DX NetOps - 20.2

Table of Contents

Getting Started

DX NetOps improves your time to value through advanced AI capabilities and unified network visibility. It delivers simplified NetOps intelligence with a user experience that traverses modern architectures through high scale, unified network monitoring. This unified monitoring enables full-stack analytics for assuring traditional and modern architectures.

DX NetOps converts inventory, topology, device metrics, faults, flow and packet analysis into actionable intelligence for network operations teams. Complimented by our AIOps solution, DX NetOps, enables IT teams to establish proactive, autonomous remediation capabilities across the applications, infrastructure, and networks that fuel superior user experiences.

The following video shows DX NetOps in action:

Key Solutions

DX NetOps includes the following integrated solutions:

- Performance Monitoring with DX NetOps Performance Management
  Performance Monitoring: Monitors, stores, analyzes, and displays a massive amount of information for assuring service quality across large, complex, multi-technology, multi-vendor network infrastructure.
- Modern Network Monitoring with DX NetOps Virtual Network Assurance
  Modern Network Monitoring: Extends traditional network monitoring to the virtual network. Provides modern network monitoring for software-defined architectures and hybrid cloud platforms. Correlates logical network entities with physical resources.
- Fault Monitoring with DX NetOps Spectrum
  Fault Monitoring: Map network topology and create alarms from performance events.
- Non-SNMP Monitoring with DX NetOps Mediation Manager
  Non-SNMP Monitoring: Integrate non-SNMP monitoring in your DX NetOps environment.
- Flow Monitoring with Network Flow Analysis
  Flow Monitoring: Monitor interface performance and bandwidth utilization with insight into the traffic going through your network.

Key Features

- **Cross domain AIOps insights**
  Delivers algorithmic noise reduction, anomaly detection, and application-centric root cause topologies.
- **Correlated, normalized, and reliable network data**
  Provides network- aware service, alarm, capacity and topology analytics.
- **Vendor agnostic modern architecture support**
  Enables project monitoring from pilot to global deployment.
- **Optimized application policies**
  Balances the end user experience and cost.
- **Operational workflows**
  Simplifies large and complex SDN technologies.
- **Unified device availability, flow, faults and packet analysis**
  Enables granular visibility.
- **Full stack, contextual, end-to-end workflows**
  Provides for different roles in a single tool.

NetOps Architecture

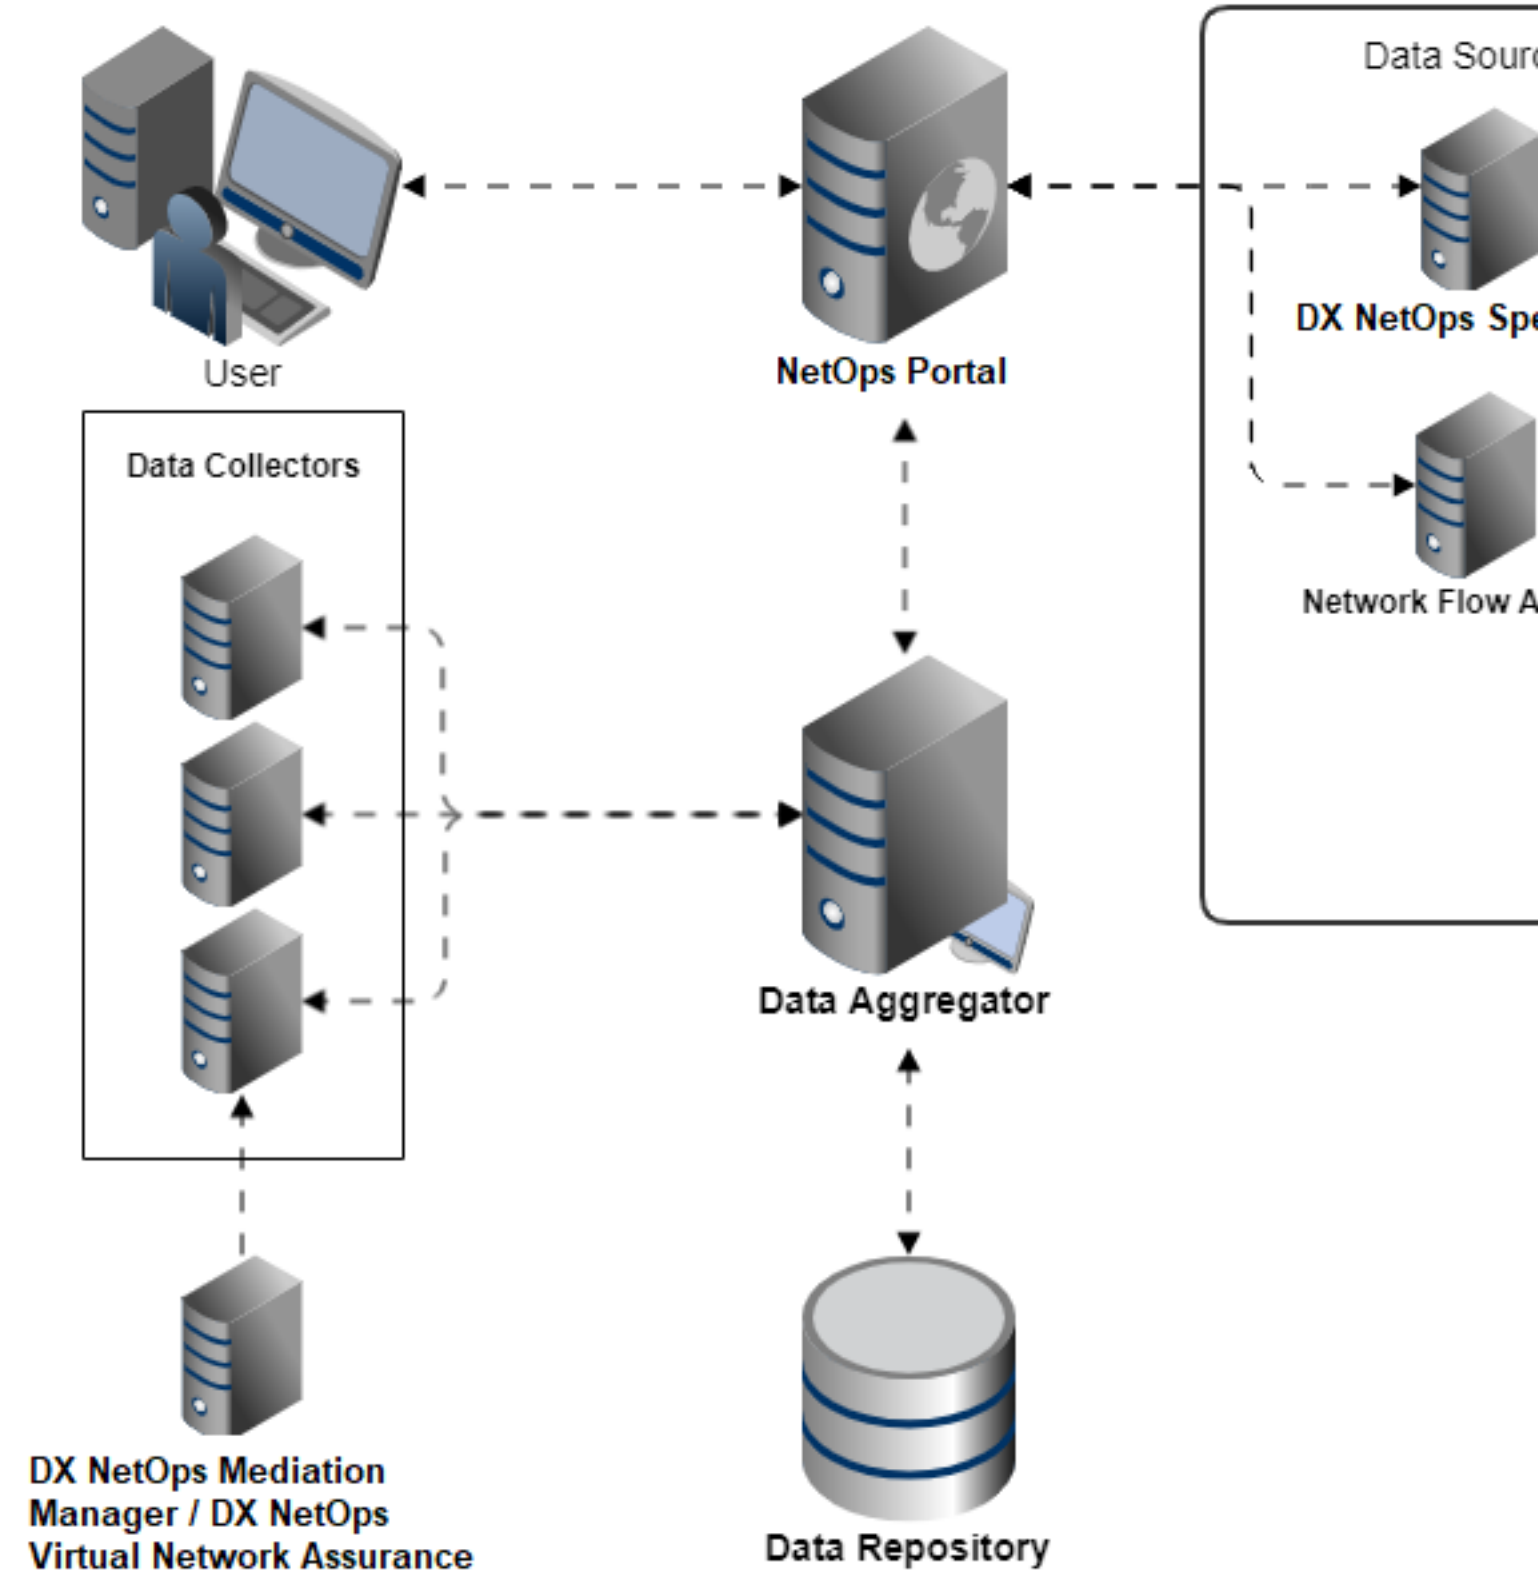
The architecture of DX NetOps supports the following NetOps monitoring:

- Performance Monitoring with DX NetOps Performance Management
- Modern Network Monitoring with DX NetOps Virtual Network Assurance
- Fault Monitoring with DX NetOps Spectrum
- Non-SNMP Monitoring with DX NetOps Mediation Manager
- Flow Monitoring with Network Flow Analysis

The following image shows the basic system architecture of DX NetOps:

NOTE
Other integrations are supported. For more information, see each monitoring section.

Figure 1: Basic System Architecture



The following video walks through the overall DX NetOps installation, which is covered in more detail in each section:

Release Notes

The Release Notes section outlines the new features and current and fixed issues for DX NetOps Performance Management. In addition, the release notes contain the Third-Party Software License Agreements, which detail the terms and conditions of using third-party software in the creation of DX NetOps Performance Management. Use the release notes as a starting point when you first install, or upgrade to a new version of DX NetOps Performance Management.

Release Comparison

This table compares the key features in recent releases for DX NetOps Performance Management:

Key Features	Release 20.2	Release 3.7	Release 3.6	Release 3.5	Release 3.2
New Group Editor	**Yes**	No	No	No	No
Flow Administration	**Yes**	No	No	No	No
Separate Health Dashboards	**Yes**	No	No	No	No
128T Plug-in	**Yes**	No	No	No	No
Broadcom Broadview Plug-in	**Yes**	No	No	No	No
Silver Peak Plug-in	**Yes**	No	No	No	No
Poll Time Configuration	**Yes**	No	No	No	No
Nuage Network Device Support	**Yes**	No	No	No	No
Spectrum Performance View (Beta) Improvements	**Yes**	No	No	No	No
Launch OneClick Clients with Context	**Yes**	No	No	No	No
Spectrum TrapInsight Dashboard View	**Yes**	No	No	No	No
CASBC Devicepack	**Yes**	No	No	No	No
CA5620SamY1731 Devicepack	**Yes**	No	No	No	No
CAPaloAltoPanOS Devicepack	**Yes**	No	No	No	No
Manage Address-Hostname	**Yes**	No	No	No	No
NFA ODataAPI QueryBuilder	**Yes**	No	No	No	No

New Features and Enhancements

The following new features have been added in this release. Some of the existing features have been improved, and are listed under the Enhancements section.

For more comprehensive and detailed information about the new features and enhancements in this release, see the Release Notes in each of the following monitoring sections:

- Performance Monitoring with DX NetOps Performance Management
- Modern Network Monitoring with DX NetOps Virtual Network Assurance
- Fault Monitoring with DX NetOps Spectrum
- Non-SNMP Monitoring with DX NetOps Mediation Manager
- Flow Monitoring with Network Flow Analysis

New Features

New Group Editor

The new and improved group editor no longer uses Adobe Flash.

The following out-of-the box group names changed:

- "Defined Tenants" changed to "Tenants"
- "Collections" changed to "Custom Collections"
- "Domains" changed to "IP Domains"
- "Service Provider Global Groups" changed to "Global Tenant Groups"
- "Service Provider Defined Groups" changed to "Global Tenant Groups"
- "Service Provider Items" changed to "Global Tenant Items"

> **NOTE**
> These name changes impact any existing custom scripts using the previous naming. You must update your scripts accordingly. The DA REST paths have changed.

For more information, see the Groups section.

Network Flow Analysis Administration

This release introduces the ability to manage network flow processing and view the overall heath status of your Network Flow Analysis reporters, harvesters, and interfaces.

For more information, see Flow Administration, Manage Network Flow Processing, View the Health of the System.

Separate Health Dashboards

In previous releases, the Data Aggregator Health Dashboard and Data Collector Health Dashboard were combined into a single dashboard. For clarity, they now appear as separate dashboards.

For more information, see Data Aggregator / Data Collector Health Dashboards.

New Plug-ins

The following plug-ins are newly supported:

- 128T SD-WAN
- Broadcom BroadView
- Silver Peak

Poll Time Configuration

The default timeout value for a poll in the engine of any plug-in is 30 minutes. If a poll requires more than the default value, you can configure the `sdn_poll_timeout_minutes` parameter in the `/etc/VNA.cfg` file. The unit for the parameter value is minutes. After you update this parameter, you must restartDX NetOps Virtual Network Assurance.

Support for Nuage Network Devices

From the current release, DX NetOps Spectrum supports monitoring of Nuage network devices through DX NetOps VNA integration. This functionality allows you to use the SD-WAN solution that is provided by Nuage. SD-WAN stands for Software-Defined Wide Area Networking. It is a combination of Software Defined Networking (SDN) and Wide Area Networking (WAN).

For more information, see Monitoring SD-WAN for Nuage.

Spectrum Performance View (Beta) Improvements

From the current release, DX NetOps Spectrum installer configures the Influx server and automatically creates the user *spectrum*. A new page named **InsideView Configuration(beta)** is added under the OneClick Administration page to configure InsideView, which has options to save, start, and stop InsideView.

For more information and to configure the influxd using https, see InsideView Configuration (beta) in OneClick Administration Pages and Spectrum Performance View (Beta).

Launch OneClick Clients with Context

Launch the OneClick WebApp in-context to open the alarm, explorer, and topology.

For more information, see Launch OneClick Clients with Context.

Spectrum TrapInsight Dashboard View

From this release, DX NetOps Spectrum TrapInsight provides a real-time trap trend analysis dashboard for the distributed DX NetOps Spectrum environment. The administrator can run this tool to get the trap analysis trend; it is disabled by default. This feature is part of SDC with TrapX installation. When a new trap is received, TrapX forwards the trap to Logstash. Logstash processes and sends the trap to the Influx database using the logstash-influx-output plugin.

For more information, see Spectrum TrapInsight Dashboard View.

CASBC Devicepack

This device pack collects performance metrics of:

- CallRecord
- SummaryRecord
- VoiceQualitySummaryRecord

CA5620SamY1731

This device pack collects cfmTwoWayDealy SAS metrics of SAM 5620 (NFM-P) through FindToFile and LogToFile by enabling JMS subscription. It collects the following performance metrics.

- MinimumResponse
- MaximumResponse
- SuccessfulAttempts
- MaxOneWayDelaySrcDest
- MinOneWayDelayDestSrc
- MaxOneWayDelayDestSrc
- MinOneWayDelaySrcDest
- PacketsLost
- PacketsSent
- PacketsArrivingAfterTimeout
- AverageJitter
- AvgResponseTime
- JitterOut
- JitterIn
- Jitter
- DelayVariation
- AvgOneWayDelaySrcDest
- AvgOneWayDelayDestSrc
- Latency
- AveragePercentPacketLoss

CAPaloAltoPanOS

This device pack collects data for the PaloAlto devices from the api and shows the performance stats for:

- Utilization
- SessionAverage
- SuccessfulAttempts
- SessionMaximum
- PacketBufferAverage
- PacketBufferMaximum
- PacketDescriptorAverage
- PacketDescriptorMaximum
- PacketDescriptorOnchipAverage
- PacketsArrivingAfterTimeout
- PacketDescriptorOnchipMaximum

Manage Address-Hostname

The NFA maintains only the latest resolved hostname against the IP address previously. From NFA 10.0.3, we maintain the historical data of the IP address and hostname association.

NOTE

More Information:

Manage Address-Hostname

IP Address and Hostname Historical Data

IP Address and Hostname API

NFA ODataAPI QueryBuilder

The ODataAPI is a flexible tool that lets users easily extract data from the DX NetOps database. The ODataAPI enables integration between DX NetOps data and external applications. The ODataAPI is a public API that uses the QueryBuilder GUI. The QueryBuilder is a guided URL builder that lets you create custom Query URLs to extract and explore performance data. The URLs return customized data in the specified format. You can view the data in a browser or process the data in a custom web application.

More Information: NFA OData QueryBuilder

NetOps Compatibility

NetOps Portal can use the following CA Technologies products as registered data sources:

- DX NetOps Virtual Network Assurance
- DX NetOps Spectrum
- Network Flow Analysis and Anomaly Detector
- CA Application Delivery Analysis
- CA Unified Communications Monitor
- CA Application Performance Management
- CA Business Intelligence

For supported releases, see the DX NetOps Interoperability.

Some components function as data sources. For these components, use only the release that is delivered as part of DX NetOps Performance Management:

- Data Aggregator
- Event Manager

Performance Monitoring

DX NetOps Performance Management monitors, stores, analyzes, and displays a massive amount of information for assuring service quality across large, complex, multi-technology, multi-vendor network infrastructure. The solution helps the largest networks successfully monetize service offerings while lowering the cost and complexity of service.

This section contains everything you need for performance monitoring from getting started to troubleshooting information.

Getting Started

DX NetOps Performance Management monitors, stores, analyzes, and displays a massive amount of information for assuring service quality across large, complex, multi-technology, multi-vendor network infrastructure. The solution helps the largest networks successfully monetize service offerings while lowering the cost and complexity of service.

Communications service providers can use DX NetOps Performance Management to improve network monitoring and delivery of revenue-generating services, such as 4G LTE, Voice over LTE, Mobile Backhaul, Metro Ethernet and more. Enterprises can use DX NetOps Performance Management to assure underlying network services for applications that drive their internal business processes and revenue-generating customer interactions.

Key Features

Very high-scale monitoring architecture on a platform that scales efficiently.

The system architecture provides scale that supports the largest networks. To understand the system requirements to support your scale, see the DX NetOps Performance Management Sizing Tool.

Unified multi-technology, multi-vendor device monitoring. Certifications for classic network devices and specialized carrier Ethernet, WiFi offloading, and mobile wireless equipment.

DX NetOps Performance Management supports the common vendors, metrics, and components in your network infrastructure. The Technology Certification Portal lists out-of-the-box certifications by Data Aggregator version, vendor certification, and metric families: http://serviceassurance.ca.com/im

The extensible certification model enables users to customize communication with monitored devices. For more information, see Self-Certification.

Intelligent analytics, high-scale visualization, and fast processing for instant reporting. Flexible, easily customizable dashboards and reports.

The customizable dashboards and views provide flexible visualization. For example, a regional manager uses a dashboard that pins views to each site group in that region and systems administrator uses a dashboard to monitor all servers. Dashboards show information that is scoped to customizable groups. Context pages show information that is related to a specific item in the system. Views provide visualization options.

Extensible architecture for easy integration and automation.

DX NetOps Performance Management supports downstream integration through the customer facing OpenAPI. For more information, see Integrating.

Predictive analytics to give a complete, unencumbered view of the network, and business key performance indicators.

Configurable and dynamic projections provide insight into capacity planning and situations to watch. For more information, see Metric Projection.

Support for modern network monitoring.

DX NetOps Virtual Network Assurance integrates with DX NetOps Performance Management and provides dashboards and views designed for modern network monitoring. For information, see Modern Network Monitoring.

Key Solutions

DX NetOps Performance Management includes the following integrated solutions:

- DX NetOps Mediation Manager Documentation
  Integrate non-SNMP monitoring in your CAPM environment.
- Network Flow Analysis Documentation
  Monitor interface performance and bandwidth utilization with insight into the traffic going through your network.

The following solutions contribute key features to DX NetOps Performance Management:

- DX NetOps Spectrum Documentation
  Map network topology and create alarms from performance events.
- DX NetOps Virtual Network Assurance Documentation
  Extends traditional network monitoring to the virtual network. Provides modern network monitoring for software-defined architectures and hybrid cloud platforms. Correlates logical network entities with physical resources.

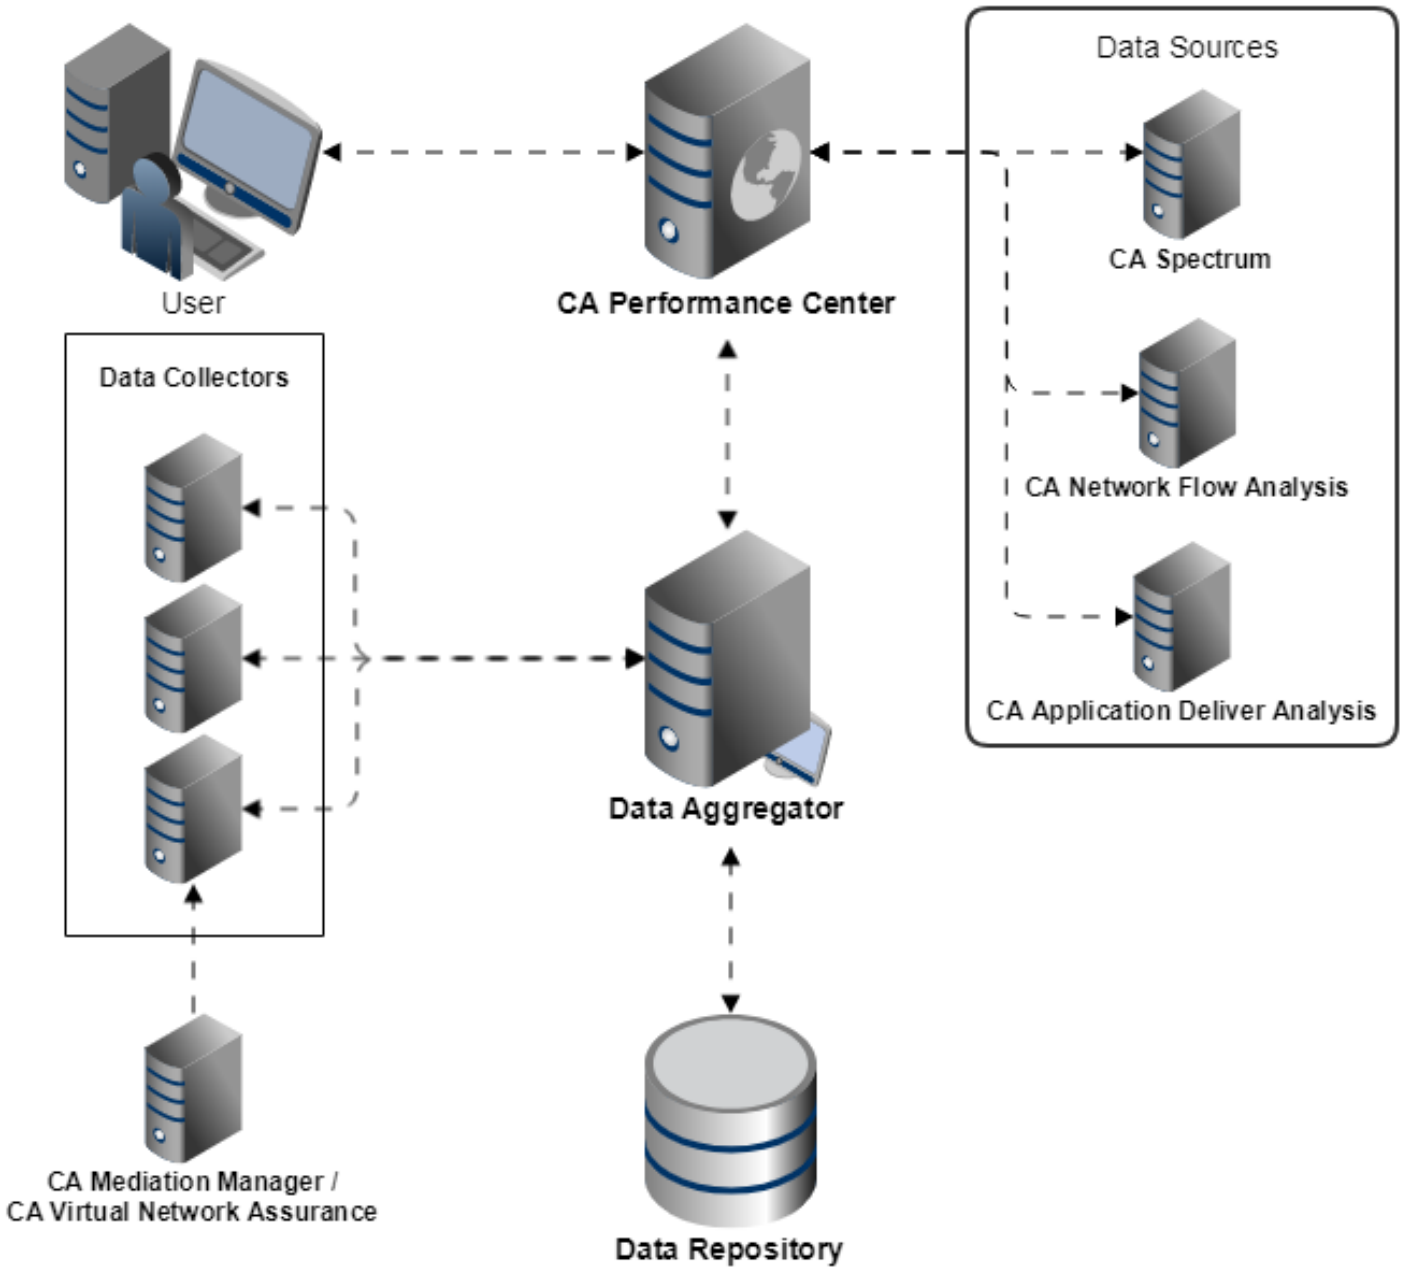
Product Architecture

DX NetOps Performance Management uses an extensible multiserver architecture to support monitoring the largest networks. DX NetOps Performance Management collects performance data and integrates with other data sources, such as CA Application Delivery Analysis and Network Flow Analysis, to provide more information about your network. This page covers the basic system architecture. Fault tolerance enables your DX NetOps Performance Management environment to continue operating properly when a hardware failure or network issue occurs.

The following diagram shows the basic system architecture:

> **NOTE**
> For DX NetOps Performance Management to work properly in a firewall-protected environment, certain ports must be open.

Figure 2: Basic System Architecture



Components

DX NetOps Performance Management includes four primary components:

- **NetOps Portal**
  - Front-end client for the console, dashboards, and reporting
  - Administration and event management
  - Integrates with other data sources
- **Data Aggregator**

  - Data loading and normalization
  - Threshold monitoring
  - OpenAPI
- **Data Repository**
  - Vertica database for Data Aggregator performance data
  - Multi-node (3-5) cluster for large networks
  - Single-node for small networks
- **Data Collector**
  - Simple Network Management Protocol (SNMP) and Internet Control Message Protocol (ICMP) discovery and data collection
  - Integration point for DX NetOps Virtual Network Assurance and DX NetOps Mediation Manager
  - Each Data Collector supports monitoring up to 500,000 monitored items
  - Deploy multiple Data Collectors to support large or geographically dispersed networks
- **DX NetOps Mediation Manager**
  - Collects non-SNMP inventory and performance data
  - Loads data to the Data Aggregator through a dedicated Data Collector
- **DX NetOps Virtual Network Assurance**
  - Collects inventory and performance data from software-defined networking (SDN) and network functions virtualization (NFV) environments
  - Loads data to the Data Aggregator through a Data Collector

Other Architectures

The following architectures reduce data loss:

- Disaster Recovery
- Fault Tolerance

A low-scale architecture is also available. A low-scale architecture matches the basic architecture, but the Data Aggregator and Data Collector are on a single node. If the sizing tool recommends a low-scale deployment, see Install a Low-Scale System.

Videos

The following videos are available for quick overviews about DX NetOps Performance Management. These videos are also embedded throughout the content.

Access Video Transcripts

If you would like to access a video transcript for accessibility reasons, you can access them from YouTube.

Follow these steps:

1. Click the video title to open it in YouTube.
2. Click the **More (...)** icon.
3. Click **Open transcript**.
   The transcript appears in the Transcript pane.

Integrations

The following video examines a DX NetOps Spectrum integration:

For more information, see Integrate CA Spectrum.

The following video examines a CABI integration:

For more information, see Integrate CA Business Intelligence.

The following video examines CA Business Intelligence reports:

For more information, see CABI Reports and Dashboards.

The following video examines the CAMM Netrounds Device Pack:

For more information, see Generate CAMM Device Packs.

Context Pages and Dashboards

The following video examines data sharing:

For more information, see Share Data with Other Users.

The following video examines custom dashboards:

For more information, see Manage Dashboards.

The following video introduces dashboards and context pages:

For more information, see Dashboards and Context Pages.

The following video examines how to set a default dashboard.

For more information, see Customize Your User Settings.

Discovery

The following video examines device discovery:

For more information, see Discovery.

The following video examines more about device discovery:

For more information, see Discovery.

Events and Notifications

The following video examines threshold events and notifications:

For more information, see Events and Configure Notifications.

The following video examines threshold profiles:

For more information, see Configure Threshold Profiles.

The following video examines event processing:

For more information, see Events.

Groups

The following video examines custom groups:

For more information, see Groups.

The following video examines grouping managed items:

For more information, see Groups.

Install and Upgrade

The following video examines the Data Collector upgrade:

For more information, see Upgrade the Data Collectors.

The following video examines the Data Repository installation:

For more information, see Install the Data Repository.

The following video examines a disaster recovery setup:

For more information, see Disaster Recovery.

Manage Devices

The following video examines device types:

For more information, see Override Device Types

The following video examines device deduplication:

For more information, see Device Deduplication.

Monitoring

The following video examines alarm monitoring:

For more information, see Alarms View.

The following video examines SD-WAN monitoring:

For more information, see Monitor SD-WAN.

The following video examines monitoring configuration:

For more information, see Configure Monitoring.

The following video examines Cisco ACI monitoring:

For more information, see Monitor Cisco ACI.

OpenAPI

The following video examines OpenAPI Apps:

For more information, see OpenAPI Apps.

The following video examines the OpenAPI and QueryBuilder:

For more information, see Use the OpenAPI QueryBuilder.

NetOps Portal User Interface

The following video introduces the basic UI features:

The following video examines how to edit user settings:

For more information, see Customize Your User Settings.

The following video examines how to log in:

Network Discovery and Monitoring

DX NetOps Performance Management uses ICMP and SNMP to discover your network and uses SNMP to collect performance data. For information about configuring monitoring, see Configure Monitoring in a New Environment.

Configurable items in the system control discovery and monitoring:

- **Collections** are groups of devices that share monitoring behavior through association with monitoring profiles.
- **Discovery profiles** identify IP address ranges for the Data Collectors to attempt to discover devices. The discovery profile defines which SNMP profiles to use to contact devices in the defined IP ranges.
- **Metric families** are related sets of metrics collected across several technologies. The metric definitions determine how to report the values for the metrics. Metric families normalize performance data from different devices and device types.
- **Monitoring profiles** define the monitoring behavior, poll cycle duration and which metrics to collect, for the associated device collections.
- **SNMP profile** include access credentials to use for discovery and monitoring.
- **Vendor certifications** map the MIB attributes for a particular vendor device to the metrics in supported metric families.

Discovery

During discovery, DX NetOps Performance Management identifies devices in your network.

1. The Data Aggregator assigns IP addresses in the discovery profile IP ranges to Data Collectors.
2. The Data Collectors determines whether devices respond to ICMP or SNMP
3. For devices that respond to SNMP, the Data Collector associates the device with a vendor certification and determines configuration data, which includes the following information:
   - The classification of the device, such as router or switch
   - The device vendor, such as Cisco or Juniper
   - The device type, such as 7700 or 8200
4. Group rules add the devices to collections.
5. The Data Collector uses information in the vendor certifications to identify components for each device.

Monitoring

During operation, the Data Collectors query devices using SNMP MIB requests.

1. For each device, the Data Collector consolidates information from each monitoring profile that is associated with each collection that the device belongs to.

2. The Data Collector requests each supported metric in each monitoring profile at the fastest rate among all monitoring profiles for the device.
3. The Data Collector staggers SNMP requests within the time of the poll cycle.
4. The Data Collector batches poll responses and send the messages to the Data Aggregator.
5. The Data Aggregator loads the performance data to the Data Repository.

Non-SNMP Inventory and Performance Data

DX NetOps Mediation Manager and DX NetOps Virtual Network Assurance collect inventory and performance data and load that data to DX NetOps Performance Management through the Data Collectors. If DX NetOps Performance Management discovers and monitors the same devices through SNMP, the Data Aggregator deduplicates devices with the inventory collected from DX NetOps Mediation Manager and DX NetOps Virtual Network Assurance.

DX NetOps Mediation Manager is the standard non-SNMP data collection tool. For more information, see the DX NetOps Mediation Manager documentation.

DX NetOps Virtual Network Assurance is the data collection and normalization tool for SDN and NFV controllers and orchestrators. For more information, see the DX NetOps Virtual Network Assurance documentation.

Determine Monitoring Requirements

Before you configure monitoring in a new environment, use the following guidelines to determine the monitoring requirements of the environment.

To determine the monitoring requirements of the environment, complete the following steps:

After you determine the monitoring requirements, configure monitoring.

Identify Data Sources

During the installation, you register the Data Aggregator as a data source. Many implementations of DX NetOps Performance Management include other data sources, such as DX NetOps Spectrum and CA Application Delivery Analysis. To import inventory from other data sources, you must register those data sources.

Plan Discovery

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in the network. You can define SNMP profiles with the authentication credentials to communicate with devices in the network and use discovery profiles to limit discovery.

Plan Collections and Monitoring Profiles

Collections are system groups that group devices for monitoring. Monitoring profiles control how often to poll devices and which metrics to collect. Associating a collection with a monitoring profile causes DX NetOps Performance Management to monitor the devices according to the parameters in that profile. You can identify a basic set of monitoring profiles and collections up front to reduce maintenance overhead.

Plan Metrics

You can assign metric families to each monitoring profile to specify the metrics that the system should collect. Consider the metrics that are most useful for monitoring the environment.

Example: You might plan to collect the following metric families:

- Interface
- CPU
- Memory
- Disk
- IPSLA
- QoS

Plan Poll Rates

In each monitoring profile, you can specify how frequently to poll for specific metrics.

Example: You might plan to collect metrics at the following poll rates:

- Interface (1 minute)
- Interface (5 minutes)
- CPU (5 minutes)
- Memory (5 minutes)
- Disk (5 minutes)
- IPSLA (5 minutes)
- QoS (5 minutes)

Plan Monitoring Profiles

You can create a matrix like the following example to determine the necessary monitoring profiles:

Polling Rate	Interface	CPU	Memory	Disk	IPSLA	QoS
1 minute	yes	no	no	no	no	no
5 minutes	**yes**	**yes**	**yes**	**yes**	yes	yes
15 minutes	no	no	no	no	no	no

You can then use the planned metrics and poll rates to plan the monitoring profiles.

In this example, the administrator plans the following monitoring profiles:

- Fast Interfaces (includes Interface metrics that are polled at 1 minute)
- Standard (includes Interface, CPU, Memory, and Disk metrics that are polled at 5 minutes)
- IPSLA (includes IPSLA metrics that are polled at 5 minutes)
- QoS (includes QoS metrics that are polled at 5 minutes)

You can use monitoring profile filters to refine which managed items the monitoring profile applies.

Plan Collections

Consider each of the managed items as you plan the collections.

In this example, the administrator plans the following collections:

- Fast Interfaces (including WAN links) for association with the Fast Interfaces monitoring profile
- Active Devices (including all active devices with some exceptions) for association with the Standard monitoring profile
- Core Routers (including routers in core) for association with the IPSLA monitoring profile
- Distributed Routers (including routers in the distributed network) for association with the QoS monitoring profile

You can use group rules to refine which managed items the collection applies.

Plan Monitoring Profile Filters

Monitoring profile filters specify criteria that governs which components are monitored. Only the component items that match the filter criteria are polled for the associated metric family. Filtering limits SNMP traffic and ensures that the system monitors only relevant components. The filters of each monitoring profile are assessed independently.

Plan Group Rules for Collections

Use rules to keep the collections up-to-date when systems and networks change. Newly discovered items that meet rule specifications are added to collections. If existing items no longer meet rule requirements, they are removed from collections. After you create a rule, you can modify it by deleting filters or adding subrules.

Plan Events

An event is a message that provides information about what is happening in DX NetOps Performance Management. Events provide information for monitoring the health and status of your system and your environment. All events include basic information, such as related devices and the time of the occurrence that triggered the event.

For more information, see Events.

Plan Threshold Profiles

Threshold profiles trigger events when specified conditions occur in associated groups. Event rules define the conditions that trigger events. Each event rule is set to a single metric family, and determines the conditions that cause or clear a violation. Each threshold profile requires at least one event rule.

Plan Monitoring Profile Event Rules

For thresholds that apply broadly to devices in the network, you can add event rules at the monitoring profile level. For example, a rule that creates an event whenever CPU utilization exceeds 95 percent could apply to any device.

Plan Dashboards

Dashboards contain sets of views that show you polled data as meaningful information. DX NetOps Performance Management includes several out-of-the-box dashboards that provide basic information about your infrastructure. To set up dashboards that match your specific monitoring requirements, create a custom dashboard or edit an out-of-the-box dashboard.

Plan Reports

You can access and share On-Demand reports, which dynamically retrieve the most recent data sets from specific sets of items or groups. You can also access and share dashboards and views.

Configure Monitoring in a New Environment

After you install DX NetOps Performance Management, determine the monitoring requirements of your environment, and configure the system to monitor your network. For information about determining the monitoring requirements of your environment, see Determine Monitoring Requirements.

This article discusses the basic procedures and best practices for monitoring. These procedures represent the simplest methods to begin monitoring. Each procedure includes links to pages that provide more information and details about complex configurations. Many of these procedures require the Administrator role.

Register Data Sources

During the installation, you registered the Data Aggregator as a data source. Many implementations of DX NetOps Performance Management include other data sources, such as CA Spectrum and CA Network Flow Analysis. To import inventory from other data sources, register those data sources. If this installation includes only the Data Aggregator, skip this procedure.

For more information about data sources and synchronization, see Manage Data Sources.

Follow these steps:

1. Log in to NetOps Portal as an administrator user. Access NetOps Portal at the following URL:
   `PC_host:8181/pc/desktop/page`
2. Hover over **Administration**, and click **Data Sources: Data Sources**.
3. Click **Add**.
4. Select the Source Type, specify the required information, and click **Save**.
   DX NetOps Performance Management synchronizes with the data sources and adds the relevant devices.

Quickly Discover SNMP Devices

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in your network. You can quickly discover SNMP devices without having to configure SNMP profiles and discovery profiles manually.

For more information, see Discovery.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Quick Device Discovery**.
2. Select **SNMP devices**.
3. Select the SNMP protocol to use.
4. Complete the following fields:
   - **IP Domain**
     If you have multiple IP domains, select the IP domain for discovery.
   - **Community Name** (SNMPv1/v2c Only)
     Specify a secure string that lets the data source query the MIB of the associated device. The community that you supply must provide read access to the device MIB.
   - **Verify Community Name**
     Specify the Community Name again for verification.
   - **Port**
     Specify the port that is used to make SNMP connections to your devices.
     Default: 161

     NOTE

     This port can also be used to send SNMP traps to trap receivers associated with this profile through notifications. In this scenario, use 162 by default. For more information, see Configure Notifications.
   - **IPs/Host**
     Specify the IP address ranges that you want to discover for IPv4. Range discovery is not supported for IPv6 addresses.
5. Click **Discover**.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.

Quickly Discover Virtual Network Devices

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in your network. You can quickly discover Virtual Network devices without having to configure discovery profiles manually.

For more information, see Discovery.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Quick Device Discovery**.
2. Select **Virtual Network Devices**.
3. Select a technology.
4. Complete the following fields for the selected technology:
   - **Viptela SD-WAN**
     - **IP Address**
     - **Protocol**
       The HTTP security scheme for vManage
     - **Port**
     - **User Name**
     - **Administrator Password**
     - **Re-enter Administrator Password**
   - **Cisco ACI**
     - **APIC Host IP Address**
       The IP address of the APIC controller host
     - **Protocol**
       The communication protocol with the APIC controller
     - **Port**
     - **User Name**
     - **Administrator Password**
     - **Re-enter Administrator Password**
   - **128T**
     - **Host Conductor IP Address/Name**
       The IP address of the 128T Conductor
     - **Protocol**
       The HTTP security scheme for 128T SD-WAN
     - **Port**
     - **User Name**
     - **Administrator Password**
     - **Re-enter Administrator Password**
   - **Nuage**
     - **VSD Host IP Address**
       The Virtualized Services Directory (VSD) host
     - **Protocol**
       The communication protocol with the VSD
     - **VSD Port**
       The port that the VSD UI/API server listens on
     - **Stats Host IP Address**
       The IP address of the stats server
     - **Stats Protocol**
       The communication protocol with the stats server
     - **Stats Port**

The port the stats server is listening on for REST requests
- **Nuage Organization**
  The name of the Nuage enterprise to manage
- **Time Zone**
  The time zone of the system, which must match the VSD time zone
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

– **SilverPeak**
- **Host Orchestrator IP Address/Name**
  The Unity Orchestrator Management host
- **Protocol**
  The communication protocol with the Orchestrator
- **Port**
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

5. Click **Discover**.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.

Discover Devices

If you do not use quick discovery, you can configure SNMP profiles and discovery profiles manually.

The following video examines the detailed steps that are required to discover devices:

For more information, see Discovery.

Configure SNMP Profiles

SNMP profiles provide authentication credentials to communicate with devices in your network.

Follow these steps:

1. Hover over **Administration**, and click **Configuration Settings: SNMP Profiles**.
2. Click **New**.
3. Complete the fields, and change any default settings. Some fields apply only to SNMPv3.
   For complete details, see SNMP Profiles.
4. Click **Save**.
   The SNMP profile is added to the system and used for discovery and polling.

Create Discovery Profiles

Discovery profiles specify which devices DX NetOps Performance Management discovers. Create granular discovery profiles for devices with different SNMP credentials or different rediscovery schedule. Granular discovery profiles reduce unnecessary SNMP requests.

For more information, see Discovery Profiles.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Discovery Profiles List**.
2. Click **New**.

3. Specify a name for the profile.
4. Specify the IP address, IP ranges, or hostnames to target for discovery.
5. (Optional) Open the **SNMP** tab, select **Use specific list of assigned SNMP profiles**, and select the SNMP profiles to include in discovery.
   Using a specific list of SNMP profiles reduces unnecessary SNMP requests.
6. (Optional) Open the Schedule tab, and define a schedule.
   During normal operation, discovery runs on a schedule basis to discover new devices in the target range.
7. Click **Save**.
   DX NetOps Performance Management uses the discovery profile to find devices in your network.

Run Discovery

To build your inventory, use the discovery profiles to run discovery.

Follow these steps:

1. Select the discovery profile.
2. Click **Run**. You can run discovery only if the State is Ready.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.
   To view a list of the discovered devices, select the discovery profile, and click History.

Configure Monitoring Profiles

Monitoring profiles control how often to poll devices and which information to collect. Metric families are related sets of metrics that are collected across several technologies. The metric definitions determine how to report the values for the metrics. Metric families normalize performance data from different devices and device types. Assigned metric families determine which metrics the system collects. Collections are system groups that group devices for monitoring. Associating a collection with a monitoring profile causes DX NetOps Performance Management to monitor the devices according to the parameters in that profile.

For more information, see Configure Monitoring Profiles.

Configure a Collection

Consider the following best practices for organizing devices into collections for monitoring:

- Create custom collections that match the monitoring requirements in the environment.
  - Consider the different layers of the network, access, distribution, and core. Devices in different layers might require different levels of monitoring.
  - Consider which technologies and metric families are required. Metric families that would be applied to all devices, such as CPU and memory, apply to broad collections. Targeted monitoring, such as QoS and IPSLA, apply to limited collections.
- Create collections that enable the flexibility to break out monitoring.
  - Some devices are included in multiple collections so that specific metric families are polled at different rates.
  - Devices in different collections have different filtering criteria.
  - Different monitoring requirements depending on importance of device

Follow these steps:

1. Hover over **Administration**, and click **Group Settings: Groups**.
2. Select the **Collections** folder in the left pane.
3. Click **Add Group**.
4. Specify a name, and click **Save**.
   The collection is created. To add devices to the collection, add rules.

5. Click the **Rules** tab, and click **+ Add Rule**.
6. Specify a rule name, select devices for the item type, add conditions as required, and click **OK**.
7. Click **Save and Run Rules**.
   DX NetOps Performance Management adds the items to the collection.

Create a Monitoring Profile

Consider the following best practices for creating monitoring profiles:

- Copy default monitoring profiles to create customer-specific monitoring profiles. Remove the collections that are applied to the default monitoring profiles. This model makes it easier to customize and manage device polling.

  NOTE

  Do not modify the DA Health Fast, Normal, and Slow monitoring profiles. These profiles are used for self-monitoring of the DX NetOps Performance Management components.
- For monitoring flexibility, use multiple monitoring profiles. Do not add all metric families that you monitor in your network to a single monitoring profile.
- Some metric families, such as CPU and Memory, apply broadly to all devices. You can apply a monitoring profile with these metric families to all-encompassing collections, such as All Routers or All Managed Devices.
- Monitoring profiles control the poll rate. To poll the same metric family on different devices at different rates, create monitoring profiles with different poll rates. Apply the faster poll rate to a collection that includes only the devices that require fast polling.
- Monitoring profiles control filtering. If different filtering criteria is required for different sets of devices, create a monitoring profile for each set of requirements.
- Apply only metric families that are applicable to the items in the associated collections. For example, do not apply a monitoring profile that contains the VMWare metric families to a collection of routers. Unnecessary metrics add processing to the Data Aggregator at every change detection period.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Monitoring Profiles**.
2. Click **New**, or select an existing profile and click **Copy**.
3. Specify a unique profile name and description.
4. Select a poll rate.

   TIP

   Five minutes is the standard poll rate for most devices in most networks. One-minute polling adds strain to the system and increases SNMP traffic.
5. To assign the metrics that the system collects for your devices, select metric families.
   Example: To report and view port information for your devices, select the Interface metric family.
6. Click **Save**.

Assign the Collection to the Monitoring Profile

Follow these steps:

1. Select your monitoring profile from the list.
2. Click the **Collections** tab.
3. Click **Manage**.
4. Select your collection, and click **Save**.
   DX NetOps Performance Management uses the metric families in the monitoring profile to poll the items in the collection.

After you configure monitoring, configure reporting. For more information, see Configure Reporting in a New Environment.

Configure Reporting in a New Environment

After you configure monitoring, configure reporting. Reporting in DX NetOps Performance Management includes dashboards and threshold alerts. Thresholds and dashboards scope reporting to items in groups.

Group Polled Items

Groups organize items logically for reporting and thresholding. When you view a dashboard, the data is scoped to your selected group. Individual user profiles are also scoped to particular groups. Each profile is mapped to an initial group that is the selected context when that user logs in.

> **TIP**
>
> Do not assign All Groups as the default for any users. Because this group includes all items in the system, this context causes dashboards to load slowly.

Organize your group structure according to business and reporting needs. To create a regional structure that represents regions, countries, and locations, use site groups. Use custom groups for other types of organizations, such as customers, services, or technologies.

Threshold profiles apply threshold rules to all items in a group. The group hierarchy requirements for thresholding are probably different from the requirements for reporting. Create separate groups that address both sets of requirements. Consider the different layers of the network and how to create thresholds for components in those layers. For example, you might threshold on CPU, memory, and interface metrics on the core network differently to the distribution layer. Create multiple groups to apply threshold rules appropriately.

For more information, see Manage Groups.

Create a Group

Follow these steps:

1. Hover over **Administration**, and click **Group Settings: Groups**.
2. Select a location in the group hierarchy.
3. Click **Add Group**.
4. Specify values for the following parameters:
   - **Group Name**
   - Select **Custom** from the **Group Type** list.
     If you are creating a Site group, select **Site** from the **Group Type** list.
     To create a Site group, specify the following parameters:
     - Latitude, Longitude, and Elevation
     - Name of the geographical location
     - Time Zone
     - Business Hours
   - **Description**
5. Confirm the setting for the following parameter:
   - **Include the children of managed items**
     Adds the children of managed items automatically when the items are added to this group. If you disable this option and you add a router to the group, the interfaces on that router are not included. Therefore, their data is not visible in drilldown views.
6. Click **Save**.
   The new group appears in the Groups tree.

Configure Group Rules

To populate the groups, configure group rules.

Follow these steps:

1. Select the group that you want to add rules to.
2. Click **New Rule**.
3. Select the item type to add to the group.
4. Click **Add Condition**, and define the condition.
   - (Optional) To add 'OR' matches, click + at the end of the condition.
   - (Optional) To add 'AND' matches, click **Add Condition**.
5. (Optional) Add more rules. Each item type requires a separate rule.
6. Click **Save**.
7. (Optional) To confirm that the new rule includes the correct items, click **Preview Results**.
   The results are shown in the Group Rules Preview window. You can expand each item type to view the items that were added.
8. Click **Save** and **Run Rules**.
   DX NetOps Performance Management saves the rules and populates the group with the specified items.

Build Dashboards

Dashboards contain sets of views that show you polled data as meaningful information. DX NetOps Performance Management includes several out-of-the-box dashboards that provide basic information about your infrastructure. To set up dashboards that match your specific monitoring requirements, create a custom dashboard or edit an out-of-the-box dashboard.

The following video shows how you can customize or create dashboards and context pages to meet your requirements:

Create a Dashboard

If an out-of-the-box dashboard is close to your requirements for a custom dashboard, copy the dashboard as a template for the new dashboard.

Follow these steps:

1. Open the dashboard that you want to copy.
2. Click **More** in the upper right corner, and click **Copy Dashboard**.
3. Select the dashboard menu where you want the copied dashboard to appear.
4. Specify the name for the dashboard in the dashboard menu.
5. Specify the title that appears at the top of the dashboard page.
6. Click **Save**.
   A copy of the dashboard is created. The new dashboard opens.
   Click **More** in the upper right corner, and click **Edit Dashboard**.

If none of the existing dashboards are a good template for your requirements, create a dashboard.

Follow these steps:

1. Click the **Dashboards** tab.
   A list of available dashboards appears. Each pane on the page corresponds to a menu.
2. Click **Add Dashboard** next to the menu where you want the new dashboard to appear.

Customize the Dashboard

Customize the new dashboard to provide the required monitoring information.

Follow these steps:

1. Complete the following fields:
   - **Dashboard Menu**
     The menu where the dashboard appears
   - **Menu Item**
     The name of the dashboard in the menu
   - **Dashboard Title**
   - The name that appears at the top of the dashboard
2. Select a layout template for the dashboard.

   TIP

   Some views, such as scorecard views and MultiTrend views, include a lot of detail and require more screen space. These views do not render well in layouts with more than one column.
3. Click and drag views to the page layout. The maximum number of views per dashboard is 25.
4. To customize the view settings, click the **Edit** (gear) icon for the view.
   For more information about configuring views, see Customize Views.

   TIP

   To limit the list of views, click **Select Context**, and select a group, item, or device. Views that you add to the layout are pinned to the selected context.
5. Click **Save**.
   The dashboard is saved, and is added to the selected menu.

Create Threshold Profiles

Threshold profiles trigger events when specified conditions occur in associated groups. Event rules define the conditions that trigger events. Each event rule is set to a single metric family, and determines the conditions that cause or clear a violation. Each threshold profile requires at least one event rule.

The following video shows the threshold profile configuration process:

For more information, see Configure Threshold Profiles.

NOTE

For thresholds that apply broadly to devices in your network, you can add event rules at the monitoring profile level. For example, a rule that creates an event whenever CPU utilization exceeds 95 percent could apply to any device. For more information, see Configure Monitoring Profiles.

Create a Threshold Profile

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Threshold Profiles**.
2. Create a folder, or select an existing folder.
3. Click **New Profile**.
4. Specify the required information.
5. Add event rules to the profile.
   a. In the Event Rules pane, click **New**.
   b. Specify the required information for the event rule. The following fields require explanation:
      - **Duration**

Specifies the total amount of time a given condition must be true within the specified Window to generate an event. The poll cycles that trigger the condition do not need to be consecutive.

- **Window**
  Specifies the overall range of time to evaluate the rule condition.
- **Aggregation**
  Specifies whether the threshold applies to an aggregate value of all components for the device. This field appears only when you select a supported metric family.

  NOTE

  Currently, only the Utilization (%) Metric for the CPU and Memory metric families are supported for aggregation. When you select this option, the event rule must use Fixed Value for the Condition Type.

c. Save the event rule.

6. Click **Save**.
   The threshold profile is added to the system. To generate events, assign the profile to a group.

Assign Groups to a Threshold Profile

Follow these steps:

1. Click the **Groups** tab in the right-hand pane.
2. Click **Manage** at the bottom of the screen.
3. Select the groups from the **Available Groups** tree, and click the right arrow to add it to the Selected list.
4. Click OK.
   The groups in the Selected list are assigned to the threshold profile. DX NetOps Performance Management applies the threshold rules to items in the assigned groups and creates events.

Get Started as a New User

NetOps Portal is a web-based interface that helps you manage your physical and virtual networks, applications, and devices. The NetOps Portal context pages, dashboards, and reports show performance data from your network and systems-monitoring products (data sources). You can compare large amounts of statistical data from multiple sources in one web page.

NetOps Portal takes a "performance-first" approach to application service delivery. This approach places end users in the primary role. To understand how well an IT organization supports application delivery, use DX NetOps Performance Management to capture and analyze data from applications, devices, and the network.

NetOps Portal offers role-specific views of application response times, traffic composition, infrastructure health, and flow-based diagnostics.

Also, modern network monitoring is available from NetOps Portal with DX NetOps Virtual Network Assurance. NetOps Portal with DX NetOps Virtual Network Assurance enables comprehensive coverage with monitoring that is scalable and heterogeneous across the greatest number of technology stacks in the following architectures:

- Traditional
- SDN
- SDDC
- SD-WAN
- NFV
- Hybrid-cloud

The following video highlights several key features of the NetOps Portal UI:

In this article:

Customize Your User Settings

Each user account provides customization options for your personal settings, such as your preferred language for the NetOps Portal UI.

Follow these steps:

1. Click the link for your user account in the upper-right corner and click **User Settings**.
2. Modify the following user settings and click **Save**:
   - **Preferred Language**
     Specify a language for the NetOps Portal user interface. NetOps Portal displays the selected language regardless of the language that is selected for the operating system or for the browser language.

     NOTE
     For a language to display appropriately, the relevant fonts must be installed.
   - **Email Address**
   - **Time Zone**
     The default time zone is UTC (Coordinated Universal Time).

     NOTE
     Changing the time zone after email schedules are set up in NetOps Portal can cause incorrect times to appear in the Scheduled Emails UI.
   - **Time Display Format**
     Select the default time format, either 12 hours or 24 hours.
   - **Default Group**
     This group is the default context when you log in. The list only includes groups from your permission groups.
   - Select one of the following options from the **View Suppression** drop-down:
     - **Suppress Views**
       View suppression is enabled and views are hidden.
     - **Display All Views**
       View suppression is disabled and all views appear.
   - Select one of the following options from the **Item Name Display Setting** drop-down:
     - **Use Display Name**
     - **Use Item Name Alias**

For more information, see Customize Your User Settings.

