the VCD so that no further extension modules may be added via mkmm. It also performs VCD compression and other operations to prepare the VCD for distribution and installation by customers.
  You should always “finish” a VCD before making it available to customers for installation.
- ***<vcddir>***
  Instructs mkcd to process VCD in the directory <vcddir>.
- ***<version>***
  Instructs mkcd to give VCD the version number <version>. The addition of the version number -- which is a required option -- makes it possible to install the VCD. The version number must contain no spaces.

Integration Tools Specification

Actual integration of DX NetOps Spectrum-compatible extensions with an installed DX NetOps Spectrum system is accomplished with the installation program, which is not a part of the SEI Toolkit and is mentioned here only for completeness.

When the installation program is given the VCD output from the SEI Toolkit, it can extract the DX NetOps Spectrum extension module files from the VCD and perform any necessary processing of the extracted files.

For more detailed information on the installation program, see the Installing DX NetOps Spectrum section.

Shippable Files

This section explains how shippable files are handled within the SEI Toolkit’s shippable software model. Extension module levels, products, and file types are explained, along with their effect on distribution and installation of shippable files. This chapter also includes tables that describe the following:

- How several common types of shippable files are written
- How various standard types of shippable files are distributed and installed

About Shippable Files

DX NetOps Spectrum extension modules support the distribution and installation of many kinds of shippable files. Files of different kinds are associated with different DX NetOps Spectrum products, and they must be developed, distributed, and installed in different ways. This section covers the basic concepts (levels, products, and file types) used within the SEI Toolkit to control distribution and installation of shippable files.

During installation, files of different types are integrated into the DX NetOps Spectrum product in different ways. This section lists the various file types and describes the processing applied to files of each type.

Among the many shippable file types supported by the SEI Toolkit are several types that either are used to customize the installation of extension modules or are commonly included in extension modules. These file types include the following:

- **Part description files** that contain part descriptions
- **Preinstall scripts** used primarily to remove or save obsolete files just prior to installing a new extension module
- **Custom install scripts** that perform customized installation functions for extension modules
- **Icon definition files** that describe icons for applications

Levels, Products, and File Types

The way in which a shippable file in an extension module is packaged, distributed, and installed is determined largely by the following factors:

- **The level of the extension module containing the file.** The extension module level is specified via the “level: <*level*>” entry in the extension module index file. <*level*> may have the value 0, 1, or 2.
- **DX NetOps Spectrum associated with the file.** A file’s product is given by the <*prod*> field of the file: or head: index file entry for the file. <*prod*> may have any one of these values: Install, SS, or OC. You can specify multiple values separated by commas.
- **The file type associated with the file.** A file’s type is given by the <*type*> field of the file: or head: index file entry for the file. There are many possible file types, all of which are documented later in this section.

Except in a few cases, the level and product of a file determine its relationship to the installed DX NetOps Spectrum product, as outlined in the following table:

<*level*>	**<*prod*>**	**Identification and Relation to Installed Product**
0, 1, 2	Install	Installation support file. Includes general DX NetOps Spectrum installation support files and installation support files for individual extension modules (for example, index files, part description files, preinstall scripts, and custom install scripts). Files of certain types (for example, mmdesc, preinst, and cus) are classified as installation support files regardless of their associated product.
0	SS	SpectroSERVER core file. Required for installation of the SpectroSERVER product. Level 0 extension modules are produced only by CA.
1	SS	SpectroSERVER management module file. May be optionally integrated into the SpectroSERVER product (typically, to help SpectroSERVER manage a particular device or device group).
2	SS	SpectroSERVER external application file. Part of a separate application or tool used in conjunction with SpectroSERVER but not integrated into SpectroSERVER itself. A level 2 extension module can be considered as belonging to its own standalone product.
0	OC	OneClick core file. Required for installation of the OneClick product. Level 0 extension modules are produced only by CA.
1	OC	OneClick management module file. Maybe optionally integrated into the OneClick product (typically to help OneClick display a particular device or device group).

2	OC	OneClick the external application file. Part of a separate application or tool used in conjunction with OneClick, but not integrated into OneClick itself. A Level 2 module can be thought of as belonging to its own standalone product.

Development of Shippable Files

The following table outlines the preferred development methods for files that are to be shipped in DX NetOps Spectrum extension modules. Each row of the table lists:

- The product of the shippable file as specified in the <*prod*> field of the file: or head: entry in the extension module index file.
- The file type of the shippable file as specified in the <*type*> field of the file: or head: entry in the extension module index file.
- A short description of the shippable file of the given product and type identifying the applicable nomenclature as a descriptive name.
- A short description of the format of the shippable file indicating the preferred method of development for the file where possible. Where special editors are recommended, the table gives references.

<*prod*>	**<*type*>**	**Description**	**File Format**
Install	doc	Documentation file	Text format
Install	file	General Install file	Any format.
Install	mmdesc	Part description file	Text file.
Install	tool	Installation tool	Compiled program, script, or data file.
SS	convtab	SS database partition conversion table	Text file. Undocumented format, internal to CA.
SS	cus	SS custom install script	Bourne shell script fragment.
SS	db	SS database import file	Data file. Format created by dbtool's export function or the Model Type Editor's export function.
SS	doc	SS documentation file	Text file.
SS	file	SS general file	Any format.
SS	icondef	icon definition for shortcuts	Used by Install to create icons on the user's desktop.
SS	iconimg	icon image for shortcuts	Used to ship icon images for use by icons created with icondef files.
SS	lib	SS library file	Compiled object library.
SS	preinst	SS preinstallation script	Text file containing Perl 5 code fragment.
SS	tool	SS related tool	Compiled program, script, or data file.
SS	vfile	SS vendor file	Text file in Alertmap file format or EventDisp file format.
OC,SS	evformat	event format file	Event format file in custom/Events/CsEvFormat.
OC,SS	pcause	probable cause file	Probable cause file in custom/Events/CsPCause.
OC	file	OneClick general file	Any format.
OC	web_xml	file to contribute to web.xml	An XML file that will be incorporated into the tomcat/webapps/spectrum/WEB-INF/web.xml file.
OC	cus	OneClick custom install script	Bourne shell script fragment.
OC	exe	OneClick executable file	A file that needs to be executed and, therefore, have the execute mode set on the file.
OC	preinst	OneClick preinstallation script	Text file containing Perl 5 code fragment.

Installation of Shippable Files

To install a usable DX NetOps Spectrum extension module, it is seldom enough to extract the files from the VCD to the correct location in the installation area. Additional processing of the installed files typically needs to be done, for example, importing SpectroSERVER database import files into the SpectroSERVER database.

The Install program performs much of this additional processing as standard installation services. Install decides what processing to perform on a shippable file by looking at the file's product and file type. For example, files of product "SS" and file type "db" are identified as database import files and imported into the SpectroSERVER database.

If a file is erroneously shipped in an extension module of an inappropriate level, Install may not correctly process the file.

Similarly, if a file is erroneously shipped with a base name extension incompatible with its file type, Install may not correctly process the file.

The following table outlines the standard installation processing performed on files of each supported product and file type. Each row of the table lists the following:

- The file type of a shippable file, as specified in the <*type*> field of the file: or head: entry in the extension module index file.
- The appropriate levels for extension modules used to ship the file, as specified via the level: entry of the extension module index file.
- The appropriate base name extensions for the shipped file (if applicable), as specified in the <*tname*> field of the file: or head: entry.
- A summary of the standard processing that Install performs on the file.

Type	Levels	Base Name	Standard Installation Processing Performed
convtab	0, 1	*.v	Installation of database partition conversion table will cause SpectroSERVER and Database partition converter executables to be linked.
cus	0, 1, 2	*.cus	Install invokes custom install scripts after extraction of all VCD records. An extension module should use such a custom install script for special install-time processing of files that it distributes to its associated VCD record.
db	0, 1	*.e	Install imports database import files into the SpectroSERVER database. Install archives and deletes database import files prior to terminating.
doc	0, 1, 2	N/A	No special installation processing.
file	0, 1, 2	N/A	No special processing is performed on general files. Any file that does not need special Install processing should be shipped as this file type.
icondef	0, 1, 2	*.icd	Install uses icondef files to create icons on the user's desktop.
iconimg	0, 1, 2	*.1.pm *.t.pm *.m.p *.ico	Used to ship icon images for use by icons created with icondef files. On Windows, icon image files must be in Windows icon file format and have the .ico extension. Windows icon files are binary files, which can be created with Microsoft Visual Studio.
mmdesc	0, 1, 2	*.mmd	Not currently used in the install but is required by mkmm.
preinst	0,1,2	*.pl	Install executes preinstall modules after start of VCD installation and prior to extraction of files from the VCD.
tool	0, 1, 2	N/A	No special installation processing.
vfile	0, 1	N/A	No special installation processing.

Extension Module Support Files

Extension module support files include shippable files which may be needed in any extension module. They are used mainly to customize the installation of extension modules. Among these files are the following:

- **Part description files:** Provide descriptions for purchasable parts.
- **Preinstall scripts:** Perform preparatory tasks for installing extension modules.
- **Custom install scripts:** Perform customized installation functions for extension modules.

Part Description Files

The mkmm utility requires each shippable extension module that defines a purchasable part to include a part description file (.mmd file). Recall that an extension module defines a purchasable part if it includes a pprep: entry. Therefore, if an index file contains a pprep: entry, a part description file is required. If it is required but not provided, mkmm will not add the extension module to the VCD.

> **NOTE**
> Since the part description file is not used by the installation program, you can create an empty file.

To include a part description file in a extension module, include in your extension module index file a line similar to the following:

```
file: Install mmdesc ? FOO.mmd ? ?
```

> **NOTE**
> In your line entry, replace FOO.mmd with the actual name of the part description file you intend to ship. You should ship a part description file only if the index file contains a pprep: entry.

Preinstall Scripts

Preinstall scripts give an extension module the ability to perform installation functions prior to the extraction of its shippable files.

To include a preinstall script in an extension module, include a line in the extension module index file similar to the following:

```
file: Install preinst ? script.pl ?
```

In your line entry, replace script.pl with the actual name of the preinstall scripts you intend to ship. If your equivalent of script.pl is not in the same directory as the index file, change the target directory field as applicable.

Preinstall Scripts

A preinstall script is a code fragment written in the Perl 5 programming language. As such, preinstall scripts can be used for very complex preinstallation tasks. However, the most common functions performed using preinstallation scripts are fairly simple and include:

- Deletion of obsolete files installed with previous versions of an extension module
- Backup of files that might be overwritten or modified when the extension module is installed
- Suspending running programs that would be adversely affected by simultaneous installation of an extension module

This section shows how to write preinstall modules to delete and back up files. More complex preinstallation functions can be easily programmed by developers skilled in the Perl 5 programming language.

The following example shows a preinstall module for deleting obsolete files installed with previous releases of an extension module. Suppose that in an older version of the fictitious FOO extension module, the following files were installed and that these files are no longer used by the current FOO extension module:

```
SG-Support/CsGIb/FooCom/CsModCnfg.30
SG-Support/CsGIb/FooCom/CsPortCfg.30
SG-Support/CsGIb/FooCom/CsPortCfg.XNT
SG-Support/CsGIb/FooCom/CsPortCfgXNT.30
```

Before installing its own files, the new version of the FOO extension module should clean up these obsolete files.

Suppose further that the old version of FOO extension module included the following configuration file which is still shipped in the current version, and that the user might have edited footool.cfg in the installation area:

```
SS-Tools/footool.cfg
```

If we do not back up footool.cfg before installing the new FOO extension module, the new version of footool.cfg would overwrite the older version, and any user edits to the older version would be lost.

To address these issues, we add preinstall scripts to the FOO extension module. The first preinstall script is associated with the SG product, and is executed prior to extracting SG files for the FOO extension module. This preinstall script would be used to delete the obsolete files:

```
removeFiles(
    "SG-Support/CsGIb/FooCom/CsModCnfg.30",
    "SG-Support/CsGIb/FooCom/CsPortCfg.30",
    "SG-Support/CsGIb/FooCom/CsPortCfg.XNT",
    "SG-Support/CsGIb/FooCom/CsPortCfgXNT.30",
);
```

The removeFiles() function, which is not a standard part of Perl, is provided by CA for use in preinstall scripts. It takes any number of relative file path names as arguments, and it deletes the path name relative to the DX NetOps Spectrum installation directory. If a path specifies a file, the file is deleted. If a path specifies a directory, the directory is recursively deleted. If a path does not exist or is absolute, it is silently ignored.

removeFiles() is designed to minimize the possibility of mistaken file deletion. In preinstall scripts, use removeFiles() in preference to Perl's unlink() function. Be careful not to delete necessary files.

The second preinstall script is associated with the SS product and is executed prior to extracting SS files for the FOO extension module. This preinstall script would be used to save footool.cfg:

```
# SS preinstall script for FOO extension module
# Save the footool configuration file
saveFiles("SS-Tools/footool.cfg");
```

Again, saveFiles() is not native Perl, and is supported for use only in preinstall scripts. saveFiles() takes any number of relative file path names as arguments, and recursively copies the file from the DX NetOps Spectrum installation directory to a save area within the Install-Tools/SAVES directory. The save areas are unique per installation, so that files saved during one installation will not be overwritten by files saved during subsequent installations. Since the save areas will accumulate over many installations, consuming disk space (which may eventually lead to installation or product failure), you should try to avoid saving very large files.

Custom Installation Scripts

The set of installation services provided by the Install utility is fairly complete, handling most extension module installation needs. A few extension modules may need to perform special installation processing not provided by the Install utility, however. To perform such processing, use custom install scripts.

Each extension module has up to three components, called the Install, SpectroSERVER, and OneClick components. The Install component includes shippable files used to install the extension module, and the SpectroSERVER and OneClick components include shippable files associated with the SpectroSERVER and OneClick products, respectively. In some cases, an extension module may not have an SS or OneClick component.

An extension module may include custom install scripts for its SpectroSERVER or OneClick component or for both (Custom scripts should not be created for the Install component). During VCD installation, Install invokes the SpectroSERVER custom scripts when the SpectroSERVER component of the extension module is installed, after the shippable files in the SpectroSERVER component have been extracted from the VCD. Similarly, Install invokes the

OneClick custom scripts when the OneClick component of the extension module is installed, after the shippable files in the OneClick component have been extracted from the VCD. It is rare that an extension module includes two or more custom scripts for a single component; if this is done, the custom scripts for the component are executed in the order in which they are specified in the index file. The custom scripts for a given component perform the special installation processing for that component.

The section that follows provides pointers on when to use custom install scripts and why to do so, gives details on writing these custom install scripts, and explains how to install these scripts. The discussion then concludes with a discussion of predefined Bourne shell variables and functions that you can use in these custom install scripts.

If an index file has a cus_dep: entry, the custom script in the specified management module runs before the custom script in the management module that has the cus_dep: entry. The index file for the specified management module should be included on the same VCD.

Uses of Custom Install Scripts

The Install utility provides standard services for the proper installation of many different types of files. Most extension modules can be properly installed using only these standard services, and these standard services should be used in preference to custom install scripts when possible. However, Install cannot provide standard services for all of the possible specialized installation functions that could conceivably be required by extension modules. When Install does not provide all the services needed to install a given extension module, custom install scripts should be used to help install the extension module. Since custom install scripts have all the capabilities of Bourne shell scripts, they can handle any special installation needs.

The following are examples of installation functions that should be handled using custom scripts:

- **Special installation methods** -- The utility installation services of the Install program are sufficient for most installation needs. However, an extension module will sometimes need to perform special installation tasks unique to itself, such as interacting with third-party software. You can use custom install scripts to perform such specialized installation functions.
- **Modifying contents of installed files to contain information specific to the installation site** -- Most of the time, the contents of a file, as extracted from the VCD, do not need to be modified during installation. There are times, however, when installed files need to contain information specific to the installation site -- such as the DX NetOps Spectrum installation directory or the installation host name -- that cannot be known until installation time. It then becomes necessary to embed that information in the installed files.
  If you must embed installation-specific information in a shippable file, you should use custom install scripts to embed the necessary information.
- **Installing files into system locations** -- In order to protect the integrity of the installation host, Install never extracts files from the VCD to locations outside of the DX NetOps Spectrum installation directory.
  If possible, you should avoid the modification of files in system areas during extension module installation. In rare cases, however, modification to files in system locations may be necessary for proper installation of an extension module. In those cases, you should use custom scripts to modify files in system locations. The custom script should be designed such as to notify the user when files in system locations are modified.
- **Embedding host-specific information into installed files** -- Custom install scripts can be used to embed host-specific information into installed files. Bourne shell commands can be used to embed host-specific information in an installed file.

When Not To Use Custom Install Scripts
When Not To Use Custom Install Scripts

Avoid using custom scripts to move installed files from their originally extracted location to some other location within the DX NetOps Spectrum installation area. The file: and head: index file entries can be modified so that any shippable

file can be extracted from the VCD to any desired location in the DX NetOps Spectrum installation area. DX NetOps Spectrum does not support individually relocatable applications.

Custom Install Scripts

The following example provides information on how to write custom install scripts. In this example, Joe Corporation ships a graphical tool called JoeTool that is used in conjunction with the OneClick product. JoeTool is to be shipped as the OC component of the JoeTool extension module. JoeTool requires a configuration file which, when installed, must include some embedded values (the installation host and the DX NetOps Spectrum installation directory) that cannot be determined until the installation is performed.

The JoeTool developer decides to write a custom install script that will dynamically create the configuration file with the embedded values at installation time. The custom script will be called joetool.cus (all custom scripts must end with the .cus extension). Here are the contents of joetool.cus:

```
# Custom install script for Joe Corporation's JoeTool
# This script creates the JoeTool configuration file
# Obtain the installation host name
# Use the UNIX hostname command
HOSTNAME=`hostname`
# Set JoeTool installation directory
# This uses $IROOT, which is the SPECTRUM installation directory
TOOLDIR="$IROOT/JoeTool"
# If the tool directory doesn't exist, create it
[ -d "$TOOLDIR" ] || mkdir  - p $TOOLDIR
# Set the configuration file name
CONFIGFILE="$TOOLDIR/.joetoolrc"
# If the configuration file already exists, save it
if [ -f "$CONFIGFILE" ] ; then
rm  - f $CONFIGFILE.save
mv $CONFIGFILE $CONFIGFILE.save
echo "JoeTool configurations saved in $CONFIGFILE.save"
fi
# Create the configuration file
# $HOSTNAME and $TOOLDIR will be expanded to their values
cat <<EOF >$CONFIGFILE
##### Start JoeTool configuration file
DISPLAY=$HOSTNAME:0.0
export DISPLAY
ND_PATH=$TOOLDIR/lib
export ND_PATH
PRF=$TOOLDIR/preferences/default.PRF
GIF_BASE=$TOOLDIR/gifs
DATA_TYPE=ATTRIBUTES
GENERATE_HTML=true
DEFAULT_FONT_SIZE=4
##### End JoeTool configuration file
EOF
# A zero exit status prevents custom script failure
exit 0
```

joetool.cus provides an example of a simple custom install script. Custom install scripts to handle more complex installation functions can easily be created by experienced Bourne shell developers.

Shipping Custom Install Scripts

Since custom install scripts perform special processing functions associated with the installation of a particular extension module, as previously noted, they must be present at the installation site in order to perform those functions. To help ensure this, a file: entry must be included in the extension module index file for each custom install script to be included in the extension module.

In the example in the preceding section, joetool.cus is the custom install script for the OneClick component of the JoeTool extension module. We assume that, in the developer's source area, joetool.cus resides in the same directory with the JoeTool extension module index file JoeTool.i. (It is recommended to keep source custom scripts in the same directory with the index file.) In order to have joetool.cus executed when the OneClick component of JoeTool is installed, joetool.cus must be shipped as a OneClick custom install script.

To do this, you would include the following entry in the index file, JoeTool.i:

```
file: OC cus ? joetool.cus ? ?
```

Custom Install Script Predefined Environment Variables

The Install utility predefines a number of environment variables, as listed and explained below, for use in custom scripts. These variables are helpful or necessary for writing proper custom install scripts. In order to maximize the portability of custom install scripts, use these variables rather than other techniques of obtaining information whenever possible.

For instance, use the value of $TARGET_OS to determine the installation platform, rather than the UNIX uname command, which is not available on all platforms.

- **$AWKUTIL**
  Should contain the name of a reliable version of the UNIX awk program on the current platform. Since the native awk utility is unreliable on some supported DX NetOps Spectrum platforms, use of $AWKUTIL is safer.
  For example, use the command:
  ```
  $AWKUTIL '$1 = "file:" { print $5 }' $INDEX
  ```
  rather then:
  ```
  awk '$1 = "file:" { print $5 }' $INDEX
  ```
- **$DEV_NULL**
  Identifies the output sink device for the platform. The $DEV_NULL variable evaluates to /dev/null on platforms and evaluates to nul: on Windows platforms.
  Make absolutely sure that all literal references to /dev/null and nul: are replaced with $DEV_NULL in your custom scripts. Failure to do this can result in both subtle and severe problems if the custom script is invoked on the wrong platform. (This is especially important for experienced UNIX shell programmers, who tend to use /dev/null in scripts without thinking).
- **$IROOT**
  Identifies the DX NetOps Spectrum installation directory. $IROOT is the current directory at the beginning of custom script execution.
  ```
  CUS_DOCS=$IROOT/OnlineDocs/helpdoc/helpdoc
  ```
- **$OC_PORT**
  The $OC_PORT variable is the Tomcat port number that can be used to create the URL for DX NetOps Spectrum.
  ```
  http://localhost:$OC_PORT/spectrum
  ```
- **$PATH**
  Is the Bourne shell command search path. Install sets $PATH to allow access to the following tools:
  - Standard installation tools ($IROOT/Install-Tools)
  - SpectroSERVER tools ($IROOT/SS-Tools)
  - Standard UNIX commands on the installation host
- **$TARGET_OS**
  Contains information about the platform on which the installation is running. Possible values are:

  - Linux
  - NT
- For example:

```
if [ "$TARGET_OS" = "NT" ]
then
    ....
fi
```

- **$TOMCAT_ROOT**
  Identifies the DX NetOps Spectrum Tomcat installation directory.

```
CUS_WEB=$TOMCAT_ROOT/webapps/spectrum
```

Non-Web-Based, Graphical Application Implementation

When writing non-web-based graphical applications designed to run within the DX NetOps Spectrum environment, you should adhere to the following recommendations:

- On Linux, DX NetOps Spectrum graphical applications should use the X windowing system, Motif window manager, and K Desktop Environment (KDE).
- On Windows, DX NetOps Spectrum graphical applications should use the Windows windowing system (included in the Windows operating system).

Icon Definition and Icon Image Files

For some external applications, (usually graphical applications), it is convenient to be able to launch the application from a desktop icon. For these applications, it is necessary to install a desktop icon and to define how the application is to be launched when the icon is opened. Icon definition files and icon image files are used to ship and install icons for desktop-launchable applications.

Each line in an icon definition file is of the form:

```
<label> <value>
```

where <*label*> is an icon definition file label from the table below, and <value> is the associated value. A label may carry the suffix .NT to indicate that the label applies only on Windows. For example, an imagefile.NT: entry is an imagefile: entry that applies on the Windows platform only.

Use of icon definition files and icon image files for desktop-launchable DX NetOps Spectrum applications currently is not supported on Linux.

The following table lists valid labels in icon definition files, as well as the interpretation of their associated values.

<*label*>	**Windows**	**Interpretation of <*value*>**
program:	Mandatory	The absolute or relative path name of the application program to be launched when the icon is opened. If the path is relative, it is taken relative to the DX NetOps Spectrum installation directory.
args:	Optional	The arguments to pass to the program when it is launched. If <*value*> is omitted, no arguments are passed.
workingdir:	Optional	The working directory when program is launched. If <*value*> is omitted, working directory defaults to “.” (current directory).

imagefile:	Optional	The icon image file. On Windows, <*value*> must be a path name, taken relative to the DX NetOps Spectrum installation directory if the path is not an absolute path. The image file may be a Windows icon file (.ico file) or a DLL containing an icon library (see the imageordinal: entry in this table). <*value*> may be omitted if the icon is included in the application program.
imageordinal:	Optional	On Windows, if the specified image file is a DLL containing an icon library, the image ordinal gives the index of the image file within the DLL.
iconfolder:	Mandatory	The desktop menu folder that will contain the icon.
iconname:	Mandatory	The descriptive name of the icon. This name appears in the menu pick for the icon and/or immediately beneath the icon on the desktop
description:	Optional	The description of the icon. On Windows, this name appears when the cursor hovers over the icon.
windowstate:	Optional	The initial state of the window launching the application. On Windows, <*value*> may be any one of the following: SW_SHOWNORMAL SW_SHOWMINIMIZED SW_SHOWMAXIMIZED SW_SHOWMINNOACTIVE SW_HIDE If <*value*> is omitted, the initial state of the launch window is SW_SHOWNORMAL.

The following is a icon definition file named appl.icd, for a hypothetical DX NetOps Spectrum application named Application. Assume that this application is associated with the OneClick application:

```
program: %IROOT%/bin/Application
args:
workingdir: .
imagefile.NT: %IROOT%/Install-Tools/icons/appl.ico
imagefile.windows: appl
iconfolder: CA
iconname: My Application
description: My <sp> Application
```

The program: entry specifies that the icon will invoke the application <*$SPECROOT*>/bin/Application when opened (clicked) on either Windows. The args: entry specifies that Application will be invoked with no arguments. The workingdir: entry specifies that Application will be invoked from the current directory (“.”) at the time the icon is opened.

On Windows, the imagefile.NT: entry specifies that the icon image file used to display the icon is to be

<*$SPECROOT*>/Install-Tools/icons/appl.ico (Note that on Windows, DX NetOps Spectrum icon image files are normally installed into the <*$SPECROOT*>/Install-Tools/icons directory). This file must be in the Windows icon file format and have an .ico extension. Windows icon files are binary files, which can be created by use of the Microsoft Visual Studio program.

If the icon had been compiled into the application, it would have been unnecessary to ship the icon image file on Windows, and the imagefile.NT: entry could have been omitted. If the icon had part of a Windows icon library, and imageordinal: entry would have been included to specify the icon's position within the library.

The iconfolder: entry specifies that, on Windows, the Application icon will appear in the CA folder under Start menu > Programs.

Shipping Icon Definition and Icon Image Files

The following index file entries might be used to ship the icon definition file and icon image files described in the scenario outlined in the previous section. These entries assume that all icon definition files and icon image files are in the same directory as the index file.

```
file: OC icondef ? appl.icd ? ?
file: OC iconimg ? appl.ico ? ? plat=intel
file: OC iconimg ? appl.l.pm ? ? plat=sun4c
file: OC iconimg ? appl.m.pm ? ? plat=sun4c
file: OC iconimg ? appl.t.pm ? ? plat=sun4c
```

DX NetOps Spectrum Extension Integration Developer Toolkit (SEI Toolkit) Troubleshooting

This section describes problems that can occur while creating the integration module. You can follow the solutions that are provided to resolve the integration errors.

Unable to Archive the Event045a0025.txt file

Symptom:

mkmm script failed with the following error message:

```
Unable to archive file /opt/spectrum/SG-Support/CsEvFormat/Event045a0025.txt
```

Solution:

You must place all the customer defined events, Pcause, and the event table files under the $*SPECROOT*\custom folder.

Web Services API Reference

About the DX NetOps Spectrum Web Services API

The DX NetOps Spectrum Web Services API provides a RESTful HTTP Web Service interface in DX NetOps Spectrum. This distributed API provides an HTTP-based integration point to the DX NetOps Spectrum data model, allowing web-centric read/write access to devices, models, relationships, attributes, actions and alarms. The DX NetOps Spectrum Web Services API is a core DX NetOps Spectrum component and is installed along with the core DX NetOps Spectrum product.

Using the DX NetOps Spectrum Web Services API, DX NetOps Spectrum data can be accessed directly from a browser or integrated into your own application. Because of the inherent standards in the REST architecture, the DX NetOps Spectrum Web Services API makes the DX NetOps Spectrum data model accessible to many different external

development environments and methods. The DX NetOps Spectrum Web Services API can be used with any language that knows how to manage HTTP integration and provides a lightweight alternative to SOAP services.

By using the DX NetOps Spectrum Web Services API, you can take advantage of functionality provided by the OneClick server, such as using its search infrastructure to more easily find groups of models. You can also perform many standard DX NetOps Spectrum functions for a single SpectroSERVER or in a distributed SpectroSERVER (DSS) environment, such as the following:

- Access devices, models, relationships, attributes, actions and alarms
- Manage devices, ports, containers, services, and links
- Read, update, and clear alarms
- Manage subscriptions and notifications

You can use the DX NetOps Spectrum Web Services API to perform these functions and more, similar to those provided by other DX NetOps Spectrum API tools such as the Command Line Interface (CLI), Modeling Gateway, AlarmNotifier, Southbound Gateway, or the SpectroSERVER Object Request Broker (SSORB) interface.

REST Architecture

Representational State Transfer (REST) is a software architectural style that promotes standardized behaviors between interacting elements, or clients and servers. Conforming to the REST constraints is referred to as being RESTful.

The REST architecture is a lightweight HTTP/HTTPS-based approach for SOAPless Web Services using create (POST), read (GET), update (PUT), and delete (DELETE) operations, or verbs.

RESTful architecture and applications are stateless, which means that no client context information is stored between requests. Each request contains all the information necessary to service the request.

The DX NetOps Spectrum Web Services API supports the REST architecture.

Supported Technologies

The DX NetOps Spectrum Web Services API provides a flexible, lightweight RESTful approach for integration of DX NetOps Spectrum data into your application. As an alternative to CORBA integration, the DX NetOps Spectrum Web Services API is language-independent and can be integrated into any development platform that supports HTTP integration, such as:

- Java
- Perl
- Ruby on Rails
- .net

The DX NetOps Spectrum Web Services API provides an HTTP/HTTPS interface, is both HTTP and XML/JSON-based, and provides Java Beans for client development.

Performance Considerations

The DX NetOps Spectrum Web Services API is a client, very similar to OneClick. Because the DX NetOps Spectrum Web Services API reuses much of the OneClick server code, performance of a single API client should generally mimic the performance of the comparable OneClick operation. The DX NetOps Spectrum Web Services API should not alter SpectroSERVER performance except through normal request load.

WARNING

The following can cause performance issues:

- Because data is cached in the OneClick server, large data requests across multiple clients can cause performance degradation.
- You may experience performance degradation and even SpectroSERVER crashes, if you create and execute new and poorly performing searches through the DX NetOps Spectrum Web Services API.
  For more information, See Troubleshooting the Web Services API Issues.

Limitations

The following should be considered when using the DX NetOps Spectrum Web Services API:

- The DX NetOps Spectrum Web Services API does not provide interfaces for the modeling catalog where data is generally static.
- While an HTML or browser application can be built on top of the DX NetOps Spectrum Web Services API, the DX NetOps Spectrum Web Services API itself does not provide HTML.
- The DX NetOps Spectrum Web Services API accepts XML only for input and produces XML or JSON for output. If you choose JSON as output, you may need to parse it out and produce XML for the next request.

NOTE
The DX NetOps Spectrum Web Services API can be used for simple CLI ad hoc commands and as an alternative to complex CLI scripting.

WARNING
The DX NetOps Spectrum Web Services API is a powerful tool. It does not provide the safeguards that OneClick does, especially related to modeling. It should be used only by DX NetOps Spectrum administrators who understand the potentially harmful effects on a network modeling scheme of haphazardly creating and destroying models and modifying model attributes.

Improve DX NetOps Spectrum REST API Capability (Swagger)

From 10.4.1, you can access DX NetOps Spectrum API documentation using Swagger. The Swagger UI lets you visualize and interact with DX NetOps Spectrum REST API by providing visual documentation.

You now have Swagger documentation and endpoints to work with DX NetOps Spectrum RESTful web services. The REST API endpoints are provided within a self-documenting framework that lets you try the methods and see the generated responses. All methods are grouped by resource type and can be displayed in a single window. Use the **Show/Hide**, **List Operations**, and **Expand Operations** options to expand and collapse the resources and methods.

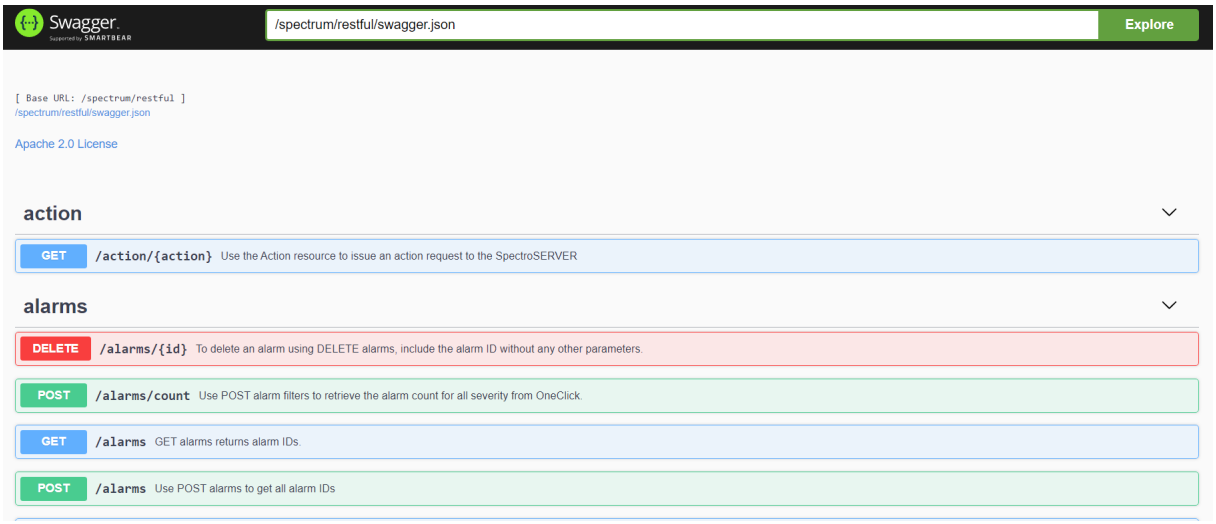
The methods are color-coded to make it easier to distinguish between the different methods. To the right of each method is a brief description of the action that is performed by the method. Documentation is provided for request parameters. Sample model schema is available for methods requiring payload in the request. Use the provided model schema to populate the body field, and then replace the default values with desired settings. Use the **Try it out!** Button to send the request and see the generated response in real-time.

The **Response Messages** section for each method provides a documented list of response codes. Use this information to help you determine a corrective action if an error condition was encountered. The response that is returned for each request appears in the method drop-down window.

Accessing the API Documentation

Click the **API Documentation** menu link in the OneClick Web interface to access the REST API.

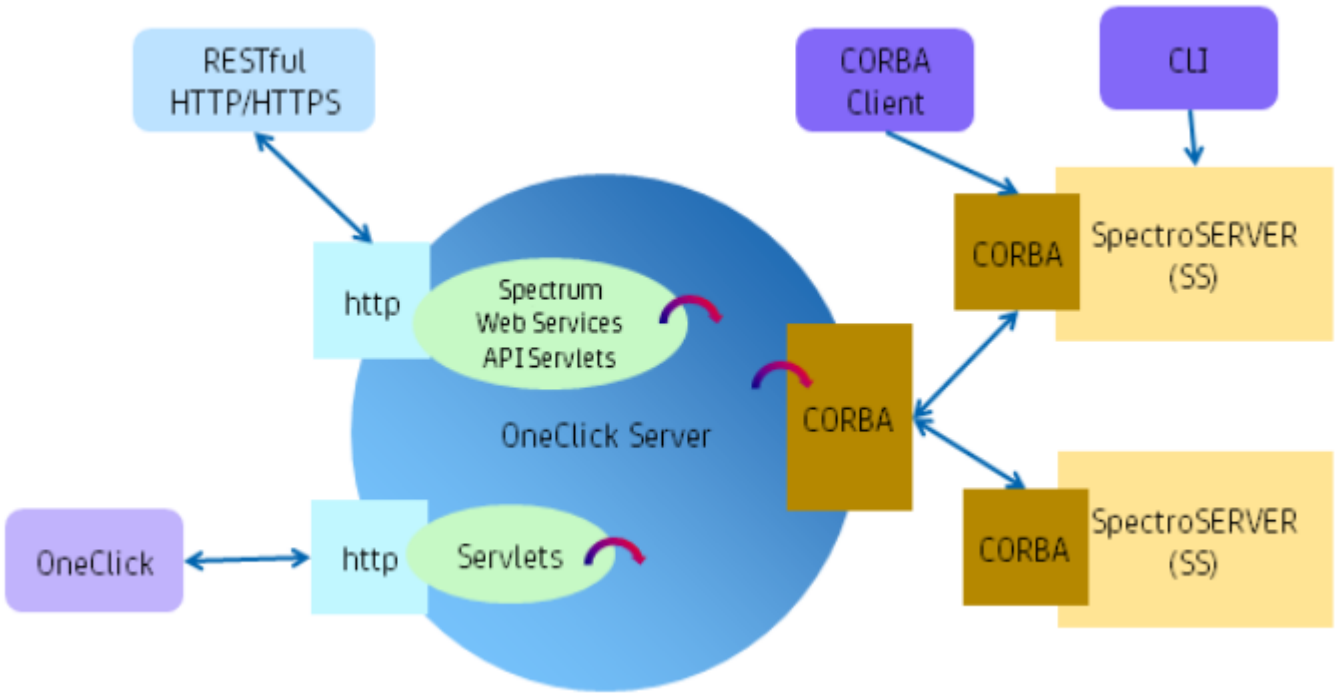
The following screenshot displays the Swagger interface. This interface displays some of the RESTful web services that DX NetOps Spectrum provides:



For more information on using Swagger for REST API, see Swagger documentation.

Web Services API and OneClick

The DX NetOps Spectrum Web Services API is hosted by and sits on top of the OneClick server. As shown in the following diagram, the DX NetOps Spectrum Web Services API servlets provide the entry point to the OneClick server:



This approach allows full access to OneClick server functions, essentially using the same code as the OneClick server. You can take advantage of OneClick features such as user authentication, search capability, and defined alarm filters. Throttled reads provide bulk query efficiency, and load-balanced OneClick servers provide high availability. The DX NetOps Spectrum Web Services API is fully supported in a distributed SpectroSERVER environment.

As with all RESTful services, the DX NetOps Spectrum Web Services API requests are stateless, requiring each request to include all necessary information to perform the operation.

How to Use the Web Services API

The following describes how to use the DX NetOps Spectrum Web Services API:

1. Generate a request to the OneClick server. The request can be in the form of a URL or imbedded in XML content. The OneClick server processes the request and returns a response.
2. Review the response, which contains the results of the request in the form of an XML or JSON document, depending on the client configuration.
3. Using information returned by the response, such as throttled results or other request-specific information, you can create follow-up requests.

Both requests and responses are regulated by defined schemas.