Explore Managed Items

Data sources discover and monitor your managed items (for example, applications, devices, or interfaces). After monitoring is configured, you can explore your managed items using the Inventory pages or search as a launch point. For more information, see Synchronize Data Sources and Configure Monitoring in a New Environment.

Navigate the Inventory

All the managed items that you have permission to view are available from the Inventory. From the Inventory, you can navigate by item type category (for example, Devices) to lists of those managed items. You can also drill down to the context page of an individual item for more details.

Follow these steps:

1. Hover over **Inventory**, and then click the item type category to view.
   The Inventory for the selected item type category provides minimal information for each item, such as device hostnames or IP addresses.

NOTE
The list for the selected item type category contains a maximum of 5,000 items. If the number of managed items for the selected item type category exceeds 5,000, use the search filter in the lower-left corner.

2. Explore the Inventory list:
   – To sort by a column, click the column heading.
   – To add or remove columns, hover over a column heading, and then click the gear icon. Hover over **Columns**, and then select or clear columns.
3. To drill down to the context page of an individual item, click the item in the list.

For more information, see Inventory Pages and Views.

Search for Managed Items

The global-level search box lets you search for text that is contained in an item string. The search returns inventory lists of all the managed items that match your search, which are sorted by item type category.

NOTE
If your search string includes the equal sign (=), you must begin your search string with an equal sign (=).

Example:`=StringWith=Sign`

Follow these steps:

1. Enter a search string in the global search box in the upper-right corner of NetOps Portal. Press **Enter**:
   The search results categorize the items by type.

   TIP
   To narrow or broaden your search, add the asterisk (*) wildcard character to the search field. The asterisk is the only supported wildcard character. Using asterisks at the beginning and end of a keyword work like quotation marks in the search. You can add multiple search words to narrow the search. If you search for devices using the string “server 192.168*”, the search returns all servers on the 192.168.0.0/16 network.
2. To drill down to the context page for an item, click the item in the list.

For more information, see Search and Filter in CA Performance Center.

View Performance Data

You can see performance data on dashboards and context pages.

- **Dashboard Pages**
  Provide performance and status data that is scoped to a group. For example, a dashboard page can provide the average performance of monitored items in a group. Dashboards often provide a drill-down path to more detailed, related pages from a selected context.
- **Context Pages**
  Provide focused performance and status data that is scoped to a specific managed item, such as a single router or server. These pages are available as drill-down links or tabs from dashboard pages.

Dashboards and context pages render views, which report collected data in a chart or a table format. Depending on the view, the data comes from the various registered data sources. Views that show data for a group contain collated and aggregated data from data sources. Views that show data for individual items provide a drill-down path to the context page for the item.
For more information, see Views.

The following video examines dashboards and context pages:

View a Dashboard

You can view and filter the performance data on a dashboard with group contexts and time ranges.

The group context lets you filter the data that appears in views on the dashboard. When you select a group for a standard dashboard, you apply a filter to all views on the page. When you select a group context, items from all subgroups that are available to you appear in views on the dashboard.

To filter data based on specific time periods, specify time ranges for your dashboards. Changing the time range is useful for troubleshooting performance issues. For example, you can change the time range to show data from the last seven days. In this case, the time range helps you to determine whether an issue is occurring regularly.

Follow these steps:

1. To view a dashboard, hover over **Dashboards**, and then click the dashboard.
2. To filter on the group context, do the following tasks:
   a. Click the **[change]** link under the title of the dashboard.
   b. Select a group from the group hierarchy.
   c. Click **OK**.
   All views on the page with dynamic context are refreshed to reflect the new data context. The change applies until you log out.
3. To filter on a specific time period, do the following tasks:
   a. Click the **[change]** link in the upper-right corner of the dashboard page.
   b. Select a default time period from the list or specify a custom time range.
   The selected time range is applied to the dashboard.

For more information, see Dashboards.

View a Context Page

You can access context pages from an inventory list or a dashboard. Unlike standard dashboard pages, item context pages are clustered in sets of tabbed pages. You can edit the predefined tabs and can change the views that are displayed on those tabs. You can add tabbed pages. You can also rearrange the tabs in an item context to change their order.

Follow these steps:

1. To view a context page, from an inventory list or dashboard, do one of the following tasks:
   – Right-click a hyperlink on an item and select a context page tab.
   – Click a hyperlink on an item to open the default context page tab.
2. To manage tabs, click the **Edit** icon in a tab, select one of the menu options, and then edit, delete, add, reorder, or restore tabs as desired.

For more information, Context Pages.

Access and Share Reports

You can access and share On-Demand reports, which dynamically retrieve the most recent data sets from specific sets of items or groups. You can also access and share dashboards and views.

For more information, see On-Demand Reports and Share Data with Other Users.

Access and Share an On-Demand Report or Dashboard

You can create or access reusable On-Demand report templates, and download a report for sharing. You can also access a dashboard and download it for sharing.

Follow these steps:

1. Do one of the following tasks:
   – Hover over **Reports**, click **On-Demand Report Templates**, and then run an existing report template.
   – Hover over **Dashboards**, and then select a dashboard.
2. Select one of the following sharing options:
   – Click **Print**, select one of the following options, and then download and share the file:
      • **Print PDF**
        Select **Portrait** or **Landscape** to specify the page layout of the PDF document.
      • **Print CSV**
        Select **Scaled** or **Unscaled** to specify whether the values in the exported dashboards are scaled. Scaled values appear with larger units, for example, 1 KB. Unscaled values appear in the raw form for the metric, for example, 1000 bytes.
   – If an email server is configured, click **Email/Schedule Report**, complete the email parameters, and then click **OK**.

Access and Share a View

You can download and share individual views.

Follow these steps:

1. Click the **Gear** icon in the upper-right corner of a view.
2. Select one of the following options:
   – **Export CSV (scaled)**
     Scaled values appear with larger units, for example, 1 KB.
   – **Export CSV (unscaled)**
     Unscaled values appear in the raw form for the metric, for example, 1000 bytes.
   – **Generate URL**
     Generate a URL for the view and complete the associated parameters.
3. Do one of the following tasks:
   – Download and share the file.
   – Copy and share the URL.

Organize Managed Items

A group is a filter definition that functions as a container for managed items. Groups let you logically organize managed items in a hierarchical tree structure, with each group containing subgroups or managed items. The structure is propagated to the data sources, where it enables drill down from top-level groups into data from an increasingly narrow but related context.

If the My Custom Groups functionality is enabled for your user account, you can create custom groups. You can define relationships, policies, and dependencies among services, devices, applications, locations, and users within your organization using the Groups tree. Then you can organize your managed items by creating group rules. The groups that appear in your **My Custom Groups** area are visible to only you.

Follow these steps:

1. Do one of the following tasks:
   – Hover over **Administration**, and then click **Group Settings: Groups**.
   – Click the name of your user account in the upper-right corner, and then click **My Custom Groups**.
2. Select a location for the new group in the **Groups** tree, and then click **Add Group**.
3. Specify the parameters for the group, and then click **Save**.
   The new group appears in the Groups tree.
4. Select the group to which you want to add managed items.

Items that have already been added to this group appear in the right pane.
5. Click **New Rule**.
6. Type a name for the rule.
7. Select the type of managed item that you would like to add to the group.
8. Specify the conditions for the rule, and then click **Save**.
9. To confirm that the new rule includes the correct items, click **Preview Results**.
10. Click the following options:
    - **Save**
      Saves the rules without running them. The group is populated during the next global synchronization, which occurs approximately every 5 minutes.
    - **Run Rules**
      Populates the group immediately.

For more information, see Groups.

Customize Your Experience

You can customize your display settings, dashboards, and views.

The following video shows how you can customize or create dashboards and context pages to meet your requirements:

Customize a Dashboard and its Views

You can edit dashboards to add, remove, rearrange, or customize views. You can also click the Gear icon in the upper-right corner of any view to edit its settings.

Follow these steps:

1. Click the **Dashboards** tab, and then select a dashboard to edit.
2. In the upper-right corner, click **More**, and then select **Edit Dashboard**.
3. Change the layout and add or remove views to your layout as desired.
4. To customize a view, click the **Gear** icon to the right of the view name in the layout.
5. Update the view settings and click **Save**.

For more information, see Manage Dashboards, and Customize Views.

Manage Events

An event is a message that provides information about what is happening in DX NetOps Performance Management. Events provide information for monitoring the health and status of your system and your environment. All events include basic information, such as related devices and the time of the occurrence that triggered the event.

To view events, access or add one of the following views:

- **Events View**
  This view displays all the events that occurred in the selected time range for the dashboard. This view can be filtered for a specific group. This view is the default view in the Events Display dashboard.
- **Filtered Event Views**
  This view includes filters for data source, severity, event type, event subtype, and threshold profile.

You can configure notifications for events that come from a data source to the Event Manager. The incoming events are evaluated against the conditions that you configure for the notification criteria. Only when the criteria are met does Event Manager take a notification action. If an event does not trigger a notification, the event can still be displayed in the Event List.

The following video examines events and notifications:

Follow these steps:

1. Do one of the following tasks:
   - Hover over **Administration**, and then click **Configuration Settings: Notifications.**
   - Click the name of your user account in the upper-right corner, and then click **Manage Notifications**.
2. Click **New**, step through the **Create Notification** wizard, and then click **Save**.

For more information, see Events and Configure Notifications.

Telemetry

Telemetry is a capability that is integrated into DX NetOps Performance Management to send product usage and system configuration data to CA Technologies, a Broadcom Company (CA). This data helps CA gain insights into customers' product usage, understand their software needs, and focus on the features and platforms that are most commonly used.

By default, the data is collected and stored in the database if the Opt-in field is set to Yes on the Edit Usage Data Sharing Settings screen or Opt-In is set to true through REST. Users can access the collected telemetry data on the System Health page. The uploaded metrics are also stored in a file that is located under <*PC Install Directory*>/PC/bin/esdplatelemetry/.

WARNING

Telemetry does not collect any personally identifiable information (PII) or sensitive information.

What Data Do We Collect?

The following table describes the data that is provided by customers:

Data	Description
Opt-In (Yes/No)	Send diagnostic and usage data to Broadcom. If you have a Portfolio License Agreement in your contract with Broadcom, specify Yes.
PLA Agreement (Yes/No)	If you have a Portfolio License Agreement in your contract with Broadcom, specify Yes.
Domain name	Your company's domain name (the last part of your company's email address). For example, in xyz@company.com, the domain name is company.com.
Enterprise site ID	Your company's site ID that is listed on the CA Support portal.
Description	(Optional) Specify a department or cost center that you use for internal tracking. For example: IT-Sales-1234.

Data	Description
Use Proxy (Yes/No)	(Optional) Details of the proxy server and user credentials to access the proxy server. The user credentials are required only if your proxy requires it. If api.segment.io is not reachable through port 443 from this machine, you can configure a proxy server to transmit anonymous usage data.Provide these details only when the telemetry service cannot be reached through the outgoing port 443 from the DX NetOps Performance Management. Selecting Yes provides you the following fields to enter proxy server credentials: **Proxy URL** - (Optional)The URL proxy address. We recommend that you use a secure protocol (https) For example: https://myproxy.company.com. **Proxy Username** - (Optional) Specify the username on the proxy to direct usage data through. **Proxy Password** - (Optional) Specify the password on the proxy to direct usage data through.

The following table describes the data that is generated by DX NetOps Performance Management:

Data	Description
version	Specifies the data source version
tenant_count	Specifies the number of tenants that are associated with this data source
domain_count	Specifies the number of IP domains that are associated with this data source
active	Specifies if the data source is enabled
source_id	Specifies the unique identifier for the represented data source
active_device_count	Specifies the number of active devices that are associated with this data source
retired_device_count	Specifies the number of retired devices that are associated with this data source
monitored_item_count	Specifies the count of monitored items that are associated with this data source
consumed_license_count	Specifies the count of the items consuming the licenses
ha_da_enabled	Indicates whether the Data Aggregator is configured for a fault tolerant environment
data_collector_count	Specifies the count of data collectors that are associated with this data source

NOTE

NetOps Telemetry takes into account only the items synced to Performance Center. It does take into account the 200 ports per licensed device coming from DX NetOps Spectrum or the Data Aggregator. CA Application Delivery Analysis, Network Flow Analysis, and DX NetOps Virtual Network Assurance use different licensing count logic because the licensing agreements for those products count differently.

How Frequently Do We Collect the Telemetry Data?

By default, telemetry collects and stores the data daily at 12.00 a.m. If the scheduler is not active at 12.00 a.m., the data is collected only in the next day run. The data is collected only once per day.

How to Configure DX NetOps Performance Management to Collect and Send Telemetry Data to CA?

As an administrator, you can configure DX NetOps Performance Management to collect and send telemetry data to CA either in the DX NetOps Performance Management user interface or using the REST API.

From the DX NetOps Performance Management user interface, perform the following steps:

1. Select Administration, Configuration Settings, Usage Data.
2. Click Change Configuration.
3. Fill out the form.
4. Click Save.

To configure telemetry through REST, post the following to http://<*PCHOST*>:<*Port*>/pc/center/webservice/insights/config

```
<Configure>
<CompanyDomain>ca.com</CompanyDomain>
<EnterpriseSiteID>105246</EnterpriseSiteID>
<InternalIdentifier> IT Sales</InternalIdentifier>
<Opt-In>true</Opt-In>
<PLAAgreement>true</PLAAgreement>
<UseProxy>false</UseProxy>
 </Configure>
```

NOTE

Specify a department or cost center that you use for internal tracking in the `InternalIdentifier` parameter. For example, "IT Sales."

More fields for using a proxy are `ProxyURI` , `ProxyUsername` , and `ProxyPassword` .

How Do You Know if Telemetry Failed to Collect or Send Data?

The `TELEMETRY_FAILURE (553)` event is generated to indicate that telemetry failed to collect or send data.

The `trapTelemetryFail (553)` trap is generated to indicate that telemetry failed to complete successfully.

Transition to Performance Management

If you are transitioning off CA eHealth, consider DX NetOps Performance Management. DX NetOps Performance Management prepares network operations teams to embrace the latest, scalable technology. Transitioning helps to ensure that the capabilities your organization relies on are met. Transitioning also helps to ensure that more value from new enhancements is realized.

The top five reasons to transition to DX NetOps Performance Management include the following items:

1. Visibility into traditional and SDNs for operational simplicity
   DX NetOps Virtual Network Assurance seamlessly integrates with DX NetOps Performance Management to provide the most comprehensive network monitoring solution for traditional, SDN, and cloud networks.
2. Big data architecture at low cost
   Flexible data acquisition and storage controls provide lowered operational costs across network environments of any size.
3. Prescriptive analytics for improved mean time to repair (MTTR)
   Real-time data analysis, baselining and alerting, with guided workflows, provide meaningful and proactive actions to network performance triage.
4. Innovative visualizations for a customized experience
   DX NetOps Performance Management is built on an open API architecture to ensure feature velocity for maximum data value and a truly customized network troubleshooting experience.

5. Open and extensible for cross-domain clarity
   Protocol-agnostic data acquisition helps eliminate silos for cross-domain visibility to deliver a one-pane-of-glass network operations experience.

DX NetOps Performance Management includes advanced network performance monitoring, relationship mapping, and advanced visualizations for improved operational assurance. The following video explains how DX NetOps Performance Management reduces complexity inherent in legacy and modern networks that are built across numerous technology stacks:

The following sections describe the transition process:

For information about transition services, see the Webcast Replay: Finding an easier and faster way to transition from CA eHealth to CA PM.

Evaluate License Entitlements

CA eHealth customers are entitled to 1:1 device licenses for DX NetOps Performance Management.

The following conditions apply:

- Maintenance must be current or brought up to date.
- You must agree to a $0.00 contract with an amendment referencing dual entitlement.
- You can maintain dual licenses for up to 12 months.
- CA eHealth support expires after a period up to 12 months (no later than the end of life date).
- DX NetOps Performance Management should move from test to production within 12 months.
- You must convert old licenses that were purchased by suite or by element to by device.

If you have any questions, reach out to your account team for assistance.

Assess the Current Environment

Before you transition, examine how you are using CA eHealth. Compare the business requirements of CA eHealth to DX NetOps Performance Management. Evaluate the existing reports, performance data collection, and business processes associated with CA eHealth:

- Identify Live Exception monitors configured in your current tool and determine which ones to transition to DX NetOps Performance Management as performance thresholds.
- Identify missing device monitoring certifications.

  NOTE
  DX NetOps Performance Management does not require some of the MIBs that CA eHealth uses for monitoring the same devices.
- Identify and prioritize business, operational, and technical risks, with risk owners and a mitigation plan.
- Identify any product integrations with your current tool.

Assess the Configured Statistics Rollup Schedule

The statistics rollup schedule parameter determines how long raw data, hourly data, and daily data is maintained in CA eHealth. You can find this parameter in CA eHealth OneClick. You can also use this method to obtain this information.

Follow these steps:

1. Start SQL*Plus:
   Windows:
   ```
   sqlplus %NH_USER%/%NH_USER%@%NH_DB_CONNECT_STRING%
   ```

Solaris/Linux:

```
sqlplus $NH_USER/$NH_USER@$NH_DB_CONNECT_STRING
```

2. Enter the following query to retrieve the rollup schedule:

```
SELECT DECODE (RLP_STAGE_NMBR, 0, 'raw data', 1, 'hourly data', 2, 'daily data')
AS DATA_TYPE, DURATION_SIZE/86400 days
FROM nh_rlp_plan
WHERE RLP_TYPE = 'ST';
```

Example Output:

```
DATA_TYPE DAYS
---------- -----------------
raw data 2
hourly data 42
daily data 490
```

The output shows that CA eHealth keeps two days of raw data (also called as-polled data), 42 days of hourly data, and 490 days of daily data.

Obtain Details for Input into the Sizing Tool

To verify that all your servers meet the minimum requirements and sizing guidelines, use the DX NetOps Performance Management Sizing Tool. You can use the following commands to obtain the following details for input into the DX NetOps Performance Management Sizing Tool.

Tips:

- If the CA eHealth systems are in a single cluster, run the following commands from the console for a total count.
- If the CA eHealth systems are in multiple clusters, run the following commands on a console in each cluster and sum the results.
- If one or more standalone CA eHealth systems exist, run the following commands on each standalone system and sum the results.
- If one or more standalone systems exist with a cluster, run the following commands on each standalone system and the cluster console. Sum the results.

Follow these steps:

1. Review the necessary input for the DX NetOps Performance ManagementSizing Tool.
2. Verify that the cluster is in good health and all systems are functioning properly.
3. Run the following commands:

   Number of Devices:

   ```
   nhListElements -elemType device | wc -l > ca-device-elements-count.txt
   ```

   Number of Interfaces:

   ```
   nhListElements -elemType interface | wc -l > ca-interface-elements-count.txt
   ```

4. To get the average number of interfaces per device, divide the number of interfaces by the number of devices.
5. To account for growth, multiply the number of devices by 1.1 and use the result in the DX NetOps Performance Management Sizing Tool.
6. Use the summarized information that is collected for devices in the DX NetOps Performance Management Sizing Tool.

Assess the Certification Coverage

Determine the types of devices that CA eHealth manages and how they map to DX NetOps Performance Management. Work with CA Services to use the `CertAnalyzerPM32_20170731.zip` package.

The tool requires the following input:

- **eHealth-DCI-Location**
  Specify the location of the DCI file. The DCI file is available from the CA eHealth poller directory. If you have multiple DCIs, put them in the same location to run the tool against all of them. To run the tool against only some of your DCIs, put the DCIs into separate folders and specify the folder to run the tool against. The DCI files must have the `.dci` file extension (for example, `elementCfgBackup.dci`). The output files are generated in this location.
- **eHealth-Poller-Version**
  The CA eHealth version number
  Default: 6.3.3.01
- **Other-Version-eHealth-Poller-Location**
  `Unzipped_CertAnalyzer_location``\CertAnalyzer\plugins\capm\def\cert_analyzer.xpp_tmp\EH-POLLER\`*`eHealth_Version`*
- **PM-Certification-Version**
  Specify the DX NetOps Performance Management version number.
- **PM-Certification-Location**
  `Unzipped_CertAnalyzer_location``\CertAnalyzer\plugins\capm\def\cert_analyzer.xpp_tmp\PM-CERT\`*`PM_Version`*
- **Ignore-Aggregation**
  Default: false
- **Ignore-IMP**
  Default: false
- **Ignore-MIB2-Variance**
  Default: true
- **Ignore-Unpolled**
  Default: true

The following results are provided:

- **Summary**
  View the percentage of coverage in DX NetOps Performance Management.
- **Details**
  View each CA eHealth MTF and the DX NetOps Performance Management certification it maps to.
- **Device List Info**
  View each device and its mappings.

The results are also exported into .xls files in the location that is specified in the eHealth-DCI-Location field. Provide the results to your account manager or pre-sales consultant for a summary analysis of your results.

Transition to DX NetOps Performance Management

Before implementation, review the key features, integrations, and architecture. For more information, see Network Discovery and Monitoring.

Execute the transition to DX NetOps Performance Management. We recommend that you take a phased approach. Plan out your group structure and test with a subset first. For more information, see Groups.

Follow these steps:

1. Deploy and configure DX NetOps Performance Management. For more information, see Installing.
2. Execute targeted monitoring setup and configuration migration. For more information, see Configure Monitoring in a New Environment.
   a. To import inventory from other data sources, register those data sources.
   b. Configure SNMP profiles, which provide authentication credentials to communicate with devices in your network.
   c. Configure discovery profiles, which specify the devices DX NetOps Performance Management discovers.
   d. To build your inventory, run discovery.

e. Configure monitoring profiles, which control how often to poll devices and which information to collect.

3. Deploy out-of-the-box reports and in-scope tailored reports. For more information, see Configure Reporting in a New Environment.
   a. Group polled items.
   b. Build dashboards.
   c. Configure performance thresholds in DX NetOps Performance Management that were identified as required from the Live Exception profiles.
4. You might retain CA eHealth to run in parallel with DX NetOps Performance Management. If so, review and approve a cut-over plan with a timeline and project milestones.
5. Get Started as a New User.

Release Notes

The Release Notes section outlines the new features and current and fixed issues for DX NetOps Performance Management. In addition, the release notes contain the Third-Party Software License Agreements, which detail the terms and conditions of using third-party software in the creation of DX NetOps Performance Management. Use the release notes as a starting point when you first install, or upgrade to a new version of DX NetOps Performance Management.

Release Comparison

This table compares the key features in recent releases for DX NetOps Performance Management:

Key Features	Release 20.2	Release 3.7	Release 3.6	Release 3.5	Release 3.2
New Group Editor	**yes**	no	no	no	no
Network Flow Analysis Administration	**yes**	no	no	no	no
Separate Health Dashboard	**yes**	no	no	no	no
Telemetry	**yes**	yes	no	no	no
Extended Flow Views	**yes**	yes	no	no	no
Administer Business Hours Role Right	**yes**	**yes**	yes	no	no
Encrypt Data Aggregator Communication	**yes**	**yes**	yes	no	no
Full PDF and CSV Generation	**yes**	**yes**	yes	no	no
Script Notification Action	**yes**	**yes**	yes	no	no
Support for Oracle Linux (OL) and SUSE Linux Enterprise Server	**yes**	**yes**	yes	no	no
Polling Control	**yes**	**yes**	yes	no	no
Alarms View	**yes**	**yes**	**yes**	yes	no
Customizable Themes	**yes**	**yes**	**yes**	yes	no

Data Aggregator Fault Tolerance	**yes**	**yes**	**yes**	yes	no
Simplified Upgrade for Data Collectors	**yes**	**yes**	**yes**	yes	no
Group Trend Reports	**yes**	**yes**	**yes**	yes	no
System Status Page	**yes**	**yes**	**yes**	yes	no
Red Hat Enterprise Linux (RHEL) 7.4 support	**yes**	**yes**	**yes**	yes	no

New Features and Enhancements

The following new features have been added in this release. Some of the existing features have been improved, and are listed under the Enhancements section.

New Features

New Group Editor

The new and improved group editor no longer uses Adobe Flash.

The following out-of-the box group names changed:

- "Defined Tenants" changed to "Tenants"
- "Collections" changed to "Custom Collections"
- "Domains" changed to "IP Domains"
- "Service Provider Global Groups" changed to "Global Tenant Groups"
- "Service Provider Defined Groups" changed to "Global Tenant Groups"
- "Service Provider Items" changed to "Global Tenant Items"

> **NOTE**
> These name changes impact any existing custom scripts using the previous naming. You must update your scripts accordingly. The DA REST paths have changed.

For more information, see the Groups section.

Network Flow Analysis Administration

This release introduces the ability to manage network flow processing and view the overall heath status of your Network Flow Analysis reporters, harvesters, and interfaces.

For more information, see Flow Administration, Manage Network Flow Processing, View the Health of the System.

Separate Health Dashboards

In previous releases, the Data Aggregator Health Dashboard and Data Collector Health Dashboard were combined into a single dashboard. For clarity, they now appear as separate dashboards.

For more information, see Data Aggregator / Data Collector Health Dashboards.

Enhancements

Data Aggregator Cleanup (20.2.3 and Higher Only)

A cleanup now runs daily by default to remove deleted items from the Data Aggregator. You can configure whether the cleanup runs. You can also disable the cleanup for attribute instance tables or relationships.

For more information, see Configure the Data Aggregator Cleanup.

Data Aggregator Upgrade (20.2.3 and Higher Only)

The `etlHealth.sh` script is now included with the Data Repository installation. We recommend you run this script well in advance of the upgrade and again directly before the upgrade.

For more information, see Upgrade the Data Aggregator.

Password Synchronization (20.2.3 and Higher Only)

NetOps Portal and Network Flow Analysis SSO cookie encryption key changes are now automatically synchronized. You no longer have to restart Network Flow Analysis for the changes to reflect. This enhancement requires you to upgrade Network Flow Analysis to 10.0.4 or higher. This enhancement requires the following patch for Network Flow Analysis 10.0.4: `NFA_10.0.4_PTF_003.`

Access Point Discovery

Previously, the associated wireless controller discovered access points and DX NetOps Performance Management managed them as device components. Access points are now managed as devices available under the device inventory. New metric families are available for Cisco wireless setup. Existing access points remain device components upon upgrade. Make sure to add new metric families for Cisco certification after the upgrade before running any metric family discovery.

If access points restart and their IP addresses change, access points are reconciled. Going forward, access points with matching MAC addresses are reconciled.

In addition, we now support the high availability Cisco setup. If DX NetOps Performance Management discovered both a primary and secondary controller, the access points are moved between the primary and secondary controller when failover occurs.

Lastly, Cisco access points are also reconciled between DX NetOps Spectrum and DX NetOps Performance Management.

Baseline Metrics for SD-WAN Monitoring

Baseline metrics are now available for SD-WAN tunnels and application/SLA paths.

Baseline Rendering

Baseline metrics are processed up to hourly and daily increments. Previously, when the resolution was less than an hour, single dots appeared for the known data points. Now, when the resolution is less than an hour, data points are interpolated between known hourly data points.

For more information, see Trend Views.

Data Collector Statuses

The System Status page now includes new status columns for your Data Collectors. The Configuration Status column indicates whether the associated Data Aggregator can process distributed item repository information from the Data

Collector. The Polling Status column indicates whether the the associated Data Aggregator is receiving poll responses from the Data Collector.

For more information, see View the Health of the System.

Email Extended Flow Views

You can now send or schedule extended flow views in a report by email. By default, the first row is selected in the Top table and the data for the following views are of the first-row selection.

For more information, see Share Data with Other Users.

Enhanced CSV Output

When you generate CSV output, the following leading characters are now removed from cells:

- Plus sign (+)
- Dash (-)
- At symbol (@)
- Equal sign (=)

This enhancement prevents characters that can be interpreted as formula injection.

For more information, see Share Data with Other Users.

Enhanced MySQL Security

As a step toward enhanced security, the Performance Center installation now allows you to set a custom MySQL password.

For more information, see Upgrade Performance Center.

Increased Maximum Alarm Filter Condition Values

You can now have a maximum of 50 overall conditions and 100 alarm filter condition values per condition. For all conditions that support multiple values, you can enable Advanced mode. In Advanced mode, you can enter a comma separated list of values. You can use "and" for all the values or you can select the checkbox to use "or". For more information, see Alarm Views.

Increased Maximum Threshold Value Digits

Threshold values for views now support up to 15 characters including decimal points.

LDAP Authentication for CA Business Intelligence Reports and Dashboards

When you integrate CA Business Intelligence 7.1.1 and higher with DX NetOps Performance Management 3.7.5 and higher, you can enable LDAP authentication for CA Business Intelligence reports and dashboards. For more information, see Enable LDAPS Authentication. You also need to enable LDAP authentication in CA Business Intelligence. For more information, see the CA Business Intelligence JasperReports Server documentation.

Map Views Include All Sites

Sites with no data now appear as gray icons in Map views. In previous versions, sites with no data were excluded from the Map view. For more information, see Map Views.

Meraki Access Point Device Reconciliation

Meraki access points are now reconciled in DX NetOps Performance Management. If the IP address of an access point changes, it is reconciled with the existing access point device in DX NetOps Performance Management. Discovery is initiated on the new IP address of the access point.

Multiple Metric Selection for MultiViews

You can now select multiple metrics within a single metric family for MultiViews. For more information, see Trend Views.

New Custom Gauge View Options

If you are configuring a custom gauge view, you can now select **Scaled** or **Unscaled** to specify whether the values in the view are scaled. Scaled values appear with larger units, for example, 1 KB. Unscaled values appear in the raw form for the metric, for example, 1000 bytes. The new options are unavailable for all existing custom gauge views, which now have "Deprecated" appended to the title.

Non-Root Performance Center Install and Upgrade

When you install and upgrade NetOps Portal, you can now specify a non-root user as the install owner.

For more information, see Install Performance Center and Upgrade Performance Center.

Search Within Specific Columns

Global searches in large-scale environments can impact performance. You can now use the following filter expressions to refine your search results and minimize the impact on performance.

ViewName1:*Column1*;*ColumnN*&*ViewName2*:*ColumnN*=*value*

> **NOTE**
> If you exclude the *ViewName* , the search applies to all views.

```
Groups:Name;Owner&Interfaces:Name;Description=cisco
```

For more information, see Search and Filter in CA Performance Center.

Single Sign-On URL Spoofing Protection

For enhanced security, this release provides enhanced Single Sign-On URL spoofing protection. Administrators can now enable Single Sign-On URL spoofing protection. When this protection is enabled, users can log in using only authorized URLs. The Log In button is disabled for all other URLs. Otherwise, users now get a warning regarding suspicious URLs.

The list of available authorized URLs is populated based on successful log in attempts before protection is enabled.

For more information, see Enable Single Sign-On Spoofing Protection.

Quickly Discover Virtual Network Devices

You can quickly discover Viptela SD-WAN, Cisco ACI, 128T, Nuage, and Silver Peak devices.

For more information, see Discovery.

Vendo Certification Import UI

The user interface for importing custom vendor certifications can now handle extensions, install, and update.

For more information, see Create or Extend Vendor Certifications.

Platform Updates

Jetty

This release upgrades Jetty to release 9.4.15.v20190215

Supported Browsers

The following browsers are supported for this release:

- Microsoft Internet Explorer version 11
- Microsoft Edge version 48.x and later
- Google Chrome 48.x and later
- Mozilla Firefox 42.x and later

New and Updated Technology Certifications

The following certifications are new or updated in this release:

For a complete list of certifications, see Technology Certification Portal.

20.2.5 Certifications

Vendor	Model	Version
CA Technologies	SystemEDGE

New Look and Feel

The Performance Center user interface has a new look and feel for CA Performance Management versions 3.7 and higher.

You might notice the following changes:

Page Header

Search

Global search now appears as an icon with a tooltip. Click the **Search** icon to open a full-width input box with the focus set in it. An **X** icon appears next to the Search box. To search, press Enter. To clear the search, click the **X** icon.

Search Results

Global search results now appear in an overlay below the header instead of on a separate page. The page that you were on before searching is available underneath the overlay. If you click the **X** icon in upper-right, the overlay with the search results closes. The containing group that the search is performed in is shown in the title along with the search term. Individual views do not have locked group indicators.

User Settings

The link to the user settings for the logged in user account is now an avatar badge with the first two letters of the user name.

Notifications

A notification icon now appears in the page header.

Filter Bar

Time Context Picker

The **Live Update Auto-Refresh** option now appears in the time context picker. If the **Live Update Auto-Refresh** option is selected, the end date appears as **Now** and the custom time range options are invalid. If the **Live Update Auto-Refresh** option is unselected, custom time range options and historic options are available.

Group Context Picker

The group context picker has changed slightly. The change link is now a down arrow.

Color

The color palette of the user interface has changed slightly. Status colors remain mostly the same. Chart colors are new and updated.

Typography

The typography has changed slightly. The font color is similar to what appeared previously. The font weights are bolder and the font sizes are larger.

Iconography

The user interface features new and updated iconography. The icons are more rounded, two-colored, and lighter gray.

Grids

In addition to minor changes to the look and feel of grids, quick filters now appear above the grid.

Fixed Issues

This release provides fixes and enhancements to pre-existing functionality:

20.2.5 Fixes

- Symptom: Under specific conditions some newly created Performance Center items at the end of current sync cycle like tenants, groups, domains might not be synced to the data source. Workaround is to perform a full sync.
  Resolution: With the fix, newly created Performance Center items at the end of current sync cycle would be synced to the data source on the next sync cycle.
  (20.2.5, DE348850, 01352680)
- Symptom: DX NetOps Virtual Network Assurance can create a flood of both email and trap notifications after email service in configuration had been unreachable or down but returned to the normal operation state.
  Resolution: With the fix, DX NetOps Virtual Network Assurance should not create a flood of notifications as send email failures should be processed gracefully.
  (20.2.5, DE439091)
- Symptom: Vulnerability tests against "https://<DAHost>:8582" show vulnerabilities for "LUCKY13" and "Secure Client Renegotiation".
  Resolution: "LUCKY13" and "Secure Client Renegotiation" vulnerabilities on data aggregator host when in https mode are resolved.
  (20.2.5, DE451369)
- Symptom: Description and error messages for a couple of OOB groups still use old names.
  Resolution: Updated description and error messages for these OOB groups to use new names.
  (20.2.5, DE463889)
- Symptom: One28T VNA plugin is slow to gather performance data.
  Resolution: Updated the One28T VNA plugin to use GraphQL interface to query the data source for poll data. It allows us to limit the request to the metrics VNA needs vs all the metrics.
  (20.2.5, DE474270)
- Symptom: Wrong number of active interfaces are seen for a router.
  Resolution: Earlier implementation used 'Router Address' to filter the active interfaces causing some other router addresses to match the filter which led to interfaces of all the matching routers to be listed. 'Router Address' was

used because NFA OData API did not support filtering on 'Router Id' for 'Active Interfaces. NFA OData API has been enhanced to support 'router id' and the corresponding changes to use 'Router Id' for filtering has been made in NetOps Portal.
(20.2.5, DE474276, 32162682)

- Symptom: VNA installs on unsupported Java version.
  Resolution: A warning message which alerts while installing a Java version which is not openjdk or Oracle has been added.
  (20.2.5, DE478257)
- Symptom: Unhanded Exceptions on the `server.log` file.
  Resolution: Handled the Exceptions gracefully.
  (20.2.5, DE478725)
- Symptom: CTRL+clicking a menu item in the navigation menu did not open the page in a new browser window or tab.
  Resolution: CTRL+clicking a menu item in the navigation menu now opens the page in a new browser window or tab.
  (20.2.5, DE479025)
- Symptom: On a Performance Center that has multiple IP addresses, Performance Center selects the first interface and first non-loopback IP for the Performance Center Service default Web Site Host value. This can lead to unreachable Performance Center IP used by Event Manger and users/services that contact the Performance Center service.
  Resolution: Update Performance Center to set the default Web Site Host by trying to determine the fully qualified hostname of Performance Center. If Performance Center cannot determine an FQHN, it falls back to first interface/first non-loopback IP. You can override by way of SsoConfig to set Remote Value for Performance Center Web Site Host.
  (20.2.5, DE479930)
- Symptom: DC out of memory due to excessive in-memory logging of poll errors.
  Resolution: Fixed maximum size calculation for polled errors log. Added options to persist all dcdebug logs to disk.
  (20.2.5, DE480361)
- Symptom: In the upgrade scenario, --no-prompt was not handled that results in posting VNA auth credentials again that leads to validation failure and results in warning message.
  Resolution: Upgrade scenario of VNA with --no-prompt handled and VNA existing credentials checked before posting new ones.
  (20.2.5, DE481089)
- Symptom: Admin group UI does allow to modify locked group by adding or removing items.
  Resolution: With the fix, Admin group UI would not allow to modify locked group by adding or removing items.
  (20.2.5, DE481382)
- Symptom: When new items come in to poll, if there is a bad polled item ID (NULL) in the request, a NullPointerException is thrown and it fails to start polling the additional item ID(s) after the NULL item ID. It does not schedule those polled item IDs.
  Resolution: Updated start polling code to handle if NULL is passed it, and print a WARN message and continue processing the non-NULL item IDs.
  (20.2.5, DE482423)
- Symptom: Rule Editor column selector has empty checkbox fields.
  Resolution: Removed gear for column selection/sorting in the Rule Editor grid. Named last two columns in Rule Editor.
  (20.2.5, DE482432)
- Symptom: Users that did not have permission to administrate groups can run rules on those groups.
  Resolution: Fixed code to grey out the **Run Rules** button. Users that cannot administrate groups cannot run rules on those groups.
  (20.2.5, DE482434)
- Symptom: When the not present items process ran, a recurring exception was appearing in the logs for items that are marked as not present and do not have a metric table because there was never any polled data.
  Resolution: When putting together a set of metric tables to check for metric data on not present items, a query is run to filter out any tables that are not in the database.
  (20.2.5, DE482445)
- Symptom: NFA admin pages are not getting loaded with NFA 10.0.5.

Resolution: Performance Center now looks for the new property (ODataApiUrl) to read OData URL from NFA, and uses it if available. If not, it looks for older property (ODataURL) and uses it. Falling back to older property lets Performance Center continue to work with older versions of NFA.
(20.2.5, DE482726)

- Symptom: Running the `testssl.sh` script against the (Fault Tolerant) data aggregator Proxy server while configured for HTTPS shows vulnerabilities for cipher order, SWEET32 and LUCKY13.
  Resolution: The data aggregator proxy's cipher suites, when configured for HTTPS, have been adjusted so that running `testssl.sh` no longer shows vulnerabilities.
  (20.2.5, DE482977)
- Symptom: On Fault Tolerant system using RHEL6, the daproxy service fails to start and shows "traefik error: error while building entryPoint http" in log.
  Resolution: On RHEL6, the `daproxy-init.sh` script has been updated to correctly reference the `daproxy.toml` file.
  (20.2.5, DE483212)
- Symptom: Custom Horizontal Bar chart when configured for SD-Wan metrics, metric families Tunnel or SLA Path, hyperlink for chart redirects to home page.
  Resolution: Addressed issue with hyperlink that redirected to home page instead of context page. The custom Horizontal Bar chart when configured for SD-Wan metrics, metric families Tunnel or SLA Path, correctly redirects user to context page.
  (20.2.5, DE483606)

20.2.4 Fixes

- Symptom: Python 2 is end-of-life (EOL), and there are a few admin/debug Python 2 scripts shipped with the data aggregator/repository.
  Resolution: Updated the Python scripts to run against Python 3. You must now install Python 3 in Linux to run these scripts.
  (20.2.4, DE440532)
- Symptom: The DX NetOps Virtual Network Assurance Viptela plugin was throwing database-related exceptions in the `Server.log` file.
  Resolution: The DX NetOps Virtual Network Assurance Viptela plugin does not throw database-related exceptions in the `Server.log` file anymore.
  (20.2.4, DE460271)
- Symptom: The procedure for configuring DAProxy and Consul services as HTTPS on a fault-tolerant DX NetOps Performance Management is incomplete and confusing. Configuring DAProxy service from the proxy server to data aggregators yields certificate_unknown errors.
  Resolution: The Traefik service has been upgraded to version 2.2.8 to resolve certificate errors between the DAProxy service and the backing data aggregators. The procedures for configuring the Traefik connection as HTTPS have been rewritten and clarified.
  For more information, see Configure the Traefik Connection as HTTPS from Proxy Server to Data Aggregator.
  (20.2.4, DE460814)
- Symptom: Items sent over from DX NetOps Virtual Network Assurance of type MANAGEMENT_SYSTEM are treated as groups instead of devices.
  Resolution: Update the NetOps mapped type for MANAGEMENT_SYSTEMs sent from DX NetOps Virtual Network Assurance.
  (20.2.4, DE463352)
- Symptom: When a Data Collector upgrade that has been initiated from the UI has failed, the Data Collector remains upgrading.
  Resolution: Update Data Collector status to failed upgrade if a registration message is not received within 10 minutes of initiating an upgrade through the UI process.

(20.2.4, DE470798)

- Symptom: When a poll value delta is calculated to be greater than max positive 32-bit or 64-bit integer, the poll response is dropped only if it happens during a rollover. This happens when an SNMP agent returns a nearly impossible delta that could happen within the poll cycle.
  Resolution: Changed the SNMP delta calculation code to handle these very large deltas even when not in a rollover situation. The max delta is controlled via configuration.
  For more information about how to increase or decrease the large 32-bit or 64-bit delta value used in this check, see Configure Counter Behavior.
  (20.2.4, DE472708)
- Symptom: The DX NetOps Virtual Network Assurance Viptela plugin is not closing the vManage connections properly after use.
  Resolution: With this fix, the DX NetOps Virtual Network Assurance Viptela plugin now closes the vManage connections properly after use.
  (20.2.4, DE472718)
- Symptom: The following behaviors are seen while using the ACI Console dashboard. 1. Application profile topology incorrectly shows endpoint groups that are associated with other application profiles; 2. Application profile topology shows more endpoint groups than the application profile hierarchy; 3. When navigating between an application profile and its endpoint groups in the topology, the Health Score on the application profile item disappears; 4. The topology fails to load initially when navigating to the ACI Console from the context of an ACI leaf switch.
  Resolution: The following changes have been implemented to address the identified issues:
  - Endpoint Groups are now distinguished between normal and L2/L3 External. This change now allows the distinction between L2/L3 External Endpoint groups in the ACI Console topology and has resolved the issue where unrelated Endpoint Groups were being incorrectly pulled into the application profile topology.
  - The Health Scores associated with topology parents are now preserved when navigating in the ACI Console. Using the ACI Console link on the Context page of an ACI Leaf/Spine switch no longer fails to load the topology for the selected item. After upgrading from a release prior to 20.2.3, perform the following on your ACI DX NetOps Virtual Network Assurance Gateways to fully take advantage of the new features.

    NOTE
    These steps cause the inventory of your DX NetOps Virtual Network Assurance Gateways to be re-evaluated in the data aggregator.

    a. Navigate to Administration, Monitored Items Management, DX NetOps Virtual Network Assurance Gateways Page.
    b. For each of your ACI DX NetOps Virtual Network Assurance Gateways, select **Edit**, set the **Administration Status** to **Down**, and then save the changes.

  (20.2.4, DE473532)
- Symptom: userName of DX NetOps Virtual Network Assurance UI accepting spaces.
  Resolution: Added validation to restrict spaces in userName.
  (20.2.4, DE475474)
- Symptom: SNMP discovered Network Interfaces that have been reconciled with DX NetOps Virtual Network Assurance discovered interfaces are deleted when the associated DX NetOps Virtual Network Assurance discovered item is deleted.
  Resolution: The software has been updated to prevent SNMP discovered Network Interfaces from being removed when aj associated DX NetOps Virtual Network Assurance discovered Interface is deleted.
  (20.2.4, DE476082)
- Symptom: "No data to display" after upgrade to 3.7.14.
  Resolution: Added ETL health check to the `dr_validate.sh` file to detect ETL issues before upgrade.
  (20.2.4, DE476111)
- Symptom: Users are not able use the Type Catalog web service to import Metric Family definitions which use the `Pollable.Indexes` attribute instead of `DeviceComponent.IndexList` . It is rejected with a parsing error.
  Resolution: Modified the Type Catalog web service to support the `Pollable.Indexes` attribute.

(20.2.4, DE476319)

- Symptom: DX NetOps Virtual Network Assurance orgVsConnectedDevicesFile during Versa Inventory poll does not get updated.
  Resolution: With this fix, the file is now updated during the inventory poll.
  (20.2.4, DE476346)
- Symptom: Non-application users are able to login to the Performance Center MySql database without providing a password.
  Resolution: Update Performance Center install script to remove anonymous user from the MySql database.
  (20.2.4, DE476790)
- Symptom: OOB groups under all old tenants displayed old group names.
  Resolution: Added upgrade script to update OOB group names of groups that still use old group names.
  (20.2.4, DE477368)
- Symptom: In alarm details panels, links are not shown as operable controls.
  Resolution: In alarm details panels, links are now shown as operable controls.
  (20.2.4, DE477700)
- Symptom: ETL failures might occur if multiple Data Aggregators are or previously have been running simultaneously while using the same Data Repository schema instance. This results in NetOps Portal dashboards showing no data or not showing data for recently discovered items. This might occur by accidentally using the same Data Repository information when installing two data aggregators (that are not intended for Disaster Recovery) or when migrating the Data Aggregator to a new system and both the old and new data aggregator are running and the Data Repository is not blocking access to the old Data Aggregator.
  Resolution: To protect the Data Repository, the data aggregator now verifies that no other data aggregator is attached to the same Data Repository schema instance during the data aggregator startup process. If a data aggregator detects that another data aggregator is actively using the Data Repository, it shuts down immediately and log information to the `shutdown.log` file as to why it has shut down. A long-running data aggregator takes precedence over a newly started data aggregator, and the newly started data aggregator shuts down while the long-running data aggregator remains running.
  (20.2.4, DE477749)
- Symptom: OC is skipping processing of few files on failure scenario.
  Resolution: Fixed issue in OC file processing.
  (20.2.4, DE477816)
- Symptom: After customizing a view, any attempts re-edit the view does not launch view settings dialogue until after the page is refreshed.
  Resolution: Addressed issue that after editing a view, the user is unable make subsequent edited to view configuration until after the page is refreshed.
  (20.2.4, DE477881)
- Symptom: The `dr_validate.sh` script requests linux user password during database connectivity testing.
  Resolution: Modified database connectivity check to use existing passwordless ssh.
  (20.2.4, DE477938)
- Symptom: Packet loss value greater than sum of packets.
  Resolution: Added a condition in the DX NetOps Virtual Network Assurance plugin. If the traffic is less than 100, packet loss displays "0".
  (20.2.4, DE478053)
- Symptom: Some rate records have incorrect tstamp value in the rate tables in the Data Repository (for example, 2 records for same item has the same tstamp). This incorrect tstamp value is sent in error by the Data Collector.
  Resolution: Made Data Collector variable that sets the cycle timestamp on poll responses volatile so it is read correctly on all threads.
  (20.2.4, DE478242)
- Symptom: Ctrl+Click on chart items (for example, entries in the chart legend) that open the clicked item opens the link in the same window (replaces the page). Ctrl+Click should open the link in a new browser window (or tab).

Resolution: Ctrl+Click on chart items (for example, entries in the chart legend) now opens the link in a new browser window (or tab).
(20.2.4, DE478277)

- Symptom: ArrayIndexOutOfBounds exception while processing the tunnel response.
  Resolution: OK Tunnel name: to_CO-GBINTX1-WOAGG03_APACBBL2-APACBBL2BAD Tunnel name: to_JPNI418BRWOBR001_APAC_WAN-APAC_WAN (the extra _'s are causing an issue with our parsing as we get back APAC and try to split it on "-").
  (20.2.4, DE478839)
- Symptom: Output of some Open API queries in CSV format might include extra columns, and device information might be missing in some rows.
  Resolution: With this fix, output of Open API queries do not have extra empty columns, and device information is correctly repeated whenever it is needed.
  (20.2.4, DE478981)
- Symptom: vEdge Interfaces that have non-unique private IP addresses are being incorrectly reconciled within DX NetOps Virtual Network Assurance. This leads to missing interface and tunnel items and also interfaces and tunnels being associated with the wrong devices.
  Resolution: The DX NetOps Virtual Network Assurance Viptela plugin has been updated to no longer use the private IP of an interface as a means to uniquely identify it. This allows the missing interfaces and tunnels to be created, and resolves the issue with items being associated with the wrong devices.
  (20.2.4, DE479272)
- Symptom: DX NetOps Virtual Network Assurance sets the Unique ID to the PK ID, but this is not unique across deployments (with multiple Orchestrators) so the IP address matching is bypassed.
  Resolution: The serial number is appended to the instance ID.
  (20.2.4, DE479296)
- Symptom: Unable to identify a user's permission group through REST to be able to set the user's default group to **My Assigned Groups**.
  Resolution: Add permission group information to user REST endpoint.
  (20.2.4, DE479547)
- Symptom: Cannot add items to groups within the User Defined Groups under the NFA data source inventory in Performance Center.
  Resolution: With this fix, users can add items to groups within the User Defined Groups under the NFA data source inventory in Performance Center.
  (20.2.4, DE479574)
- Symptom: When SSO is running on https/443 and SAML2 is being used, SSO fails to validate the SAML2 Assertion, and fail to log in. Also, if user overrides SSO Virtual Directory, some SSO URLs are made with wrong path, as they were hard coded to use /sso.
  Resolution: Updated the validation code to handle when the assertion is coming in with https/443 or https/no port. Both are acceptable. Also, updated the various places SSO URLs are generated to now use the SSO Virtual Directory setting in SsoConfig.
  (20.2.4, DE479656)
- Symptom: Sometimes there are duplicate entries in the Help drop-down menu.
  Resolution: Validate that the help menu has been created. If it exists, do not re-create the Help menu and drop-down items.
  (20.2.4, DE479752)
- Symptom: The ACI Console fails to load the topology when selecting certain items.
  Resolution: The ACI Console logic has been updated to more gracefully handle incorrectly formatted Open API responses.
  (20.2.4, DE480372)

20.2.3 Fixes

- Symptom: Progress bars and loading indicators in the user interface did not have aria attributes set on them to make them visible to screen readers.
  Resolution: Progress bars and loading indicators in the user interface now have aria attributes set on them to make them visible to screen readers.
  (20.2.3, DE434593)
- Symptom: Disclosures (blocks of text that hide/show) in the user interface did not have aria attributes set on them to make them visible to screen readers.
  Resolution: Disclosures (blocks of text that hide/show) in the user interface now have aria attributes set on them to make them visible to screen readers.
  (20.2.3, DE434594)
- Symptom: "VNA Domains" is not translated for non-EN users.
  Resolution: With this fix, 'VNA Domains' gets correctly translated in French and Japanese.
  (20.2.3, DE463156)
- Symptom: When navigating to the Context Page of a Service Chain Item, the Service Chain Topology graph is left blank.
  Resolution: When navigating to the Context Page of a Service Chain Item, the Service Chain Topology graph has the correct diagram with all the correct images.
  (20.2.3, DE465512)
- Symptom: When the user sorts on the 'Last Flow' column in 'All Interfaces' page, the sorting happens on string format of the date rather than on epoch time.
  Resolution: To avoid sorting on String format of date, an invisible column is created holding the epoch time in long format which is sorted when the user sorts on the last flow column.
  (20.2.3, DE470887)
- Symptom: The DX NetOps Virtual Network Assurance Installer does not maintain an `install.history` file that can be helpful to understand when upgrades occurred, and which versions have been installed.
  Resolution: The installer has been updated to create and maintain a history file to track DX NetOps Virtual Network Assurance installations/upgrades. The `install.history` file exists in the base product directory (for example, /opt/CA/VNA/install.history).
  (20.2.3, DE471049)
- Symptom: The System Status in Performance Center UI does not show the backend DA's - only shows daproxy - on a system configured for fault Tolerance, when the consul service on DAproxy is configured for HTTPS.
  Resolution: Performance Center was not recognizing the consul service is configured for HTTPS when calling consul rest services. Performance Center and data aggregator have been updated to recognize when FT's consul is in HTTPS mode, so DA's can be shown in System Status.
  (20.2.3, DE471182)
- Symptom: On a system configured for fault tolerance, /odataquery points to the active data aggregator instead of DAproxy.
  Resolution: With this fix, on a system configured for fault tolerance, /odataquery now points to the DAproxy.
  (20.2.3, DE471203)
- Symptom: Removing Proxy port field from Viptela Config is causing NPE in the `Server.log` file.
  Resolution: Added additional checks for NPE in the DX NetOps Virtual Network Assurance `server.log` file.
  (20.2.3, DE473370)
- Symptom: Active access points are reported incorrectly.
  Resolution: Active access points filed in broker code are no longer behaving like static.
  (20.2.3, DE473478)
- Symptom: End of DX NetOps Virtual Network Assurance installation, the ReadMe is still pointing to docops.ca.com.
  Resolution: Updated to point to the correct location of the documentation on techdocs.broadcom.com.
  (20.2.3, DE473504)
- Symptom: Observed exceptions in oc logs while query for events in network where the specific deviceType does not exists.

Resolution: Before query for events in network for any productType its existence is checked.
(20.2.3, DE473799)

- Symptom: When we click on an Item in the ACI console topology view that does not have a topology (eg. Vswitch, Contracts, etc), the loading symbol remains indefinitely, even though nothing is loading.
  Resolution: Updated ACI Console to have only a few items be clickable.
  (20.2.3, DE473842)
- Symptom: When configured to use fixed context items, device or interface, with On-Demand Report or Dynamic Trend View if the items profile cannot be determined, as in retired device, configuration warning message is shown when there is no data to display.
  Resolution: No data to display is displayed when there is no metric data to report with with fixed context items with On-Demand Report and Dynamic Trend View. Previously when configured to use fixed context items, device or interface, if the item metric profile cannot be determined view showed configuration warning.
  (20.2.3, DE474023)
- Symptom: In the data aggregator `karaf.log` file, there can be massive warning messages generated from the Event Manager on the CPU and Memory component items due to Syncable facet being mistakenly attached to them.
  Resolution: Improved the component discovery not to create Syncable facet on the CPU and Memory components.
  (20.2.3, DE474142)
- Symptom: An exception is thrown for a Threshold Profile ending with a percent (ie. "95%") when you click on it in the Threshold Profiles tab on the Monitored Devices page.
  Resolution: Fixed issue when a Threshold Profile ending with a percent (ie. "95%") threw an exception.
  (20.2.3, DE474143)
- Symptom: While installing DX NetOps Virtual Network Assurance the end timestamp is displaying as dd_mm_yyyy_hh_mm_ss instead of actual timestamp.
  Resolution: Display the actual end timestamp.
  (20.2.3, DE474261)
- Symptom: CARE files for the Data Aggregator and Data Collector no longer include log files and other important information after installing version 20.2.x.
  Resolution: Update the CARE script to look for the updated product name.
  (20.2.3, DE474321)
- Symptom: An insufficiently sized thread pool leads to a WARN message to be logged for a mis-fired Poll Item or Group ETL job every hour when the DIM Item ETL is running at the same time.
  Resolution: The ETL scheduler's thread pool size was increased and made configurable.
  (20.2.3, DE474462)
- Symptom: "No data to display" after upgrade to 3.7.14.
  Resolution: Added new `etlHealth.sh` script to the upgrade process to detect ETL issues before upgrade.
  (20.2.3, DE474520)
- Symptom: There is no indication of what version of CE is installed.
  Resolution: Update the CE installer to write the version when installing.
  (20.2.3, DE474889)
- Symptom: Dynamic Trend View is not properly suppressed on Device Context Page when configured within the Dashboard Editor.
  Resolution: Addressed issue that the Dynamic Trend View is not properly suppressed on Device Context Page when configured within the Dashboard Editor.
  (20.2.3, DE474985)
- Symptom: The Add Data Source dialog showed incorrect options when adding a CA Business Intelligence Data Source.
  Resolution: The Add Data Source dialog shows the correct options when adding a CA Business Intelligence Data Source.

(20.2.3, DE475210)

- Symptom: Multiple records with the same item_id and facet_id value pairs are present in the item_facet table in the Data Repository. There are internal workflows in the Data Aggregator that can result in the same facet being added to the same item in a single database request.
  Resolution: The item repository data base layer now removes duplicate item_facet records when inserting a single batch.
  (20.2.3, DE475453)
- Symptom: After running the Performance Center disaster recovery script, the new Event Manager IP might not be sent to Data Aggregator due to timing between EM synchronization and event poller threads.
  Resolution: Updated Performance Center disaster recovery script to update the DB field, used for the EM URL sent to the Data Aggregator during re-registration, with the new EM IP address. This allows the event poller thread to see it on startup and send the correct EM URL to Data Aggregator.
  (20.2.3, DE475891)
- Symptom: Odata count query on the metricfamilyhistory entity with a filter might return incorrect count of entities.
  Resolution: With this fix, odata count query on the metricfamilyhistory entity with a filter now returns correct count of entities.
  (20.2.3, DE476454)
- Symptom: The "Détection rapide des unités" ("Quick Discovery") page is blank for French users.
  Resolution: The "Détection rapide des unités" ("Quick Discovery") page displays correctly for French users.
  (20.2.3, DE476675)

20.2.2 Fixes

- Symptom: In a trend view that supports "zoom", there was no way to "zoom" in using the keyboard (it could only be done with the mouse).
  Resolution: In a trend view that supports zoom, you can now zoom into the chart using the keyboard. Pressing space bar while an element in the chart has focus marks the start of the zoom. After using the left/right arrow keys to move focus to another part of the chart, pressing space bar again zooms into the selection.
  (20.2.2, DE406325)
- Symptom: Grids with editable fields in them such as the final pane of the user definition wizard do not support keyboard access or work with screen readers.
  Resolution: Grids with editable fields in them such as the final pane of the user definition wizard now can be used via the keyboard and work with screen readers.
  (20.2.2, DE406328)
- Symptom: The refresh icon is missing from some data aggregator Admin pages grids.
  Resolution: Add the code to display the missing refresh icon in all data aggregator Admin pages that require this grid refresh.
  (20.2.2, DE416639)
- Symptom: The Neighbor Topology in the Alarm Console has some nodes cut off in Firefox. logy tab. The nodes drawn are over to the left and cut off.
  Resolution: Modified the d3 code to arrange the nodes slightly so that they are not cutoff in Firefox.
  (20.2.2, DE431384)
- Symptom: Traps generated for events on Tunnel components do not contain all event properties.
  Resolution: Improved logging and error checking in trap sender.
  (20.2.2, DE431603)
- Symptom: The Create/Edit User and Create/Edit Notification wizards are missing some aria attributes that identify them as wizards to screen readers.
  Resolution: The Create/Edit User and Create/Edit Notification wizards now have additional information in them to make them easier to use with screen readers.
  (20.2.2, DE434592)
- Symptom: If you can capture the cookies from a Performance Center session, then you can use the cookies to impersonate that user even after they have logged out.

Resolution: When the user logs out, the cookies are invalidated and so can't be used to impersonate that user.
(20.2.2, DE438456)

- Symptom: OData API is fetching old metric data when start time and end time equals ZERO.
  Resolution: OData API now returns empty data when start time and end time equals ZERO.
  (20.2.2, DE442822)
- Symptom: Data aggregator failed over to the standby data aggregator with no clear indicator in the logs about why the decision was made to fail the over to the standby.
  Resolution: Connection and read timeouts have been added to the data aggregator ActiveMQ and REST status checks. Additionally, the Consul Extension logging has been updated to be more verbose when a system that is currently the active data aggregator goes down and a fail-over occurs.
  (20.2.2, DE448360, 31918553)
- Symptom: When the browser window width is less than 1024 pixels, the user interface is clipped on the left and none of the controls (including a scroll bar) can be manipulated.
  Resolution: When the browser window width is less than 1024 pixels, the user interface now displays a horizontal scroll bar at the bottom of the window which allows all of the interface to be accessed. Elements within the user interface (such as dialog boxes) also now support horizontal scroll bars if elements are clipped.
  (20.2.2, DE450132)
- Symptom: Old RIB document files can build up in the Performance Center /tmp/ribcache.
  Resolution: Performance Center now cleans up the old version(s) of a RIB document file when a new version is available.
  (20.2.2, DE452506)
- Symptom: When TransientDBConnection logging is set to debug, SQL statements with passwords are logged.
  Resolution: Update logger to sift out SQL with passwords.
  (20.2.2, DE456484)
- Symptom: The REST endpoint requesting the SNMPv3 EngineID every time returns a new SNMPEngineID that is one that is not much used in traps.
  Resolution: With this fix, the REST endpoint requesting the SNMPv3 EngineID returns the correct SNMPEngineID that is one that is much used in traps.
  (20.2.2, DE457958)
- Symptom: The Group Editor's Group Description gets stuck on the invalid description if over 255 chars long.
  Resolution: The Group Editor allows the user to modify a description that is over 255 characters.
  (20.2.2, DE458149)
- Symptom: When discovering Check Point firewall virtual systems with context support, many virtual system items are duplicated with empty context names.
  Resolution: Enhanced the virtual system validation process. The virtual systems that are improperly configured with empty context names are no longer discovered.
  (20.2.2, DE461334)
- Symptom: 8443 HTTPS is enabled by default in DX NetOps Virtual Network Assurance, though HTTPS is not supported.
  Resolution: Disabled HTTPS port on wildfly.
  (20.2.2, DE462717)
- Symptom: On-Demand, view option **Chart per item with multiple metrics** when applying Metric Calculate level by Device the sort order is not being honored.
  Resolution: Addressed issue with On-Demand, view option **Chart per item with multiple metrics** when applying Metric Calculate level by Device the sort order is not being honored.
  (20.2.2, DE464964)
- Symptom: Data Aggregator is unresponsive to RIB, REST, or any other request, but java memory usage/garbage collection is fine. Could be a deadlock situation between a couple tasks the data aggregator is running. There is a deadlock possibility when doing a REST/UI delete, change detection, discovery profile running, and an OData call that filters on groups.
  Resolution: Updated the OData filter code to negate the possibility of the deadlock situation.

(20.2.2, DE464968)

- Symptom: BST Feature update task cannot complete due to incorrect logic in BST Feature Update Task Builder (race condition). 2020-06-03 20:20:03,614 WARN (EE-ManagedThreadFactory-default-Thread-112) [OC_BROADVIEW_PLUGIN] BSTFeatureTaskBuilder$SimpleBSTFeatureUpdateTask 105 Timeout occurs for BST Feature Configuration Update thread, timeout value = 90000.
  Resolution: ManagedScheduledExecutorService was replaced by ScheduledThreadPoolExecutor with a fixed coreThread number. It allows to control thread pool size for scheduled tasks and can help avoid potential thread problems (unexpected growth. etc.) 1. Timeouts for tasks were changed according to plugin config variables; 2. Optimized AlarnClearTaskBuilder logic - removed supervisor thread such as plugin always used only one thread to clear all alarms; added CountDownLatch's logic to control alarm clear thread by a timeout; 3.Implemented new logic for BST Feature Update task (for example, task builder).
  (20.2.2, DE465379)
- Symptom: An OData query might not return device information in expand when it starts from metric family/component, for example:
  ```
  portmfs?$expand=device
  ```
  Resolution: An OData query now returns device information in expand when it starts from metric family/component for example:
  ```
  portmfs?$expand=device
  ```
  (20.2.2, DE465743)
- Symptom: Open API in some circumstances might not honor tenants boundaries.
  Resolution: With this fix, Open API now always honors tenant boundaries.
  (20.2.2, DE466422)
- Symptom: When discovering Cisco switch's Environment sensors, only one of the relevent metric families is discovered; or, all of the environmental sensors metric families, but some have no components.
  Resolution: Improved discovery logic for Cisco Environmental Sensor vendor certs. Added new MVEL method that allows discovery expressions to scan all table entries for an OID, instead of only the first entry.
  (20.2.2, DE466858)
- Symptom: On the System Health page, when you page to the next page in a table the section is collapsed each time.
  Resolution: Instead of setting the collapsed property to be purely based on the status of the section, we're also taking into account the current collapsed state.
  (20.2.2, DE467043)
- Symptom: When proxying as a user who uses a different Locale, the Group Rule Editor shows incorrect translations in its group selector.
  Resolution: Modified group selector to get locale from active user.
  (20.2.2, DE467052)
- Symptom: Scheduling "All Pages of multiple page views" for On-Demand report option "Per metric by single item" the PDF output combines multiple metrics the trend charts.
  Resolution: Fixed issue when scheduling On-Demand report option "Per metric by single item" using "All Pages of multiple page views" report the PDF output combines multiple metrics the trend charts.
  (20.2.2, DE467175)
- Symptom: The responsiveness of the ACI Console dashboard has been improved by updating the ACI Console to request data for multiple items at a time. This should prevent the dashboard from taking excessive time to load when a large number of switches are part of the topology.
  Resolution: The ACI Console can take up to a minute to respond after clicking on one of the icons in the hierarchy. The extended time that it takes to load the topology is ultimately based on number of switches that show up in the topology view on the right.
  (20.2.2, DE467188)
- Symptom: The ACI console displays non-ACI User Domains in the hierarchy.
  Resolution: The ACI console has been updated to display only user domains that contain ACI technology group. By having the user domains in data aggregator store the information about the technology groups, Performance Center can directly fetch user domains that contain ACI.

(20.2.2, DE467199)

- Symptom: When installing/upgrading the Performance Center, Data Aggregator or DAProxy, and there is 1 private IP address and 1 public IP address on the machine, the installer doesn't prompt for which IP address to use for consul to bind and listen on. It instead just uses the private IP address.
  Resolution: Updated the installers to ask if there is 1 private and any number of public IP addresses.
  (20.2.2, DE467204)
- Symptom: The initial state of the sections displayed in the new Administration Group Editor was confusing as some sections were initially uncollapsed and some sections were collapsed.
  Resolution: The initial state of the sections displayed in the new Administration Group Editor is now consistent with all sections except Properties initially collapsed. As before, excepting the Items section, as you move between groups (or pages of the UI), your configuration of what is expanded and collapsed is maintained throughout the user session.
  (20.2.2, DE467211)
- Symptom: Two jre directories are created during installation of Performance Center.
  Resolution: Update the installer sub-module to no longer install the extra JRE.
  (20.2.2, DE467362)
- Symptom: When selecting SD-Wan Tunnel/App Path metrics By Component level with the Scorecard Trend might be missing component items.
  Resolution: When selecting SD-Wan Tunnel/App Path metrics By Component level with the Scorecard Trend always render component items.
  (20.2.2, DE467610)
- Symptom: SDWan Performance and Baseline charts show spikes on trend lines, chart renders with clutter when resolution is under 30 minutes.
  Resolution: With SDWan trend charts are forced to use 30 minute resolution when time range is two more hours to eliminate spikes on trend lines that that clutters rendered charts.
  (20.2.2, DE467612)
- Symptom: DX NetOps Virtual Network Assurance is sending multiple IP addresses as the outofbandmanagment IP address on VM.
  Resolution: DX NetOps Virtual Network Assurance now sends the correct IP as the outofbandManagment IP address. .
  (20.2.2, DE467747)
- Symptom: Zooming did not work in trend charts (when it was allowed).
  Resolution: Zooming now works in trend charts that support it.
  (20.2.2, DE468020, 32162368)
- Symptom: When running Alarm Console against Spectrum 10.4.x+ (20.2.x), it might time out or throw an error when not using a custom group. This is because the landscape group synchronized from DX NetOps Spectrum to Performance Center changed and Alarm Console did not take that into account. It uses global collection groups, and if no global collections are defined, it uses all synced DX NetOps Spectrum items. DX NetOps Spectrum also has a limit on 150 comparisons in the webservice used for Alarm Console, so if too many global collections are passed, it fails.
  Resolution: Updated the logic to check for the old and new DX NetOps Spectrum landscape group IDs. By using landscape group, DX NetOps Spectrum can return all events for the landscape group members quicker than specifying all items in groups. In addition, to resolve the issue with 150 comparisons, up to 150 comparisons are added to the webservice request, and a message is printed to the `PCService.log` file when more than 150 comparisons is hit.
  (20.2.2, DE468346)
- Symptom: During installation of the data repository, the I/O scheduler is always set to the same value regardless of type of storage.
  Resolution: Update the data repository installation process to allow the I/O scheduler to be updated to a different value based on storage type.
  (20.2.2, DE468411)
- Symptom: When device is discovered that are related to F5 metric the context tabs for F5, available on Switch Context page, are not available on the Device Context page. When preference is to not associate the device as a switch device, requires manual creating F5 Tabs on the Device Context page.

Resolution: When F5 related devices are discovered as generic device and prefer to not associate the device as a switch. Provide an automated script to import context tabs for F5, available on Switch Context page, to the Device Context page.
(20.2.2, DE468840)

- Symptom: During Performance Center and DR install, the disaster recovery scripts that might have been customized are overwritten without a backup.
  Resolution: Update the Performance Center and DR installers to make backups of the disaster recovery scripts before setting down updated versions.
  (20.2.2, DE468863)
- Symptom: Group Admin Item section could become non responsive after it shows "no items were added to the group" message.
  Resolution: Group Admin Item section continues to work as expected after it shows "no items were added to the group" message.
  (20.2.2, DE469448)
- Symptom: The Group Editor's rule editor does not allow you to edit or create new rules.
  Resolution: Fixed missing comma in `.jsp` file.
  (20.2.2, DE469478)
- Symptom: Manage Groups admin page is missing Device Component Items section.
  Resolution: With this fix, the Manage Groups admin page properly displays Device Component Items section.
  (20.2.2, DE469491)
- Symptom: The DX NetOps Virtual Network Assurance SilverPeak Plugin - 401 Invalid username or password specified.
  Resolution: The logintype has been fixed - value 2 for TACACS authentication for Silver Peak.
  (20.2.2, DE469607)
- Symptom: Card view on SD-Wan Tunnel Statistics dashboard page does not align with site count being reported with the Geo-Map View.
  Resolution: Addressed issue with the number of Site being reported by the Card view on SD-Wan Tunnel Statistics dashboard page, not aligning with site count in Geo-Map View.
  (20.2.2, DE469805)
- Symptom: The Open API might not return all groups in expand clause for queries starting from configuration entity types (devices,interfaces,etc.) if the total number of groups is more then a hundred.
  Resolution: With this fix, the Open API returns all groups in expand clause for queries starting from configuration entity types (devices,interfaces,etc.) regardless of the number of groups.
  (20.2.2, DE470008)
- Symptom: Multi-View Trend for Interface Utilization, Discards and Errors when configured to use bi-directional metrics, In and Out, might render with 'No Data to Display'.
  Resolution: Fixed the 'No Data to Display' problem with Multi-View Trend for Interface Utilization, Discards and Errors when configured to use bi-directional metrics, In and Out.
  (20.2.2, DE470045, 32099937, 32154068)
- Symptom: With multiple columns trend chart views, the Y-axis title is partially hidden when metric unit is scaled to numeric values that forces axis height to 1000 units.
  Resolution: Addressed the partially visible Y-axis title when numeric values forces axis height on trend chart to 1000 units seen with multiple columns trend chart views.
  (20.2.2, DE470115)
- Symptom: A debug logging message is shown when running the Performance Center installer.
  Resolution: The debugging message has been removed from the installer.
  (20.2.2, DE470139)
- Symptom: Items cannot be manually added to the group(s) in the Admin Group Editor.
  Resolution: With this fix, the administrator can now manually add items to the group(s) using Admin Group Editor.

(20.2.2, DE470634)

- Symptom: Read-only checkbox in the group editor triggers a "form is dirty" state (Save button is enabled) if they were clicked on or given focus.
  Resolution: Read-only checkbox fields in the group editor no longer causes the Save button to be enabled (the form becoming dirty) if clicked on or given focus.
  (20.2.2, DE471045)
- Symptom: In 20.2.1, when logging into odataquery, the login box shows a Host field. The default was changed by mistake.
  Resolution: Updated the sign in page to only show Host field when it should, like in 3.7.x.
  (20.2.2, DE471202)
- Symptom: Site Context Pages rendering business hours in subtitle when business hour filter is disabled.
  Resolution: Fixed issue seen on Site Context Pages with business hours rendered in subtitle when business hour filter is disabled.
  (20.2.2, DE471214)
- Symptom: The data aggregator proxy is unable to write to the `daproxy.log` file.
  Resolution: Update the owning group of the log directory for data aggregator proxy.
  (20.2.2, DE471368)
- Symptom: After upgrading Performance Center to 20.2, event data appears in Chinese until the data aggregator is upgraded to 20.2. Problem occurs after Performance Center upgrade, and ends after data aggregator upgrade.
  Resolution: Modified the Event Manager sync code to ignore translations for languages that are no longer supported.
  (20.2.2, DE471566)
- Symptom: DAProxy installer fails due to missing jre folder.
  Resolution: Update consul server installer to not cleanup extra jre folder on upgrade.
  (20.2.2, DE471583)
- Symptom: A few icons displayed in scorecards were not drawing correctly when using the White theme.
  Resolution: All the icons used in scorecards draw correctly when using the White theme.
  (20.2.2, DE471739)
- Symptom: When device is discovered that are related to F5 metric the context tabs for F5, available on Switch Context page, are not available on the Device Context page. When preference is to not associate the device as a switch device, requires manual creating F5 Tabs on Device Context page.
  Resolution: When F5 related devices are discovered as generic device and prefer to not associate the device as a switch. Provide an automated script to import context tabs for F5, available on Switch Context page, to the Device Context page. Updated to better handle view suppression within the Device Context Page.
  (20.2.2, DE471952)
- Symptom: Custom Site Group are not able to reported as sub-group sites with out of the box SD-WAN Tunnel/App Path Scorecard view.
  Resolution: Enhanced the out of the box SD-WAN Tunnel/App Path Scorecard view to support Custom Site Group when used a sub-group sites.
  (20.2.2, DE471965)
- Symptom: When a role for a user with My Custom Groups was changed via the REST API, the My Custom Groups group was deleted.
  Resolution: Update the role REST API call to pass down the permission group ID for the user. A mismatch for the new permission group was causing the deletion.
  (20.2.2, DE472070)
- Symptom: When selecting SD-Wan Tunnel/App Path metrics with mix of core and baseline metrics at times is missing both metric types.
  Resolution: When selecting SD-Wan Tunnel/App Path metrics with mix of core and baseline metrics always render item to process both metric types.
  (20.2.2, DE472250)
- Symptom: In the Rule Editor, you cannot add multiple values for each condition or sub-rule.
  Resolution: With this fix, the Rule Editor's OR condition icon (plus sign) is always displayed when it is required.

(20.2.2, DE472271)

- Symptom: Sub-Rule's "type" and "condition" columns in the Group Editor's Rule grid are not localized for French and Japanese users.
  Resolution: Use Culture instead of Locale so the Sub-Rule's "type" and "condition" columns in the Group Editor's Rule grid are localized for French and Japanese users.
  (20.2.2, DE472464)
- Symptom: The Vsphere plugin sends all the IPs discovered as outofband Management IP address.
  Resolution: The Vsphere plugin now only sends the management IP only in the outofband management IP address set.
  (20.2.2, DE472565)
- Symptom: When creating notification emails, the subject and body fields do not behave correctly (they take forucs from other fields, do not correctly respond to clicking the Insert button, and do not maintain changes made to their content).
  Resolution: When creating notification emails, the subject and body fields now behave correctly.
  (20.2.2, DE472636)
- Symptom: Cisco ISPLA polling can fail with NullPointerException if component IndexList has unexpected format for a given AttributeGroup.
  Resolution: Cisco IPSLA poller gracefully handles the unexpected component IndexList format, log an appropriate message, and ensure data from the other valid AttributeGroups can be collected.
  (20.2.2, DE472770)
- Symptom: InnoDB fails to initialize during install. A common symptom is that functions that should have installed into MySql did not. Confirmation can be found in the MySql log.
  Resolution: Update the installer to check the fs.aio-max-nr setting and update it to a higher recommended value.
  (20.2.2, DE472860)
- Symptom: When generating CSV reports for trend chart views the CSV Export of data does not reflect Business Hour periods in both raw and scaled format.
  Resolution: Export of data when generating CSV reports for trend chart views data dis not reflect Business Hour periods in both raw and scaled format.
  (20.2.2, DE473237)
- Symptom: ClassCastException in the `expression.log` file.
  Resolution: Improved error handling in mvel snmpProtectedDiv function, and improved expression logging.
  (20.2.2, DE473263)
- Symptom: Some tooltips displayed poorly (the contents line wraps after individual characters or pairs of characters) in some browsers.
  Resolution: Tooltips now display correctly in all browsers.
  (20.2.2, DE473508)
- Symptom: When selecting multiple groups within the On-Demand report to be aggregated at group level not all groups are included in generated report by view type 'Chart per Metric by Single Item'.
  Resolution: Address issue with On-Demand report for view type 'Chart per Metric by Single Item' selecting multiple groups to be aggregated at group level that not all groups are included in generated report.
  (20.2.2, DE473710)

20.2.1 Fixes

- Symptom: Notification traps might show the following error in logs: Operation not permitted
  (sendto failed).
  Resolution: Updated notification trap sender to retry up to two additional times, when receiving this error from the operating system. The error is relogged if retry attempts also fail.
  (20.2.1, DE384374, 01175358, 01261904)
- Symptom: Availability stats were missing from the DX NetOps Virtual Network Assurance Versa plugin in some cases.
  Resolution: Availability stats are now available from the DX NetOps Virtual Network Assurance Versa plugin.

(20.2.1, DE402507)

- Symptom: Items appear in Excluded Items tab for a group after a rule is removed from a group. And can only be added back into the group after removing them from Excluded Items list.
  Resolution: Updated SQL to clear the ByRule flag on items removed from a group due to the rule being removed. Items do not appear in the Excluded Items list, and can be added back via a new rule.
  (20.2.1, DE403297, 01287437)
- Symptom: A number of icons in dialog boxes and message boxes did not have the correct aria attributes set on them. As a result screen readers were unable to read the purpose of the user interface component.
  Resolution: All icons in dialog boxes and message boxes have the correct aria attributes assigned to them so that screen readers can read the purpose of the user interface component.
  (20.2.1, DE406123)
- Symptom: User inteface components used to search and filter did not have the correct aria attributes set on them so that screen readers could provide information about how to use the control and it's components.
  Resolution: All user inteface components used to search and filter now have the correct aria attributes set on them so that screen readers can provide information about how to use the control and it's components.
  (20.2.1, DE406124)
- Symptom: Addressed the missing SD-Wan Application Path metric family when customizing a view with context value that is an DX NetOps Virtual Network Assurance Site.
  Resolution: When building custom view with SD-Wan metric if the context selected is a DX NetOps Virtual Network Assurance Site the Application Path metric family is not available in the metric family selector.
  (20.2.1, DE407396)
- Symptom: During install of the cabi_reports zip file from Performance Center on to the CABI server, if user specified HTTPS scheme, it saves with HTTP scheme.
  Resolution: Fixed the installer to correctly save the scheme for Performance Center as HTTPS when specified during install.
  (20.2.1, DE407715)
- Symptom: Editing a dashboard brings up a blank page and cannot be edited. The `PCService.log` file shows a message like "Caused by: java.util.NoSuchElementException: Property missing: Panel/Pane".
  Resolution: If Pane/Row properties are missing from a view, we now default them to 0 and post a message to user, allowing the dashboard to be recovered.
  (20.2.1, DE408142, 01309964,01328507)
- Symptom: Selecting metrics with different units does not get correctly render with when configuring custom Horizontal Bar Chart views.
  Resolution: Alter and validate unit type when selecting metrics when configuring custom Horizontal Bar Chart views.
  (20.2.1, DE409154)
- Symptom: If the ActiveMQ process on the data aggregator or Data Collector runs out of memory, it is not restarted.
  Resolution: Added '-XX:OnOutOfMemoryError=/opt/IMDataAggregator/scripts/activemq stop' as JVM parameter to data aggregator and Data Collector broker processes.
  (20.2.1, DE409714, 01294980)
- Symptom: IM Card View does not support Threshold values more than 10 digits long.
  Resolution: IM Card View now supports Threshold values up to 12 digits long.
  (20.2.1, DE410339, 01324894)
- Symptom: Sync intermittently fails with high heap usage.
  Resolution: Improved the group path caching mechanism to reduce the memory used by the cache.
  (20.2.1, DE411395, 01331371)
- Symptom: Availability Poll is not closing the session properly and throwing exception while closing the session.
  Resolution: Delivered a code fix to close the availability poll as expected.
  (20.2.1, DE413247)
- Symptom: During install or upgrade, the installation process might fail during a check to see if MySql is running. This is particularly true when using an externalized MySql as we are looking for the running process.

Resolution: The installation process has been improved to check if MySql is running by testing the MySql connection port instead of the mysql process. This allows for the check to validate that MySql is available regardless of whether is it running on the same machine or a different machine.
(20.2.1, DE413399, 01340717,01337090)

- Symptom: Customer is not able to integrate DX NetOps Virtual Network Assurance with one vCenter server.
  Resolution: Provided a code fix after adding a null check for dvsPortStatus.
  (20.2.1, DE413974, 01339886)
- Symptom: Custom PE Interfaces context page suppressed CBQOS Context Tab after upgrading to 3.6 service pack.
  Resolution: Resolved the Custom PE Interfaces context page being suppressed CBQOS Context Tab after upgrading to 3.6 service pack.
  (20.2.1, DE414383, 01317817)
- Symptom: Several combo-boxes used to select time values were missing labels which made them difficult to use with screen readers.
  Resolution: Combo-boxes used to select time values are now labelled with either label tags or aria-label attriibutes so that screen readers can provide context.
  (20.2.1, DE414787)
- Symptom: Edit User wizard shows a password error when saving changes to a user using LDAP authentication.
  Resolution: Disabled password strength checking when the password fields are disabled.
  (20.2.1, DE415377, 01350459,01349270)
- Symptom: At times, clicking a group in the group tree on the Manage Groups page takes a large amount of time and the group is not accessible.
  Resolution: With this fix, clicking a group in the group tree on the Manage Groups page now takes a reasonable amount of time.
  (20.2.1, DE415423, 01345758)
- Symptom: If the `Drilldown` or `DetailedLogging` parameters are not included in a generated URL in DX NetOps Performance Management, (such as when a URL from pre-3.6 is used on 3.6+ DX NetOps Performance Management), the rendered view shows the gear icon and allows editing the view settings.
  Resolution: If the `Drilldown` or `DetailedLogging` parameters are not included in the URL, DX NetOps Performance Management defaults to `Drilldown` and/or `DetailedLogging` , and the view cannot be edited.
  (20.2.1, DE415632, 01351680)
- Symptom: Customers want the option to have the system automatically discover devices contributed through DX NetOps Virtual Network Assurance as SNMP manageable.
  Resolution: There is now a **DiscoverVNADeviceAsSnmpManageable** option under the discoverydefaultconfig data aggregator REST endpoint. Setting this option to `true` causes the data aggregator to create a discovery profile for the IP Domain with any new DX NetOps Virtual Network Assurance IPs.
  (20.2.1, DE415805, 01349698)
- Symptom: Exception on looking up IP address for vm in OC Engine for vsphere plugin.
  Resolution: Handled the scenario where IP address was not available for Virtual machine in vsphere plugin.
  (20.2.1, DE416260, 01354780)
- Symptom: Operation status of the DX NetOps Virtual Network Assurance gateway is shown as "NoSuchMessage" on Performance Center when the Data Collector was not reachable.
  Resolution: Performance Center shows correct operation status for the DX NetOps Virtual Network Assurance gateway when the Data Collector is not reachable.
  (20.2.1, DE416277)
- Symptom: Virtual Machines ,Clusters and Hosts were not discovered which were in Folders.
  Resolution: Fixed the issue , added logic to discover Inventory in folders.
  (20.2.1, DE416658, 01353535)
- Symptom: When loading the ACI Console at larger scales, it takes the tree a significant time to load the health scores.
  Resolution: Updated the ACI Console to load the health scores in a more efficient manner, so the tree renders significantly faster.

(20.2.1, DE417378, 01356232)

- Symptom: SslConfig could not import key or certificate from a PKCS12 file.
  Resolution: With this fix, SslConfig does allow to import key and certificate from a PKCS12 file.
  (20.2.1, DE417649, 01358678)
- Symptom: Access Point is shown as Other device instead of manageable device.
  Resolution: The Access Point is now shown as manageable device from other devices.
  (20.2.1, DE417857)
- Symptom: Exceptions in the performance and inventory capture causing the inventory and performance not to not populate for the customer.
  Resolution: Handled the exceptions in the code, Now the data is populated.
  (20.2.1, DE417918, 01339886)
- Symptom: When discovering the Performance Center device via SNMP in the data aggregator, you cannot view SNMP metrics on the Performance Center item.
  Resolution: Updated the Performance Center item to have same default SNMP metric context tabs and ability to add a custom tab of SNMP metrics, when discovered from Data Aggregator.
  (20.2.1, DE417930, 01356609)
- Symptom: On any request OData service responds with "Invalid entity collection or function name 'odata'.".
  Resolution: With this fix, if the issue is seen again, the OData server now logs full trace back of the exception.
  (20.2.1, DE418095)
- Symptom: When the Data Collector runs as a non-root user, the user cannot re-assign the Data Collector to a different tenant and/or IP domain due to permissions to restart the Data Collector from inside the Data Collector.
  Resolution: Updated the restart logic to call sudo to restart the Data Collector if it's running as non-root user. Be sure to check the documentation for an additional sudo command to allow the Data Collector to run as the install user.
  (20.2.1, DE418500, 01363625)
- Symptom: A new vendor set "AWS_IPSEC_TUNNEL" created for aws tunnel metrics and mapped to SDN Tunnel MF this is turned out to be a default VC for SDN Tunnel MF, which should not be the case.
  Resolution: Added <Vendor>Amazon</Vendor> in AWS_IPSEC_TUNNEL Vendor Cert and updated the version of the SDN Tunnel MF which was missing in earlier delivery.
  (20.2.1, DE418710)
- Symptom: RIB queries that target a Data Aggregator and do not include any GROUP BY, ORDER BY, or LIMIT clause started to fail due to parsing errors on the Data Aggregator after a recent Data Aggregator upgrade.
  Resolution: Fixed the Data Aggregator's RIB query parsing logic for this scenario.
  (20.2.1, DE418891, 01367393)
- Symptom: When the system Performance Center is set to have localization other than en_US.UTF-8, the caperfcenter_console service fails to start.
  Resolution: In the `caperfcenter_console` script, locally set the localization to en_US.UTF-8. This allows the expected error checking to proceed and let the process start up.
  (20.2.1, DE418968, 01366004)
- Symptom: When rendering baseline and core metrics on same trend chart when resolution is less than an hour trend line for baseline metric appears as dots that are not connected due to gap data points.
  Resolution: Addressed issue with baseline metric appearing as dots, not connected when rendering baseline and core metrics on same trend chart when resolution being applied is less than an hour.
  (20.2.1, DE419012)
- Symptom: When I select a global collection or enter a string filter value with an ampersand, for example, a global collection named "Demo & Development Systems", I get an error on the alarm console.
  Resolution: Modified the code that generates the built in filters, and user defined filters for the alarm console to properly escape values when generating XML requests for alarm data.
  (20.2.1, DE419546, 01368197)
- Symptom: When doing an OData query that had multiple filter groups, it was incorrectly combining the checks to return the wrong items.
  Resolution: Updated the OData filter group handling to correctly group the checks for items to find.

(20.2.1, DE419659, 01366295)

- Symptom: DVS elements were not collected when the they are under multiple network folder structure levels.
  Resolution: Fixed the code to support multiple folder structure for DVS.
  (20.2.1, DE419699, 01354247)
- Symptom: Wildfly reload fails on initial Installation.
  Resolution: Using Synchronized Version of reload method for Wildfly.
  (20.2.1, DE419709)
- Symptom: When running Remote Engineer on Performance Center, it complains that it cannot find em.properties.
  Resolution: Updated the `re.sh` script to use the correct path to `em.properties` .
  (20.2.1, DE419850)
- Symptom: The `commons-fileupload-1.2.2.jar` file is present in the `PCInstallDirectory/PerformanceCenter/PC/webapps/pc/WEB-INF/lib/` directory. It has been highlighted as a security vulnerability by some sites.
  Resolution: Upgrade the `commons-fileupload` file to version 1.4.
  (20.2.1, DE419870, 01372590)
- Symptom: NFA "Top ..." Pie Chart with Table views intermittently take a long time to render. Sometimes they are quick, other times they take minutes.
  Resolution: NFA "Top ..." Pie Chart with Table views now render in one pass rather than repeatedly updating the Table and Pie sections of the view.
  (20.2.1, DE419970, 01342689,20020017)
- Symptom: When upgrading to 3.7, it might fail to run the mysql_upgrade program because the password for the account used was not being passed. Check `/opt/CA/MySql/mysql_upgrade_results.txt` to see if it complained about bad password or other error.
  Resolution: Updated Performance Center installer to pass the password to the mysql_upgrade program during upgrade.
  (20.2.1, DE420025)
- Symptom: On a scale system Global Search could become too slow since the search criteria is applying a LIKE to every column for each view.
  Resolution: With this fix, the search criteria is applying to a given subset of columns for each view.
  (20.2.1, DE420103)
- Symptom: On Migration from Wildfly 10 to Wildfly 13 & 17, the `JBOSS_CONSOLE_LOG` property changed in the wildfly initialization Script.
  Resolution: Added the `JBOSS_CONSOLE_LOG` property to `/dev/null` in Wildfly 13 and 17.
  (20.2.1, DE420361)
- Symptom: DX NetOps Virtual Network Assurance gateway runs in TLSv1.0 or TLSv1.1.
  Resolution: Updated DX NetOps Virtual Network Assurance gateway to run using TLSv1.2 only.
  (20.2.1, DE420450)
- Symptom: When discovering existing devices and an abort discovery happens before it can complete device discovery and could set the flag that the device was existing, it deleted the existing device.
  Resolution: Updated the discovery abort logic to not delete any existing devices.
  (20.2.1, DE420542)
- Symptom: The contrast of link text
  (a shade of blue) on a selected row in a grid
  (which has a background color of a pale gray or blue), was insufficient. On certain monitors, the background color wasn't visible
  (appeared to be white). The shade of blue used for links had a contrast against the background color that was insufficient to meet Accessibility text on background contrast ratio requirements.
  Resolution: The background color for selected rows in grids and lists has been darkened and the color used for link text has been adjusted so that it meets accessibility contrast requirements when the link is drawn on the new background color.

(20.2.1, DE420630)

- Symptom: For Viptela environments with a large number of devices/tunnels, the performance polling results in high memory usage on the DX NetOps Virtual Network Assurance. This causes DX NetOps Virtual Network Assurance to run out of memory and/or slow down.
  Resolution: The DX NetOps Virtual Network Assurance Viptela plugin polling logic has been updated to more efficiently process lists of polled data.
  (20.2.1, DE420663)
- Symptom: Threshold values in Group Scorecard Trend are not reversed (so that low values are Red/Critical) when only Critical and Major values are provided, and Minor is set to 0 (zero - disabled) in the view settings.
  Resolution: Threshold handling has been updated so that forward or reverse direction is correctly detected when any two threshold values are set, and the third is set to zero / disabled in the view settings. If only one threshold value is provided (others are zero), the direction is set to forward (High values are Red/Critical).
  (20.2.1, DE420784, 20003177)
- Symptom: Geo location attributes cleared in Performance Center group editor for the Site groups are not cleared on the data aggregator, so the OpenAPI shows the last numerical value before they were changed to blank.
  Resolution: With this fix, the geo location attributes cleared in Performance Center group editor for the Site groups is now cleared on the data aggregator and OpenAPI-provided values now match Performance Center values.
  (20.2.1, DE420818)
- Symptom: DX NetOps Virtual Network Assurance reports Virtual Machine and Host Metrics to wrong metric family in data aggregator.
  Resolution: Fixed and Mapped Virtual Machine and Host metrics to the correct Metric family in the data aggregator.
  (20.2.1, DE421149)
- Symptom: The Data Collector can stop receiving inventory and performance data from DX NetOps Virtual Network Assurance under the following scenario: (1) In Performance Center, go to DX NetOps Virtual Network Assurance Gateways admin page, set the Administrative State to **Down** and then to **Up**. (2) Later on, Data Collector loses connection to DX NetOps Virtual Network Assurance because of network issue or if DX NetOps Virtual Network Assurance itself goes down.
  Resolution: Fixed logic in the Data Collector to ensure that is always restores the connection to DX NetOps Virtual Network Assurance when it becomes available.
  (20.2.1, DE421399)
- Symptom: When group memberships in Performance Center are removed during global synchronization (and moved to deleted table), due to item being deleted, it does not remove the BY_RULE flag from the relationship. This causes the relationship to appear in Excluded Items.
  Resolution: When removing a group relationship and the relationship is moved to the deleted table, the BY_RULE flag is removed. Now, the relationship is not considered for Excluded Items list, and if the item comes back, the group rules can re-add the relationship.
  (20.2.1, DE422002, 01287437)
- Symptom: When using the DX NetOps Virtual Network Assurance VMware plugin and the data aggregator is on a virtual machine managed by the plugin, removing the DX NetOps Virtual Network Assurance gateway could cause the data aggregator item to be deleted and re-created on startup.
  Resolution: Added check to the DX NetOps Virtual Network Assurance gateway removal code to not remove any data aggregator or Data Collector device items, and just remove the DX NetOps Virtual Network Assurance facets off them instead.
  (20.2.1, DE422039)
- Symptom: During Global Synchronization, if a deadlock or cannot acquire lock issue arises, temporary tables are dropped and the connection is remade. This results when the command is re-run, it could not find the temporary table.
  Resolution: Updated the retry query handler to not remake the connection on deadlock or cannot acquire lock errors. So when command is re-tried, the temporary tables are still there.
  (20.2.1, DE422072)
- Symptom: When a user with only access to dashboards and **Drill into View** role right, the menu bar disappears when drilling into an item due to NullPointerException in _topbar.jsp.

Resolution: Resolved the issue causing NullPointerException, when drilling into a context page from a dashboard without **View Inventory and Search** role right.
(20.2.1, DE422134, 20022262)

- Symptom: A DX NetOps Virtual Network Assurance device could be mis-reconciled to an SNMP device if the DX NetOps Virtual Network Assurance device's primary is found in the SNMP device's secondary IP list.
  Resolution: Modified the DX NetOps Virtual Network Assurance device reconciliation algorithm to have the Unique ID have a higher precedence than the IP list match.
  (20.2.1, DE422172)
- Symptom: OpenAPI does not show all paths to a group, as a result, you cannot to create a filter to get groups that belong to a path show in Performance Center.
  Resolution: With this fix, OpenAPI now shows all paths to a group separated by ";".
  (20.2.1, DE422272, 20025914,20025914)
- Symptom: After a long period of operation, MySQL process eventually consumes a large percentage of overall system memory even though the process memory settings are properly sized. This is due to MySQL's performance_schema, which is an in-memory schema and not used for Performance Center, being enabled by default.
  Resolution: The MySQL performance_schema has been disabled in the `my.cnf` file installed with Performance Center.
  (20.2.1, DE422458)
- Symptom: When Data Aggregator root logger is changed to ERROR, an erroneous ERROR message was printed during schema validation when there were no differences found.
  Resolution: Updated to check that there are differences before printing the ERROR message.
  (20.2.1, DE422638)
- Symptom: Export the Global Search results to CSV produce a file that is virtually empty.
  Resolution: With this fix, export of the Global Search results now produces a CSV file containing the search results.
  (20.2.1, DE422647)
- Symptom: After an Event Manager full synchronization is requested, EM spawns its inventory synchronization. During inventory sync, the group path cache is refreshed. If another EM synchronization is kicked off during this time, it could throw an error that group path cache is being rebuilt.
  Resolution: Removed the unneeded check during EM PULL to determine if group path cache was currently being rebuilt. EM synchronization should succeed.
  (20.2.1, DE422795)
- Symptom: Inventory updates result in processing exceptions and ultimately fail to be processed. This results in Persistence exceptions filling up the DX NetOps Virtual Network Assurance log files and might result in missing inventory in DX NetOps Performance Management and DX NetOps Spectrum.
  Resolution: The DX NetOps Virtual Network Assurance datamodel has now been updated to cleanup orphan Subnetted IP Addresses when persisting NetworkInterfaces. The upgrade process now also identifies and cleans up any duplicated Subnetted IP Address objects in the database.
  (20.2.1, DE423138)
- Symptom: Inventory might not update. During upgrade, an exception is thrown in log, containing the following: "Caused by: org.hibernate.NonUniqueResultException: query did not return a unique result: 3".
  Resolution: Updated inventory processing logic to delete multiple instances of cache key entries with the same keystring.
  (20.2.1, DE423273)
- Symptom: The Jetty server might expose its details on error pages.
  Resolution: With this fix, the Jetty server does not expose details on error pages.
  (20.2.1, DE423311)
- Symptom: In a multiple data sources environment, any device changes from other data source could trigger the data aggregator to run the inventory discovery during the Performance Center and data aggregator sync process.
  Resolution: The sync process has been improved so that only if a new device IP is pushed down from Performance Center can the inventory discovery be run in the data aggregator.

(20.2.1, DE423494)

- Symptom: Devices with multiple poll rates for same metric family lose polling after data aggregator restart.
  Resolution: Fixed a flaw in the polling configuration recalculation logic that runs during data aggregator startup that causes a loss of polling.
  (20.2.1, DE423637, 20015980)
- Symptom: When re-connecting to a DX NetOps Virtual Network Assurance Gateway, the data aggregator deletes relationships that should still exist. This ultimately leads to group memberships disappearing in the DX NetOps Virtual Network Assurance Domains hierarchy in Performance Center.
  Resolution: Updated the data aggregator logic around determining which relations should be removed when re-connecting to a DX NetOps Virtual Network Assurance Gateway. The data aggregator no longer deletes relationships that should still exist.
  (20.2.1, DE423878)
- Symptom: Scheduled Reports List and Edit dialog intermittently show incorrect time for the schedule run, and are off by the number of hours between the user's time zone and the system time zone. If saved while in this state, the scheduled report now runs at the incorrectly offset time. If not saved, the scheduled email still runs at the originally defined time.
  Resolution: Certain dashboard views were modifying the thread's TimeZone to the user's TimeZone and not restoring it, which injected an incorrect time zone offset in the Scheduled Reports UI. This has been corrected.
  (20.2.1, DE423920)
- Symptom: Tenant themes might switch back to CA-Blue after changing them to another theme. This is because the data aggregator tenant entry in Performance Center data source tenant table still had CA-Blue.
  Resolution: Updated Data Aggregator pull sync code to send up tenant and ip domain changes sent during previous push sync, so data aggregator data source table entries are updated with new theme.
  (20.2.1, DE424092)
- Symptom: Performance Center takes a very long time possibly to consolidate SDWAN tunnels and application paths at large scale.
  Resolution: Rewrote SQL queries to consolidate SDWAN tunnels and application paths in an acceptable time frame.
  (20.2.1, DE424244)
- Symptom: User's default group is not accessible via REST.
  Resolution: Added defaultGroupId tag to user REST service. Added new REST endpoint to set default group: http://{PC}:8181/pc/center/webservice/users/userId/{User ID}/defaultGroup/{group ID}.
  (20.2.1, DE424967, 20028161,20030925)
- Symptom: When device's Reachability is not backed by the ICMP vendor cert and the device is down, the device's status in the context page are shown as Unknown, instead of Down.
  Resolution: Improved the polling process to better handle the SNMP rechability so that the device status can be shown correctly.
  (20.2.1, DE425145)
- Symptom: When doing a Data Aggregator synchronization, it might take a long time during PUSH group stage, when there are many site groups using business hours at very large pollable item scale. Checking kill -3 on the data aggregator process during PUSH shows getBusinessHoursID in one of the stacks and repeating after 5 mins and seeing the same stack on the same thread confirms.
  Resolution: Sped up the getBusinessHoursID search greatly by just looking at items with business hour tag on it, and not also checking all items with polllable tag.
  (20.2.1, DE425157)
- Symptom: When using the Performance Center REST service to clone a user who uses external (LDAP) authentication, the new user cannot log in.
  Resolution: For users with external authentication, modified the clone operation to set the correct authentication flags. For users with internal authentication, modified the clone operation to expire the password immediately; new users must change their password on login.
  (20.2.1, DE425283)
- Symptom: The parseSyncTimes.pl script provided with the Performance Center product does not include sync stage timings for data sources that use the HTTPS protocol.

Resolution: The parseSyncTimes.pl script has been modified to report sync stage timings for data sources that use the HTTPS protocol.
(20.2.1, DE425408)

- Symptom: Inventory discovery hangs when the Data Collector does not return a response to the Data Aggregator. This is due to the Data Collector throwing an ArrayIndexOutOfBoundsException when it receives invalid SNMP GetNext response, causing it to stop processing instead of returning a response.
  Resolution: Fixed the logic to ensure an SNMP Get next response contains the appropriate number of var binds based on the request. If this not the case, the Data Collector sends a failure response to the data aggregator.
  (20.2.1, DE425425)
- Symptom: Parsing the SSO token could result in retrieving wrong field for version.
  Resolution: Updated the SSO token parsing code to correctly retrieve version from the token.
  (20.2.1, DE425577)
- Symptom: If a sync push or pull phase for a data source fails due to an exception, there is no END PULL or END PUSH message logged for the sync cycle for that data source. This can make it difficult to understand when each sync phase completes when reviewing the logs.
  Resolution: The END PULL and END PUSH messages are logged even if there is a failure during the cycle. The error that caused the failure is logged shortly after then END PULL or END PUSH log.
  (20.2.1, DE425597)
- Symptom: DX NetOps Virtual Network Assurance and CAMM metrics for devices and their components are dropped after using the Stop and then Start Polling actions. .
  Resolution: The SDN and EMS Polling Configurations are now correctly recreated when the Start Polling action is sent to a device.
  (20.2.1, DE426041)
- Symptom: A small number of UI elements that need labels in order for screen readers to successfully explain the purpose of the element were missing associated label tags or were missing aria-label attributes.
  Resolution: All UI elements that need labels in order for screen readers to successfully explain the purpose of the element now have either explicit label tags associated with them or have aria-label attributes associated with them.
  (20.2.1, DE426089)
- Symptom: Disabled buttons are present in the keyboard tab order even though they cannot be operated and the focus indicator is barely visible.
  Resolution: Disabled buttons are no longer in the keyboard tab order.
  (20.2.1, DE426090)
- Symptom: Labels in some types of charts are drawn in a color that does not have sufficient contrast against the background color.
  Resolution: Labels in some types of charts are now drawn in a color that has sufficient contrast against the background color.
  (20.2.1, DE426091)
- Symptom: Open API does not allow to filter on null values, so it is not possible to create a filter expression find all for example device that have Description property value as null .
  Resolution: With this fix, OpenAPI now allows filtering on null value for String property types. Filtering on other property type values, such as Double and Integer, is not possible due to OData2 framework limitation. The issue is fixed in Odata4 framework.
  (20.2.1, DE426201)
- Symptom: The Data Collector does not send a poll request if it is determined to be "late". This can happen if the Data Collector system time moves ahead by at least 90 seconds (if Data Collector is polling items at 1 minute) or by at least 450 seconds (if Data Collector is polling items at 5 minutes).
  Resolution: The Data Aggregator generates events indicating that a Data Collector is having this issue, and also generate events on devices for which poll requests are dropped.
  (20.2.1, DE426204)
- Symptom: The Edit Metric Expression dialog did not display its contents correctly.
  Resolution: The Edit Metric Expression dialog now displays correctly.

(20.2.1, DE426590)

- Symptom: Time-selection combo-boxes did not work correctly with screen readers.
  Resolution: Time-selection combo-boxes work correctly with screen readers.
  (20.2.1, DE426904)
- Symptom: Fields associated with picking dates or times do not all have either label tags associated with them or aria-label attributes associated with them so that screen readers can identify the purpose of the field.
  Resolution: Fields associated with picking dates or times now have either label tags associated with them or aria-label attributes associated with them so that screen readers can identify the purpose of the field.
  (20.2.1, DE426917)
- Symptom: Description Field for Notifications in MySql is only 255 Char , So when the String to be added is more than 255 char it is throwing an persistence Exception.
  Resolution: Increased the Description Field for Notifications to 1024 Char.
  (20.2.1, DE427528, 20030542)
- Symptom: Inventory not detected by DX NetOps Spectrum in case of Aggregator scenario.
  Resolution: We Improved the logging to stop such issues in the future.
  (20.2.1, DE427652)
- Symptom: After a DX NetOps Virtual Network Assurance gateway has been removed from the Data Aggregator, temporary DX NetOps Virtual Network Assurance items and relationships are not cleaned up.
  Resolution: Update the delete DX NetOps Virtual Network Assurance Gateway logic to also clean up temporary SDN items.
  (20.2.1, DE427863)
- Symptom: When the Performance Center MySQL instance is installed on a host that is remote to the Performance Center services, firewall rules might close idle DB connections which leads the SSO process to exhaust its connection pool, and eventually hang while processing login requests. This problem should not be present if MySQL is co-located with the Performance Center services.
  Resolution: Fixed a defect related to persistent DB connections that "leaked" connections if the connection was closed by an external agent, such as firewalls do with idle connections. Reconfigured DB connection pools used by all Performance Center services to periodically validate idle connections to keep them from being closed by firewalls.
  (20.2.1, DE427880)
- Symptom: DX NetOps Virtual Network Assurance Notifications are dropped if the value of the string is more than the mysql database char size.
  Resolution: The Description field and the cause field are auto -truncated if the size of the chars is more than 1024 and 255 chars respectively.
  (20.2.1, DE428342)
- Symptom: The data sources with host name length greater than 50 fail in data source registration.
  Resolution: The max length of data source host name has been increased to 255.
  (20.2.1, DE428397)
- Symptom: Performance Center's console service is unable to start on a system that doesn't have wget installed.
  Resolution: In the Performance Center console start-up script, check if wget is installed and report an error to the user if it isn't.
  (20.2.1, DE428440)
- Symptom: The ipadress from Vcenter is sent with invalid spaces at the end of the ip address , which causing error on adding the device to the database.
  Resolution: The Ipaddress from Vcenter is trimmed before adding to the database.
  (20.2.1, DE428464)
- Symptom: Component name aliases in data aggregator were being synced to Performance Center, and if longer than 255 characters, throws SQL error about data truncation. This causes data aggregator PULL phase of synchronization to fail.
  Resolution: Updated data aggregator synchronization code to no longer send component name aliases to Performance Center. The data aggregator should never have been synced to Performance Center. Performance Center should only be pushing the name alias to data aggregator.

(20.2.1, DE428603)

- Symptom: Some separators (horizontal rules) in pages and in drop-down lists were in the tab order of the page (and had nothing associated with the that a screen reader could use). This issue manifested itself only in Firefox.
  Resolution: Separators in pages and drop-down lists are no longer tab stops at any time or in any browser.
  (20.2.1, DE428706)
- Symptom: Our enhanced keyboard navigation didn't have protection from overloading the tab contents loading queue. So, when "zipping" through the tabs with the keyboard, a user might see a dialog pop up with a `500 Server Error.` Hitting refresh in the browser cleared this error, but it was annoying.
  Resolution: We added protection so that navigating with the keyboard was protected, like navigating with the mouse.
  (20.2.1, DE429272)
- Symptom: Trend/Table views with Business Hours applied shows no shading in Trend for time ranges longer than 14 days.
  Resolution: The Trend in Trend/Table view has been corrected to request hourly data instead of daily for longer time ranges when Business Hours filtering is applied. This allows the shading to be rendered correctly.
  (20.2.1, DE429361)
- Symptom: After proxying to a user and loading user's default dashboard, if the user then brings up the group selection dialog, it hangs when trying to close the dialog.
  Resolution: Proxying takes you to the user's default dashboard. The url contains a "pg" parameter with no value. That was causing a problem when bringing up the group context selector dialog. We added protective code to handle this case properly.
  (20.2.1, DE429375, 20044304)
- Symptom: Global synchronization for devices could throw error about "Data too long for column 'IPs'" if there were too many devices with same common IP.
  Resolution: Removed the function that contained the offending SQL, as it was no longer needed.
  (20.2.1, DE429382)
- Symptom: When a Data Collector goes down and back up during a discovery, the discovery could get into a state of trying to be aborted by the hang detector and not fully get aborted and cleaned up. Resulting in the number of running discoveries to be clogged up by discoveries not running.
  Resolution: Added additional info/debug to discovery code around aborting discovery to help track these what is happening.
  (20.2.1, DE430011)
- Symptom: Items are missing from DX NetOps Virtual Network Assurance due to persistence failures while processing messages. .
  Resolution: Updated the DX NetOps Virtual Network Assurance persistence error handling to prevent failures from rolling back message processing. Additionally, updated the persistence logic to correctly persist objects that were previously leading to persistence failures.
  (20.2.1, DE430044)
- Symptom: Upgrading Performance Center after previously upgrading to a recent monthly update appears to be successful, but the `dbmigrate` log file in the `InstallLogs` directory shows errors similar to the following:

```
        Sep 04, 2019 11:20:11 AM com.ca.im.installanywhere.util.DbMigrateApp
  main SEVERE: java.lang.IllegalArgumentException: Expected scheme name at index
  0: :mysql\\://localhost\\:3306/netqosportal?characterEncoding\\=UTF-8&useSSL\
 \=true&verifyServerCertificate\\=false at java.net.URI.create(URI.java:852) at
  com.ca.im.installanywhere.util.DbMigrateApp.runMigrateMode(DbMigrateApp.java:286)
  at com.ca.im.installanywhere.util.DbMigrateApp.run(DbMigrateApp.java:164) at
  com.ca.im.installanywhere.util.DbMigrateApp.main(DbMigrateApp.java:54)
```

  This problem requires two Performance Center upgrades to be exhibited.
  Resolution: The Performance Center installer adds escape characters to the database URLs in the various properties files, which were not expected by the DB migration utilities, and were causing errors in parsing such URLs. The DB migration utilities have been updated to properly handle URLs if they have escape characters.

(20.2.1, DE430601)

- Symptom: The overall performance of Performance Center becomes very slow in a high scale environment when telemetry data is being collected.
  Resolution: Update the telemetry database queries to optimize performance.
  (20.2.1, DE430708)
- Symptom: Inventory discovery could hang and then abort when discovering a device that has class D or E IP addresses.
  Resolution: Enhanced the device discovery to properly handle IP class D and E IP addresses.
  (20.2.1, DE430883)
- Symptom: DX NetOps Virtual Network Assurance device items were not showing up within the DX NetOps Virtual Network Assurance group hierarchy.
  Resolution: Updated the Data Collector to correctly handle situations where DX NetOps Virtual Network Assurance sends more than one type of relation for an entity.
  (20.2.1, DE430894)
- Symptom: When threshold events are forwarded to DX NetOps Spectrum, the quotes around the item are not displayed correctly.
  Resolution: Updated threshold event message to use ASCII single quote and double-quotes instead which are displayed correctly.
  (20.2.1, DE431054)
- Symptom: Certain special characters within a custom database password were causing database setup to fail for Performance Center.
  Resolution: Updated the installer logic to better handle when special characters are included in the database password.
  (20.2.1, DE431277)
- Symptom: Reconciliation of entities between Performance Center and DX NetOps Spectrum is not happening in aggregator scenario of DX NetOps Virtual Network Assurance, due to mismatch in Entity IDs.
  Resolution: Introduced Sub Entity ID which is sent in aggregator scenario which DX NetOps Spectrum uses for reconciliation in case of aggregator scenario.
  (20.2.1, DE431335)
- Symptom: When trying to override the device type for a Meraki device, discovered via SNMP, it shows Other.
  Resolution: Updated the CiscoMerakiManagementMib vendor certification to pass the SysObjectID read from the device to the device type MVEL function. Now it can use the custom `DeviceTypes.xml` to override the type.
  (20.2.1, DE431612)
- Symptom: Inventory view for "Virtual Interfaces" was incorrectly labeled as an Event List view. The incorrectly label view confused user when configuring dashboard page.
  Resolution: Correct the name used for a Virtual Interfaces inventory view that was labeled as an Event List view. .
  (20.2.1, DE431708)
- Symptom: Fips is unable to be configured with an encrypted password in the `sso.properties` configuration file.
  Resolution: Update Fips configuration to be able to handle encrypted passwords.
  (20.2.1, DE431709)
- Symptom: Emails could not be sent securely if email server supported STARTTLS.
  Resolution: Updated Performance Center email properties to enable STARTTLS on all emails being sent. Removed Use SSL button, as Performance Center tries and sends all emails securely if email server supports STARTTLS.

  NOTE
  This now requires the email server certificate and any intermediate/root certificates to be imported into the `/opt/CA/jre/lib/security/cacerts` directory, so the email server certificate is trusted on connection. For more information, see Set the Email Server.

  (20.2.1, DE432418)
- Symptom: Configuring custom Trend Chart to generate comma-separated, CSV, report non-baseline metrics were missing when combined with baseline metrics as primary sort column.