Web Services API Files

DX NetOps Spectrum Web Services API files are located in <*$SPECROOT*>/RestfulExamples, which includes the following folders:

- **lib**
  Contains all .jar files necessary for Java client development.
- **src**
  Contains the following folders:
  - **test**
    Contains example Java code that demonstrates basic functionality, JAXB beans, and hard-coded XML. An Eclipse .project and .classpath are also provided. For more information about provided examples, see Java Code Examples.
  - **xsd**
    Contains xsd files. For more information, see XML Schema Definitions.
- **xml**
  Contains sample XML for GET Tunneling requests. For more information about provided examples, see XML Examples.

  NOTE
  For more about GET Tunneling, see Simple and Complex Requests.

Requests

To use the DX NetOps Spectrum Web Services API, you generate a request to the OneClick server for which you receive results in response. The request can be in the form of a URL or imbedded in XML content.

RESTful Web Service URLs are noun-oriented, and the HTTP operation itself represents the verb. The following is the base URL when generating a request using the DX NetOps Spectrum Web Services API:

```
http://<hostname><:portnumber>/spectrum/restful/<request>
```

- ***request***
  Specifies the DX NetOps Spectrum Web Services API RESTful resource. Any request that requires a body will use the types defined in the Request.xsd.

NOTE
Because RESTful architecture and applications are stateless, no client context is stored between requests. Each request contains all the information necessary to service the request in the URL or XML content.

Request Types

There are two types of requests used in the DX NetOps Spectrum Web Services API. Both request types offer the same performance.

- **URL Requests**
  Used when a resource targets a specific model. For example, DELETE <*mh*> deletes a specific model. This type of request works well for simple requests with few parameters, does not require body text, and can be used as a browser URL.

  NOTE
  All URL requests have GET Tunneling equivalents.
- **GET Tunneling Requests**
  Used when a resource targets multiple models using complex parameters. An HTTP GET command can only support a limited number of parameters in a URL and does not support a body. The GET Tunneling operation tunnels a GET request through a POST body, allowing complex requests to be created. The XML body can contain rich filters by using new and existing search criteria and pre-defined alarm filters. Semantics of GET Tunneling requests are defined by Request.xsd and Filter.xsd schemas and can be created manually or generated from request beans.

General URL Parameters

The following are general parameters that are supported for some of the resources, depending on application. In general, the order of URL parameters in a list does not matter. Any exceptions are noted.

WARNING
Parameters are preceded by either ? or &. In accordance with standard HTTP syntax, the first parameter specified must be preceded by ?, and any subsequent parameters must be preceded by &. All of the following parameters are shown preceded by &. Use the appropriate prefix depending on the location of the parameter in the list.

- **&attr=<*attr_ID*>&val=<*num*>**
  Specifies attribute value pairs, which are used to obtain specific attribute values for the resource being queried. For example, if you GET alarms, you get the alarm IDs only by default. However, if you retrieve alarms with specified attributes you get the alarm IDs with their specific attribute values.
  When attribute value pairs are specified, especially when updating attribute values, attribute ID and values must occur in sequence for proper binding of the ID and value, as in the following:
  ```
  ?attr=0x10062&val=text&attr=0x10001&val=12334
  ```
  This pairing tells the RESTful servlet that an attr ID will be followed by the desired value for that ID when updating the value of the attribute.
  Multiple attribute-value pairs can be specified.
- **&landscape=<*landscape_handle*>**
  Specifies which landscapes to include in query. Multiple landscape parameters can be specified.
- **&mh=<*model_handle*>**
  Specifies the model handle.
- **&throttlesize=<*num*>**
  Specifies the number of items from the result set to retrieve per response. If the throttlesize value is less than the total number of items in the result set, the results contain a "next" link. This link can be used to retrieve more results. See Using Throttle and Next.

NOTE
Not all resources support the throttlesize parameter.

Security

User Security in OneClick

All requests using the DX NetOps Spectrum Web Services API respect DX NetOps Spectrum user model-based security.

WARNING
The DX NetOps Spectrum Web Services API is a powerful tool. It does not provide the safeguards that OneClick does, especially related to modeling. It should be used only by DX NetOps Spectrum administrators with strong knowledge of the DX NetOps Spectrum data model.

Secure Connections

The DX NetOps Spectrum Web Services API supports secure connections to the OneClick server. To use secure connections, the OneClick server must be configured for Secure Sockets Layer (SSL).

NOTE
For information about configuring OneClick for SSL, see the Administration section.

Responses

Responses are in the form of an XML or JSON document, as determined by the client's accept header value/MIME type. This flexible output makes the output data easy to integrate into client development. Responses are defined by Response.xsd schema.

NOTE
The DX NetOps Spectrum Web Services API supports both application/xml and application/json MIME types in the accept header. If you choose JSON as output, you may need to parse it out and produce XML for the next request.

The following describes elements of a response output:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<resource-response-list xmlns="http://www.ca.com/spectrum/restful/schema/response" error="<msg>"
 throttle="<num>" total-resource="<num>">
  <resource-responses>
...
  </resource-responses>
<link rel="next" href="http://<hostname><:portnumber>/spectrum/restful/alarms?
id=<result_set_ID>&start=3&throttlesize=<num>" type="application/xml" />
</resource-response-list>
```

- **error="<*msg*>"**
  Indicates the overall success or failure of the operation. If there is a failure, additional information is provided. "EndOfResults" indicates that all items in the result set have been returned.
- **throttle="<*num*>"**
  Indicates the number of items returned in this response, as specified by the throttlesize parameter on the request. If the throttle number is less than the total results found by the server, a "next" link is provided. If the complete set of data is returned, there is no "next" link.
- **total-*resource*="<*num*>"**

Indicates the total number of items in the result set. *Resource* varies depending on the type of request (for example, alarms, landscape, model, models).

- **link rel="next" href="<*URL*>"**

  NOTE
  The "next" link appears only if additional items remain in the result set.

  Indicates that additional items remain in the result set and provides the URL to obtain them according to the throttle value. This link conforms to the HATEOAS (Hypermedia as the Engine of Application State) constraints and can be used in a client or a browser to issue the "next" request. By using this link, the full cost of the original call is avoided. The location is cached on the OneClick server and expires after ten minutes of inactivity. After expiration, the URL returns the string "The cursor is no longer valid".

  NOTE
  Each RESTful call has its own cache.

  The following parameters appear in the generated URL:

  – **id=<*result_set_ID*>**
  Specifies the location of the result set on the OneClick server. The data expires after ten minutes of inactivity.
  – **start=<*element_num*>**
  Indicates the start position within the result set.
  – **throttlesize**
  Indicates the number of items to return in the next response.

  NOTE
  The format of the parameters within the generated link may vary depending on your environment. For example, "&" may be generated as "&" This is due to differences between XML, HTTP, and JSON formatting standards.

RESTful Resources (Nouns)

The DX NetOps Spectrum Web Services API provides the URLs for the appropriate RESTful HTTP operations against the DX NetOps Spectrum data model nouns, as displayed in the following table. All nouns are lowercase.

Resource	Description	POST	GET	PUT	DELETE
action	Used to send actions		yes		
alarms	Read, update, and delete alarms	GET Tunneling	yes	yes	yes
associations	Create, read, update, and delete associations	yes	yes		yes
attribute	Reads values for enumerated attribute values		yes		
connectivity	Reads connectivity information for a specified IP address		yes		
count	Retrieves total alarm counts of critical, major, and minor severity		yes		
devices	Reads devices and attributes		yes		
filters	Retrieves names of all the alarm filters, and also retrieves the alarms based on alarm filters	yes	yes		
landscapes	Reads landscape information		yes		
model	Creates, reads, and updates attributes and deletes models	yes	yes	yes	yes
models	Reads and writes models attributes	GET Tunneling	yes*	yes	

Events	Creates one or more events on single or multiple models	yes			
subscription	Creates a request for change notification	yes	yes		yes

* GET can only be performed against the result set created by POST (GET Tunneling).

action

Use the Action resource to issue an action request to the SpectroSERVER. An internal action code determines which operation is performed by the action.

- **Base URL**
  `http://<hostname><:portnumber>/spectrum/restful/action`

GET action

GET action issues an action request to the SpectroSERVER. Initiated as an HTTP GET, the action performed on the SpectroSERVER, including modifying data, is specified by an action code. All actions return results, which differ by the requested action.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/action/<action_code>[?mh=<model_handle>]`
  `[&attr=<attr_ID>&val=<num>][&throttlesize=<num>]`
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing. Content differs depending on requested action.

URL Parameters

- ***action_code***
  Specifies the action to perform on the SpectroSERVER. The following table contains some common actions.

Action	Target Model	Description
0x1000e	device	Reconfigures a model (reconfig)
0x480003	watch	Activates a watch (activate)
0x480004	watch	Deactivates a watch (deactivate)
0x210008	device	Reconfigures application models on Cisco and Wellfleet devices (reconfigure_apps)
0x100a2	VNM	Updates the SpectroSERVER with changes to EventDisp and AlertMap files (reload_event_disp)
0x100f6	global collection	Updates membership for periodic search-based global collections
0x10274	VNM	Turns on EMS debugging

0x10275	VNM	Turns off EMS debugging
0x10301	VNM or global collection	Turns on Search Debug for all searches if directed to the VNM model or for a single global collection if directed to a global collection
0x10300	VNM or global collection	Turns off Search Debug for all searches if directed to the VNM model or for a single global collection if directed to a global collection
0xbc614d	RFC2790App	Toggles debug for File System Monitoring
0xbd6146	RFC2790App	Toggles debug for Process Monitoring

- **&mh=<*model_handle*>**
  (Optional) Specifies the target of the action.
- **&attr=<*attr_ID*>&val=<*num*>**
  (Optional) Specifies attribute values as input to the action. Multiple attribute-value pairs can be specified.
- **&throttlesize=<*num*>**
  (Optional) Specifies a throttle size.

Example

The following URL initiates the 'FIND_DEV_MODELS_BY_IP' action (0x10093) against the SearchManager model (0x400018):

```
http://<hostname><:portnumber>/spectrum/restful/action/0x10093?
mh=0x400018&attr=0&val=172.22.96.11&attr=1&val=172.22.96.5
```

NOTE

- The SearchManager model handle will differ from SpectroSERVER to SpectroSERVER.
- You can also find device models by IP by embedding the correct locater search in the POST body of a GET models.

Using Alarm Resources

Use the Alarms resource to read, modify, and delete DX NetOps alarms. Asynchronous responses are supported.

- **Base URL**
  ```
  http://<hostname><:portnumber>/spectrum/restful/alarms
  ```

POST alarms (GET Tunneling)

Use POST alarms (GET Tunneling) to get all alarm IDs. POSTing an alarms request allows you to provide an XML document that specifies the alarms to be retrieved. The document can specify specific alarms by ID or by a model specification. A model specification can be a list of model handles, XML search criteria or a reference to existing search criteria on the OneClick server. It is also possible to GET alarms that satisfy a specific alarm attribute filter. An attribute filter is a subset of the search criteria.

WARNING
This POST is a form of GET Tunneling. You cannot create an alarm with POST alarms. DX NetOps alarms are created in response to events, as defined by the Event Disposition files.

- **URL**
  ```
  http://<hostname><:portnumber>/spectrum/restful/alarms[?symptoms=no][?symptoms=yes]
  ```
- **HTTP Method**

POST

- **Body**
  Examples are provided in <*$SPECROOT*>/RestfulExamples/xml/Alarms. These XML files provide examples of properly formed XML for different purposes. Use these examples as a basis for your own XML:
  – GetAlarmsByModelHandles.xml
  – GetAlarmsBySearchCriteria.xml
  – GetAlarmsForAllDevices.xml
  – GetAlarmsByAlarmIDs.xml
  – GetAlarmsByAttributeFilter.xml
  The following example is a simple xml criteria to retrieve alarm ids and their associated details like Model Type, Model Type of Alarmed Model, Security String, Condition, Model Name, Model Class:

```
<?xml version="1.0" encoding="UTF-8"?>
 <rs:alarm-request throttlesize="0"-->
 xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../
xsd/Request.xsd ">
 <rs:requested-attribute id="0x10000"/> <!--Model Type Name-->
 <rs:requested-attribute id="0x10001"/> <!--Model Type of Alarmed Model-->
 <rs:requested-attribute id="0x10009"/> <!--Security String-->
 <rs:requested-attribute id="0x1000a"/> <!--Condition-->
 <rs:requested-attribute id="0x1006e"/> <!--Model Name-->
 <rs:requested-attribute id="0x11ee8"/> <!--Model Class-->
<rs:landscape id="0x100000"/>
</rs:alarm-request>

<!--If you include landscape attribute(s) in the xml criteria, alarms of all the
 landscapes that are included are retrieved.-->
```

- **Body Content**
  application/xml
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing all alarms in the SpectroSERVER or distributed SpectroSERVER
  Example
  The following is an example call:

```
Java GenericPoster noun=Alarms file=resources/xml/Alarms/GetAlarmsBySearch.xml server=localhost username=jdoe
 password=spectrum port=8080
```

URL Parameters

- **<?symptoms=no>**
  Use this parameter to retrieve all the alarm ids excluding the symptom alarm ids.
  Based on the example xml body, the following output is returned for "http://<hostname><:portnumber>/spectrum/restful/alarms?symptoms=no":

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<alarm-response-list error="EndOfResults" throttle="18" total-alarms="18">
 <alarm-responses>
```

```
 <alarm id="55d30306-7d7b-1000-02a9-6c8814e75b4c">
<attribute id="0x10000">WA_Link</attribute>
<attribute id="0x10001">0x102e2</attribute>
<attribute id="0x10009" />
<attribute id="0x1000a">3</attribute>
<attribute id="0x1006e">10.10.10.0</attribute>
<attribute id="0x11ee8">7</attribute>
 </alarm>
  </alarm>
 </alarm-responses>
</alarm-response-list>
```

- **<?symptoms=yes>**
  Use this parameter to retrieve all the alarm ids including the symptom alarm ids.
  Based on the example xml body, the following output is returned for "http://<hostname><:portnumber>/spectrum/restful/alarms?symptoms=yes":

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<alarm-response-list error="EndOfResults" throttle="20" total-alarms="20">
 <alarm-responses>
 <alarm id="55d30306-7d7b-1000-02a9-6c8814e75b4c">
<attribute id="0x10000">WA_Link</attribute>
<attribute id="0x10001">0x102e2</attribute>
<attribute id="0x10009" />
<attribute id="0x1000a">3</attribute>
<attribute id="0x1006e">10.10.10.0</attribute>
<attribute id="0x11ee8">7</attribute>
 </alarm>
 </alarm-responses>
</alarm-response-list>
```

- **?lasthour=<*num*>**
  (optional) Use this parameter to retrieve alarm ids generated in the last <*num*> of hours, where <*num*> of hours. For example, to retrieve the alarm ids generated in the last two hours, use the following url:

```
http://<hostname><portnumber>/spectrum/restful/alarm?lasthour=2
<?xml version="1.0" encoding="UTF-8"?>
<rs:alarm-request xmlns:rs="http://www.ca.com/spectrum/restful/schema/request" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance" throttlesize="100" xsi:schemaLocation="http://www.ca.com/spectrum/
restful/schema/request ../../../xsd/Request.xsd ">
   <rs:requested-attribute id="0x11f56" />
   <rs:requested-attribute id="0x12b4c" />
   <rs:requested-attribute id="0x1006e" />
</rs:alarm-request
```

GET alarms

GET alarms returns alarm IDs. You can retrieve specific alarm attributes by using the &attr=<*attr_id*> parameter.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/alarms[?attr=<attr_ID>][&landscape=<landscape_handle>]
[&throttlesize=<num>]
```

- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing alarms in the SpectroSERVER or distributed SpectroSERVER
  The following is an example taken from our environment for retrieving only alarm ids:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<alarm-response-list error="EndOfResults" throttle="20" total-alarms="20">
 <alarm-responses>
<alarm id="55d30306-7d7b-1000-02a9-6c8814e75b4c" />
<alarm id="55d2d38b-47a6-1000-02a9-6c8814e75b4c" /
>
 </alarm-responses>
</alarm-response-list>
```

This is an example based on our environment.

URL Parameters

- **&attr=<*attr_ID*>**
  (Optional) Specifies the requested attributes. Multiple attribute parameters can be specified.

  > **NOTE**
  > There are many attributes on a model; for best performance you should limit attribute selection to attributes of interest.
- **&landscape=<*landscape_handle*>**
  (Optional) Filters which landscapes are queried. Multiple landscape parameters can be specified.
- **&throttlesize=<*num*>**
  (Optional) Specifies a throttle size.

```
http://<hostname><portnumber>/spectrum/restful/alarm
```

The following output is generated:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
<alarm-response-list error="EndOfResults" throttle="6" total-alarms="6">
 <alarm-responses>
<alarm id="55d30306-7d7b-1000-02a9-6c8814e75b4c" />
<alarm id="55d2d38b-47a6-1000-02a9-6c8814e75b4c" /
>
 </alarm-responses>
</alarm-response-list>
```

This is an example based on our environment.

GET alarm filters

Use GET alarm filters to retrieve the alarm filters defined in OneClick.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/alarms/filters`
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  The following xml output containing the alarm filter names is returned:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
- <alarmfilters-response xmlns="http://www.ca.com/spectrum/restful/schema/response">
<alarmfilter>LAN_alarms</alarmfilter>
<alarmfilter>Chassis_Alarms</alarmfilter>
<alarmfilter>core_router_alarms</alarmfilter>
</alarmfilters-response>
```

This is an example based on our environment.

POST alarm count

Use POST alarm filters to retrieve the alarm count for all severity from OneClick.

- **URL**
  `http://<hostname><portnumber>/spectrum/restful/alarms/count`
- **HTTP Method**
  POST
- **Body**
  You can use an extensive xml criteria to retrieve the required alarm count. For example, use the following body:

```
<?xml version="1.0" encoding="UTF-8"?>
<rs:alarms-count-request xmlns:rs="http://www.ca.com/spectrum/restful/schema/
request"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request
../../../xsd/Request.xsd ">

<rs:alarm-filter name="def"/>

</rs:alarms-count-request>
```

- **Body Content**
  application/xml
- **Header**
  application/xml, application/json
- **Output**

The following xml output containing the alarm count for all severity is returned:

```
<alarmcount-response>
    <critical>4</critical>
    <major>21</major>
    <minor>4</minor>
</alarmcount-response>
```

PUT alarms

Use PUT alarms to update alarm attributes.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/alarms/<alarm_id>?attr=<attr_ID>&val=<num>`
- **HTTP Method**
  PUT
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing indicating success or failure

URL Parameters

- ***alarm_ID***
  Specifies the alarm ID.
- **&attr=<*attr_ID*>&val=<*num*>**
  Specifies the attributes and values. Multiple attribute-value pairs can be specified.

DELETE alarms

To delete an alarm using DELETE alarms, include the alarm ID without any other parameters.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/alarms/<alarm_id>`
- **HTTP Method**
  DELETE
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing indicating success or failure

URL Parameters

- ***alarm_ID***
  Specifies the alarm to delete.

associations

Use the Associations/Relation resource to create, read, or delete associations.

> **NOTE**
> Associations cannot be updated. To modify an association, delete the existing association and create a new one. Association operations are restricted to one SpectroSERVER at a time.

- **Base URL**

```
http://<hostname><:portnumber>/spectrum/restful/associations/relation
```

> **NOTE**
> The Associations noun is a pass-through noun. You must also specify the Relation noun to create, read, or delete associations.

POST associations

POST associations creates an association. A specific relation is created between two models. Only models on the same SpectroSERVER can be associated.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/associations/relation/<rel_handle>/leftmodel/<LMhandle>/
rightmodel/<RMhandle>
```

- **HTTP Method**
  POST
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing association information

URL Parameters

- ***rel_handle***
  Specifies the relation handle.
- ***LMhandle***
  Specifies the handle of the left model in the relation.
- ***RMhandle***
  Specifies the handle of the right model in the relation.

> **NOTE**
> To get the left or right model handle, you can use the CLI show associations command, as follows:

```
show associations mh=<model_handle_of_device/port>
```

> **NOTE**
> For more information about this command, see the Command Line Interface section.

GET associations

GET associations returns associations for a specific relation and model. Associations are read based on the side of the association that the model handle is on.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/associations/relation/<rel_handle>/model/<model_handle>?
side=[left|right]
```

- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing association information

URL Parameters

- ***rel_handle***
  Specifies the relation handle.
- ***model_handle***
  Specifies the handle of the model in the relation.
- **side=[left|right]**
  Specifies the side of the association that the model handle is on.

DELETE associations

DELETE associations removes associations by deleting a specific relation between two models.

- **URL**
  ```
  http://<hostname><:portnumber>/spectrum/restful/associations/relation/<rel_handle>/leftmodel/<LMhandle>/
  rightmodel/<RMhandle>
  ```
- **HTTP Method**
  DELETE
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing indicating success or failure

URL Parameters

- ***rel_handle***
  Specifies the relation handle.
- ***LMhandle***
  Specifies the handle of the left model in the relation.
- ***RMhandle***
  Specifies the handle of the right model in the relation.

attribute

Use the Attribute resource to retrieve strings for enumerated attributes.

- **Base URL**

```
http://<hostname><:portnumber>/spectrum/restful/attribute
```

GET attribute

GET attribute returns XML describing the enumerations for the specified attribute.

- **URL**
  ```
  http://<hostname><:portnumber>/spectrum/restful/attribute/<attr_ID>/enums
  ```
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  XML describing the enumerations for the specified attribute

URL Parameters

- ***attr_ID***
  Specifies the attribute ID.

  NOTE
  Do not use external attributes.

Example

The following URL requests the enumerations for the model class attribute (0x11ee8):

```
http://localhost:8080/spectrum/restful/attribute/0x11ee8/enums
```

The following is returned for the request:

```
<?xml version="1.0" encoding="UTF-8"?>
<attrtribute-enum-response xmlns="http://www.ca.com/spectrum/restful/schema/response">
    <attribute id="0x11ee8"/>
    <enum id="0" value="Unknown"/>
    <enum id="1" value="Other"/>
    <enum id="2" value="Switch"/>
    <enum id="3" value="Router"/>
. . .
```

connectivity

Use the Connectivity resource to retrieve connectivity, and device and port condition information for a specified device model based on its IP address.

- **Base URL**
  http://<*hostname*><:*portnumber*>/spectrum/restful/connectivity

GET connectivity

GET connectivity returns XML describing all the connectivity from a requested end point.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/connectivity/[ip_address][model_handle]
```

- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  XML describing the connectivity

URL Parameters

- ***ip_address***
  Specifies the IP address to retrieve connectivity information for.

Example

The following URL requests connectivity, and device and port condition information for the specified IP address:

```
http://chave10-w7:80/spectrum/restful/connectivity/138.42.94.149
```

The following is returned for the request:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>

devices

Use the Devices resource to retrieve DX NetOps Spectrum devices and attribute information.

> **NOTE**
> A *device* is defined as all models returned by the SpectroSERVER action FIND_ALL_DEVICE_MODELS (0x1023a).

- **Base URL**

  ```
  http://<hostname><:portnumber>/spectrum/restful/devices
  ```

GET devices

GET devices returns all device model handles. You can retrieve specific model attributes by using the &attr=<*attr_id*> parameter.

- **URL**

  ```
  http://<hostname><:portnumber>/spectrum/restful/devices[?attr=<attr_ID>][&landscape=<landscape_handle>]
  [&throttlesize=<num>]
  ```

- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing all device model handles and requested attributes in the SpectroSERVER or distributed SpectroSERVER

URL Parameters

- **&attr=<*attr_ID*>**
  (Optional) Specifies the requested attributes. Multiple attribute parameters can be specified.

  NOTE
  There are many attributes on a model; for best performance you should limit attribute selection to attributes of interest.
- **&landscape=<*landscape_handle*>**
  (Optional) Filters which landscapes are queried. Multiple landscape parameters can be specified.
- **&throttlesize=<*num*>**
  (Optional) Specifies a throttle size.

Example

The following URL requests the name and model type of all devices:

```
http://<hostname><:portnumber>/spectrum/restful/devices?attr=0x1006e&attr=0x10000
```

The following is returned for the request:

```
   <?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
 - <model-response-list xmlns="http://www.ca.com/spectrum/restful/schema/response" error="EndOfResults"
  throttle="5" total-models="5">
   - <model-responses>
     - <model mh="0x1800178">
        <attribute id="0x1006e">ciscoRPM-9.18.ca.com</attribute>
        <attribute id="0x10000">Rtr_Cisco</attribute>
       </model>
     - <model mh="0x1800351">
        <attribute id="0x1006e">Rtr7301IPT_248</attribute>
        <attribute id="0x10000">Rtr_Cisco</attribute>
       </model>
     - <model mh="0x1800082">
        <attribute id="0x1006e">jun2300-96.17</attribute>
        <attribute id="0x10000">JuniperJUNOSRtr</attribute>
       </model>
     - <model mh="0x1800062">
        <attribute id="0x1006e">junM7i-96.20</attribute>
        <attribute id="0x10000">JuniperJUNOSRtr</attribute>
       </model>
     - <model mh="0x18002fb">
        <attribute id="0x1006e">AdminActive</attribute>
        <attribute id="0x10000">HPBladeOnboardAdmin</attribute>
       </model>
     </model-responses>
   </model-response-list>
```

Events

Use the events resource to create events.

NOTE
The events resource operates on a single model or groups of models.

- **Base URL**
  `http://<hostname><:portnumber>/spectrum/restful/events`

POST event

POST event creates a new event.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/events/<eventType>/model/<model_handle>[?varbind=<varbind id>][&val=<varbind value>]`
- **HTTP Method**
  POST
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Encoding**
  UTF-8
- **Output**
  XML or JSON listing the model handle of the created model or the error if the model cannot be created.

URL Parameters

- **<eventType>**
  Specifies the event type to be created.
- **<model_handle>**
  Specifies the model handle on which the event will be created.
- **<varbind id>**
  Specifies the varbind id.
- **<varbind value>**
  Specifies the varbind value.

POST events

Use POST events to create one or more events on one or more models. POSTing an event request lets you provide an XML document that specifies the events to create and the models on which to create them. The document contains a list of model handles, XML search criteria, or a reference to the existing search criteria on the OneClick server.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/events`
- **HTTP Method**
  POST
- **Body**
  Examples are provided in <$SPECROOT>/RestfulExamples/xml/Events. These XML files provide examples of properly formed XML for different purposes. Use these examples as a basis for your own XML:
  – CreateEventByModelHandleList.xml
  – CreateEventByModelSearch.xml
  – CreateMultipleEventsByModelHandle.xml
- **Body Content**
  application/xml
- **Header**

application/xml, application/json

- **Encoding**
  UTF-8
- **Output**
  XML or JSON listing of models satisfying the request input in the SpectroSERVER or distributed SpectroSERVER

Example: Create an event 0x10f06 on all RTR_Cisco Model Types, with 4 varbinds

The following is an example of creating an event 0x10f06 on all RTR_Cisco Model Types, with 4 varbinds

- **URL**

Post the following XML body to:

```
http://<hostname><:portnumber>/spectrum/restful/events
```

- **Body**

```
<?xml version="1.0" encoding="UTF-8"?>
<!--This sample event request will create an event of type 0x10f06 (generates a High Memory Utilization alarm)
 on all models found by the specified locater search (all models derived from RTR_Cisco) -->
<rs:event-request throttlesize="10" xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"

              <attribute id="AttributeID.MTYPE_HANDLE">
                <value>0x21000c</value> <!-- RTR_Cisco -->
              </attribute>
            </is-derived-from>
          </filtered-models>
        </rs:search-criteria>
      </rs:models-search>
    </rs:target-models>
   <!-- event ID -->
    <rs:event-type id="0x10f06"/>
    <!-- attributes/varbinds -->
    <rs:varbind id="0">75</rs:varbind>
    <rs:varbind id="1">99</rs:varbind>
    <rs:varbind id="3">mem_instance</rs:varbind>
    <rs:varbind id="5">name</rs:varbind>
  </rs:event>
</rs:event-request>
```

POST events (GET Tunneling)

This API is used to retrieve events of a model handle.

NOTE

This API is supported only on device models.

Attributes	Description
`model handle`	Specifies the device model handles to retrieve events
`start time and end time`	Specifies the start and end time in the epoch format.
`subcomponents events`	Specifies the events for subcomponents. Set to True if sub-components events are needed.
`exclude events`	Specifies the events which are excluded. These events if more than one are separated by coma.
`tags`	Specifies the requested attributes can be customized as per the user's preference, either fewer or more attributes can be requested.
`landscape`	Only one landscape can be supported.
`null`	Null value attributes will be returned if there is no existing value for the attribute.

- **URL**
  `http://ocserver:portnumber/spectrum/restful/events/getEvents`
- **HTTP Method**
  POST
- **Sample Body or Payload**

```

</get-event-responses>
<link type="application/xml" href="http://ocserver-portnumber/spectrum/restful/
events/getEvents?
id=cdf7caef-9c4a-4f28-9270-6b4b8e87feb6&amp;start=2&amp;throttlesize=2" rel="next"/>
</get-event-response-list>
```

- **Body Content**
  application/xml, application
- Header
  application/xml, application/json
- **Output**
  XML or JSON listing of model-response indicating the success or failure of each update.

landscapes

Use the Landscapes resource to retrieve landscape information.

- **Base URL**

```
http://<hostname><:portnumber>/spectrum/restful/landscapes
```

GET landscapes

GET landscapes returns information about all landscapes.

- **URL**
  http://<*hostname*><:*portnumber*>/spectrum/restful/landscapes
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing all landscapes in SpectroSERVER or distributed SpectroSERVER

Example

The following URL requests all landscapes:

```
http://localhost/spectrum/restful/landscapes
```

The following is returned for the request:

```
  <?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
- <landscape-response xmlns="http://www.ca.com/spectrum/restful/schema/response" total-landscapes="1">
  - <landscape>
      <id>0x1800000</id>
      <name>comp001</name>
      <isPrimary>true</isPrimary>
      <spectrumVersion>9.2.1.005</spectrumVersion>
    </landscape>
  </landscape-response>
```

model

Contents

Use the model resource to create or delete a model and to read or modify model attributes. An example that illustrates model creation is included in this section. For more information, see Example: Create a Model Based on Model Type.

NOTE
The model resource operates on a single model at a time. For groups of models, use the models resource.

- **Base URL**
  `http://<hostname><:portnumber>/spectrum/restful/model`

POST model

The POST model lets you creates a new model and update list attribute on the Specified model.

Create a New Model

The following POST model creates a new model and returns the model handle.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/model[?landscapeid=<landscape_handle>]`
  `[&mtypeid=<mtype_handle>][&agentport=<snmp_port>][&commstring=<comm_str>][&retry=<retry_cnt>]`
  `[&timeout=<timeout_val>][&ipaddress=<ip_address>][&parentmh=<model_handle>][&relationid=<rel_handle>]`
  `[&attr=<attr_id>&val=<num>]`
- **HTTP Method**
  POST
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing the model handle of the created model or the error if the model cannot be created

URL Parameters

- **&landscapeid=<*landscape_handle*>**
  (Optional) Specifies the landscape where the model will be created.
- **&mtypeid=<*mtype_handle*>**
  (Optional) Specifies the model type handle of the model to be created. Required if the ipaddress parameter is not specified (see below).
- **&agentport=<*snmp_port*>**
  (Optional) Specifies the SNMP management port on the device.
  Default: 161
- **&commstring=<*comm_str*>**
  (Optional) Specifies the community string.
  Default: public
- **&retry=<*retry_cnt*>**
  (Optional) Specifies the retry count.
  Default: 3
- **&timeout=<*timeout_val*>**
  (Optional) Specifies the timeout value.

Default: 3000

- **&ipaddress=<*ip_address*>**
  (Optional) Specifies the IP address.
- **&parentmh=<*model_handle*>**
  (Optional) Specifies the parent (left Association) model.
- **&relationid=<*rel_handle*>**
  (Optional) Specifies the association from the parent to this model.
  Default: Collects
- **&attr=<*attr_id*>&val=<*num*>**
  (Optional) Specifies attribute ID and value.

Update List Attribute on the Specified Model

The following POST model updates the list attribute on the specified model.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/model/attr/update`
- **HTTP Method**
  POST
- **Body**
  XML
- **Body Content**

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<update-model-attrlist-request xmlns="http://www.ca.com/spectrum/restful/schema/request">
  <model mh="<model_handle>"/>
  <attribute-list id="<attribute_id>">
    <instance oid="<instance_id_0>" value="<value>"/>
    <instance oid="<instance_id_1>" value="<value>"/>
  </attribute-list>
</update-model-attrlist-request>
```

- **Body Parameters**
  <model mh="<model_handle>"/>
  Specifies the model to update.
  <attribute-list id="<attribute_id>">
  Specifies the attribute ID to update.
  <instance oid="<instance_id_0>" value="<value>"/>
  Specifies the instance id and values to update.

  NOTE
  Repeat the instance id tag to update multiple instances in the list attribute.
- **Header**
  application/xml, application/json
- **Output**
  XML listing the model handle of the updated model or an error if the model cannot be updated.

GET model

GET model reads attributes from the specified model.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/model/<model_handle>[?attr=<attr_ID>]`
- **HTTP Method**

GET

- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing of the requested attributes

URL Parameters

- ***model_handle***
  Specifies the model.
- **&attr=<*attr_ID*>**
  (Optional) Specifies the requested attributes. Multiple attribute parameters can be specified.

PUT model

PUT model updates attributes on the specified model.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/model/<model_handle>?attr=<attr_ID>&val=<num>`
- **HTTP Method**
  PUT
- **Body**
  None
- **Body Content**
  Not Used
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing of the requested attributes

URL Parameters

- ***model_handle***
  Specifies the model to update.
- **&attr=<*attr_ID*>&val=<*num*>**
  Specifies the attributes and values to update. Multiple attribute-value pairs can be specified.

DELETE model

DELETE model deletes the specified model.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/model/<model_handle>`
- **HTTP Method**
  DELETE
- **Body**
  None
- **Body Content**
  Not Used
- **Header**

application/xml, application/json

- **Output**
  XML or JSON listing indicating success or failure

URL Parameters

- ***model_handle***
  Specifies the model to delete.

Example Create a Model Based on Model Type

You can use the POST method to create a model based on a model type. Use the model noun and the model type ID for the model type that you want to create. You can deploy this basic method to create pingable models, user models, maintenance schedules, containers, and any other type of model that you can create using DX NetOps Spectrum web services.

The basic format to use is shown in the following URL. Variables are indicated with *italics*:

http*://hostname*:*portnumber*/spectrum/restful/model[?mtypeid=*modeltype_of_a_device*][&parentmh=*model_handle*][&relationid=*rel_handle*][&attr=*attr_id*&val=<num>]

Example

Use any REST client to post the following URL:

http://*host IP address*:*portnumber*/spectrum/restful/model?mtypeid=0x00010290&parentmh=0x40000005&attr=0x12d7f&val=10.13.12.111

In this example, we supplied the following parameters:

- **val**
  The IP address of a pingable device (in this example, 10.13.12.111).
- **mtypeid**
  The model type of a device that you are modeling. In this example, it is a pingable device, 0x00010290. To find the model type ID for the model type that you want to create, use the Search feature in the Model Type Editor.
- **parentmh**
  The model_handle for a universe.
- **relationid**
  (Optional) The relation ID to identify an association between two models in the model domain (a relation).
- **attr**
  The attribute ID of ipaddress. The value is the device IP address.

models

Use the Models resource to retrieve and update models and attributes.

NOTE
The models resource operates on groups of models. For a single model, use the model resource.

Base URL

```
http://<hostname><:portnumber>/spectrum/restful/models
```

POST models (GET Tunneling)

Use POST models to get all model handles and requested attributes. POSTing a models request lets you provide an XML document that specifies the models to retrieve. The document contains a list of model handles, XML search criteria, or a reference to the existing search criteria on the OneClick server.

WARNING
POST models is a form of GET Tunneling used to retrieve multiple models. You cannot create a model with POST models. To create a model, use POST model.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/models`
- **HTTP Method**
  POST
- **Body**
  Examples are provided in <*$SPECROOT*>/RestfulExamples/xml/Models. These XML files provide examples of properly formed XML for different purposes. Use these examples as a basis for your own XML:
  – GetCiscoRouterModels.xml
  – GetModelsByModelHandles.xml
  – GetModelsFromExistingSearch.xml
- **Body Content**
  application/xml
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing of models satisfying the request input in the SpectroSERVER or distributed SpectroSERVER

Example 1: Java CALL

The following is an example call:

```
Java GenericPoster noun=Models file=resources/xml/Models/GetCiscoRouterModels.xml server=localhost
 username=jdoe password=spectrum port=8080
```

Example: Request XML to find device models by IP address

The following is an example of how to find device models by IP address by embedding the correct locater search in the POST body of a models GET. This operation searches all landscapes in a distributed SpectroSERVER environment as well as allowing you to specify the attributes of interest.

- **URL**
  POST the following XML body to:
  `http://<hostname><:portnumber>/spectrum/restful/models`
- **Body**

```
<?xml version="1.0" encoding="UTF-8"?>
<rs:model-request throttlesize="5"
 xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/
Request.xsd">
<rs:target-models>
 <rs:models-search>
 <rs:search-criteria xmlns="http://www.ca.com/spectrum/restful/schema/filter">
 <action-models>
```

```
 <filtered-models>
 <equals>
 <model-type>SearchManager</model-type>
 </equals>
 </filtered-models>
 <action>FIND_DEV_MODELS_BY_IP</action>
 <attribute id="AttributeID.NETWORK_ADDRESS">
 <value>172.22.96.6</value>
 </attribute>
 </action-models>
 </rs:search-criteria>
 </rs:models-search>
 </rs:target-models>
<rs:requested-attribute id="0x1006e" />
 <rs:requested-attribute id="0x10000" />
 <rs:requested-attribute id="0x10032" />
 <rs:requested-attribute id="0x12de2" />
</rs:model-request>
```

Example 2: Query list of device names and ip addresses that belong to a Global Collection

Method 1: The following is an example of how to query device names and IP addresses that belong to a Global Collection.

- **URL**
  POST the following XML body to:
  `http://<hostname><:portnumber>/spectrum/restful/models`
- **Body**

```
<?xml version="1.0" encoding="UTF-8"?>
<rs:model-request throttlesize="5"
 xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/
Request.xsd">
<rs:target-models>
 <rs:models-search>
 <rs:search-criteria
 xmlns="http://www.ca.com/spectrum/restful/schema/filter">
 <filtered-models>
 <has-substring>
 <attribute id="0x12adb"> <!-- This attribute stores the list of global collections
 to which a model belongs -->
 <value>gc1</value> <!-- Name of the Global Collection -->
 </attribute>
 </has-substring>
 </filtered-models>
 </rs:search-criteria>
 </rs:models-search>
```

```
    </rs:target-models>
   <rs:requested-attribute id="0x1006e" /> <!-- Model Name -->
    <rs:requested-attribute id="0x12d7f" /> <!-- Network Address -->
   </rs:model-request>
```

Method 2: You can also create a custom search criteria file (xml file) at "<SPECROOT>\tomcat\webapps\spectrum\WEB-INF\topo\config", and use it in the following xml file:

The following is the content of the search-devices-criteria.xml:

```
<?xml version="1.0" encoding="utf-8"?
>
 <search-criteria id="search-devices-criteria"
   xmlns="http://www.aprisma.com"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.aprisma.com../../common/schema/search-criteria-
config.xsd">
   <action-models>
     <filtered-models>
       <equals>
         <model-type>SearchManager</model-type>
       </equals>
     </filtered-models>
     <action>0x10474</action>
     <attribute id="AttributeID.MODEL_NAME">
       <value>gc1</value>
     </attribute>
   </action-models>

 </search-criteria>
```

Example 3: The following is an example of how to get JuniperJUNOSRtr model type from one landscape in a DSS environment.

- **URL**

  ```
  http://OCServer/spectrum/restful/models
  ```

- **Body**

  ```
  <rs:model-request throttlesize="500"
   xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/
  Request.xsd
   ">
   <rs:landscape id="0x100000" />
   <rs:target-models>
   <rs:models-search>
   <rs:search-criteria xmlns="http://www.ca.com/spectrum/restful/schema/filter">
   <filtered-models>
   <and>
  ```

```
 <equals>
 <attribute id="0x10001">
 <value>0x3b10002</value>
 </attribute>
 </equals>
 </and>
 </filtered-models>
 </rs:search-criteria>
 </rs:models-search>
 </rs:target-models>
 <rs:requested-attribute id="0x1006e" />
</rs:model-request>
```

- **Response**

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<model-response-list xmlns="http://www.ca.com/spectrum/restful/schema/response"
 total-models="1" throttle="1" error="EndOfResults">
 <model-responses>
 <model mh="0x1001d4">
 <attribute id="0x1006e">junM7i-96.19</attribute>
 </model>
 </model-responses>
</model-response-list>
```

NOTE

More than one landscape can be mentioned as shown:

<rs:landscape id="0x100000" />
<rs:landscape id="0x600000" />

GET models

GET models returns model handles and requested attributes. To retrieve specific model attributes, use the &attr=<*attr_id*> parameter.

WARNING
GET models can be used only after a POST (GET Tunneling) models has been performed. POST models generates the result set, and GET models is used to retrieve model handles and attribute information for the items within that result set.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/models?id=<result_set_pointer>[&attr=<attr_ID>]
[&landscape=<landscape_handle>][&throttlesize=<num>]
```

- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  Not used
- **Header**
  application/xml, application/json
- **Output**

XML or JSON listing of models satisfying the request input in the SpectroSERVER or distributed SpectroSERVER

URL Parameters

- **?id=<*result_set_pointer*>**
  Specifies the location of the result set on the OneClick server. This value is generated by using POST (GET Tunneling) models and appears on the "next" relative link. The location expires on the OneClick server after ten minutes of inactivity.
- **&attr=<*attr_ID*>**
  (Optional) Specifies the requested attributes. Multiple attribute parameters can be specified.

  NOTE
  There are many attributes on a model; for best performance you should limit attribute selection to attributes of interest. Not all models support the same set of attributes. Unsupported attributes will return 'NoSuchAttribute'
- **&landscape=<*landscape_handle*>**
  (Optional) Filters which landscapes are queried. Multiple landscape parameters can be specified.
- **&throttlesize=<*num*>**
  (Optional) Specifies a throttle size.

PUT models

PUT models updates attributes across multiple models. The models can be selected by a variety of techniques including search criteria. Not all selected models need to support the attributes being modified.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/models`
- **HTTP Method**
  PUT
- **Body**
  Uses Request.xsd:update-models-request. The Request.xsd is located in <*$SPECROOT*>/RestfulExamples/src/xsd
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing of model-response indicating the success or failure of each update.

GET (/models)

This API can be used to retrieve the models of a Global Collection. This rest call will accept the Global Collection name and retrieve those devices which are a part of the Global Collection.

- **URL**
  `http://ocserver:port/spectrum/restful/models`
- **HTTP Method**
  GET
- **Body**

```
<?xml version="1.0" encoding="UTF-8"?>
<rs:model-request throttlesize="100"
 xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
 xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/
Request.xsd
 ">
 <rs:target-models>
 <rs:gc name="GC1"/>
 </rs:target-
models>
 <rs:requested-attribute id="0x1006e" />
 <rs:requested-attribute id="0x10000" />
 <rs:requested-attribute id="0x10032" /
>
 </rs:model-request>
```

- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing of model-response indicating the success or failure of each update.

subscription

Use the Subscription resource to create or retrieve subscriptions. A *subscription* is a request to be notified of activity on any of the following:

- Model types/attributes. Registers watches for model creation/deletion of type and attribute changes on those types.

  NOTE
  ModelType subscriptions watch for new models.
- Models/attributes. Registers watches on specified models and related attribute changes.
- Alarms/attributes. Registers watches for alarm creation/clearing and attribute changes.
- **Base URL**

```
http://<hostname><:portnumber>/spectrum/restful/subscription
```

POST Subscription

POST subscription creates a subscription. Subscriptions are *pull* or *push*. A *pull* subscription requires that the client poll the subscription ID whereas a *push* subscription requires that the client provide a URL to which notifications can be POSTed. Notifications contain change information in XML or JSON format.

NOTE
Push subscriptions are useful when the integration client is another OneClick server.

- **URL**

```
http://<hostname><:portnumber>/spectrum/restful/subscription
```

- **HTTP Method**
  POST
- **Body**
  Uses Request.xsd:subscription-request. The Request.xsd is located in <*$SPECROOT*>/RestfulExamples/src/xsd
  For specific examples of Subscription XML, see the following:

  - In <*$SPECROOT*>/RestfulExamples/xml/Alarms:
    - PullAlarmsSubscription.xml
  - In <*$SPECROOT*>/RestfulExamples/xml/Models
    - PullAttrWatchForAllDevices.xml
  - In <*$SPECROOT*>/RestfulExamples/xml/MTypes:
    - PullWatchForNewMTypes.xml
    - PushWatchForNewMTypes.xml
    - PushWatchForNewMTypesBatchMode.xml
    - PushWatchForNewMTypesNoExpiration.xml
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  XML or JSON listing the subscription-id
  - **subscription-id**
    Identifies the subscription. This value is used with GET subscription and DELETE subscription and expires if not used.

Body Parameters

The following parameters are used in the subscription request body XML.

- For pull subscriptions:
  - **max-notifications**
    Specifies the number of notification items.
    Default: 100
  - **max-queue-size**
    Specifies the number of notifications to queue.
    Default: 10000
  - **pull-interval**
    Specifies the frequency of polling in milliseconds.

    NOTE
    Subscriptions expire if not polled.

    Minimum: 5000

    NOTE
    If you expect a high frequency of notifications, you can accommodate plenty of notifications in the queue by increasing the **max-queue-size**. Simultaneously, to avoid a full queue, increase the **max-notifications** to pull more notifications in every poll. To empty the queue at a faster rate, reduce the **pull-interval**.

    For a POST Subscription request containing multiple InstanceRequests in it (for example, multiple GC Models in the body), allocate ThreadPoolSize, so that these individual InstanceRequests can be processed in parallel by individual threads. The default value is 20 and it should be sufficient. You can set the ThreadPoolSize in OneClickService.conf (Windows) or catalina.sh (Non-Windows) by adding this property under jvm_opts:

    ```
    restful.subscription.ThreadPoolSize=<int-value>
    ```

- For push subscriptions:
  - **destination-url**
    Specifies the URL where notifications are POSTed.
    A test notification servlet has been if prints results to the DX NetOps Spectrum tomcat log. This servlet is installed with DX NetOps Spectrum, and no additional configuration is required. To use the servlet, set the destination-url to:

    ```
    http://<hostname><:portnumber>/spectrum/restful/TestNotifications
    ```

Each time a notification is received it is printed to the DX NetOps Spectrum tomcat log, as follows:
- For Windows: <*$SPECROOT*>/tomcat/logs
- For Linux: <*$SPECROOT*>/tomcat/logs/catalina.out

– **username**
Specifies the user name required by the destination URL.
– **password**
Specifies the password required by the destination URL.
– batch-notifications
- **max-notifications**
Specifies the number of notifications in a batch. If this number is reached, notification is sent immediately.
Default: 100
- **max-time**
Specifies the time in milliseconds to wait before sending notifications. If this number is reached, notifications are sent immediately.
Default: 1000

– **heartbeat-interval**
Specifies the interval in milliseconds that the subscription is validated. The subscription servlet sends a message every hearbeat-interval to the receiving servlet (designated by the destination-url) to indicate that the subscription is active. If the receiving servlet stops receiving the heartbeat message, it knows that the subscription has stopped (for example, if the OneClick server stops or restarts). If the receiving servlet becomes unavailable, notifications stop.

NOTE
The TestNotifications servlet does not print the heartbeat message.

Example

The following is an example subscription registration snippet:

```
<rs:destination-url>http://<hostname><:portnumber>/spectrum/restful/TestNotifications</rs:destination-url>
<rs:username><user></rs:username>
<rs:password><password></rs:password>
```

The following is an example Java call:

```
Java GenericPoster noun=Models file= RestfulExamples/xml/Models/PullAttrWatchForAllDevices.xml
 server=localhost username=jdoe password=spectrum port=8080
```

GET Subscription

Use GET subscription to return XML describing all the changes of interest based on the initial subscription request.

NOTE
GET subscription applies to the pull model only.

- **URL**
  `http://<hostnumber><:portnumber>/spectrum/restful/subscription/<subscription_ID>`
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json

URL Parameters

- ***subscription_ID***
  Specifies the subscription ID. This value is returned from the original subscription request (POST subscription) or GET subscription/requests. It is used to obtain the set of changes since the last request.

GET subscription/requests

Use GET subscription/requests to return a string of the current, active subscriptions. This request is used primarily for debugging or verification purposes to see if a particular model, type or attribute is registered for notification.

> **NOTE**
> To pull the actual model, model type, and attribute changes, see GET subscription.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/subscription/requests`
- **HTTP Method**
  GET
- **Body**
  None
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json
- **Output**
  HTML page listing the subscription-id and other subscription-related information for each current, active subscription
  - **subscription-id**
    Identifies a subscription. This value is used with GET subscription and DELETE subscription.

DELETE subscription

DELETE subscription deletes the specified subscription.

- **URL**
  `http://<hostname><:portnumber>/spectrum/restful/subscription/<subscription_ID>`
- **HTTP Method**
  DELETE
- **Body**
  None
- **Body Content**
  application/xml, application
- **Header**
  application/xml, application/json

URL Parameters

- ***subscription_ID***
  Specifies the subscription to delete. This value is returned from the original subscription request (POST subscription) or GET subscription/requests.

Alarm and Model Attributes

The follow table contains alarm and model attributes that are commonly used when using the DX NetOps Spectrum Web Services API. *Italicized* items are model attributes. Non-italicized items are alarm-specific attributes.

Attribute Specification	Attribute Name	Data Type
0x10000	*Model Type Name*	*Text String*
0x10001	*Model Type of Alarmed Model*	*Model Type Handle*
0x10009	*Security String*	*Text String*
0x1000a	*Condition*	*Integer*
0x1006e	*Model Name*	*Text String*

REST Operations (Verbs)

The following REST verbs are supported in the DX NetOps Spectrum Web Services API. All operations respect standard DX NetOps Spectrum user security.

- POST (Create)
- GET (Read)
- PUT (Update)
- DELETE (Delete)

> **NOTE**
> The HEAD, OPTIONS, and TRACE verbs are not supported in the DX NetOps Spectrum Web Services API.

Web Application Description Language (WADL) URL

The following is the WADL URL for the DX NetOps Spectrum Web Services API:

```
http://<hostname><:portnumber>/spectrum/restful/services
```

> **NOTE**
> The WADL is provided for advanced users and describes the simple URLs but does not describe GET Tunneling. Use the schema files for GET Tunneling.

XML Schema Definitions

Input and output data transfer is done in XML, conforming to a strict schema that enables standard access to data from different applications. The schemas provided in the DX NetOps Spectrum Web Services API defines the correct data layout for all valid requests and responses.

Used to define the required syntax for GET Tunneling, the schema files are also more useful than WADL for advanced usage. The schema files are used to generate the JAXB beans that can be used for java and javascript development. These beans are available in <*$SPECROOT*>/RestfulExamples/lib/spectrumrest.jar.

DX NetOps Spectrum provides the following XML Schema Definitions (.xsd) files, which are located in <*$SPECROOT*>/RestfulExamples/src/xsd:

- **Filter.xsd**
  Specifies the XML for attribute filters and search criteria.

  > **NOTE**
  > This is the same XML that is used by the DX NetOps Spectrum Locater; however, the Filter.xsd is only used by the DX NetOps Spectrum Web Services API.
- **Request.xsd**
  Defines the XML format used in GET Tunneling. All POST body XML must have a tag like the following:
  ```
  xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/Request.xsd">
  ```
- **Response.xsd**
  Defines the XML or JSON format for all synchronous responses and XML format for all asynchronous responses.

Java Code and XML Examples

Java Code Examples

The DX NetOps Spectrum Web Services API provides example Java code that demonstrates basic functionality, JAXB beans, and hard-coded XML. An Eclipse .project and .classpath are also provided. The files are located in <*$SPECROOT*>/RestfulExamples/src/test.

NOTE
Each of the example programs requires certain parameter values to be provided.

The following examples are provided in the /client subfolder.

- **AlarmPoller**
  Subscribe for and pull alarms.
- **CreateSimilarModels**
  Create many models of the same type.
- **GenericPoster**
  A generic way to POST XML.
- **GetAllAlarms**
  A simple alarm reader.
- **GetAllDevices**
  A simple example that reads attributes on devices.
- **GetAllLandscapes**
  The simplest example.
- **GlobalCollectionExample**
  Creates a new Global Collection Model.

For more information, see the readme.txt files and internal documentation.

Program Arguments

The following program arguments are used by the provided Java code examples.

- **server={*server*}**
  Specifies the host name of the OneClick server.
- **username={*username*}**
  Specifies a user name for the OneClick server.
- **password={*password*}**
  Specifies the username password for the OneClick server.
- **method={*method*}**
  Specifies the REST verb, or HTTP method.
  Values: GET, POST, PUT, DELETE
- **port={*port*}**
  (Optional) Specifies the port number of the OneClick server.
  Default: 80
- **accept={*acceptType*}**
  (Optional) Specifies the accept header value/MIME type.
  Values: application/xml, application/json
  Default: application/xml
- **inputdata={*inputdataType*}**
  (Optional) Specifies the body content type.
  Value: application/xml
- **secure=true|false**
  (Optional) Specifies whether to secure the connection to the OneClick server.
  Default: False

If set to True, the following parameters are required:

- **keystore_file={*fqfn for keystore file*}**
  Specifies the fully-qualified keystore file name.
- **keystore_password={*keystore password*}**
  Specifies the password for the keystore.
- **alias={*certificate alias*}**
  Specifies the certificate alias name.

> **NOTE**
> To use a secure connection, the OneClick server must be configured for SSL. For information about configuring OneClick for SSL, see the OneClick Administration section.

XML Examples

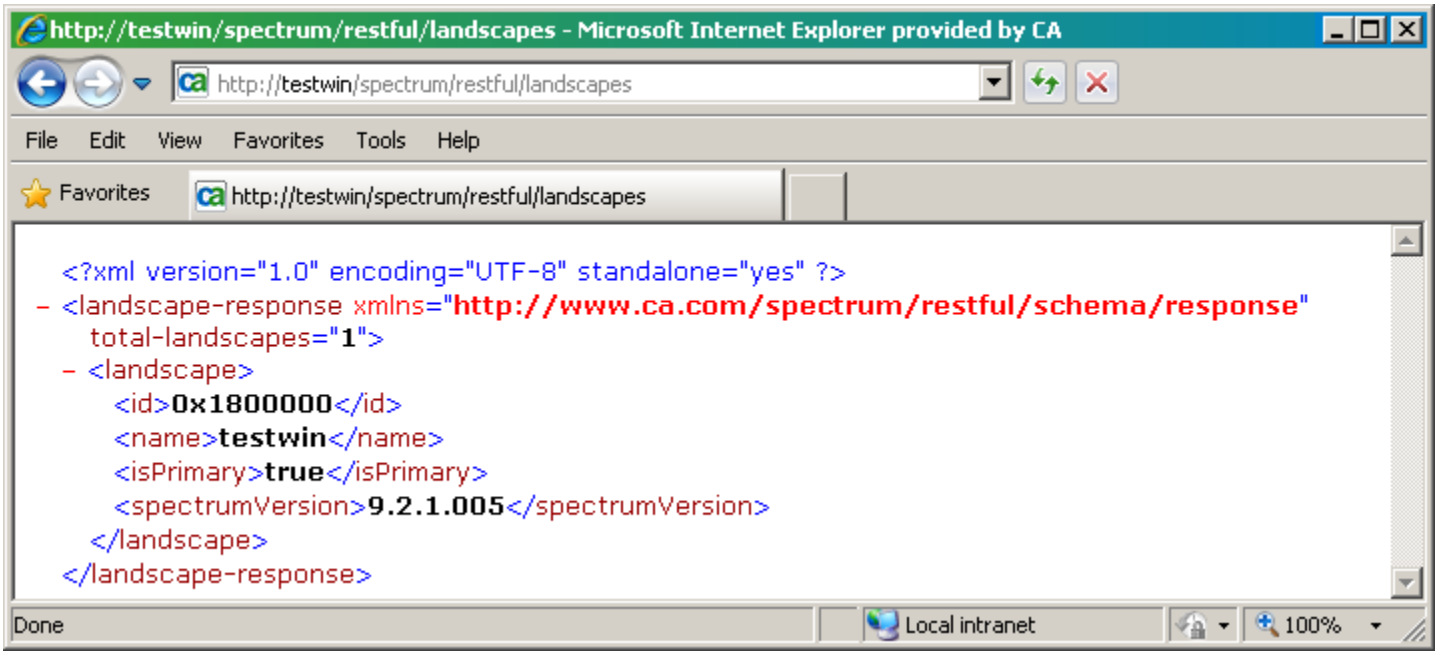
The DX NetOps Spectrum Web Services API provides example XML for GET Tunneling requests. The files are located in <*$SPECROOT*>/RestfulExamples/xml.

The following examples are provided:

- Alarms
  - GetAlarmsByAlarmIDs.xml
  - GetAlarmsByAttributeFilter.xml
  - GetAlarmsByModelHandles.xml
  - GetAlarmsBySearchCriteria.xml
  - GetAlarmsForAllDevices.xml
  - PullAlarmsSubscription.xml
  - FilterSecondaryAlarmsWhenInMaintenance.xml
- Events
  - CreateEventByModelHandleList.xml
  - CreateEventByModelSearch.xml
  - CreateMultipleEventsByModelHandle.xml
- Models
  - GetCiscoRouterModels.xml
  - GetModelsByModelHandles.xml
  - GetModelsFromExistingSearch.xml
  - PullAttrWatchForAllDevices.xml
  - PutModelsByModelHandles.xml
- ModelTypes (MTypes)
  - PullWatchForNewMTypes.xml
  - PushWatchForNewMTypes.xml
  - PushWatchForNewMTypesBatchMode.xml
  - PushWatchForNewMTypesNoExpiration.xml

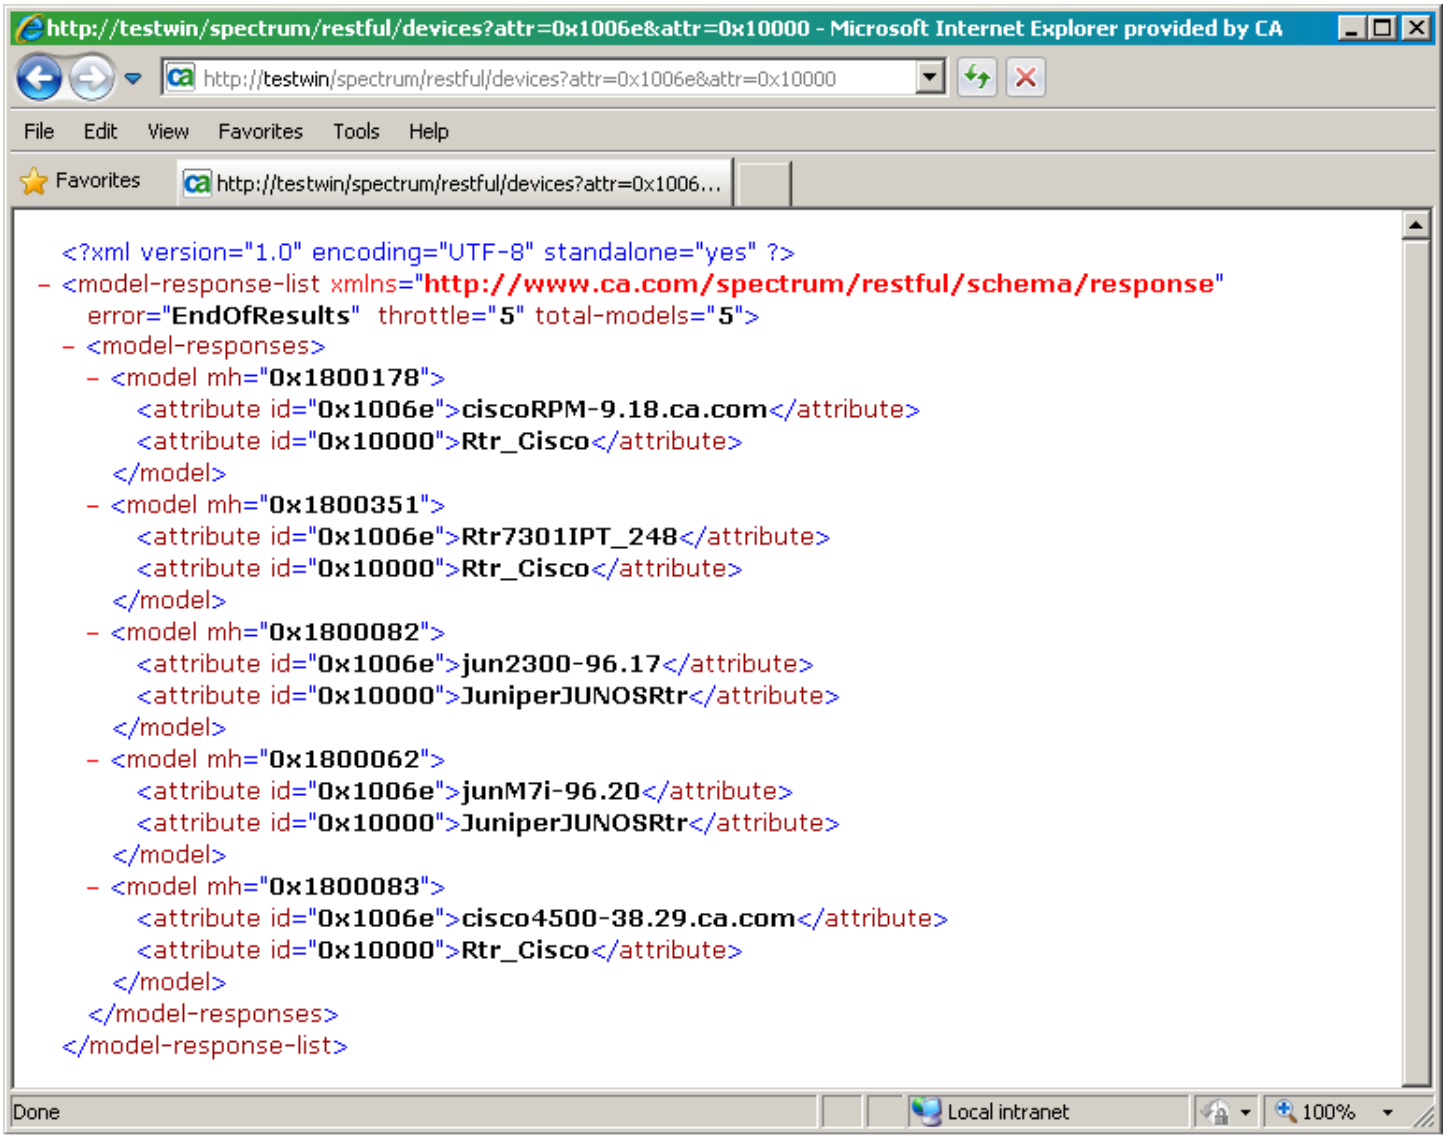
Simple URL Request in Browser

This example shows a GET landscapes request and results in a browser window. The GET verb is implied in the browser environment. Parameters are not necessary on the URL to return a list of all landscapes in the distributed SpectroSERVER environment.



Simple URL Request with Parameters in a Browser

This example uses the devices noun with URL parameters to request the name (0x1006e) and model type (0x10000) of all devices. The GET verb is implied in the browser environment.



Using Throttle and Next

This example uses GET alarms to retrieve all alarms and shows how the throttle and "next" link are used.

Follow these steps:

1. Use the following request, which asks for all alarms to be returned but only three at a time:

   ```
   http://comp001/spectrum/restful/alarms?throttlesize=3
   ```

   Notice the following in this request:

   – **throttlesize**
   Indicates the number of items to return at a time. This example requests three alarms to be returned at a time.

   The following response returns from the SpectroSERVER. This response indicates that a total of five alarms exist and only three are returned. A relative link is provided that points to the next items in the list.

   ```
   <?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
   - <alarm-response-list xmlns="http://www.ca.com/spectrum/restful/schema/response" throttle="3" total-alarms="5">
   ```

```
- <alarm-responses>
    <alarm id="4e77f4fd-1c9b-1000-0336-000874f00c29" />
    <alarm id="4e77f4fe-1ca2-1000-0336-000874f00c29" />
    <alarm id="4e80da2b-a48e-1001-0336-000874f00c29" />
  </alarm-responses>
  <link rel="next" href="http://comp001/spectrum/restful/alarms?id=c6a367df-0b3e-4461-aa8d-
aad451a45bf7&start=3&throttlesize=3" type="application/xml" />
  </alarm-response-list>
```

Notice the following in this response:

- **throttle**
  Indicates the number of items returned in this response. In this example, three alarms have been returned in this response.
- **total-alarms**
  Indicates the total number of items in the result set. In this example, there a five total alarms in the result set.
- **link rel="next"**
  Indicates the URL to retrieve the next items in the result set. This link can be used in a browser or a program to issue the next request.
  - **id=<*result_set_ID*>**
    Specifies the location of the result set on the OneClick server. The data expires after ten minutes of inactivity.
  - **start=<*element_num*>**
    Indicates the position within the result set.

2. Use the "next" relative link from the previous response to request the next three items in the result set:

```
http://comp001/spectrum/restful/alarms?id=c6a367df-0b3e-4461-aa8d-
aad451a45bf7&start=3&throttlesize=3
```

The following response returns from the SpectroSERVER:

```
  <?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
- <alarm-response-list xmlns="http://www.ca.com/spectrum/restful/schema/response" error="EndOfResults"
 throttle="2" total-alarms="5">
- <alarm-responses>
    <alarm id="4e83d694-18e1-1002-0336-000874f00c29" />
     <alarm id="4e77f4fe-1c9e-1000-0336-000874f00c29" />
  </alarm-responses>
</alarm-response-list>
```

Notice the following in this response:
error="EndOfResults"
Indicates that all items in the list have been retrieved.

Using URL and GET Tunneling for Same Request

This example shows the same request made by a URL request and a GET Tunneling request.

- URL Request
- GET Tunneling Request

URL Request

This example uses GET devices, in a simple URL request format, to retrieve attributes for all devices, throttling at 100.

Initial request

This request specifies the attributes to read:

```
http://localhost/spectrum/restful/devices?attr=0x1006e&attr=0x10000&attr=0x10032&attr=0x12de2&throttlesize=100
```

All matching devices are found and cached. The first 100 devices are returned, and, if there are more than 100, a link to get the next 100.

Subsequent request

Using the link from the initial request-response, the following request pulls the next set of results from the cache:

```
http://localhost/spectrum/restful/devices?id=0120a63a-e2d3-4175-9563-c17c90c783a7&start=100&throttlesize=100
```

GET Tunneling Request

This example uses GET devices, in embedded XML request format, to retrieve attributes for all devices, throttling at 100.

```
<?xml version="1.0" encoding="UTF-8"?>

<rs:model-request throttlesize="100"
  xmlns:rs="http://www.ca.com/spectrum/restful/schema/request"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.ca.com/spectrum/restful/schema/request ../../../xsd/Request.xsd ">

    <rs:target-models>
      <rs:models-search>
        <rs:search-criteria-file>
          topo/config/search-devices-criteria.xml
        </rs:search-criteria-file>
      </rs:models-search>
    </rs:target-models>

    <rs:requested-attribute id="0x1006e" /> <!-- Model name -->
    <rs:requested-attribute id="0x10000" /> <!-- Model Type Name -->
    <rs:requested-attribute id="0x10032" /> <!-- Manufacturer -->
    <rs:requested-attribute id="0x12de2" /> <!-- NRM_RunningFirmwareFilters -->

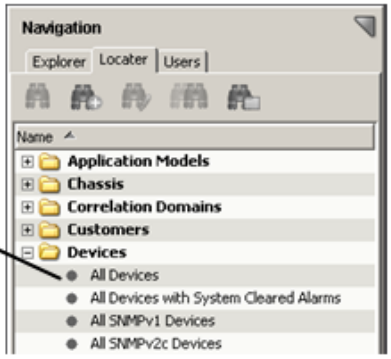
</rs:model-request>
```

Throttlesize set to 100

Schema

Uses existing search in OneClick Server

Attributes to read



The following portions of Request.xsd are of interest for this example. This request uses the *model-request* type. The type definition determines the parameters that can be specified, in this case, "target-models", "requested-attribute", and "throttlesize".

> **NOTE**
> See the complete contents in <*$SPECROOT*>/RestfulExamples/src/xsd/Request.xsd.

```
<xs:complexType name="model-request">
  <xs:sequence>
    <xs:element name="target-models" type="rs:target-models" minOccurs="1"
      maxOccurs="1" />
    <xs:element name="requested-attribute" type="rs:requested-attribute"
      minOccurs="0" maxOccurs="unbounded" />
  </xs:sequence>
  <xs:attribute name="throttlesize" type="xs:int" />
</xs:complexType>
   .
   .
   .
```

```
<xs:complexType name="target-models">
  <xs:choice>
    <xs:element name="model" type="rs:model" minOccurs="0" maxOccurs="unbounded" />
    <xs:element name="models-search" type="rs:models-search" minOccurs="0"
      maxOccurs="1"/>
  </xs:choice>
</xs:complexType>
   .
   .
   .
<!-- Elements -->

<xs:element name="alarm-request" type="rs:alarm-request" />
<xs:element name="model-request" type="rs:model-request" />
<xs:element name="subscription-request" type="rs:subscription-request" />
<xs:element name="update-models-request" type="rs:update-models-request" />
```

Troubleshooting the Web Services API Issues

Common Issues

If you are experiencing problems when using the DX NetOps Spectrum Web Services API, check the following:

- Is the URL constructed correctly?
- Is the correct verb used with the noun?
- Is the Request XML for GET Tunneling constructed correctly?
- Have the proper credentials been entered?
- Has the "accept" header and "Content-type" been set correctly for XML or JSON?
- Do any DX NetOps Spectrum Web Services API errors appear in the tomcat log?

"Next" Link Does not Work

Symptom:

The "next" link that was generated in a response does not work correctly when I try to retrieve the next throttled set of results.

Solution:

The format of the parameters within the generated link may vary depending on your environment. For example, "&" may be generated as "&" This is due to differences between XML, HTTP, and JSON formatting standards. Notice the difference in the prefixes for the start and throttlesize parameters in the following URLs:

```
http://localhost/spectrum/restful/models?id=5b03b5ba-64ed-4603-
b3e1-8e71919fccd8&#38;start=2&#38;throttlesize=2
http://localhost/spectrum/restful/models?id=5b03b5ba-64ed-4603-b3e1-8e71919fccd8&start=2&throttlesize=2
```

To correct, change '&amp' to '&' in your URL.

> **NOTE**
> This applies to XML only (not JSON).

Web Services API Search Crashes the SpectroSERVER

Symptom:
The DX NetOps Spectrum SpectroSERVER crashes shortly after running a webservices api search.
The stack output will look similar to this (with the key beingCsModelDomainSrvc::getModelIDListByXmlSearchCriteria):