Resolution: Addressed issue when generating a comma-separated, CSV, report was missing non-baseline metrics when combined with baseline metric as primary sort column on custom Trend Chart views. .
(20.2.1, DE432700)

- Symptom: The adminStatus and operationalStatus of the OpenDayLight controller in DX NetOps Virtual Network Assurance were not captured correctly.
  Resolution: The adminStatus and operationalStatus of the OpenDayLight controller in DX NetOps Virtual Network Assurance are now captured correctly.
  (20.2.1, DE432780)
- Symptom: The time displayed in the time picker
  (upper right corner of dashboard) shows incorrect/next year for the last week of the year. December 30, 2019 Displays as December 30, 2020.
  Resolution: Modified the date formatter to use yyyy instead of YYYY which formats the last week of the year correctly. The time displayed in the time picker now shows the correct year for the last week of the year, for example, December 30, 2019.
  (20.2.1, DE433614, 20197781)
- Symptom: Vendor cert "Cisco IPSLA Ethernet DMM and IP Statistics" and "Cisco IPSLA Ethernet SLM (Synthetic Loss Measurement) Statistics" were coupled with vendor cert "Cisco IPSLA Ethernet Jitter Precision Statistics". If "Cisco IPSLA Ethernet Jitter Precision Statistics" is not supported, the other two vendor certs are not discovered as supported even though they were configured on the devices.
  Resolution: Decoupled the three vendor certs so that they can be discovered properly and independently. .
  (20.2.1, DE433784)
- Symptom: Metric family "Response Path Test Ethernet Jitter" missed two metrics: FrameLossRatioSrcDest and FrameLossRatioDestSrc.
  Resolution: Added two metrics FrameLossRatioSrcDest and FrameLossRatioDestSrc to metric family "Response Path Test Ethernet Jitter".
  (20.2.1, DE433788)
- Symptom: When installing the consul service for Fault Tolerance in the proxy and Data Aggregator, the installer isn't asking which IP address to bind to, if there are multiple IPs on the machine.
  Resolution: Updated the proxy and data aggregator installers to prompt for which IP address to bind consul service to, if there are multiple IPs on the machine.
  (20.2.1, DE434128)
- Symptom: A recurring message of dropped relations appears in the data aggregator whenever it receives an inventory update from the DX NetOps Virtual Network Assurance.
  Resolution: Change the logging level of the message to debug so we aren't always seeing the message, just for debugging.
  (20.2.1, DE434146)
- Symptom: When DX NetOps Spectrum pulls events from Event Manager, you could see duplicate events. This is due to the item being contributed by multiple data sources, and not using DISTINCT in EM DB queries.
  Resolution: Updated the EM DB query to use DISTINCT when getting events to send to DX NetOps Spectrum.
  (20.2.1, DE434444)
- Symptom: The data aggregator might fail to start due to an ArrayIndexOutOfBoundsException when initializing the RelationshipImporter. This is due to inconsistent values in the attributes used to persist previously imported relationships. The inconsistency could have been caused by a bug in the item repository persistence layer where attribute writes that should have been committed in a single transaction were committed individually.
  Resolution: Fixed a bug in the item repository persistence layer's transaction management. Fixed the relationship importer's initialization process to re-initialize the history of previously imported relationships if the history attributes are inconsistent. If the attributes are found to be inconsistent, an error is logged and any automatically generated relationships that had previously been removed are returned and must be removed again via the UI.
  (20.2.1, DE434597)
- Symptom: Items are missing from DX NetOps Virtual Network Assurance due to persistence failures while processing messages. .

Resolution: Updated the DX NetOps Virtual Network Assurance persistence error handling to prevent failures from rolling back message processing. Additionally, updated the persistence logic to correctly persist additional objects that were previously leading to persistence failures.
(20.2.1, DE435483, 20099081,20093248)

- Symptom: Percentage of Actively Memory used was not calculated for ESX hosts.
  Resolution: Updated the vendor cert to support the percentage of Active memory used.
  (20.2.1, DE435721)
- Symptom: After upgrade to 3.7.5, the Dashboards menu might contain duplicate entries. Upgrade was calling create_dashboards, when it should only be calling create_new_dashboards.
  Resolution: Updated installer to not call create_dashboards on upgrade.
  (20.2.1, DE435768)
- Symptom: Users are unable to access Performance Center from the DX SaaS tile page.
  Resolution: Users can now access Performance Center after successfully logging into DX SaaS.
  (20.2.1, DE435872)
- Symptom: Group Scorecards when combining total rate and percentiles metrics throws query processing error.
  Resolution: Addressed error when combining total rate and percentile metrics on the Group Scorecards view.
  (20.2.1, DE435901)
- Symptom: When setting the NetOPs group context to be a spectrum global collection, you only see device level alarms, and not interface level alarms. One Click shows both.
  Resolution: Modified the way that the global collection filter is sent to DX NetOps Spectrum, so that the alarm view now shows device and interface level alarms when the alarm view context is set to a synchronized spectrum global collection.
  (20.2.1, DE436170)
- Symptom: If you select an Interface in Inventory, and then select the IP Performance Tab, and then zoom into one of the charts. After clicking Apply To Dashboard for that chart, the time does not change in the Time Display for the dashboard.
  Resolution: The dashboard's time range field was updated to reflect the "Apply to Zoom" feature.
  (20.2.1, DE436188)
- Symptom: Dateparser was not handling few cases of date format during alarm processing in Versa.
  Resolution: Added the possible date formats.
  (20.2.1, DE436625)
- Symptom: Performance poll was running sequentially for various device types , which is consuming time thereby missing every other poll.
  Resolution: Added Multi Threading for processing performance poll.
  (20.2.1, DE436698)
- Symptom: There is a spike while calculating Delta for DX NetOps Virtual Network Assurance metrics on the reports when the engine or DX NetOps Virtual Network Assurance is down for a particular time.
  Resolution: Data Collector now discards first poll after the DX NetOps Virtual Network Assurance or Engine is down, if the value is more than 2 polls.
  (20.2.1, DE436702)
- Symptom: NetOps user interface experiencing performance issue when attempting to render Trend Chart with Events reporting when greater than monthly period.
  Resolution: Added safeguard to limit the time range to 31 days when attempting to render Trend Chart with Events reporting to address performance impact./ .
  (20.2.1, DE436873)
- Symptom: Unable to Print "SDN/NFV vSwitch Performance Overview" page to PDF, yields "Property missing: Title" exception in log.
  Resolution: This could occur on systems that were upgraded from a pre-3.0.0 release due to a view removed from this page in 3.0.0. The properties of the deprecated view are now restored and the page can now be printed or edited without "Property Missing" exception.

(20.2.1, DE436879)

- Symptom: When an error happens in the middle of a Full Pull data source stage, it can result in all items not sent by the data source to be removed from the Performance Center inventory. This could result in new item ids being assigned to them if they only come from a single data source like spectrum global collections.
  Resolution: Updated the Performance Center Full Pull synchronization logic to only mark items, not sent by the data source, after the stage is complete. For example, this should stop spectrum global collections from getting assigned a new Performance Center item id, if there is an error during Full pull for groups.
  (20.2.1, DE437034, 01142425)
- Symptom: After upgrade of a very high scale system, Performance Center user REST services are significantly slower.
  Resolution: Optimized telemetry queries.
  (20.2.1, DE437335, 20103983)
- Symptom: OK and Cancel buttons on On Demand's Add/Remove Item/Groups dialogs were missing the text (OK, Cancel). They were blank buttons. Also, Add/Remove Group for the On Demand from Search Results emitted a 500 Server error.
  Resolution: Modified the properties files to reflect new page (18 for nested dialog). Also changed add/remove groups to nested dialog.
  (20.2.1, DE437351)
- Symptom: Engine which is deleted an not cleaned up properly is remaining in the collector folder. On Wildfly restart, DX NetOps Virtual Network Assurance is considering it a running engine and trying to start the same.
  Resolution: On Restart of DX NetOps Virtual Network Assurance, now it checks if the engines exist in the DB. All engines which don't exist are deleted.
  (20.2.1, DE437603)
- Symptom: When data aggregator thought Data Collectors were disconnected, it aborts all currently running discoveries. Due to a un-handled exception in the aborting process, the counter of the running discoveries was not decreased. When the number of running discoveries reached to the maximum number of concurrent discoveries, all discoveries are stuck on Performance Center.
  Resolution: Improved the discovery abort process and handled all the exceptions so that the discovery counter can work properly.
  (20.2.1, DE437748)
- Symptom: With On-Demand report view option Chart per Item with Multiple Metrics when reporting at the component level item titles on chart can mismatched with graph data.
  Resolution: Addressed titles on chart mismatched with graph data with On-Demand report view option Chart per Item with Multiple Metrics when reporting at the component level.
  (20.2.1, DE437961, 20108850)
- Symptom: Data Collector could fail to start due to a NULL pointer exception when it tries to sync items from the Data Aggregator.
  Resolution: Improved the sync process between data aggregator and Data Collector to handle all possible exceptions properly.
  (20.2.1, DE438315)
- Symptom: Some fields in out product weren't adequate protection against HTML/JavaScript injection. .
  Resolution: We added the injection protection to all the identified fields.
  (20.2.1, DE438451)
- Symptom: One of the services displays a stack trace to the client when an exception was thrown. This potentially gives and attacker information about the underlying code.
  Resolution: The stacktrace is now logged and sent back a standard server error code.
  (20.2.1, DE438461)
- Symptom: When DX NetOps Virtual Network Assurance receives a time filter larger than 24hrs, it throws an error, which results in client not able to get further updates.
  Resolution: DX NetOps Virtual Network Assurance now sends a FULL update on receiving a time filter larger than 24hrs, which helps auto renew connections with the client.

(20.2.1, DE438556)

- Symptom: In a system with DX NetOps Virtual Network Assurance installed, the data aggregator/Performance Center sync process can be very expensive. It checks the item creation time on all items in the system to find out the newly created DX NetOps Virtual Network Assurance domain group items.
  Resolution: Improved performance of DA/Performance Center sync process by dramatically narrowing down the search scope.
  (20.2.1, DE438808)
- Symptom: Tunnels from the router(customer gateay) which was discovered through snmp are missing./Its not the issue of snmp reconciliation.
  Resolution: There was an aws technology specific code written in data aggregator based on the vendor attribute, due to which further code that builds tunnels getting restricted. Upon discussion with Abe/Li this code cleaned-up, that fixed the issue.
  (20.2.1, DE438825)
- Symptom: If any ec2 is in terminated state in AWS console and its ip's are deleted and empty/null ip not handled, due to which entire inventory failed.
  Resolution: Terminated ec2's are handled so that upon null/empty ip, the entire inventory poll shall not fail.
  (20.2.1, DE439129)
- Symptom: When rendering shade area on trend chart related to standard deviation the processing performance impacted memory resource usage.
  Resolution: Address the processing performance impact when rendering shade area on trend chart related to standard deviation.
  (20.2.1, DE439284)
- Symptom: 1. The data aggregator falls behind in processing DX NetOps Virtual Network Assurance changes. This results in models missing from existing DX NetOps Virtual Network Assurance Domains or else DX NetOps Virtual Network Assurance Domains not being created after configuring an additional SDN Gateway.2. All of the Groups under a DX NetOps Virtual Network Assurance Domain disappear after toggling the Administration Status of the applicable SDN Gateway.
  Resolution: Enhancements were made to the DX NetOps Virtual Network Assurance integration to allow inventory updates to be processed much faster. These enhancements also added more robust logic to avoid exceptions previously seen during response processing and also to prevent Items and Relationships from incorrectly being deleted when toggling the Administration Status of a DX NetOps Virtual Network Assurance.
  (20.2.1, DE439424)
- Symptom: Distributed Item Repository communication between Data Aggregator and all Data Collectors can be disrupted if one Data Collector gets into a bad state. An example is seen when a Data Collector broker stops consuming messages from the DA, causing a back up in its DIM.request queue. Once the data aggregator broker detects this queue is 100% full, all other data aggregator/Data Collector communication is disrupted.
  Resolution: Reworked data aggregator side Distributed Item Repository processing to isolate workloads per Data Collector so that when one Data Collector gets into a bad state, communication is not disrupted for all Data Collectors.
  (20.2.1, DE439788)
- Symptom: Time bar view does not sort as expected when initially rendered on the page, required column selection to sort correctly.
  Resolution: Addressed issue where time bar view does not sort as expected when initially rendered on the page, required column selection to sort correctly.
  (20.2.1, DE440194)
- Symptom: Running the `testssl.sh` script against Performance Center shows vulnerabilities for "Secure Client-Initiated Renegotiation", "LOGJAM
  (CVE-2015-4000)", and "LUCKY13
  (CVE-2013-0169)".
  Resolution: Vulnerabilities for "Secure Client-Initiated Renegotiation", "LOGJAM
  (CVE-2015-4000)", and "LUCKY13
  (CVE-2013-0169)" have been resolved in Performance Center, and are no longer flagged by the `testssl.sh` script.

(20.2.1, DE440319)

- Symptom: The Data Aggregator misinterprets an exception from the database as an outage and shuts down.
  Resolution: Updated the regular expression for expected exceptions from the database that should not be interpreted as an outage.
  (20.2.1, DE440348)
- Symptom: Report Analyzer view, Interfaces over Threshold, renders missing image icon on interface name column with Firefox.
  Resolution: Addressed the missing image icon with Firefox appearing on interface name column when rendering Report Analyzer view, Interfaces over Threshold.
  (20.2.1, DE440550)
- Symptom: Cannot delete group using Performance Center REST service, when the user has "My Assigned Groups".
  Resolution: Fixed permission checking code in Performance Center REST API.
  (20.2.1, DE440557)
- Symptom: When upgrading Performance Center, the service (Performance Center, DM, EM, sso) properties files, that store settings, loses any user added entries.
  Resolution: Modified install to preserve any user added settings in the service properties files.
  (20.2.1, DE440676)
- Symptom: Some of the metrics were missing and for those, broker code throwing Null Pointer exception.
  Resolution: Null check added for the metrics, so that it avoids the null pointer exceptions.
  (20.2.1, DE441345)
- Symptom: CSV report export only includes first page for legacy systems that upgraded to Service Pack 3.7.4 or above.
  Resolution: Addressed upgrade Service Pack 3.7.4 or above issue that CSV report export only includes first page.
  (20.2.1, DE441538)
- Symptom: When Domain is a selected inventory column rendering No Data when applying filter to table view search.
  Resolution: Addressed issue when applying filtered search to table with Domain inventory column that sometimes renders No Data to Display.
  (20.2.1, DE441661)
- Symptom: After configuring a Scorecard table that contains percentile metric; when removing percentile metric from list metrics with hierarchy option still renders percentile entry.
  Resolution: Addressed issue when removing percentile metric from Scorecard Table with hierarchy option still renders percentile entry in view.
  (20.2.1, DE441793)
- Symptom: Certain DX NetOps Virtual Network Assurance entities are deleted and recreated every poll cycle even though there are no changes occurring in the environment.
  Resolution: The Persistence logic in DX NetOps Virtual Network Assurance has been updated. With the new implementation, if keys are to be removed from the ID service, the key is checked to make sure it associated with the entity's ID. If it is associated with a different ID, a warning is printed and it is no longer removed from the ID service.
  (20.2.1, DE442571)
- Symptom: The global search can hang on a search string that contains '=' character.
  Resolution: With this fix, the global search works, however if the search string contains '=' character, add a new '=' character to the beginning of the search string.
  (20.2.1, DE442778, 20140853)
- Symptom: SslConfig on Performance Center and `sslConfig.sh` on data aggregator uses SHA1WithRSA when generating private key for HTTPS use.
  Resolution: Updated both tools to use SHA256WithRSA when generating private key for HTTPS.
  (20.2.1, DE442855)
- Symptom: When Spectrum system time is behind Event Manager system time, events might not be getting created in DX NetOps Spectrum when pulled from Event Manager.
  Resolution: Updated Event Manager to only handle when current time on Event Manager is older than the end timestamp being requested by DX NetOps Spectrum. It time shifts the start/end request timestamps to EM local

timestamp. Event Manager no longer time shifts forward Spectrum start/end request timestamps, if older than Event Manager local timestamp.
(20.2.1, DE443851)

- Symptom: When business hour filter is applied to context page incorrectly shown on view subtitle for data source not related to Data Aggregator.
  Resolution: Addressed view subtitle showing business hour filter on context page for data sources that are not related to Data Aggregator.
  (20.2.1, DE444080)
- Symptom: Generate URL not always initially rendering correctly when when view container is enabled on URL Generate dialog.
  Resolution: Addressed problem when generate URL that view is collapsed if view container is enabled on URL Generate dialog.
  (20.2.1, DE444200)
- Symptom: If the user's time zone causes "last 8 hours" to shift into the prior day, then the dashboard's time display incorrectly says Today instead of yesterday's date.
  Resolution: With this fix, the timezone is now included when checking to see if the date is today's date.
  (20.2.1, DE444215)
- Symptom: Calendar Heat charts were not accessible.
  Resolution: Calendar Heat charts are now fully accessible and meet Section 508 accessibility requirements.
  (20.2.1, DE444413)
- Symptom: Reports using custom group of SDWAN tunnels shows no data. Custom groups of devices shows data for SDWAN tunnels they are a participant in.
  Resolution: Updated Data Aggregator SQL view to check if the SDWAN tunnel is in the group, in addition to either device of the tunnel.
  (20.2.1, DE444464)
- Symptom: Vulnerable version of jQuery.
  Resolution: Updated to latest version of jQuery.
  (20.2.1, DE444735)
- Symptom: When Performance Center restarts, if MySql does not start in 6 seconds, then the Performance Center services fails to start.
  Resolution: Fixed comparison in MySql check script to do integer comparison, not string compare that resulted in the check exiting earlier than expected. Also increased check to 120 seconds.
  (20.2.1, DE445174)
- Symptom: NFA Hierarchy sub-table for By Host and By Protocol intermittently does not display the interface data, as item are selected in top table the lower table is still blank.
  Resolution: Addressed intermittent issue when selecting item in top table the lower table does not render interface data with NFA Hierarchy sub-table for By Host and By Protocol view.
  (20.2.1, DE446176)
- Symptom: Vcenter is sending IP address in invalid format, which is causing Persistence failures.
  Resolution: Added check for Invalid IP addresses coming from the Vcenter. The plugin lookups for IP address for the VM, if the IP address is invalid.
  (20.2.1, DE446231)
- Symptom: During global synchronization stage on Performance Center, a SQL exception might be thrown during tenant or IP domain stage about truncating LocalID in ds_items table. Large model handles from DX NetOps Spectrum were causing the SQL exception.
  Resolution: Updated the SQL call to do string comparison instead of numeric. The LocalID column is a string and should've been comparing as a string but was using numeric comparison that could result in truncation issues.
  (20.2.1, DE447006)
- Symptom: After configuring Scorecard Trend view with baseline metric renders 'No Data to Display'.
  Resolution: Addressed issue when selecting baseline metric with Scorecard Trend view renders 'No Data to Display'.

(20.2.1, DE447990)

- Symptom: When selecting SD-Wan Tunnel/App Path metrics By Component level with the Scorecard Trend might be missing component items.
  Resolution: When selecting SD-Wan Tunnel/App Path metrics By Component level with the Scorecard Trend always render component items.
  (20.2.1, DE448032)
- Symptom: NFA Stacked Protocol Trend views rendered No Data to Display when time range is greater than 2 hours.
  Resolution: Addressed No Data to Display rendered on NFA Stacked Protocol Trend views when time range is greater than 2 hours.
  (20.2.1, DE448349, 31842884,31828116)
- Symptom: New NFA views on interface context page has default row value of 1000 that creates long running view processing.
  Resolution: New NFA views on interface context page modified row items in view selection and default row value to avoid long running view processing, altered views include; IP Performance Protocol- Protocol List, IP Performance ToS - ToS List, IP Performance Host - Hosts List, IP Performance Conversation - Conversation List.
  (20.2.1, DE449080)
- Symptom: Installers complain about SLES 12 SP4+ not passing kernel check.
  Resolution: Updated installers to pass kernel check with SLES 12 SP4, and SP5.
  (20.2.1, DE449181, 20310176)
- Symptom: When doing a new data aggregator fault tolerant silent install, the data aggregator data directory uses default instead of the `DA_DATA_HOME` value in properties file provided.
  Resolution: Updated silent installer logic to not set the `DA_DATA_HOME` to a default if already set via properties file.
  (20.2.1, DE449615)
- Symptom: DX NetOps Virtual Network Assurance was not sending the correct out of band management IP address for some Versa devices.
  Resolution: A new configuration has been added to DX NetOps Virtual Network Assurance that enables finding and sending the correct out of band management IP address for Versa devices.
  (20.2.1, DE450038)
- Symptom: When a device has more than 150 interfaces the Alarms View on Alarms tab of device context page fails with error, "An unexpected error has occurred".
  Resolution: Addressed issue that Alarms View on Alarms tab of device context page fails with error when a device has more than 150 interfaces.
  (20.2.1, DE450059)
- Symptom: A cross-site scripting vulnerability exists for a url passing javascript to the "pg=" parameter,
  like this example which raises an alert dialog: https://your_pc_host:8182/pc/desktop/page?timeRange=0&endTime=2020-01-28+14%3A25&startTime=2020-01-28+13%3A25&mn=5&pg='%2Balert(15)%2B'&parentid=13
  Resolution: The vulnerability for the "pg=" parameter has been resolved - the alert in the example url no longer executes./ .
  (20.2.1, DE451032)
- Symptom: Plugin logger exposing passwords in plaintext when category OC_ACQUISITION is set to level DEBUG. Sample message: oc.log:2020-03-11 13:53:43,328 DEBUG (EE-ManagedThreadFactory-default-Thread-3) Viptela_17664d4c-c80b-44b1-8722-aa768696e4e9=Inventory Poll [OC_ACQUISITION] TimReflectionHelper 213 inject vman#2837 to method setPassword.
  Resolution: Added logic to the OC_ACQUISITION plugin logger to suppress debugging of password values.
  (20.2.1, DE451580)
- Symptom: When SNMP MIB table read encountered PARTIAL_FAILURE error during a metric family change detection process, it could create some incomplete component items. Next time when the MIB table is read successfully, the incomplete items are marked as Not Present. If a device's SNMP agent frequently returns PARTIAL_FAILURE for its MIB table reads, a lot of Not Present components is created.
  Resolution: Improved the metric family discovery not to create any component items when a SNMP PARTIAL_FAILURE is encountered. .

(20.2.1, DE451685)

- Symptom: When sending email via STARTTLS, Performance Center only allows TLSv1.0. If email server is TLSv1.1 or TLSv1.2, the email server rejects the email connection.
  Resolution: Updated Performance Center to support TLSv1.2, TLSv1.1 and TLSv1.0 when email server supports STARTTLS.
  (20.2.1, DE451724)
- Symptom: When LogoutService is called during SAML logout, it throws an exception "net.shibboleth.utilities.java.support.component.UninitializedComponentException: Component has not yet been initialized and cannot be used." while trying to decode the HTTP request.
  Resolution: Resolved the exception by initializing the decoder code before using it. This exception was hit due to admins trying to not have Performance Center logout of SAML server when logging out of Performance Center. So this fix also includes code to allow admins to not provide a SingleLogoutService in the metadata XML from the IDP. When Performance Center/sso sees there is no SingleLogoutService, it logs the user out of Performance Center. The user can still remain logged into SAML.
  (20.2.1, DE452302)
- Symptom: ACI filter Configuration is reset to default after the upgrade and all customer has to re-configure the same .
  Resolution: It is a code fix to take backup of existing filter configurations and retain the same after upgrading DX NetOps Virtual Network Assurance.
  (20.2.1, DE452507)
- Symptom: Daily scheduled email jobs are sent multiple times during Spring DST transition when email TZ is UTC and scheduled time is between 00:00 - 01:00.
  Resolution: Some combinations of Performance Center host TZ
  (a DST TZ like ESTEDT) and scheduled email TZ
  (non-DST TZ like UTC), when scheduled time is between midnight and 1AM were leading to incorrect calculation of next run time, causing run time to be repeated until after 1AM. The date math has been corrected to better account for the email timezone when calculating next run time.
  (20.2.1, DE453071)
- Symptom: The DX NetOps Virtual Network Assurance Meraki plugin was fetching the client performance data for only a few of the access points.
  Resolution: The DX NetOps Virtual Network Assurance Meraki plugin now fetches the client performance data for all the access points.
  (20.2.1, DE453478)
- Symptom: The DX NetOps Virtual Network Assurance Meraki plugin was not discovering any access point without a lan ip address.
  Resolution: The DX NetOps Virtual Network Assurance Meraki plugin now discovers access points without a lan ip address.
  (20.2.1, DE453486)
- Symptom: If other (1) and softwareLoopback (24) are re-enabled in Interface or High Speed Interface vendor certifications, users cannot select them in monitoring profile filters for Interface metric family under Type.
  Resolution: Updated monitoring profiles Interface metric family filter support for Type to show other and softwareLoopback values, and treat them as supported.
  (20.2.1, DE453520)
- Symptom: Custom Gauge View automatically scales the gauge needle when using the fixed end point combined with percent option.
  Resolution: Custom Gauge View allows for option whether to scale the gauge needle when using the fixed end point combined with percent option.
  (20.2.1, DE453522)
- Symptom: Interfaces were not processed when an HTTP Request fails ,which is creating a null or empty file.
  Resolution: Added null check for content in the files when HttpRequestFailure occurs.
  (20.2.1, DE454311)
- Symptom: Suborgs were not processed earlier in versa plugin.
  Resolution: Added support for processing SubOrgs.

(20.2.1, DE454336, 31812847)

- Symptom: DX NetOps Virtual Network Assurance installer is allowing duplicate domain names across multiple DX NetOps Virtual Network Assurances.
  Resolution: Updated installer banner text and DX NetOps Virtual Network Assurance Swagger update domain with a caution message "Domain name should be unique across VNAs".
  (20.2.1, DE455141)
- Symptom: After upgrading to 3.7.10, the following symptoms were seen on certain data aggregators that were monitoring SDWAN environments with DX NetOps Virtual Network Assurance: 1. High CPU Usage after upgrade caused Performance Center to lose contact with the data aggregator (see: \u003Ca class="cke-link-popover-active" href="https://knowledge.broadcom.com/external/article?articleId=188059"https://knowledge.broadcom.com/external/article?articleId=188059\u003C/a); 2. Changes in the monitored DX NetOps Virtual Network Assurance environment were not being reflected in Performance Center. These include, but might not be limited to: Sites, Tunnels and SLAPaths; 3. Prior to and after upgrading to 3.7.10 "duplicate" / "stale" items and SDN Domains were seen in Performance Center under the SDN Domains group.
  Resolution: The data aggregator's processing of DX NetOps Virtual Network Assurance data has been updated to be more efficient during the processing of data from SDWAN environments. The changes include: 1. A reduction in the upper limit of the number threads available for SDN processing to 1/3 of the CPUs on the Data Aggregator; 2. General improvements to the DX NetOps Virtual Network Assurance processing to improve the efficiency of processing DX NetOps Virtual Network Assurance updates from SDWAN environments; 3. Additional protections have been added to the DX NetOps Virtual Network Assurance processing to resolve missing items seen after upgrading; 4. SDN processing in the data aggregator has been updated to prevent Items from being created for SDN Gateways that had already been deleted from the DA.
  (20.2.1, DE455285)
- Symptom: In the CSV output OpenAPI might not correctly match expand metric family data with its corresponding configuration entity for example a query like the following `devices?$expand=interfaces,portmfs` might return metric data in the line for a different interface.
  Resolution: With this fix, OpenAPI now matches all expand data correctly.
  (20.2.1, DE455825)
- Symptom: When using DX NetOps Virtual Network Assurance as an aggregator inventory items/keys are removed after upgrade. This is especially applicable to DX NetOps Spectrum. After upgrade, it was unable to reconcile the changes which has the effect of the system creating duplicate items.
  Resolution: Migration script modified to only modify ID cache if DX NetOps Virtual Network Assurance is not operating in "aggregator" mode.
  (20.2.1, DE456076)
- Symptom: For consolidated devices, Performance Center maintained IP address of the device that was sync'ed up first (Data aggregator device IP was not given priority over Spectrum).
  Resolution: Updated Global sync to give data aggregator device IP priority over Spectrum device IP during device consolidation based on primary-secondary IP matching.
  (20.2.1, DE456272)
- Symptom: Reporting views using business hours, that have multiple timezones to consider, can take minutes to run the query in the database. This is partly due to the amount of memory the database reserves to run the query, which is based on 65k characters for timezone values.
  Resolution: Updated the sql view, for comparing timezone, to select only 255 characters from the timezone attribute. This results in far less memory being needed to run the query. It could result in steps of the query now being multi-threaded, where before it couldn't due to memory requirements. This could result in some business hour queries running much faster than before.
  (20.2.1, DE456460)
- Symptom: When TransientDBConnection logging is set to debug, SQL statements with passwords are logged.
  Resolution: Update logger to sift out SQL with passwords.
  (20.2.1, DE456484)
- Symptom: Web service calls to DX NetOps Spectrum for Alarm Console or the subscription alarm service might timeout after 100 seconds. This usually is due to DX NetOps Spectrum's response time to the request being made.

Resolution: Updated the timeout to 120 secs, but also made it configurable via the netqosportal.general table or Performance Center admin debug global attributes page. To increase the Alarm Console timeout, run: REPLACE INTO netqosportal.general VALUES('AlarmView_WebService_Timeout', '<timeout in seconds>');
To increase the Spectrum alarm status subscription timeout, run: REPLACE INTO netqosportal.general VALUES('SpectrumStatus_WebService_Timeout', '<timeout in seconds>');.
(20.2.1, DE456697, 20294595)

- Symptom: Performance Center global synchronization fails if duplicate tunnels and/or SLA paths are synchronized from any data source. Error similar to the following is found in the `DMService.log` file upon failure: "MySQLIntegrityConstraintViolationException: Duplicate entry '5868174-14' for key 'PRIMARY".
  Resolution: Updated the global sync SQL calls to not error when duplicate tunnels/SLA paths are sent from data source(s).
  (20.2.1, DE456711)
- Symptom: Data Aggregator operations that require internal attribute reads such as data aggregator REST calls, DX NetOps Virtual Network Assurance inventory processing, etc are subject to slowness at high concurrency due to excessive use of java locking objects.
  Resolution: Refactored Item Repository read functionality to more efficiently use java locking objects.
  (20.2.1, DE456931)
- Symptom: On Deletion of Engine, a few Entities are not deleted.
  Resolution: The issue is caused due to inconsistent Hashcode on the Properties. Updated the hashcode.
  (20.2.1, DE458021)
- Symptom: After applying edit changes context page with F5 device there is an error when attempting to save context tab, requiring name entry. Workaround required add entry to context tab prior to being able to save modifications.
  Resolution: Address error that required F5 context tab manually add title entry to context tab prior to being to save modifications on context page.
  (20.2.1, DE458272)
- Symptom: Various security CVEs reported against the version of Consul used by Performance Management.
  Resolution: Upgraded the version of Consul to 1.7.2. For the new version of Consul to be enabled after Performance Center is upgraded, the user must run the following commands. If these commands are skipped, the old version of Consul remains running after the install.
  Run the following commands:
  a. `service capc-consul stop`
  b. `rm -rf <CA_Performance_Center_Directory>/consul/data/*` **Example:** `rm -rf /opt/CA/PerformanceCenter/consul/data/* )`
  c. `service capc-consul start`
  (20.2.1, DE458789)
- Symptom: The DX NetOps Virtual Network Assurance Viptela plugin is sending data with many disparate sample time values, resulting in many timestamps with few items in the sdn_tunnel_rate table in the DR. This is inefficient for threshold evaluation because each timestamp results in a threshold evaluation query in the DR. This causes long running threshold evaluation times for the NormalizedSDNTunnelInfo metric family and causes the System Health to indicate a degraded state for Data Aggregator Threshold evaluation.
  Resolution: Provided an option in the Data Collector to modify sample times for each incoming DX NetOps Virtual Network Assurance metric so that they appear on a boundary (for example, samples collection at 1:00, 1:02, 1:03, et al) has a sample time of 1:00. This greatly reduces the number of timestamps that need to be evaluated for threshold evaluation, thus keeping the evaluation time for the NormalizedSDNTunnelInfo metric family to comparable values as other metric families.
  (20.2.1, DE459147)
- Symptom: After an upgrade of Performance Center, entries for service properties files add backslash before colons and equals, causing some of the scripts to not run successfully.
  Resolution: Updated the upgrade custom code to not add backslashs before colon and equals characters in service properties files.

(20.2.1, DE459183)

- Symptom: The ACI Console is very unresponsive to mouse clicks in environments that contain a large number of groups.
  Resolution: The ACI Console was updated to use more efficient OpenAPI queries for the performance metrics displayed in the dashboard.
  (20.2.1, DE459510)
- Symptom: If a Calix chassis has multiple blades that shares the same IP address of the chassis, only one of them can be discovered properly.
  Resolution: Improved the Calix blade discovery to properly handle the shared IP on the blades.
  (20.2.1, DE459921)
- Symptom: When not providing a SsoProductCode to the sign-out.jsp, a NullPointerException are shown.
  Resolution: Updated the logout code to return an informative error message, if no SsoProduceCode is provided.
  (20.2.1, DE460006)
- Symptom: Alarms are generated with unknown severity.
  Resolution: Made changes in AlarmNotifications to not change the severity to unknown when the alarms are cleared.
  (20.2.1, DE460254)
- Symptom: When using a combo-box, the pop-up menu associated with the control always "opens downwards". If the menu is positioned near the bottom of the browser window, it is clipped such that some or all of the menu is not available.
  Resolution: When using a combo-box, the pop-up menu associated with the control now opens "upward" if it is clipped by the bottom of the browser window.
  (20.2.1, DE460315)
- Symptom: When global synchronization runs, it might throw a SQL exception
  like: com.mysql.jdbc.MysqlDataTruncation: Data truncation: Data too long for column 'SourceIds' at row 672.
  Resolution: Fixed the SQL statement so it won't throw a data truncation error causing global sync to fail.
  (20.2.1, DE460948)
- Symptom: VM and Host metrics were polled on the wrong values on the vsphere client.
  Resolution: VM and Host Metrics are polled now on the correct values from the Vsphere client.
  (20.2.1, DE461311)
- Symptom: The value of Added By column of group items created by a rule could be overwritten if a new item is added to the group manually.
  Resolution: With this fix, a new item added to a group manually does not override Added By column value of the items created by a rule.
  (20.2.1, DE463375)
- Symptom: Some telemetry SQL queries in Performance Center could still run a long time at scale, due to not using available indexes. They could interfere with queries run for UI tasks, making the UI unresponsive.
  Resolution: Updated the remaining telemetry SQL queries that needed additional comparisons to cause them to use indexes to speed up queries.
  (20.2.1, DE464384)
- Symptom: The product key used for on-prem telemetry is invalid.
  Resolution: Update the product key for on-prem telemetry to the correct value.
  (20.2.1, DE464806)
- Symptom: odata query might not return device information in expand when it starts from metric family/component, for example portmfs?$expand=device.
  Resolution: With this fix, odata query now returns device information in expand when it starts from metric family/component, for example portmfs?$expand=device.
  (20.2.1, DE465743)
- Symptom: The Data Collector might not start polling all components if many calls are made to data aggregator REST webservice to start/stop polling on an individual component.
  Resolution: Fixed NullPointerException in the Data Collector so we can better handle polling change requests from the Data Aggregator.

(20.2.1, DE466104)

- Symptom: Running a Discovery Profile for ranges that were discovered by a DX NetOps Virtual Network Assurance Gateway can lead to items being deleted if the IP addresses are pingable but not SNMP contactable.
  Resolution: Updates were made to the discovery process which now prevents items from being deleted when they have been previously discovered by a DX NetOps Virtual Network Assurance Gateway.
  (20.2.1, DE466358)
- Symptom: Open API in some circumstances might not honor tenants boundaries.
  Resolution: With this fix, Open API should honor tenant boundaries all the tine.
  (20.2.1, DE466422)
- Symptom: On the System Health page, when you page to the next page in a table the section is collapsed each time.
  Resolution: Instead of setting the collapsed property to be purely based on the status of the section, the product also takes into account the current collapsed state.
  (20.2.1, DE467043)

Known Limitations

The following limitations have been identified in this release of DX NetOps Performance Management:

Alarms Tab on Customized Context Pages

The Alarms tab is automatically added to most device-level context pages. For customized device-level context pages, you must manually add the Alarms tab. If you have many tenants with customized device-level context pages, see the ReadMe file in the following location to streamline the addition of the Alarms tab:

`/PC_install_directory/PerformanceCenter/SQL/plugins/custom_context_spectrum`

Apostrophes in Custom Attribute Descriptions

When a custom attribute description contains an apostrophe, the tooltip for the attribute does not render correctly in some situations.

Blank CA Business Intelligence Dashboard Output

In some cases, synchronized users (created in NetOps Portal) see blank PDF output from scheduled reports.

In some cases, users see blank PDF output because of a misconfiguration in the `js.config.properties` file.

For more information, see the Jaspersoft Community.

Broken Links in a DX Spectrum Integration

In an integration with DX NetOps Spectrum, you might find broken links from DX NetOps Spectrum OneClick to NetOps Portal. For the linking to work correctly, the fully qualified domain name is required.

To prevent this issue, complete the following steps:

1. Log in to the Performance Center host.
2. Navigate to the Performance Center directory:
   `cd PC_Install_Directory/PerformanceCenter`
3. Launch the SSO Configuration utility:
   `./SsoConfig`
4. Select and run option 1: CA Performance Center.
5. Select and run option 3: Performance Center.

6. Select and run option 1: Remote Value.
7. Select and run option 7: Web Site Host.
8. Enter `u` to update.
9. Specify the fully qualified domain name of the Perfomance Center host.
10. Sync the DX NetOps Spectrum data source.

Bulk Data Export Unsupported in Fault Tolerant Environments

The bulk data export feature is unsupported in environments with fault tolerant Data Aggregators.

CA Business Intelligence Chart Errors in Scheduled Jobs

When a scheduled CA Business Intelligence (CABI) report or dashboard is executed, pie charts may appear incomplete or may be missing a color.

This issue occurs in the CA Business Intelligence JasperReports Server.

To prevent this issue, complete the following steps:

1. Open <*CABI_INSTALL*>/WEB-INF/js.quartz.base.properties.
2. Change the default values as follows:

```
org.quartz.jobStore.clusterCheckinInterval = 3600000
org.quartz.threadPool.threadCount=9
org.quartz.threadPool.threadPriority=9
org.quartz.jobStore.misfireThreshold=3600000
```

CA Business Intelligence Failed Export for Scheduled Jobs

If you export everything for a scheduled job from the CABI user interface, the dashboards are not exported.

To prevent this issue, use the user interface, js-export, or the REST API to export each dashboard individually.

CA Business Intelligence Report and Input Control Issues

Scheduled CABI reports and saved input controls for reports might work incorrectly after upgrade. This issue occurs because this release introduces changes to the report input controls. Some input controls were added, some were removed, and some were changed. For example, if a TopN report was scheduled for two metrics of Interface metric family, after you upgrade, the scheduled report shows four variables. We recommend that your recreate scheduled reports and report templates after upgrade.

cEdge Device and Tunnel Data Unavailable

DX NetOps Virtual Network Assurance collects inventory and performance metrics from Viptela to support DX NetOps Performance Management SD-WAN monitoring. While the plug-in collects inventory for vEdge routers, vEdge interfaces, tunnels, and application/SLA paths, it cannot collect data for cEdge devices due to a Cisco bug. This limitation results in missing cEdge devices in the interface inventory and missing tunnels that originate or terminate from or on cEdge interfaces.

For more information, see the Cisco documentation.

Data Collector Polling Status Issue

Before you upgrade the Data Collectors, after you upgrade the Data Aggregator to the 20.2 GA release, the Polling Status column on the System Status page inaccurately says "Not Connected" for each Data Collector. However, a connection

remains. No data loss should occur. After you upgrade the Data Collectors, the correct status appears. This issue will be fixed in releases after the 20.2 GA release.

Deprecated Top Performance by Application View

A change starting with CA Application Delivery Analysis 10.5 deprecated the Top Performance By Application view.
For this version of DX NetOps Performance Management, the new Port List field replaces the Begin Port and End Port fields.
The deprecated view is now the Top Performance By Application - Deprecated view.
The new Top Performance By Application view was created to replace the deprecated view.
If all versions of CA Application Delivery Analysis have been upgraded to at least version 10.5, administrators can edit the dashboards and can replace the deprecated view with the new view.
If not all Application Delivery Analysis data sources are above the specified version, administrators can edit the view title to remove the "Deprecated" text.

Disabled Trend Charts with Events

Trend charts with events are disabled when the time range is greater than 3 months.

Device Context Page:

- Availability Trend with Events
- Average CPU Utilization Trend with Events
- Average Memory Utilization Trend with Events

Interface Context Page:

- Interface Utilization/Discard Out Trend with Events
- Interface Utilization/Discard In Trend with Events
- Interface Utilization Out Trend/Baseline Detail with Events
- Interface Utilization In Trend/Baseline Detail with Events

Empty PDFs After Scheduled Job Executions for CABI Dashboards

The PDFs of DX NetOps Performance Management Monitoring Status and DX NetOps Performance Management Overview – Product Usage dashboard reports are not generated after a scheduled job execution. There is no workaround to generate the PDFs for the two dashboard reports as we do not have a menu item to save the reports in the PDF format.

Extended Flow Views

You can drill down into Network Flow Analysis data for an interface within NetOps Portal without having to navigate to Network Flow Analysis.

Extended flow views have the following known limitations:

- The search box on the related table views does not filter the content in the data results.
- Extended flow views on the interface context page cannot be exported in a scheduled report.
- Extended flow views on the dashboard page cannot be exported in a scheduled report containing all pages.
- The maximum rows are limited for performance. By default, the Top Selection table views are 1000 rows and the Trend Table views are 25 rows.
- For upgrades only, you must manually add extended flow views to customized interface context pages. If you have many tenants with customized interface context pages, do the following post-installation steps:
  a. On the NetOps Portal server, change to the following directory:
     `cd PC_install_directory/SQL/plugins/reporter`
  b. Follow the steps described in the ReadMe file.

NOTE

Even for environments with Network Flow Analysis 9.x and earlier, we recommend that you run the post-installation script. Running the post-installation script helps to ensure compatibility with the latest version when it is enabled.

- If the data source is Network Flow Analysis 10.x and higher, the links in the charts and tables in the IP Performance page open the corresponding network flow pages within DX NetOps Performance Management. If the data source is Network Flow Analysis 9.x and earlier, the links open the corresponding pages in the Network Flow Analysis console.

For more information, see Context Pages.

Flow Administration Issues with IPv6

If the Flow Administration page is empty, check `PCService.log` .

If the following message appears, the Network Flow Analysis Console server might be configured with an IPv6 address:

```
Failed in sending REST: http://[0000:0000:0000:0000:0000:0000:0000:0001]:8981/odata/api/AuthToken
 java.net.ConnectException
```

Follow these steps:

1. Disable the IPv6 address.
   For more information, see Windows Support.
2. Make sure only one Network Interface Card (NIC) is present on the Network Flow Analysis Console server.
3. Run the following command and verify that there are no IPv6 addresses:
   ```
   ipconfig
   ```

Future Web Services Deprecation

When you use the NetOps Portal UI to export vendor certifications, the **genericWS** format is used. The **genericWS** format will be deprecated in a future release. Therefore, we recommend that you use the **typecatalog** web services instead of the NetOps Portal UI.

For more information about using the **typecatalog** web services, see Create or Extend Vendor Certifications.

Group Scorecard Table Metric Fields

The first time you edit the view settings for a group scorecard table view you might encounter an issue with the selected metrics. If you change between Hierarchy Calculate Levels and Metric Calculate Levels, your selected metric fields might clear. For example, if you select several metric fields, and then change the selection from **Device Hierarcy** to **by Device**, your selected metric fields clear.

Input Parameter for Schema During CABI Installation Not Updated

Issue:
During the CABI content installation when you provide the input parameter for schema as "https", the DX NetOps Performance Management Data Source page schema field displays "http".

Workaround:

After you install CABI content, login as administrator in the CABI server.

Open View, Repository page and extract "root-Public-ca-Performance Management - datasources" folder.

Edit the CA PM datasource to change Schema parameter to "https" and click Save.

You need not restart the CABI service.

Invalid Certificates

- For the first discovery, invalid certificates might cause devices, interfaces, and tunnels to be missing.
- After discovery, invalid certificates remove all items that belong to any invalidated devices (routers, interfaces, tunnels, and possibly sites).

Keys for ActiveMQ Communication

If you have authenticated and encrypted activeMQ communication, you must regenerate the keys before this upgrade. For more information, see Authenticate and Encrypt ActiveMQ Communication.

> **NOTE**
> For the first and last name prompt, you must enter the host name of the system where you are creating the certification.

Without new keys, the Data Aggregator and Data Collector cannot communicate.

MultiViews

You can now select multiple metrics for MultiViews. However, existing legacy MultiViews remain the same during upgrade and do not support multiple metrics. If you want an existing view to include multiple metrics, configure a new view in the dashboard builder.

Screen Reader Limitations

When you use a screen reader with the Chrome browser, the contents of charts (for example, points, legend entries, and so on) are not read aloud. This issue is cause by a limitation with the Chrome browser. When you use a screen reader with other browsers including Firefox and Safari, the contents of charts are read alound.

When you use a screen reader to read the contents of charts, the up and down arrow keys are not available. Usually, you must use the screen reader key in conjunction with the left and right arrow keys to move focus in the chart.

When you use a screen reader to read the contents of grids using Internet Explorer, the tooltips associated with icons in the grids are not always read aloud due to a limitation in Internet Explorer.

When use a web browser with the zoom setting of the browser set to greater than 100%, the minimum supported browser window size increases by the zoom factor. For example, if the zoom setting is set to 200%, the minimum required browser window width is 2048 pixels (1024 pixels times 2).

SDN/NFV Dashboard Limitations

The VNF Count by Type Stacked Chart in the SDN/NFV Virtual Inventory Overview dashboard does not show data for the last period. The data for the same period appears when you export the data to a CSV file.

SD-WAN Monitoring

The following limitations apply to SD-WAN monitoring:

- All SD-WAN tunnel reporting is processed at the device component level. Parent devices do not appear in the reported raw data. The edge device source, and destination, can be manually added to the tabular related reports. Pick the inventory columns on the rendered grid.
- The SD-WAN tunnel metrics (latency, packet loss, and jitter) do not support minimum, maximum, or baselines variants. Support for percentile metrics is available, but the support is not provided out-of-the-box and must be configured. For more information, see Edit a Metric.
- The Data Aggregator Administration UI lets you configure projection metrics for the SD-WAN tunnel metrics (latency, packet loss, and jitter). However, these metrics do not have baselines. Therefore, projection metrics are unsupported for the SD-WAN tunnel metrics. For more information, see Edit a Metric.
- No direct reconciliation of the SD-WAN edge devices to SNMP physical devices occurs. Therefore, reporting for the CPU and Memory utilization of edge devices is done from the virtual host metric family.
- No direct reconciliation of virtual interfaces to SNMP physical interfaces occurs.
- The parented edge device of the tunnel must report the virtual interface of the SD-WAN tunnels. Direct queries by the tunnel item are unsupported.
- SD-WAN tunnels do not have values in the description fields. The description values are always blank.
- The alias setting for the SD-WAN tunnel items is unsupported.
- The VNA Domain Sites are initially shown as numeric values. The site group can be altered with the Group Admin UI. Other alterations are not recommended under the SD-WAN Sites group.
- The SD-WAN Tunnel metric family is unsupported for On-Demand reports.
- If you set a custom time range to 30 minutes on an SD-WAN dashboard, the time bar charts and trend views have data gaps.

SD-WAN Tunnel and Application Paths Dashboard Limitations

In DX NetOps Performance Management releases before 3.6, the site selected in the Map view filtered the Time Bar view. In DX NetOps Performance Management release after 3.6, the selected site in the Map view does *not* filter this view. However, you can use the search bar to filter the view by site name. For more information, see Monitor SD-WAN.

Search for NFA Drill-Down Pages

- Search must be on name or description fields.
- Protocol search does not work on the group protocols(ip,ipv6,tcp,udp) as they are not single protocols.
- When searching the Hosts, you must provide the host name without braces. For example, if the host name is (10.10.1.2), the host name you must search will be 10.10.1.2.
- When searching a conversation, you must use the Server IP or the Client IP. For example, when searching for the conversation "10.19.19.179 - 10.20.20.179", the search value must be 10.19.19.179 or 10.20.20.179. "10.19.19.179 - 10.20.20.179" is not allowed.
- For ToS search, search without braces '()' of ToS description. For example, if the ToS description is ToS 20 (ToS 20), the search value must be ToS20. For a ToS format like AF12 (DSCP12) ECT=0;CE=1 (ToS 49), the search value must be AF12 (DSCP12) ECT=0.
- Search does not work on 'other' as it is group of items.

Theme Deployment Hangs

Theme deployment occasionally hangs when you use the Chrome browser. If this known limitation occurs, deploy the theme using Firefox or Internet Explorer as your browser.

Time Zone Limitation in CA Business Intelligence Reports

When you change a time zone for a CA Business Intelligence report, you can select only a time zone with a different offset. If the time zone is **(UTC-05:00) Bogota, Lima, Quito**, the system does not register a selection with the same

offset, such as **(UTC-05:00) Eastern Time**. To work around this issue, select a time zone with a different offset before selecting the desired time zone.

Top Enterprise Flow Views

If you have CA Network Flow Analysis 10.0 or higher, the links in the Top Enterprise Hosts by Volume view and the Top Enterprise Protocols by Volume view do not work. If you have view suppression enabled, these views do not appear in the relevant dashboards (for example, the Infrastructure Overview dashboard) or context pages. You can find useful information in the new Network Interface Performance dashboard. These views perform as expected with CA Network Flow Analysis 9.5 and lower.

Use Defaults Button Limitations

A view cannot be converted to report at a group level under the following circumstance:

- A context item filter is applied when adding on-demand reports or dynamic trend views to a page within Dashboard Builder.

Avoid reverting the view settings with the Use Defaults button at the All Tenant Users level under the following circumstance:

- You are editing a view that is locked to a device or interface that no longer exists in the system.

If the Use Defaults button is applied, do the following tasks:

- Edit the view twice to restore the metric selection.
- Add a new device or interface to the view before rendering data.

Viptela Inventory Includes Only Devices with Valid Certificates

The Viptela plug-in accurately interprets vEdge devices with "valid" certificate states. The Viptela plug-in cannot accurately interpret vEdge devices with "invalid" certificate states. If the certificate of a vEdge device is invalidated, the vEdge device is no longer discovered in the inventory. Associated interfaces are no longer reported, however tunnels are still reported and reference the interface underlay.

A vEdge device must have a valid security certificate to participate in a Viptela network. You can configure the certificate state from the vManage Certificates administration page.

To administer a certificate for a vEdge device:

1. Log in to vManage.
2. Select **Certificates** from the **Configuration** sidebar drop-down.
3. Select the desired administrative state for the device certificate in the **Validate** column (Invalid, Staging, Valid).

For more information, see the Viptela product documentation. Viptela online documentation is available by clicking the question mark (?) icon in the top menu bar in vManage.

Viptela Scale Boundary

Viptela has an upper boundary for the number of managed items. For example, depending on the size of your physical system, more than 1000 vEdge devices might cause issues.

The boundary depends on the following factors:

- Network bandwidth between DX NetOps Virtual Network Assurance and vManage
- Number of vEdge devices
- Tunnel topology (for example, hub-and-spoke versus full mesh)
- Number of interfaces
- Number of SLA classes/policies

If the upper boundary is hit, you might notice the following issues:

- 24 hours after a fresh install, the inventory is incomplete.
- Managed items are missing.
- Performance data is missing.
- The performance cycle does not complete within the allotted time (10 minutes for inventory, 30 minutes for performance).

If you suspect an issue, go to the log in the following directory and look for any warnings or errors indicating a failure to receive responses:

VNA_install_directory/VNA/standalone/log

Virtual and SNMP Interface Reconciliation

Virtual interfaces from DX NetOps Virtual Network Assurance are now reconciled with existing SNMP interfaces. When the VNA Gateway restarts (for example, during upgrade), the virtual interfaces are reconciled with existing SNMP interfaces, and the virtual interface is deactivated. Currently, the performance data on the virtual interface is not migrated over to the SNMP interface. All new performance data goes to the SNMP interface. The performance data on the virtual interface is not easily accessible.

Interface Utilization

For interface utilization, Cisco recommends looking at the higher of utilization in and utilization out. DX NetOps Performance Management uses this method. The advantage of this method is that if either utilization in or out is high, utilization shows the problem.

The legacy monitoring solution CA eHealth shows the average of the two values. The advantage of this method is that high utilization indicates a problem with utilization in *and* utilization out. The disadvantage is that if either utilization in or utilization out is high, the utilization metric alone does not reflect the severity of the problem. As a result, the DX NetOps Performance Management method might show higher overall utilization values than CA eHealth.

To apply the CA eHealth method to the utilization metric in DX NetOps Performance Management, apply the extension to the relevant vendor certification:

ifXUtilizationTableMIB

```
<DataModel namespace="http://im.ca.com/certifications/snmp" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance"

```

Hide Gaps in Trend Views

By default, DX NetOps Performance Management shows gaps in all trend type charts when no data exists for that data point. Gaps can occur when DX NetOps Performance Management does not have data for the item for a timeframe. The following circumstances cause gaps in the data:

- The device does not respond to a poll request.
- The device is down.
- A network problem causes the poll response to be lost.
- The Data Collector is down.
- For as polled data, a counter rollover or bad poll occurred.
  For more information about counters, see Configure Counter Behavior.

DX NetOps Performance Management includes a mechanism to hide gaps. The chart draws a straight line from the last data point to the next data point.

WARNING

When gaps are hidden, trend charts have no indication that a gap exists in the data. The connected line *does not* reflect the real behavior for the device during the period with missing data. Gaps are visible in exported data.

Follow these steps:

1. Log in to the Data Aggregator host.
2. Create the following file:
   `apache-karaf-2.4.3/etc/com.ca.im.dm.ribsource.RIBSourceWsImpl.cfg`
3. Add the following line to that file:
   `gapShowingOn=false`

All trend type views hide gaps. To apply the new behavior, refresh the view.

Metric Family Changes

DX NetOps Performance Management introduces the following changes to metrics and metric families:

Metric Name Changes

Change occurred in release 3.5

Old Metric Display Name	New Metric Display Name
Mobile WLAN Access Point	Wireless Access Point
Mobile Stations	Wireless Stations

Change occurred in release 2.6.

To ensure ease of use, long metric display names have been shortened, as follows:

Old Metric Display Name	New Metric Display Name
Fail Fast Chan Change Requests Rcvd from Std Def Channels	Std Def Channel Change Fail
Ttl Aggregate BW of The Currently Running Egress Streams	Running Egress Aggregate BW
Number of Currently Active Connections Getting Optimized	Active Connections Optimizing
IPv6 Prefixes from Peer Which Were Suppressed By Damping	Peer IPv6 Prefix Damping Suppressed
VPN IPv6 Prefixes from Peer Which Were Suppressed By Damping	Peer VPN IPv6 Prefix Damping Suppressed
Next Sequence No Identifier to Be Sent In A Linktrace Msg	Next Sequence No ID LinkTrace
Next Sequence No Identifier to Be Sent In A Loopback Msg	Next Sequence No ID LoopBack
Overall CPU busy percentage in last cpmCPUMonInterval period	CPU Busy Last cpmCPUMonInterval
The overall CPU busy percentage in the last 5 second period	CPU Busy Last 5 Second
Max outstanding snmp requests reached in last poll cycle	Max Outstanding SNMP Requests
CPU Capacity Priority Weight Units Currently Unallocated	CPU prority weight unallocated
Average One Way Delay Destination to Source with Precision	Avg 1-way delay dest to src w/precision
Average One Way Delay Source to Destination with Precision	Avg 1-way delay src to dest w/precision
Maximum One Way Delay Destination to Source with Precision	Max 1-way delay dest to src w/precision
Maximum One Way Delay Source to Destination with Precision	Max 1-way delay src to dest w/precision
Minimum One Way Delay Destination to Source with Precision	Min 1-way delay dest to src w/precision
Minimum One Way Delay Source to Destination with Precision	Min 1-way delay src to dest w/precision
Percent of Time in Off State Critical Central Office Relay	Pct Time Off State Critical
Percent of Time in On State Critical Central Office Relay	Pct Time On State Critical
Percent of Time in Unknown State - Chassis Audible Alarm	Pct Time Unknown Chassis Alarm
Percent of Time in Unknown State Major Central office Relay	Pct Time Unknown State Major
Percent of Time in Unknown State Minor Central office Relay	Pct Time Unknown State Minor
Mobile IP Registration Denied PDSN - Missing Home Address	Mobile IP Reg Denied Missing Home Address
Number of Registration Requests Discarded - Mobile IP HA	Registration Requests Discarded - Mobile IP HA

Number of Registration Requests - FA Authentication Failure	Registration Requests FA Auth Failure
Number of Registration Requests - Authentication Failure	Registration Requests Auth Failure
Number of L3 Egress Classifications Matching a Drop Policy	L3 Egress Class Drop Policy Count
Number of L3 Ingress Classifications Matching a Drop Policy	L3 Ingress Class Drop Policy Count
The total number of Double Data Rate channel sync errors	DDR Channel Sync Errors
Num of Active Conn Going Through TCP Plus Other Optimization	Active TCP Connections Plus Optimization
Connections Declined due to Non-availability of Resources	Connections Declined - Non Availability
URL Requests Resource Dropped per second (last 5 minutes)	URL Resource Dropped per second (last 5 min)
Number of Instances Received Packet Matches The Filter Rule	Instances Rcvd Packet Matching Filter Rule
Reserved Memory Used for Running VM in this Resource Pool	VM Resource Pool Reserved Memory
Count Successful location report between 50 and 150 meters	Successful Location Report 50-150m
Count SUPL Transactions Using LLPW with MSA And OTDO Method	SUPL Transactions Using LLPW w/MSA &OTDO
Lower Threshold on Total Number of Instances of Running Process	Running Process Instances Lower Threshold
Upper Threshold on Total Number of Instances of Running Process	Running Process Instances Upper Threshold
Number of Poll Groups Stopped Due to Prior Timeouts (internal)	Poll Groups Stopped Due to Prior Timeouts (internal)
Pct Tx Frames Arrived with Delay Variation Greater Than Thresh	Pct Tx Delay Variance Over Threshold
Total Number of Cache Misses Bytes Excluding Uncacheable Data	Cache Misses Bytes Excluding Uncacheable Data
Number of Frame Relay Link Q921 Call Control Subsystem Errors	Q921 Call control subsystem errors
Mobile IP Registration Requests Denied PDSN - Authentication Failure	Mobile IP Reg Req Denied PDSN Auth Failure
Number of Handoff Registration Requests Accepted - Mobile IP HA	Mobile IP HA Handoff Reg Requests Accepted
Number of Handoff Registration Requests Denied - Mobile IP HA	Mobile IP HA Handoff Reg Requests Denied
Number of Sessions Released which Failed the IP Control Protocol	Sessions Released Failed IP Control
The Total Number of Cells Input Packet and Cells Output Packet	Total Cells I/O Packets
Limit Buffer To High Priority Traffic When List 1 Is Below Threshold	Buffer High Priority List 1 Below Thresh
Limit Buffer To High Priority Traffic When List 2 Is Below Threshold	Buffer High Priority List 2 Below Thresh
Limit Buffer To Low Priority Traffic When List 1 Is Below Threshold	Buffer Low Priority List 1 Below Thresh
Limit Buffer To Low Priority Traffic When List 2 Is Below Threshold	Buffer Low Priority List 2 Below Thresh
Limit Buffer To Medium Priority Traffic When List 1 Is Below Threshold	Buffer Med Priority List 1 Below Thresh
Limit Buffer To Medium Priority Traffic When List 2 Is Below Threshold	Buffer Med Priority List 2 Below Thresh
Limit Buffer To Urgent Priority Traffic When List 1 Is Below Threshold	Buffer Urgent Priority List 1 Below Thresh
Limit Buffer To Urgent Priority Traffic When List 2 Is Below Threshold	Buffer Urgent Priority List 2 Below Thresh

Interface Metric Family

Change occurred in release 2.5.

The Interface Metric Family now includes new metrics:

- Bits Per Second
- Bits Per Second In
- Bits Per Second Out

The following metrics have been disabled in this metric family:

- Bytes
- Bytes In
- Bytes Out

This change disrupts existing thresholds or views that use Bytes, Bytes In, or Bytes Out.

NOTE

the Starent device pack for CA Mediation Manager uses the Bytes metrics. If you use this device pack, you may want to enable Bytes metrics for this vendor certification. The XML to extend this vendor certification is located in the following directory:

```
/opt/IMDataAggregator/examples/vendorCertification/
```

Enable Bytes Metrics

WARNING

Enabling Bytes metrics for the interface metric family may affect system performance.

To enable the Bytes, Bytes In, and Bytes Out metrics for individual vendor certifications, extend the certification. The XML to enable the metric is included in the following directory:

```
/opt/IMDataAggregator/examples/vendorCertification/
```

Merge the example XML with your extension XML. For information about how to extend the vendor certification, see Create or Extend Vendor Certifications.

Mobile WLAN Access Point (certified since 2.3) – renamed into **Wireless Access Point**

OpenAPI Changes

DX NetOps Performance Management introduces the following changes to the OpenAPI in release 2.8:

Removed Entities

The `pollgroup` entity was removed, which included the following attributes:

- `NormalizedFacetType`
- `CertificationFacetType`
- `PollingInterval`

Removed Relationships

The following table lists the relationships that were removed:

`interface`	`qosclassmap`
`qosclassmap`	`qospolicer`

qosclassmap	qoscontract
qosclassmap	qosqueuing
qosclassmap	qosred
qosclassmap	qostrafficshaping

Impact:

The QoS elements hierarchy is no longer supported.

Examples:

```
odata/api/interfaces?&$expand=qosclassmaps
odata/api/qosclassmaps?&$expand= qosreds
```

Updated Entities

Component

The following attributes were removed for the `component` entity type:

- `IsAlso N/A`
- `MDRItemID`
- `IsFiltered`
- `IndexList`
- `SourceFacetTypes`
- `IsExcludedFromReports`

The `IsAlso` attribute was removed.

Impact:

No information is available on the entity type when querying for devices and components.

Examples:

```
odata/api/devices?$top=10&$filter=substringof('router', IsAlso) eq true and
 substringof('switch', IsAlso) eq true

odata/api/components?$top=10&$filter=substringof('cpu', IsAlso) eq true or
 substringof('memory', IsAlso) eq true
```

Cpu

The following attributes were removed for the `cpu` entity type:

- `MDRItemID`
- `IsFiltered`
- `IndexList`
- `SourceFacetTypes`
- `IsExcludedFromReports`

Memory

The following attributes were removed for the `memory` entity type:

- `MDRItemID`
- `IsFiltered`
- `IndexList`
- `SourceFacetTypes`
- `IsExcludedFromReports`
- `CertificationFacetTypes`
- `EMSEngineId`
- `DiscoverTime`
- `EMSSourceFacetType`

Interface

The following attributes were removed for the `interface` entity type:

- `MDRItemID`
- `IsFiltered`
- `IndexList`
- `SourceFacetTypes`
- `IsExcludedFromReports`
- `ItemSubType`
- `ItemType`
- `SpeedOutOverride`
- `SpeedInOverride`

Monitoringprofiles

The following attributes were removed for the `monitoringprofiles` entity type:

- `PollGroupIDs`

Mplsinterface

The following attributes were removed for the `mplsinterface` entity type:

- `MDRItemID`
- `IsFiltered`
- `IndexList`
- `SourceFacetTypes`
- `IsExcludedFromReports`
- `CertificationFacetTypes`
- `EMSEngineId`
- `DiscoverTime`
- `EMSSourceFacetType`

Mplsinsegment

The following attributes were removed for the `mplsinsegment` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- CertificationFacetTypes
- EMSEngineId
- DiscoverTime
- EMSSourceFacetType

Mplsoutsegment

The following attributes were removed for the `mplsoutsegment` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- CertificationFacetTypes
- EMSEngineId
- DiscoverTime
- EMSSourceFacetType

Qosclassmap

The following attributes were removed for the `qosclassmap` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Qospolicer

The following attributes were removed for the `qospolicer` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Qoscontract

The following attributes were removed for the `qoscontract` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Qosqueuing

The following attributes were removed for the `qosqueuing` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Qosred

The following attributes were removed for the `qosred` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Qostrafficshaping

The following attributes were removed for the `qostrafficshaping` entity type:

- MDRItemID
- IsFiltered
- IndexList
- SourceFacetTypes
- IsExcludedFromReports
- ParentItemID
- ChildItemIDs

Device

The following attributes were removed for the `device` entity type:

- MDRItemID
- ItemSubType
- ItemType
- ConsolidatedMonitoringProfile
- SupportsOnDemandMFDiscovery

The IsAlso attribute was removed.

Impact:

No information is available on the entity type when querying for devices and components.

Examples:

```
odata/api/devices?$top=10&$filter=substringof('router', IsAlso) eq true and
 substringof('switch', IsAlso) eq true

odata/api/components?$top=10&$filter=substringof('cpu', IsAlso) eq true or
 substringof('memory', IsAlso) eq true
```

The LifeCycleState column was added.

Router

The following attributes were removed for the router entity type:

- MDRItemID
- ItemSubType
- ItemType
- ConsolidatedMonitoringProfile
- SupportsOnDemandMFDiscovery
- MACAddresses

The State attribute was renamed LifeCycleState.

Switch

The following attributes were removed for the switch entity type:

- MDRItemID
- ItemSubType
- ItemType
- ConsolidatedMonitoringProfile
- SupportsOnDemandMFDiscovery
- MACAddresses

The State attribute was renamed LifeCycleState.

Server

The following attributes were removed for the server entity type:

- `MDRItemID`
- `ItemSubType`
- `ItemType`
- `ConsolidatedMonitoringProfile`
- `SupportsOnDemandMFDiscovery`
- `MACAddresses`
- `FirstMDRItemID`
- `StatusEvaluationType`
- `ChangeDetectionDisabledMFs`
- `CalculatedContactStatus`

The `State` attribute was renamed `LifeCycleState`.

Data Source Compatibility

NetOps Portal can use the following CA Technologies products as registered data sources:

- DX NetOps Virtual Network Assurance
- DX NetOps Spectrum
- Network Flow Analysis and Anomaly Detector
- CA Application Delivery Analysis
- CA Unified Communications Monitor
- CA Application Performance Management
- CA Business Intelligence

For supported releases, see the DX NetOps Interoperability.

Some components function as data sources. For these components, use only the release that is delivered as part of DX NetOps Performance Management:

- Data Aggregator
- Event Manager

For more information, see Manage Data Sources.

Language Support

DX NetOps Performance Management supports the following locales:

- English (US)
- French (France)
- Japanese

> **NOTE**
> DX NetOps Performance Management 3.7 and earlier support Simplified Chinese and Traditional Chinese. These languages have been deprecated in this release.
> For more information:
>
> - About this feature deprecation, see Deprecated Features.
> - About how to customize the language for your user account, see Customize Your User Settings.

The Help icons in the Simplified Chinese UI and Traditional Chinese UI link to the English documentation.

Additional languages might be supported in future releases. The following items are not translated:

Untranslated Items in DX NetOps Performance Management

The following items are not localized in DX NetOps Performance Management:

Component and Device Type Names

Component types are not localized, and the following device type names are not localized when you view them in report dashboards, groups, and inventory views:

- **Device types**
  - Other Devices
  - Pingable Devices
  - Call Server

The Device Components label and description in the Group Rule dialog are not localized.

Custom Context Types from Data Sources

Custom context types synchronized by data sources, such as the context types display in the Dashboard Editor, are not localized.

Data Collector Installer Download Page

The Data Collector installer download page (`http://data_aggregator:port/dcm/install.htm`) is not localized. For more information about how to download the Data Collector installer without accessing the webpage, see Installing.

Data Collector Names

The names of data collectors are not localized.

Data Source Localization Limitations

The names, descriptions, and other aspects of the predefined monitoring profiles and threshold event profiles that you can view in DX NetOps Performance Management administration are not localized.

Network Flow Analysis is only translated into French, Simplified Chinese, and Japanese. The Network Flow Analysis bookshelf displays in English if the user language preference is set to Traditional Chinese.

Event information from CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor data sources, such as event descriptions and event types, is not localized.

DX NetOps Performance Management supports integration with CA eHealth. However, integration with NetOps Portal is provided only in English versions of CA eHealth. The Japanese and French versions of CA eHealth do not support the NetOps Portal integration.

Custom Item Types from Data Sources

Some data sources support unique managed item types. For example, the DX NetOps Performance Management Data Aggregator data source supports a "Device Component" managed item type.

When data sources synchronize managed items with unique item types, the items appear in the Inventory, but their names and types are not localized.

Data Source Role Rights

Some of the supported data sources have their own sets of role rights to let selected users access product features. In some cases, the data source user interface is not localized into all of the supported languages. Role rights that are synchronized from such data sources that appear in the Edit Role Rights dialog are not localized.

Additional data sources like CA Application Delivery Analysis and CA Unified Communications Monitor also have limitations.

Role rights that are synchronized from CA Application Delivery Analysis, CA Unified Communications Monitor, and Network Flow Analysis are not localized.

Direction Terms

The Direction terms "In" and "Out" are not localized in the Interfaces Over Threshold view.

DNS Names

DNS names are not localized.

English String in NetOps Portal Installer

When you run the installer on a server or in command line with a locale set to a language other than English, the string "DEFAULT:" appears in English. This string is not localized.

How To Videos

Videos that supplement the documentation are not translated.

Installation Scripts

The following Data Repository scripts are not localized: `dr_validate.sh` and `dr_install.sh` .

Limitations on Custom Strings

You cannot provide multiple translations for strings that you customize, such as the following strings:

- Group Name
- Tenant Name
- Domain Name
- Role Name
- View Title
- Monitoring Profile Name
- Threshold Event Profile Name
- Discovery Profile Name

Monitoring Profiles

The names and descriptions of the product default monitoring profiles are not localized.

MIB Compiler Errors

MIB compiler errors are not localized.

Overview Tab in NetOps Portal

CA Unified Communications Monitor uses some tabs on the top-level dashboards. The Overview tab is not localized. The workaround is to manually create a new dashboard that contains the CA Unified Communications Monitor views.

Theme Names

Theme names are not localized.

XML Tag Names

The XML tag names for vendor certification and metric family files are not localized.

Third-Party Information

The following third-party information is not localized:

License Agreements for Third-Party Products

The license agreements for third-party products are not localized.

Third-Party Scripts

Any third-party scripts included in the product, such as the capabilities of a script, are not localized.

Known Issues

The following localization issues currently exist in DX NetOps Performance Management:

Date Format Incorrect on Heat Charts

The date format tooltip on heat charts in Traditional Chinese is incorrect. The correct date format is yyyy/mm/dd.

Date Format Incorrect on Performance Tab

The date format is incorrect in Asian languages on the Performance tab of the Device context pages.

Third Party Agreements

DX NetOps Performance Management

Deprecated Features

DX NetOps Performance Management 3.7 and earlier support Simplified Chinese and Traditional Chinese. These languages have been deprecated in this release. These language options are not available from the User Settings menu.

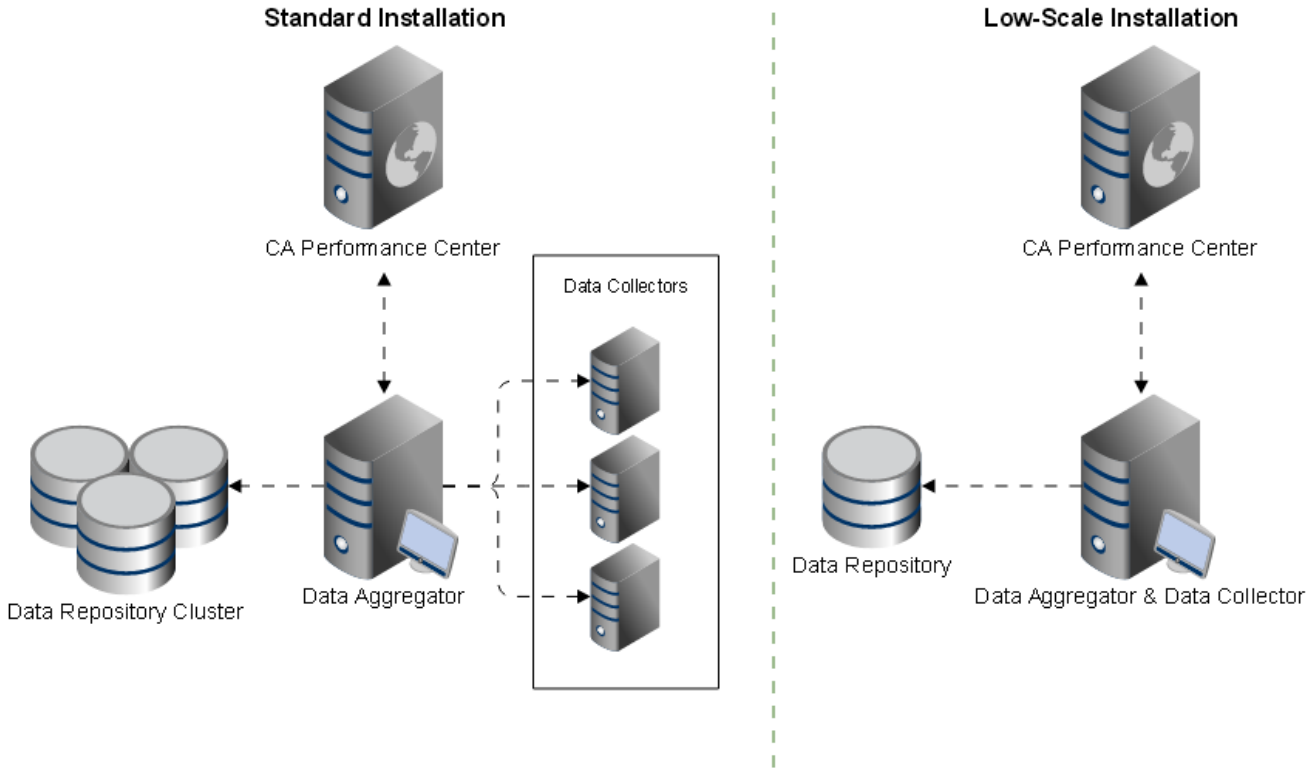
Installing

DX NetOps Performance Management is a distributed application that includes multiple components across several servers. A successful deployment includes installing these components in the following order:

1. NetOps Portal
2. Data Repository
3. Data Aggregator
4. Data Collectors

Your deployment strategy depends on the number of devices, location of these devices, and which metrics you want to monitor. The following diagram shows the installation options:

Figure 3: CA Performance Management Component Installation Options



Install DX NetOps Performance Management

NOTE

This process describes a standard installation. For low-scale systems, see Install or Uninstall the Proxy Server.

DX NetOps Performance Management requires the installation of linked components. To install the product, use the following installation order:

1. Review Installation Requirements and Considerations
2. Prepare to Install Performance Center
3. Install Performance Center
4. Prepare to Install the Data Repository
5. Install the Data Repository
6. Prepare to Install the Data Aggregator
7. Install the Data Aggregator
8. Prepare to Install the Data Collectors
9. Install the Data Collectors
10. Complete the Post-Installation Configuration
11. (Optional) Install CA Mediation Manager

NOTE

You can configure DX NetOps Performance Management to use FIPS-compliant encryption and hashing algorithms (where applicable). For more information, see FIPS-Compliant Encryption.

Review Installation Requirements and Considerations

Review the following information before you install the product:

Operating System Requirements

DX NetOps Performance Management supports the latest version of Red Hat 7.x unless otherwise specified.

The following operating systems have been verified:

- SUSE Linux Enterprise Server (SLES) 12 SP2
- Oracle Linux (OL) 7.3 (Red Hat compatible kernel only)

The following Red Hat Enterprise Linux (RHEL), SLES, and OL versions were verified:

NOTE
A RHEL installation offers packages and add-ons. DX NetOps Performance Management supports a minimal install environment for RHEL.

Release	Kernel
SLES 12.2	4.4.103
OL 7.3	3.10.0-514
RHEL 7.5	3.10.0-862
RHEL 7.4	3.10.0-693
RHEL 7.3	3.10.0-514
RHEL 6.9	2.6.32-696
RHEL 6.8	2.6.32-642
RHEL 6.7	2.6.32-573
RHEL 6.6	2.6.32-504

NOTE
RHEL 6.8, 6.9, 7.3, or 7.4 are recommended for all DX NetOps Performance Management components.

DX NetOps Performance Management does not support the following RHEL versions:

- RHEL 5.x
- RHEL 6.5 and lower
- RHEL 7.0 - 7.2
- RHEL kernel versions before 2.6.32.504

Root or Sudo User Access

Administrative privileges are required to install the software. Typically, the root users installs the software. In some environments, unrestricted root user access is not available.

If root user access is not available, configure a sudo user with access to a limited set of commands.

If you install the components with a sudo user account, add the 'sudo' prefix to commands that require the same user as the service owner, such as restart commands and SSL set up.

User Interface Access Requirements

Supported Browsers

The following browsers are supported:

- Microsoft Internet Explorer version 11
- Microsoft Edge version 42.x and later
- Google Chrome 70.x and later
- Mozilla Firefox 60.x and later

Other Requirements

- The minimum supported screen resolution is 1280x1024.

Virtual and SAN Environment Requirements

Review the CA Support Statement for Running CA Infrastructure Management Products in Virtualization and SAN Environments document. This document discusses CA policies for installing and operating Infrastructure Management products on virtualized servers or Storage Array Networks (SAN).

> **NOTE**
> You must be logged in as a registered user to view documentation on CA Support Online.

Package Requirements

The installer for each component requires the following packages:

Components	Packages
All (SLES)	• `dialog` • `mcelog` • `zip` • `unzip`
All (RHEL 7.x, OL)	• `dialog` • `mcelog` • `zip` • `unzip` • `chrony`

All (RHEL 6.x)	• dialog • mcelog • zip • unzip • glibc
NetOps Portal (SLES)	• fontconfig • libaio1 • libnuma1 • wget
NetOps Portal (RHEL 6.x)	• fontconfig • libaio • libaio-devel • numactl • wget
NetOps Portal (RHEL 7.x, OL)	• fontconfig • libaio • libaio-devel • numactl-libs • wget
Data Repository (RHEL 6.x, RHEL 7.x, SLES, OL)	• bc • pstack • gstack For RHEL 7.x, the pstack and gstack packages are included in the gdb package.
Data Collectors (RHEL 6.x, RHEL 7.x, SLES, OL)	• at

Common Considerations

- Install each component on a separate system.
- Verify that all your servers meet the minimum requirements and sizing guidelines.

  TIP
  To provide high availability for your data, future scalability, and best end-user experience, deploy your Data Repository as a cluster.

  For information about the sizing requirements, see the DX NetOps Performance Management Sizing Tool.

  NOTE
  If the sizing tool recommends a low-scale deployment, see Install a Low-Scale System.
- If you plan to stand up DX NetOps Performance Management in the cloud, see Review Cloud Sizing Guidelines.
- Time synchronization using NTP is required. Start the NTP daemon on Linux if it is not running. All machines must use the same NTP server.

  NOTE
  Except for anti-virus, system management, and time-synchronization software, do not install third-party software, especially third-party network monitoring software, on the same server as DX NetOps Performance Management components. Third-party software can interfere with the monitoring abilities of the CA system, and could void the warranty.

  If you install third-party software on a CA system, CA Support might ask you to uninstall this software before troubleshooting an issue on the server.

Multi-tenant Deployment Considerations

In a multi-tenant deployment, note the following information:

- The Data Aggregator is shared between tenants. The information for each tenant is secure and other tenants cannot view this information.
- In a standard tenant deployment, each tenant has a dedicated Data Collector. A tenant can have more than one Data Collector. For multiple tenants that reside in the same IP routing space, DX NetOps Performance Management can be configured to use fewer Data Collectors. For more information, see Tenant-Agnostic Data Collectors.
- Where a managed service provider is monitoring devices for multiple tenants, you can install Data Collector at the MSP site.

  NOTE
  This setup requires the Data Collector to gain access through a tenant firewall to poll the devices that are being managed.

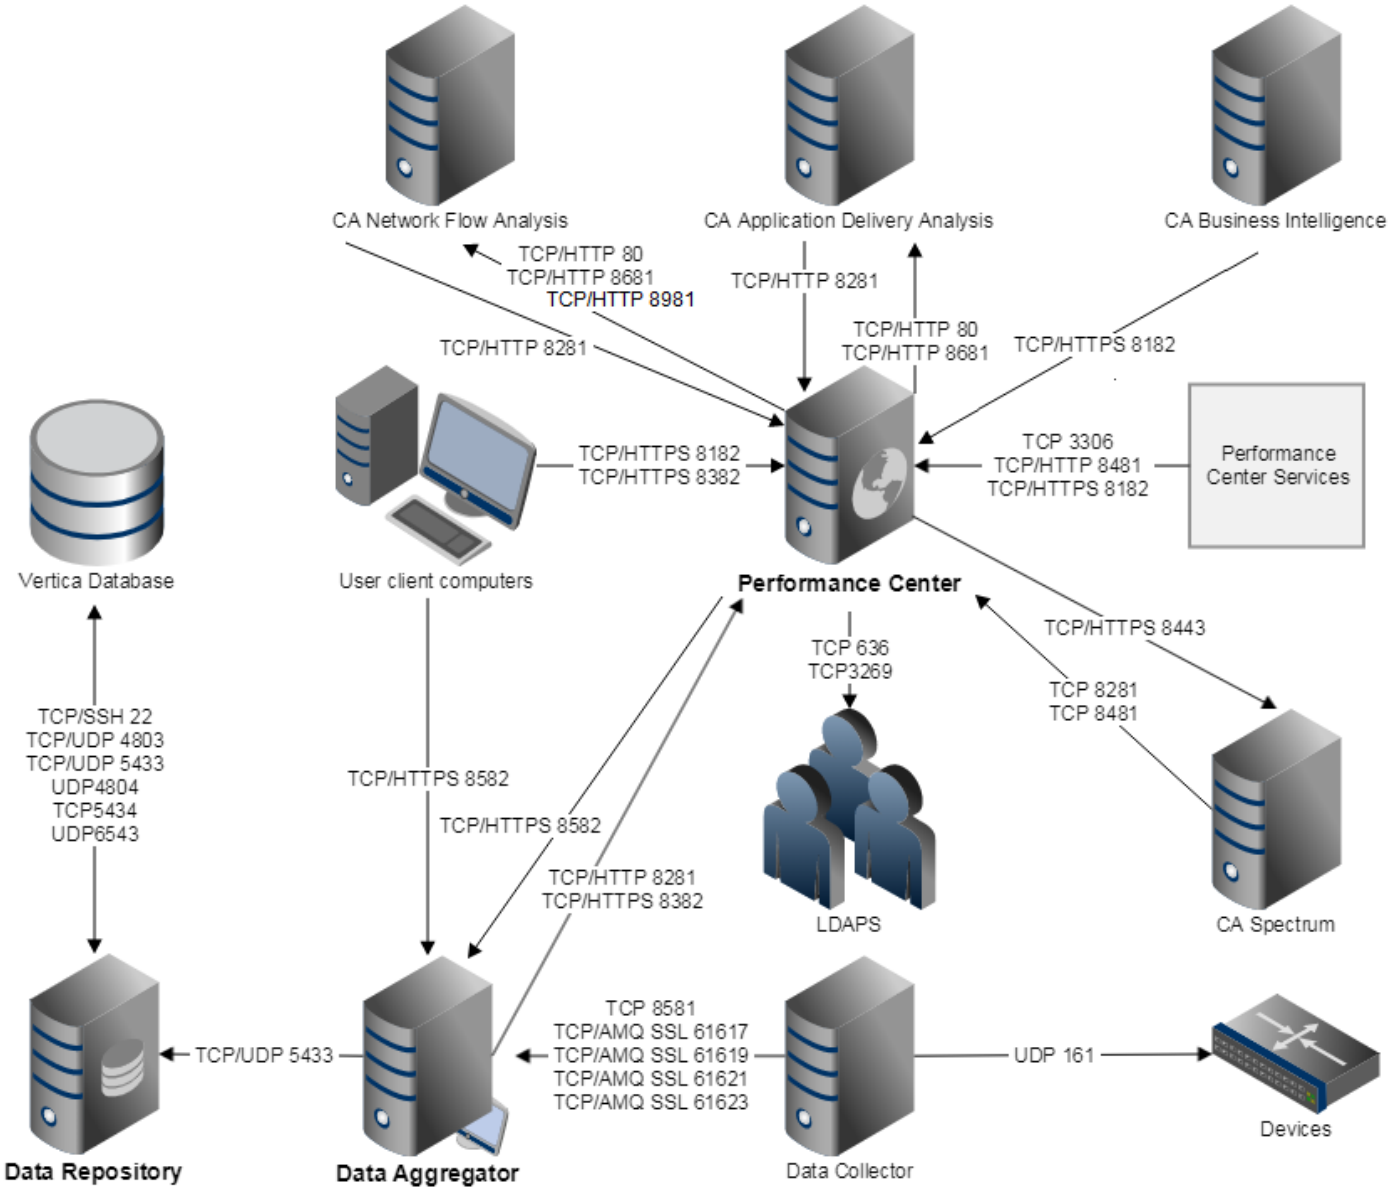
Firewall and Connectivity Considerations

For DX NetOps Performance Management to work correctly in a firewall-protected environment, certain ports must be open.

The following diagram shows the required ports for a hardened environment with a single data aggregator:

NOTE
If you changed the Network Flow Analysis OData API port and you have integrated Network Flow Analysis with NetOps Portal, the port value is synced in the next poll cycle of NetOps Portal or you can perform a manual resync with the Network Flow Analysis data source.

Figure 4: Port_Diagram



Open the following ports to allow DX NetOps Performance Management communications to function properly. For more information, see Prepare to Install Performance Center.

NOTE
Throughout the documentation 8182, 8382, 8582, 61617, 61619, 61621, and 61623 appear as suggested port numbers for secured communications. In the instances where these ports appear, you are free to use any value you want as long as no other processes are using it.

For more information about individual data sources, see the appropriate product documentation.

From	To	Port [Function]
NetOps Portal services	NetOps Portal	• **TCP 3306** Enables communications to the MySQL database (inbound) from the NetOps Portal services. • **TCP/HTTP 8481** Enables communications between the Device Manager and Console services. • **TCP/HTTPS 8182** This port is the default port for NetOps Portal if configured using the HTTPS documentation. For more information, see Configure the Port and Website for HTTPS.
User client computers	NetOps Portal	If you put the application behind a firewall, and you want customers to access only the user interface, open the following ports to the world: • **TCP/HTTP 8181** Enables communications between client computers and the NetOps Portal server. • **TCP/HTTP 8381** Enables communications between client computers and the NetOps Portal server. Also enables login using the single sign-on authentication component. For secured communications, use the following ports instead of 8181 and 8381: • **TCP/HTTPS 8182** This port is the default port for NetOps Portal if configured using the HTTPS documentation. For more information, see Configure the Port and Website for HTTPS. • **TCP/HTTPS 8382** This port is the default port for Single Sign-On if configured using the HTTPS documentation. For more information, see Configure the Port and Website for HTTPS.
User client computers	Data Aggregator	• **TCP/HTTP 8581** Allows for OpenAPI access. Opening this port exposes the rest of the Data Aggregator services. • **TCP/HTTPS 8582** Allows for secure OpenAPI access. Opening this port exposes the Data Aggregator REST services. Open only for clients that require direct access to the Data Aggregator services for administrative and automation purposes.

User client computers	Proxy Server	• **TCP/HTTP 8581** Allows for OpenAPI access in a fault tolerant environment. Opening this port exposes the Data Aggregator REST services. Open only for clients that require direct access to the Data Aggregator services for administrative and automation purposes. • **TCP/HTTP 8581** Allows for secure OpenAPI access in a fault tolerant environment. Opening this port exposes the Data Aggregator REST services. Open only for clients that require direct access to the Data Aggregator services for administrative and automation purposes.
Proxy Server	Data Aggregator	• **TCP/HTTP 8581** Allows for OpenAPI access in a fault tolerant environment. Opening this port exposes the Data Aggregator REST services. Open only for clients that require direct access to the Data Aggregator services for administrative and automation purposes. • **TCP/HTTP 8581** Allows for secure OpenAPI access in a fault tolerant environment. Opening this port exposes the Data Aggregator REST services. Open only for clients that require direct access to the Data Aggregator services for administrative and automation purposes.

Data Aggregator	NetOps Portal	• **TCP/HTTP 8281** Enables communications between the Event Manager, which is installed automatically with the NetOps Portal software, and the data aggregator. The data aggregator initiates communication and pushes data through this port. • **TCP/HTTP 8381** Enables communication between the Data Aggregator and NetOps Portal for direct authentication of OpenAPI queries. For secured communications, use the following ports: • **TCP/HTTPS 8382**If NetOps Portal is configured to use HTTPS, this port enables secured communication between the data aggregator and NetOps Portal for direct authentication of OpenAPI queries. For more information, see Configure the Port and Website for HTTPS.
NetOps Portal	Data Aggregator	• **TCP/HTTP 8581** Enables synchronization with DX NetOps Performance Management for the Data Aggregator. NetOps Portal initiates communication and pulls data through this port. For secured communications, use the following ports: • **TCP/HTTPS 8582** If you have configured the data aggregator to use HTTPS, this port enables secured synchronization with DX NetOps Performance Management for the Data Aggregator. NetOps Portal initiates communication and pulls data through this port. For more information, see Configure the Port and Website for HTTPS.

NetOps Portal	Proxy Server	• **TCP/HTTP 8581** In a fault tolerant environment, enables synchronization with DX NetOps Performance Management for the Data Aggregator. NetOps Portal initiates communication and pulls data through this port. For secured communications, use the following ports: • **TCP/HTTPS 8582** If you have configured the data aggregator to use HTTPS, this port enables secured synchronization with DX NetOps Performance Management for the Data Aggregator in a fault tolerant environment. NetOps Portal initiates communication and pulls data through this port. For more information, see Configure the Port and Website for HTTPS.
NetOps Portal	Network Flow Analysis	• **TCP/HTTP 80** Enables synchronization with Network Flow Analysis to retrieve configuration data. • **TCP/HTTP 8681** Enables synchronization with Network Flow Analysis to retrieve device data. • **TCP/HTTP 8981** Enables communication between Network Flow Analysis and NetOps Portal.
NetOps Portal	CA Application Delivery Analysis	• **TCP/HTTP 80** Enables synchronization with CA Application Delivery Analysis to retrieve configuration data. • **TCP/HTTP 8681** Enables synchronization with CA Application Delivery Analysis to retrieve device data.
CA Business Intelligence	NetOps Portal	• **TCP/HTTP 8181** Enables communications between CA Business Intelligence and the NetOps Portal server. For secured communications, use the following port instead of 8181: • **TCP/HTTPS 8182** This port is the default port for NetOps Portal if configured using the HTTPS documentation. For more information, see Configure the Port and Website for HTTPS.

Data Collector	Data Aggregator	• **TCP 8581** Enables the simplified upgrade for Data Collectors. For more information, see Upgrade the Data Collectors. • **TCP/AMQ 61616** Enables only ActiveMQ traffic between the Data Collector and Data Aggregator. • **TCP/AMQ 61618** Enables poll response delivery traffic between the Data Collector and Data Aggregator. • **TCP/AMQ 61620** Enables distributed IREP traffic between the Data Collector and Data Aggregator. • **TCP/AMQ 61622**Enables large data transfers between the Data Collector and Data Aggregator. This port also enables the simplified upgrade for Data Collectors. For more information, see Upgrade the Data Collectors. For secured communications, use the following ports instead of 61616, 61618, 61620, 61622: The following ports are the default ports for Secure ActiveMQ communication if configured using the AMQ SSL documentation. For more information, see Authenticate and Encrypt ActiveMQ Communication. • **TCP/AMQ SSL 61617** Enables only ActiveMQ secured communications between the Data Collector and Data Aggregator. • **TCP/AMQ SSL 61619** Enables poll response delivery secured communications between the Data Collector and Data Aggregator. • **TCP/AMQ SSL 61621** Enables distributed IREP secured communications between the Data Collector and Data Aggregator. • **TCP/AMQ SSL 61623** Enables secured large data transfers between the Data Collector and Data Aggregator.
Data Collectors	Devices	• **UDP 161** Enables SNMP and ICMP connections to devices. To enable ping during discovery and reachability checks, ICMP must be enabled on the devices and the network.

Data Aggregator	Data Repository	• **TCP/UDP 5433** Enables communication between the Data Aggregator and the Data Repository for Java Database Connectivity.
Data Repository	Data Repository	• **TCP/SSH 22** Enables Vertica administration tools and backup to run between nodes. • **TCP/UDP 4803** Enables spread communication between nodes. • **TCP/UDP 5433** Enables communication between the Data Aggregator and the Data Repository for Java Database Connectivity. Open the following ports for the Vertica database: • **UDP 4804** • **TCP 5434** • **UDP 6543**
Data Repository	Backup Hosts	• **TCP 50000** Enables the Data Repository host to access the custom rsync/ssh on the backup hosts.
Data Repository	Disaster Recovery Hosts	• **TCP 50000** Enables the Data Repository host to access the custom rsync/ssh on the disaster recovery hosts.
DX NetOps Spectrum	NetOps Portal	• **TCP 8281** For event integration, enables the DX NetOps Spectrum OneClick server to communicate to the NetOps Portal host. • **TCP 8481** Enables the DX NetOps Spectrum OneClick server to communicate to the Device Manager.
NetOps Portal	LDAP	• **TCP 389** Enables Clear Text communication from the client to the LDAP server. • **TCP 3268** If you are using the global catalog for searches, enables communication from the client to the LDAP server.
NetOps Portal	LDAPS	• **TCP 636** Enables encrypted and secure communication from the client to the Secure LDAP server. • **TCP 3269** If you are using the global catalog for searches, enables communication from the client to the Secure LDAP server.

Consul Servers (the proxy server, active Data Aggregator, inactive Data Aggregator)	Consul Servers (the proxy server, active Data Aggregator, inactive Data Aggregator)	• **TCP 8300** In a fault tolerant environment, enables communication between the proxy server and the Data Aggregators. • **TCP/UDP 8301** In a fault tolerant environment, enables LAN communication between the proxy server and the Data Aggregators. • **TCP 8500** In a fault tolerant environment, enables communication between the proxy server and the Data Aggregators to the HTTP API.

Review Cloud Sizing Guidelines

If you plan to stand up CA Performance Management in the cloud, review the following cloud sizing guidelines. You can choose from a variety of cloud platforms including Amazon Web Services (AWS), Google Cloud Platform (GCP), and so on. Our current guidelines focus on AWS.

Follow these steps:

1. Complete the CA Performance Management sizing tool to determine the estimated requirements of your environment.
   For more information, see the CA Performance Management Sizing Tool.
2. Review the estimated disk requirements from the sizer and consider your data retention rates. Your data retention rates impact disk requirements greatly.
   For more information, see Configure Data Retention Rates.
3. Review the other entries in the sizer, which impact the requirements of your environment.
4. Adjust the entries in the sizer until they most accurately reflect the needs of your environment.
5. Review the guidelines for your cloud platform.

AWS

Components	Instance Types	Descriptions	Added Storage	Notes	Examples
Data Repository / Vertica	r5.4, r5.8, r5.12	r5 instance types are memory optimized instances. These instances are designed to deliver fast performance for workloads that process large data sets in memory. We recommend r5 instance types for the Data Repository because Vertica supports them. For more information, see the Vertica on Amazon Web Services documentation. Also, the core to memory ratio best matches what our sizer recommends. Storage does not factor into this recommendation. Use one of the recommended added storage options from EBS to cover the recommended disk size from the sizer.	IOPS SSD, Thoughput HDD	To select the instance type best suited for your Data Repository, review the estimated CPU requirements in the sizing tool. The Data Repository requires storage beyond the boot disk. Amazon EBS allows you to create storage volumes and attach them to Amazon EC2 instances. Use EBS for the catalog directory and the data directory.	Using the sizer with the default values and 50,000 devices, the expected Data Repository sizing would be 14 cores and 224 GiB RAM. The r5.8 has 32 hyperthreaded cores and 256 GiB RAM. You can deselect the hyperthreaded option to run at 16 cores and 256 GiB RAM, which gives the expected ratio by the sizer. You are not required to deselect the hyperthreaded option, as the benefit can vary from deployment to deployment.
Data Aggregator	m5.1, m5.2, m5.4	m5 instance types provide a balance of compute, memory, and networking resources. The 1:4 CPU to memory ratio best matches the recommendations from our sizer.	No	To select the instance type best suited for your Data Aggregator, review the estimated memory requirements in the sizing tool.	Using the sizer with the default values and 50,000 devices, the expected Data Aggregator sizing is 18 cores and 48 GiB RAM. The m5.4 is the closest fitting instance type.

Data Collector	c5d.1, c5d.2, c5d4	c5 instance types are compute optimized instances. These instances are designed for compute bound applications that benefit from high performance processors. The 1:2 CPU to memory ratio best matches the recommendations from our sizer.	No	To select the instance type best suited for your Data Collectors, consider the following guidance: • Select c5d.1 in a small environment monitoring around 100K items. • Select c5d.2 in a medium environment monitoring around 500K items. • Select c5d.4 in a large environment monitoring around 1000K items or an environment with intensive metrics or polling rates.	Using the sizer with the default values and 50,000 devices, the expected Data Colector sizing would be 8 cores and 16 GiB RAM. The c5d.2 fits the sizer recommendations exactly.
Performance Center MySQL Database Node	m5.1, m5.2, c5	m5 instance types provide a balance of compute, memory, and networking resources. c5 instance types are compute optimized instances. These instances are designed for compute bound applications that benefit from high performance processors.	IOPS SSD	To select the instance type best suited for your Performance Center MySQL Database Node, review the estimated memory requirements in the sizing tool. The MySQL Database Node requires storage beyond the boot disk. Amazon EBS allows you to create storage volumes and attach them to Amazon EC2 instances. Use EBS for the MySQL data directory.	Using the sizer with the default values and 50,000 devices, the expected Performance Center MySQL node sizing would be 12 cores and 32 GiB RAM. In this example, we recommend the m5.2. If you have a high user load, it might be best to use a c5.4 to help with concurrent requests made by users.

Performance Center Core Services Node	c5.4	c5 instance types are compute optimized instances. These instances are designed for compute bound applications that benefit from high performance processors.	No	To select the instance type best suited for your Performance Center Core Services Node, review the estimated CPU requirements in the sizing tool.	Using the sizer with the default values and 50,000 devices, the expected Performance Center MySQL node sizing would be 12 cores and 32 GiB RAM. In this example, we recommend the m5.2. If you have a high user load, it might be best to use a c5.4 to help with concurrent requests made by users.
CA Virtual Network Assurance	r5.2	r5 instance types are memory optimized instances. These instances are designed to deliver fast performance for workloads that process large data sets in memory. CA Virtual Network Assurance, varying based on the plugins deployed, is a memory intensive application. The r5 instance type scales best for both smaller and larger VNA deployments.	No	r5.2 is the only recommended instance type for CA Virtual Network Assurance.	
CA Spectrum SS Node	c5.2, c.5.4	c5 instance types are compute optimized instances. These instances are designed for compute bound applications that benefit from high performance processors. The 1:2 CPU to memory ratio best matches the recommendations from our sizer.	No	To select the instance type best suited for your CA Spectrum SS Node, review the estimated memory requirements in the CA Spectrum Sizing Tool.	

CA Spectrum OC Node	c5.1, c5.2, c5.4	c5 instance types are compute optimized instances. These instances are designed for compute bound applications that benefit from high performance processors. The 1:2 CPU to memory ratio best matches the recommendations from our sizer.	No	To select the instance type best suited for your CA Spectrum OC Node, review the estimated memory requirements in the CA Spectrum Sizing Tool.	

Prepare to Install Performance Center

To ensure that your NetOps Portal installation is successful, complete the requirements before you install NetOps Portal:

Verify the Prerequisites

- Review Installation Requirements and Considerations.
- The software can be installed in any filesystem to which the root user has write access. The default installation directory is /opt/CA/PerformanceCenter. The setup program lets you select another location.
- Verify that Security Enhanced Linux (SELinux) is disabled on the server where you plan to install NetOps Portal. By default, some Linux distributions enable this feature, which does not allow the product to function properly.

  NOTE
  For information about configuring an SELinux security policy, see the Red Hat documentation.
- By default, the MySQL database is installed to /opt/CA/MySql/, but you can select another location during the installation. Verify that the selected filesystem has enough allocated disk space to support a database.
- To avoid database corruption, exclude the installation directory, and all its subdirectories, from antivirus scans. Prevent scanning by a local instance of an antivirus client and scanning by a remote antivirus instance. Exclude the following directories:
  - `/opt/CA/MySql/`
  - `/opt/CA/MySql/bin`
  - `/opt/CA/MySql/data`
  - `/opt/CA/MySql/tmp`
  - `/opt/CA/PerformanceCenter`
- NetOps Portal requires DNS resolution. If DNS is not configured, add system entries to the /etc/hosts file on your server manually.
- Verify that your /tmp location has at least 4 GB of space available.
- The installer requires the zip and unzip packages. If these packages are not installed, use one of the following commands to install them:

  ```
  yum -y install zip unzip
  ```

  SLES:

  ```
  zypper install -y zip unzip
  ```
- NetOps Portal requires the wget package. If this package is not installed, use one of the following commands to install it:

  ```
  yum -y install wget
  ```

SLES:

```
zypper install -y wget
```

- Perl is required to run some of the available scripts.

Set the Limit on the Number of Open Files

Verify that the user account that is installing NetOps Portal has a value of at least 65536 on the number of open files. Set this value permanently.

> **NOTE**
>
> For systems where a sudo user installs NetOps Portal, the installation user might not have the required permissions to complete this procedure. Work with the system administrator to configure the limit.

Follow these steps:

1. Log in to the NetOps Portal host.
2. Edit the following file:
   `/etc/security/limits.conf`
3. Add the following lines to the file:

```
# Added by Performance Center
* soft nofile 65536
# Added by Performance Center
* hard nofile 65536
```

4. Restart the login session.
5. Verify that the number of open files is set properly:

```
ulimit -n
```

   The command returns the limit that you have specified.

Verify Communication Ports

NetOps Portal uses multiple ports to communicate with various components, particularly data sources. In addition, some of the products and components that integrate with NetOps Portal have specific port requirements. Consult the documentation of each data source for the list of required ports.

> **WARNING**
> For any firewall that protects this server, open the required ports and protocols for the data sources you are deploying. The product documentation for each data source provides a list of required ports and protocols.

Each data source uses unique ports.

The following communication ports allow NetOps Portal services to communicate with NetOps Portal:

- **TCP 3306**
  Enables communications to the MySQL database (inbound) from the NetOps Portal services.
- **TCP/HTTP 8481**
  Enables communications between the Device Manager and Console services.

The following communication ports allow users to contact NetOps Portal:

- **TCP/HTTP 8181**
  Enables communications between client computers and the NetOps Portal server. Enables console communications with data sources.
- **TCP/HTTP 8381**
  Enables communications between client computers and the NetOps Portal server. Also enables login using the single sign-on authentication component.

The following communication ports allow other data sources to contact NetOps Portal for eventing and OpenAPI single sign-on:

- **TCP/HTTP 8281**
  Enables communications between the Event Manager, which is installed automatically with the NetOps Portal software, and the data sources. The Data Aggregator initiates communication and pushes data through this port.
- **TCP/HTTP 8381**
  Enables communication between the Data Aggregator and NetOps Portal for direct authentication of OpenAPI queries.

The following communication ports must be open on the other data sources:

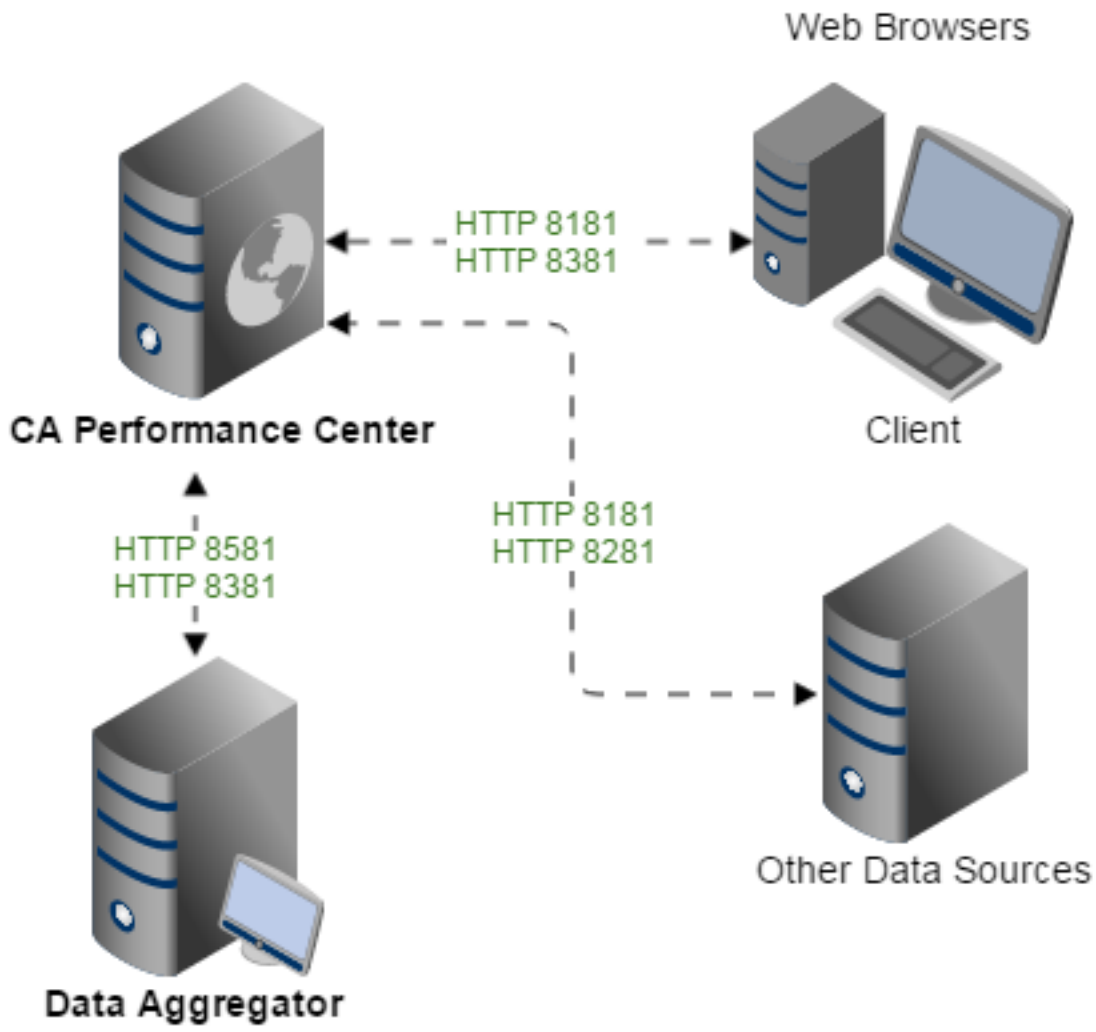
- **TCP/HTTP 80**
  Enables synchronization with CA Network Flow Analysis to retrieve configuration data.
- **TCP/HTTP 8681**
  Enables synchronization with CA Network Flow Analysis to retrieve device data.
- **TCP/HTTP 8581**
  Enables synchronization with DX NetOps Performance Management. For the Data Aggregator, NetOps Portal initiates communication and pulls data through this port.

The following diagram illustrates the default port usage:

NOTE

For DX NetOps Performance Management to work properly in a firewall-protected environment, certain ports must be open. Throughout the documentation 8182, 8382, and 61617 appear as suggested port numbers for secured communications. In the instances where these appear, you are free to use any value you want as long as no other processes are using it. For more information about firewall and connectivity considerations, see Review Installation Requirements and Considerations

Figure 5: Performance Management Ports



Verify Time Synchronization

Time synchronization using the Network Time Protocol (NTP) daemon is required for NetOps Portal and is recommended for all data source consoles. On Linux servers, the NTP daemon ensures that the clocks on the hosts are synchronized for timing purposes. Verify that the daemon is running on the NetOps Portal host server.

SLES System

Use the following procedure to verify time synchronization on an SLES system.

Follow these steps:

1. Open a console and type the following command:
   ```
   $ systemctl status ntpd
   ```
2. Verify that the NTP daemon is in an active (running) state.

3. Type the following command to start and enable the NTP daemon manually:
   ```
   $ systemctl start ntpd
   $ systemctl enable ntpd
   ```
   The daemon is started.

RHEL 7.x or OL 7.x System

RHEL 7.x and OL 7.x. run NTP with `chronyd` . Use the following procedure to verify time synchronization on a RHEL 7.x or OL 7.x system.

Follow these steps:

1. Open a console and type the following command:
   ```
   $ systemctl status chronyd
   ```
2. Verify that the `chrony` daemon is in an active (running) state.
3. Type the following command to start and enable the `chrony` daemon manually:
   ```
   $ systemctl start chronyd
   $ systemctl enable chronyd
   ```
   The daemon is started.

RHEL 6.x System

Use the following procedure to verify time synchronization on a RHEL 6.x system.

Follow these steps:

1. Open a console and type the following command:
   ```
   $ chkconfig --list ntpd
   ```
   If the NTP daemon is installed, the output resembles the following example:
   ```
   ntp 0:off 1:off 2:on 3:on 4:off 5:on 6:off
   ```
   The output indicates the runlevels where the daemon runs.
2. Verify that the current runlevel of the system (usually 3 or 5) has the NTP daemon set to 'on'. If you do not know the current runlevel, type the following commands to find it:
   ```
   $ runlevel
   N 3
   ```
   If the current runlevel does not have the NTP daemon enabled, enable it by typing the following command:
   ```
   $ chkconfig --level current_runlevel ntpd on
   ```
   Example:
   ```
   $ chkconfig --level 3 ntpd on
   ```
3. Type the following command to start the NTP daemon manually:
   ```
   $ service ntpd start
   ```
   The daemon is started.

(Optional) Configure the Sudo User Account for NetOps Portal

If you do not have root access to install and run NetOps Portal, configure the sudo user account.

Follow these steps:

1. Locate the following file on the NetOps Portal host:
   `/etc/sudoers`
2. Add a command alias with the following permissions to the file:

- /tmp/CAPerfCenterSetup.bin
- /etc/init.d/caperfcenter_console **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_devicemanager **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_eventmanager **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_sso **(for RHEL 6.x)**
- /etc/init.d/mysql
- /opt/CA/PerformanceCenter/PC/bin/caperfcenter_console **(for RHEL 7.x, SLES, OL)**
- /opt/CA/PerformanceCenter/DM/bin/caperfcenter_devicemanager **(for RHEL 7.x, SLES, OL)**
- /opt/CA/PerformanceCenter/EM/bin/caperfcenter_eventmanager **(for RHEL 7.x, SLES, OL)**
- /opt/CA/PerformanceCenter/sso/bin/caperfcenter_sso **(for RHEL 7.x, SLES, OL)**
- /opt/CA/PerformanceCenter/Tools/bin/npcshell.sh
- /opt/CA/PerformanceCenter/SsoConfig
- /opt/CA/PerformanceCenter/Uninstall_MySql
- /opt/CA/PerformanceCenter/Uninstall_PerformanceCenter
- /opt/CA/PerformanceCenter/Uninstall_SSO
- /sbin/service
- /opt/CA/MySql/bin/mysql
- /opt/CA/MySql/bin/mysqldump
- /opt/CA/PerformanceCenter/sso
- /opt/CA/PerformanceCenter/PC
- /opt/CA/PerformanceCenter/PC/webapps/pc/apps
- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Blue/images
- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images
- /usr/bin/vim
- /opt/CA/jre/bin/keytool
- /opt/CA/PerformanceCenter/RemoteEngineer/re.sh
- /opt/CA/PerformanceCentre/SslConfig

Separate the permissions with commas and place all permissions on a single line.