```
#0 0x00002b2f85bc9ca0 in CsBuffer::makestr(int, char) const () from /opt/SPECTRUM/lib/libGlobl.so.1
#0 0x00002b2f85bc9ca0 in CsBuffer::makestr(int, char) const () from /opt/SPECTRUM/lib/libGlobl.so.1
#1 0x00002b2f7e8d46cb in CsLandscape::search_keyed_models(CsFindSpec const*, CsULHashTable*,
 CsFindSpec::LogicalOp_e, CsULHashTable*, int) () from /opt/SPECTRUM/lib/../SS/libsskrnl.so.1
#2 0x00002b2f7e8d4ad7 in CsLandscape::terminal_find_model_handles(CsFindSpec const*, CsULHashTable*,
 CsFindSpec::LogicalOp_e, CsError::CsError_e*, int) () from /opt/SPECTRUM/lib/../SS/libsskrnl.so.1
#3 0x00002b2f7e8d4ee6 in CsLandscape::find_model_handles(CsFindSpec const*, CsError::CsError_e*, CsSecurityIf
 const*, int) () from /opt/SPECTRUM/lib/../SS/libsskrnl.so.1
#4 0x00002b2f7e8d5786 in CsLandscape::find_models(CsFindSpec const*, CsSecurityIf const*, int) () from /opt/
SPECTRUM/lib/../SS/libsskrnl.so.1
#5 0x00002b2f7e8d5871 in CsLandscape::find_models(CsFindSpec const*, CsSecurityIf const*) () from /opt/
SPECTRUM/lib/../SS/libsskrnl.so.1
#6 0x00002b2f7e8f8d04 in CsModelDomainSrvc::get_model_desc_list(CsSecurityIf const&, char const*, char const*,
 CsULHashTable*) () from /opt/SPECTRUM/lib/../SS/libsskrnl.so.1
#7 0x00002b2f7e8f9b4c in CsModelDomainSrvc::getModelIDListByXmlSearchCriteria(CsCAttribute::CsCValue const&,
 CsSecurityIf const&) () from /opt/SPECTRUM/lib/../SS/libsskrnl.so.1
#8 0x00002b2f7e858217 in CModelDomainItcM::processItcRequest(ITC_Request_Parms*) () from /opt/SPECTRUM/lib/../
SS/libsskrnl.so.1
#9 0x00002b2f80fb30d4 in ITC_Request_Parms_Corba::processRequest_TransferExceptions() () from /opt/SPECTRUM/
lib/libitc.so.1
#10 0x00002b2f80fb28e1 in ItcWorkQueue::process_work_item(ItcQdItem*) () from /opt/SPECTRUM/lib/libitc.so.1
#11 0x00002b2f80fb26a2 in ItcWorkQueue::process_work_node(CsWorkNode*) () from /opt/SPECTRUM/lib/libitc.so.1
#12 0x00002b2f8340d3aa in CsWorkScheduler::do_work() () from /opt/SPECTRUM/lib/libwkmgr.so.1
#13 0x00002b2f7ebde7a3 in moot_thread_start () from /opt/SPECTRUM/lib/libmoot.so.1
#14 0x00000031a16419e0 in ?? ()
```

Cause:
The cause is due to an incompatible search type in the web service query.
For example, the isManaged attribute (0x1295d) only supports and "equal" value.
It will not support "has-substring" or "has-substring-ignore-case"

Solution:
Check your web services search. If you are using an "incorrect" search type for the attribute you are searching on you will need to correct it. If you are unsure that you are using an incorrect search type, you can create the same search in the OneClick Locater and save the search. Then review the xml associated to the search on the OneClick web server in the <SPECROOT>/custom/console/config directory.

For example, this search for the isManaged attribute (0x1295d) will crash your SpectroSERVER because the isManaged attribute will not work with a substring search:

<has-substring-ignore-case>
<attribute id="0x1295d">
<value>no</value>
</attribute>
</has-substring-ignore-case>
This needs to be updated to be:
<equals>
<attribute id="0x1295d">
<value>no</value>
</attribute>

</equals>

DX NetOps Spectrum Integrator

The following section provides an overview of the DX NetOps Spectrum Integrator features and capabilities, as well as in-depth procedures to perform integration activities.

Integrator Overview

The following section provides a brief overview of the DX NetOps Spectrum Integrator features and capabilities.

Integrating Third-Party Applications with DX NetOps Spectrum

IT organizations often use multiple applications to manage various aspects of their infrastructure. Integrating other management applications with DX NetOps Spectrum can be beneficial. You can create a powerful architecture that lets you combine the automation features and analysis from multiple management systems.

When designing a distributed automation architecture, evaluate how each tool contributes to the overall solution. Consider how the integrated tools can exchange data. This section can help you decide how to integrate third-party applications with DX NetOps Spectrum. The topics in this space demonstrate where and how you can exchange data with DX NetOps Spectrum.

Typically, an integration plan for DX NetOps Spectrum seeks to accomplish one or more of the following tasks:

- Send alert information to DX NetOps Spectrum
- Send network topology information to DX NetOps Spectrum
- Retrieve alarm information from DX NetOps Spectrum
- Create new SNMP device management modules within DX NetOps Spectrum
- Launch an external application from within a managed object context from one or more DX NetOps Spectrum application user interfaces
- Package and distribute an integrated system

This section discusses your options for accomplishing those tasks.

DX NetOps Spectrum Toolkits

DX NetOps Spectrum has several toolkits to help you complete integration tasks. This section provides an overview of each of the available toolkits and refers you to sources of more information.

- The Southbound Gateway lets you send alert data from third-party systems to DX NetOps Spectrum. The third-party system and all the sources for the appropriate alerts are automatically modeled in DX NetOps Spectrum. As a result, the network administrator can monitor this portion of the environment from OneClick.
- The Modeling Gateway imports network topology information into the SpectroSERVER database. An XML specification standardizes the information that is required to create the topological information. You can configure DX NetOps Spectrum to check for updated information at specified intervals.
- The AlarmNotifier and DX NetOps Spectrum Alarm Notification Manager (SANM) extract alarm data from DX NetOps Spectrum and pass it along to a user-defined application.
- The Model Type Editor and the GnSNMPDev model type let you derive new model types that are based on third-party MIBs. You can use these types to create new SNMP device management modules.
- You can edit DX NetOps Spectrum support files to enable the launching of third-party applications from OneClick. Context data can pass to the application as it is launched.
- The DX NetOps Spectrum Extension Integration (SEI) toolkit provides a series of tools and files that let you package all the components for an integration. You can then install these components on a DX NetOps Spectrum host system.

All of these tools and features provide safe, stable mechanisms for integration.

You can also use a programmatic interface with DX NetOps Spectrum. However, the programmatic interface requires an in-depth understanding of the DX NetOps Spectrum knowledge base (information model). This knowledge base includes many attributes, relations, and model types. A full understanding of component interactions is required to avoid risky changes that affect DX NetOps Spectrum operation. Also, a tight programmatic integration requires frequent updates to the integration code as DX NetOps Spectrum technology evolves.

Therefore, we recommend that both developers and end users rely on the tools that are detailed in this section whenever possible. These integration points reduce risk and maintain a flexible, powerful integration interface. DX NetOps Spectrum integration tools not only minimize the complexity of the integration tasks, but also enhance the functioning of the solution.

CORBA API Toolkit

The DX NetOps Spectrum CORBA API is an advanced toolkit that lets you develop C++ or Java based advanced extensions to DX NetOps Spectrum. Use this toolkit to create programs that integrate with the SpectroSERVER through an object-oriented remote method invocation interface.

Programming with this API requires an in-depth knowledge of DX NetOps Spectrum. Use the API only when necessary. The other toolkits that are discussed in detail in this section have been designed for use by most integrators. We recommend using them in most situations.

Command Line Interface

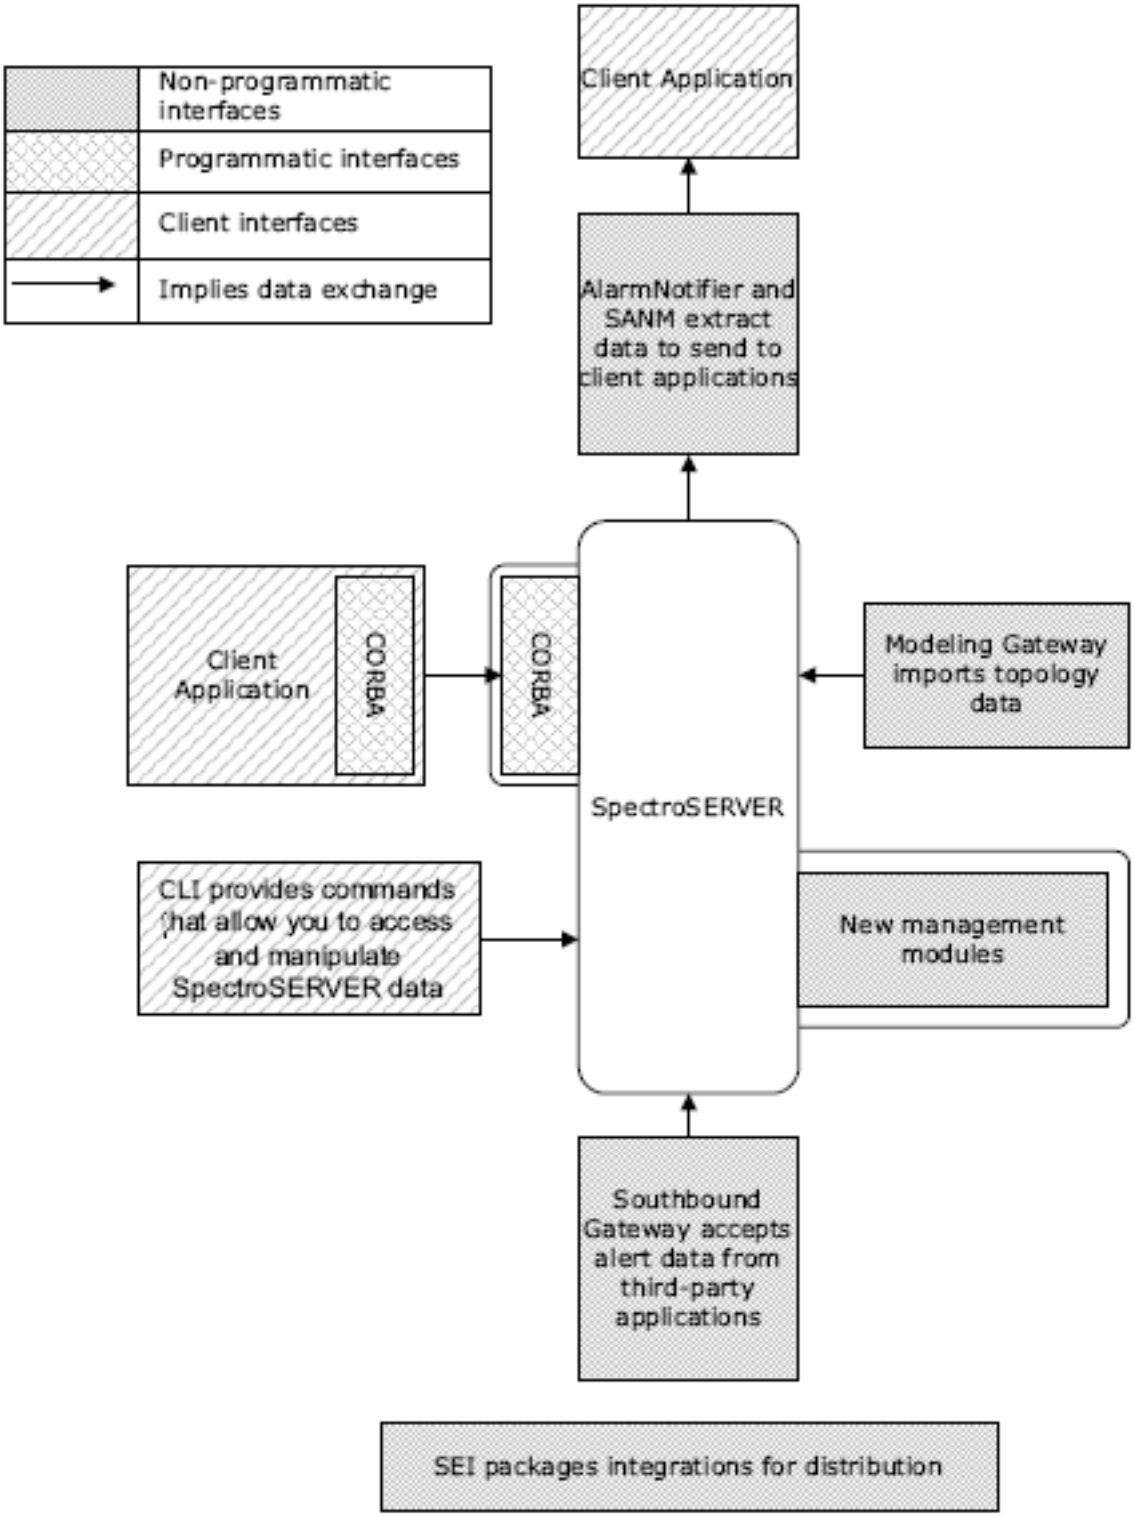
The DX NetOps Spectrum Command Line Interface (CLI) lets you access the data in the DX NetOps Spectrum knowledge base from a Unix shell environment or Windows command prompt. These commands can also be used in script files. Use the CLI to view, create, modify, and delete DX NetOps Spectrum data about models, alarms, events, and associations.

The CLI does not provide the safeguards that are available from the OneClick interface. We therefore do not recommend using it if you are unfamiliar with DX NetOps Spectrum and its modeling scheme. We also recommend testing a CLI-based integration with each release of DX NetOps Spectrum to verify the preservation of the intended behavior.

The CLI can also be an effective tool to use before working directly with the CORBA API. Use the CLI to test a prototype of your code as it interacts with the DX NetOps Spectrum knowledge base. If the data is as expected, you can then be more confident in your approach toward the CORBA API, which carries some risks.

The following diagram illustrates the integration points available in DX NetOps Spectrum:

SPECTRUM Integration Points



Benefits of Southbound Gateway and Modeling Gateway

Both the Southbound Gateway and the Modeling Gateway provide well-defined integration points for data exchange. These gateways were designed for the most common areas where third-party developers want to exchange data with DX NetOps Spectrum.

The Southbound Gateway integration point has built-in model types and inference handlers that are designed to handle integration with a third-party alert source. You can further customize the Southbound Gateway integration by using the EventAdmin model type or the EventModel model type as a derivation point. Use these types as you would use the GnSNMPDev model type to derive a new model type.

The Modeling Gateway provides a set of XML elements that lets you port data from a provisioning database or other network topology database. In addition, you can expand and customize the elements and attributes in the XML syntax to accommodate most integrations. You can also use the Modeling Gateway to export DX NetOps Spectrum topology data to an XML file.

Prerequisites for Developers

Significant experience using DX NetOps Spectrum is required before you attempt to use any of the DX NetOps Spectrum integration points.

In addition, a Developer ID is required to distribute your integrations.

NOTE
For more information, see *DX NetOps Spectrum* Getting Started .

Required Components

Many of the toolkits described in this section are packaged and sold as separate components. The following toolkits and the associated components are needed for each integration:

- **Southbound Gateway Toolkit**
  Available as an add-on component for some DX NetOps Spectrum packages that you can purchase.
  - **DX NetOps Spectrum Extension Integration (SEI)**
    Available as part of the Level 1 Toolkit.

    NOTE
    The Level 1 Toolkit includes the Model Type Editor and the SEI Toolkit.
  - **[assign the value for corba in your book]**
    (Optional) Required only if you want a programmatic Southbound Gateway integration. Available as an add-on component for some DX NetOps Spectrum packages that you can purchase.
- **Modeling Gateway Toolkit**
  Available as an add-on component for some DX NetOps Spectrum packages that you can purchase.
- **AlarmNotifier Application**
  Included with all DX NetOps Spectrum packages.
- **DX NetOps Spectrum Alarm Notification Manager (SANM)**
  Available as an add-on component for some DX NetOps Spectrum packages that you can purchase.
- **Model Type Editor**
  Available as part of the Level 1 Toolkit.
- **SPECTRUM Extension Integration (SEI)**
  Available as part of the Level 1 Toolkit.
- **Launch Point Integration**
  None
- **CLI Application**
  Included with all DX NetOps Spectrum packages.
- **[assign the value for corba in your book]**

Available as an add-on component for some DX NetOps Spectrum packages that you can purchase.

Sending Alert Data to the Product

The following topics cover in detail the various ways in which incoming alert data is managed and processed by ,

Southbound Gateway Model Types

Two model types are available for managing incoming alert data from a Southbound Gateway integration:

- EventAdmin
- EventModel

The EventAdmin model type is designed to represent a third-party system sending alerts to DX NetOps Spectrum. Each instantiated EventAdmin model represents an individual instance of a running external management application. Specific events that have come from the third-party application are sent to the EventAdmin. The EventAdmin models have built-in functionality that receives the events and appropriately transfers the event data to another model, with optional alarm creation. The event data is typically transferred to EventModels, but it is also possible to transfer to device models. EventAdmin models are also containers that are used to group one or more instantiated EventModel models.

The EventModel model type represents a unique source of event data within the system that the EventAdmin application manages. Each event that has been received through the Southbound Gateway contains information that uniquely identifies its source. The EventAdmin receives the event, finds the unique event source, and passes the event to the EventModel for the source.

If no EventModel exists for the source, DX NetOps Spectrum creates an EventModel model to represent it. All new EventModel models are placed in the corresponding EventAdmin container model. You can cut or copy EventModel models from an EventAdmin container model. You can then paste them into other types of container models in the Topology, Location, or Organizational view. You can also cut or copy the EventAdmin model and paste it into those same views.

Southbound Gateway Support Files

As the Southbound Gateway integrator, you create or add data to support files that supply information to the EventAdmin and EventModel models. You can work with the following files:

- **AlertMap file**
  If the alert source sends SNMP traps, you create a text file that adds data to the EventAdmin AlertMap file. These additions let the AlertMap file receive the SNMP traps and convert them to DX NetOps Spectrum events.
- **XML file**
  If the alert source does not send SNMP traps, you create an XML file to send events to DX NetOps Spectrum. The syntax of this XML file follows the document type definition (DTD) provided with this toolkit.
- **EventDisp file**
  You create text files that add data to the EventDisp files at the EventAdmin and EventModel level. These additions define how the events are processed.
- **Event Format file**
  You create Event Format files to give supporting textual information about each event.
- **Probable Cause file**
  You create Probable Cause files to give supporting textual information about each alarm.

The following diagram illustrates how data flows from the third-party system into DX NetOps Spectrum through the Southbound Gateway. It shows the model types and support files working together to process the data.

Third-party Application

Integration Steps

To set up a Southbound Gateway integration, take the following three required steps:

- Direct Alert Information from the Third-Party System to DX NetOps Spectrum.
- Map the Alert Information to a DX NetOps Spectrum Event.
- Define Support Files for the Event.

Direct Alert Data to the Product

The method to set up and configure a third-party system to send alert data to the Southbound Gateway depends on the individual system. The most important decision to make is the type of alert that the third-party system sends.

If the system can send SNMP traps to DX NetOps Spectrum, perform the required configuration. The application must send the trap data to the host name and TCP port where the SpectroSERVER is listening. By default, the SpectroSERVER is configured to receive SNMP traps on port 162. DX NetOps Spectrum processes the traps that it receives from the third-party application in accordance with the AlertMap file that is associated with the EventAdmin model type. The AlertMap file translates the trap data into a DX NetOps Spectrum event. Create a text file that adds the appropriate data to the AlertMap file so that it can properly process the trap information.

If your application cannot send SNMP alert data, you can import your data using the Southbound Gateway import tool. This tool requires data formatting using the XML elements from the document type definition in the Southbound Gateway toolkit.

Map Alert Information to a DX NetOps Spectrum Event

Mapping the Alert Information to a DX NetOps Spectrum Event

Regardless of whether the third-party application can send SNMP alerts, use the Southbound Gateway Event Data Template to map the data from the trap or alert to the DX NetOps Spectrum event. This template, which is described in the following table, indicates how to organize the alert variables. The template also lets you specify variables that constitute an identifier for the unique alert source. An event variable ID is assigned to the alert variables. Identification of each unique alert source lets the integration route the event to the proper EventModel model. Event Variables 1 - 6 designate the variable alert data that uniquely identifies the alert source. Other variable alert data is mapped to the Event Data Template variable that matches its content.

Variable ID	Name	Type	Description	Required/Optional
1	Unique ID 1	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.

2	Unique ID 2	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.
3	Unique ID 3	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.
4	Unique ID 4	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.
5	Unique ID 5	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.
6	Unique ID 6	String/Integer	The Unique ID variables are used to identify a target EventModel by a Unique Identifier string. The Unique Identifier is a composite of up to 6 variable data items (1-6). The final unique identifier string is composed as follows: <1>_<2>_<3>_<4>_ <5>_<6> Use that exact order. If one of the unique identifier components is not provided, it is not included within the composite unique identifier. If an existing EventModel with the Unique Identifier string cannot be found, one is created.	Either one unique identifier or a Target Name (field 7) or Target Address (field 8) is required.

7	Target Name	String	This field lets you specify a target model by model name. An EventModel is not created when a target model cannot be found while using the Target Name event variable. This field is case-sensitive. The 'Target Name Case Insensitive' field that is defined by Variable ID Field 16 instructs Southbound Gateway not to consider case when identifying the model by model name.	
8	Target Address	Octet/Text String	This field lets you specify a target model by IP address. Use this field if you want to send the event to a model other than an EventModel.	
9	Reserved			
10	Event Model Name	String/Intege	This field lets the user give a model name that is different than the unique identifier. If this data is not provided, the composite unique identifier becomes the model name.	Optional
11	Model Class	Integer	Populates the Model Class attribute of the target EventModel with the value specified in this event variable	Optional
13	Network Address	Octet/Text String	Populates the Network Address attribute of the target EventModel with the value specified in this event variable	Optional
14	MAC Address	Octet/Text String	Populates the MAC Address attribute of the target EventModel with the value specified in this event variable.	
15	Manufacturer	String	Populates the Manufacturer attribute of the target EventModel with the value specified in this event variable.	Optional
16	Target Name Case Insensitive	String	This field lets you specify a target model by model name. An EventModel is not created if a target model cannot be found when using the Target Name Case Insensitive event variable. This field is case-insensitive. If you want Southbound Gateway to consider the case when identifying the model by model name, use the Target Name field defined by Variable ID Field 7 (Target Name), which is case sensitive.	
17-99	Reserved			
Any other variable ID greater than or equal to 100.	Any Data	Any Type	This data is forwarded to the EventModel model unchanged. The data type and data are preserved. This data can be viewed within an event message.	Optional

Define Support Files

The following topics are covered in this section:

Defining Support Files

Once the alert has been translated into an event, define information for the support files. The EventDisp files, Event Format files, and Probable Cause files enable the correct processing and display of the alert data.

EventDisp Files

EventDisp files define DX NetOps Spectrum handling for each event. Two different EventDisp files support the EventAdmin model type and the EventModel model type.

The EventDisp file for the EventAdmin model type defines the events that are received from the external alert or trap source. The EventDisp file for the EventModel gives the desired properties to the events. This support file indicates whether the event is logged, the event severity, and whether the event becomes an alarm.

Event Format Files

Event Format files determine the contents of an event message when the event is displayed in OneClick. The These files can contain variable data from a specific occurrence of an event. The assigned event variable ID from the Event Data Template identifies this variable data within the Event Format file.

Probable Cause Files

Alarms that are generated as a result of the EventDisp file usually contain a probable cause as part of the alarm message. The text of this probable cause information is defined in the Probable Cause file.

Extracting Alarm Data

This section includes information about how to extract alarm data from DX NetOps Spectrum.

AlarmNotifier

DX NetOps Spectrum AlarmNotifier is a SpectroSERVER client application that provides a way to extract alarm information from DX NetOps Spectrum. The AlarmNotifier tool is launched from the command line and connects to a single SpectroSERVER. Once connected, it monitors alarm information from that server.

AlarmNotifier uses three scripts to get data from alarms:

- SetScript
- ClearScript
- UpdateScript

AlarmNotifier receives information from the SpectroSERVER when an alarm is sent, cleared, or updated. AlarmNotifier invokes a relevant script in response to alarm data. These scripts, which are located in the DX NetOps Spectrum Notifier directory, enable the display of alarm data. You can customize each script to send alarm data in an email notification or to another third-party application, such as a trouble ticketing system. The scripts contain parameters to reduce the amount of information that is displayed or is sent to other applications.

DX NetOps Spectrum Alarm Notification Manager (SANM)

The following topics are covered in this section:

About the DX NetOps Spectrum Alarm Notification Manager (SANM)

DX NetOps Spectrum Alarm Notification Manager (SANM) supports and enhances the AlarmNotifier application. SANM lets the AlarmNotifier monitor alarm information from all landscapes in the SpectroSERVER landscape map. SANM also provides more alarm data for the AlarmNotifier. When SANM has been installed on the SpectroSERVER, SetScript, ClearScript, and UpdateScript have additional parameters to provide detailed alarm data. SANM lets you acknowledge and clear alarms from the terminal shell where the alarm data is displayed. You can control the scope and volume of alarm data using the SANM Policy Administrator tool.

The Policy Administrator tool is the only way to work with SANM directly. SANM works directly with the AlarmNotifier to extend its functionality. You continue to work with the AlarmNotifier using the added SANM capability. For more information, see Alarm Notification Manager .

Policy Administrator Tool

The Policy Administrator configuration tool lets you create, save, and implement alarm notification filtering policies. You can create policies that specify the types of alarms that are sent to an alarm-processing application. Or you can create policies that exclude irrelevant or unimportant alarms or alarm data. You can also schedule associations between policies and applications so that alarm data filtered through that policy is sent to the particular application during the specified time period.

Policies can be very simple or quite complex. A simple policy can instruct SANM to pass information about critical alarms for all routers to an application that is associated with the policy. A more complex policy can instruct SANM how to handle information about critical and major alarms that remain unresolved for 10 minutes for a device with specific characteristics.

SANM Architecture

The following diagram shows the architecture of AlarmNotifier and SANM.

Sending Topology Data to the Product

Modeling Gateway Architecture

The following types of input files can be used with the Modeling Gateway:

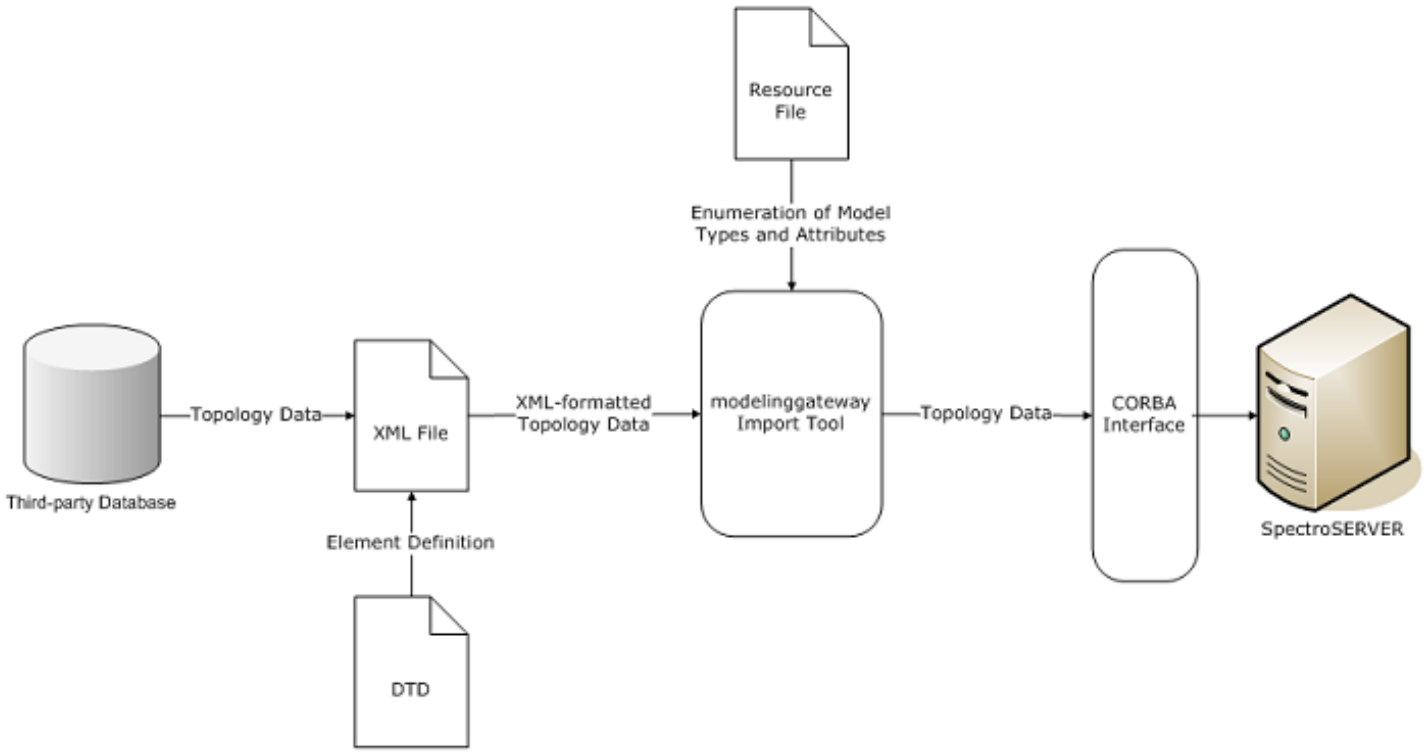
- XML file
- comma-delimited ASCII text file

The comma-delimited input file is used for creating connections for Frame Relay and ATM circuits. The XML input file provides a wider range of functionality. In addition to specifying Frame Relay and ATM circuit connections, you can also create, update, and destroy models and other types of connections.

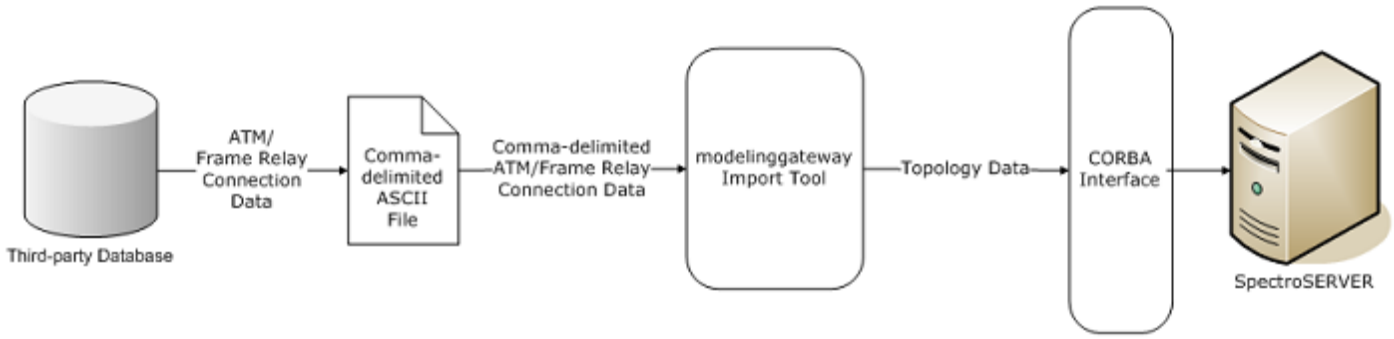
The integrator creates the XML input file that structures the network data for import. If you have a thorough understanding of the network topology, you can more easily represent network data in XML format. DX NetOps Spectrum provides a Document Type Definition (DTD) file that defines the XML elements and their associated syntax rules. A second file, the .modelinggatewayresource.xml file, shows you the DX NetOps Spectrum model types and attributes that are available. Create the XML input file, and then use the import tool (modelinggateway) to import the data into the SpectroSERVER database.

NOTE
For more information, see the Modeling Gateway Toolkit *section.*

The following diagram shows how the Modeling Gateway uses an XML file for importing data. Data that flows from the third-party database is formatted in the XML file using the syntax from the DTD and .modelinggatewayresource.xml. The import tool interprets the XML file and sends data into DX NetOps Spectrum through the DX NetOps Spectrum CORBA interface.



The following diagram illustrates the process for using a comma-delimited ASCII text file to import Frame Relay and ATM connection information.



NOTE
For more information about the comma-delimited file, see the Modeling Gateway Toolkit *section.*

Modeling Gateway Integration Mechanics

Integration requires information about how network data is formatted when it is imported. The modeling gateway uses input files to format the data that it imports. Create input files that specify data formatting rules.

NOTE
The following sections assume that you have a basic knowledge of XML and Document Type Definition files (DTDs). If you lack experience working in XML, we recommend becoming familiar with XML syntax before working with these files.

Gateway Modeling Tool for Input

During the integration process, you take your network data from a third-party database and create an input file. Depending on the content, this input file can be an XML file or a comma-delimited ASCII file.

If you only want to import data from Frame Relay or ATM connections, use the comma-delimited file.

Use an XML file to import more complex topology information. Use the DX NetOps Spectrum DTD file and the modelinggatewayresource.xml file to format the data properly. The following section contains an overview of each of these files.

NOTE
Note: For more information, see the Modeling Gateway Toolkit *section.*

Document Type Definition (DTD) File

The DTD file (.modelinggateway.dtd) outlines all of the elements and attributes that can be contained in the XML file. This file shows you the structural hierarchy of elements, indicating which elements can act as child elements for any given element and which attributes can be specified for each element.

The root element in the DTD is the Import element. This required element specifies the type of import to perform. The Import element has several possible child elements such as Topology, Location, GenericView, Update, Destroy, and Connection. To import new models, use the Topology, Location, or GenericView elements. The element that you select determines the OneClick view where the imported data appears.

Use the Update element to change an existing collection of models. Use the Destroy element to remove existing models, and use the Connection element to establish connections between ports or devices. These elements all have child elements, which define the components of the network.

You can customize the DTD file to meet the needs of your specific integration. For example, the GenericView element lets you create your own view in which to place container and device models. You can then modify and add to the child elements of the GenericView element to define the contents of your customized view.

The .modelinggatewayresource.xml File

All of the possible model types and attributes that can be used in the XML input file are defined in the .modelinggatewayresource.xml file. This file lists many DX NetOps Spectrum model types and the model type handles that uniquely identify them. It also lists many DX NetOps Spectrum attributes and their attribute IDs. This file lets you use model type and attribute names in the XML file rather than their hexadecimal identifiers. As a result, the XML file is more intuitive to create and read. The .modelinggatewayresource.xml file can be modified to include any instantiable, visible model type that exists in DX NetOps Spectrum and any attribute.

Gateway Modeling Tool for Import

Once you have set up the input file, use the Modeling Gateway import tool to import the network data into the SpectroSERVER database. The import tool is a command-line utility that is located in the SS-Tools directory.

> **NOTE**
> Copy the modelinggateway tool and all of its supporting files to run it on another server. For more information, see the *Distributed SpectroSERVER* Administrator *section.*

The following example command shows the modelinggateway tool syntax for import.

```
modelinggateway -vnm <vnm_name> -i <import_file> [-o <outputfile>] [-debug]
```

- **-vnm *vnm_name***
  Is the name of the SpectroSERVER host.
- **-i *import_file***
  Is the filename of the XML file with the input information that is compiled with .modelinggateway.dtd.
- **-o *outputfile***
  (Optional) Logs the error information to the file named in the outputfile parameter. If no file is specified, error information is logged to a file named import_file.log, where 'import_file' is the name of the XML input file.
- **debug**
  (Optional) Creates a debugging output file during the import process. The debug file is named ModelingGatewayDebug.txt in the running directory.

View Import Status and Import Errors

The DX NetOps Spectrum Modeling Gateway provides mechanisms to verify the safety and accuracy of each database import operation. DX NetOps Spectrum Modeling Gateway maintains an audit trail that includes a record of each creation, deletion, association, and update. You can view information about the import from within OneClick. You can also track import problems in the error and debug logs.

Verify the results of the Modeling Gateway import from the Information Tab for the VNM model in OneClick.

Follow these steps:

1. Select the applicable VNM model in the OneClick Console.
2. Click the Information tab in the Component Detail view.
3. Expand the Modeling Gateway node.
4. Review the table in the Modeling Gateway section for information about recent imports.

All errors and their possible causes are logged in an error log file. By default, the import tool creates an error log named <*nameofimportfile*>.log, where <*nameofimportfile*> is the name of your import file. You can also specify a name for your log file. For more information, see Import Tool.

When the import is complete, the log file appears in the SS-Tools directory. The log file records the number of successful creations, deletions, and updates of models and connections and each failure that occurred during the import.

The import tool also lets you enable a debug log, which is also created in the SS-Tools directory. This file, ModelingGatewayDebug.txt, explains each step in the import process.

NOTE
For more information see the Modeling Gateway Toolkit *section.*

Further References - Using the Modeling Gateway

For more information about importing topology data using the Modeling Gateway, see the following spaces:

- Modeling Gateway Toolkit provides information about the toolkit and the syntax used in its support files.
- Getting Started provides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.
- Distributed SpectroSERVER Administration provides information about moving the modeling gateway tool to another server.

Exporting Topology Data from the Product

Configure Topology Data for Export

The .modelinggatewayresource.xml file controls the content of the exported information. All types of data are exported by default. To limit the data that is exported, use the ExportConfiguration element. This element contains the following attributes:

- **export_devices**
  Exports device models.
- **export_containers**
  Exports container models.
- **export_port_attributes**
  Exports port attributes.
- **export_links**
  Exports device links.
- **export_topology_layout**
  Exports device and container models x,y coordinates.
- **export_annotation**
  Exports annotations and model group information.
- **export_WA_Link_models**
  Exports WA_Link models. If you do not export WA_Link models, they are treated as transparent. Wide area links between two device models are exported as a direct link.
- **export_spectrum_settings**
  Exports DX NetOps Spectrum settings, such as the settings for Fault Isolation, Discovery, and VNM Control.
- **export user models**
  Exports user models, licenses, privileges, preferences, and all other user-related relations attributes and models.
- **export service modeling**
  Exports service management schemes and attributes.

NOTE
For more information, see the Service Manager User section.

- **export schedules**
  Exports schedules.
- **export global collections**
  Exports static and dynamic global collections including all models in each global collection, all dynamic collection criteria, zoomed list, grouped list, and topology layout.
- **export discovery configs**
  Exports Discovery configurations.
- **export from primary SpectroSERVER only**
  Specifies whether Modeling Gateway connects to the secondary SpectroSERVER when the primary SpectroSERVER is down.

```
<ExportConfiguration
  export_devices = "true"
  export_containers = "true"
  export_port_attributes = "true"
  export_links = "true"
  export_topology_layout = "true"
  export_annotation = "true"
  export_WA_Link_models = "true"
  export_spectrum_settings = "true"
  export_user_models = "true"
  export_service_modeling  = "true"
  export_schedules = "true"
  export_global_collections = "true"
  export_discovery_configs = "true"
  export_from_primary_ss_only = "true"
/>
```

For example, to exclude port attribute information, set export_port_attributes to false.

The attributes that are exported for devices, containers, and ports are defined in the following elements:

- DeviceExportAttributes
- ContainerExportAttributes
- PortExportAttributes

Add and subtract attributes from these elements as needed.

The SpectrumConfigurationExport element controls what types of DX NetOps Spectrum configuration data are exported if the export_spectrum_settings flag in the ExportConfiguration element is set to true. For example, the following element controls the attributes that are exported for the LostFound model:

```
<SpectrumConfigurationExport model_type="LostFound" >
        <Automatic_Model_Destruction attribute_id="0x11de1" />
        <Model_Destruction_Interval_Hours attribute_id="0x11de3" />
        <Model_Destruction_Interval_Minutes attribute_id="0x11de4" />
</SpectrumConfigurationExport>
```

By default, all topology and modeling information under the Universe container is exported. Modify the RootContainerToExport element to specify a different root container from which to export. All of the contents of the root container and each of its subcontainers are exported.

NOTE
For more information, see the embedded comments in the *.modelinggatewayresource.xml* file.

Gateway Modeling Tool for Export

The Modeling Gateway command-line tool (modelinggateway, or modelinggateway.bat on Windows) is located in the SS-Tools directory. The syntax for export is:

```
modelinggateway -vnm <vnm_name> -e <export_file> [-o <outputfile>] [-debug]
```

For more information, see Gateway Modeling Tool for Import.

> **NOTE**
> Copy the modelinggateway tool and all of its supporting files to run it on another server. For more information, see the *Distributed SpectroSERVER* Administrator *section.*

Export DX NetOps Spectrum Topology Data

You can export DX NetOps Spectrum topology data using the modelinggateway tool. Use the -e flag to export DX NetOps Spectrum topology data.

For example, running the following command exports the data from the SpectroSERVER on NOC1_DX NetOps Spectrum into a Modeling Gateway formatted xml file named NOC1_data.xml:

```
modelinggateway -vnm NOC1_Spectrum -e NOC1_data.xml
```

Import Modeling Gateway XML file

You can import the data from a Modeling Gateway formatted XML file into DX NetOps Spectrum. Use the -i flag to import from a Modeling Gateway formatted xml file.

For example, running the following command imports the data from NOC1_data.xml into the SpectroSERVER at NOC2_Spectrum.

```
modelinggateway -vnm NOC2_Spectrum -i NOC1_data.xml
```

Launching Applications from OneClick

The following section details how you can launch application from the DX NetOps Spectrum OneClick.

Launch Applications from the OneClick Interface

A configuration file contains examples for adding custom menus and menu items to your OneClick Console. Find this file in the following directory:

```
<$SPECROOT>/tomcat/webapps/spectrum/WEB-INF/console/config/custom-menu-config.xml
```

Copy this file into the <*$SPECROOT*>/custom/console/config/ directory. Add your custom menu items to this XML file.

The <launch-application> element lets you launch a specified executable and pass attribute values to that executable.

```
<launch-application>
    <command>myapp {0}</command>
    <param>
        <attribute>AttributeID.NETWORK_ADDRESS</attribute>
    </param>
</launch-application>
```

The previous example launches an application on the client computer. The <command> element specifies the command or executable to run. You can provide the path to the command or executable in either of the following ways:

- You can specify the path on each client using an environment variable. On Windows, select My Computer, Properties, Advanced, and then click Environment Variables.
- You can specify an absolute path to the executable or command. Verify that the path is the same on each OneClick client. Path statements in the Windows environment use a double backslash instead of a single backslash. For example:
  C:\\Windows\\system32\\cmd.exe

You can pass multiple parameters to the launched application or URL. The previous example launches an application named myapp and passes the IP address of the selected model.

The command element must conform to the following syntax rules:

- Use only spaces to delimit command arguments. To include a space within an argument, either place quotation marks around the argument or use the escape character '\' before the space.
- To embed quotes within an argument, place the escape character '\' before the quotation marks.
- If your command arguments contain commas, DX NetOps Spectrum automatically places the argument within quotation marks. For example, an argument is a numeric value containing commas.
- DX NetOps Spectrum replaces arguments that come back null or have a string length of zero with empty quotes.

The following example uses the <platform> element to specify commands for different platforms.

Example: <launch-application> Code

```
<launch-application>
   <platform>
   <os-name>Windows</os-name>
   <command>cmd.exe /c start "ping {0}" cmd /c "ping.exe {0}
   &#38;&#38;pause"</command>
   </platform>
   <platform>
   <os-name>SunOS</os-name>
   <command>>/usr/dt/bin/dtterm -e ping {0}</command>
   </platform>
   <param>
   <attribute>AttributeID.NETWORK_ADDRESS</attribute>
   </param>
</launch-application>
```

- **<os-name>**
  (Optional) Specifies the operating system
- **<command>**
  Specifies the command to execute on the specified operating system.

If you do not specify the <os-name>, the associated command is executed if no other platforms match.

At run time, DX NetOps Spectrum compares the specified OS names to the name that the ‘os.name’ Java property returns. DX NetOps Spectrum uses a best-match algorithm that lets you specify a prefix. The following operating system names are accepted:

- Windows for all Windows platforms
- Windows 9x for Windows 95/98 only
- Windows 2000 for Windows 2000 only
- Windows XP for Windows XP only
- Linux for the Linux platform
- Mac for the Macintosh platform

If none of the specified platforms matches, the associated menu item is disabled.

NOTE
For more information, see OneClick Customization .

Launch URLs in Web Browsers from the OneClick Interface

You can configure OneClick to launch specified URLs and to pass parameters to the URL. These parameters can be hard-coded values or values from model attributes.

NOTE
For more information, see OneClick Customization .

Launch OneClick Clients with Context

You can launch OneClick clients within the context of a certain topology, model, or a Global Collection. Contextual parameters and values can be included with the URL that launches OneClick. The following URL is an example of such parameters:

http://<*hostname*>/spectrum/oneclick.jnlp?<*parameter*>=<*value*>

The following parameters are available:

- **Topology**
  Supply a model handle, IP address, or name of a Global Collection. This parameter launches a OneClick client or reuses an existing one, selects the Explorer tab or the Topology tab, expands the tree to show the model, or selects the specified model in the Topology panel.
  Examples
  - http://<*hostname*>/spectrum/oneclick.jnlp?topology=0x3780003d
  - http://<*hostname*>/spectrum/oneclick.jnlp?topology=10.253.9.7
  - http://<*hostname*>/spectrum/oneclick.jnlp?topology=East
- **Explorer**
  Supply a model handle, IP address, or name of a Global Collection. This parameter launches a OneClick client or reuses an existing one, selects the Explorer tab, or expands the tree to show the model. The currently selected tab in the Contents panel reflects the new model.
  Examples
  - http://<*hostname*>/spectrum/oneclick.jnlp?explorer=0x3780003d
  - http://<*hostname*>/spectrum/oneclick.jnlp?explorer=10.253.9.7
  - http://<*hostname*>/spectrum/oneclick.jnlp?explorer=East
- **Alarm**
  Supply the integer alarm ID (to facilitate the integration with legacy applications), the complete global alarm ID (in the form 3f983d3d-2045-1000-012b-000bdb5a1c31), or <model handle>@<alarm ID>. This parameter launches a OneClick client or reuses an existing one, selects the Explorer or Alarms tab, expands the tree to show the model, and selects the alarm.
  Examples
  - http://<hostname>/spectrum/oneclick.jnlp?alarm=0x3780003d@7710
    where 0x3780003d@7710 is <modelhandle>@<alarm ID> and
  - http://<hostname>/spectrum/oneclick.jnlp?alarm=7710
    where 7710 is the integer <alarm ID>

If you are passing the integer alarm ID, pass the model handle also. The integer alarm ID is not always unique across SpectroSERVERs. The full global alarm ID, which is unique across SpectroSERVERs, is preferable. However, that ID is not always available to the application that is launching OneClick.

NOTE
When launching in context, a new instance of OneClick is not launched if an instance is already running on the host. Instead, the context is changed in the current instance of OneClick. For more information, see the OneClick Administrator.

Launch Applications with Process Daemon

A process launching and tracking daemon (processd) lets DX NetOps Spectrum control various processes that are running on a workstation. This daemon operates in the background. The processd automatically starts during DX NetOps Spectrum installation and whenever the system restarts. Once processd is started, it automatically starts and manages other processes. You can create an application that processd can launch as part of the DX NetOps Spectrum startup process.

The lib/SDPM/partslist directory is used by processd to determine executable locations and arguments. For application tracking, processd uses the lib/SDPM/runtime directory. The partslist directory lists everything that the process daemon can launch and monitor. The runtime directory lists everything that processd is tracking.

To let processd launch and track your application, create an install ticket file (.idb). Save the file in the partslist directory.

NOTE
For more information, see Distributed SpectroSERVER Administration.

Further References - Launching Applications from DX NetOps Spectrum

For more information about launching applications from DX NetOps Spectrum, see the following spaces:

- OneClick Customization provides details about launching applications in OneClick.
- OneClick Administration provides details about launching OneClick with context.
- Distributed Administration provides a complete reference for launching applications.
- Getting Started provides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.

Create New Management Modules

Creating New Management Modules

The following section provides information and procedures to create new Management Modules:

Model Type Editor

To derive new model types and import MIBs, use the Model Type Editor. This tool is available from the Configure menu in the DX NetOps Spectrum Control Panel. The Model Type Editor lets you select the model type for your new model type and import proprietary MIBs. It also allows you to set selected attribute values within the model type.

NOTE
For more information, see Model Type Editor .

OneClick Topology Support

After creating model types using the Model Type Editor, you can specify how they appear in OneClick topologies using XML. The following list describes the customizations that you can perform:

- Create icons for model types
- Register model icons
- Configure icons for OneClick themes
- Design on and off-page reference icons
- Create icon labels
- Define text components
- Define selection components
- Define tool tips for model icons

NOTE
For more information, see OneClick Customization.

Event Configuration Files

Once you have edited the appearance of the new model type, build the support files that let the model type receive and process SNMP traps. These Event Configuration files include the AlertMap file, the EventDisp file, and all applicable Event Format and Probable Cause files. The AlertMap file maps SNMP alerts to DX NetOps Spectrum events. The EventDisp file contains information about event handling. For example, the event can be logged, can be turned into an alarm, or can be used to clear an alarm. The EventFormat file provides information about the event, and the Probable Cause file provides information about the alarm.

Use a text editor to edit any of these files. You can also use the Event Configuration tool to edit EventDisp, Event Format, and Probable Cause files.

NOTE
For more information, see Event Configuration

DX NetOps Spectrum Extension Integration (SEI) Toolkit

After you have created the support files, use the DX NetOps Spectrum Extension Integration (SEI) toolkit to create a virtual CD. The virtual CD installs your new management model on any SpectroSERVER.

Watches

When models of your newly derived model type have been instantiated, you can track and analyze information about their condition. Create one or more watches for a particular model to monitor and analyze the internal and external attribute values of that model. Watches can include expressions that incorporate one or more attribute values. These attribute values, or an expression that is based on these values, can then be measured against a defined threshold value.

Watch results can be used to generate events and alarms and can be logged for historical tracking and report information. Results can also be sent to script files. DX NetOps Spectrum polls attributes to evaluate the attribute values that are defined in a watch. Keep in mind that this polling can have an impact on network traffic and system resources. Delete the watches that are no longer useful.

NOTE
For more information, see Watches.

Further References - Using the GnSNMPDev Model Type

For more information about using the GnSNMPDev model type to create new model types, see the following DX NetOps Spectrum spaces:

- Certification provides complete information about the GnSNMPDev management module.
- Model Type Editor gives in-depth instructions for using the Model Type Editor.
- Getting Started provides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.
- OneClick Customization describes how to create your own DX NetOps Spectrum views or customize generic DX NetOps Spectrum views.
- Extension Integration Developer provides details about using SEI to package integration for distribution.
- Event Configuration describes the Event Configuration utility, which lets you edit EventDisp, Event Format, and Probable Cause files from a graphical user interface. It also provides an in-depth look at EventDisp, Event Format, and Probable Cause files.
- Watches provides information about creating a watch. This space provides examples for generating events or alarms, sending this information to a script, or using this information in a report.

Distribute Integration Files

Distributing Integration Files:

Create an Index File

An index file defines the components of an integration, identifies their location, and specifies where to install them on the DX NetOps Spectrum server. Index files include references to all files that are necessary for the operation and installation of the integration on the DX NetOps Spectrum host. Depending on the type of integration that you have created, the index file includes references to different types of files.

You can include scripts in the index file that support the installation process. Custom installation scripts are launched during installation. These scripts can copy the contents of an installable text file into an existing text file on the DX NetOps Spectrum host, for example.

Create index files manually, or use the mmship tool.

Run mkmm

After creating your index file, build a package that contains all of the files that are referenced. Use the mkmm tool to build this package. This tool references the index file to create a VCD that contains all of files that must be installed on the SpectroSERVER.

The mkmm tool is saved in the SPECTRUM INSDK directory. However, you run this tool from the directory where your index file is saved. To run the tool, type the following command:

```
../INSDK/mkmm *.i
```

Run mkcd

The mkcd tool performs three final functions to complete an installable integration file. This script checks dependencies between purchasable parts and extension modules on the virtual CD. Any inconsistencies or errors are reported. The mkcd script adds a version number to the VCD, which enables installation. And it locks the VCD against the addition of files. The mkcd tool is located in the SPECTRUM INSDK.

Use the following syntax to execute the command in the directory that contained the VCD directory:

```
../INSDK/mkcd  -f <vcddir><version>
```

- **<vcddir>**

Specifies the name of the vcd directory that mkmm created (usually vcd).

- **<version>**
  Specifies the version number of your integration. The version number must not contain spaces.

Further References - SEI Toolkit

For more information about the SEI toolkit, see the following sections:

- DX NetOps Spectrum Extension Integration Developer provides details about using SEI to package an integration for distribution.
- Getting Started provides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.

Use CLI to Exchange Data

Using CLI Components to Exchange Data with DX NetOps Spectrum

CLI Components

The CLI includes the following four separate components:

- A set of executable commands that let you communicate with the SpectroSERVER.
- A set of environment variables that can affect executable command behavior. Depending on the operating system, they can be required to enable the script or executable command to operate.
- A daemon that maintains communication with the SpectroSERVER.
- A set of sample scripts that include CLI commands.

When you use the CLI to connect to the SpectroSERVER, the communication daemon that acts as a CLI local server starts. You can then use the executable commands and environment variables on the command line or in a script. Each CLI command sends success or failure information to standard error. Normal output that results from a successful command is sent to standard output.

Each command also generates a return code of zero on success and a non-zero error code on failure. These return codes are useful in scripts to determine the success or failure of a command.

CLI Commands

The following list describes the available executable CLI commands:

- **ack alarm**
  Acknowledges an alarm.
- **connect**
  Connects to the SpectroSERVER.
- **create**
  Creates a new alarm, association, event, or model in a specified landscape.
- **current**
  Sets a model as the 'current' model or a landscape as the 'current' landscape to be acted on by other CLI commands, or displays the current model and current landscape.
- **destroy**
  Destroys (removes) an alarm, association, or model in a specified landscape.
- **disconnect**

Disconnects from the SpectroSERVER.

- **jump**
  Returns to a model and a landscape that were saved with the setjump command.
- **seek**
  Finds a model in a specified landscape.
- **setjump**
  Saves the current model and the current landscape under a user-defined text string label. The jump command can then be used to return to this model and landscape.
- **show**
  Displays information about objects in a specified landscape.
- **stopShd**
  Disconnects all users from SpectroSERVER and terminates the CLI locale server.
- **update**
  Updates the attributes of a model or model type.

Further References - Working with CLI

For more information about working with CLI, see the following sections:

- Command Line Interface provides a complete reference to the CLI environment and its commands.
- Getting Startedprovides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.

Extending with the CORBA API

Overview of the DX NetOps Spectrum CORBA API

The DX NetOps Spectrum CORBA API provides programmatic access to the SpectroSERVER. Use the API to develop C ++ or Java client applications.

The CORBA API lets you develop your own client application that exchanges data with and manipulates data contained in the DX NetOps Spectrum knowledge base. This interface is especially useful for integrating web-based (Java) applications. The DX NetOps Spectrum CORBA API consists of Interface Definition Language (IDL) files for the interfaces we provide, as well as some helper classes.

Considerations

Use the CORBA API with caution. If you can use one of the non-programmatic toolkits described in this section to accomplish the goals of your integration, you should do so. This powerful interface requires an in-depth understanding of DX NetOps Spectrum functionality and the DX NetOps Spectrum knowledge base.

If you intend to use the CORBA API to integrate client applications that share alarm and event data with DX NetOps Spectrum, consider using the Southbound Gateway, AlarmNotifier, and SANM toolkits. These toolkits are specifically designed for this purpose, so you can save considerable time and effort by using them. The toolkits do not necessarily require deep knowledge of DX NetOps Spectrum.

Further References - Working with CORBA API

For further information about working with the DX NetOps Spectrum CORBA API, see the following:

- Development API Reference is an introductory reference for the DX NetOps Spectrum CORBA API.
- Getting Started provides an overview of the DX NetOps Spectrum technology and the terminology that is used throughout the DX NetOps Spectrum documentation.

Security Policy Statement

The DX NetOps Spectrum Security Policy Statement applies to the DX NetOps Spectrum product and is applicable as long as the product is used within the documented procedures defined in the product documentation.

The DX NetOps Spectrum Security Policy Statement details the encryption and hashing that is used by specific DX NetOps Spectrum components.

The DX NetOps Spectrum Security Policy Statement communicates the FIPS 140-2 statement for the DX NetOps Spectrum product. Specifically, it does the following:

- Clearly states what DX NetOps Spectrum modules are FIPS-compliant and which are FIPS-compatible
- Identifies FIPS certificate numbers for the encryption modules or hash algorithms used
- Communicates additional items that require extra physical security or protection
- Identifies the application boundaries surrounding the different application modules using encryption and or hashing
- Identifies what data is protected
- Communicates how keys are protected
- Explains how to enable FIPS mode on the software component

Definitions

The following terms are used in the DX NetOps Spectrum Security Policy Statement:

FIPS-compliant means that the component is capable of running FIPS-compliant encryption and hashing modules and offers the ability to run in FIPS mode.

FIPS-compatible means that the component uses FIPS-certified algorithms for encryption and hashing, but does not offer the ability to run in FIPS mode.

FIPS 140-2 Compatibility Matrix

The following table shows the extent to which DX NetOps Spectrum uses FIPS-compliant algorithms:

DX NetOps Spectrum Software Component	Module	Version	Certificate1	Algorithms2	Algorithm Cert#3	Mode4
SpectroSERVER User Password Storage**	BSAFE Crypto-J	5.1.1	1502	SHA-256	1549	Compatible
OneClick User Password Storage	BSAFE Crypto-J	5.1.1	1502	AES-256	1766	Compatible
Integration Password Storage	BSAFE Crypto-J	5.1.1	714	AES-256	1766	Compatible
eHealth Password Storage	BSAFE Crypto-J	5.1.1	714	AES-256	1766	Compatible

EEM Single SignOn (Proxy Password)	BSAFE Crypto-J	5.1.1	714	AES-256	1766	Compatible
CA Service Desk Password Storage	BSAFE Crypto-J	5.1.1	714	AES-256	1766	Compatible
MySQL Password Storage	BSAFE Crypto-J	5.1.1	714	AES-256	1766	Compatible
SRAdmin Data Transmission	BSAFE Crypto-C ME	2.0	608	3DES	378	Compatible
SNMPv3 Privacy Data Transmission	OpenSSL***	0.9.8	2097	3DES, AES-128, AES-256, SHA	1302	Compatible
Secure Domain Manager*	BSAFE Crypto-C ME	2.0	608	3DES, SHA	378	Compliant
Secure Domain Manager	OpenSSL	0.9.8	2097	3DES, SHA-256	1302	Compatible
SDConnector Data Transmission	BSAFE Crypto-C ME	2.0	608	3DES	378	Compatible
Certgen	OpenSSL	0.9.8	2097	3DES, SHA	1302	Compatible

Notes:

- * You can configure a different algorithm for Secure Domain Manager (SDM) and the SDM Connector. You do not have to use 3DES.
- ** Credentials of old user models using SHA are updated to SHA-256 on first-time login to 9.4. For the newly created models (from 9.4), credentials are hashed using SHA-256.
- *** OpenSSL module is part of CAPKI. In FIPS mode, it is FIPS-2 complaint as all consumer products use only FIPS approved algorithm from Crypto-C ME of CAPKI. These certificate and algorithm certs are from Crypto-C ME (4.0.1).
- You can find NIST certificate numbers at: http://csrc.nist.gov/groups/STM/cmvp/validation.html
- These are the only algorithms the software supports. You can find more information at: http://csrc.nist.gov/groups/STM/cavp/validation.html
- Verify algorithm certificate numbers by looking up the certificate number at NIST, opening the Security Policy, or reading the 'Level/Description' column associated with the Certificate number.
- N/A means the software does not offer the ability to operate in FIPS mode. Compatible or Compliant means the software is capable of operating in FIPS mode according to the definitions of those terms.

Detailed Component Descriptions

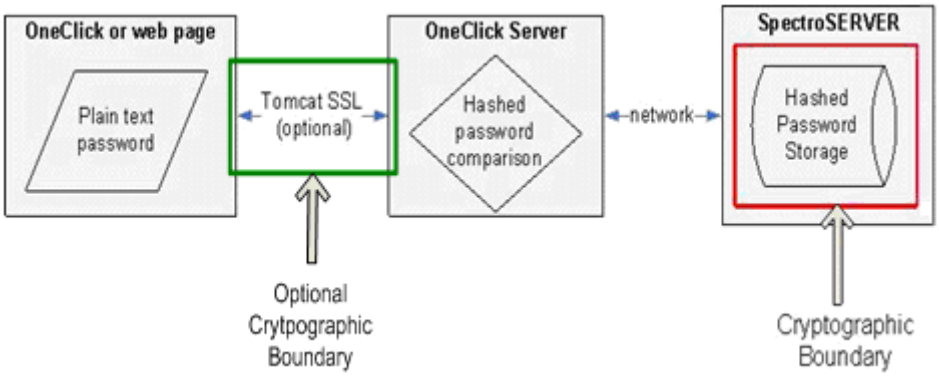
This chapter describes the encryption and hashing that is used by specific DX NetOps Spectrum components.

SpectroSERVER User Password Storage

From 9.4 onward, passwords are hashed using SHA-256, and are stored in the SpectroSERVER database for comparison when a user attempts to log in. Passwords of user models that were created before 9.4, are updated to SHA-256 after first-time login to 9.4 or above. All newly created user models in 9.4 and above versions support SHA-256 for hashing and authentication.

NOTE
Enable "Tomcat Secure Sockets Layer (SSL)" for protection over the wire.

The following image illustrates the Cryptographic Boundary for SpectroSERVER user password storage:



The DX NetOps Spectrum password is protected. For more information about configuring and using SSL, see the Create User Accounts and User Groups *section*.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Modeguide

SHA-256 password hashing is enabled out of the box.

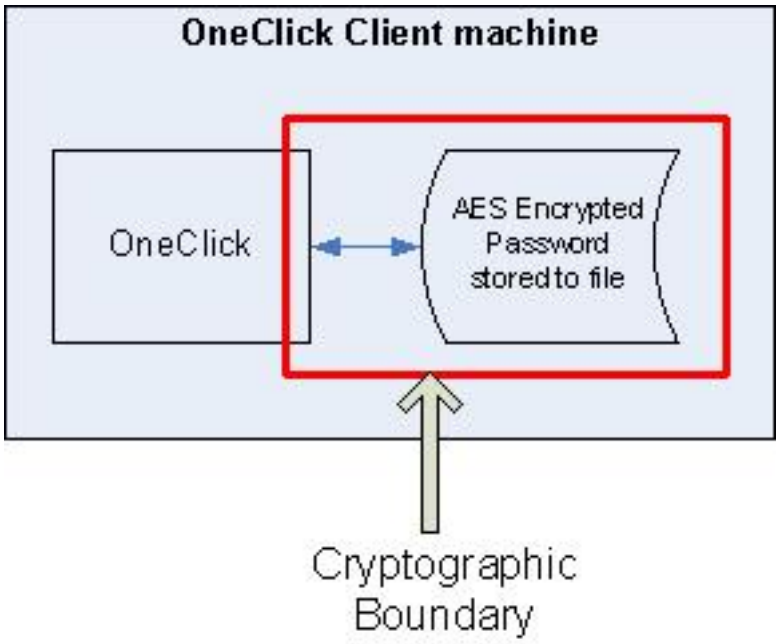
Changing Root Certificate

Not applicable at this time.

OneClick User Password Storage

When the "Remember my password" option is selected in the OneClick home page, OneClick passwords are stored to a file. It is part of Windows Security, and nothing to do with Spectrum. For Spectrum, the username and password are encrypted and stored in the SpectroSERVER database.

The Cryptographic Boundary for the OneClick password storage is as follows:



The OneClick username and password is encrypted with AES-256 in the file.

NOTE
For more information about the OneClick login, see the Using OneClick *section*.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Mode

AES-256 password and username encryption is enabled out of the box.

Changing Root Certificate

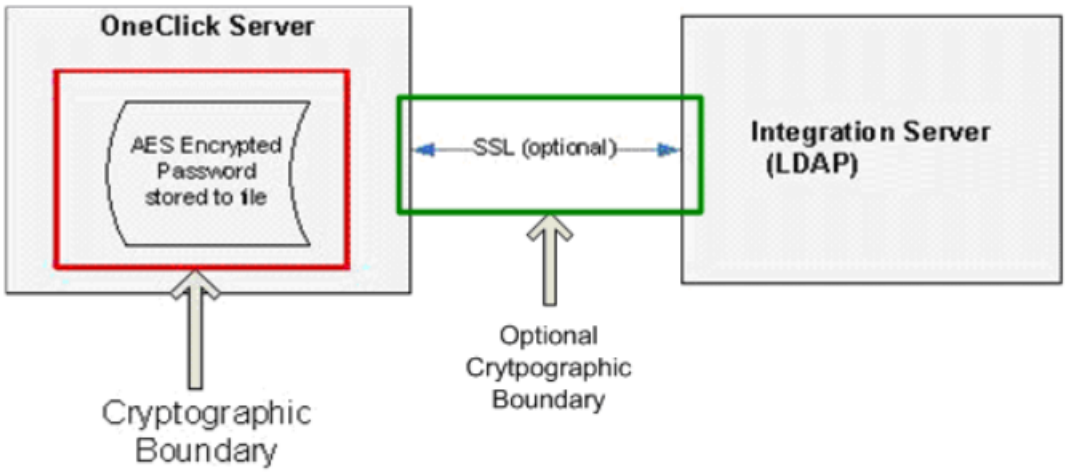
Not applicable at this time.

Integration Password Storage

Passwords for OneClick integrations are stored to a file and are encrypted using AES-256.

NOTE
For encryption over the network, enable SSL for integrations between DX NetOps Spectrum and CA eHealth, and DX NetOps Spectrum and Lightweight Directory Access Protocol (LDAP).

The Cryptographic Boundary for integration password storage is as follows:



The password is encrypted with AES-256 in the file.

> **NOTE**
> For more information about configuring and using LDAP, see the Create User Accounts and User Groups section.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Mode

AES-256 password encryption is enabled out of the box.

Changing Root Certificate

Not applicable at this time.

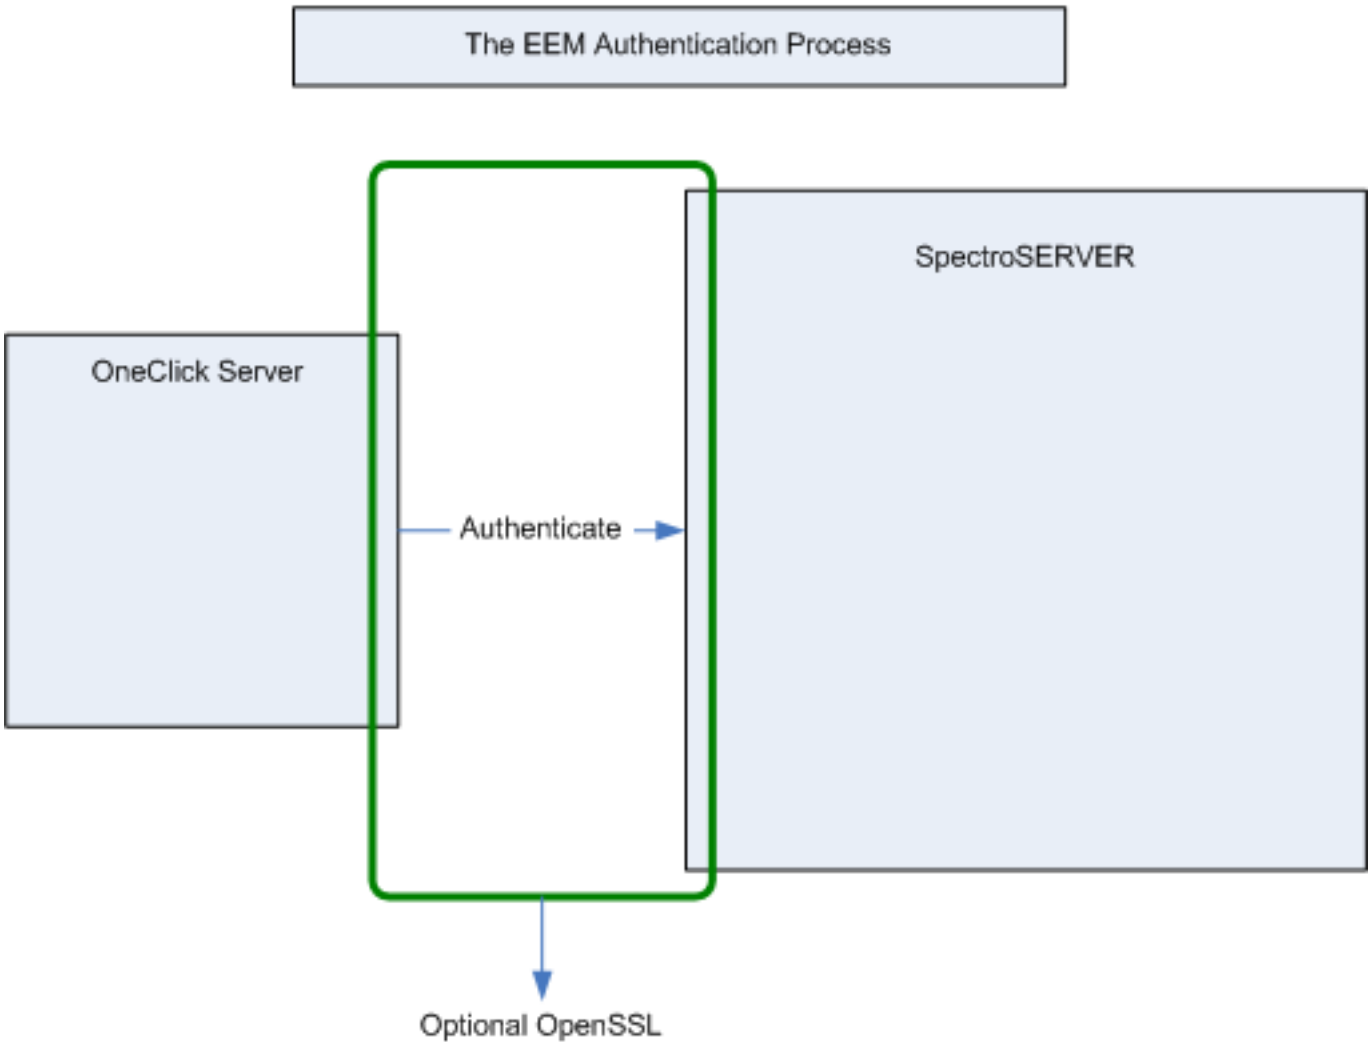
Embedded Entitlements Manager (EEM) Single Sign-On (Proxy Password)

Single Sign-On functions are used mainly for logging in, but can also be used to access cross-platform resources, such as CA eHealth reports.

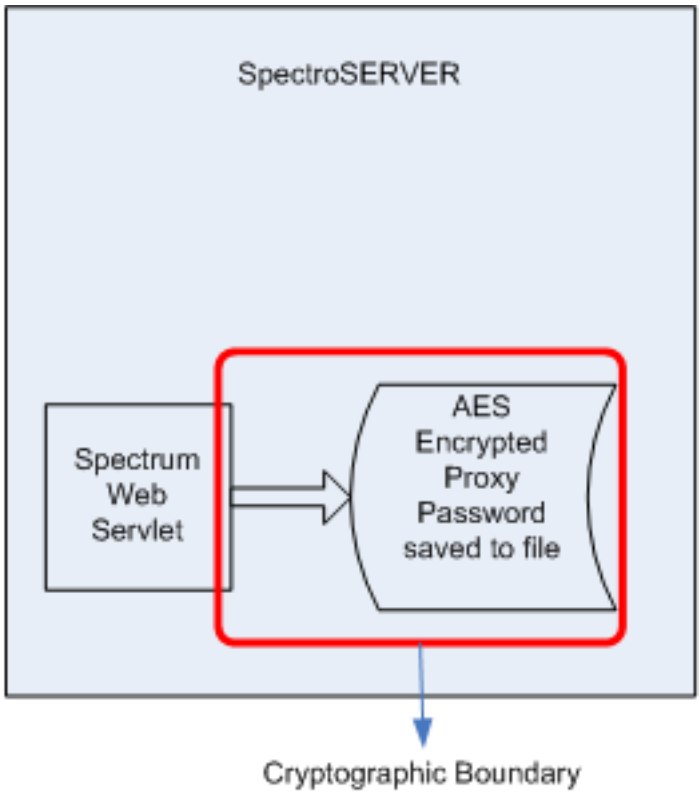
> **NOTE**
> If the token expires and a resource requires authentication, the authentication process repeats.

The following figures illustrate the Cryptographic Boundary for Embedded Entitlements Manager (EEM) single sign-on (proxy password).

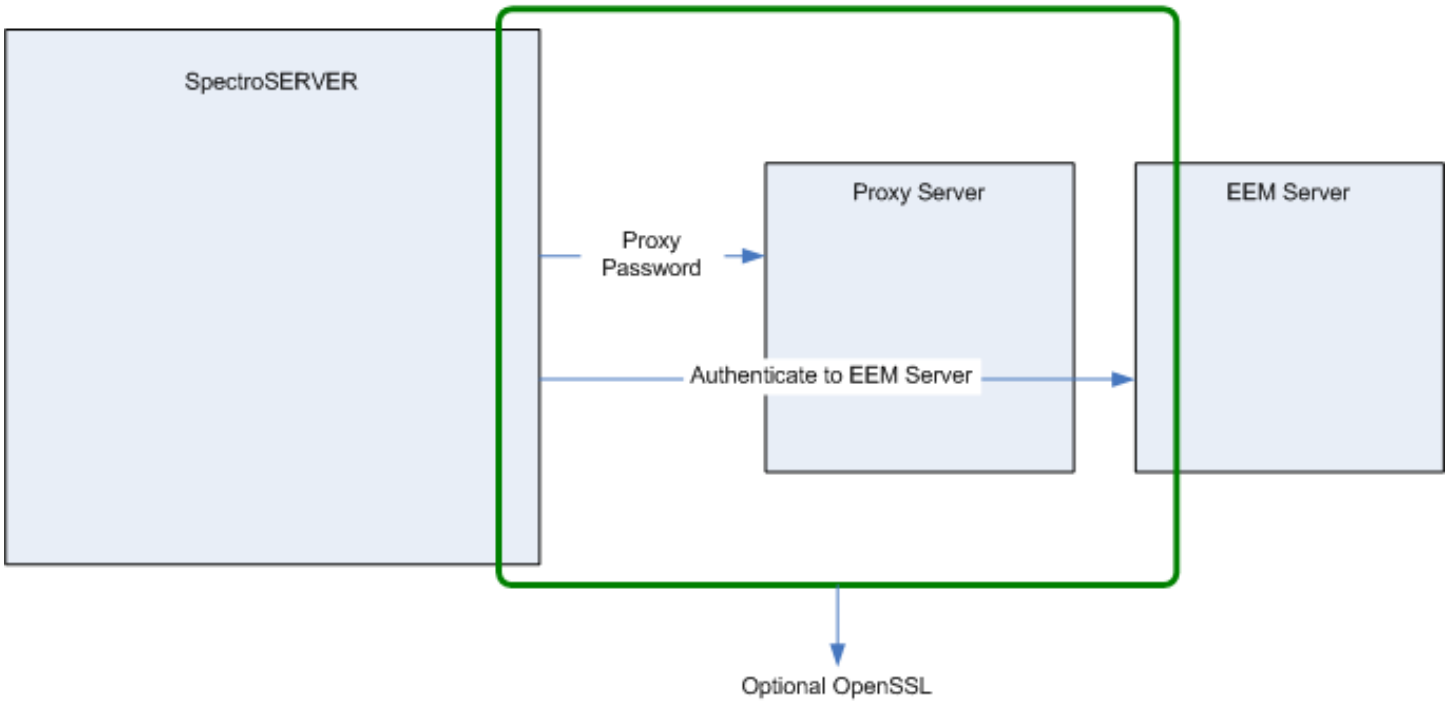
The following figure illustrates how the OneClick web server communicates with the SpectroSERVER to authenticate which OneClick web server transmissions can be encrypted with OpenSSL:



The following figure illustrates how the SpectroSERVER uses a configuration file to determine the authenticator. In this instance, the authenticator is configured to be Single Sign On through an EEM server, behind a proxy server. The password for the proxy server is AES-256 encrypted and is stored on the SpectroSERVER in a file:



The following figure illustrates how the proxy password is transmitted to the proxy server, which then allows the SpectroSERVER to communicate to the EEM server for authentication. These transmissions can also be encrypted with OpenSSL:



The proxy password is encrypted with AES-256 in the file. The transmission of the data between servers can protected by SSL, but is not required.

> **NOTE**
> For more information about the EEM login and configuration information, see How to Configure DX NetOps Spectrum/CA EEM Integration section. For more information about configuring the SSL, see the Configure OneClick for Secure Sockets Layer section.

Special Protection and Key Storage

There is no special protection for the file; however, the key is internal to DX NetOps Spectrum.

Enable FIPS Mode

AES-256 password encryption is enabled out of the box. It cannot be turned off. SSL is optional, and can be turned off.

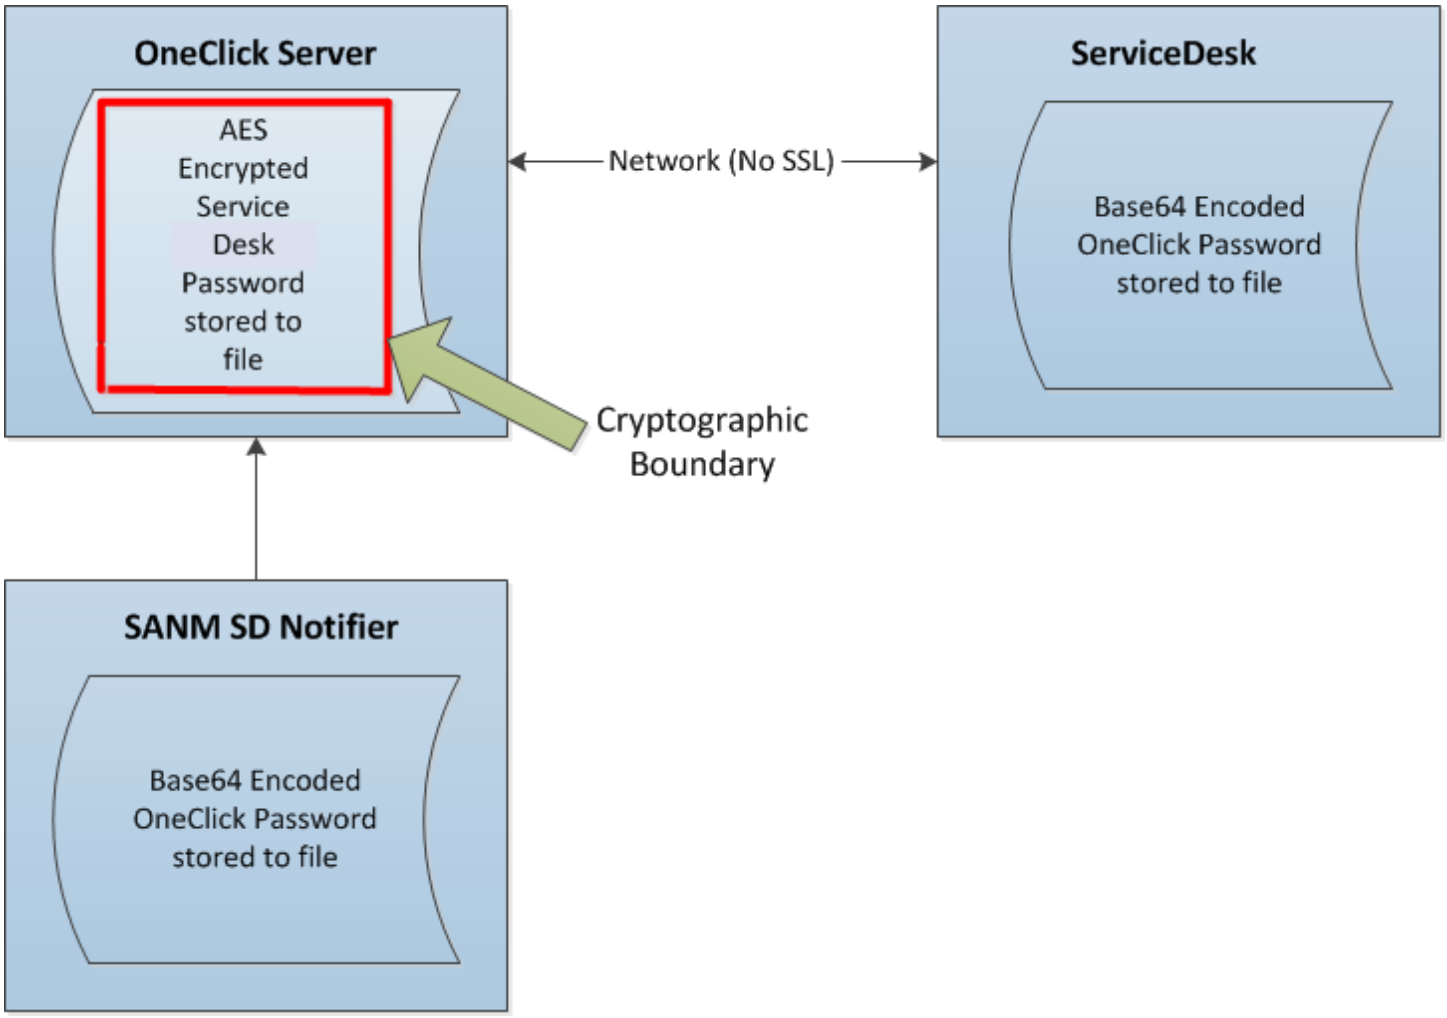
Changing Root Certificate

Not applicable at this time.

CA Service Desk Password Storage

The CA Service Desk password is stored to a file with AES-256 encryption. The OneClick password is stored to a file with Base64 encoding.

The Cryptographic Boundary for CA Service Desk password storage is as follows:



NOTE
For more information about integrating with CA Service Desk, see the DX NetOps Spectrum and CA Service Desk Integration section.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Mode

AES-256 password encryption and Base64 encoding is enabled out of the box.

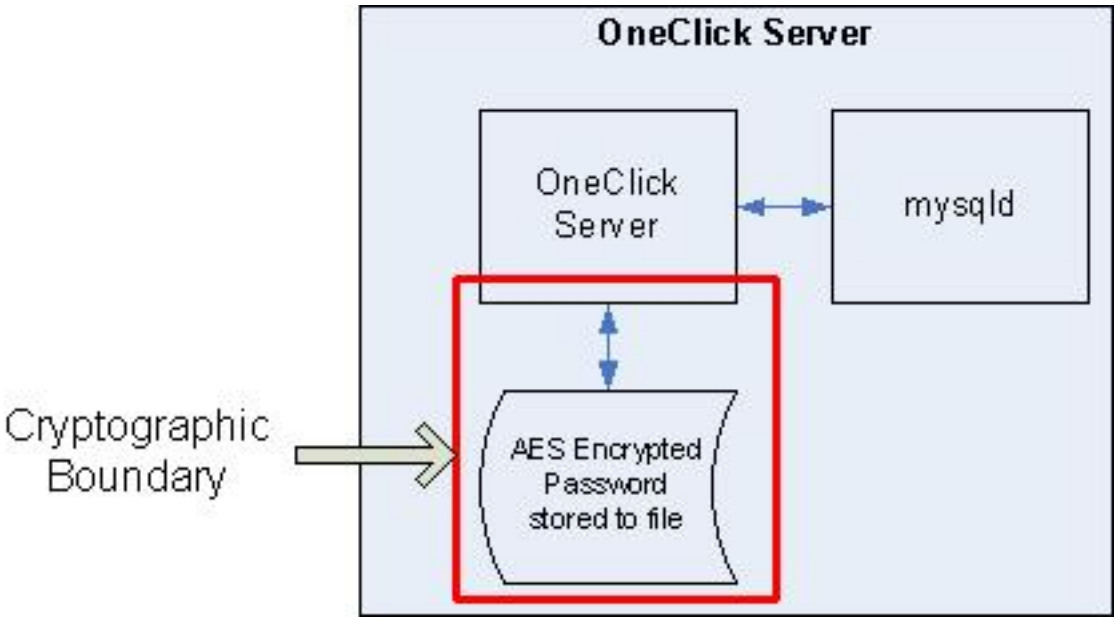
Changing Root Certificate

Not applicable at this time.

MySQL Password Storage

The mysql password is stored to a file with AES-256 encryption.

The Cryptographic Boundary for a MySQL password storage is as follows:



NOTE
For more information about configuring and using MySQL, see the Administration *section*.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Mode

AES-256 password encryption is enabled out of the box.

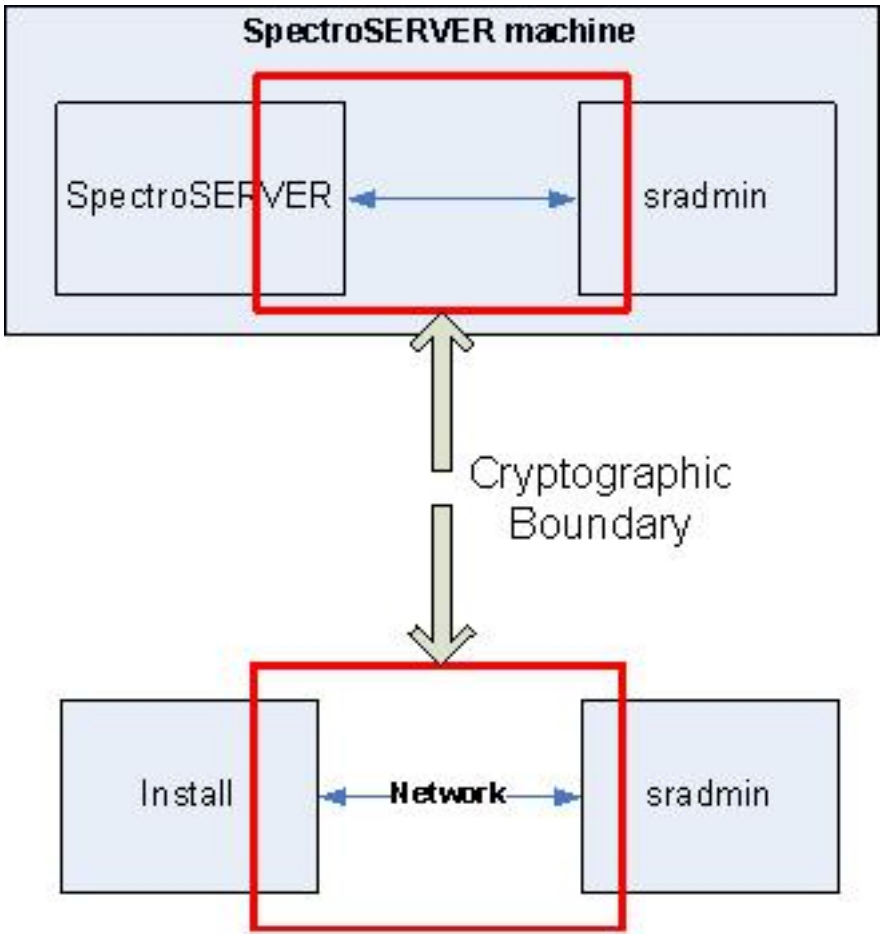
Changing Root Certificate

Not applicable at this time.

SRAdmin Data Transmission

The username and password for DX NetOps Spectrum Remote Administration (SRAdmin) is encrypted using 3DES.

The Cryptographic Boundary for SRAdmin data transmission is as follows:



The sradmin username and password are encrypted with 3DES and are sent over the network.

> **NOTE**
> For more information about configuring and using SRAdmin, see the Installation section.

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum and is also based off the time of the system.

Enable FIPS Mode

3DES username and password encryption is enabled out of the box.

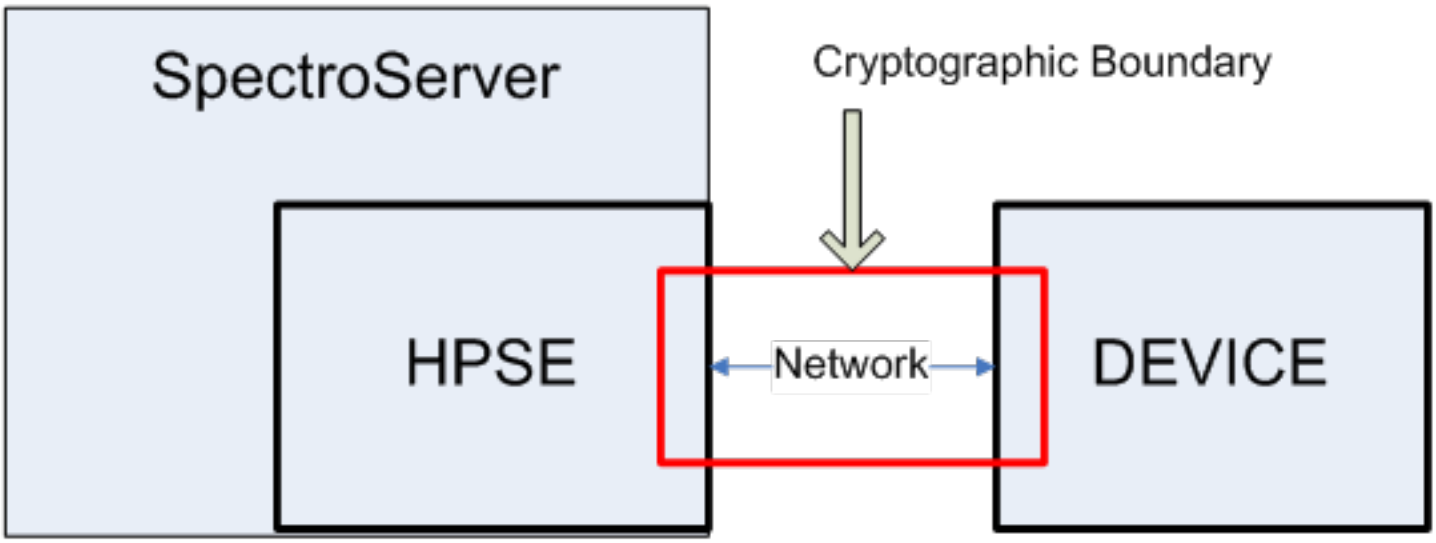
Changing Root Certificate

Not applicable at this time.

SNMPv3 Privacy Data Transmission

To query devices using SNMPv3 with the authentication and privacy, DX NetOps Spectrum can be configured so that the SNMPv3 messages are encrypted using 3DES, AES-128, or AES-256. DX NetOps Spectrum can also be configured to use SHA for authentication when querying devices using SNMPv3 with only authentication or authentication with privacy.

The Cryptographic Boundary for SNMPv3 privacy data transmission is as follows:



The SNMPv3 messages are encrypted using 3DES, AES-128 (AES), or AES-256 and are sent over the network.

NOTE
For more information about configuring and using SNMPv3, see the Modeling and Managing Your IT Infrastructure Administrator *section.*

Special Protection and Key Storage

The encryption key is internal to DX NetOps Spectrum.

Enable FIPS Mode

SNMPv3 does not support FIPS mode, but SNMPv3 supports FIPS-compliant algorithms.

To change the default privacy encryption algorithm for all device models to 3DES, AES or AES-256, the snmpv3_default_priv_protocol parameter in the <*$SPECROOT*>\SS\.vnmrc file must be set to 3DES, AES, or AES256.

For example:

```
snmpv3_default_priv_protocol=3des
```

or

```
snmpv3_default_priv_protocol=aes
```

or

```
snmpv3_default_priv_protocol=aes256
```

Alternatively, to override the default privacy encryption algorithm for a particular device model, append the encryption algorithm to the SNMP community string for that device model.

For example:

```
#v3/<authPW>:3DES^<privPW>/<user>
#v3/<authPW>:AES^<privPW>/<user>
#v3/<authPW>:AES256^<privPW>/<user>
```

To change the default authentication algorithm for all device models to SHA, the snmpv3_default_auth_protocol parameter in the <*$SPECROOT*>\SS\.vnmrc file must be set to "sha".

For example:

```
snmpv3_default_auth_protocol=sha
```

Alternatively, to override the default authentication algorithm for a particular device model that uses authentication only, append the authentication algorithm to the SNMP community string in the following format:

For example:

```
#v3/SHA^<authPW>/<user>
```

To override the default authentication algorithm for a particular device model that uses authentication with privacy, append the authentication algorithm to the SNMP community string in the following format:

```
#v3/SHA^<authPW>:<privPW>/<user>
#v3/<authPW>:AES^<privPW>/<user>
#v3/<authPW>:AES256^<privPW>/<user>
```

NOTE
For more information, see the Modeling and Managing Your IT Infrastructure Administrator *section.*

Changing Root Certificate

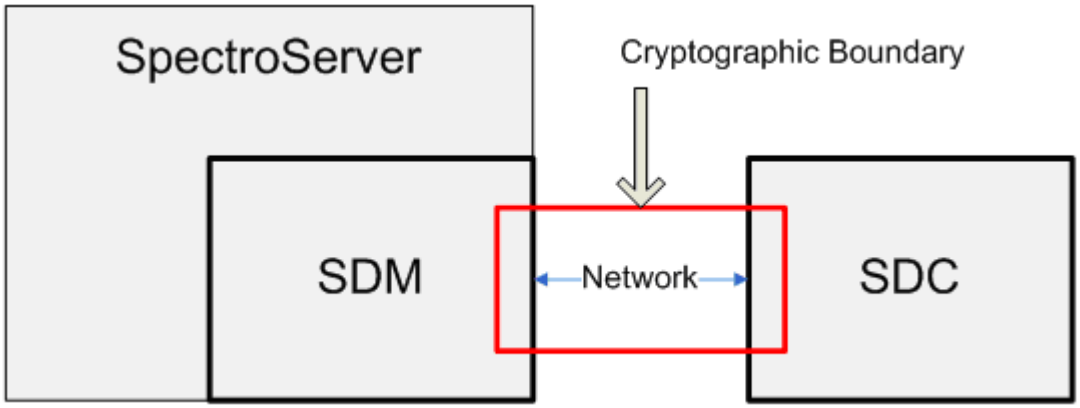
Not applicable at this time.

Secure Domain Manager

A bi-directional communication takes place between the Secure Domain Manager (SDM) and the Secure Domain Connector (SDC).

NOTE
When not running in FIPS mode, DX NetOps Spectrum, using SDM and SDC, runs in a FIPS-compatible state.

The Cryptographic Boundary for the Secure Domain Manager is as follows:



SNMP or ICMP requests and replies, and SNMP traps communication are protected. No other communication takes place.

NOTE
For more information about configuring and using the Secure Domain Manager, see the Secure Domain Manager (SDM) section.

Special Protection and Key Storage

The SDM private key is located at <*$SPECROOT*>/SDM/CERTS/SDMCAKey.pem. The private key requires administrator read and write privileges only.

Enable FIPS Mode

Locate the sdm.config file and add the - withfips option.

NOTE
Any time this option is changed, the entire system needs to be restarted.

Changing Root Certificate

Run the following command to create a new network security certificate for the SDManager:

```
CertGen.exe  - t cert  - c <Country Code>
```

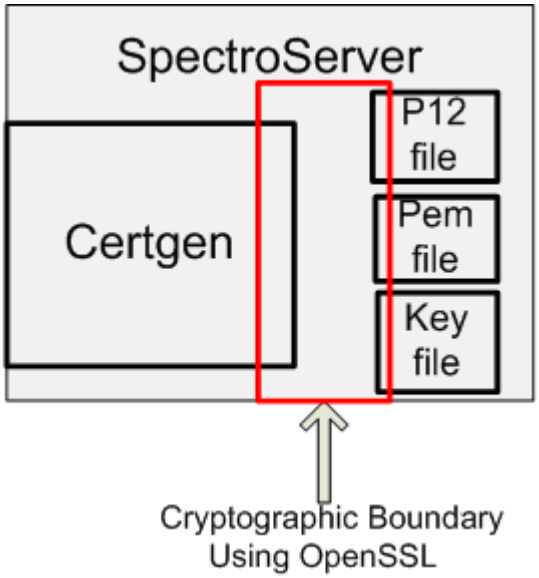
For added security, use the -p option to generate the certificate with a password as follows:

```
CertGen.exe  - t cert  - p <password> -c <Country Code>
```

Certgen

Certgen uses openSSL 0.9.8 to create certificate authorities, key files, and security certificates that are used to encrypt communications between SDM and SDC. The algorithm that is used to create the certificate is 3DES.

The Cryptographic Boundary for Certgen is as follows:



The p12 certificate is used primarily to protect the data being transferred between the Secure Domain Manager and the Secure Domain Connectors.

NOTE
For more information about configuring and using the CertGen, see the Secure Domain Manager section.

Special Protection and Key Storage

All certificate authority, private keys, and certificates are located at <*$SPECROOT*>/SDM/CERTS. All files require administrator read and write privileges.

Enable FIPS Mode

No FIPS mode required.

Changing Root Certificate

Run the following command to create a new network security certificate for the SDManager:

```
CertGen.exe  - t cert  - c <Country Code>
```

For added security, use the -p option to generate the certificate with a password as follows:

```
CertGen.exe  - t cert  - p <password> -c <Country Code>
```

Additional Resources

Provides additional resources to assist you in maximizing your product experience.

This section provides additional resources to assist you in maximizing your product experience; for example:

- Frequently Asked Questions
- Glossary
- Collect Troubleshooting Data
- CA Green Books

Product Videos

Access the following YouTube link to view the DX NetOps Spectrum videos:

- DX NetOps Spectrum YouTube Playlist

Frequently Asked Questions

Following is the list of frequently asked questions and their responses respectively:

Features

Q: What are the key updates to the current release of DX NetOps Spectrum?

A: For the complete list of new features and enhancements, review the Feature and Enhancements page.

Install and Upgrade

Q: Are there any changes to the operating systems that are supported in the current release of DX NetOps Spectrum?

A. Review the System Requirements for Installing DX NetOps Spectrum for more information.

Q: Is the current release a full release?

A. Yes, it is a full release.

Q. Is a base version required to install the current release of DX NetOps Spectrum?

A. No base version is required to install this release.

Q. Have the CA integration components changed?

A. Yes, review the Integration Compatibility Matrix page for the specific version support.

Q. What is the supported Java version in the current release of DX NetOps Spectrum?

A. Adopt OpenJDK 1.8u242

Third-Party Software Updates

Q. What are the third-party software agreements in the current release of DX NetOps Spectrum?

A. To view the list of the third-party software agreements applicable for this release, see the third-party license agreements page.

JasperSoft/CABI

Q. What version of CABI is supported in the current release of DX NetOps Spectrum?

A. See the Integration Compatibility Matrix page for the specific version support.

Glossary

Active Directory Domain Services (AD DS) server role

The *Active Directory Domain Services (AD DS) server role* stores directory data for all objects in your network. The AD DS server role also manages communication between users and domains, including authentication requests and directory searches.

action

An *action* is any operation that is not part of the basic set of operations that DX NetOps Spectrum defines for use with a model.

active node

An *active node* is a system in a cluster environment where application processes (as part of a resource group) are currently running. Within DX NetOps Spectrum Cluster Manager, an active node has resource groups as children. A solid workstation icon represents an active node in the Cluster Manager hierarchy.

ADES AIM Discovery

ADES AIM Discovery is the process that the ADES AIM performs to identify hosts in Active Directory and Exchange Server environments. ADES AIM Discovery uses the Global Catalogs to extract information that is based on user configurations. These configurations specify domain name, management entity (Active Directory, Exchange Server, or both) and management mode (domain-based or host-based). Hosts that ADES AIM Discovery identifies are made available to DX NetOps Spectrum for management.

ADES Host Manager

Active Directory and Exchange Server Host Manager (ADES Host Manager) is the DX NetOps Spectrum model that represents a host that contains the ADES AIM. Successful creation of this model indicates that all requisite intelligence to support ADES Manager has been installed on the host.

ADES Manager Discovery

ADES Manager Discovery is the modeling within DX NetOps Spectrum of Active Directory and Exchange Server hosts that ADES Manager is going to manage. ADES Manager Discovery also includes the modeling of any other required components for ADES Manager. ADES Manager Discovery obtains information about the hosts that are determined as available for management by ADES AIM Discovery.

alarm

An *alarm* is an indication that an abnormal condition exists for a model.

alarm severity

An *alarm severity* is a value found in an EventDisp file that indicates the condition of a model. Conditions represent the presence and seriousness of an alarm. The valid values are 0 through 6 and all represent a different colored condition.

alert

An *alert* is an unsolicited message that is sent from a managed element to the SpectroSERVER.

alert code

An *alert code* is a string that identifies an alert. An alert that is received from an SNMP source contains an alert code that consists of a generic trap followed by a dot (.) followed by an enterprise-specific trap.

AlertMap file

An *AlertMap file* exists for each model type. This file maps incoming SNMP trap data to DX NetOps Spectrum events.

application insight module (AIM)

The SystemEDGE agent provides a plug-in architecture through which it can load optional *application insight modules (AIMs)* when it initializes. AIMs are functional extensions to the SystemEDGE agent.

application programming interface (API)

An *application programming interface (API)* is a set of routines that are used to make calls to another software package.

association

An *association* is a link that is formed between two models by a relation.

asynchronous call

An *asynchronous call* is a call to a method that begins (but does not necessarily complete) a requested operation before allowing a program to continue. At some point, the requested operation completes and notifies the program. In the meantime, the program and the requested operation can both proceed simultaneously.

attribute

An *attribute* is the declarative knowledge in DX NetOps Spectrum that defines a model type. Attributes are defined using the Model Type Editor.

Attribute Editor

The *Attribute Editor* is a OneClick utility that lets you change attributes configured at the device level.

available host

An *available host* is an Active Directory or Exchange Server host that ADES AIM Discovery has identified and which qualifies for management by DX NetOps Spectrum ADES Manager.

DX NetOps Spectrum event

A *DX NetOps Spectrum event* is an event that is generated based on alerts received from MOM- or SCOM-managed hosts.

channel

A channel is a data transmission link between two or more points.

client

A *client* is the application process in a client-server architecture.

cluster

A *cluster* is a group of locally attached machines that provide distributed processing power and high availability. A cluster appears to clients as a single system image and IP address.

client-server architecture

Client-server architecture is a system design that is based on the relationship between a service-providing process (the *server*) and a service-using process (the *client*).

Cluster Manager discovery

Cluster Manager discovery is the modeling within DX NetOps Spectrum of your cluster components. After the cluster technology AIM is modeled successfully, Cluster Manager obtains information about the cluster components in your environment from the AIM. Using a list of machines that is obtained from the AIM, Cluster Manager uses AutoDiscovery to model each cluster node. All supporting cluster components (clusters, resource groups, and resources) are also modeled.

cluster node

A *cluster node* is an independent computer system that participates in a cluster. A cluster node can be active or inactive. The active node has application processes (as part of a resource group) currently running. An inactive node is a system that is allocated to a cluster but not currently processing any resources.

configuration

A *configuration* contains the parameters you specify to determine which network entities in your infrastructure you want *Discovery* to locate and identify for review, export, or modeling.

connection

A *connection* is a link between two modeled elements in a view.

container

A *container* is a graphical icon that you can use to depict a group of modeled devices by network technology such as LAN, Network, ATM, or to represent some other containment concept such as a Department.

CORBA (Common Object Request Broker Architecture)

CORBA is a software component architecture that lets various and different software components communicate. The software components can be written in different languages (C, C++, Java, Smalltalk, COBOL, ADA, Lisp, Perl, Tcl, Eiffel, Python). The software components can also reside on different machines and can be written for different operating systems.

custom installation script

A *custom installation script* is a script that can be included in a VCD. The script executes as the integration package is being installed on the SpectroSERVER.

database

A *database* is a collection of interrelated data that is organized to facilitate efficient and accurate inquiries and updates.

database availability group (DAG)

A *database availability group (DAG)* is a cluster of Exchange Mailbox servers that are used for continuous replication, providing failover at the database level. The databases on any of the DAG members can be replicated to the other DAG members. At any given time, the database is active on one DAG member only, while the databases on the other DAG

members are passive. A passive database can then be activated in the event of failure. The DAG feature was introduced in Exchange 2010.

database management system

A *database management system* is a software package that organizes and maintains a database.

developer ID

A *developer ID* consists of a 14-character developer name and a four-character prefix. The developer name must be alpha-numeric and can include underscores, however, no other punctuation marks are allowed. The prefix must also be alpha-numeric, however, no underscores or other punctuation marks are allowed. DX NetOps Spectrum uses *developer IDs* to verify that the objects, such as model types, attributes, or relations, created by users or integrators have unique identifiers. These objects can therefore be distributed to other users without conflict.

To obtain a developer ID, contact CA Support.

Development API

The *Development API* is the CORBA-based application program interface (API) to the SpectroSERVER. The Development API is also referred to as the SpectroSERVER Object Request Broker (SSORB) interface because it depends on an object request broker (ORB).

device

A *device* is a managed element.

device attributes

Device attributes are the configuration settings written to a device or interface.

Device Communications Manager (DCM)

The *Device Communications Manager (DCM)* is a multiprotocol communication engine in the SpectroSERVER that handles the communication with all managed elements, regardless of their protocol. The DCM translates the SpectroSERVER requests into protocols that the individual devices understand.

Discovery

Discovery is a OneClick feature that automates the process of discovering and modeling the entities in your IT infrastructure. You can create and edit Discovery and modeling configurations to customize and simplify the process. DIscovery also lets you filter and export the results of Discovery or modeling sessions.

Distributed SpectroSERVER (DSS)

The *Distributed SpectroSERVER (DSS)* is a modeling feature that uses the concept of landscapes to improve DX NetOps Spectrum performance when managing a large computing infrastructure. DSS technology distributes the load that management traffic introduces and lets you delegate management functions to remote workstations.

distributed SpectroSERVER (DSS) environment

A *distributed SpectroSERVER (DSS) environment* consists of more than one SpectroSERVER. This environment enables management of a large-scale infrastructure. The SpectroSERVERs in this environment can be located within a single physical location or in multiple physical locations.

domain

A *domain* is an Active Directory container structure that contains a collection of objects that share a common set of policies, name, and security database. A domain is at the lowest level of the logical structure of an entire network. The domain name identifies the domain.

domain controller

A *domain controller* is a host that is running AD DS. Typically multiple domain controllers host Active Directory within a domain, and you can manage your network resources from any domain controller within your domain.

domain tree

A *domain tree* is an Active Directory container structure that contains a collection of one or more domains in a network.

domain-based management

Domain-based management is a configuration option in the ADES AIM where all newly discovered, available hosts in the domain are automatically managed by default. Domain-based management is typically used with domains that are small enough for a single ADES AIM to manage.

Edit Mode

Edit Mode lets you edit the current view in DX NetOps Spectrum. Selecting Edit Mode displays the File and Edit options in the menu bar.

element management system

An *element management system* lets you provision, manage, and monitor elements in a network infrastructure.

event

An *event* is a significant message from the SpectroSERVER.

event code

An *event code* is a hexadecimal number that uniquely identifies an event.

event data template

An *event data template* is a series of integers that Southbound Gateway uses to format variable data coming from an alert.

event discriminators

Event discriminators are references to event variables that let you to generate alarms for events based on the values of the variables.

event format file

An *event format file* contains the message about the event that appears in the Events tab in the OneClick Console when the event occurs.

event message

The *event message* is the message that is displayed on the Events tab in OneClick when the event occurs.

event severity

Event severity is a numeric value that is found in an EventDisp file entry that indicates the seriousness of an event. Valid values are from 0 through 100, with 0 being the least severe.

event variable ID

An *event variable ID* is an ID that represents the event variable data. Use of this ID returns the event variable value.

EventAdmin

EventAdmin is the Southbound Gateway model type that represents a third-party management system.

EventDisp file

An *EventDisp file* exists for each model type and determines how DX NetOps Spectrum processes events for that model type.

EventModel

An *EventModel* is a model type in DX NetOps Spectrum that represents a unique alert source within a Southbound Gateway integration.

failover/failback (MSCS)

Failover is a transfer process where resource groups that are hosted on a particular node that fails move to another node in the cluster. The reverse process is "failback". Failback occurs when the failed node becomes active again, and the groups that were failed over to other nodes transfer back to the original node.

fall over/fall back (IBM PowerHA)

Fall over is a transfer process where resource groups that are hosted on a particular node that fails move to another node in the cluster. The reverse process is "fall back". Fall back occurs when the failed node becomes active again, and the groups that moved to other nodes transfer back to the original node.

forest

A *forest* is an Active Directory container structure that contains a collection of Active Directory objects, their attributes, and attribute syntax. A forest is at the highest level of the logical structure. A forest is a collection of domain trees sharing a common global catalog, directory configuration, directory, schema, and logical structure.

head-end device

The LSP *head-end device* is a Provider Edge router device used to create the LspHead model in MPLS Transport Manager. This model groups your LSPs by ingress device in the OneClick Navigation panel, making it easier to view and locate data about your LSPs within the MPLS environment.

host-based management

Host-based management is a configuration option in the ADES AIM where all newly discovered, available hosts in the domain are automatically not managed by default. Host-based management is typically used with domains that are large enough that multiple ADES AIMs manage them.

Hub Transport server role

The Exchange Server *Hub Transport server role* handles email flow and routing. All messages are delivered through this role, regardless of whether they are being delivered locally or remotely.

IBM PowerHA Cluster Manager

The *IBM PowerHA Cluster Manager* is the DX NetOps Spectrum model that represents a host that contains the HACMP AIM. The HACMP AIM monitors the IBM PowerHA cluster elements (clusters, nodes, resource groups, and resources) in your environment.

ICMP (Internet Control Message Protocol)

ICMP supports packets that contain error, control, and informational messages.

icon

An *icon* is a visual representation of something that is displayed on a screen.

inactive node

An *inactive node* is an available cluster node that has no resource groups currently running on it. In DX NetOps Spectrum, unlike a model in maintenance mode or hibernation mode, the inactive node model is fully functional. Data is gathered for the node, and any alarm activity or events for the node post to the model. Within the Cluster Manager hierarchy, an inactive node does not have any resource groups as children. A transparent icon represents an inactive node.

index file

An *index file* is a file that is created using the DX NetOps Spectrum Extension Integration (SEI) Toolkit and defines the components of the integration. The index file indicates where the integration components exist on the host and their location on the customer host.

Inductive Modeling Technology (IMT)

Inductive Modeling Technology (IMT) is a CA set of artificial intelligence techniques. These techniques allow a computing infrastructure of arbitrary complexity to be modeled such that every element is given intelligence.

inference handler

Inference handlers are the intelligence behind DX NetOps Spectrum. Inference handlers monitor the changes in the environment, the changes between related models, and the changes in relationships between models and attributes.

instance variable

The *instance variable* stores the instance portion of the OID. If the variable binding identifies a particular object from a table variable within the trap MIB, it likely includes an instance ID.

instance variable ID

An *instance variable ID* is the integer that identifies the instance variable in the OID map. Use of this ID returns the instance variable.

instantiate

In object-oriented design, to *instantiate* is to create a particular occurrence of something.

intelligence circuit

An *intelligence circuit* is a collection of inference handlers that defines the behavior of a model type.

knowledge base

The *knowledge base* is the collection of everything that DX NetOps Spectrum can model and managed including concepts, relationships, declarative knowledge, and procedural knowledge.

knowledge base management system

The *knowledge base management system* is the software that is used to define and manage the information in the knowledge base.

label

A *label* is a fixed-size field contained in a packet header that can be used as an exact-match key in determining how to forward a protocol data unit.

Label Switch Router (LSR)

A *Label Switch Router (LSR)* is a router in an MPLS network that switches the routing label on a data packet before forwarding it to the next hop in the LSP. The LSR uses a look-up table to determine the new label.

Label Switched Path (LSP)

A *Label Switched Path (LSP)* is the path within the MPLS network along which labeled packets are forwarded. Packets forwarded using a label are forwarded along the same path as other packets using the same label.

landscape

A *landscape* is all the data that is specific to any one virtual network machine (VNM) in a single network. The term also identifies the network domain that is managed by a single SpectroSERVER. In OneClick, a landscape is the network view of one SpectroSERVER.

legacy SNMP community string

The DX NetOps Spectrum *legacy SNMP community string* has been replaced in OneClick by access groups and privileges. The legacy SNMP community string can still be viewed and edited in OneClick under the Details tab for a selected user in the Users tab. The legacy SNMP community string is still used by non-OneClick DX NetOps Spectrum applications.

license

A *license* determines which privileges can be granted to holders of that license. Launching a OneClick client consumes any licenses granted to that user.

Mailbox server role

The Exchange Server *Mailbox server role* provides email storage (including user mailboxes), advanced scheduling services, and supports public folders. Continuous replication technology provides a reliable failover mechanism in the event of failure. In Exchange 2007, continuous replication failover is at the server level. With Exchange 2010 and the introduction of database availability groups (DAGs), failover is at the database level.

managed element

A *managed element* is an item or device whose status is being monitored and controlled. A managed element can be a network device, host system, application, service, or other computing infrastructure component.

managed host

A *managed host* is an Active Directory or Exchange Server host that DX NetOps Spectrum ADES Manager manages, as reflected by the Managed Host Table. The ADES AIM polls all managed hosts for Active Directory and Exchange Server metrics. Management of a host can be controlled by using the Universal Host Table view in DX NetOps Spectrum.

Managed Host Table (MHT)

The *Managed Host Table (MHT)* contains all hosts that the ADES AIM is managing (polling for Active Directory and Exchange Server metrics). To clarify, the Universal Host Table contains all hosts that an AIM *can* manage. The Managed Host Table contains those hosts that *are* managed. The MHT table resides on the ADES AIM and is viewable in DX NetOps Spectrum. ADES Manager uses the MHT as its basis for creating, deleting, or updating Active Directory and Exchange Server host models.

managed object

A *managed object* is a variable on a managed element containing one piece of information about the node. Each node can have several objects.

management agent

A *management agent* is an implementation of a management protocol that exchanges information for the managed element with the management station.

management entity

Management entity is a configuration option in the ADES AIM on a per-domain basis that controls what technologies to monitor by the ADES AIM: Active Directory, Exchange Server, or both.

management mode

Management mode is a configuration option in the ADES AIM that controls monitoring of the Active Directory and Exchanger Server environments on a per-domain basis. Domain-based monitoring automatically manages all newly discovered Active Directory and Exchange Server hosts in the domain. Host-based monitoring automatically does not manage all newly discovered Active Directory and Exchange Server hosts in the domain.

Microsoft Cluster Manager

The *Microsoft Cluster Manager* is the DX NetOps Spectrum model that represents a host that contains the MSCS AIM. The MSCS AIM monitors the Microsoft Clusters Service elements (clusters, nodes, resource groups, and resources) in your environment.

Management Station Access Provider (MSAP)

Management Station Access Provider (MSAP) is a software task that provides an object with access to a management station.

manual modeling

Manual modeling is the act of manually representing individual devices and their connections within a OneClick topology view.

meta-rules

Meta-rules specify which model types can participate in a relation.

migration

Migration is the movement of a resource group from one node to another. Different terms are used to describe migration depending on the cluster technology; for example, failover, fall over, failback, and fallback.

model

A *model* in DX NetOps Spectrum represents a modeled network element.

MIB (Management Information Base)

A *MIB (Management Information Base)* is a database that resides on a network device and represents that device as a hierarchical collection of objects. A MIB object represents an individual element of information, such as the uptime of a device. MIBs themselves are text files with special syntax.

mkcd

The *mkcd* is a tool that is a part of the DX NetOps Spectrum Extension Integration (SEI) Toolkit. This tool finishes the VCD by adding a version number and making the VCD installable on a DX NetOps Spectrum host.

mkmm

The *mkmm* is a tool that is a part of the DX NetOps Spectrum Extension Integration (SEI) Toolkit. This tool creates the VCD using the index file and the applicable component files.

model

A *model* is a collection of information that forms a specific occurrence of some basic defined type. In DX NetOps Spectrum, models are instances of model types.

model type

A *model type* is a template that describes the attributes, actions, and associations that are related to a managed element in DX NetOps Spectrum.

Model Type Editor (MTE)

The *Model Type Editor (MTE)* is the primary tool that defines the concepts, relationships, meta-rules, and declarative knowledge in the DX NetOps Spectrum knowledge base.

Model by Host Name

Model by Host Name is a modeling feature that you can use in the Universe, World, or TopOrg topology. This feature lets you manually model a new device by specifying the host name for the device.

Model by IP Address

Model by IP Address is a modeling feature that you can use in the Universe, World, or TopOrg topology. This feature lets you manually model a new device by specifying the device IP address.

Model by Model Type

Model by Model Type is a modeling feature you can use in the Universe, World, or TopOrg topology. This feature lets you manually model container icons or devices by a model type.

modeling methods

There are two *modeling methods* available for modeling your network infrastructure. You can automate the process using *Discovery,* or you can manually model the individual entities and later enhance the model presentation using the Topology Edit Mode tools.

modeling session

A *modeling session* occurs when you instruct *Discovery* to model the results of a *Discovery session*. It uses the modeling options specified to model the network entities discovered in that *configuration.*

Modular Object Oriented Threads (MOOT)

Modular Object Oriented Threads (MOOT) is a task control manager that is used in the SpectroSERVER.

Multiprotocol Label Switching (MPLS)

Multiprotocol Label Switching (MPLS) refers to a group of technologies that marries IP to Layer 2 technologies (such as ATM) by overlaying a protocol on top of IP networks.

Navigation Mode

Navigation Mode is the moving from one view to the next in DX NetOps Spectrum. The menu bar contains the File and View options when in Navigation Mode. Navigation Mode does not allow editing of a view.

Network management agent

A *network management agent* is an implementation of a management protocol that exchanges information about the managed element with the management station.

network management protocol

A *network management protocol* is the means by which the management station and the managed elements exchange information.

network management station

A *network management station* is the host system or workstation that is running the network management applications and protocol.

object-oriented design (OOD)

Object-oriented design (OOD) is design that encompasses the process of breaking a system into parts. Each part represents some class or object from the problem domain. OOD is applied by viewing the world as a collection of objects that cooperate with one another to achieve some desired functionality. OOD typically includes a notation for depicting logical or physical and static or dynamic models of the system under design.

OneClick Console client

The *OneClick Console client* is a Java JNLP application which provides network operators with a view into the details and health of the network.

OneClick web server

The *OneClick web server* is the server responsible for moving data between SpectroSERVERs and OneClick clients.

OID

An *OID* is an identifier for a managed object.

OID map

An *OID map* is the syntax that is used to map an alert variable to an event variable.

path

A *path* is a large communications pipe that pre-allocates bandwidth and allows for greater flexibility in establishing PVCs. A defined amount of bandwidth is leased from a service provider, and as many PVCs as necessary within the limits of that bandwidth can be established.

In an MPLS environment, a *path* is the route taken by a data packet through a series of devices in the network. This route is defined hop by hop.

permanent virtual circuit (PVC)

A permanent virtual circuit (PVC) is a logical connection that is manually created by a network administrator. This connection is maintained at all times even if it is not always in use. PVCs can exist without being a part of a PVP.

permanent virtual path (PVP)

A permanent virtual path (PVP) is a logical communications path that has a defined amount of leased bandwidth. The path is maintained at all times even if it is not always in use.

pipe

A *pipe* is an icon that represents a connection between two devices or ports.

pollable attribute

A *pollable attribute* is an attribute for which the VNM regularly queries the managed element to obtain current values. Attributes are defined as pollable or non-pollable through the Model Type Editor.

probable cause file

The *probable cause file* is an ASCII text file that defines the symptoms, probable causes, and recommended corrective actions for an alarm. When an event generates an alarm, the text in the associated probable cause file is displayed on the Alarm Details tab in OneClick.

procedural knowledge

In DX NetOps Spectrum, *procedural knowledge* is information that defines how a concept behaves or reacts to environmental changes.

protocol

A *protocol* is a set of rules that computers use to communicate with each other.

proxy management

Proxy management is the act of managing network devices using an alternate management source in place of or in addition to the device itself. For example, DX NetOps Spectrum can manage Active Directory or Exchange Server hosts by contacting them directly or through the ADES AIM.

relation

A *relation* is information describing the connection that models have with each other.

resource

A *resource* is a logical component or entity (for example, a file system or an application) that runs on only one node at a time. A resource can move from one cluster node to another.

resource group

A *resource group* is a collection of resources that forms a functional unit existing on a single cluster node.

role (SPECTRUM)

A *role* is a reusable set of user privileges that you can assign to an access group. For example, the default role (OperatorRW) grants the set of read/write privileges typically needed by a OneClick operator.

SANM

The Alarm Notification Manager (*SANM*) is a DX NetOps Spectrum component that enhances the functionality of DX NetOps Spectrum alarm-processing applications.

security community

A *security community* determines user access to secure models. DX NetOps Spectrum users are selectively granted access to models that are secured with a *security string*.

security string

Security strings are expressions that define security communities. Security communities define access to models, securing them from unauthorized users. Security strings are set at the model level for modeled elements in OneClick.

sequential window

A *sequential window* is a type of type time window in which non-overlapping time windows are examined, one after another, to determine if the requisite number of events has occurred within the time window. This type of time window is best suited for detecting a long, sustained train of events.

Service Level Agreement (SLA)

A *Service Level Agreement (SLA)* is typically a contractual agreement between a business and its subscribers guaranteeing a specified level of service, such as 99.9 percent availability. An SLA sometimes contains a penalty clause for noncompliance.

server

A *server* is a process that provides services in response to a client request in a client-server architecture.

server role

A *server role* is the primary duty that a server performs. Active Directory and Exchange Server use server roles to assign specific functions to specific hosts.

sliding window

A *sliding window* is a type of time window where if the specified number of events (or more) ever occurs within any window of the specified time period, the output event is created in response. This type of time window is best suited for accurately detecting a short burst of events.

SNMP (Simple Network Management Protocol)

SNMP (Simple Network Management Protocol) is a network protocol that is used to monitor devices and applications on a network.

SNMP trap

An *SNMP trap* is an occurrence that is either broadcast or directed to a network management application, notifying the application of device or network activity. SNMP-enabled devices or applications generate traps.

SpectroSERVER

The *SpectroSERVER* is the server responsible for providing network management services such as polling, trap management, notification, data collection, fault management, and so on. This server is also referred to as the Virtual Network Machine (VNM).

DX NetOps Spectrum Extensions Integration (SEI) Toolkit

The *SEI Toolkit* is a set of tools for packaging and distributing an integration so that it can be installed on other DX NetOps Spectrum host machines.

SSORB client

The *SSORB client* is an application that accesses the DX NetOps Spectrum CORBA interface, SSORB.

super user

A *super user* is a DX NetOps Spectrum user that has all possible DX NetOps Spectrum privileges and access in OneClick. A user that has been designated a super user is automatically granted all OneClick license roles and privileges.

switched virtual circuit (SVC)

A switched virtual circuit (SVC) is a temporary connection that is established and maintained only for the duration of a data transfer session.

synchronous call

A *synchronous call* is a call to a method that performs the entire requested action before a program can continue running. The program continues only after the completion of the called method.

trap

A *trap* is an *alert* that is generated by an SNMP-compliant device.

timing interval

A *timing interval* is the frequency with which the current view updates displayed model attribute information. The default is one request per model every 5 seconds for some number of attributes.

Traffic Engineering (TE)

Traffic Engineering (TE) is the application of constraint-based routing in which a traffic engineer uses a set of link characteristics to select a route and assigns specific traffic to that route.

Universal Host Table (UHT)

The *Universal Host Table (UHT)* contains all hosts that are available for management by an ADES AIM. Using the Universal Host Table view in DX NetOps Spectrum, you can control which hosts DX NetOps Spectrum ADES Manager manages.

user (Spectrum)

A *user* in OneClick can refer to either a OneClick user account or the actual individual associated with the account. This account is created by a OneClick administrator. It provides a single OneClick user with access to OneClick and stores information about the user, such as password, access, and privileges in the DX NetOps Spectrum database.

user group

A *user group* in OneClick is a logical grouping of users that are organized together for a common purpose. Users within the same group can share the privileges granted by the group. When you specify privileges at the group level, OneClick grants each group member those privileges in addition to any privileges they have at the user level.

value variable ID

A *value variable ID* is an ID that is used to retrieve the value of a variable binding that is sent with an SNMP trap.

variable bindings

A *variable binding* is variable data that is sent as a part of an SNMP trap.

VCD (virtual CD)

A *VCD (virtual CD)* is a series of files that the DX NetOps Spectrum Extension Integration (SEI) Toolkit creates. The VCD lets developers easily package and distribute their integrations.

view

A *view* is one of many representations of the network landscape.

virtual channel identifier (VCI)

The virtual channel identifier (VCI) is a field of a cell header that contains the address of the virtual channel.

virtual channel link (VCL)

A virtual channel link (VCL) is a unidirectional method of transport for ATM cells that begins at the point where a VCI value is assigned and ends at the point where the VCI value is translated or removed.

virtual network machine (VNM)

Within the SpectroSERVER, the virtual network machine (VNM) is the software level that provides access to data regardless of where the data is stored. The data can be stored in the database, the VNM memory, or any of the managed elements on the network. The VNM also embodies the DX NetOps Spectrum intelligence that is known as the Inductive Modeling Technology (IMT).

virtual path identifier (VPI)

The virtual path identifier (VPI) is a field of a cell header that contains the address of the virtual path.

virtual path trunk (VPT)

A *virtual path trunk (VPT)* is a unidirectional method of transport for ATM cells that begins at the point where a VPI value is assigned and ends at the point where the VPI value is translated or removed. A VPT is made up of a group of VCLs with the same VPI value.

virtual technology manager

A *virtual technology manager* is the SystemEDGE agent with a virtual technology AIM loaded. Virtual Host Manager uses virtual technology managers to manage virtual devices. For more information, see the Virtual Host Manager section.

AlarmNotifier

AlarmNotifier is a SpectroSERVER-client application that installs with core DX NetOps Spectrum components. The AlarmNotifier application connects to a single SpectroSERVER and invokes scripts that provide notifications about DX NetOps Spectrum alarm status.

CAMM Presenter (Huawei SingleCLOUD)

The *Huawei SingleCLOUD CAMM Presenter* model represents a CA Mediation Manager (CAMM) Presenter. The CAMM Presenter model allows configuration of the virtual IP addresses used by the CAMM Engines to communicate with Huawei SingleCLOUD GalaX. Each CAMM Presenter model can support multiple Huawei SingleCLOUD Managers.

CNA FIP (Huawei SingleCLOUD)

The *Huawei SingleCLOUD CNA FIP* represents the management interface of the CNA that is hosting the virtual machines. This model is assigned the IP address of the CNA FIP and lives within the host container.

Computing Node Agent (CNA) (Huawei SingleCLOUD)

The *Computing Node Agent (CNA)* is an administrative process used in the Huawei SingleCLOUD platform that resides on a server that hosts virtual machines. A CNA is represented by a Huawei SingleCLOUD Host model in DX NetOps Spectrum. The Huawei SingleCLOUD CNA FIP model is assigned the IP address of the CNA.

datacenter (VMware)

A *datacenter* serves as a container for your hosts, virtual machines, resource pools, or clusters. Depending on their virtual configuration, datacenters can represent organizational structures, such as geographical regions or separate business functions. You can also use datacenters to create isolated virtual environments for testing or to organize your infrastructure.

ESX host (VMware)

An *ESX host* is a physical computer that uses ESX Server virtualization software to run virtual machines. Hosts provide the CPU and memory resources that virtual machines use and give virtual machines access to storage and network connectivity.

ESX service console (VMware)

The *ESX service console* is a Linux kernel running on the ESX host that provides a management interface to the hosted virtual machines.

Hardware Management Console

The *Hardware Management Console (HMC*) is the IBM LPAR virtualization technology application used to configure IBM LPARs. This console provides centralized management of the IBM LPAR environment.

Huawei SingleCLOUD

The *Huawei SingleCLOUD* platform is an enterprise-grade turn-key offering that consists of a complete system of network, storage, servers and software for creating private or public clouds.

Huawei SingleCLOUD GalaX

Huawei SingleCLOUD GalaX is the software suite that collectively manages the Huawei SingleCLOUD. It includes the Operation and Management Module (OMM), which is responsible for managing the Universal Virtualization Platform (UVP).

Huawei SingleCLOUD Manager

The *Huawei SingleCLOUD Manager* represents a virtual IP address on the CAMM Presenter. CAMM monitors the Huawei SingleCLOUD GalaX, which is responsible for managing the Huawei SingleCLOUD virtual platform. Information for each Huawei SingleCLOUD GalaX being monitored by CAMM is provided through a virtual IP address on the CAMM Presenter and is represented by a Huawei SingleCLOUD Manager model.

Hyper-V Host

A *Hyper-V Host* is a physical computer that uses Microsoft Hyper-V virtualization software to run virtual machines. Hosts provide the CPUs and memory resources that Hyper-V virtual machines use. They also give these virtual machines access to storage and network connectivity.

Hyper-V management operating system

The Hyper-V management operating system is the original operating system running on the Hyper-V Host. Microsoft Hyper-V uses this operating system to configure the hosted Hyper-V virtual machines.

IBM LPAR

An *IBM LPAR* is a logical partition instance configured on the IBM LPAR Host that, like a physical computer, runs an operating system and applications. An IBM LPAR dynamically consumes resources on its physical host, depending on its workload and configuration.

IBM LPAR Host

An *IBM LPAR Host* is a physical computer that uses IBM LPAR virtualization software to host IBM LPAR instances. IBM LPAR Hosts provide the CPU and memory resources that IBM LPARs use. They also give these IBM LPARs access to storage and network connectivity.

IBM LPAR Manager

The *IBM LPAR Manager* in Virtual Host Manager is the CA eHealth SystemEDGE agent with the IBM LPAR AIM enabled. The IBM LPAR Managers are responsible for reporting on all of the configured IBM LPARs. Virtual Host Manager communicates with the IBM LPAR Managers to gather details about your IBM LPAR virtual environment.

Operation and Management Module (OMM)

The *Operation and Management Module (OMM)* is part of the Huawei SingleCLOUD GalaX software application that is responsible for managing the Huawei SingleCLOUD Hypervisor Universal Virtualization Platform (UVP).

pingable model (Spectrum models)

A *pingable model* is a generic type of network model created in DX NetOps Spectrum based on a non-SNMP model type. DX NetOps Spectrum can poll these devices to provide basic model management, but SNMP-capable monitoring is not available.

Universal Virtualization Platform (UVP)

The *Universal Virtualization Platform (UVP)* is the Huawei HyperVisor, a part of the Huawei SingleCLOUD solution that consists of the hosts and virtual machines that make up its cloud architecture.

vCenter

vCenter is a VMware application that provides centralized management, operational automation, and resource optimization for ESX environments.

VHM model

A *VHM model* in DX NetOps Spectrum represents a virtual entity managed by Virtual Host Manager. Instead of retrieving status and management information from SNMP like some traditional DX NetOps Spectrum models, a VHM model communicates with the proxy manager for its fault and virtual management capabilities. A VHM model can additionally communicate via SNMP if an SNMP agent is installed and configured on the modeled device.

virtual machine

A *virtual machine (VM)* is a software computer that, like a physical computer, runs an operating system and applications. A virtual machine dynamically consumes resources on its physical host, depending on its workload. Because virtual machines are flexible computing units, their deployment comprises a wide range of environments. Examples include environments such as data centers, cloud computing, test environments, or desktops and laptops. In data center implementations, they are used for server consolidation, workload optimization, or higher energy efficiency.

VMware Manager

The *VMware Manager* in Virtual Host Manager is the CA eHealth SystemEDGE agent with the vCenter Server AIM loaded. The VMware Manager is responsible for reporting on all of the configured virtual machines it manages. Virtual Host Manager communicates with the VMware Managers to gather details about your VMware virtual environment.

resource pool (VMware)

A *resource pool* defines partitions of physical computing and memory resources of a single host or a cluster. You can partition any resource pool into smaller resource pools to divide and assign resources to specific groups or for specific purposes. You can also hierarchically organize and nest resource pools.

Center Server (VMware)

VMware vCenter Server provides the central point of control for configuring, provisioning, and managing a virtual vSphere environment. vCenter Server runs as a service on Microsoft Windows Servers and Linux Servers.

virtual NIC (VMware)

A *virtual NIC* is a virtual Ethernet adapter on a virtual machine. The guest operating system communicates with the virtual Ethernet adapter through a device driver as if the virtual Ethernet adapter was a physical Ethernet adapter. The virtual Ethernet adapter has its own MAC address, one or more IP addresses, and responds to the standard Ethernet protocol like a physical NIC.

main location server (MLS)

The *main location server (MLS)* is the primary SpectroSERVER used to coordinate the information and events from all other SpectroSERVERs connected in a DSS environment.

Provider Edge (PE)

Provider Edge (PE) typically refers to the customer-facing router that is managed by the ISP. These routers interface with the customer network to carry network traffic from one customer server to another within the same LAN.

Service Level Agreement (SLA)

A *Service Level Agreement (SLA)* is typically a contractual agreement between a business and its subscribers guaranteeing a specified level of service, such as 99.9 percent availability. An SLA sometimes contains a penalty clause for noncompliance.

Virtual Forwarding Instance (VFI)

A *Virtual Forwarding Instance (VFI*) is a logical collection of VPLS Sites that are part of the same virtual packet forwarding instance. These VPLS Sites share a common Layer 2 forwarding database, much the same way that Layer 3 devices may share a common routing table.

Virtual Private LAN Service (VPLS)

Virtual Private LAN Service (VPLS) is a way to provide Ethernet-based multi-point to multi-point communication over IP/MPLS networks.

VPLS Site

A *VPLS Site* represents the service delivered to a customer over an interface in your VPLS environment.

Microsoft Operations Manager (MOM)

Microsoft Operations Manager (MOM) is an application that provides real-time events and alerts on the performance of Microsoft Windows servers and applications in your network.

MOM agent

The *MOM agent* is installed agent software that resides on a system managed by MOM. A MOM agent collects system events and statistics.

MOM Connector

MOM Connector is an application that synchronizes alarm data between DX NetOps Spectrum and Microsoft Operations Manager. The MOM Connector uses the DX NetOps Spectrum SSORB CORBA API to interface with DX NetOps Spectrum. It uses the MOM Connector Framework (MCF) to interface with Microsoft Operations Manager.

MOM host server

The *MOM host server* is responsible for management tasks, such as event-based alert generation.

SCOM agent

SCOM agent is installed agent software that resides on a system managed by Microsoft System Center Operations Manager. A SCOM agent collects system events and statistics.

SCOM Connector

The *SCOM Connector* is an application that synchronizes alarm data between DX NetOps Spectrum and System Center Operations Manager. The SCOM Connector uses the DX NetOps Spectrum SSORB CORBA API to interface with DX NetOps Spectrum. It uses the Operations Manager Connector Framework to interface with SCOM.

SCOM host server

SCOM host server is responsible for management tasks, such as event-based alert generation.

System Center Operations Manager (SCOM)

System Center Operations Manager (SCOM) is an application that provides real-time events and alerts on the health of servers and applications in your IT environment.

Use the CA Remote Engineer Tool to Collect Troubleshooting Data

CA Remote Engineer is a tool that automates the collection of diagnostic data for installed CA software products. CA Remote Engineer scans the system, collects log or configuration file information packages, and transmits the file to CA Support. This tool helps technicians troubleshoot problems with the system or software. This diagnostics tool simplifies the diagnostics process and ensures business continuity. The tool collects and shares CA Support Engineers the exact data they need from your environment to resolve the issues faster. The metrics that are gathered by Remote Engineer are protected by the customer support agreement which states that the gathered information is deleted within 30 days of the resolution of an issue.

The CA Remote Engineer tool collects configuration and diagnostic data that helps CA Support Engineers troubleshoot problems with the system or software.

Collect Troubleshooting Information

CA Remote Engineer collects the following configuration and diagnostic data to troubleshoot problems with the system or software:

- Product information: Version, product logs, and configuration information
- Hardware information: CPU, memory, ports, IRQ, interrupts, devices, and disk partitions
- Operating system information: OS version, patch levels, network information, disk information, CA product registry keys, running process information, and environment variables

Use CA Remote Engineer for DX NetOps Spectrum

From 10.3.1, the CA Remote Engineer tool is shipped with the product. The **CA_RemoteEngineer.zip** file is available in the DX NetOps Spectrum installation folder, extract the .zip file to a preferred location.

Perform the following steps to run Remote Engineer and collect troubleshooting data for your DX NetOps Spectrum:

1. Log in to the DX NetOps Spectrum computer where you want to run the diagnosis tool.
2. Unzip the **CA_RemoteEngineer.zip** file to a proper location on that server and go to the newly created '**RemoteEngineer**' directory.
3. Run the **RemoteEngineer.exe** file.
4. Select **CA Spectrum** from the **Product Name** drop-down.
5. Select the **Run Diagnostics** button.
6. Enter the Spectrum Installation Drive details then select **Enter**. The tool starts diagnosing for the following details of Spectrum:
   a. OS Version
   b. CPU
   c. Memory
   d. Disk Space
   e. Product Version
   f. Product Checks details.

   CA Remote Engineer collects troubleshooting data for the server and stores in the diagnostic_results folder in the Remote Engineer directory.

CA Remote Engineer Output

CA Remote Engineer writes the information that it collects in a local zip file in the CA Remote Engineer installation directory. Navigate to the **diagnostic_results** folder to review the results and detailed troubleshooting information.

Output file format:

- Product information:
  - Logs and configuration files (located in the same locations as in the installed product file structure)
  - CA Registry output in caprodinfo.xml
- Operating system and hardware information:
  - diaginfo.txt
  - machineinfo.xml

For more information about CA Remote Engineer, see the CA Remote Engineer Product Information page.

CA Green Books

CA Green Books provide knowledge focused on CA solution implementations and deployments. They deliver best practices and considerations based on real-world scenarios and knowledge compiled from global CA team experiences. Cross-functional teams of CA technical employees from field services, support and education collaborate with Technical Information to apply their expertise and create publications that deliver practical knowledge that goes beyond an "out-of-the-box" installation. Here is the link to the DX NetOps Spectrum Green Book:

Troubleshooting section for CA Support Partners

Documentation Legal Notice

Non-SNMP Monitoring

DX NetOps Mediation Manager monitors the performance for non-SNMP based devices, such as mobile wireless, fiber-optic switch, radio access, and 3G or 4G voice data. DX NetOps Mediation Manager supports a wide range of protocols to access data, for example, SOAP, SSH, XML, SQL, JMS, SFTP, and HTTP. DX NetOps Mediation Manager is portable across all platforms.

This section contains everything you need for non-SNMP monitoring from getting started to troubleshooting information.

Release Notes

Contents

20.2 Service Pack 2 (SP 2) New Features and Enhancements

This release of DX NetOps Mediation Manager includes the following new features and enhancements.

CA5620SamY1731 device pack enhancements

- Included jms plugin along with the engine.
- Splitted findToFile big xml file (size around 300MB) into small chunks (chunk size can be configurable) before performance conversion.
- Performance conversion logic enhanced to consider the logToDBAndFile stats as well.
- Optimized the performance conversion logic.
- Added new variable **SPLIT_GROUP_SIZE** with default size **2500** in Global Variables.

  NOTE
  Maximum Java Heap size can be configurable based on the findToFile file size.

  If findToFile size is around 300 MB then recommended MAXIMUM_JAVA_HEAP_SIZE value as 6144.

20.2 New Features and Enhancements

This release of DX NetOps Mediation Manager includes the following new features and enhancements.

New Device Packs

This release supports the following device packs:

CASBC Devicepack

This device pack collects performance metrics of:

- CallRecord
- SummaryRecord
- VoiceQualitySummaryRecord

CA5620SamY1731

This device pack collects cfmTwoWayDealy SAS metrics of SAM 5620 (NFM-P) through FindToFile and LogToFile by enabling JMS subscription. It collects the following performance metrics.

- MinimumResponse
- MaximumResponse
- SuccessfulAttempts
- MaxOneWayDelaySrcDest
- MinOneWayDelayDestSrc
- MaxOneWayDelayDestSrc
- MinOneWayDelaySrcDest
- PacketsLost
- PacketsSent
- PacketsArrivingAfterTimeout
- AverageJitter
- AvgResponseTime
- JitterOut
- JitterIn
- Jitter
- DelayVariation
- AvgOneWayDelaySrcDest
- AvgOneWayDelayDestSrc
- Latency
- AveragePercentPacketLoss

CAPaloAltoPanOS

This device pack collects data for the PaloAlto devices from the api and shows the performance stats for:

- Utilization
- SessionAverage
- SuccessfulAttempts
- SessionMaximum
- PacketBufferAverage
- PacketBufferMaximum
- PacketDescriptorAverage
- PacketDescriptorMaximum
- PacketDescriptorOnchipAverage
- PacketsArrivingAfterTimeout
- PacketDescriptorOnchipMaximum

Enhancements

The following device pack enhancements have been made in this release:

1. CAAVIController
   - AVI Controller device pack updated to support non-snmp devices for those controllers which are hosted in the cloud. Since DNS of the cloud devices maps to multiple IP's.
   - AVI controller device pack updated to support following controller metrics
     - controllerstatsavgcpuusage
     - controllerstatsavgdiskusage
     - controllerstatsavgmemusage

New Features

This release of DX NetOps Mediation Manager includes the following new features

- Delete devices from Component in DX NetOps MM using any API development environment
  You can delete one or more devices discovered in the device pack component using the delete API.

  NOTE
  Before Deleting the Devices, Stop the Engine.

  Scenario:
  – Primary Multi Controller is installed at **DX_NetOps_MM_HOST** with the default web server port number (8880).
  – Two Local Controllers are connected to the primary Multi Controller.
  – Delete device(s) from CAVerizonSatellite device pack

  Request URL Format:
  http://<DX_NetOps_MM_HOST>:<DX_NetOps_MM_WEB_PORT>/tim-web/rest/components/<Component_Id>/devices

  For the given scenario:
  http://localhost:8880/tim-web/rest/components/<Component_Id>/devices

  Content Type: Text or XML

  HTTP Verb: DELETE

  Sample Request Body:
  <Device>SAT-Device4-75644</Device>
  <Device>SAT-Device5-75645</Device>
  <Device>SAT-Device8-75648</Device>

  Sample Response

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
     <response url="components/ENGINE_CAVerizonSatellite/devices">
        <status>
            <code>200</code>
            <message>Success</message>
        </status>
    </response>
```