Example:

```
Cmnd_Alias CAPERFCENTER = /tmp/CAPerfCenterSetup.bin,/opt/CA/
PerformanceCenter/PC/bin/caperfcenter_console,/opt/CA/PerformanceCenter/
DM/bin/caperfcenter_devicemanager,/opt/CA/PerformanceCenter/EM/bin/
caperfcenter_eventmanager,/opt/CA/PerformanceCenter/sso/bin/caperfcenter_sso,/
etc/init.d/mysql,/opt/CA/PerformanceCenter/Tools/bin/npcshell.sh,/opt/CA/
PerformanceCenter/SsoConfig,/opt/CA/PerformanceCenter/Uninstall_MySql,/opt/
CA/PerformanceCenter/Uninstall_PerformanceCenter,/opt/CA/PerformanceCenter/
Uninstall_SSO,/sbin/service,/opt/CA/MySql/bin/mysql,/opt/CA/MySql/bin/mysqldump,/
opt/CA/PerformanceCenter/sso,/opt/CA/PerformanceCenter/PC,/opt/CA/PerformanceCenter/
PC/webapps/pc/apps,/opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Blue/images,/opt/
CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images,/usr/bin/vim,/opt/CA/jre/bin/
keytool,/opt/CA/PerformanceCenter/RemoteEngineer/re.sh,/opt/CA/PerformanceCentre/
SslConfig
sudouser ALL = CAPERFCENTER
```

- ***sudouser*** Specify the user who can run the sudo commands.

With the sudo user configured, add the sudo prefix to all commands to install NetOps Portal.

Example:

```
sudo ./CAPerfCenterSetup.bin
```

Configure UTF-8 Support

Configure NetOps Portal host to support UTF-8 encoding. If UTF-8 encoding is disabled, characters might not display properly during the installation.

The appropriate language packs are also required to support localized deployments.

> **NOTE**
> Some scripts that are used in the installation of selected components are not localized and run in English. For more information, see the *Localization Status Readme* file.

Follow these steps:

1. Do one of the following steps:
   a. Type the following command from a Korn or bash shell:
      `export LANG=LANG_value ; export LC_ALL=$LANG`
      LANG_value specifies the language that you want the product to support. The following variables are supported:
      - **English:** `en_US.utf8`
      - **French:** `fr_FR.utf8`
      - **Japanese**:`ja_JP.utf8`
      - **Simplified Chinese:** `zh_CN.utf8`
      - **Traditional Chinese:** `zh_TW.utf8`

      For example:
      `export LANG=zh_TW.utf8 ; export LC_ALL=$LANG`
   b. Type the following command from a Bourne Shell:
      `LANG=LANG_value ; export LANG`
      `LC_ALL=LANG_value ; export LC_ALL`
      For example:
      `LANG=zh_CN ; export LANG`
      `LC_ALL=zh_CN ; export LC_ALL`

   The language variable is set.

Install Support for Required and Non-English Fonts

For the installer to run, and for NetOps Portal to generate PDF files, follow the standard instructions for installing the necessary fonts on your operating system.

NetOps Portal and its data sources support multiple languages. The administrator can select a preferred language for each unique product operator. Language packs take advantage of operating system support for localized environments.

Product operators with some language preferences may not be able to view dashboard data in reports by default. To support these language preferences, install the fonts on the NetOps Portal host.

Follow these steps:

1. Log in to the NetOps Portal host.
2. Run one of the following commands to install the fonts:
   `yum groupinstall fonts`
   SLES:
   ```
   zypper install dejavu-sans-fonts dejavu-fonts-common arphic-ukai-fonts arphic-uming-fonts ipa-ex-mincho-fonts ipa-mincho-fonts ipa-pmincho-fonts xano-mincho-fonts baekmuk-bitmap-fonts baekmuk-ttf-fonts liberation-fonts
   ```
3. Run the following command to rebuild the font caches:

```
fc-cache –v
```

SLES:

```
fc-cache -fv
```

4. Restart NetOps Portal.

Install Performance Center

After you have met the requirements to install NetOps Portal, complete the installation as follows:

MySQL Password Requirements (3.7.3 and Higher Only)

As a step toward enhanced security, the Performance Center installation prompts you to set a custom MySQL password.

The MySQL password must meet the following requirements:

- Excludes the user names "root" or "netqos"
- Minimum length of 8 characters
- Maximum length of 30 characters
- Contains at least 3 of the following types of characters:
  - Special Characters (!#&?)
  - Uppercase
  - Lowercase
  - Numbers (0-9)
- Excludes the percentage sign (%), apostrophe ('), or quotation mark (")
- **(3.7.3 through 3.7.4 Only)** Excludes the asterisk (*), or the dollar sign ($)

Install NetOps Portal

Select one of the following options:

Install from the Command Line

Use the NetOps Portal Setup program to install and configure the database and website. The Setup program supports two types of installations. Select one of the following types during installation:

- **Complete:** Installs NetOps Portal services and the MySQL database on a single node.
- **Advanced:** Installs NetOps Portal services and the MySQL database on separate nodes for better performance. First, run the Setup program to install the database. Then, run the Setup program on a different node to install the services.

Follow these steps:

1. Log in to the NetOps Portal host as the root or the `sudo` user.
2. Copy the `CAPerfCenterSetup.bin` file to the `/tmp` directory.

   NOTE
   Verify that your `/tmp` location has at least 4 GB of space available.
3. Change to the `/tmp` directory by issuing the following command:
   ```
   cd /tmp
   ```
4. Change the permissions for the installation file by issuing the following command:
   ```
   chmod +x CAPerfCenterSetup.bin
   ```
5. Run the installation file by issuing the following command:
   ```
   ./CAPerfCenterSetup.bin -i console
   ```

6. Follow the instructions in the console.

   NOTE
   You are prompted to specify an install owner. You can specify a non-root user.

   The installation checks to see whether the partition with the MySQL data directory has enough disk space to handle storage engine upgrades. If there does not appear to be enough disk space to complete the installation successfully, exit the installer, allocate more space for the data partition, and reinstall NetOps Portal.

   (3.7.2 and Higher Only) As a step toward enhanced security, the Performance Center installation prompts you to set a custom MySQL password.

   The installation runs. The following Linux daemons are created and started during the installation:
   - **caperfcenter_console**
     The console daemon. Uses port 8181.
   - **caperfcenter_devicemanager**
     The Device Manager daemon. Uses port 8481.
   - **caperfcenter_eventmanager**
     The Event Manager daemon. Uses port 8281.
   - **caperfcenter_sso**
     The Single Sign-On daemon. Uses port 8381.
   - **mysql**
     The database daemon. Uses port 3306.

   When the installation has completed, a message states that the program has been installed successfully.

Install in Silent Mode

To install NetOps Portal without entering user inputs, install the component in silent mode.

Follow these steps:

1. Log in to the NetOps Portal host as the root or the sudo user.
2. Copy the `CAPerfCenterSetup.bin` file to the `/tmp` directory.

   NOTE

   Verify that your `/tmp` location has at least 4 GB of space available.
3. Change to the `/tmp` directory by issuing the following command:
   ```
   cd /tmp
   ```
4. Change the permissions for the installation file by issuing the following command:
   ```
   chmod +x CAPerfCenterSetup.bin
   ```
5. Run the following command on all servers where you want to install NetOps Portal:
   ```
   ./CAPerfCenterSetup.bin -r /tmp/silent.properties
   ```
6. Follow the prompts until you get to the summary, type `quit` , and then press the return key on your keyboard.
   The `silent.properties` file is created in the `/tmp` directory.
7. Review the `/tmp/silent.properties` file.
8. If present, confirm the values for the following variables in the `silent.properties` file:
   - **USER_INPUT_INSTALL_OWNER**
     Designates a user as the install owner. You can specify a non-root user.
     Default: `root`
   - **USER_INSTALL_DIR**
     Designates the directory where the application is installed.

Default: /opt/CA

- **MYSQL_DATA_FOLDER**
  Designates the location for the MySQL data directory.
  Default: /opt/CA/MySql/data
- **MYSQL_TEMP_FOLDER**
  Designates the location for the directory to store MySQL temporary files.
  Default: /opt/CA/MySql/tmp
- **DB_PASSWORD_VARIABLE**
  Designates the MySQL password.
- **DB_PASSWORD_CONFIRM**
  Confirms the MySQL password.

9. Run the following command on all servers where you want to install NetOps Portal:
   ```
   ./CAPerfCenterSetup.bin -i silent -f /tmp/silent.properties
   ```
   The installation begins.
   An empty prompt indicates that components have been installed.

Verify the Installation

NetOps Portal requires the following Linux daemons:

service_name	Description
`mysql`	Database process
`caperfcenter_devicemanager`	Device Manager process
`caperfcenter_console`	NetOps Portal console process
`caperfcenter_sso`	Single Sign-On process
`caperfcenter_eventmanager`	Event Manager process

After a successful installation, the services listed in this table are running. Check the status of a daemon by issuing the following command:

```
service service_name status
```

Access NetOps Portal at the following URL:

```
http://PC_host:8181/pc/desktop/page
```

- **PC_host** is the hostname or IP address of the NetOps Portal host.

  NOTE
  8181 is the default port. If you specified a different port during the installation, use the custom port number.

If the NetOps Portal login screen appears, Performance center has installed successfully.

IMPORTANT
At the initial login, you are required the change the **admin** and **user** passwords. We recommend that you change these passwords immediately after a fresh install.

If you have Network Flow Analysis as a data source, you must restart the CA NFA OData Service:

1. Click **Administration Services**, and then **Services**.
2. Right-click the **CA NFA OData Service**.
3. Click **Restart**.

(Optional) Review Log Files

The following log files help you track events that occur during the installation:

Installation Errors and Configuration Events

`/opt/CA/PerformanceCenter/InstallLogs`

During the installation, a history file that indicates the installed version is generated in this directory.

Device Manager Daemon

`/opt/CA/PerformanceCenter/DM/logs`

Website and Console Errors

`/opt/CA/PerformanceCenter/PC/logs`

MySQL Database Errors

`/opt/CA/MySql/data/<hostname>.err`

Event Manager (Other Events)

`/opt/CA/PerformanceCenter/EM/logs`

User Authentication (Single Sign-On)

`/opt/CA/PerformanceCenter/sso/logs`

Prepare to Install the Data Repository

To ensure that your Data Repository installation is successful, complete the requirements before you install Data Repository:

For more information about Data Repository configuration options and administration, see Data Repository Administration.

Verify the Prerequisites

Verify the following prerequisites before you install Data Repository:

- Review Installation Requirements and Considerations.
- Review the Vertica documentation.
- Verify whether the dialog and chrony packages are installed on each Data Repository host:

  NOTE

  The chrony package is required only for RHEL 7.x and OL 7.x.

  ```
  rpm -qa | grep ^dialog
  rpm -qa | grep ^chrony
  ```

  If either command does not return results, install the package:

  NOTE

  If you are not the root user, use the sudo prefix.

  ```
  yum install dialog
  yum install chrony
  ```

  If this package is not installed, the validation and installation scripts fail.
- The installer requires the zip and unzip packages. If these packages are not installed, use the following command to install them:

```
yum -y install zip unzip
```

- Verify that you have at least 2 GB of swap space on Data Repository host.
- Verify that the Data Repository hosts use the ext4 file system. Vertica does not support XFS or btrfs. All disks with Vertica should use ext4.

  WARNING

  The default file system for RHEL 7.x and OL 7.x is the XFS file system. The default file system for SLES is btrfs. Vertica does not support XFS or btrfs. The database performs best with the ext4 file system.
- Verify that the following ports are open on the Data Repository systems:
  - Port 22 (TCP protocol)
  - Port 4803 (TCP and UDP protocol)
  - Port 4804 (UDP protocol)
  - Port 5433 (TCP protocol)
    Remote access is required to this port.
  - Port 5434 (TCP protocol)
  - Port 6543 (UDP protocol)
- To avoid database corruption, exclude the installation directory, and all its subdirectories, from antivirus scans. Prevent scanning by a local instance of an antivirus client and scanning by a remote antivirus instance. Exclude the following directories:
  - /opt/vertica/*
  - /opt/vconsole/*
  - The specified data directory
    Default: /drdata/data
  - The specified catalog directory
    Default: /drdata/catalog
  - Vertica temporary files in /tmp
    - /tmp/4803
    - /tmp/vbr/*
  - The directory where you back up the Data Repository
- If a file named 'release' appears in the /etc directory, remove it. Otherwise, the Data Repository installation fails.
- Verify the access according to your installation type:
  - **Single Node:** Root access is required to install Data Repository. Determine whether you can install Data Repository as root.
  - **Cluster:** Verify that the root user or sudo user can create database administrator user accounts, or can have an administrator create these accounts.
- Verify that CPU frequency scaling is disabled. Disable CPU frequency scaling through the host system BIOS and OS settings.

  NOTE

  If CPU frequency scaling is enabled, you might experience inconsistent performance for similar queries in Vertica. CPU frequency scaling can cause observable slowness and variation in dashboard loading.
- Verify that you are not using Logical Volume Manager (LVM) for /data and /catalog directories.
- (Cluster only) Verify all the hosts in the cluster are in the same subnet.
- (Cluster only) Verify that the root user can use Secure Shell (SSH) to log in (ssh) to all the hosts in the cluster.

  NOTE

  Set up SSH for the root user for the Data Repository installation or upgrade.
- The default shell environment must be `bash` .
- (Cluster only) Select the hosts where you install Data Repository nodes.

WARNING
Warning! Database software is deployed on each participating host in a cluster. This software represents a 'node' in the cluster. A three-node cluster represents the simplest configuration that can tolerate the loss of a single node. You can, however, include more than three hosts in the cluster. If more than one node fails or shuts down, Data Repository is no longer available for use and Data Aggregator shuts down automatically.

Install the Data Repository on VMs

For best performance, install the Data Repository in a bare-metal environment. However, if you install the Data Repository in VMware virtual machines, verify the following requirements:

- Use VMware version 5.5 or greater.
- The number of VMs per host does not exceed the number of physical processors.
- Pre-allocate and reserve 4 GB of memory for each of the VMs.
- Each VM has a dedicated 10 GB NIC.
- Disable CPU frequency scaling at the host level and for each VM.
- Disable VMotion. VMotion can disrupt communication, and can cause the Data Repository to shut down.
- Set the VMware parameters for hugepages to the version 5.5 default values.
- Verify the hardware and network performance. Use the Vertica diagnostic tools described bellow to verify performance.

For more information about running Vertica on VMs, see the Vertica documentation.

Install the Data Repository on Shared Storage (SAN)

To install the Data Repository on SAN, verify the following requirements:

- The hosts have no contention for disk space or bandwidth.
- Each host has a unique catalog and data location. The hosts cannot share the location for these directories.
- The storage has enough I/O bandwidth for each node to access the storage independently. To verify the I/O bandwidth, simultaneously run vioperf from all hosts in the Data Repository cluster. For more information, see the following procedures.

Set a Unique Hostname for Each Data Repository Host

Set a unique hostname for each Data Repository host in the cluster.

Follow these steps:

1. As the root user, log in to each Data Repository host, and verify the unique hostname.
   The hostname must be associated with the IP address and *not* the loopback address of 127.0.0.1.
2. Verify that the following lines appear in the /etc/hosts file on each computer:
   ```
   Do not remove the following line, or various programs
   # that require network functionality will fail.
   127.0.0.1   localhost localhost.localdomain localhost4 localhost4.localdomain4
   ::1         localhost localhost.localdomain localhost6 localhost6.localdomain6
   IP address of your hostYourHostName YourHostName.domain
   ```
3. If you change the file, run the following command:
   ```
   service network restart
   ```
   The /etc/hosts file is configured correctly.
   The unique host name is set.
4. (Cluster installations only) The hostnames of all hosts in the cluster must resolve correctly. If the hostname resolution is incorrect, the Data Repository cluster does not install or work properly. All participating hosts in the cluster must use

static IP or permanently leased DHCP addresses. Set up the /etc/hosts file on each of the hosts you selected for the cluster. The hosts file must contain entries for all hosts in the cluster.
Example: This example shows the /etc/hosts file for a cluster where the hosts are named host01, host02, and host03:

```
127.0.0.1 localhost.localdomain localhost
192.168.13.128 host01.domain host01
192.168.13.129 host02.domain host02
192.168.13.130 host03.domain host03
```

NOTE
Do not remove the loopback address (127.0.0.1) line. The local Data Repository hostname cannot be on the 127.0.0.1 line. Also, do not use the loopback address or localhost name when you are defining hosts in the cluster.

5. Verify that hostname resolution works for each host in the cluster.
   For example, on host01, the following syntax is correct:

```
$ /bin/hostname -f
host01
```

   Hostname resolution is configured.

(Optional) Set Up Passwordless SSH for the Root or Sudo User

The hosts in a Data Repository cluster require passwordless ssh for the root or sudo user during the Data Repository installation or upgrade. The `dr_validate.sh` script sets up passwordless SSH, but requests the password many times. To avoid repeatedly specifying the root or sudo user password, set up passwordless ssh before you run the validation script.

Repeat this procedure for each pair of hosts. If you have passwordless ssh set up for the root user, but you do not have root access to install and run the Data Repository, configure a sudo user account. You also have an alternative method to install the product without requiring to enter the root password by using the sudo user account. For more information about configuring the passwordless sudo user account for Data Repository, see the section Configure the passwordless Sudo User Account for Data Repository.

NOTE

Passwordless SSH is automatically set up for the Data Repository admin user when you install the Data Repository.

Follow these steps:

1. Open a console and log in to the Data Repository host as the root or sudo user.
2. Run the following commands:

```
ssh-keygen -N "" -t rsa -f ~/.ssh/id_rsa
cat ~/.ssh/id_rsa.pub >> ~/.ssh/authorized_keys2
chmod 644 ~/.ssh/authorized_keys2
```

3. Copy the root or sudo user public key into the list of authorized keys on the remote hosts:

```
ssh-copy-id -i user@remotehost
```

   remotehost specifies a host in the cluster where you are copying the SSH ID.
4. To verify that passwordless ssh is set up correctly, log in to the remote host from the local host:

```
ssh user@remotehost ls
```

   If the passwordless SSH has been set up successfully, you are not prompted for a password. You also see a directory listing from the ‘ls command’.

(Optional) Configure the Sudo User Account for the Data Repository

If you have passwordless ssh set up for the root user, but you do not have root access to install and run the Data Repository, configure a sudo user account.

For cluster environments, complete this procedure on each host in the cluster.

Follow these steps:

1. Locate the following file:
   `/etc/sudoers`
2. Add a command alias with the following permissions to the file:

```
Cmnd_Alias CA_DATAREP = /tmp/installDR.bin,/opt/CA/IMDataRepository_vertica9/
dr_validate.sh,/opt/CA/IMDataRepository_vertica9/dr_install.sh,/usr/bin/vim,/usr/bin/
reboot,/usr/bin/yum,/opt/CA/IMDataRespository_vertica9/RemoteEngineer/re.sh
## Allows the Data Repository user to manage the Data Repository
sudouser ALL = CA_DATAREP
```

- ***sudouser*** Specify the user who can run the sudo commands.

This command alias details the commands that the sudo user must be able to run.
With the sudo user configured, add the sudo prefix to all commands to install the Data Repository.
Example:

```
sudo ./installDR.bin
```

(Optional) Configure the Passwordless Sudo User Account for the Data Repository

Due to certain security policies, in some environments, you cannot enable passwordless SSH for the root users on the host servers. The following procedure provides you an alternative method to install the product without requiring that level of access by using the sudo user account.

> **NOTE**
>
> This functionality is not supported on RHEL 6.x

1. Locate the following file:
   /etc/sudoers
2. Add command aliases with the following permissions to the file:

- On RHEL 7

```
Cmnd_Alias CA_DATAREP=/opt/vertica/sbin/install_vertica,/tmp/installDR.bin,/opt/
CA/IMDataRepository_vertica9/dr_validate.sh,/opt/CA/IMDataRepository_vertica9/
dr_install.sh,/usr/bin/vim,/usr/bin/reboot,/opt/CA/IMDataRespository_vertica9/
RemoteEngineer/re.sh,/bin/mkdir*,/usr/bin/whoami,/bin/echo,/sbin/service,/bin/grep,/
usr/bin/test,/sbin/iptables,/opt/vertica/oss/python/bin/python,/usr/bin/tee,/usr/
sbin/ntpd,/etc/init.d/ntpd,/sbin/blockdev,/etc/init.d/sshd,/etc/sysconfig/sshd,/etc/
ssh/sshd_config,/bin/su,/usr/sbin/sshd restart,/usr/bin/ssh,/bin/df,/bin/mv,/bin/rm,/
usr/bin/install

Cmnd_Alias VERTICA = /opt/vertica/bin/,/opt/vertica/sbin/,/opt/vertica/oss/python/
bin/
```

```
Cmnd_Alias VERTICA_INSTALL = /bin/echo,/bin/ps -A,/bin/cp /opt/vertica/config/
admintools.conf /opt/vertica/config/admintools.conf.bak.*,/bin/rm -rf /tmp/
dbRPM.rpm,/bin/df --portability /tmp,/usr/bin/install --owner * --mode 700 -d *,/bin/
mv -f /tmp/vstage-*/file /tmp/*,/bin/rm -rf /tmp/vstage-*,/usr/bin/id *,/bin/cp -T /
opt/vertica/* /tmp/vstage-*,/bin/su --login dbadmin *,/bin/mkdir -p /opt/vertica/*,/
bin/touch /opt/vertica/*,/bin/rm -rf /opt/vertica/*,/bin/mv -f /tmp/vstage-* /opt/
vertica/*,/bin/mkdir -p /opt/vertica/*,/bin/touch /opt/vertica/config/users/dbadmin/
agent.conf,/bin/su dbadmin *,/bin/sh -c *,/usr/bin,/opt/vertica/share/binlib/test/*,/
usr/bin/su dbadmin,/bin/test [ -e /* ],/usr/bin/[ -e /* ]

Cmnd_Alias USEFUL = /usr/bin/lshw,/usr/bin/yum,/bin/rpm,/sbin/reboot,/sbin/shutdown,/
usr/bin/cpan,/bin/chgrp,/bin/chmod,/bin/chown,/bin/mnt,/usr/bin/test,/bin/[,/sbin/
service

## Allows the Data Repository user to manage the Data Repository
sudouser ALL = CA_DATAREP, VERTICA , VERTICA_INSTALL , USEFUL

Defaults env_keep +="VERT_DBA_USR VERT_DBA_HOME VERT_DBA_GRP VERT_DBA_DATA_DIR
 _ENV_VPWD_VAR"
```

- On SLES 12

```
Cmnd_Alias CA_DATAREP =/opt/vertica/sbin/install_vertica,/tmp/installDR.bin,/opt/
CA/IMDataRepository_vertica9/dr_validate.sh,/opt/CA/IMDataRepository_vertica9/
dr_install.sh,/usr/bin/vim,/usr/bin/reboot,/opt/CA/IMDataRespository_vertica9/
RemoteEngineer/re.sh,/usr/bin/mkdir, /sbin/SuSEfirewall2 off *,/usr/bin/whoami,/
usr/bin/echo,/usr/bin/id,/usr/bin/env,/usr/sbin/service,/usr/bin/grep,/usr/bin/
test,/sbin/iptables,/opt/vertica/oss/python/bin/python,/usr/bin/tee,/usr/sbin/

```

```
Cmnd_Alias USEFUL = /usr/bin/lshw,/usr/bin/yum,/bin/rpm,/sbin/reboot,/sbin/shutdown,/
usr/bin/cpan,/bin/chgrp,/bin/chmod,/bin/chown,/bin/mnt,/usr/bin/test,/bin/[,/sbin/
service

## Allows the Data Repository user to manage the Data Repository
sudouser ALL = CA_DATAREP, VERTICA , VERTICA_INSTALL , USEFUL

Defaults env_keep +="VERT_DBA_USR VERT_DBA_HOME VERT_DBA_GRP VERT_DBA_DATA_DIR
 _ENV_VPWD_VAR"
```

Install the Data Repository

After you meet the prerequisites described in Prepare to Install the Data Repository, complete the installation as follows:

NOTE
You can install the database with root user passwordless SSH or with sudo user passwordless SSH configured.

The following video shows the installation process:

The Data Repository installation creates two users. A third user is created when you install the data aggregator. The following table provides information about these users:

New User Example	Password Example	Operating System User Account?	Vertica Database User Account?	Notes	Permissions
dradmin	drpass	Yes	Yes	This user is the first user that you created when you installed the Data Repository. When this user is created, the verticadba group is also created. This user is added to this group.	This user can run the Data Repository processes and the Administration Tools utility. This user owns Data Repository catalog files, data files, and so on.
dauser	dbpassword	No	Yes	This useris the user that the data aggregator uses to interact with the database. The installation script creates this user during the data aggregator installation.	

NOTE
Vertica includes the verticadba group for tighter control over filesystem access in the `/opt/vertica/` directories. During the installation, the verticadba group is created, and existing users are added to the group

with permissions set to 775. This setting grants full privileges to the verticadba group and read/execute privileges to all other users. The `/opt/vertica/log` and `/opt/vertica/config` directories are the folders with the modified permissions.

Install the Database with Root User Passwordless SSH

To set up the Data Repository, you can install and configure the Vertica database as the root user or sudo user that has or will have passwordless SSH configured.

In a cluster installation, initiate the Data Repository installation from any of the hosts that participates in the cluster. The instation pushes the required software components to the additional nodes.

Follow these steps:

1. Log in to any host in the Data Repository cluster as the root user.
2. Copy the `installDR.bin` file locally.
3. Change permissions for the installation file by issuing the following command:
   ```
   chmod u+x installDR.bin
   ```
4. Extract the installation file using one of the following options:
   - As the root user by issuing the following command:
     ```
     ./installDR.bin
     ```
   - As the sudo user by issuing the following command:
     ```
     sudo ./installDR.bin
     ```

     NOTE
     The `installDR.bin` file extracts the Data Repository rpm, the license file, and the three installation scripts. You install the Data Repository later in this procedure.
5. Follow the instructions in the console.
6. When prompted, specify the installation directory to which to extract the Data Repository installation package and Vertica license file. The default installation directory is `/opt/CA/IMDataRepository_vertica`*`Version`*`/` . Press the Return key on your keybaord twice.

   NOTE
   The installation script generates WARN messages for any LVM present in the environment. For help, contact Support.

   The Data Repository installation package, license file, and associated setup scripts are extracted to the chosen directory.
7. Adjust the following parameters in the `drinstall.properties` file to reflect your installation-specific values. This file applies to `dr_validate.sh` and `dr_install.sh` . The `drinstall.properties` file exists in the installation directory that you specified previously.
   - DbAdminLinuxUser
     The Linux user that is created to serve as the Vertica database administrator.
     Default: dradmin
   - DbAdminLinuxUserHome
     The Vertica Linux database administrator user home directory.
     Default: `/export/dradmin`

     NOTE
     This directory is created if the Vertica installer creates the user. Ensure that the directory leading up to the home account already exists on the system. For example, if you are using `/export/dradmin` , be sure that `/export` exists.
   - DbDataDir
     The location of the data directory.

Default: `/data`

IMPORTANT
Do not use the Logical Volume Manager (LVM) for the data directory.

- DbCatalogDir
  The location of the catalog directory.
  Default: `/catalog`

  IMPORTANT
  Do not use the Logical Volume Manager (LVM) for the catalog directory.
- DbHostNames
  The comma-delimited list of hostnames for the Data Repository.
  Default: yourhostname1,yourhostname2,yourhostname3
- DbName
  The database name.
  Default: drdata

  NOTE
  This parameter is case-sensitive.
- DbPwd
  The database password.
  Default: dbpass

  NOTE
  The `dr_install.sh` installation script uses the database password that you define here during the installation of the data aggregator. You can use special characters (except for single quotation marks) in passwords. To use special characters, encase the password with single quotation marks (for example, `DbPwd='test$tr|ng'`). If the script does not find the `DbPwd` property or if it is blank, the script prompts for this information at runtime.

8. Run the `dr_validate.sh` validation script. This script verifies the OS settings and modifies the settings if necessary. To run the validation script as the root user, issue the following command:
   `./dr_validate.sh -p` *`properties_file`*

   The validation script establishes SSH without a password for the root user across all hosts in a cluster. If SSH without a password does not exist for the root account, you are prompted for a password. You are sometimes prompted multiple times.

   TIP
   You can use the `-l` flag to allow `localhost` as the value for the `DbHostNames` property. You can use the `-n` flag to skip database connectivity checks.
9. Review any on-screen output for failures or warnings. You can run the validation script multiple times after you fix any failures or warnings. The script automatically corrects many failures or warnings. Proceed only if the final status is “PASSED”. If the final status is not "PASSED", contact Support.
   The validation script might ask you to reboot.

   NOTE
   The validation script and the installation script generate a log file in the *`installation_directory`*`/logs` directory on the Data Repository host from which you run the scripts. These log files include the step-by-step output of the scripts. To validate successful/failed script runs, review the script output.

   The following example shows the script output and lists what settings the script verifies and changes:

```
Log File: logs/install_log_validate_10-29-2015_11-14-11.log
================================================================================

Fresh install of Vertica is being performed - skipping database connectivity testing.

Data Repository Prerequisite Compliance Status on host verticahost-dr -- PASSED
```

```
================================================================================
Script finished - /user/home/verticahost/dr_validate.sh
================================================================================
```

NOTE
If the `dr_install.sh` installation fails early enough in the process, the log file might be available in the home directory of the root or sudo user.

10. Run the `dr_install.sh` installation script:
    `./dr_install.sh -p properties_file`
    This script installs the data repository, creates the database, and disables unnecessary Vertica processes on all the hosts in the cluster.
    If the database administrator user does not already exist, the installation script creates the user. The script prompts you to assign a new password. If the database administrator user exists, but passwordless SSH is not set up, the script prompts for the password to set up.
    If the installation script returns a WARN message for LVM on directories that Vertica does not use, contact Support.
11. Verify that the installation script has installed the Data Repository successfully by doing the following steps:
    a. Log in to the database server as the database administrator user by issuing the following command:
       `su - dradmin`
    b. Issue the following command:
       `/opt/vertica/bin/adminTools`
       The Administration Tools dialog opens.
    c. Select **(1) View Database Cluster State**, and then select **OK** or press the return key on your keyboard.
       The database name appears and the State is reported as UP.
    d. Select **OK** to acknowledge that the database is UP.
    e. Select **(E) Exit**, and then press the return key on your keyboard.

NOTE
If the database does not start automatically, to avoid the data aggregator installation failure, start the database manually by selecting **Start DB**.

Install the Database with Sudo User Passwordless SSH Configured

To set up the Data Repository, you can install and configure the Vertica database as the sudo user.

NOTE
RHEL 6.x does not support this functionality.

Follow these steps:

1. Log in to *each* node in the data repository cluster as the sudo user.
2. Copy the `installDR.bin` file locally.
3. Change permissions for the installation file by typing the following command:
   `chmod u+x installDR.bin`
4. Extract the installation file as the sudo user by issuing the following command:
   `sudo ./installDR.bin`

   NOTE
   The `installDR.bin` file extracts the Data Repository rpm, the license file, and the three installation scripts. You install the Data Repository later in this procedure.
5. Follow the instructions in the console.
6. When prompted, specify the installation directory to extract the Data Repository installation package and Vertica license file to. When you are installing the Data Repository using the sudo user account with passwordless SSH, after

extracting, you must run the installation on *each* host in the cluster using the same location. The default installation directory is `/opt/CA/IMDataRepository_vertica*Version*/` . Press Enter twice.

NOTE

The script generates WARN messages for any LVM present in the environment. For help, contact CA Support.

The Data Repository installation package, license file, and associated setup scripts are extracted to the chosen directory.

7. Adjust the following parameters in the `drinstall.properties` file to reflect your installation-specific values. This file applies to the `dr_validate.sh` and `dr_install.sh` scripts. The `drinstall.properties` file exists in the installation directory that you specified previously.
   - DbAdminLinuxUser
     The Linux user that is created to serve as the Vertica database administrator.
     Default: dradmin
   - DbAdminLinuxUserHome=*The Vertica Linux database administrator user home directory*
     Default: /export/dradmin

     NOTE
     This directory is created if the Vertica installer creates the user. Be sure that the directory leading up to the home account already exists on the system. For example, if you are using /export/dradmin, be sure that /export exists.
   - DbDataDir=*The location of the data directory*
     Default: /data

     NOTE
     Do not use the Logical Volume Manager (LVM) for the data directory.
   - DbCatalogDir=*The location of the catalog directory*
     Default: /catalog

     NOTE
     Do not use the Logical Volume Manager (LVM) for the catalog directory.
   - DbHostNames=*The list of hostnames for Data Repository*
     Default: yourhostname1,yourhostname2,yourhostname3

     NOTE
     For this step, list the local hostname only. You add all other nodes in a later step.
   - DbName=*The database name*
     Default: drdata

     NOTE

     This parameter is case-sensitive.
   - DbPwd=*The database password*
     Default: dbpass

     NOTE
     The database password that you define here is used during the installation of the data aggregator. You can use special characters (except for single quotation marks) in passwords. To use special characters, encase the password with single quotation marks (for example, `DbPwd='test$tr|ng'`). If the `DbPwd` property is not found or blank, the script prompts for this information at runtime.
8. Run the validation script with the `-sp` command line argument on *each* node:

```
sudo ./dr_validate.sh -sp properties_file
```

TIP
You can use the `-l` flag to allow `localhost` as the value for the `DbHostNames` property. You can use the `-n` flag to skip database connectivity checks.

9. Review any on-screen output for failures or warnings. You can run this script multiple times after you fix any failures or warnings. The script automatically corrects many failures or warnings. Proceed only if the final status is “PASSED”. If the final status is not "PASSED", contact Support.
   The validation script may ask you to reboot.

   NOTE
   The validation script and the installation script generate a log file in *installation_directory*`/logs` on the Data Repository host from which you run the scripts. These log files include the step-by-step output of the scripts. To validate successful/failed script runs, review the script output.

   The following example shows the script output and lists what settings the script verifies and changes:

```
Log File: logs/install_log_validate_10-29-2015_11-14-11.log

Data Repository Prerequisite Compliance Status on host verticahost-dr -- PASSED
================================================================================
Script finished - /user/home/verticahost/dr_validate.sh
================================================================================
```

NOTE
If the installation fails early enough in the process, the log file might be available in the home directory of the root or sudo user.

10. Repeat the previous steps for *each* node.
11. Go to the first node and edit the `DbHostnames` parameter in the `drinstall.properties` file to include *all* the nodes in the cluster.
12. Run the installation script with the `-sp` command line argument:
    ```
    sudo ./dr_install.sh -sp properties_file
    ```
    NOTE
    To run the script as sudo, passwordless SSH (public key) must be set up for the sudo account between the Data Repository hosts. If passwordless SSH does not exist for the sudo account, you cannot proceed. For more information, see Prepare to Install the Data Repository.

    This script installs the Data Repository, creates the database, and disables unnecessary Vertica processes on all the hosts in the cluster.

    NOTE
    If the database administrator user does not already exist, the installation script creates the user. The script prompts you to assign a new password. If the database administrator user exists, but passwordless SSH is not set up, the script prompts for the password to set up.

    If the installation script returns a WARN message for LVM on directories that Vertica does not use, contact Support.
13. Verify that Data Repository has been installed successfully by doing the following steps:
    a. To log in to the database server as the database administrator user, issue the following command:
       ```
       su - dradmin
       ```
    b. Issue the following command:
       ```
       /opt/vertica/bin/adminTools
       ```
       The Administration Tools dialog opens.
    c. Select **(1) View Database Cluster State**, and then select **OK** or press Enter.
       The database name appears and the State is reported as UP.

d. Select **OK** to acknowledge that the database is UP.
e. Select **(E) Exit**, and then press Enter.

NOTE
If the database does not start automatically, select Start DB to start the database manually. If the database is not started, the Data Aggregator installation fails.

(Optional) Secure Data Repository

To limit the users who can log in to the database to only the Data Repository administrative account and the root user, lock down the database.

Follow these steps:

1. Modify the `/etc/pam.d/sshd` file by adding the following entry, for the PAM access module, after the "account required pam_nologin.so" entry:
   ```
   account required pam_access.so accessfile=/etc/security/sshd.conf
   ```
   NOTE
   If the `/etc/security/sshd.conf` file is missing, you must create it using the SSHD documentation.
2. If the following line from the `/etc/security/access.conf` file exists, remove it:
   ```
   -:ALL EXCEPT database_admin_user root:LOCAL
   ```
   For example:
   ```
   -:ALL EXCEPT dradmin root:LOCAL
   ```

Configure Log Rotation for Data Repository

To prevent the underlying Data Repository log file (`vertica.log`) from becoming too large, configure log rotation for Data Repository. The recommended configuration for the log rotation is a daily rotation with logs retained for 21 days.

WARNING
Configuring the log rotation is required. The `vertica.log` file can grow substantially.

Follow these steps:

1. Log in to the database server for Data Repository as the database administrator user by issuing the following command:
   ```
   su - dradmin
   ```
2. Issue the following command:
   ```
   /opt/vertica/bin/admintools -t logrotate -d database_name -r frequency -k number
   ```
   – **-d** indicates the database name.

   NOTE
   This parameter is case-sensitive.
   – **-r** specifies how often to rotate the daily logs.
   Values: daily, weekly, monthly
   – **-k** specifies how many logs to keep according to the frequency. For example, if the frequency is weekly, a value of 3 keeps three weeks of daily log files.
   Example:
   ```
   /opt/vertica/bin/admintools -t logrotate -d drdata -r daily -k 14
   ```
3. (Optional) To verify that the vertica.log rotation has been configured correctly, look at the new gzipped vertica.log files in the Vertica catalog directory for previous days. The log files use the following filename format:
   `vertica.log.YYYYMMDD.gz`

Set Up Automatic Backups of Data Repository

To preserve your data against failures, set up automatic backups of the Data Repository.
For more information, see Back Up the Data Repository.

Prepare to Install the Data Aggregator

To ensure that your Data Aggregator installation is successful, complete the requirements before you install Data Aggregator:

Verify the Prerequisites

Meet the following prerequisites before installing Data Aggregator:

- Review Installation Requirements and Considerations.
- Verify that Data Repository installation is complete and the service is running.
- Verify that port numbers 8581, 61616, 61618, 61620, and 61622 are open on the Data Aggregator system. Remote access is required to these ports.

  NOTE
  Throughout the documentation 8182, 8382, 61617, 61619, 61621, and 61623 appear as suggested port numbers for secured communications. In the instances where these ports appear, you are free to use any value you want as long as no other processes are using it. You can change port 616xx to another port after you install the Data Aggregator. For more information, see Complete the Post-Installation Configuration.
- Verify that ports 1099 and 11099 are blocked from external access.
  These ports must remain open locally for internal communication.
- Verify that Security Enhanced Linux (SELinux) is disabled or permissive on the computer where you are going to install Data Aggregator. By default, some Linux distributions have this feature enabled, which does not allow Data Aggregator to function properly. Disable SELinux, set to permissive, or create a policy to exclude Data Aggregator processes from SELinux restrictions. If you would like Security Enhanced Linux (SELinux) to be enforcing, consult the Red Hat documentation.

  NOTE
  For information about configuring an SELinux security policy, see the Red Hat documentation.
- To avoid potential corruption of data, exclude the installation directory, the backup directory, and all subdirectories, from antivirus scans. Prevent scanning by a local instance of an antivirus client and scanning by a remote antivirus instance. For more information about Data Aggregator backups, see Back Up Data Aggregator.
- Verify that the directory where you are going to install has write privileges for your Data Aggregator user.
- The installer requires the zip and unzip packages. If these packages are not installed, use one of the following commands to install them:

  ```
  yum -y install zip unzip
  ```

  SLES:

  ```
  zypper -y install zip unzip
  ```
- For a fault tolerant environment, verify that proxy server is installed. For more information, see Install or Uninstall the Proxy Server.

(Optional) Configure the Sudo User Account for Data Aggregator

If you do not have root access to install and run the Data Aggregator, configure the sudo user account.

Follow these steps:

1. Locate the following file on the Data Aggregator host:

```
/etc/sudoers
```

2. Add one of the following command aliases with the following permissions to the file:

```
Cmnd_Alias CA_DATAAGG = /tmp/installDA.bin,/sbin/service dadaemon *,/opt/
IMDataAggregator/Uninstall/Uninstall, /opt/IMDataAggregator/RemoteEngineer/re.sh
## Allows the Data Aggregator user to manage the Data Aggregator
sudouser ALL = CA_DATAAGG
```

   – ***sudouser*** Specify the user who can run the sudo commands.

   This command alias details the commands that the sudo user must be able to run.

   SLES:

```
Cmnd_Alias CA_DATAAGG = /tmp/installDA.bin,/usr/sbin/service dadaemon *,/usr/sbin/
service activemq *,/opt/IMDataAggregator/Uninstall/Uninstall, /opt/IMDataAggregator/
RemoteEngineer/re.sh
## Allows the Data Aggregator user to manage the Data Aggregator
dasudouser_name ALL = CA_DATAAGG
```

   – ***sudouser*** Specify the user who can run the sudo commands.

   This command alias details the commands that the sudo user must be able to run.

3. With the sudo user configured, add the sudo prefix to all commands to install the Data Aggregator.

   Example:

```
sudo ./installDA.bin
```

Configure the Limit on the Number of Open Files on Data Aggregator

Verify that the user that is installing Data Aggregator has a limit of at least 65536 on the number of open files. Set this value permanently.

Follow these steps:

1. As the root user or a sudo user, log in to the Data Aggregator host.
2. Change the ulimit for the open files limit to at least 65536:

```
ulimit -n ulimit_number
```

   For example:

```
ulimit -n 65536
```

3. Open the following file:

```
/etc/security/limits.conf
```

4. Add the following lines:

```
# Added by Data Aggregator
* soft nofile 65536
# Added by Data Aggregator
* hard nofile 65536
```

   NOTE

   Restart Data Aggregator for these changes to take effect. If you are upgrading, the upgrade process automatically restarts Data Aggregator.

5. Verify that the number of open files is set properly:

```
ulimit -n
```

   The command returns the limit that you specified earlier.

Configure UTF-8 Support

Configure the Data Aggregator host to support UTF-8 encoding. If UTF-8 encoding is not enabled, characters might not display properly during the installation.

The appropriate language packs are also required to support localized deployments.

NOTE
Some scripts that are used in the installation of selected components are not localized and run in English. For more information, see Language Support.

Follow these steps:

1. Do one of the following steps:
   a. Type the following command from a Korn or bash shell:
      ```
      export LANG=LANG_value ; export LC_ALL=$LANG
      ```
      - **LANG_value** specifies the value of the language you want the product to support. The following variables are supported:
        English: `en_US.utf8`
        French: `fr_FR.utf8`
        Japanese: `ja_JP.utf8`
        Simplified Chinese: `zh_CN.utf8`
        Traditional Chinese: `zh_TW.utf8`

      For example:
      ```
      export LANG=zh_TW.utf8 ; export LC_ALL=$LANG
      ```
   b. Type the following command from a Bourne shell:
      ```
      LANG=LANG_value ; export LANG
      LC_ALL=LANG_value ; export LC_ALL
      ```
      For example:
      ```
      LANG=zh_CN ; export LANG
      LC_ALL=zh_CN ; export LC_ALL
      ```
   The language variable is set.

Install the Data Aggregator

Once you have met the requirements to install Data Aggregator, complete the installation as follows:

Install the Data Aggregator

To install a Data Aggregator in silent mode, run the installation and create a response file. Use the response file to run future installations in silent mode. To generate the response file, follow the installation procedure, and add the response file argument when you run the installDA.bin file.

TIP

To install the Data Aggregator, the Data Repository must be running. To verify the status of the Data Repository, run the following command on the Data Repository host:

```
su - dr_admin_user -c "/opt/vertica/bin/admintools -t show_active_db"
```

Follow these steps:

1. Log in to the Data Aggregator host as the root user or the sudo user.

2. Copy the installDA.bin file to the /tmp directory.
3. Change to the /tmp directory:

```
cd /tmp
```

4. Change permissions for the installation file:

```
chmod a+x installDA.bin
```

5. To run the console installation, do one of the following steps:
   - To run the installation as the root user, type the following command:

     ```
     ./installDA.bin -i console
     ```

   - To run the installation as the sudo user, type the following command

     ```
     sudo ./installDA.bin -i console
     ```

     NOTE

     To generate a response file for silent installation, add the following argument:

     ```
     -r response_file
     ```

     response_file specifies the directory the directory path and file name for the response file.
     Example: /temp/installer.properties

     Follow the prompts until you get to the summary, type "quit", and press Enter.

     To run the installation in silent mode, use the following command:

     ```
     ./installDA.bin -i silent -f response_file
     ```

     response_file is the directory path and file name of the previously generated response file.
6. Follow the instructions in the console.

   WARNING

   When you are prompted for the data directory, use the default directory. Do not use *DA_Install_Directory*/apache-karaf-*version*/data .
7. When prompted, specify the following parameters for Data Repository:
   - **Data Repository server hostname/IP**
     Defines either a name or an IP address for the Data Repository server host.
     For a Data Repository cluster, specify the name or the IP address of any one host in the cluster. The installer automatically determines the name and IP address of the remaining nodes.
   - **Data Repository server port**
     Defines the port number for the Data Repository server.

Default: 5433

- **Database name**
  Defines the database name of Data Repository.
- **Data Repository username**
  Specifies the username that Data Aggregator uses to connect to the database. The username and the password cannot match. This username and password combination is added to the database during the installation.
  Example: dauser
- **Data Repository admin username**
  Specify the Linux user account that was used to install Data Repository. This username is needed for administration, such as backing up and restoring Data Repository, or updating the database schema.
  Example: dradmin
- **Data Repository admin password**
  Defines the password for the Data Repository admin username.

  NOTE
  This database user account password was specified when you created the database after the Data Repository installation.

  Example: dbpassword

  TIP

  If necessary, a `doEncryption.sh` script is available to edit the `dbconnection.cfg` file. For example, you can use the script to change your Data Repository admin password.

8. (Optional) When prompted, specify the following parameters for fault tolerance. For more information, see Fault Tolerance.
   - **Configure Data Aggregator For Fault Tolerance**
     Specify 2 to configure fault tolerance.
     Default: 1

     NOTE

     The default is for a non-fault tolerant environment.
   - **Data Aggregator Proxy Host**
     Specify the host name/IP address of the proxy server.
   - **Consul HTTP port:**
     Specify the port for communication with Consul.
     Default: 8500
   - **Choose host IP address for Consul**

     NOTE

     This prompt appears only when multiple public IP addresses are configured.

     Specify the bind address that the Consul agents use to communicate with each other. The Consul agents include the proxy host and both Data Aggregators in the cluster. If prompted for an address, specify an address that the other two hosts in the Consul cluster can reach.
9. The Data Aggregator is installed and started.

Verify the Data Aggregator Installation

NOTE

For the Data Aggregator installations, we use the static location of /etc/DA.cfg to store where the Data Aggregators are installed and the chosen installation options for upgrade.

Follow these steps:

1. Verify that the Data Aggregator service is running:

   ```
   service dadaemon status
   ```

2. Review the following log file on the Data Aggregator host:

   ```
   /opt/IMDataAggregator/Logs/
   CA_Performance_Management_Data_Aggregator_Install_timestamp.log
   ```

   If the installation is successful, the log shows 0 Warnings, 0 NonFatalErrors, and 0 FatalErrors.

   NOTE

   If the installation fails early enough in the process, the log file may be available in the home directory of the root or sudo user.

3. Verify that the ActiveMQ broker is running:

   ```
   service activemq status
   ```

4. Open a browser on a computer where you have HTTP access to Data Aggregator. Navigate to the following address:

   ```
   http://da_host:8581/rest
   ```

   da_host specifies the Data Aggregator host name or IP address.
   The return is a list of hyperlinks for available web services. When you click a link, the XML content describing the selection displays.

Register Data Aggregator as a Data Source

To connect NetOps Portal to the Data Aggregator, register Data Aggregator as a data source.

Follow these steps:

1. Log in to NetOps Portal as an administrator user. Access NetOps Portal at the following URL:

   ```
   PC_host:8181/pc/desktop/page
   ```

2. Navigate to **Administration**, **Data Sources**.
3. Click **Add**.
4. Select Data Aggregator for the Source Type, specify the required information, and click **Save**.

   NOTE

   For a fault tolerant environment, specify the proxy server host name. For more information, see Fault Tolerance.

   Wait a few minutes for Data Aggregator to synchronize automatically with NetOps Portal.

Prepare to Install the Data Collectors

To ensure that your Data Collector installation is successful, complete the requirements before you install a Data Collector:

Review Data Collector Considerations

In a standard tenant deployment, each tenant has a dedicated Data Collector. For multiple tenants that reside in the same IP routing space, DX NetOps Performance Management can be configured to use fewer Data Collectors. For more information, see Tenant-Agnostic Data Collectors.

The following considerations apply to a standard tenant deployment:

- Review Installation Requirements and Considerations.
- You can install more than one Data Collector. Each Data Collector must be installed on a separate host.
- In a standard tenant deployment, a Data Collector supports only one Data Aggregator.
- In a multi-tenant environment where a managed service provider is monitoring devices for multiple tenants, you can take the following steps:
  - Install Data Collector at the MSP site.

    NOTE
    This setup requires Data Collector to gain access through a tenant firewall to poll the devices that are being managed.
  - Install Data Collector at each tenant site.
- If Data Aggregator is IPv6 only, Data Collector must support the IPv6 protocol.
  To verify that Data Collector supports IPv6, take the following steps:
  - On the Data Aggregator host, type the following command to find the IPv6 address of the computer:
    ```
    > ifconfig
    ```
  - On the Data Collector host, type the following command to ensure that Data Collector can contact Data Aggregator using its IPv6 address:
    ```
    > ping6 ipv6_address_of_Data Aggregator
    ```

Verify the Prerequisites

Meet the following prerequisites before you install Data Collector:

- On the Data Aggregator system, verify that ports 61616, 61618, 61620, and 61622 are open. These ports enable communication between the Data Collector and the Data Aggregator.
- Verify that ports 1099 and 11099 are blocked from external access.
  These ports must remain open locally for internal communication.
- Verify that Security Enhanced Linux (SELinux) is disabled on the computer where you are going to install Data Collector. By default, some Linux distributions enable this feature, which does not allow Data Collector to function properly. Disable SELinux or create a policy to exclude Data Collector processes from SELinux restrictions.

  NOTE
  For information about configuring an SELinux security policy, see the Red Hat documentation.
- To avoid database corruption of ActiveMQ broker files, exclude the installation directory, and all its subdirectories, from antivirus scans. Prevent scanning by a local instance of an antivirus client and scanning by a remote antivirus instance.
- Ensure that your desired tenant and corresponding IP domain are provisioned in NetOps Portal. While a single IP domain can be associated with more than one Data Collector, each Data Collector can have only one IP domain assigned to it.

  NOTE
  If you are not deploying multi-tenancy, use the Default Tenant and the Default Domain.
- The installer requires the zip and unzip packages. If these packages are not installed, use one of the following commands to install them:

```
yum -y install zip unzip
```

SLES:

```
zypper install -y zip unzip
```

- The Data Collector uses the "at" package to schedule the restart of the application when assigning a Tenant or IP Domain. Verify whether the "at" package is installed on each Data Collector host:

  ```
  rpm -qa | grep ^at
  ```

  If the command does not return a result, install the package:

  NOTE

  If you are not the root user, use the sudo prefix.

  ```
  yum install at
  zypper install -y at
  ```

(Optional) Configure the Sudo User Account for Data Collector

If you do not have root access to install and run the Data Collector, configure the sudo user account.

Follow these steps:

1. Locate the following file on the Data Collector host:
   `/etc/sudoers`
2. Add one of the following command aliases with the following permissions to the file:

   ```
   Cmnd_Alias CA_DATACOLL =  /tmp/install.bin,/sbin/service dcmd *, /opt/
   IMDataCollector/Uninstall/Uninstall, /opt/IMDataCollector/RemoteEngineer/re.sh, /opt/
   IMDataCollector/scripts/dcmd
   ## Allows the <caimdc> user to manage the <caimdc>
   sudouser ALL = CA_DATACOLL
   ```

   – ***sudouser***
   Specify the user who can run the sudo commands.

   This command alias details the commands that the sudo user must be able to run.

   SLES:

   ```
   Cmnd_Alias CA_DATACOLL = /tmp/install.bin,/usr/sbin/service dcmd *,/usr/sbin/
   service activemq *,/opt/IMDataCollector/Uninstall/Uninstall, /opt/IMDataCollector/
   RemoteEngineer/re.sh, /opt/IMDataCollector/scripts/dcmd
   ## Allows the <caimdc> user to manage the <caimdc>
   sudouser ALL = CA_DATACOLL
   ```

   – ***sudouser***
   Specify the user who can run the sudo commands.

   This command alias details the commands that the sudo user must be able to run.
3. With the sudo user configured, add the sudo prefix to all commands to install the Data Collector.
   Example:

   ```
   sudo ./install.bin
   ```

Configure UTF-8 Support

Configure the Data Collector host to support UTF-8 encoding. If UTF-8 encoding is not enabled, characters might not display properly during the installation.

The appropriate language packs are also required to support localized deployments.

NOTE
Some scripts that are used in the installation of selected components are not localized and run in English. For more information, see the *Localization Status Readme* file.

Follow these steps:

1. Do one of the following steps:
   a. Type the following command from a Korn or bash shell:
      ```
      export LANG=LANG_value ; export LC_ALL=$LANG
      ```
      - **LANG_value** specifies the value of the language you want the product to support. The following variables are supported:
        English: `en_US.utf8`
        French: `fr_FR.utf8`
        Japanese: `ja_JP.utf8`
        Simplified Chinese: `zh_CN.utf8`
        Traditional Chinese: `zh_TW.utf8`

      For example:
      ```
      export LANG=zh_TW.utf8 ; export LC_ALL=$LANG
      ```
   b. Type the following command from a Bourne shell:
      ```
      LANG=LANG_value ; export LANG
      LC_ALL=LANG_value ; export LC_ALL
      ```
      For example:
      ```
      LANG=zh_CN ; export LANG
      LC_ALL=zh_CN ; export LC_ALL
      ```
   The language variable is set.

Set a Unique Hostname for the Data Collector Host

Set a unique hostname for the computer where you plan to install Data Collector.

Follow these steps:

1. As the root user, log in to the Data Collector host
2. Verify the unique hostname on the computer.
   The hostname for the computer must be associated with the IP address and *not* the loopback address of 127.0.0.1.
3. Verify that the following lines appear in the /etc/hosts file on the computer:
   ```
   Do not remove the following line, or various programs
   # that require network functionality will fail.
   127.0.0.1   localhost localhost.localdomain localhost4 localhost4.localdomain4
   ::1         localhost localhost.localdomain localhost6 localhost6.localdomain6
   IP address of your host YourHostName YourHostName.ca.com
   ```
4. If the hostname required any changes, restart the network:
   ```
   service network restart
   ```
   The /etc/hosts file is configured correctly.
   The unique host name is set.

These ports must remain open locally for communication between the Data Aggregator and Data Collectors.

Install the Data Collectors

Install Data Collectors after you install Data Aggregator.

To install a Data Collector in silent mode, run the installation and create a response file. Use the response file to run future installations in silent mode. To generate the response file, follow the installation procedure, and add the response file argument when you run the install.bin file.

If you are installing multiple Data Collectors, install each Data Collector instance on a separate host.

If you are reinstalling a Data Collector, see Update the Data Collector.

Follow these steps:

1. Log in to the Data Collector host either as the root user or the sudo user.
2. Access the Data Collector installation package by doing one of the following actions:
   - If you have HTTP access to the Data Aggregator host *and* you are running an X Window System, open a web browser on the Data Collector host. Navigate to the following address and download the installation package:
     `http://data_aggregator:port/dcm/install.htm`
     - ***data_aggregator*:*port***
       Specifies the Data Aggregator host name and the required port number.
       Default: 8581, unless you specified a nondefault value during the Data Aggregator installation.

     Save the installation package to the /tmp directory.
   - If you have HTTP access to the Data Aggregator host and you are *not* running an X Window System, open a command prompt on the Data Collector host. Download the installation package to the /tmp directory using one of the following commands:
     - `wget`
       is available:
       `wget -P /tmp -nv http://data_aggregator:port/dcm/InstData/Linux/VM/install.bin`
       - ***data_aggregator*:*port***
         Specifies the Data Aggregator host name and the required port number.
         Default: 8581, unless you specified a nondefault value during the Data Aggregator installation.
     - `wget`
       is unavailable:
       `curl -o /tmp/install.bin http://data_aggregator:port/dcm/InstData/Linux/VM/install.bin`
   - If you do *not* have HTTP access to the Data Aggregator host, open a command prompt on a computer that *does* have HTTP access.
     a. Download the installation package to your Desktop directory using one of the following commands:
        - `wget`
          is available:
          `wget -P ~/Desktop -nv http://data_aggregator:port/dcm/InstData/Linux/VM/install.bin`
          - ***data_aggregator*:*port***
            Specifies the Data Aggregator host name and the required port number.
            Default: 8581, unless you specified a nondefault value during the Data Aggregator installation.
        - `wget`
          is unavailable:
          `curl -o /tmp/install.bin http://data_aggregator:port/dcm/InstData/Linux/VM/install.bin`

     b. Transfer the install.bin file to /tmp on the Data Collector host.
3. Change to the /tmp directory:
   `cd /tmp`
4. Change the permissions for the installation file:

```
chmod a+x install.bin
```

5. To run the console installation, do one of the following steps:
   - To run the installation as the root user, type the following command:
     ```
     ./install.bin -i console
     ```
   - To run the installation as the sudo user, type the following command
     ```
     sudo ./install.bin -i console
     ```

     NOTE

     To generate a response file for silent installation, add the following argument:

     ```
     -r response_file
     ```

     response_file specifies the directory the directory path and file name for the response file.
     Example: /temp/installer.properties

     Follow the prompts until you get to the summary, type "quit", and press Enter.

     To run the installation in silent mode, use the following command:

     ```
     ./install.bin -i silent -f response_file
     ```

     response_file is the directory path and file name of the previously generated response file.
6. Follow the instructions in the console.
7. When the installer prompts you for the Data Aggregator host information, specify the IP address or the hostname for Data Aggregator.

   WARNING
   Specify the Data Aggregator host information correctly. If you specify the Data Aggregator host information incorrectly, the Data Collector shuts down after installation. An error message is logged in the *DC_installation_directory*/apache-karaf-<*vers*>/shutdown.log file. Uninstall and reinstall Data Collector.
8. When you are asked whether to associate this Data Collector with the Default Tenant, enter 'y' or 'n'.
   - If you are planning to deploy multi-tenancy, enter 'n'. You can then associate each Data Collector installation with a tenant.
   - If you are not deploying multi-tenancy, enter 'y'.
9. (Optional) When prompted, specify the following parameters for fault tolerance. For more information, see Fault Tolerance.
   - **Is the Data Aggregator configured with fault tolerance?**
     If fault tolerance was configured for the Data Aggregators, specify 2 for Yes.
     Default: 1
   - **Inactive Data Aggregator Host/IP Address**
     Specify the host name or IP address of the inactive Data Aggregator responsible for this Data Collector.

     NOTE
     To view the status of your Data Aggregators in NetOps Portal, hover over **Administration**, and click **Data Sources: System Status**.

   Data Collector is installed, started, and connects to Data Aggregator.

   NOTE
   If you restart the Data Collector host, the Data Collector service automatically restarts and connects to Data Aggregator.

Verify the Installation

NOTE

For the Data Collector installations, we use the static location of /opt/DCM.cfg to store where the Data Collectors are installed and the chosen installation options for upgrade.

Follow these steps:

1. Verify that Data Collector is running on the Data Collector host:
   ```
   service dcmd status
   ```
2. Review the the following log file on the Data Collector host:
   ```
   /opt/IMDataCollector/Logs/
   CA_Performance_Management_Data_Collector_install_timestamp.log
   ```
   If the installation is successful, the log shows 0 Warnings, 0 NonFatalErrors, and 0 FatalErrors.

   NOTE

   If the installation fails early enough in the process, the log file may be available in the home directory of the root or sudo user.
3. Verify that the Data Collector connection is successful after the installation by doing the following actions:
   a. Log in to NetOps Portal as the global administrator.
   b. Navigate to the Data Aggregator administration view and expand the System Status view.
   c. Select Data Collectors from the menu.
   d. Verify that Data Collector appears in the list.

   NOTE
   The list can take several minutes to refresh and show the new Data Collector installation.
4. Assign a tenant and IP domain to each Data Collector if the Tenant and IP Domain are blank:
   a. Select the Data Collector instance and click Assign.
   b. Select another tenant and an IP domain for this Data Collector in the Assign Data Collector dialog and click Save.

Complete the Post-Installation Configuration

Perform the following optional and recommended steps after you install DX NetOps Performance Management:

Set Up Autostart on Data Repository

You can set up autostart on Data Repository. If autostart is set up and you reboot the computer where Data Repository is installed, Data Repository starts automatically.

WARNING
This feature might not work if Data Repository did not shut down properly. If the database did not shut down properly, the database might require manual intervention during startup to restore the last good epoch. If the Vertica database does not start automatically after an improper shutdown, use admintools to start it manually.

Data Aggregator stops automatically when Data Repository becomes inaccessible. Restart Data Aggregator manually once Data Repository is online again.

Do one of the following steps:

- Start the Data Aggregator service:
  ```
  service dadaemon start
  ```

NOTE

For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.

- (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
  - **RHEL 6.x:**
    `service dadaemon activate`
  - **RHEL 7.x, SLES, or OL:**
    DA_Install_Directory`/scripts/dadaemon activate`

Follow these steps:

1. To become the Linux user account for the database administrator user, type the following command:
   `su` *dradmin*
2. Verify that the Linux user account for the database administrator user is set up with a passwordless ssh key:
   a. To see if a passwordless ssh key is already set up, type the following command:
      `ssh` *dr_host* `ls`
      If the passwordless ssh key is set up, you are *not* prompted for a password. You do not need to do anything further.
   b. If you *are* prompted for a password, ignore the prompt, press Ctrl+C, and complete step 5.
3. (Optional) Set up the Linux user account for the database administrator user with a passwordless ssh key.
   a. To generate a public key, type the following command. In a cluster installation, type this command on each host that is participating in the cluster:
      `ssh-keygen -N "" -t rsa -f ~/.ssh/id_rsa`
   b. Copy the contents of the public key to the authorized_keys2 file on the same computer. In a cluster installation, copy the contents of the public key to the authorized_keys2 file on each host in the cluster:
      `cat ~/.ssh/id_rsa.pub >> ~/.ssh/authorized_keys2`
   c. (Cluster installation only) Copy the contents of the public key from each host to each of the other hosts:
      - As the database administrator user on the first host, type the following command and copy the content of the file:
        ```
        vi ~/.ssh/id_rsa.pub
        vi ~/.ssh/authorized_keys2
        vi ~/.ssh/authorized_keys2
        ```
      - As the database administrator user on the second host, type the following command:

      Paste the contents from the id_rsa.pub file on the first host to the end of the authorized_keys2 file on the second host.
   d. As the database administrator user on the third host, type the following command:
      `vi ~/.ssh/authorized_keys2`
      Paste the contents from the id_rsa.pub file on the first host to the end of the authorized_keys2 file on the third host.
4. To enable you to ssh from one host to another without being prompted for a password, repeat these steps for all hosts in the cluster:
   a. To set permissions for the authorized_keys2 file, type the following command. In a cluster environment, type these commands on each host in the cluster:
      `chmod 644 ~/.ssh/authorized_keys2`
   b. As the root user, type the following commands to restart the ssh daemon. In a cluster environment, type this command on each host in the cluster:
      ```
      su root
      service sshd restart
      ```

c. (Single-node installations only) To confirm that you are not prompted for a password, type the following commands:
```
su dradmin
ssh dradmin@hostname ls /tmp
```
d. (Cluster installations only) To confirm that you are not prompted for a password, type the following commands on the first host in the cluster:
```
su dradmin
ssh dradmin@host1 ls /tmp
ssh dradmin@host2 ls /tmp
ssh dradmin@host3 ls /tmp
```
Repeat this step on each host in the cluster.

WARNING
If you do not set up the passwordless ssh key, you cannot configure autostart on Data Repository.

5. Type the following command:
```
/opt/vertica/bin/adminTools
```
The Administration Tools dialog opens.
6. Select (6) Configuration Menu and select OK.
7. Select (4) Set Restart Policy and select OK.
The Select Database dialog opens.
8. Select the database name and select OK.
The Select policy dialog opens.
9. Select 'always' when doing a single-node Data Repository installation. Select 'ksafe' when doing a cluster installation. Select OK.

NOTE
In a single-node installation, ‘always’ means that, Data Repository automatically restarts when the system restarts. In a cluster installation, ‘ksafe’ means that, upon the system restarting, the Data Repository node automatically restarts if the database still has a status of ‘UP’.

The Restart Policy setting is saved.
10. Select OK to close the Select policy dialog.
11. Return to the (M) Main Menu.
12. Select (E) Exit.
13. (Optional) Test that Data Repository starts when you reboot the computer where Data Repository is installed:
a. Reboot the computer where Data Repository is installed.

NOTE
Log in as the root user or sudo user to reboot the computer.

b. Become the Linux user account for the database administrator user. Type the following command:
```
su dradmin
```
c. Type the following command:
```
/opt/vertica/bin/adminTools
```
The Administration Tools dialog opens.
d. Select (1) View Database Cluster State and select OK.
e. The state is "UP." Select OK.

NOTE
Data Repository can take several minutes to start up after you reboot.

Configure the Automatic Recovery for the Data Aggregator Process

Configure the automatic recovery of the Data Aggregator process.

If the database server runs out of memory, or if Data Repository is unavailable for a time, Data Aggregator shuts down automatically to ensure that data consistency is maintained. When Data Aggregator shuts down, an audit message is logged in the following log file:
`DA_installation_directory/apache-karaf-<vers>/shutdown.log`

When the Data Aggregator is unavailable, the Data Collectors continue polling. The Data Collector caches the poll responses in memory, up to a configurable limit. When the Data Aggregator host becomes available, the cached polled data is sent to Data Aggregator.

We recommend that you disable this cron job before you upgrade Data Aggregator. If you shut down Data Aggregator manually with the service dadaemon stop command, the cron job does not restart Data Aggregator automatically. Maintenance can be performed without having the cron job disrupt the system when it is expected to be down.

> **NOTE**
>
> In a fault tolerant environment, this procedure is unnecessary because Consul manages the start and stop state of the Data Aggregator. For more information, see Fault Tolerance.

Follow these steps:

1. Log in to the computer where the Data Aggregator is installed as the root user.
2. Open a console and type the following command:
   ```
   crontab  -e
   ```
   A vi session opens. If there are no cron jobs for the database administrator user, an empty file opens. Otherwise, the file contains existing cron job definitions.
3. Add the following lines to the file for the cron job:
   ```
   * * * * * /sbin/service dadaemon start > /dev/null
   ```
   The cron job issues a start command to Data Aggregator every minute. If Data Aggregator is running, the start command is ignored.

(Optional) Modify the External ActiveMQ Memory Limit

The Data Aggregator installer calculates the memory that is needed on your system to accommodate the Apache ActiveMQ process. However, you can manually modify the memory limit settings to fine tune ActiveMQ on your Data Aggregator system. For example, you can modify the settings under the following circumstances:

- When the system memory has changed.
- When the number of Data Collector systems have changed.
- To optimize the memory settings.
- When you have determined that the performance of ActiveMQ is degraded. Monitor the performance through the JConsole or the DX NetOps Performance Management custom chart with ActiveMQ metrics.

Follow these steps:

1. Calculate the amount of memory for ActiveMQ based on the following settings:
   - **Maximum java heap size**
     Default: 20%
     Minimum: 512M
   - **Initial minimum java heap size**
     50% of maximum java heap size
   - **Young generation java heap size**
     25% of the maximum java heap size
   - **Memory limit for all messages**

50% of the maximum java heap size

– **Memory limit per queue**
Calculate based on how many Data Collector installations you have.
Example: The memory per queue
(system memory for all messages)/5/(Data Collector count)

2. Log in to the computer where Data Aggregator is installed. Log in as the root user or a sudo user with access to a limited set of commands.
3. Type the following command to stop the ActiveMQ broker:
```
service activemq stop
```
4. Modify the java heap size for ActiveMQ:
   a. Access the **activemq** file under *DA_INSTALL_DIRECTORY*/broker/apache-activemq-*version*/bin.
   b. Locate the line that defines ACTIVEMQ_OPTS_MEMORY.
   c. Change - Xms to be the Initial minimum java heap size.
   d. Change - Xmx to be the Maximum java heap size.
   e. Change –Xmn to be the Young generation java heap size.
   f. Save the file.
5. Modify the ActiveMQ memory limit for the producer flow control:
   a. Access the activemq.xml file in *Data Aggregator installation directory*/broker/apache-activemq-*version*/conf.
   b. Locate the following line and change the value to Memory limit for all messages:
```
<memoryUsage limit=”value”/>
```
   c. Locate the following line, change the value to Memory limit per queue:
```
<policyEntry queue=">" producerFlowControl="true" memoryLimit="value"/>
```
6. Type the following command to start the ActiveMQ broker:
```
service activemq start
```
Your new settings are activated.

(Optional) Change the Opened Port Number on the Data Aggregator Host

After you install Data Aggregator, you can change the port that is opened on the Data Aggregator host.

NOTE
You opened port 61616 before you installed Data Aggregator and Data Collector.

Follow these steps:

1. Log in to the computer where Data Aggregator is installed. Log in as the root user or a sudo user with access to a limited set of commands.
2. Do one of the following steps:
   – Stop the Data Aggregator service:
```
service dadaemon stop
```
   – (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     • **RHEL 6.x:**
```
service dadaemon maintenance
```
     • **RHEL 7.x, SLES, or OL:**
```
DA_Install_Directory/scripts/dadaemon maintenance
```
3. Type the following commands to remove the data directory and the local-jms-broker.xml file from the deploy directory:
```
rm -rf <caimda> installation directory/apache-karaf-<vers>/data
```

```
rm -rf <caimda> installation directory/apache-karaf-<vers>/deploy/local-jms-
broker.xml
```

4. Edit the `activemq.xml` file in the *DA_installation_directory*`/broker/apache-activemq-<`*vers*`>/conf` directory:
   a. Locate the following lines:

```
<transportConnectors>
     <transportConnector name="openwire" uri="tcp://0.0.0.0:61616"/>
     <transportConnector name="PRQ" uri="tcp://0.0.0.0:61618"/>
     <transportConnector name="IREP" uri="tcp://0.0.0.0:61620"/>
     <transportConnector name="blob" uri="tcp://0.0.0.0:61622"/>
   </transportConnectors>
```

   b. Replace 61616, 61618, 61620, 61622 with the ports that you want to use for incoming connections on Data Aggregator.

NOTE

If you have a fault tolerant environment, ensure that both Data Aggregators use the same ActiveMQ ports.

5. Do one of the following steps:
   – Start the Data Aggregator service:

```
service dadaemon start
```

   – (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
     - **RHEL 6.x:**

```
service dadaemon activate
```

     - **RHEL 7.x, SLES, or OL:**

DA_Install_Directory`/scripts/dadaemon activate`

6. Wait a few minutes, then type the following command to verify that the port change is successful:

```
netstat -a | grep port
```

   – ***port***
   The port number that you specified previously for incoming connections on Data Aggregator.
7. If the port change is successful, Data Aggregator waits for incoming connections on that port. If Data Aggregator is not waiting for incoming connections, type the following command to review the karaf.log file for errors:

```
grep ERROR karaf.log
```

8. Resolve the errors.
9. Log in to the computer where Data Collector is installed. Log in as the root user or a sudo user with access to a limited set of commands.

NOTE
For more information about the sudo user, see the *Data Aggregator Installation Guide*.

10. Open a command prompt and type the following command:

```
service dcmd stop
```

11. Type the following commands to remove the data directory and the local-jms-broker.xml file from the deploy directory:

```
rm -rf <caimda> installation directory/apache-karaf-<vers>/data
rm -rf <caimda> installation directory/apache-karaf-<vers>/deploy/local-jms-
broker.xml
```

12. Edit the `activemq.xml` file in the *DC_installation_directory*`/broker/apache-activemq-<`*vers*`>/conf` directory:
    a. Locate the following lines:
    ```
    <networkConnector name="da_manager" uri="static:(tcp://scalematda:61616)"
     duplex="true"
         suppressDuplicateTopicSubscriptions="false">
    <networkConnector name="da_manager-PRQ" uri="static:(tcp://scalematda:61618)"
     duplex="true"
         suppressDuplicateTopicSubscriptions="false">
    <networkConnector name="da_manager-IREP" uri="static:(tcp://scalematda:61620)"
     duplex="true"
         suppressDuplicateTopicSubscriptions="false">
    <networkConnector name="da_manager-blob" uri="static:(tcp://scalematda:61622)"
     duplex="true"
         suppressDuplicateTopicSubscriptions="false">
    ```
    b. Replace 61616, 61618, 61620, and 61622 with the ports that you specified previously in the `activemq.xml` file on the Data Aggregator host.
13. Open a command prompt and type the following command to start Data Collector:
    ```
    service dcmd start
    ```
14. Wait a few minutes, then type the following command to verify that each port change is successful:
    ```
    netstat -a | grep port
    ```
    – ***port***
      The port number that you specified in a previous step for incoming connections on Data Aggregator.

    If the port change is successful, the console shows a connection between the Data Aggregator and the Data Collector. If you do not see a connection, type the following command to review the karaf.log file for errors:
    ```
    grep ERROR karaf.log
    ```
15. Resolve the errors.
    The opened port numbers on the Data Aggregator host is changed.

(Optional) Disable the ActiveMQ Admin Console for the Data Aggregator or Data Collector

Generally, the ActiveMQ admin console should not be available on the network. Therefore, you can disable it for the Data Aggregator or Data Collector.

Follow these steps:

1. Go to one of the following files:
   – **Data Aggregator**
     DA_Install_Directory`/broker/apache-activemq-`*version*`/conf/activemq.xml`
   – **Data Collector**
     DC_Install_Directory`/broker/apache-activemq-`*version*`/conf/activemq.xml`
2. Comment out
   ```
   <import resource="jetty.xml"/>
   ```
   .
3. Shut down the ActiveMQ broker on each Data Collector:
   ```
   service activemq stop
   ```
4. Shut down the ActiveMQ broker on the Data Aggregator:
   ```
   service activemq stop
   ```
5. Start the ActiveMQ broker on the Data Aggregator:

```
service activemq start
```

If you do not, the Data Aggregator starts the broker automatically.

6. The Data Collectors automatically restart the ActiveMQ brokers. Use the following command to restart the brokers manually:

```
service activemq start
```

(Optional) Update ActiveMQ Admin Console Access

Generally, the ActiveMQ admin console should not be available on the network. However, if certain users absolutely need the console, you can grant them access.

Follow these steps:

1. Go to one of the following files:
   - **Data Aggregator**
     DA_Install_Directory/broker/apache-activemq-*version*/conf/activemq.xml
   - **Data Collector**
     DC_Install_Directory/broker/apache-activemq-*version*/conf/activemq.xml
2. To update user access, edit the
   `jetty-realm.properties`
   .
3. To encrypt the user passwords, run one of the following commands:
   - **Data Aggregator**

     ```
     java -cp DA_Install_Directory/broker/apache-activemq-version/lib/web/jetty-all-9.2.22.v20170606.jar org.eclipse.jetty.util.security.Password passwordpassword
     ```

   - **Data Collector**

     ```
     java -cp DC_Install_Directory/broker/apache-activemq-version/lib/web/jetty-all-9.2.22.v20170606.jar org.eclipse.jetty.util.security.Password passwordpassword
     ```

4. Shut down the ActiveMQ broker on each Data Collector:

   ```
   service activemq stop
   ```

5. Shut down the ActiveMQ broker on the Data Aggregator:

   ```
   service activemq stop
   ```

6. Start the ActiveMQ broker on the Data Aggregator:

   ```
   service activemq start
   ```

   If you do not, the Data Aggregator starts the broker automatically.
7. The Data Collectors automatically restart the ActiveMQ brokers. Use the following command to restart the brokers manually:

   ```
   service activemq start
   ```

Authenticate and Encrypt ActiveMQ Communication

By default, the communication between the Data Aggregator and Data Collector is unencrypted and unauthenticated. To secure communications, secure the communication between the ActiveMQ brokers on these servers.For more information, see Authenticate and Encrypt ActiveMQ Communication.

Install Mediation Manager

DX NetOps Mediation Manager monitors the performance for non-SNMP based devices, such as mobile wireless, fiber-optic switch, radio access, and 3G or 4G voice data. DX NetOps Mediation Manager supports a wide range of protocols to

access data, such as, SOAP, SSH, XML, SQL, JMS, SFTP, and HTTP. DX NetOps Mediation Manager is portable across all platforms.

You create and migrate device packs using DX NetOps Mediation Manager for Infrastructure Management. The device packs are vendor-specific API plug-ins that collect data from a device or from an Element Management System (EMS). Follow this process to install DX NetOps Mediation Manager for Infrastructure Management.

> **WARNING**
> Install DX NetOps Mediation Manager after you install DX NetOps Performance Management.
>
> **NOTE**
> When the same metric family data is collected through SNMP and through DX NetOps Mediation Manager, some of the data might not be correctly included in rollups. To avoid this problem, collect data from DX NetOps Mediation Manager though a dedicated data collector with a separate IP domain. The data from each IP domain is rolled up independently.

Follow these steps:

1. Install the MultiController on the NetOps Portal host.
2. Install the LocalController on the data collector host.
3. Install the required device packs.

For more information, see the DX NetOps Mediation Manager documentation.

Monitoring System Health with CA Systems Performance for Infrastructure Managers

To monitor the health of the servers in your system that host the Data Repository, Data Aggregator, Data Collector, and NetOps Portal, use the CA Systems Performance for Infrastructure Managers tool. Monitoring system health is optional. You are not required to download the Linux SystemEdge agent.

Install the agent on the distributed servers that you want to monitor. Use NetOps Portal to discover the agent on these servers, and to visualize agent data, such as CPU, memory, file systems, and other critical resources for each server.

You can download the agent image, including a Readme that provides complete installation instructions, from the CA Support Download Center.

Follow these steps to locate the agent image:

1. In a web browser, navigate to support.ca.com.
2. Log in with your email address and password. You must be a registered user on www.ca.com to access the Support pages.
   The Support home page opens.
3. Select **Download Center**, **Download Products**.
4. Type 'CA Systems Performance for Infrastructure Managers' in the **Enter the Product Name here** field.
5. Select **12.8** from the **Select a Release** drop-down list.
6. Select **SP 02** from the **Select a Gen level** drop-down list.
7. Click **Go**.
   The download links appear for the CA Systems Performance for Infrastructure Managers - MULTI-PLATFORM UNIX and Windows.
8. Click **Download**.

Install a Low-Scale System

In a standard large-scale deployment, the data aggregator and data collector components require dedicated nodes. For some smaller deployments of 150,000 polled items or less, you can run these components on a shared single node.

WARNING

Do not deploy the data aggregator and data collector on a single node in high-scale environments.

Limitations

Deploying DX NetOps Performance Management with the data aggregator and data collector on a single node does not support the following options:

- Calculated metrics beyond 150,000 metrics per second
- Fast (1 minute) polling
- Integration with DX NetOps Mediation Manager or DX NetOps Virtual Network Assurance
- Multiple DCs
- Multiple IP domains
- Multiple tenants
- Polling beyond 150,000 items

WARNING

This configuration does not persist through upgrades. After you upgrade the data aggregator, upgrade and configure the data collector according to the procedures described in this article.

How to Install a Low-Scale System

Use the following process to deploy DX NetOps Performance Management with the data aggregator and data collector on a single node:

1. Review Installation Requirements and Considerations.
2. Install .
   For more information, see Install Performance Center.
3. Install the Data Repository.
   NOTE
   Because the Data Repository in a low-scale system is deployed on a single node, skip the steps that refer to cluster installation.
   For more information, see Install the Data Repository.
4. Install the data aggregator
   For more information, see Install the Data Aggregator.
5. Install the data collector on the data aggregator host using the following procedures:
6. Complete the Post-Installation Configuration.

Install the Data Collector

Install and configure the data collector on the same host as the data aggregator.

Follow these steps:

1. Log in to the shared host.
2. Verify that the data aggregator service is running by issuing the following command:
   ```
   service dadaemon status
   ```
   NOTE
   For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.
3. If the service is not running, do one of the following steps:
   – Start the data aggregator service by issuing the following command:

```
service dadaemon start
```

– (Fault tolerant environment) Issue one the following commands to enable the fault tolerant data aggregator so that it can start when necessary:
  - **RHEL 6.x:**
    ```
    service dadaemon activate
    ```
  - **RHEL 7.x, SLES, or OL:**
    ```
    DA_Install_Directory/scripts/dadaemon activate
    ```

4. Verify that the ActiveMQ broker is running by issuing the following command:
   ```
   service activemq status
   ```
   If the service is not running, start the ActiveMQ service by issuing the following command:
   ```
   service activemq start
   ```
5. Download the data collector installer:
   ```
   wget -nv http://da_host:8581/dcm/InstData/Linux/VM/install.bin
   ```
6. Make the install file executable by issuing the following command:
   ```
   chmod a+x install.bin
   ```
7. Do one of the following steps:
   – Stop the data aggregator and ActiveMQ services by issuing the following commands:
     ```
     service dadaemon stop
     service activemq stop
     ```
   – (Fault tolerant environment) If the local data aggregator is running, issue one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**
       ```
       service dadaemon maintenance
       ```
     - **RHEL 7.x, SLES, or OL:**
       ```
       DA_Install_Directory/scripts/dadaemon maintenance
       ```
8. Install the data collector by issuing the following command:
   ```
   ./install.bin -i console
   ```
9. Follow the instructions in the console.
   The installer prompts you for the hostname or IP address of the data aggregator host. Supply the hostname of the shared host. The data collector is installed and the data collector and ActiveMQ services start. After a short time, the data collector service fails because the data aggregator service is not running.
10. Uninstall the Data Aggregator ActiveMQ service by issuing the following command:
    ```
    /opt/IMDataAggregator/scripts/activemq uninstall
    ```
11. Install the data collector ActiveMQ service by issuing the following command:
    ```
    /opt/IMDataCollector/scripts/activemq install
    ```

Reconfigure the Data Collector

After you install the data collector on the shared host, reconfigure the data collector to use the shared host. On a shared host, the data aggregator and data collector use a single ActiveMQ broker.

This procedure includes the following variables:

- `<DA_Install_Directory>`
  The installation directory for the data aggregator.
  Default: `/opt/IMDataAggregator`
- `<DC_Install_Directory>`

The installation directory for the data collector.
Default: `/opt/IMDataCollector`

Follow these steps:

1. Stop the data collector and ActiveMQ services by issuing the following commands:
   ```
   service dcmd stop
   service activemq stop
   ```
2. Modify the data aggregator startup script:
   a. Edit the *DA_Install_Directory*`/scripts/dadaemon` file.
   b. Modify the ACTIVEMQ_HOME variable to point to the data collector ActiveMQ broker by issuing the following command:
      ```
      ACTIVEMQ_HOME="<DC_Install_Directory>/broker/apache-activemq-version" export
       ACTIVEMQ_HOME
      ```
      - ***version***
        Specify the ActiveMQ version. To find the correct version, go to the *<DC_Install_Directory>*`/broker` directory.
3. Disable the data aggregator ActiveMQ broker heartbeat:
   a. Create the *<DA_Install_Directory>*`/apache-karaf-2.4.3/etc/com.ca.im.dm.core.amq.cfg` file.

      NOTE
      Create this file as the user running the data aggregator to ensure the correct permissions are set on the new file.
   b. Edit the file and insert the following property configuration:
      ```
      jmsbroker-heartbeat-disabled=true
      ```
   c. To disable log messages that are related to the data aggregator heartbeat manager, edit the *<DA_Install_Directory>*`/apache-karaf-2.4.3/etc/org.ops4j.pax.logging.cfg` file.
   d. Insert the following property configuration:
      ```
      # Disable ActiveMQ Health Monitoring log messages in shared DA/data collector mode
      log4j.logger.com.ca.im.core.jms.heartbeat.JmsHeartbeatManager=OFF
      ```
4. Modify the Apache Karaf JMX management properties:
   a. Edit the *<DC_Install_Directory>*`/apache-karaf-2.4.3/etc/org.apache.karaf.management.cfg` file.
   b. Set the following properties:
      ```
      rmiRegistryPort = 1199
      rmiServerPort = 44445
      ```
5. (Optional) To support the ability to debug the data aggregator and data collector components simultaneously, modify the Karaf debug port:
   a. Edit the *<DC_Install_Direcotry>*`/apache-karaf-2.4.3/bin/karaf` file.
   b. Set the following property:
      ```
      DEFAULT_JAVA_DEBUG_PORT=5006
      ```
6. Do one of the following steps:
   – Start the data aggregator service by issuing the following command:
     ```
     service dadaemon start
     ```
   – (Fault tolerant environment) Issue one the following commands to enable the fault tolerant data aggregator so that it can start when necessary:
     - **RHEL 6.x:**
       ```
       service dadaemon activate
       ```
     - **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon activate
```

7. Start the data collector service by issuing the following command:
   ```
   service dcmd start
   ```
8. The data aggregator and data collector services start on the single host. Complete post installation configuration for your deployment.

Validate the Deployment

Validate the deployment by verifying that the required services are functioning as expected.

Follow these steps:

1. Validate that the data aggregator service is running by issuing the following command:
   ```
   service dadaemon status
   ```
2. Validate that the data collector service is running by issuing the following command:
   ```
   service dcmd status
   ```
3. Validate that the ActiveMQ Broker is running by issuing the following command:
   ```
   service activemq status
   ```
4. Validate that the ActiveMQ Broker being run is the data collector broker by issuing the following command:
   ```
   service activemq status
   ```
   The returned message must include the following information:
   `Status for ActiveMQ: INFO: Loading '<DC_Install_Directory>/broker/apache-activemq-version/bin/env'`
   If the message does not show the data collector installation directory, repeat the step in the previous procedure to modify the data aggregator startup script.

Uninstall Performance Management

To uninstall DX NetOps Performance Management from your system, uninstall NetOps Portal and the data aggregator components.

Remove the components in the following order:

1. Uninstall Performance Center.
2. Uninstall the Data Aggregator Component.
3. Uninstall the Data Collectors.
4. Uninstall the Data Repository.

Uninstall Performance Center

To uninstall DX NetOps Performance Management, first remove the NetOps Portal component. To remove NetOps Portal, follow the steps in one of the following sections:

Uninstall NetOps Portal

To uninstall NetOps Portal using command line, run the Uninstallation program from a command prompt.

Follow these steps:

1. Log in to the server as 'root', or use the 'sudo' account that you have configured for the installation.
2. Navigate to the Uninstall_PerformanceCenter program.

NOTE
The Uninstall program is stored in /opt/CA/PerformanceCenter by default.

3. Run the following command:
   ```
   ./Uninstall_PerformanceCenter -i console
   ```
   The uninstallation program starts.
4. Press Enter to continue.
   The uninstaller shows the progress as it removes the NetOps Portal files, folders, registry entries, and shortcuts. The application and all of your unwanted components are removed from the server.

NOTE

MySQL data directory is preserved. In addition, the following directories are preserved:

- CA/PerformanceCenter/InstallLogs: Contains the uninstallation log.
- CA/jre: Preserved for other CA products that use the jre.

Clean Up After a Failed Installation

In some cases, the NetOps Portal installation can fail to complete. For example, if the /tmp directory lacks sufficient space for the installation files, the installation fails. If you experience an installation failure, clean up the directories before you reinstall the software.

Follow these steps:

1. To clean up the /tmp directory, remove unnecessary files.
2. To remove the /opt/CA directory, run the following command:
   ```
   rm  -rf /opt/CA
   ```
3. To remove the installer Registration File, run the following command:
   ```
   rm /var/.com.zerog.registry.xml
   ```
4. To remove all of the NetOps Portal service files, run the following command:
   ```
   rm service caperfcenter_*
   ```
5. Restart the server.
6. Install the software again.

Prepare for an Upgrade with a New Installation Directory

The installation procedure lets you select a new directory for the installation, or use the default directory. In some cases, you want to use a different installation directory for a new version of the software when you upgrade NetOps Portal. This scenario requires extra steps during the uninstallation. The goal is to remove all of the links from an initialization file that are related to NetOps Portal. The new installation can then obtain the correct links for the variables that determine the location of the Device Manager, Event Manager, and other processes.

You can uninstall processes individually to clean up your installation directories for an upgrade that uses a different installation directory.

Follow these steps:

1. Navigate to the installation directory for the old installation.
2. Switch to the DM subdirectory, and then to the uninstall subdirectory.
3. Run the uninstaller for the Device Manager process:
   ```
   ./Uninstall_DM
   ```
4. When the uninstallation of the Device Manager has completed, switch back to the installation directory, and then switch to the uninstall subdirectory of the EM subdirectory:
   ```
   cd ../
   ```

```
cd EM/uninstall
```

5. Run the uninstaller for the Event Manager process:
   ```
   ./Uninstall_EM
   ```
6. (Optional) Do a grep for the Device Manager and Event Manager variables:
   ```
   ls  - al /etc/init.d  | grep cap
   ```
   The variables caperfcenter_devicemanager and caperfcenter_eventmanager should not be present after a successful uninstallation of the Device Manager and Event Manager processes.
7. Uninstall NetOps Portal.

Uninstall the Data Aggregator Component

After you uninstall the NetOps Portal component, uninstall the Data Aggregator component. To remove Data Aggregator, follow the steps in one of the following sections:

(Optional) Configure the Sudo User Account for Data Aggregator

If root user access is not available, create a sudo user with access to a limited set of commands.

Follow these steps:

1. Log in to the computer where you want to install Data Aggregator as the root user.
2. Add the following command alias to the command alias section of the /etc/sudoers file:

   ```
   Cmnd_Alias CA_DATAAGG = /tmp/installDA.bin, service dadaemon, /opt/IMDataAggregator/
   uninstall

   ## Allows the Data Aggregator user to manage the Data Aggregator

   dasudouser_name ALL = CA_DATAAGG
   ```

   This command alias details the commands that the sudo user must be able to run.
   The sudo user account is configured.

Uninstall Data Aggregator from the Command Line

You can uninstall Data Aggregator that is installed on a computer in your networking environment.

Follow these steps:

1. Open a command prompt. Type the following command to log in to the computer where you want to uninstall Data Aggregator as the root user:

   ```
   su - root
   ```

   If you cannot log in as the root user, configure a sudo user account with access to a limited set of commands.
2. Type the following command to access the uninstallation directory:

   ```
   cd <caimda> installation directory/Uninstall
   ```

3. Type the following command to run the uninstaller:

```
./Uninstall
```

You are prompted to uninstall.

4. Select option 1 for a complete uninstallation and press Enter.
   Data Aggregator is uninstalled.

Uninstall Data Aggregator in Silent Mode

You can uninstall Data Aggregator silently. You cannot discover new devices or manage existing polled devices whose IP addresses fall within the IP domain that is associated with the uninstalled Data Aggregator.

Follow these steps:

1. Open a command prompt. Type the following command to log in to the computer where you want to uninstall Data Aggregator as the root user:

   ```
   su - root
   ```

   If you cannot log in as the root user, configure a sudo user account with access to a limited set of commands.
2. Type the following command to access the uninstallation directory:

   ```
   cd <caimda> installation directory/Uninstall
   ```

3. Type the following command to run the uninstaller:

   ```
   ./Uninstall
   ```

   Data Aggregator is uninstalled.

Uninstall Data Aggregator with the Installation Wizard

You can uninstall Data Aggregator using the installation wizard.

Follow these steps:

1. Open a command prompt. Type the following command to log in to the computer where you want to uninstall Data Aggregator as the root user:

   ```
   su - root
   ```

   If you cannot log in as the root user, configure a sudo user account with access to a limited set of commands.
2. Type the following command to access the uninstallation directory:

   ```
   cd <caimda> installation directory/Uninstall
   ```

3. Type the following command to run the uninstaller:

   ```
   ./Uninstall
   ```

   You are prompted to uninstall.
4. Click Next.
   The Uninstall Options dialog opens.

5. Select Complete Uninstall and click Next.
   Data Aggregator is uninstalled.

Uninstall the Data Collectors

After you uninstall the Data Aggregator component, uninstall the Data Collector component.

(Optional) Configure the Sudo User Account for Data Collector

If you cannot log in as the root user, create a sudo user with access to a limited set of commands.

Follow these steps:

1. Log in to the computer where you want to install Data Collector as the root user.
2. Add the following command alias to the command alias section of the /etc/sudoers file:

   ```
   Cmnd_Alias CA_DATACOLL = /tmp/install.bin, service dcmd, /opt/IMDataCollector/
   Uninstall/Uninstall

   ## Allows the <caimdc> user to manage the <caimdc>

   sudouser_name ALL = CA_DATACOLL
   ```

   This command alias details the commands that the sudo user must be able to run.
   The sudo user account is configured.

Uninstall the Data Collector

You can uninstall Data Collector that is installed on a computer in your networking environment.

Follow these steps:

1. Log in to the Data Collector host as the root user or sudo user.
2. Open a command prompt.
3. Access the uninstallation directory:

   ```
   cd DC_installation_directory/Uninstall
   ```

4. Run the uninstaller:

   ```
   ./Uninstall
   ```

   You are prompted to uninstall.
5. Select option 1 for a complete uninstallation, and press Enter.
6. Remove the following file:
   `/var/.com.zerog.registry.xml`
   Data Collector is uninstalled.

Uninstall the Data Repository

After you uninstall the Data Collector and Data Aggregator components, uninstall the Data Repository component.

TIP

Back up your Data Repository for later use.

Follow these steps:

1. Open a console and type the following command to become the Linux user account for the database administrator user:
   `su - Linux user account for the database administrator user`
   For example:
   `su - dradmin`
2. Type the following command:
   `/opt/vertica/bin/adminTools`
   The Administration Tools dialog opens.

   NOTE
   If the database is running in a cluster, you can launch adminTools from any node in the cluster.
3. Select (4) Stop Database and select OK.
   If Data Repository does *not* stop, select (7) Advanced Menu, then (2) Stop Vertica on Host. If Data Repository still does not stop, select (3) Kill Vertica Process on Host in the Advanced menu.

   NOTE
   If Data Repository is running in a cluster, you may need to select (3) Kill Vertica Process on Host on more than one host in the cluster.

   Data Aggregator stops automatically.
4. Note the location of the Data Repository data directory as follows:
   a. Select (6) Configuration Menu.
   b. Select (3) View Database.
   c. The database directory for the database is the parent of the catalog directory that is shown in the output.
5. Drop the database within the Administration Tools dialog as follows:
   a. Select (6) Configuration Menu.
   b. Select (7) Drop Database.
6. Exit as the database admin user and su, or login as the root/sudo user.
7. Type the following command to find the name of the Data Repository package that is installed:
   `rpm -qa | grep vertica`

   NOTE
   If Data Repository is running in a cluster, repeat this step for each host participating in the cluster.
8. Type the following command to remove the Data Repository package:
   `rpm -e package name retrieved in the previous step`

   NOTE
   If Data Repository is running in a cluster, repeat this step for each host participating in the cluster.
9. Delete the following directories:
   a. Type the following command to delete the /opt/vertica/ directory and all subdirectories:
      `rm -rf /opt/vertica/`
   b. Type the following command to display the database directory:
      `ls data_repository_directory`
      - **data_repository_directory**
        Specify the installation directory of your Data Repository.
        Default: `/opt/CA/IMDataRepository_verticaVersion/`

Verify that the database directory specified is correct.
Type the following command to delete the database directory:

```
rm -rf data_repository_directory
```

NOTE
If Data Repository is running in a cluster, repeat this step for each host participating in the cluster.

Data Repository is uninstalled.

Upgrading

To upgrade DX NetOps Performance Management from a previous release, complete the following steps:

NOTE

If you enable FIPS-compliant encryption and you upgrade NetOps Portal before the Data Aggregator as recommended, temporary FIPS compatibility synchronization errors occur. This temporary condition is resolved when the Data Aggregator is upgraded.

WARNING

Do not enable FIPS when a product upgrade is in progress and different versions of NetOps Portal and the Data Aggregator might be in place. Doing so could disable the Data Aggregator data source.

NOTE

If you are setting up fault tolerance for the first time, see Fault Tolerance.

1. Review the Upgrade Requirements and Considerations.
2. Plan the Upgrade or Migration.

   NOTE

   You must upgrade the existing system to the product version you are migrating to before migrating.
3. Upgrade the Data Repository.

   WARNING

   This release includes an update to the Data Repository backup procedure. Configure a new backup. For more information, see Back Up the Data Repository.
4. Upgrade Performance Center.
5. Upgrade the Data Aggregator.

   NOTE

   To upgrade the Data Aggregators in an existing fault tolerant environment, see Upgrade Fault Tolerant Data Aggregators.
6. Upgrade the Data Collectors.

   NOTE

   For a low-scale system where the Data Collector shares a host with the Data Aggregator, complete the configuration to enable the components to run on the same host. For more information, see Install a Low-Scale System.
7. Complete the Upgrade.

   TIP

   During an upgrade that includes a Data Repository upgrade, update the Data Repository first. If the validation script fails, you can restart your system with the previous version to reduce downtime.

Upgrade Requirements and Considerations

Before you upgrade, review the following information to ensure that you have met all the requirements:

For cloud environments, see Rehydrating Data in a Cloud Environment.

Verify System Requirements

To ensure that you successfully upgrade DX NetOps Performance Management, verify that your environment meets the system requirements. To verify the sizing requirements, use the DX NetOps Performance Management Sizing Tool.

The following operating systems were verified:

- SUSE Linux Enterprise Server (SLES) 12 SP2
- Oracle Linux (OL) 7.3 (Red Hat compatible kernel only)

The following RHEL versions were verified:

NOTE

A RHEL installation offers packages and add-ons. DX NetOps Performance Management supports a Minimal Install environment for RHEL.

- RHEL 6.6 - 6.9
- RHEL 6.10
- RHEL 7.3 - 7.5

NOTE

RHEL 6.8, 6.9, 7.3, or 7.4 are recommended.

The following RHEL versions are not supported:

- RHEL 5.x
- RHEL 6.5 and lower
- RHEL 7.0 - 7.2

DX NetOps Performance Management components that are installed on unsupported RHEL versions require an OS upgrade before upgrading the DX NetOps Performance Management components. You might also need to move the DX NetOps Performance Management components, including configurations, customizations, and data, from one system to another system. For more information, see Plan the Upgrade or Migration.

Package Requirements

The installer for each component requires the following packages:

Components	Packages
All (SLES)	• `dialog` • `mcelog` • `zip` • `unzip`
All (RHEL 7.x, OL)	• `dialog` • `mcelog` • `zip` • `unzip` • `chrony`

All (RHEL 6.x)	• dialog • mcelog • zip • unzip • glibc
NetOps Portal (SLES)	• fontconfig • libaio1 • libnuma1 • wget
NetOps Portal (RHEL 6.x)	• fontconfig • libaio • libaio-devel • numactl • wget
NetOps Portal (RHEL 7.x, OL)	• fontconfig • libaio • libaio-devel • numactl-libs • wget
Data Repository (RHEL 6.x, RHEL 7.x, SLES, OL)	• bc • pstack • gstack For RHEL 7.x, the pstack and gstack packages are included in the gdb package.
Data Collectors (RHEL 6.x, RHEL 7.x, SLES, OL)	• at

Direct Upgrade Paths

Because releases 20.2 and higher upgrade the Data Repository to Vertica release 9.1, we support Data Repository upgrades directly from the following releases only to 20.2:

- DX NetOps Performance Management 3.6
- DX NetOps Performance Management 3.7

NOTE

For DX NetOps Performance Management releases before 3.6, you must upgrade to the 3.6 release before upgrading the Data Repository to 20.2. The Vertica release 9.1 is the same for DX NetOps Performance Management 3.7 and 20.2. Therefore, a Data Repository upgrade is unnecessary from 3.7 to 20.2.

For other DX NetOps Performance Management components, we support upgrades directly from the following releases to 20.2:

- DX NetOps Performance Management 3.2
- DX NetOps Performance Management 3.5
- DX NetOps Performance Management 3.6
- DX NetOps Performance Management 3.7

For more information, see Plan the Upgrade or Migration.

Sudo User Installations

For systems without root access, sudo user accounts are used to install and run the software. Add the sudo prefix to commands to upgrade the components. Verify that your sudo accounts contain the correct permissions for each component.

For more information, see the sudo user configuration details for each component:

- Prepare to Install the Data Repository
- Prepare to Install Performance Center
- Prepare to Install the Data Aggregator
- Prepare to Install the Data Collectors

Back Up DX NetOps Performance Management

Before you begin the upgrade process, back up all aspects of the product:

- Data Repository
  For more information, see Back Up the Data Repository.
- NetOps PortalFor more information, see Back Up Performance Center.
- Data Aggregator
  For more information, see Back Up Data Aggregator.

Low-Scale Systems

For a low-scale system where the Data Collector shares a host with the Data Aggregator, complete the configuration to enable the components to run on the same host. For more information, see Install a Low-Scale System.

CA Business Intelligence Integrations

If you have an existing CA Business Intelligence (CABI) integration, this version of DX NetOps Performance Management supports CABI 6.4.2 and higher.

> **WARNING**
>
> After you upgrade to a supported CABI version, you must re-install your CABI content. For more information, see Install CA Business Intelligence Reports and Dashboards.

ActiveMQ Versions

To minimize data loss when you upgrade your Data Collectors, ActiveMQ continues to run unless its version is upgraded with the release.

The following DX NetOps Performance Management releases correspond with the following ActiveMQ versions:

DX NetOps Performance Management	ActiveMQ
2.5 and earlier	5.5.1
2.6, 2.7	5.11.1
2.8, 3.0, 3.1, 3.2	5.13.1
3.5 and later	5.15.2

Apache Karaf Update

Release 2.7 introduced an update to Apache Karaf that changes the name of the Karaf directory. Karaf now uses the following directory: `installation_directory/apache-karaf-2.4.3`

NetOps Upgrade Considerations

The DX NetOps Performance Management user interface now supports supports the co-existence of retired and replacement devices coming from CA Network Flow Analysis. If your system is integrated with CA Network Flow Analysis, you must upgrade CA Virtual Network Assurance along with DX NetOps Performance Management to ensure that Items monitored by both the Data Aggregator and Virtual Network Assurance are properly reconciled when Lifecycle changes occur.

Review the Known Limitations

To ensure that your system runs successfully after the upgrade, review the limitations of DX NetOps Performance Management 3.7. For more information, see Known Limitations.

Plan the Upgrade or Migration

The path that you take for your upgrade or migration depends on various factors. Use the following sections to plan your upgrade:

For cloud environments, see Rehydrating Data in a Cloud Environment.

Verify ETL Health

Before you upgrade, run the `etlHealth.sh` script. For releases 20.2.3 and higher, the script is included with the Data Repository installation. For earlier releases, contact Support. We recommend you run this script well in advance of the upgrade and again directly before the upgrade.

Follow these steps:

1. Log in to one of the Data Repository nodes as the root user.
2. Run the validation script:
   `./etlHealth.sh dauser dapassword`
3. Do one of the following:
   - If the health check passes, proceed with the upgrade.
   - If the health check fails, follow the instructions in the prompt to collect the irep and the data collected by the `etlHealth.sh` script, and submit these details in a Support ticket.

Plan the DX NetOps Performance Management Upgrade

Because releases 20.2 and higher upgrade the Data Repository to Vertica release 9.1, we support Data Repository upgrades directly from the following releases only to 20.2:

- DX NetOps Performance Management 3.6
- DX NetOps Performance Management 3.7

> **NOTE**
>
> For DX NetOps Performance Management releases before 3.6, you must upgrade to the 3.6 release before upgrading the Data Repository to 20.2. The Vertica release 9.1 is the same for DX NetOps Performance Management 3.7 and 20.2. Therefore, a Data Repository upgrade is unnecessary from 3.7 to 20.2.

For other DX NetOps Performance Management components, we support upgrades directly from the following releases to 20.2:

- DX NetOps Performance Management 3.2
- DX NetOps Performance Management 3.5
- DX NetOps Performance Management 3.6
- DX NetOps Performance Management 3.7

The following table describes the best upgrade paths for indirect upgrades to 20.2:

NOTE
For information about previous releases, see the previous documentation. For assistance locating releases 3.1 and earlier, contact your Support representative.

Current Version	Upgrade Path
3.2	3.5 to 3.6 to 20.2 (Data Repository) 20.2 (other components)
3.5	3.6 to 20.2 (Data Repository) 20.2 (other components)

NOTE
For the upgrade paths for releases before 3.2, see the previous documentation.

Plan the Operating System Upgrade or Install

The following operating systems were verified:

- SUSE Linux Enterprise Server (SLES) 12 SP2
- Oracle Linux (OL) 7.3 (Red Hat compatible kernel only)

The following Red Hat Enterprise Linux (RHEL) versions were verified:

NOTE

A RHEL installation offers packages and add-ons. DX NetOps Performance Management supports a Minimal Install environment for RHEL.

- RHEL 6.6 - 6.9
- RHEL 7.4
- RHEL 7.5

NOTE

RHEL 6.8, 6.9, 7.3, or 7.4 are recommended.

To plan your OS upgrade and understand your upgrade scenario, review the following details and answer the following questions:

NOTE

The following numbered questions correlate to the numbered decision steps in the following flowchart.

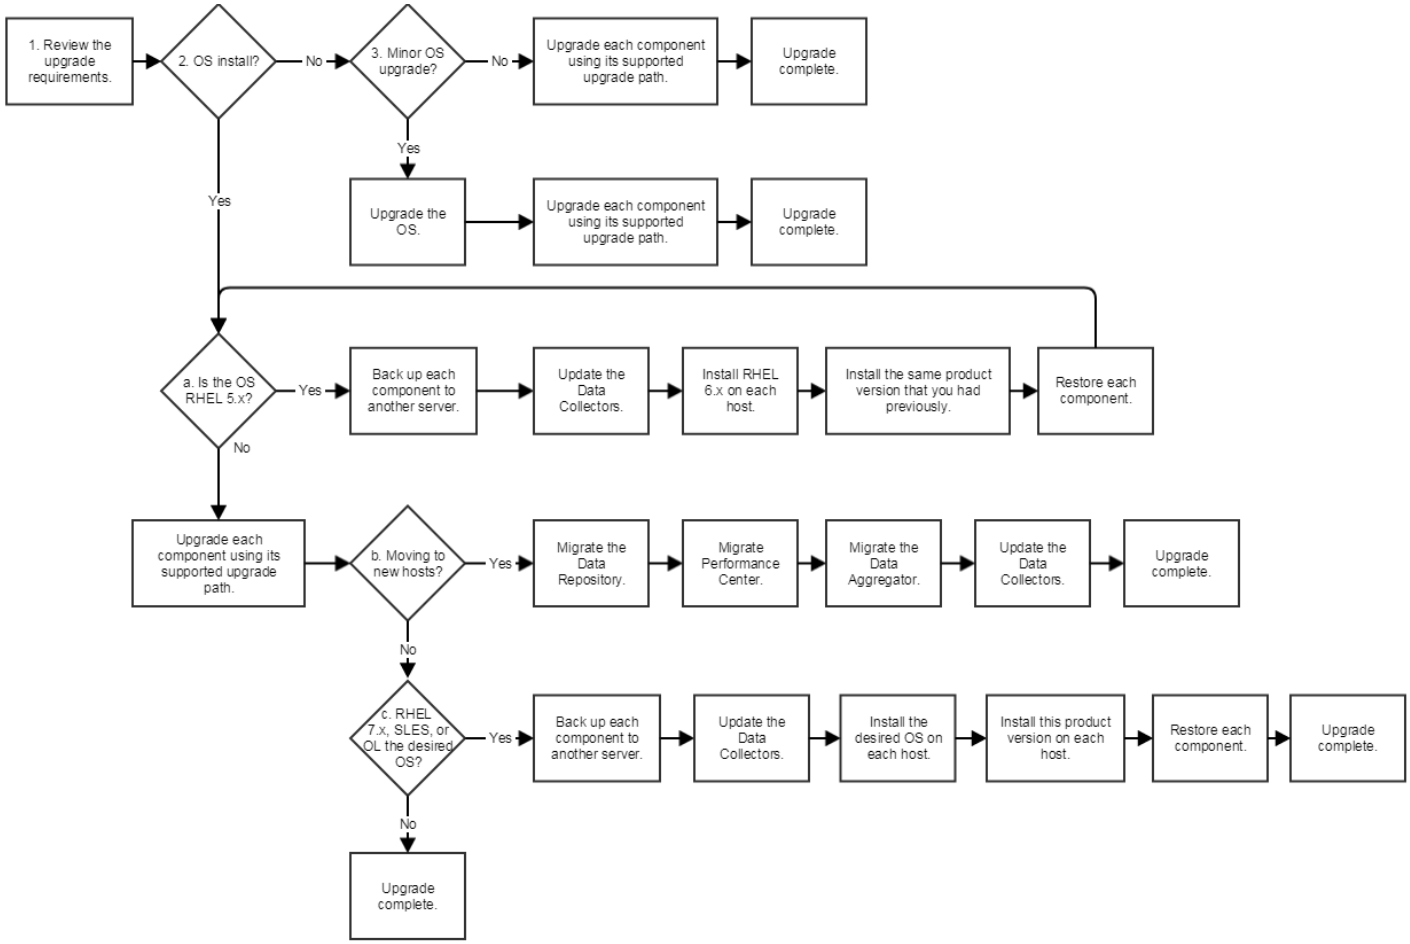
1. If you have not yet, review the Upgrade Requirements and Considerations.
2. Are you going to perform an OS installation (for example, going from RHEL 6.9 to RHEL 7.5 or SLES 12 SP2)?
   a. Is your current OS RHEL 5.x?
   b. Are you going to move to new hosts?
   c. Is RHEL 7.x, SLES, or OL the desired OS?
3. Are you going to perform a minor OS upgrade (for example, RHEL 6.5 to RHEL 6.9)?

The following OS upgrade and install scenarios upgrade or install the OS for all components. However, your unique scenario might upgrade or install the OS for a select set of components.

Upgrade Scenarios

Review the following graphic to help identify your upgrade scenario. Then use the procedures that are outlined in the following sections. The following graphic provides a high-level overview of some common upgrade scenarios:

Figure 6: Plan_Upgrade



Upgrade DX NetOps Performance Management without an OS Upgrade

If this version of DX NetOps Performance Management supports your current OS, you can upgrade each component using its supported upgrade path. For more information, see Upgrading.

Upgrade DX NetOps Performance Management with a Minor OS Upgrade

If you are performing a minor OS upgrade (for example, RHEL 6.5 to RHEL 6.9), do the following tasks:

1. Upgrade your OS.
2. Upgrade each component using its supported upgrade path. For more information, see Upgrading.

Migrate to New Hosts from a Supported OS

Migration involves moving the DX NetOps Performance Management components, including configurations, customizations, and data, from one system to another system.

The following situations require migration:

- You are moving to new hosts for an OS install (for example, RHEL 6.9 to RHEL 7.5 or SLES 12 SP2).
- The current database hardware no longer meets sizing requirements.
- You are moving from virtual machines to physical hardware for the database.

If you are moving DX NetOps Performance Management components to new systems with new IP addresses and hostnames from a supported OS, use the following procedures:

1. Upgrade each component using its supported upgrade path. For more information, see Upgrading.

   NOTE

   You must upgrade the existing system to the product version you are migrating to before migrating.
2. Migrate the Data Repository.

   NOTE

   Depending on the amount of data, migrating the Data Repository can take a significant amount of time.

   TIP

   To minimize downtime, perform incremental backups after your initial backup.
3. Migrate Performance Center.

   NOTE

   This migration procedure copies over NetOps Portal and does not require you to install NetOps Portal on the new host.
4. Migrate the Data Aggregator.
5. Update the Data Collector.
   a. For DX NetOps Mediation Manager, see the CAMM documentation.
   b. For DX NetOps Virtual Network Assurance, see the CA VNA documentation.

Migrate to New Hosts from an Unsupported OS

NOTE

If your current OS is RHEL 5.x, you must first move to RHEL 6.x.

If you are moving DX NetOps Performance Management components to new systems with new IP addresses and hostnames from an unsupported OS, use the following procedures:

1. Upgrade each component using its supported upgrade path until you reach a version from which you can upgrade directly to 20.2. For more information, see the Upgrading documentation for the version from which you are upgrading.
2. Back up each component to another server:
   a. Back Up the Data Repository.

      NOTE

      Depending on the amount of data, backing up and restoring the Data Repository can take a significant amount of time.

      TIP

      To minimize downtime, perform incremental backups after your initial backup.
   b. Back Up Performance Center.
   c. Back Up Data Aggregator.
3. Install the OS on each host.

4. Install the same product version from your recent upgrade on each host. For more information, see the Installing documentation for the recommended version.
5. Restore each component:

   NOTE

   For each component, verify that the backup is copied over.

   a. Restore Data Repository.
   b. Restore Performance Center.
   c. Restore Data Aggregator.
6. Upgrade each component to this product version. For more information, see Upgrading.
7. Migrate the Data Repository.

   NOTE

   Depending on the amount of data, migrating the Data Repository can take a significant amount of time.

   TIP

   To minimize downtime, perform incremental backups after your initial backup.
8. Migrate Performance Center.

   NOTE

   This migration procedure copies over NetOps Portal and does not require you to install NetOps Portal on the new host.
9. Migrate the Data Aggregator.
10. Update the Data Collector.
    a. For DX NetOps Mediation Manager, see the CAMM documentation.
    b. For DX NetOps Virtual Network Assurance, see the CA VNA documentation.

Perform an OS Installation from a Supported OS

If you are performing a major OS upgrade from a supported OS (for example, RHEL 6.9 to RHEL 7.5 or SLES 12 SP2) on the same systems with the same IP addresses and hostnames, use the following procedures:

1. Upgrade each component using its supported upgrade path. For more information, see Upgrading.

   NOTE

   You must upgrade the existing system to the product version you are backing up and restoring to before backing up and restoring.
2. Back up each component to another server:
   a. Back Up the Data Repository.

      NOTE

      Depending on the amount of data, backing up and restoring the Data Repository can take a significant amount of time.

      TIP

      To minimize downtime, perform incremental backups after your initial backup.
   b. Back Up Performance Center.
   c. Back Up Data Aggregator.
3. Update the Data Collector.
   a. For DX NetOps Mediation Manager, see the CAMM documentation.
   b. For DX NetOps Virtual Network Assurance, see the CA VNA documentation.

4. Install the OS on each host.
5. Install this product version on each host. For more information, see Installing.
6. Restore each component:

   NOTE

   For each component, verify that the backup is copied over.

   a. Restore Data Repository.
   b. Restore Performance Center.
   c. Restore Data Aggregator.

Perform an OS Installation from an Unsupported OS

NOTE

If your current OS is RHEL 5.x, you must first move to RHEL 6.x.

If you are performing a major OS upgrade from an unsupported OS (for example, RHEL 5.x to RHEL 6.9) on the same systems with the same IP addresses and hostnames, use the following procedures:

1. Upgrade each component using its supported upgrade path until you reach a version from which you can upgrade directly to 20.2. For more information, see the Upgrading documentation for the version from which you are upgrading.
2. Back up each component to another server:
   a. Back Up the Data Repository.

      NOTE

      Depending on the amount of data, backing up and restoring the Data Repository can take a significant amount of time.

      TIP

      To minimize downtime, perform incremental backups after your initial backup.

   b. Back Up Performance Center.
   c. Back Up Data Aggregator.
3. Update the Data Collector.
   a. For DX NetOps Mediation Manager, see the CAMM documentation.
   b. For DX NetOps Virtual Network Assurance, see the CA VNA documentation.
4. Install the OS on each host.
5. Install the same product version from your recent upgrade on each host. For more information, see the Installing documentation for the recommended version.
6. Restore each component:

   NOTE

   For each component, verify that the backup is copied over.

   a. Restore Data Repository.
   b. Restore Performance Center.
   c. Restore Data Aggregator.
7. Upgrade each component to this product version. For more information, see Upgrading.

Upgrade the Data Repository

Upgrade the Data Repository first. If the dr_validate.sh script detects issues that you must resolve before the upgrade, you can restart your system while you resolve the issue.

NOTE
The Vertica release 9.1 is the same for DX NetOps Performance Management 3.7 and 20.2. Therefore, a Data Repository upgrade is unnecessary from 3.7 to 20.2.

To upgrade the Data Repository, complete the following steps:

Verify the Prerequisites

Verify the following prerequisites before you upgrade Data Repository:

NOTE
For information about previous releases, see the previous documentation. For assistance locating releases 3.1 and earlier, contact your Support representative.

- If your current Data Repository is running Vertica 7.2.3 (the version that is used in DX NetOps Performance Management 3.0 / 3.1), you must do an intermediate upgrade to Vertica 8.1.
  - Check the version running by using admintools as the database admin:
    ```
    /opt/vertica/bin/admintools -t list_allnodes
    ```
  - Use the 3.5_installDR.bin provided with the 3.6 Media to upgrade to Vertica 8.1.
  - Refer to the 3.5 Data Repository upgrade procedures.
  - Once Data Repository is running on Vertica 8.1, proceed with the DX NetOps Performance Management 3.6 Data Repository upgrade.
- If your current Data Repository is running Vertica 7.1.2 (the version that is used in DX NetOps Performance Management 2.7 / 2.8), you must do an intermediate upgrade to Vertica 7.2.3.
  - Check the version running by using admintools as the database admin:
    ```
    /opt/vertica/bin/admintools -t list_allnodes
    ```
  - Use the 3.1_installDR.bin provided with the 3.5 Media to upgrade to Vertica 7.2.3.
  - Refer to the 3.1 Data Repository upgrade procedures.
  - Once Data Repository is running on Vertica 7.2.3, proceed with the DX NetOps Performance Management 3.5 Data Repository upgrade.
- Verify whether the dialog, chrony, zip, and unzip packages are installed on each Data Repository host:

  NOTE

  The chrony package is required only for RHEL 7.x and OL 7.x.