- Apache Tomcat upgraded to 8.5.51 version to address **Ghostcat CVE-2020-1938** issue related to AJP connector.

Known Issues

The following are the known issues for DX NetOps Mediation Manager 20.2.

- **The device pack does not appear in CA Performance Center 2.7 and later version.**
  This issue occurs when you upgrade CA Performance Management from 2.6 or lower version to 2.7 and later version but use CA Mediation Manager 2.6 or lower version.
  To resolve this issue, follow these steps:
  a. Log in to Mediation Manager after you upgrade to version 3.7, and click the **Device Packs** tab.
  b. Select the sub component ***PRESENTER_CAPM*****,** and click **Stop.**
  c. Ensure that the ***PRESENTER_CAPM*** is selected, and click
     Advanced
     The PRESENTER_CAPM window appears **.**
  d. Click **Configuration** on the right pane.
  e. Update the value in **OUTPUT_DIRECTORY** as follows:
     /opt/IMDataCollector/apache-karaf-2.4.3/MediationCenter/
  f. Click **Save**, **Close**.

g. On the Device Pack window, select **PRESENTER_CAPM,** and click **Start**.

WARNING

This issue can also occur if Mediation Manager is upgraded from version 2.7 to version 20.2 but **PRESENTER_CAPM** is not upgraded. In that scenario, either upgrade PRESENTER_CAPM or manually modify the OUTPUT_DIRECTORY value as specified in step 5.

- **DX NetOps Mediation Manager versions 2.4, 2.5, 2.6, 2.7, 2.8 fails to deploy device pack certificates in CA Performance Management version 3.0 or later.**
  This is a compatibility issue. To resolve this issue, upgrade CA Mediation Manager to version 3.0 or later because the Mediation Manager versions 2.4 through 2.8 are not compatible with CA Performance Management version 3.0 or later.
- **DX NetOps Mediation Manager** on Windows and Solaris Supports only Multi-Controller
  Even if the DX NetOps Mediation Manager Local Controller is installed on Windows and Solaris, you must manually copy the Queue folder (where the input files get collected) to the Data collector.
- **CAAVIController device pack supports single AVI Controller**
- **CERT deployment fails when the corresponding CERT folders are zipped at the parent level**
  The CERT deployment fails when the following folders are zipped at the parent level (CERT_<DevicePack_Name>).
  – components
  – device_mapper
  – metric_families
  – vendor_certs
  As a workaround, ensure that you zip the preceding four folders.
- While installing Mediation Manager in Windows environment, make sure that JRE path should be an environment variable with JAVA_HOME name and bin directory of JRE shall be in path.

Third-Party Software Acknowledgements

Third-party software was used in the creation of DX NetOps. All third-party software has been used in accordance with the terms and conditions for use, reproduction, and distribution as defined by the applicable license agreements. This section contains all third-party software license agreements for applications that are included as part of the current release of DX NetOps.

The following license agreements are available as an attachment. Click here to download the license agreements.

- AdoptOpenJDK_v8
- Ant 1.10.5
- aopalliance 1.0
- Apache Commons FileUpload 1.4
- Apache Commons DbUtils 1.6
- ASM 3.2
- Bootstrap 3.3.2
- cglib-nodep 2.1.3
- Commons Cli 1.2
- Commons Codec 1.11
- Commons Collections 3.2.1

Collecting Data for DevicePack Generation

DX NetOps Mediation Manager (DX NetOps MM) monitors the performance of non-SNMP devices in Element Management System, such as, mobile wireless, fiber-optic switch, radio access, and 3G or 4G voice data. CA Mediation Manager supports a wide range of protocols to access the data.

For example, REST, SOAP, SSH, XML, SQL, JMS, (S)FTP, and HTTP(S).

Element Management System

An Element Management System (EMS) consists of systems and applications for managing Network Elements (NE) on the Network Element-Management Layer (NEL) of the Telecommunications Management Network (TMN) model. Provide the following details of EMS.

- **Name of the EMS:** <ems_name>
- **Vendor Name:** <vendor_name>
- **Version:** <version_number>

For example,

- **Name of the EMS:** <Service Aware Manager (SAM) 5620>
- **Vendor Name:** <Nokia (Alcatel)>
- **Version:** <14R1>

Data Collection

Data collection provides details of DX NetOps MM DevicePack that collects data from the EMS system. DX NetOps MM supports SFTP, FTP, HTTP(S), REST, JMS, JDBC communication protocols.
Example: If an EMS creates archive of hourly data and the data is placed in an FTP Server, then the following details are required:

- **Communication Protocol:** <FTP/SFTP>
- **Hostname/IPAddress:** <CAMMSIM.ca.com>
- **(if applicable) Port:** <22>
- **Username:** <camm_ftp_user>
- **Password:** <ftp_password>

If the EMS has any proprietary communication protocol, provide the EMS Integration or API Guide.

Data Format

Provide the details in a data format.
For example, CSV, XML, JSON, COMMANDPROMPTOutput, or others.
Example of CSV data file format:

DeviceID	DeviceName	CollectionTime	CPU (%)	Memory Utilization (MB)	Total Memory (MB)
3145741	NE A	9/19/2016 22:15	10	20	1024
3145742	NE B	9/19/2016 22:15	20	30	1024

(Optional) Granularity of Data

The time period of receiving the data from the EMS.

For example, 5 minutes, 10 minutes or 60 minutes, and so on.

Frequency of Data file Generation

The frequency of the time the data file is generated.

For example, 5 minutes, 10 minutes, or 60 minutes, and so on.

Sample Data

The location of the sample files.
Example: CA Support Case FTP, any public Cloud Drive location such as, Microsoft OneDrive, Dropbox, and so on.

Metrics

The metric is the name that you want to view in the CA PC reports. If the columns are self-explanatory in the CSV data format file, then the metric name is not required.
Example:

The following table describes the metrics for the table mentioned in the **Data Format** section.

Metric Family Name	Metric Name	Units
EMS_Name_DeviceHealth	CPU	Percent
EMS_Name_DeviceHealth	Total Memory	Bytes

Units possible values: Percent, Packets, PacketsPerSecond, DiscardedPackets, ErroredPackets, Bits, BitsPerSecond, Bytes, BytesPerSecond, Seconds, Microseconds, Milliseconds, UnixTime, Observations

KPI Formulas

If you want DX NetOps MM or CAPM to derive any KPIs on top of the out of the box metrics, then provide the KPI formulas.
For example, Memory Utilization % = Memory Utilization/Total Memory x 100>

More Details to Develop a Device Pack

Provide any other details which help to develop a Device Pack.
For example, API Guides, EMS Vendor Contact details, VPN to your LAB where the EMS is hosted, and so on.

Getting Started

DX NetOps monitors the performance for non-SNMP based devices, such as mobile wireless, fiber-optic switch, radio access, and 3G or 4G voice data. DX NetOps supports a wide range of protocols to access data, for example, SOAP, SSH, XML, SQL, JMS, SFTP, and HTTP. DX NetOps is portable across all platforms.

Architecture and Components

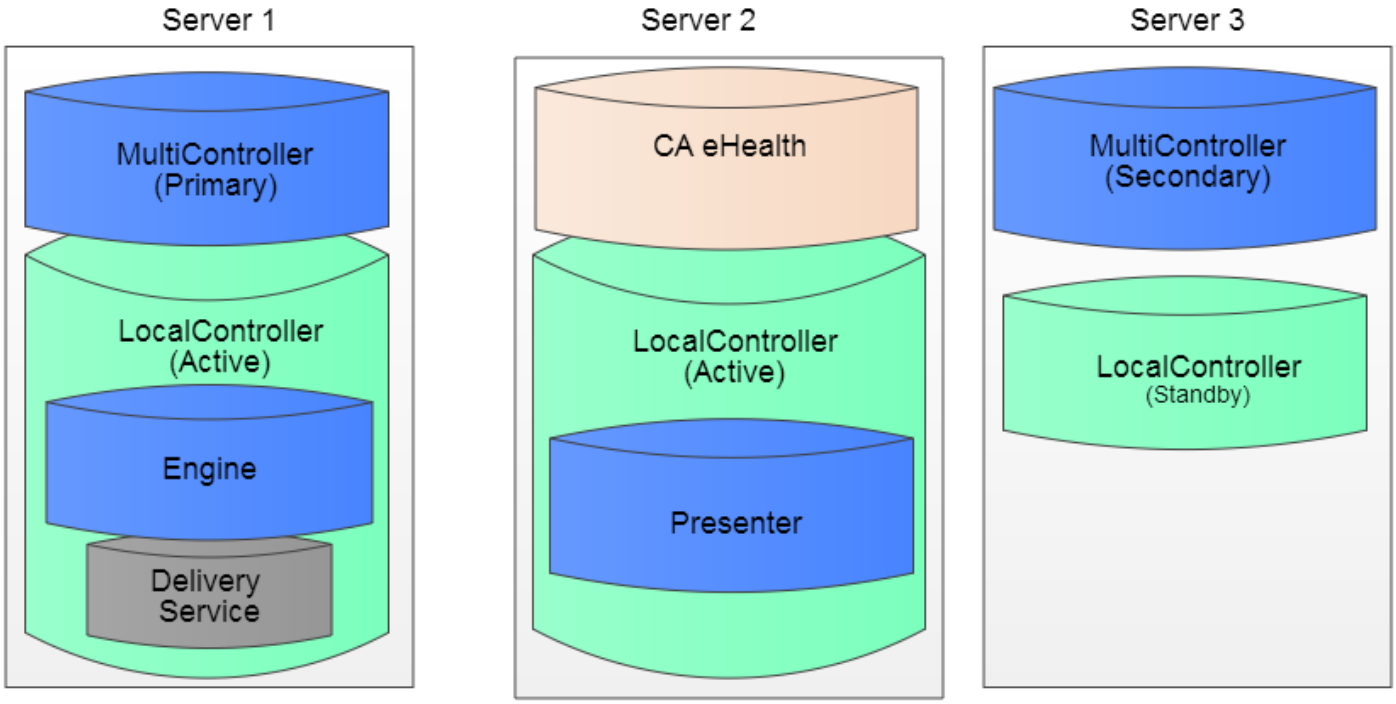
This article contains the following topics:

The architecture lets you quickly develop any required vendor-specific API plug-ins, named device packs, to collect the data directly from a device or from an Element Management System (EMS). DX NetOps enables deployment in a standalone or distributed architecture.

In a standalone deployment, the installation is usually performed on the management server being integrated. In a distributed deployment, the application is deployed across multiple servers to meet the high demands of current Communication Service Provider (CSP) environments.

The following diagram describes the general architecture of DX NetOps for CA eHealth in a multiserver installation:

Figure 83: DX NetOps Mediation Manager architecture--XML



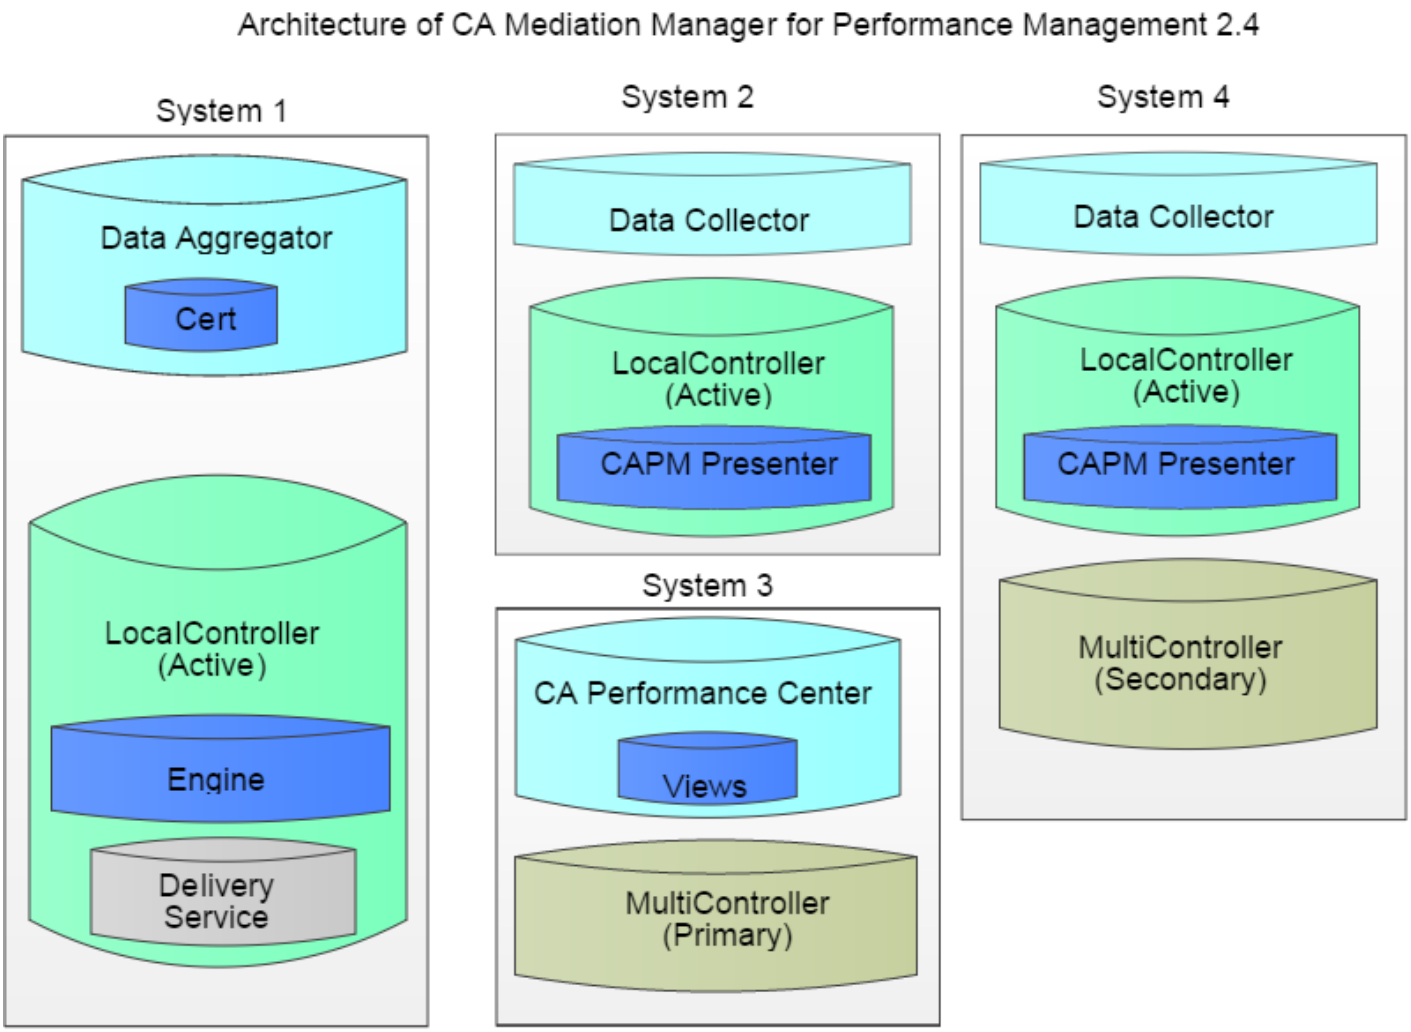
When you install DX NetOps Mediation Manager for Performance Management 2.3.4 or later in distributed systems,install the components of Performance Management and DX NetOps Mediation Manager as follows:

- Data Aggregator, Data Collector, and CA Performance Center in individual systems.
- Cert and Views respectively in the system that has Data Aggregator and CA Performance Center.
- CAPM Presenter and LocalController in every system that has a Data Collector.
- Primary MultiController in a system that has CA Performance Center.
- LocalController with Engine and Delivery Service in another system that has Data Aggregator.

> **NOTE**
> Install Primary MultiController and LocalController with Engine and Delivery Service in different systems based on the RAM and CPU sizes of the systems. If there is no sufficient memory, install Primary MultiController and LocalController with Engine and Delivery Service in individual systems.

The following diagram describes the general architecture of multiserver installation of DX NetOps for Performance Management with two Data Collectors:

Figure 84: DX NetOps MM for PM in 4 Systems



NOTE
An extra component, the Generic Executor is not shown in both the diagrams, but is described in this document.

The components of DX NetOps include the following set of core software entities:

- MultiController
- LocalController
- Web Manager
- Generic Executor
- Delivery Service

The subcomponents of DX NetOps include the following entities:

- Engine
- Presenter or CAPM Presenter

MultiController

You can deploy up to two MultiControllers, primary and secondary, in a cluster. Deploy at least one MultiController per cluster. A MultiController performs the following actions in your cluster environment:

- Monitors heartbeat messages from LocalController components on remote servers.
- Acts as the centralized licensing server for the cluster.
- Stores centralized configuration files for components in the cluster.

LocalController

Install one LocalController on each physical server in the cluster where a subcomponent (Engine or Presenter) resides. A LocalController performs the following actions:

- Communicates with the subcomponents that are installed on the server.
- Monitors heartbeat messages for subcomponents on the local server and automatically restarts subcomponents if they fail.
- Uses a delivery service to process output from the Engine. This service delivers XML documents in a compressed and encrypted format to a local or remote Presenter.

Web Manager

The Web Manager lets you manage the device pack deployment using its web-based interface. The interface displays the following information:

- Status of the running device packs.
- Status of the LocalControllers on which the device packs are installed.
- Status of the primary and secondary MultiController.

Generic Executor

All components in a cluster share a common set of functions for communication and execution. The Generic Executor starts the Engine and Presenter subcomponents and cleans the temporary and log files.

The Generic Executor starts at system startup and listens on a specific TCP port. To start a component like the MultiController, the DX NetOps Control Utility, cammCtrl, sends a MultiController XML configuration file to the Generic Executor. When the Generic Executor receives this data, it identifies and starts the MultiController component using the information in the configuration file.

Delivery Service

When an Engine finishes its poll cycle, it generates one or more DX NetOps-standard XML documents in the queue directory. The Delivery Service monitors the queue directory independently and distributes the data to one or more local or remote Presenters. Delivery Service determines the correct Presenter by sending a request to the MultiController through the LocalController and identifies the IP address and TCP port of the Presenter. The Delivery Service does not process the queue until the local or remote Presenter becomes available.

Engine

The Engine is the main, threaded polling engine in DX NetOps. You can deploy the Engine in the active or standby mode. The Engine performs the following actions:

- Gathers information from devices using XML, CSV, Telnet, SSH, and so on. The engine then processes the data to a DX NetOps-standard XML document.
- Deploys the DX NetOps-standard XML document to the queue for processing by the Delivery Service.

Presenter

The Presenter is required only for DX NetOps for eHealth and one Presenter is required for each device pack. It is a threaded presentation engine that performs the following actions:

- Receives the DX NetOps-standard XML document from the Engine.
- Formats the data to the required output format, such as CSV, XML, SNMP, and DDI.

CAPM Presenter

The CAPM Presenter is required only for DX NetOps for CA Performance Management. The CAPM Presenter must be installed in Data Collector that supports DX NetOps. Similar to the Presenter, CAPM Presenter receives the DX NetOps-standard XML document from the Engine. But, CAPM Presenter does not format the data to a required output format.

The number of CAPM Presenter depends on the number of complex device packs.

Default Ports and Data Flow

DX NetOps Default Ports

The following lists the default ports:

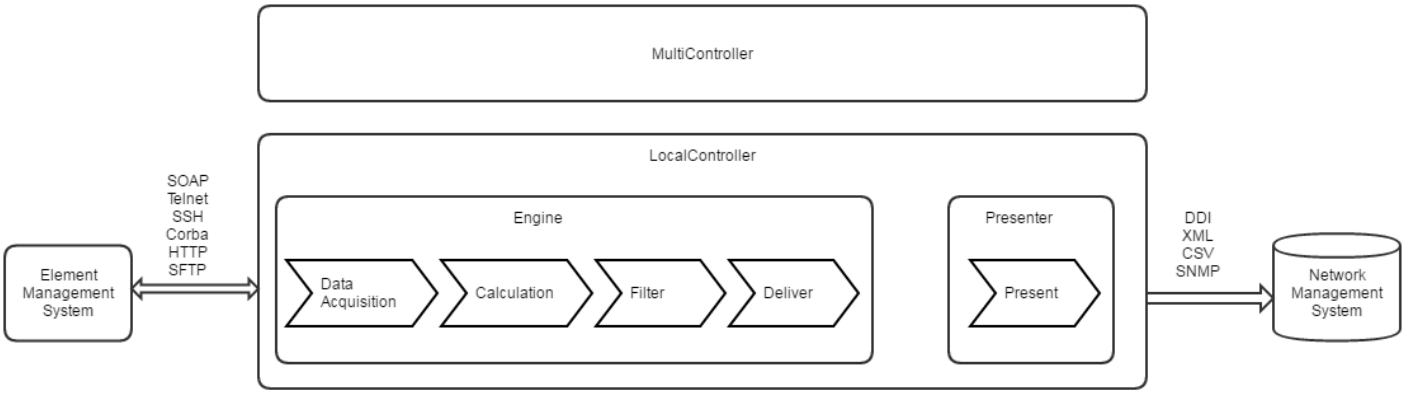
Component	Port	Type	Comments
MultiController	29599	TCP	Communicates with LocalController via heartbeats to maintain status.
LocalController	29598	TCP	Communicates with MultiController via heartbeats to maintain status.
Generic Executor	29560	TCP	Listens on this TCP port to receive XML configuration files from MultiController and LocalController.
Web Manager	8880	HTTP	Administrators browse to the Web Manager (located on the MultiConroller) server over port 8880.

Data Flow

- Engine polls the Element Management System.
- Engine converts data to XML format.
- Engine performs any calculation or filtering required.
- Engine delivers data in CAMM2XML format to the queue directory.
- Deleivery Service reads queue and transfers XML file to the Presenter(s) (Local or Remote) using the name service.
- Presenter reads the XML file and outputs the data in the required format.

The following diagram shows the typical data flow in DX NetOps.

Figure 85: Data Flow in CAMM



Installing

This section helps you install DX NetOps, device pack in DX NetOps, and device pack in DX NetOps for Performance Management.

DX NetOps Mediation Manager is a distributed application that includes multiple components across several servers. A successful deployment includes installing the these components in the following order:

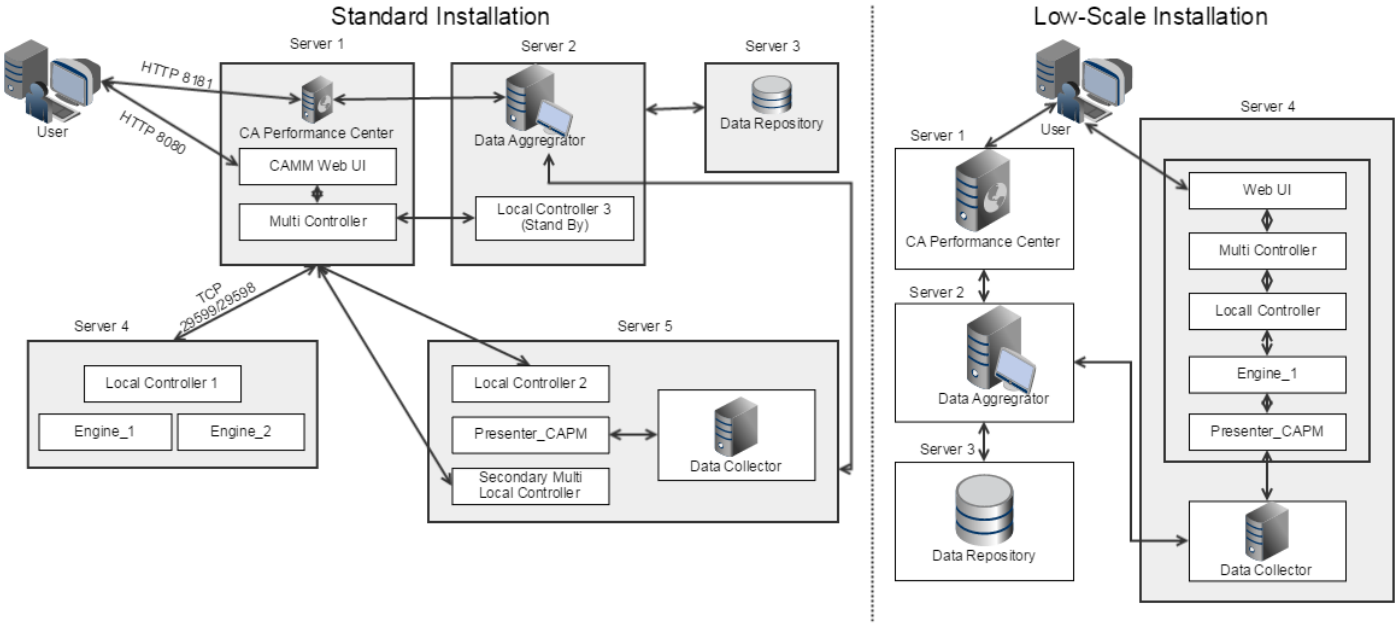
- CAPM (CAPC, DR, DA & DC)
- DX NetOps MM Multi Controller
- DX NetOps MM Local Controller
- DX NetOps MM Local Controller for Presenter on DC system
- DX NetOps MM Secondary Multi Controller*
- DX NetOps MM Local Controller for LC failover*

NOTE

The *** (asterisk)** indicates the failover of MC & any LC.

Your deployment strategy depends on the number of devices, the location of these devices, and which metrics you want to monitor. The following diagram shows the installation options:

Figure 86: DX NetOps MM Standard and Low-Scale Installation



System Requirements

Review the following information before you install the product:

Hardware Requirements

The following table describes the minimum hardware requirements for each supported operating system:

Operating System	Architecture	CPU	Memory	Disk
SUSE Linux Enterprise Server (SLES) 12 SP2	-	-	-	-
Oracle Linux (OL) 7.3 (Red Hat compatible kernel only)	-	-	-	-
Solaris 9 or 10	SPARC (64-bit)	1 x 1.4 GHz	4 GB	18 GB
Red Hat Enterprise Linux 6.x Red Hat Enterprise Linux 7.3	64-bit	1 x 2 GHz	4 GB	18 GB
Windows 2008	32-bit, 64-bit	1 x 2 GHz	4 GB	18 GB
Windows 2012	64-bit	1 x 1.8 GHz	4 GB	18 GB

NOTE
Maintain consistency between the JRE and the operating system architecture. For example, on 64-bit operating systems, the JRE you use to install and run DX NetOps must also be 64-bit.

Web Browser Requirements

A web browser is required to access DX NetOps Mediation Manager UI (User Interface). The following browser applications are supported:

- Microsoft Internet Explorer version 9 or above
- Mozilla Firefox (current version)
- Google Chrome (current version)

Java Support

- AdoptOpen JDK 1.8.0.212 (From CA Mediation Manage 3.7 SP 3)
- Oracle JRE 1.8.x (CA Mediation Manager 3.7)

Supported Platforms

CA Mediation Manager supports the following platforms:

- CA eHealth 6.x
- CA Performance Management r2.7 through 20.2

Compatibility Matrix

The following table provides the compatibility matrix for DX NetOps Mediation Manager:

	CA Performance Management 3.1	CA Performance Management 3.2	CA Perf
CA Mediation Manager 3.1	Compatible	Compatible	Compati
CA Mediation Manager 3.2	Compatible	Compatible	Compati
CA Mediation Manager 3.5	Compatible	Compatible	Compati
CA Mediation Manager 3.6	Compatible	Compatible	Compati
CA Mediation Manager 3.7	Compatible	Compatible	Compati
CA Mediation Manager 20.2	Compatible	Compatible	Compati

*Check the Known Issue section in Release Notes.

Install DX NetOps Mediation Manager

Use this article to install DX NetOps on the Windows or UNIX systems. This article contains the following topics:

Installation Planning

The installation prerequisites are as follows:

- Ensure that users of DX NetOps and CA Performance Management are in the same user group.
- Administrator privileges on Windows systems
- Comply with the system requirements, web browser requirements, supported platforms, and compatibility matrix. For more information, see System Requirements.
- Java Runtime Environment (JRE) version 1.8 or later
  We recommend that you obtain the latest version of JRE from the Java download site.

Install DX NetOps

This procedure describes the steps to install DX NetOps on Windows or UNIX systems.

Follow these steps:

1. Log in to the server with the user ID that you want the DX NetOps processes to use.

   NOTE
   We refer to the user ID throughout this document as CAMM_USER. If you use an invalid user ID, an error occurs and the installation fails.
2. Start the DX NetOps installation with the corresponding command based on your operating system:
   - UNIX systems
     ```
     $JAVA_HOME/bin/java  -jar CAMM-Installer-20.2.x.jar
     ```
   - Windows systems
     a. Insert the installation CD-ROM and open Windows Explorer.
     b. Locate and double-click the executable JAR file, CAMM-Installer-20.2.x.jar.
3. Click Next on the Welcome dialog.
4. Read the Important Information and click Next.
5. Review the licensing agreement, accept, and click Next.
6. Specify a target path for the installation. Or click Choose to browse to an installation location.

   NOTE
   When installing on a Windows System, the default installation directory is C:\Program Files\CA\CAMM.
   When installing on a UNIX System (Linux or Solaris), the default installation directory is /opt/CA/CAMM.
7. Select Typical for the new installation.
8. Select one or more required installation packages.
   - MultiController
   - LocalController
9. Configure the following DX NetOps foundation parameters:
   - **User ID**
     Specifies the user ID for the Generic Executor for the DX NetOps installation. The user ID is the CAMM_USER and defaults to the current user ID.
     Default: root

     WARNING

     Use the same user ID that you used to install Data Collector or the user must have read and write group access to $DATA_COLLECTOR_INSTALL/apache-karaf-x.y.z/MediationCenter.
   - **Port**
     Specifies the port where the Generic Executor listens.
     Default: TCP port 29560
10. Specify whether you install primary or secondary MultiController.
11. (Optional) Configure the following parameters of primary MultiController:

    NOTE
    For the first installation, configure the primary MultiController. You can configure the secondary MultiController in the subsequent step.

    - **MC IP**Specifies the IP address or host name for the primary MultiController.

      NOTE
      Make sure that the host name is resolved to an IP address for to function properly. supports IP V4.
    - **Failover Threshold**Determines the elapsed time, in seconds, with no received heartbeat messages, in seconds, and signals LocalController failure. When this threshold is reached, the MultiController activates the standby LocalController.
      Default: 600
    - **Will the other MC exist in the cluster?**Indicates that another MultiController exists or may exist in the cluster.

12. (Optional) Configure the following parameter for another MultiController in the same cluster:
    - **The Other MC IP**
      Specifies the secondary MultiController IP address, if you installed and configured a primary MultiController.
      If you installed a secondary MultiController in a previous step, this value is the primary MultiController IP address.
      If this server is a backup server, install the secondary MultiController on a different host server.
13. Configure the following parameters for the web authentication:
    - **User**
      Specifies the login name for the DX NetOps Web Manager.
      Default: admin
    - **Password**
      Specifies the login password for the DX NetOps Web Manager.
      Default: camm
    - **Web Port**
      Specifies the port for the web UI.
      Default: 8880
14. (Optional) Configure the following parameters for LocalController. At least one LocalController is required on any server where the Engine and Presenter subcomponents are running.
    - **LC IP**
      Specifies the IP address or host name for the LocalController.

      NOTE

      Make sure that the host name is resolved to an IP address for DX NetOps to function properly.

      DX NetOps supports IP V4.
    - **LC Port**
      Specifies the port for this LocalController.
      Default: 29598
    - **Failover Threshold**
      Determines the time (in seconds) that can elapse with no received heartbeat messages. The loss of heartbeat messages indicates the subcomponent failure. When the threshold is reached, the LocalController restarts the Engine, Presenter, or both components.
      Default: 600
15. Review the installation summary and click Install.
16. Click Done.
    The installation is complete.
17. Navigate to $CAMM_HOME and check the installer information in the version.xml file. The contents of the version.xml file resemble the following format:

```
<?xml version="1.0" ?>
<CAMM-Version>
   <Current>
     <Version><20.2.x>/Version>
     <Revision><Installer revision number></Revision>
   </Current>
</CAMM-Version>
```

18. To start the application, type http://<*PrimaryMCMachineIP*>:<*web-port*> in a browser.
    Where <*web-port*> is the port number that is configured during the DX NetOps Installation and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
19. Type the login credentials.
    The DX NetOps application starts.

    NOTE
    For more information about using the options in UI, see the Using section.

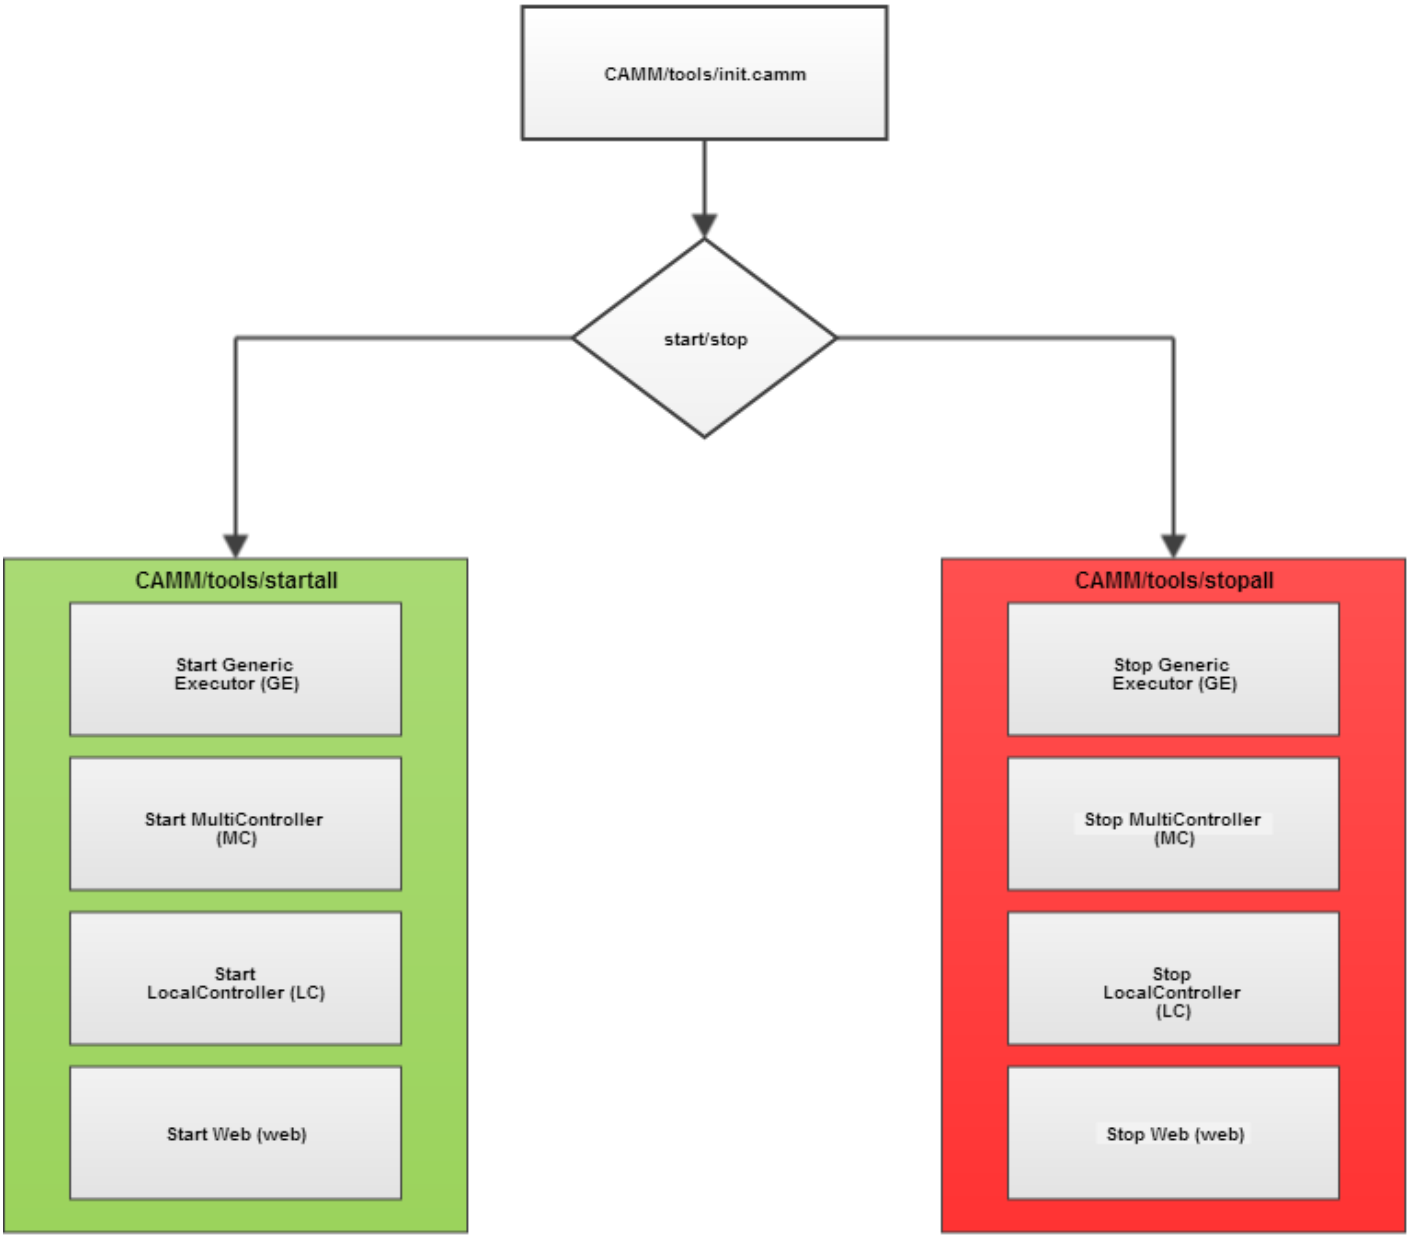
Starting and Stopping Services

This section describes how to start and stop services on the following operating systems:

During the DX NetOps installation, the Generic Executor and the Web Manager are registered as Services. The service names are CAMM-GE-{user}-{port}, and CAMM-tomcat7-8880. You can automatically start or stop DX NetOps at the system startup or shut down by executing specific commands as discussed in this section.

The following diagram illustrates the process flow of starting and stopping services:

Figure 87: Process flow diagram for starting and stopping services-XML



UNIX

You can execute the startall or stopall script or the init.camm script to start or stop DX NetOps. The init.camm script is in the Tools directory in the DX NetOps MM Home directory.

Execute the following init.camm.install script, as root or sudo su, to start or stop DX NetOps automatically at the system startup or shut down:

```
shell# tools/init.camm.install
```

Execute the following init.camm.uninstall script to remove the setting that automatically starts or stops DX NetOps:

```
shell# tools/init.camm.uninstall
```

Windows

Execute init.camm.install.bat to install the setting that automatically starts or stops DX NetOps:

```
C:/CAMM/tools/init.camm.install.bat
```

Execute init.camm.uninstall.bat to remove the setting that automatically starts or stops DX NetOps:

```
C:/CAMM/tools/init.camm.uninstall.bat
```

Install a Device Pack in DX NetOps Mediation Manager

Use this article to install a device pack in DX NetOps on the Windows or UNIX systems. This article contains the following topics:

A device pack is a set of XML configuration, ServingXml or Groovy, and XQuery files. Device packs pull data from a specific set of devices and convert it to a form that can be read by eHealth, CA Spectrum, CA Infrastructure Management, or Performance Management.

Install Engine and Presenter

You can install the Engine and Presenter through the DX NetOps Web UI.

Follow these steps:

1. Launch the DX NetOps Web Manager:
   ```
   http://<PrimaryMCMachineIP>:<web-port>
   ```
   Where <w*eb-port* > is the port number that is configured during the DX NetOps installation, and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Enter the login credentials.

   NOTE
   Confirm that the working environment is CA eHealth.
3. Select the Device Packs tab and click Install**.**
4. Specify the destination of the LocalController using the LocalController drop-down.
5. Perform one of the following steps in the Device Pack configuration dialog:
   - If the device pack is located in the Device Pack repository that is shipped with the current release of DX NetOps, select the DevicePack Repository check box.
   - If the device pack is not located in the Device Pack repository and resides in the local system, click Browse and locate the device pack.
6. Select the ENGINE_<*devicepack*>.zip file or the PRESENTER_<*devicepack*>.zip file that you want to install.
7. Click Next.

8. Provide the configuration parameters in Global External Variables and Component Configuration for the Engine or Presenter being installed.

   NOTE
   For more information about specific device pack configuration files, see the corresponding Engine readme file by selecting ReadMe from the Web UI.
9. Select Finish.
   The device pack is installed.

Install CA eHealth Certification

To view the reports in CA eHealth, install eHealth certification. Installation of certification consists of the following two steps:

- Deploy Certification manually or automatically
- Manually import the elements to CA eHealth.

Deploy the eHealth Certification Automatically

Deploy the eHealth Certification automatically through DX NetOps Mediation Manager Web.

Follow these steps:

1. Launch the DX NetOps Mediation Manager Web UI:
   http://<*PrimaryMCMachineIP*>:<*web-port*>
   Where <*web-port* > is the port number configured during the DX NetOps Installation and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Enter the login credentials.
3. Select the Device Packs tab and click Certification.
4. Specify the Certification destination from the Destination drop-down.
5. (Optional) Select OverWrite Existing cert check box.
6. Do one of the following steps:
   – If the Certification to install is in the eHealth Certification repository shipped with the current release of DX NetOps, select eHealth Cert.
   – If the Certification to install is in the local system, click Browse and locate the Certification.
7. Select the Certification and select Deploy.

Deploy the Certification Manually

Deploy the eHealth Certification manually.

Follow these steps:

1. Verify that you meet the following prerequisites:
   – The LocalController is installed on the CA eHealth server using the same user credentials that are used for installing eHealth.
   – The PRESENTER_<*devicepack*> component is installed on the LocalController that is running on the CA eHealth server.
   – $NH_HOME is set to the eHealth installation directory. To confirm, execute the following command:
   ```
   echo $NH_HOME
   ```
2. Copy the $CAMM_HOME/MC/eHealthCerts/CERT_<*devicepack*>.zip file to the $NH_HOME directory of your eHealth server.
3. Open a command prompt, type bash, and execute the following command:
   ```
   unzip CERT_<devicepack>.zip
   ```

4. Modify the $NH_HOME/modules/<*devicepack*>/camm.env script to provide the path details to JRE and the CAMM installation folder.
5. Create a soft link from $CAMM_HOME/output/PRESENTER_<*devicepack*> to $NH_HOME/modules/<*devicepack*>/ddiData.
6. Append the content of the $NH_HOME/db/data/variable.usr_<*devicepack*> file to $NH_HOME/db/data/variable.usr.
   - Before you combine the content, verify if there are any duplicate variables in both files. If you find duplicate variables, remove the duplicate variables and save the final $NH_HOME/db/data/variable.usr file.
   - Consider the final variables in the variable.usr file and map the variables.
   - Verify the mapping of the variable IDs in the variable.usr file and the elementTypeVariable.usr file.
   - Make sure that the variable IDs mapped in the elementTypeVariable.usr file are located in the variable.usr file.
7. Append the content of the $NH_HOME/db/data/elementTypeVariable.usr_<*devicepack*> file to $NH_HOME/db/data/elementTypeVariable.usr.

Import the Elements

Manually import the elements to CA eHealth.

Follow these steps:

1. Stop the CA eHealth server with the following command:
   ```
   nhServer stop
   ```
2. Convert the database schema for a software upgrade using the following command:
   ```
   nhConvertDb
   ```
   Wait until the database conversion executes successfully.
3. Start the eHealth server with the following command:
   ```
   nhServer start
   ```
4. Modify $NH_HOME/modules/<devicepack>/modules.defaults.init to suit your specific poll requirements.
5. Go to $NH_HOME/modules/camm<devicepackname> directory and execute the following command to discover your new elements:
   ```
   ./cammpoll  - c  - j -l
   ```
   eHealth automatically calls cammpoll to poll the elements.
   cammpoll is successful when you see the elements in eHealth OneClick in Manage Resources, Groups, <devicepack>.

   NOTE
   You only execute cammpoll manually once. Take note of any situation afterward in which you execute the cammpoll command manually, because it represents an error condition. In normal operations, eHealth executes the cammpoll command automatically.

Install Device Packs in DX NetOps Mediation Manager for Performance Management

A device pack for DX NetOps for Performance Management comprises of Engine, CAPM Presenter, Certification, and Views. Install these components to pull data from devices.

This article contains the following topics:

Prerequisites

Before you install device packs, confirm whether the following packages are installed:

- FTP or SFTP on the device server
- CA Performance Center
- Data Aggregator
- Data Collector

NOTE
For information about installing CA Performance Center and Data Aggregator, see the respective installation documents.

Install Device Packs in DX NetOps Mediation Manager for Performance Management 2.3.4 and later

You can install a device pack in DX NetOps for Performance Management 2.3.4 and later through the DX NetOps Web UI.

Follow these steps:

1. Launch the DX NetOps Web UI:
   http://<*PrimaryMCMachineIP*>:<*web-port*>
   Where <*web-port*> is the port number that is configured during the DX NetOps Installation and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Type the login credentials.

   NOTE

   Confirm that the working environment is CA Performance Management.
3. Click the Device Packs node and select Install.
4. The Device Pack Selection dialog appears.
5. Perform one of the following steps:
   – If the device pack to install is in the Device Pack repository that is shipped with the current release of DX NetOps Mediation Manager, select Device Pack Repository.
   – If the device pack to install is in the local system, click Browse and locate the device pack.
6. Select a device pack and click Next.
   Cert and Views of the selected device pack are deployed and the dialog to configure CAPM Presenter appears.
7. Specify the LocalController destination from the drop-down.
8. Provide the parameters in Global External Variables and Component Configuration.

   WARNING

   - The PRESENTER_ID of the Engine must match with the COMPONENT_ID of the CAPM Presenter.
   - To update the text in COMPONENT ID, append text or numeral with underscore. Do not modify the existing text in COMPONENT ID.

   NOTE

   If you already installed a CAPM Presenter, you can skip the CAPM Presenter installation by clearing the check box at the top of the dialog. For more information about specific Device Pack configuration files, see the corresponding Engine readme file by selecting ReadMe from the Web UI.

   The polling time is defined in the fields, such as PERFORMANCE_POLL_RATE and INVENTORY_POLL_RATE.
   Format: Crontab format in which the time is specified in the seconds-minutes-hour order.
   Examples:

   */30 * * specifies that polling occurs every 30 seconds.
   * 5 * specifies that polling occurs at the fifth minute after an hour.
   0 0 2,14 specifies that polling occurs at 2 A.M and 2 P.M.
   - - - specifies that no polling is scheduled.

9. Provide the following parameters for tmp, logbase, and local in Cleanup Configuration to clean the files in the tmp, logbase, and local directories and click Next:
   expire
   Specifies the time after which the file is deleted.
   Format: <*number*><s/m/h/d/y>
   Where, s = second, m = month, h = hour, d = number of days, y = number of years
   Examples: 6s, 4m, 2h, 10d, or 1y
   match
   Specifies the matching string to be searched.
   Example: *.file
   achivePrefixSpecifies the prefix for the archived file.
   achiveSuffix
   Specifies the suffix for the archived file.
10. Provide the parameters for Engine and click Finish.
    CAPM Presenter and Engine are deployed.

Back Up and Restore

Back Up and Restore DX NetOps MM

When you migrate DX NetOps MM, ensure that you back up the following DX NetOps MM files and restore them:

- /opt/CA/CAMM/MC/repository
- /opt/CA/CAMM/COMPONENTS/ENGINE_<DevicePackName>/tmp/input/*

Back Up and Restore the Device Pack

Before you reinstall DX NetOps Mediation Manager or redeploy the MultiControllers, back up the device packs by executing the cammBackup script. On executing the backup script, all files in the <*Install_folder*>/MC/repository folder are backed up. By executing the cammRestore script, you can restore the device packs that are backed up.

WARNING

- The scripts work only on Linux and Solaris systems.
- Stop all device packs before executing the scripts.

Back up the Device Pack

Execute the following command in the system where MultiController is installed:

```
./cammBackup /<Destination_Folder>
```

Example: ./cammBackup /MC/repository

Restore the Backed up Device Packs

Execute the following command:

```
./cammRestore /<location and Name of the backedup files>
```

Example: ./cammRestore /tmp/cammBackup_2015_02_10_03_59_32.tar.gz

If you restore the device packs to a system other than from where it was backed up, ensure to rename the MultiController or LocalController. So that they both are synchronized and work correctly.

Upgrading

This section provides steps to upgrade DX NetOps, upgrade a device in DX NetOps, and upgrade device packs in DX NetOps for Performance Management.

Upgrade DX NetOps Mediation Manager

Upgrade DX NetOps when the latest release is available. Also, when you upgrade CA Performance Management, check the compatibility matrix in System Requirements and, if needed, upgrade DX NetOps Mediation Manager. If MultiController and LocalController are installed in discrete systems, upgrade the components in the following order:

- Primary MultiController
- Secondary MultiController
- LocalController

Follow these steps:

1. Start the DX NetOps installation with the respective command based on your operating system:
   - UNIX systems:
     ```
     # $JAVA_HOME/bin/java  -jar CAMM-Installer-20.2.x.jar
     ```
   - Windows systems:
     a. Stop CAMM Components
        ```
        %CAMM_HOME%/tools/stopall.bat
        ```
     b. Insert the installation media and open Windows Explorer.
     c. Locate and double-click the executable JAR file, CAMM-Installer-20.2.x.jar.
2. Click Next on the Welcome dialog.
3. Read the Important Information and click Next.
4. Review the licensing agreement and click Next.
5. Specify a target path to install DX NetOps. Alternatively, click Choose to browse for a location.

   NOTE

   When installing on a Windows System, the default installation directory is C:\Program Files\CA\CAMM.

   When installing on a Unix System (Linux or Solaris), the default installation directory is /opt/CA/CAMM.
6. Select Upgrade and click Next.
7. Review the upgrade summary and click Install to start the upgrade process.
8. Click Done.

   NOTE
   DX NetOps starts before the installer exits.

   The installer stops DX NetOps and starts the upgrade process. All existing files are overwritten.
   Files in the following folders are preserved:
   - $CAMM_INSTALL_DIR/MC/repository
   - $CAMM_INSTALL_DIR/Queue
   - $CAMM_INSTALL_DIR/output
   - $CAMM_INSTALL_DIR/COMPONENTS

     NOTE
     We recommend that you back up any custom scripts in the CAMM_INSTALL_DIR/tools folder.

   DX NetOps is upgraded.
9. Navigate to $CAMM_HOME and review the upgraded installer information in the version.xml file. The content format in the version.xml file is similar to the following format:

```
<?xml version="1.0" ?>
<CAMM-Version>
   <Current>
     <Version><20.2.x>/Version>
     <Revision><Installer revision number></Revision>
   </Current>
   <History>
      <Build>
         <Version>3.6.0 or 3.7.0</Version>
         <Revision>Installer revision number</Revision>
      </Build>
  </History>
</CAMM-Version>
```

Upgrade a Device Pack in DX NetOps Mediation Manager

You can upgrade a device pack by using the DX NetOps Web UI.

Follow these steps:

1. Launch the DX NetOps Web Manager:
   `http://<PrimaryMCMachineIP>:<web-port>`
   Where <w*eb-port* > is the port number that is configured during the DX NetOps installation, and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Enter the login credentials.

   NOTE
   Confirm that the working environment is CA eHealth.
3. Click the Device Packs tab, select the subcomponent (Engine or Presenter) that you want to upgrade, and click Upgrade**.**
4. Perform one of the following steps:
   – If the Device Pack you want to upgrade is located in the Device Pack repository that is shipped with the current release of DX NetOps, select the Device Repository checkbox.
   – If the Device Pack you want to upgrade is not located in the Device Pack repository and resides in the local system, click Browse and locate the Device Pack.
5. From the LocalController drop-down, select the LocalController where you want to upgrade the Device Pack.
6. Select the ENGINE_<*devicepack*>.zip file that you want to upgrade and click Next.
7. Provide the configuration parameters in Global External Variables and Component Configuration for the Engine or Presenter being upgraded.

   NOTE
   For more information about specific device pack configuration files, see the corresponding engine readme file by selecting Readme from the Web UI.
8. Select Finish.
   The device pack is upgraded.

Upgrade Device Packs in DX NetOps Mediation Manager for Performance Management

A device pack consists of Engine, Certification, and Views. Upgrade a device pack in DX NetOps for CA Performance Management through the DX NetOps Mediation Manager Web UI.

Upgrade using the Typical Option

Use the Typical option to upgrade Engine and the corresponding CERT and Views seamlessly.

Follow these steps:

1. Launch the DX NetOps Web Manager:
   `http://<PrimaryMCMachineIP>:<web-port>`
   Where <w*eb-port* > is the port number that is configured during the DX NetOps installation, and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Enter the login credentials.

   NOTE
   Confirm that the working environment is CA Performance Management.
3. Click the Device Packs tab, select the Engine that you want to upgrade, and click Upgrade, Typical**.**
4. Select the Device Pack Repository check box, select a device pack, and click Next.

   NOTE

   Do no click the Browse button. If you click Browse, you have to manually upgrade the individual components.
5. Review the configuration parameters in Global External Variables and Component Configuration for the Presenter and Engine being upgraded and update the new parameters.

   WARNING

   The PRESENTER_ID of the Engine must match with the COMPONENT_ID of the CAPM Presenter.

   NOTE
   In Global External Variables, the previously modified values for the existing parameters are preserved during the upgrade. So, modify the values for the existing parameters, only if needed. However, the new parameters are populated with the default values. So, modify the new values according to your requirement. To know the new parameters, click ReadMe in the Web UI; the list of device pack configuration files that consists of the parameters appear. Select DPInfo_<*devicepack*>.txt and click Open.
6. Click Finish.
   The device pack is upgraded.

Upgrade using the Custom Option

Use the Custom option to upgrade, Engine, Presenter, CERT, and Views individually. This method is most suited for the Presenter upgrade.

Follow these steps:

1. Launch the DX NetOps Web Manager:
   `http://<PrimaryMCMachineIP>:<web-port>`
   Where <w*eb-port* > is the port number that is configured during the DX NetOps installation, and <*PrimaryMCMachine IP*> is the IP address or hostname of the primary MultiController system.
2. Enter the login credentials.

   NOTE
   Confirm that the working environment is CA Performance Management.
3. Click the Device Packs tab, select the Engine or Presenter that you want to upgrade, and click Upgrade, Custom**.**
4. Perform one of the following steps:
   - If the Device Pack you want to upgrade is located in the Device Pack repository that is shipped with the current release of DX NetOps, select the Device Pack Upgrade check box and select a device pack.
   - If the Device Pack you want to upgrade is not located in the Device Pack repository and resides in the local system, click Browse, locate the device pack.

5. Click Engine, CERT, or View radio button and select the corresponding subcomponent, and click Next.
6. (Only for Presenter and Engine) Review the configuration parameters in Global External Variables and Component Configuration for the subcomponent being upgraded and update the new parameters.

   WARNING

   The PRESENTER_ID of the Engine must match with the COMPONENT_ID of the CAPM Presenter.

   NOTE
   In Global External Variables, the previously modified values for the existing parameters are preserved during the upgrade. So, modify the values for the existing parameters, only if needed. However, the new parameters are populated with the default values. So, modify the new values according to your requirement. To know the new parameters, click Help, DevicePacl ReadMe in the Web UI; the list of device pack configuration files that consists of the parameters appear. Select DPInfo_<*devicepack*>.txt and click Open.
7. Click Finish.
   The subcomponent is upgraded.

Migrating Device Pack

This section contains steps to migrate a device pack and self-monitoring device pack from one version of CA Performance Management to another. To move the Engine from one LocalController to another, see the Moving Device Pack Engine between LocalControllers section.

Limitation:
On account of limitations with the CA Performance Management, you cannot migrate a Presenter from a LocalController in a Data Collector to another Local Controller in another Data Collector

Device Pack Migration

This section provides you the steps to migrate the device pack in DX NetOps Mediation Manager for Performance Management.

The following table provides the installer type available for DX NetOps Mediation Manager:

	CA Infrastructure Management 2.3.3 or older	**CA Performance Management 2.3.4**	CA Performance Management 2.4 and 2.5
CA Mediation Manager 2.2.5 or older	ems-installer-<*version*>.zip	Not Compatible	Not Compatible
CA Mediation Manager 2.2.6	ems-installer-<*version*>.zip	CAMM-Installer-<*version*>.jar	Not Compatible
CA Mediation Manager 2.4 and 2.5	ems-installer-<*version*>.zip	CAMM-Installer-<*version*>.jar	CAMM-Installer-<*version*>.jar

When you upgrade DX NetOps Mediation Manager without upgrading CA Infrastructure Management or CA Performance Management releases, there is no need for migration of device packs. [Schematically, you move vertically down in the table.]

When you upgrade CA Performance Manager with or without upgrading DX NetOps Mediation Manager, you need to migrate the device pack. [Schematically, you move horizontally right-side in the table.]

The two possible scenarios and the device pack migration process are follows:

Scenario1: Upgrade CA Infrastructure Management r2.3.3 to CA Performance Management r2.5
Perform the following steps:

1. Install DX NetOps Mediation Manager 20.2.

2. Execute the migratePMtoCAMM script to migrate the engine. Execute the script in the machine where Data Collector is installed. The script is available at <*CAMM_Install_Folder*>/tools. For the step-by-step instructions, see the Migrate Device Pack Generated by the Device Pack Generator or Migrate Device Pack Existing in the Repository section.
3. Stop the Data Aggregator.
4. Execute the camm-tools-cert-migration-<*version*>-SNAPSHOT-jar-with-dependencies.jar script to migrate the certifications. The script is packaged with the Data Aggregator file (CA_DA_<version>_Linux.tar.gz). To execute the script, unzip CA_DA_<version>_Linux.tar.gz, which you download from the CA Performance Management page in CA Support Site. For more information, see CA Performance Management documentation.
5. Upgrade CA Infrastructure Management r2.3.3 to CA Performance Management r2.5. Refer to CA Performance Management 2.5 installation document.
6. Start the migrated device pack from DX NetOps Mediation Manger Web UI.

Scenario2: Upgrade CA Performance Management r2.3.4 to CA Performance Management r2.5
Perform the following step:

1. Stop the Data Aggregator.
2. Execute the camm-tools-cert-migration-<*version*>-SNAPSHOT-jar-with-dependencies.jar script to migrate the certifications. The script is packaged with the Data Aggregator file (CA_DA_<*version*>_Linux.tar.gz). To execute the script, unzip CA_DA_<version>_Linux.tar.gz, which you download from the CA Performance Management page in CA Support Site. For more information, see CA Performance Management documentation.
3. Upgrade CA Performance Management r2.3.4 to CA Performance Management r2.5. Refer to CA Performance Management 2.5 installation document.
4. Upgrade DX NetOps Mediation Manager to release 20.2.

> **NOTE**
>