  ```
  rpm -qa | grep ^dialog
  rpm -qa | grep ^chrony
  rpm -qa | grep ^zip
  rpm -qa | grep ^unzip
  ```

  If a required package for your OS is missing, install the package:

  NOTE

  If you are not the root user, use the sudo prefix.

  ```
  yum -y install dialog
  yum -y install chrony
  yum -y install zip
  yum -y install unzip
  ```

SLES:

```
zypper install dialog -y
zypper install zip -y
zypper install unzip -y
```

If this package is not installed, the validation and installation scripts fail.

- Verify that the Data Repository host has at least 2 GB of swap space.
- Verify that the Data Repository hosts use the ext4 file system for data and catalog directories. If not, remake the file system as ext4.

  WARNING

  The default file system for RHEL 7.x and OL 7.x is the XFS file system. The default file system for SLES is btrfs. Vertica does not support XFS or btrfs. The database supports only the ext4 file system.
- Verify that you are not using Logical Volume Manager (LVM) for data and catalog directories.

Verify Hardware and Network Performance

Vertica provides a set of utilities that test the performance of your hardware for the Data Repository. To verify that the environment is ideal for the database, run these tests before you upgrade the Data Repository.

NOTE

If you have already installed the Data Repository, you can perform these tests at any time to verify performance. The utilities are available on each node in `/opt/vertica/bin` .

If the tests do not meet the recommendations, fix the issues before you continue the upgrade.

vcpuperf

This utility measures the CPU processing speed of the host and compares the speed against benchmarks for common server CPUs. The utility measures how long the server requires to complete the test, and determines whether CPU throttling is enabled.

Follow these steps:

1. Execute the following command on *each* Data Repository node:

   ```
   ./vcpuperf > /tmp/vcpuperf.out
   ```

2. Verify that the performance meets the following requirements:
   - The CPU time is consistent with the benchmark values in the output.
   - The low load time and high load time are within 10 microseconds. If the difference is grater than 50 microseconds, CPU throttling might be enabled on your system. Disable CPU throttling.

Example:

The following example shows the return from this utility:

```
$ /opt/vertica/bin/vcpuperf

Compiled with: 4.1.2 20080704 (Red Hat 4.1.2-52)

Expected time on Core 2, 2.53GHz: ~9.5s
```

```
Expected time on Nehalem, 2.67GHz: ~9.0s

Expected time on Xeon 5670, 2.93GHz: ~8.0s

This machine's time:

CPU Time: 7.740000s

Real Time:7.740000s

Some machines automatically throttle the CPU to save power.

This test can be done in <100 microseconds (60-70 on Xeon 5670, 2.93GHz).

Low load times much larger than 100-200us or much larger than the corresponding high
 load time

indicate low-load throttling, which can adversely affect small query / concurrent
 performance.

This machine's high load time: 67 microseconds.

This machine's low load time: 64 microseconds.
```

This test was performed on a system with 2.67-GHz processors, so the real time is acceptable. The difference between the high load time and low load time is within the expected tolerance.

For more information about this utility, see the Vertica documentation.

vioperf

This utility tests the performance of the disk input and output (I/O). The utility performs a series of reads and writes.

NOTE

To measure the read/write speeds when using the same SAN/NAS for the disk or VM disk, you must run vioperf on all nodes of the cluster at the same time for the data or catalog directory.

Follow these steps:

1. Execute the following commands on *each* Data Repository node:

   ```
   ./vioperf /data > /tmp/vioperf.out --duration=60sec
   ```

   /data is the full path of the data directory.

   ```
   ./vioperf /catalog > /tmp/vioperf.out --duration=60sec
   ```

   /catalog is the full path of the catalog directory.
2. Verify the Write and Read counter values at least 40 MB/s per core.
   The recommended I/O is 40 MB/s per physical core on each node. For example, the recommended I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 480 MB/s.

   WARNING

   If the **thread count** column shows a value of 1, the utility cannot determine the number of cores. Add the following arguement to the command to run the utility:

   ```
   --thread-count=CORES
   ```

   Cores defines the number of cores in the system as a fixed integer.

Example:

The following example shows the return from this utility for the data directory:

```
The minimum required I/O is 20 MB/s read and write per physical processor core on each
 node, in full duplex i.e. reading and writing at this rate simultaneously, concurrently
 on all nodes of the cluster. The recommended I/O is 40 MB/s per physical core on each
 node. For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs
 is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/drdata"
```

```
test      | directory                                        | counter name        |
 counter value       | counter value (10 sec avg)      | counter value/core  | counter
 value/core (10 sec avg) | thread count  | %CPU  | %IO Wait  | elapsed time (s)|
 remaining time (s)

-------------------------------------------------------------------------------------------

Write     | /drdata                                          | MB/s
  | 873                | 873                             | 54.5625             |
 54.5625                         | 16            | 29    | 40        | 10              |
 5

Write     | /drdata                                          | MB/s
  | 868                | 865                             | 54.25               |
 54.0625                         | 16            | 28    | 30        | 15              |

 275.438                         | 16            | 3     | 15        | 15              |
 0
```

This server has 16 cores. The Read and Write counter values indicate the I/O is greater than 40 MB/s per core.

For more information about this utility, see the Vertica documentation.

vnetperf

This utility tests the network performance of the Data Repository hosts. The utility measures network latency and the throughput for the TCP and UDP protocols.

> **WARNING**
>
> This utility causes a high network load and affects database performance. Do not run this utility while the database is running.

Follow these steps:

1. Log in as a user that has passwordless ssh between the nodes.
2. Execute the following command on *one* of the Data Repository nodes:

   ```
   ./vnetperf --hosts DAhost,DRhost1,DRhost2,DRhost3 > /tmp/vnetperf.out
   ```

   Specify the hostname or IP address of the Data Aggregator host and each Data Repository host.
3. Verify that the network performance meets the following requirements:
   - Round-trip time (RTT) latency of 200 microseconds or less
   - Clock skew under 1 second
   - Throughput of 800 MB/s or more
     The utility runs a series of throttled tests. Verify the throughput for the highest speed test.

For more information about this utility, see the Vertica documentation.

Verify the Limit on the Number of Open Files

Verify that the user that is installing Data Repository has a value of at least 65536 on the number of open files. Set this value permanently. Complete this procedure for each node in the Data Repository cluster.

Follow these steps:

1. As the root or sudo user, log in to the Data Repository host node.
2. Run the following command:

   ```
   su dradmin
   ```

3. Verify the number of open files:

   ```
   ulimit -n
   ```

   The command returns the ulimit number. This number must be at least 65536.

   > **NOTE**
   >
   > The number must be the same on all nodes in the cluster.

4. If this number is not at least 65536, do the following steps:
   a. Change the ulimit for the open files limit to 65536:
      ```
      ulimit -n 65536
      ```
   b. Open the /etc/security/limits.conf file on each Data Repository node, and add the following lines:
      ```
      # Added by Vertica
      * soft nofile 65536
      # Added by Vertica
      * hard nofile 65536
      # Added by Vertica
      *       soft    fsize   unlimited
      # Added by Vertica
      *       hard    fsize   unlimited
      ```
   c. Restart the sshd service on each Data Repository node:
      ```
      service sshd restart
      ```

      NOTE

      For RHEL 7.x, and OL 7.x `service` invokes `systemctl` . You can use `systemctl` instead.

      NOTE

      If you do not have the restart argument, stop and start sshd:

      ```
      service sshd stop
      service sshd start
      ```

   d. Verify that the number of open files is set properly:
      ```
      ulimit -n
      ```

      The command returns the ulimit number that you specified earlier.

Disable the Automatic Recovery of the Data Aggregator Process

The recovery process restarts the Data Aggregator. Disable the automatic recovery before you upgrade. For a fault tolerant environment, put the inactive Data Aggregator and then the active Data Aggregator into maintenance mode.

Follow these steps:

1. Log in to the Data Aggregator host as the root user.
2. Open a console and type the following command:
   ```
   crontab -e
   ```

   A vi session opens.
3. If the following line exists, add # to the beginning of the line to comment it out:
   ```
   # * * * * * /etc/init.d/dadaemon start > /dev/null
   ```

   The automatic recovery is disabled.

(Fault Tolerant Environment) Turn on Maintenance Mode

WARNING

If you are upgrading the Data Aggregators in an existing fault tolerant environment, you must put the Data Aggregator into maintenance mode before upgrade.

Put the inactive Data Aggregator into maintentance mode first. Then put the active Data Aggregator into maintenance mode.

For more information, see Fault Tolerance.

Follow these steps:

1. Log in to the Data Aggregator host as the root user or a sudo user.
2. Run one of the following commands to shut down the inactive Data Aggregator and prevent it from restarting until the upgrade is complete:

- – **RHEL 6.x:**

```
service dadaemon maintenance
```

– **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon maintenance
```

Upgrade Data Repository

You can initiate the Data Repository installation from any of the hosts in the cluster. The required software components are pushed to the other nodes during the installation.

Follow these steps:

1. Log in to one of the Data Repository nodes as the root user.
2. Determine which hosts Vertica is running on:
   a. As the database administrator user, open the Vertica Administration Tools:
   ```
   /opt/vertica/bin/adminTools
   ```
   b. Select option 6 (Configuration Menu).
   c. Select option 3 (View Database).
   d. Select the database.
   e. Note the IP addresses and database name for use later in this procedure.
   f. Exit the adminTools utility, and revert to the root user or sudo user.
3. Copy the installDR.bin file to /tmp.
4. Change directory to the location of the installDR.bin file:
   ```
   cd /tmp
   ```
5. Change the executable permissions:
   ```
   chmod u+x installDR.bin
   ```
6. Extract the installation files:
   ```
   ./installDR.bin
   ```
7. Follow the instructions in the console.
   This script extracts the following installation scripts:

- **dr_validate.sh** verifies that the system meets the prerequisites for the Data Repository upgrade.
- **dr_install.sh** upgrades the Vertica database.

8. If available from the Data Repository with the older version of Vertica, copy the existing drinstall.properties to the following directory:
   `/opt/CA/IMDataRepository_vertica`*`Version`*

   NOTE
   This path is the default location.
9. Change directories to the location where you extracted the installation scripts:
   `cd /opt/CA/IMDataRepository_vertica`*`Version`*

   NOTE

   This path is the default location.
10. Verify that the parameters in the drinstall.properties file are correct. Review the following parameters:
    - DbAdminLinuxUser=*The Linux user who is created to serve as the Vertica database administrato*r
      Default: dradmin
    - DbAdminLinuxUserHome=*The Vertica Linux database administrator user home directory*
      Default: /export/dradmin
    - DbDataDir=*The location of the data directory*
      Default: /data

      NOTE

      To verify the data directory or catalog directory, complete the following steps:

      1. Open the /opt/vertica/config/admintools.conf file.
      2. Scroll down until you see the [Nodes] section.
      3. Locate one of the lines that begins with v_*dbname*_node####.
         This line contains the IP address of the node, the location of the catalog directory, and the location of the data directory.
         Example:
         `v_drdata_node0001 = 10.42.1.1,/catalog,/data`

    - DbCatalogDir=*The location of the catalog directory*
      Default: /catalog
    - DbHostNames=*The comma-delimited list of hostnames for Data Repository*
      Default: yourhostname1,yourhostname2,yourhostname3
    - DbName=*The database name*
      Default: drdata

      NOTE

      This parameter is case-sensitive.
    - DbPwd=*The database password*
      Default: dbpass

      NOTE

      You can use special characters (except for single quotation marks) in passwords. If the `DbPwd` property is not found or blank, the script prompts for this information at runtime.

    NOTE
    The InstallDestination is no longer used and can be safely removed.
11. Verify that Data Repository is running.

12. On the Data Aggregator host, open a command prompt. Do one of the following steps:
    - Stop the Data Aggregator service:
      ```
      service dadaemon stop
      ```
    - (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
      - **RHEL 6.x:**
        ```
        service dadaemon maintenance
        ```
      - **RHEL 7.x, SLES, or OL:**
        ```
        DA_Install_Directory/scripts/dadaemon maintenance
        ```
13. Run the validation script:
    ```
    ./dr_validate.sh -p drinstall.properties
    ```

    TIP

    You can use the `-l` flag to allow `localhost` as the value for the `DbHostNames` property. You can use the `-n` flag to skip database connectivity checks.

    The script validates the system settings. Review and resolve any errors or warnings. You can run this script multiple times to verify that all system configuration options are set properly. The validation script may prompt you to reboot.
14. Use Vertica adminTools to stop the Data Repository:
    a. Switch to the database admin user.
    b. Open adminTools:
       ```
       /opt/vertica/bin/adminTools
       ```
    c. Select (4) Stop Database.
    d. Select the database, confirm the selection, and provide the password.
    e. Exit the adminTools utility, and revert to the root user or sudo user.
15. Run the installation script:
    ```
    ./dr_install.sh -p drinstall.properties
    ```

    The installation script upgrades the data repository and disables unnecessary Vertica processes. You might be prompted for the Vertica Linux database administrator user password.

    NOTE

    If passwordless SSH is not set up, the script prompts for the password to set up.

    If the installation script returns a WARN message for LVM on directories that Vertica does not use, contact CA Support.
16. Verify that you upgraded Data Repository correctly by doing the following steps:
    a. As the database administrator user, open the Vertica Administration Tools:
       ```
       /opt/vertica/bin/adminTools
       ```
    b. Verify that the top of the banner indicates that the database version is 9.1.1-5.
17. Restart the Data Repository selecting option 3 (Start Database) from the main menu of the Administration Tools dialog.

NOTE

If this is the first time you have stopped the database after the 30 June 2015 leap second, Vertica might fail to start. For more information, see Vertica Fails to Start.

The Data Repository restarts.

Update the Backup

This release includes new functionality for the Data Repository backup. Previous backups and backup configuration files are not compatible with this release. Set up a new version of the backup. For more information, see Back Up the Data Repository.

Upgrade Performance Center

After you upgrade the Data Repository component, upgrade the NetOps Portal component.

NOTE

If you enabled FIPS-compliant encryption, and you upgrade NetOps Portal before the Data Aggregator, temporary FIPS compatibility synchronization errors occur. These errors occur until the Data Aggregator is upgraded. To avoid this temporary condition, upgrade the Data Aggregator before upgrading NetOps Portal.

To host the NetOps Portal database on a separate node, first upgrade to this release, then migrate the database to a separate system.

NOTE
If you have the MySQL database on one node and the Performance Center services on another, run the upgrade on the MySQL database first.

The upgrade requires the zip and unzip packages. If these packages are not installed, use one of the following commands to install them:

```
yum -y install zip unzip
```

SLES:

```
zypper install -y zip unzip
```

NetOps Portal requires the wget package. If this package is not installed, use one of the following commands to install it:

```
yum -y install wget
```

SLES:

```
zypper install -y wget
```

To upgrade NetOps Portal, complete the following procedures:

MySQL Password Requirements (3.7.3 and Higher Only)

As a step toward enhanced security, the Performance Center installation prompts you to set a custom MySQL password.

The MySQL password must meet the following requirements:

- Excludes the user names "root" or "netqos"
- Minimum length of 8 characters
- Maximum length of 30 characters
- Contains at least 3 of the following types of characters:

  - Special Characters (!#&?)
  - Uppercase
  - Lowercase
  - Numbers (0-9)
- Excludes the percentage sign (%), apostrophe ('), or quotation mark (")
- **(3.7.3 through 3.7.4 Only)** Excludes the asterisk (*), or the dollar sign ($)

Verify the ulimit Value

Verify that the user account that is installing CA NetOps Portal has a value of at least 65536 on the number of open files. Set this value permanently.

Follow these steps:

1. As the root user or a sudo user, log in to NetOps Portal host.
2. Open a command prompt and type the following command to verify the ulimit value:
   ```
   ulimit -n
   ```
3. If the value is not at lease 65536, change the value:
   a. Type the following command:
      ```
      ulimit -n 65536
      ```
   b. Open the /etc/security/limits.conf file, and add the following lines:
      ```
      # Added by Performance Center
      * soft nofile 65536
      # Added by Performance Center
      * hard nofile 65536
      ```

Upgrade CA NetOps Portal

The CA NetOps Portal installer includes features to support product upgrades. To perform an upgrade of the software, run the installation file for the new version that you received from CA.

To determine which version you have installed, access the .history file in the /opt/CA/PerformanceCenter/InstallLogs directory.

Follow these steps:

1. Save the installation file to /tmp on the CA NetOps Portal server.

   NOTE

   Verify that your /tmp location has at least 2 GB of space available.
2. Run the following command:
   ```
   cd /tmp
   ```
3. Change the directory permissions:
   ```
   chmod +x CAPerfCenterSetup.bin
   ```
4. Run the following command:
   ```
   ./CAPerfCenterSetup.bin -i console
   ```
   The installation begins in Console mode.

   NOTE

   1. To generate a response file for silent installation, add the following argument:
      ```
      -r response_file
      ```

response_file specifies the directory the directory path and file name for the response file.
Example: /tmp/installer.properties

Follow the prompts until you get to the summary, type "quit", and press Enter.

2. (Optional) On upgrade, the disaster recovery script is backed up. If a backup file already exists, you can overwrite it with the current file. To overwrite the disaster recovery script backup, add the following to the response file:

   ```
   -fileOverwrite_/opt/CA/PerformanceCenter/product_version_capc.sh=Yes
   ```

3. To run the installation in silent mode, use the following command:

   ```
   ./installDA.bin -i silent -f response_file
   ```

   response_file is the directory path and file name of the previously generated response file.

5. Follow the instructions in the console.

   NOTE

   If the current install owner is the `root` user, you are prompted to specify an install owner. You can specify a non-root user.

   The installation checks to see whether the partition with the MySQL data directory has enough disk space to handle storage engine upgrades. If there does not appear to be enough disk space to complete the installation successfully, exit the installer, allocate more space for the data partition, and reinstall NetOps Portal.

   (3.7.3 and Higher Only) As a step toward enhanced security, the Performance Center installation prompts you to set a custom MySQL password.

   WARNING

   When you upgrade from a release before DX NetOps Performance Management 3.6 to release 3.6 or higher, the storage engine is migrated. The upgrade might take longer than expected up to an hour. Do not cancel the installation while it runs.

6. (Optional) When prompted, specify the following parameters for fault tolerance. For more information, see Fault Tolerance.
   - **Configure with Fault Tolerant Data Aggregator**
     If fault tolerance was configured for the Data Aggregators, specify 2 for Yes.
     Default: 1
   - **Data Aggregator Proxy Host**
     Specify the host name/IP address of the proxy server.

   The upgrade operation installs the software. The progress indicator may pause.
   When the upgrade is complete, the console displays a confirmation message.

Reapply Custom MySQL Settings

For upgrades from releases before DX NetOps Performance Management 3.0, this upgrade includes updates to MySQL. These updates require replacing my.cnf. The upgrade backs up the existing my.cnf files as my.cnf.bak. If my.cnf.bak already exists, the backup adds a number to the end of the file name. To retain custom MySQL settings, reapply the settings in the my.cnf files.

Follow these steps:

1. Locate my.cnf and my.cnf.bak in the following directories:
   - /etc/my.cnf
   - /opt/CA/MySql/my.cnf
     This path reflects the default.
2. Copy the relevant setting values from my.cnf.bak to my.cnf.
3. Restart MySQL:

```
service mysql restart
```

Clear Browser Cache

Instruct DX NetOps Performance Management users to clear their browser cache before accessing the upgraded version.

(Optional) Restart the CA NFA OData Service

If you have Network Flow Analysis as a data source, you must restart the CA NFA OData service:

1. Click **Administration Services**, and **Services**.
2. Right-click the CA NFA OData Service.
3. Click **Restart**.

(Optional) Review Log Files

Review the log files in the following directory to track any issues with the upgrade:

Installation Errors and Configuration Events

```
/opt/CA/PerformanceCenter/InstallLogs
```

Verify that the directory contains each log with the install date and time:

- `MySql_*`
- `SSO_*`
- `Device_Manager_*`
- `Event_Manager_*`
- `Console_*`
- `Install_*`

If any logs are missing, the installation is incomplete. Review each log for any fatal errors. Verify that the `.history` file is updated to the latest version.

Migrate the Performance Center Database to a Separate Node

You can isolate the resources used for the database and allow for independent performance tuning by installing the NetOps Portal database on a separate node.

To use a separate MySQL database, upgrade to the latest release, *then* migrate data from the existing database to a separate MySQL database.

> **NOTE**
> In the following steps, *original node* refers to the node which has the single node deployment of NetOps Portal. After you complete these steps, this node hosts only the NetOps Portal services.
>
> *Database node* refers to the new node hosts the externalized database.

1. Run the NetOps Portal installation on the original node to upgrade it to the current release.
2. Run the NetOps Portal installation on the database node. Select **Advanced Installation**, and then install the Database feature.
3. Stop the NetOps Portal services on the original node by running the following commands:

```
service caperfcenter_sso stop
 service caperfcenter_console stop
service caperfcenter_devicemanager stop
service caperfcenter_eventmanager stop
```

4. Dump the NetOps Portal **netqosportal** and **em** databases on the original node by running the following commands:
   ```
   /opt/CA/MySql/bin/mysqldump --routines -u root -pnetqos --databases netqosportal
    > <backupdir>/netqosportal.sql
   /opt/CA/MySql/bin/mysqldump --routines -u root -pnetqos --databases em
    > <backupdir>/em.sql
   ```

5. Transfer the dumped database SQL files to a directory (`backupdir`) on the database node. Run the following commands to import the dumped files into the database:
   ```
   mysql -unetqos -pnetqos -e 'source <backupdir>/netqosportal.sql'
    mysql -unetqos -pnetqos -e 'source <backupdir>/em.sql'
   ```

6. Run the `/opt/CA/PerformanceCenter/Tools/bin/uninstall_database_component.sh` script on the original node.
   This script removes the Database feature from the registry and removes the NetOps Portal `/opt/CA/PerformanceCenter/CAPC_Database_SeedFile.xml` database seed file.
7. Rerun the NetOps Portal installation on the original node.
   When prompted, provide the hostname and port (3306) of the externalized database on the database node.
8. Verify that you can now access NetOps Portal through port 8181 on the original node.
9. Uninstall MySQL from the original node by running the following script:
   `/opt/CA/PerformanceCenter/Uninstall_MySql`

   NOTE
   This procedure does not remove the stored data. To remove the stored data, run the following command:
   ```
   rm -rf /opt/CA/MySql
   ```

Upgrade the Data Aggregator

To upgrade the Data Aggregator, complete the following steps:

NOTE

If you enabled FIPS-compliant encryption, and you upgrade NetOps Portal before the Data Aggregator, temporary FIPS compatibility synchronization errors occur. These errors occur until the Data Aggregator is upgraded. To avoid this temporary condition, upgrade the Data Aggregator before upgrading NetOps Portal.

Verify the Prerequisites

Meet the following prerequisites before you upgrade the Data Aggregator:

- If you have authenticated and encrypted activeMQ communication, you must regenerate the keys before this upgrade. For more information, see Authenticate and Encrypt ActiveMQ Communication.

  NOTE
  For the first and last name prompt, you must enter the host name of the system where you are creating the certification.

  Without new keys, the Data Aggregator and Data Collector cannot communicate.
- Verify that ports 8581, 61616, 61618, 61620, and 61622 are open for communication between your Data Collectors and your Data Aggregators.
  For the detailed port list, Review Installation Requirements and Considerations.
- Before you upgrade, verify the zip and unzip packages are installed. If these packages are not installed, use the following command to install them:

```
yum -y install zip unzip
```

- For the Data Aggregator and the Data Collectors, the default maximum memory is 80% of the total system memory. AMQ uses 20% of total memory on both components. Both components reserve 2 GB of memory for the operating system. These maximum values can be modified, however the modifications are not preserved during an upgrade. For more information, see Modify Maximum Memory Usage for Data Aggregator and Data Collector Components.

Verify the Limit on the Number of Open Files on Data Aggregator

Verify that the user that is installing Data Aggregator has a limit of at least 65536 on the number of open files. Set this value permanently.

Follow these steps:

1. As the root user or a sudo user, log in to the Data Aggregator host.
2. Change the ulimit for the open files limit to at least 65536:
   ```
   ulimit -n ulimit_number
   ```
   For example:
   ```
   ulimit -n 65536
   ```
3. Open the following file:
   ```
   /etc/security/limits.conf
   ```
4. Add the following lines:
   ```
   # Added by Data Aggregator
   * soft nofile 65536
   # Added by Data Aggregator
   * hard nofile 65536
   ```

   NOTE
   Restart Data Aggregator for these changes to take effect. If you are upgrading, the upgrade process automatically restarts Data Aggregator.
5. Verify that the number of open files is set properly:
   ```
   ulimit -n
   ```
   The command returns the limit that you specified earlier.

Verify That the Data Repository Is Running

The Data Aggregator Upgrade requires that the Data Repository is running.

Follow these steps:

1. Log in to the Data Repository host.
2. Verify that the Data Repository is running:
   ```
   /opt/vertica/bin/vsql -U dauser -w dapass -c 'select version()'
   ```
   The expected return shows the version of the Data Repository:
   ```
                version
   -----------------------------------
    Vertica Analytic Database vx.x.x-x
   ```

(Optional) Temporarily Connect to Older Versions of Data Collectors

You can reduce data loss during an upgrade by temporarily connecting existing Data Collectors (version 3.0, 3.1, or 3.2) to an upgraded Data Aggregator. Consider this upgrade option if you have many Data Collectors to upgrade.

> **WARNING**
>
> Important! Connecting 3.x versions of Data Collectors to upgraded Data Aggregators is only supported on a temporary basis.
>
> New features in DX NetOps Performance Management 3.5 may not be compatible with older Data Collectors. Before using new features or making configuration changes, upgrade all Data Collectors to the same version as the Data Aggregator.

Follow these steps before upgrading the Data Aggregator:

1. Create a file called com.ca.im.dm.core.collector.controller.cfg in the following location: /opt/IMDataAggregator/apache-karaf-2.4.3/etc/
2. Add the following single line to the file:
   ```
   allowed-mismatch-dc-version=3.0.0.0
   ```
3. Save the file.
4. Proceed with upgrading the Data Aggregator.

Verify ETL Health

Before you upgrade, run the `etlHealth.sh` script. For releases 20.2.3 and higher, the script is included with the Data Repository installation. For earlier releases, contact Support. We recommend you run this script well in advance of the upgrade and again directly before the upgrade.

Follow these steps:

1. Log in to one of the Data Repository nodes as the root user.
2. Run the validation script:
   ```
   ./etlHealth.sh dauser dapassword
   ```
3. Do one of the following:
   - If the health check passes, proceed with the upgrade.
   - If the health check fails, follow the instructions in the prompt to collect the irep and the data collected by the `etlHealth.sh` script, and submit these details in a Support ticket.

Upgrade the Data Aggregator

To upgrade the Data Aggregator, run the installation as the root or sudo user.

Follow these steps:

1. Log in to the Data Aggregator host as the root user or a sudo user.
2. Copy the installDA.bin file to the /tmp directory.
3. Change to the /tmp directory:
   ```
   cd /tmp
   ```
4. Change permissions for the installation file:
   ```
   chmod a+x installDA.bin
   ```

5. To run the upgrade, do one of the following steps:
   - Run the installation as the root user:
     ```
     ./installDA.bin -i console
     ```
   - Run the installation as the sudo user:
     ```
     sudo ./installDA.bin -i console
     ```

     NOTE

     To generate a response file for silent installation, add the following argument:

     `-r response_file`

     response_file specifies the directory the directory path and file name for the response file.
     Example: /temp/installer.properties

     Follow the prompts until you get to the summary, type "quit", and press Enter.

     To run the installation in silent mode, use the following command:

     `./installDA.bin -i silent -f response_file`

     response_file is the directory path and file name of the previously generated response file.
6. Follow the instructions in the console.

   WARNING

   If the Data Repository was migrated, follow the Data Aggregator upgrade instructions in the console. Answer NO when prompted to drop the schema and the upgrade continues. If you answer YES, you lose your migrated data.

   WARNING

   When you are prompted for the data directory, use the default directory. Do not use `DA_Install_Directory/apache-karaf-version/data`.
7. (Optional) When prompted, specify the following parameters to configure fault tolerance. For more information, see Fault Tolerance.

   WARNING

   If you are upgrading an existing fault tolerant environment, see Upgrade Fault Tolerant Data Aggregators.

   - **Configure Data Aggregator For Fault Tolerance**
     Specify 2 to configure fault tolerance.
     Default: 1

     NOTE

     The default is for a non-fault tolerant environment.
   - **Data Aggregator Proxy Host**
   - Specify the host name/IP address of the proxy server.
   - **Consul HTTP port:**
     Specify the port for communication with Consul.
     Default: 8500
   - **Choose host IP address for Consul**

NOTE

This prompt appears only when multiple public IP addresses are configured.

Specify the bind address that the Consul agents use to communicate with each other. The Consul agents include the proxy host and both Data Aggregators in the cluster. If prompted for an address, specify an address that the other two hosts in the Consul cluster can reach.

Data Aggregator is upgraded. The console displays a confirmation message.
The installer restarts Data Aggregator automatically when the upgrade is complete.
Wait for Data Aggregator to synchronize automatically with CA NetOps Portal. This process can take 30 minutes or longer.

8. Verify that Data Aggregator is running:
   ```
   service dadaemon status
   ```

   IMPORTANT
   Before you upgrade the Data Collectors, after you upgrade the Data Aggregator to the 20.2 GA release, the Polling Status column on the System Status page inaccurately says "Not Connected" for each Data Collector. However, a connection remains. No data loss should occur. After you upgrade the Data Collectors, the correct status appears. This issue will be fixed in releases after the 20.2 GA release.
9. Verify access to the Data Aggregator REST endpoints. Open a Web browser on a computer with HTTP access to Data Aggregator. Navigate to the following address:
   ```
   http://data_aggregator:port/rest
   ```

   data_aggregator:port specifies the Data Aggregator host name and the required port number.
   The return is a list of hyperlinks for available web services. When you click a link, the XML content describing the selection displays.

   WARNING

   Table segmentation is required for systems where the original installation was a release earlier than 2.3.3. Segmentation is a one-time task that improves database performance and reduces the required disk space. If you received a message during the upgrade that the database tables require segmentation, complete table segmentation after the upgrade. For more information, see Segment Database Tables.

   NOTE

   The Karaf log in the Data Aggregator includes the following error after upgrading the installation:

   ```
   ERROR | tenderThread-178 | 2013-01-24 13:36:40,431 |
   ndorCertificationPriorityManager | nager.core.cert-mgr.impl |
         | Failed to load the MetricFamilyVendorPriority for bundle:
   BundleURLEntry [bundle=198, resourceURL=file:/opt/IMDataAggregator/
  apache-karaf-<vers>/data/cache/resources/198--xml-vendorpriorities-
  ReachabilityVendorPriorities.xml
   ```

   This error for Reachability is expected and harmless. Other occurrences of this error are not expected.

Upgrade Fault Tolerant Data Aggregators

In this article:

NOTE
If you have enabled FIPS-compliant encryption, and you upgrade NetOps Portal before the data aggregator, temporary FIPS compatibility synchronization errors occur. These errors occur until you upgrade the data aggregator. To avoid this temporary condition, upgrade the data aggregator before upgrading NetOps Portal.

If you are setting up fault tolerance for the first time, see Fault Tolerance.

Verify the Prerequisites

Meet the following prerequisites before you upgrade the data aggregator:

- Verify that ports 8581, 61616, 61618, 61620, and 61622 are open for communication between the data collectors and the data aggregators.
  For the detailed port list, Review Installation Requirements and Considerations.
- Before you upgrade, verify that the zip and unzip packages are installed. If these packages are not installed, use the following command to install them:
  ```
  yum -y install zip unzip
  ```
- For the data aggregator and the data collectors, the default maximum memory is 80% of the total system memory. AMQ uses 20% of total memory on both components. Both components reserve 2 GB of memory for the operating system. You can modify these maximum values, however the modifications are not preserved during an upgrade. For more information, see Modify Maximum Memory Usage for Data Aggregator and Data Collector Components.
- Ensure that you have a shared data directory (example: `/DASharedRepo`) and that the same user ID is shared between data aggregator hosts. Data from whichever data aggregator is active is stored in this directory.
  For information about the sizing requirements, see the DX NetOps Performance Management Sizing Tool.

  NOTE
  If you are using NFS, only NFS 4 and higher is supported because of the ActiveMQ Kaha locking requirements.

  IMPORTANT
  The shared data directory must be accessible at all times. If the shared data directory is down and is inaccessible, no data is loaded and data loss occurs.

Verify the Limit on the Number of Open Files on the Data Aggregator

Verify that the user that is installing the data aggregator has a limit of at least 65536 on the number of open files. Set this value permanently.

Follow these steps:

1. As the root user or a sudo user, log in to the data aggregator host.
2. Change the ulimit for the open files limit to at least 65536:
   ```
   ulimit -n ulimit_number
   ```
   For example:
   ```
   ulimit -n 65536
   ```
3. Open the following file:
   `/etc/security/limits.conf`
4. Add the following lines:
   ```
   # Added by Data Aggregator
   * soft nofile 65536
   # Added by Data Aggregator
   * hard nofile 65536
   ```

NOTE
Restart the data Aggregator for these changes to take effect. If you are upgrading, the upgrade process automatically restarts the data aggregator.

5. Verify that the number of open files is set properly:
   ```
   ulimit -n
   ```
   The command returns the limit that you specified earlier.

Verify That the Data Repository Is Running

The data aggregator upgrade requires that the data Repository is running.

Follow these steps:

1. Log in to the data repository host.
2. Verify that the data repository is running:
   ```
   /opt/vertica/bin/vsql -U dauser -w dapass -c 'select version()'
   ```
   The expected return shows the version of the Data Repository:
   ```
                 version
   ----------------------------------
    Vertica Analytic Database vx.x.x-x
   ```

(Optional) Temporarily Connect to Older Versions of Data Collectors

You can reduce data loss during an upgrade by temporarily connecting existing data collectors (version 3.0, 3.1, or 3.2) to an upgraded data aggregator. Consider this upgrade option if you have many data collectors to upgrade.

IMPORTANT
Connecting 3.x versions of data collectors to upgraded data aggregators is only supported on a temporary basis.

New features in DX NetOps Performance Management 3.5 might not be compatible with older data collectors. Before using new features or making configuration changes, upgrade all data collectors to the same version as the data aggregator.

Follow these steps:

1. Create a file called `com.ca.im.dm.core.collector.controller.cfg` in the following location: /opt/IMDataAggregator/apache-karaf-2.4.3/etc/
2. Add the following single line to the file:
   ```
   allowed-mismatch-dc-version=3.0.0.0
   ```
3. Save the file.
4. Proceed with upgrading the data aggregator.

Upgrade the Proxy Server

Before you upgrade your existing fault tolerant data aggregators, upgrade the proxy server.

Follow these steps:

1. Uninstall the proxy server. For more information, see Install or Uninstall the Proxy Server.
2. (RHEL 7.x, SLES, and OL only) Run the following command on the proxy server host as the root or sudo user:
   ```
   systemctl daemon-reload
   ```
3. Run the following command on the proxy server host as the root or sudo user:
   ```
   service consul stop
   ```
4. Delete the proxy installation directory:

```
rm -rf daproxy/
```

5. Install the proxy server. For more information, see Install or Uninstall the Proxy Server.

Upgrade Fault Tolerant Data Aggregators

If you are upgrading data aggregators in an existing fault tolerant environment, do the following upgrade steps in the following order:

> **NOTE**
> To view the status of the data aggregators in NetOps Portal, hover over **Administration**, and click **Data Sources: System Status**.

1. Put the inactive Data Aggregator(B) into maintenance mode.
2. Upgrade the inactive Data Aggregator(B).
3. Activate the inactive Data Aggregator(B).
   This Data Aggregator(B) becomes available for failover.
4. Put the active Data Aggregator(A) into maintenance mode.

   > **WARNING**
   > This step causes failover. The previously inactive Data Aggregator(B) becomes the active data aggregator.
5. Upgrade the now inactive Data Aggregator(A).
6. Activate the now inactive Data Aggregator(A).
   This Data Aggregator(A) becomes available for failover. The other Data Aggregator(B) is the active data aggregator.

Turn on Maintenance Mode

> **IMPORTANT**
> If you are upgrading the data aggregators in an existing 3.5 GA fault tolerant environment, put the data aggregator into maintenance mode before upgrade.

For more information, see Fault Tolerance.

Follow these steps:

1. Log in to the data aggregator host as the root user or a sudo user.
2. Run one of the following commands to shut down the inactive data aggregator and prevent it from restarting until the upgrade is complete:
   - **RHEL 6.x:**
     ```
     service dadaemon maintenance
     ```
   - **RHEL 7.x, SLES, or OL:**
     ```
     DA_Install_Directory/scripts/dadaemon maintenance
     ```

Upgrade the Data Aggregator

> **WARNING**
>
> If you are upgrading the data aggregators in an existing 3.5 GA fault tolerant environment, you must put the data aggregator into maintenance mode before upgrade.

Upgrade the inactive data aggregator first and then activate it. Then upgrade and activate the active data aggregator.

Follow these steps:

1. Log in to the data aggregator host as the root user or a sudo user.
2. Copy the `installDA.bin` file to the `/tmp` directory.
3. Change to the `/tmp` directory:

```
cd /tmp
```

4. Change permissions for the installation file:
   ```
   chmod a+x installDA.bin
   ```
5. To run the upgrade, do one of the following steps:
   - Run the installation as the root user:
     ```
     ./installDA.bin -i console
     ```
   - Run the installation as the sudo user:
     ```
     sudo ./installDA.bin -i console
     ```

     NOTE
     To generate a response file for silent upgrade, add the following argument:
     `-r response_file`

     response_file_directory specifies the directory the directory path and file name for the response file.
     Example: /temp/installer.properties

     To run the upgrade in silent mode, use the following command:

     ```
     ./installDA.bin -i silent -f response_file
     ```

     response_file is the directory path and file name of the previously generated response file.
6. Follow the instructions in the console.

   WARNING
   If the Data Repository was migrated, follow the data aggregator upgrade instructions in the console. Answer **NO** when prompted to drop the schema and the upgrade continues. If you answer YES, you lose your migrated data.

   The data aggregator is upgraded. The console displays a confirmation message.
7. Verify access to the data aggregator REST endpoints. Open a Web browser on a computer with HTTP access to the data aggregator. Navigate to the following address:
   `http://DA_Proxy:port/rest`

   DA_Proxy:port Specify the data aggregator proxy host name and the required port number.
   The return is a list of hyperlinks for available web services. When you click a link, the XML content describing the selection displays.

   WARNING
   Table segmentation is required for systems where the original installation was a release earlier than 2.3.3. Segmentation is a one-time task that improves database performance and reduces the required disk space. If you received a message during the upgrade that the database tables require segmentation, complete table segmentation after the upgrade. For more information, see Segment Database Tables.

   NOTE
   The Karaf log in the data aggregator includes the following error after upgrading the installation:

   ```
   ERROR | tenderThread-178 | 2013-01-24 13:36:40,431 |
    ndorCertificationPriorityManager | nager.core.cert-mgr.impl |
         | Failed to load the MetricFamilyVendorPriority for bundle:
    BundleURLEntry [bundle=198, resourceURL=file:/opt/IMDataAggregator/
   apache-karaf-<vers>/data/cache/resources/198--xml-vendorpriorities-
   ReachabilityVendorPriorities.xml
   ```

   This error for Reachability is expected and harmless. Other occurrences of this error are not expected.
8. (Optional) In the NetOps Portal user interface, hover over **Administration**, select **Data Sources: System Status**, and verify the status of the data aggregator.

IMPORTANT
Before you upgrade the data collectors, after you upgrade the data aggregator to the 20.2 GA release, the Polling Status column on the System Status page inaccurately says "Not Connected" for each data collector. However, a connection remains. No data loss should occur. After you upgrade the data collectors, the correct status appears. This issue will be fixed in releases after the 20.2 GA release.

Activate the Data Aggregator

If you upgraded the data aggregators in an existing fault tolerant environment, activate each data aggregator after upgrade.

For more information, see Fault Tolerance.

NOTE
The data aggregator might take several minutes to start.

Follow these steps:

1. Log in to the data aggregator host that is in maintenance mode as the root user or sudo user.
2. Issue one the following commands to enable the fault tolerant data aggregator so that it can start when necessary:
   - **RHEL 6.x:**
     ```
     service dadaemon activate
     ```
   - **RHEL 7.x, SLES, or OL:**
     ```
     DA_Install_Directory/scripts/dadaemon activate
     ```

Upgrade the Data Collectors

After you upgrade the Data Aggregator, upgrade the Data Collectors.

IMPORTANT
Before you upgrade the Data Collectors, after you upgrade the Data Aggregator to the 20.2 GA release, the Polling Status column on the System Status page inaccurately says "Not Connected" for each Data Collector. However, a connection remains. No data loss should occur. After you upgrade the Data Collectors, the correct status appears. This issue will be fixed in releases after the 20.2 GA release.

If you are upgrading from DX NetOps Performance Management 3.5 or higher as the `root` user, you can upgrade the Data Collector easily using the Upgrade button in NetOps Portal. This button is an extra and easier avenue for upgrading your Data Collectors. If you are upgrading from DX NetOps Performance Management 3.6 or higher as a non-root user, you can also use the Upgrade button.

WARNING

To use this feature, the Data Collectors must be running as the `root` user or a user with the necessary `sudo` privileges. If you are upgrading from any 3.5 release as a non-root user, you must upgrade the Data Collectors manually. Also, anyone upgrading from a release before 3.5 must upgrade the Data Collectors manually.

NOTE

For a major release, the user interface indicates that an upgrade is required. For a minor incremental upgrade (for example, a monthly update), the user interface does not indicate that an upgrade is required. However, you can still use the Upgrade button to upgrade to the latest release.

The Data Collectors can continue to run during the upgrade and cache polled data to disk. When the Data Aggregator and Data Repository upgrade completes, the Data Collectors load the cached data. All the Data Collectors are upgraded at once through a staged process where up to two Data Collectors upgrade in parallel. This upgrade method allows you to upgrade your Data Collectors with a minimal reporting gap. Also, an upgraded Data Aggregator (at version 3.5 or

higher) can continue to communicate with the previous versions of your Data Collectors (at version 3.5 or higher) as they upgrade.

NOTE

Before you upgrade the Data Collectors, each Data Collector must have a Tenant and IP Domain assigned. The upgrade process skips any Data Collectors with no Tenant or IP Domain assigned.

WARNING

This upgrade method does not support remote upgrade for Data Collectors that are assigned with a Pseudo Tenant Proxy. For more information, see Tenant-Agnostic Data Collectors.

The upgrade for these Data Collectors might hang with an "Upgrade Pending" status. You must manually upgrade these Data Collectors. If this issue occurs, the Data Collectors continue to collect data as normal and other Data Collectors continue to upgrade.

If you have authenticated and encrypted activeMQ communication, you must regenerate the keys before this upgrade. For more information, see Authenticate and Encrypt ActiveMQ Communication.

NOTE
For the first and last name prompt, you must enter the host name of the system where you are creating the certification.

Follow these steps:

1. If you are running the upgrade as a non-root user, complete the following steps:
   a. Locate the following file on the Data Collector host:
      `/etc/sudoers`
   b. Add the following command alias with the following permissions to the file:
      dcuser dchostname = (root) NOPASSWD: *DC_install_directory*/upgrade/install.bin

      NOTE

      If `requiretty` is enabled, add the following text to disable `requiretty` for the Data Collector installer:

      Defaults!*DC_install_directory*/upgrade/install.bin !requiretty
2. Log in to NetOps Portal as the global administrator.
3. Hover over **Administration**, and click **Monitored Items Management: Data Collectors**.
4. Select all the Data Collectors and click **Upgrade**.
   A confirmation message appears.
5. To proceed with the upgrade, click **Yes**.
   The status of the upgrade appears in the Status column.

If you are upgrading from any 3.5 release as a non-root user, you must upgrade the Data Collectors manually. Also, anyone upgrading from a release before 3.5 must upgrade the Data Collectors manually.

Verify the Prerequisites for a Manual Upgrade

Meet the following prerequisites before you upgrade the Data Collector:

- On the Data Aggregator system, verify that ports 61616, 61618, 61620, and 61622 are open. These ports enable communication between the Data Collector and the Data Aggregator.
- Before you upgrade, verify the zip and unzip packages are installed. If these packages are not installed, use the following command to install them:
  ```
  yum -y install zip unzip
  ```
- The Data Collector uses the "at" package to schedule the restart of the application when assigning a Tenant or IP Domain. Verify whether the "at" package is installed on each Data Collector host:

```
rpm -qa | grep ^at
```

If the command does not return a result, install the package:

NOTE

If you are not the root user, use the sudo prefix.

```
yum install at
```

Upgrade the Data Collector Manually

To upgrade the Data Collector manually, run the installation as the root or sudo user.

Follow these steps:

1. Log in to the Data Collector host as the root user or a sudo user.
2. Change to the /tmp directory:
   ```
   cd /tmp
   ```
3. Use `wget` , `curl` , or a browser to download the installation package to the /tmp directory:
   ```
   wget http://data_aggregator:port/dcm/InstData/Linux/VM/install.bin
   curl -o /tmp/install.bin http://data_aggregator:port/dcm/InstData/Linux/VM/
   install.bin
   ```
   Default port: 8581
4. Change permissions for the installation file:
   ```
   chmod a+x install.bin
   ```
5. To run the upgrade, do one of the following steps:
   - Run the installation as the root user:
     ```
     ./install.bin -i console
     ```
   - Run the installation as the sudo user:
     ```
     sudo ./install.bin -i console
     ```

     NOTE

     To generate a response file for silent installation, add the following argument:

     ```
     -r response_file
     ```

     response_file specifies the directory the directory path and file name for the response file.
     Example: /temp/installer.properties

     Follow the prompts until you get to the summary, type "quit", and press Enter.

     To run the installation in silent mode, use the following command:

     ```
     ./installDA.bin -i silent -f response_file
     ```

     response_file is the directory path and file name of the previously generated response file.
6. Follow the instructions in the console.
7. (Optional) When prompted, specify the following parameters for fault tolerance. For more information, see Fault Tolerance.
   - **Is the Data Aggregator configured with fault tolerance?**
     If fault tolerance was configured for the Data Aggregators, specify 2 for Yes.
     Default: 1
   - **Inactive Data Aggregator Host/IP Address**
     Specify the host name/IP address of the inactive Data Aggregator responsible for this Data Collector.

NOTE
To view the status of your Data Aggregators in NetOps Portal, hover over **Administration**, and click **Data Sources: System Status**.

8. When the upgrade is complete, the console displays a confirmation message.
9. Verify that Data Collector is running:
   ```
   service dcmd status
   ```

Verify a Manual Upgrade

After you upgrade the Data Collectors manually, verify the upgrade.

Follow these steps:

1. Log in to NetOps Portal as the global administrator.
2. Navigate to the Data Aggregator data source.
3. Expand **System Status**, and click **Data Collectors**.
4. Verify that Data Collector appears in the list.

NOTE
The list can take several minutes to refresh and show the new Data Collector installation.

Complete the Upgrade

To complete the upgrade, complete the following steps:

Re-Enable the Automatic Recovery of the Data Aggregator Process

Re-enable the automatic recovery of the Data Aggregator process. You disabled the automatic recovery before you upgraded Data Aggregator. When enabled, if the database server runs out of memory, or if Data Repository is unavailable for a time, Data Aggregator shuts down automatically to help ensure that data consistency is maintained.

NOTE

In a fault tolerant environment, this procedure is unnecessary because Consul manages the start and stop state of the Data Aggregator. For more information, see Fault Tolerance.

Follow these steps:

1. Log in to the computer where the Data Aggregator is installed as the root user.
2. Open a console and type the following command:
   ```
   crontab -e
   ```
   A vi session opens.
3. Uncomment out the following line by removing the pound symbol (#) from the beginning of the following line:
   ```
   # * * * * * /sbin/service dadaemon start > /dev/null
   ```
   For example:
   ```
   * * * * * /sbin/service dadaemon start > /dev/null
   ```
   The automatic recovery of the Data Aggregator process is re-enabled.

Perform Post-Upgrade Configuration

Do the following steps after you upgrade DX NetOps Performance Management:

- If you use the Java Cryptography Extension (JCE), upgrade the JCE to version 8.

NOTE
For the Java 8 version of the JCE, visit the Oracle site.

- Upgrading Data Aggregator backs up the /opt/IMDataAggregator/apache-karaf-<*vers*> directory to the /opt/IMDataAggregator/backup/apache-karaf directory. Customizations that are located in the /opt/IMDataAggregator/apache-karaf-<*vers*>/etc/ directory, such as default logging levels or other configurations are backed up, but are not restored to the installation directory automatically. To avoid losing these customizations, restore the customizations manually after you have successfully upgraded.
- Upgrading Data Collector backs up the /opt/IMDataCollector/apache-karaf-<*vers*> directory to the /opt/IMDataCollector/backup/apache-karaf directory. Customizations that are located in the /opt/IMDataCollector/apache-karaf-<*vers*>/etc/ directory, such as default logging levels or other configurations are backed up, but are not restored to the installation directory automatically. To avoid losing these customizations, restore the customizations manually after you successfully upgraded.

Vendor Certification Priorities

New vendor certifications are placed at the bottom of the Vendor Certification Priorities list for the corresponding metric family. To take advantage of the new vendor certifications, manually change the vendor certification priorities.

For example, F5 CPU vendor certifications are modeled as normal CPUs but do not get discovered because F5 also supports Host Resources. After an upgrade, the Host Resources CPU priority entry is higher than the F5 entries appended to the end of the priority list. To discover F5 CPU devices and components, update the vendor certification priority for the CPU metric family.

CA Business Intelligence Integrations

If you have an existing CA Business Intelligence (CABI) integration, this version of DX NetOps Performance Management supports CABI 6.4.2 and higher.

WARNING

After you upgrade to a supported CABI version, you must re-install your CABI content. For more information, see Install CA Business Intelligence Reports and Dashboards.

(Optional) Disable the ActiveMQ Admin Console for the Data Aggregator or Data Collector

Generally, the ActiveMQ admin console should not be available on the network. Therefore, you can disable it for the Data Aggregator or Data Collector.

Follow these steps:

1. Go to one of the following files:
   - **Data Aggregator**
     `DA_Install_Directory/broker/apache-activemq-version/conf/activemq.xml`
   - **Data Collector**
     `DC_Install_Directory/broker/apache-activemq-version/conf/activemq.xml`
2. Comment out
   ```
   <import resource="jetty.xml"/>
   ```
   .
3. Shut down the ActiveMQ broker on each Data Collector:
   ```
   service activemq stop
   ```
4. Shut down the ActiveMQ broker on the Data Aggregator:
   ```
   service activemq stop
   ```
5. Start the ActiveMQ broker on the Data Aggregator:

```
service activemq start
```

If you do not, the Data Aggregator starts the broker automatically.

6. The Data Collectors automatically restart the ActiveMQ brokers. Use the following command to restart the brokers manually:

```
service activemq start
```

(Optional) Update ActiveMQ Admin Console Access

Generally, the ActiveMQ admin console should not be available on the network. However, if certain users absolutely need the console, you can grant them access.

Follow these steps:

1. Go to one of the following files:
   - **Data Aggregator**
     DA_Install_Directory/broker/apache-activemq-*version*/conf/activemq.xml
   - **Data Collector**
     DC_Install_Directory/broker/apache-activemq-*version*/conf/activemq.xml
2. To update user access, edit the
   `jetty-realm.properties`
   .
3. To encrypt the user passwords, run one of the following commands:
   - **Data Aggregator**

     ```
     java -cp DA_Install_Directory/broker/apache-activemq-version/lib/web/jetty-all-9.2.22.v20170606.jar org.eclipse.jetty.util.security.Password passwordpassword
     ```
   - **Data Collector**

     ```
     java -cp DC_Install_Directory/broker/apache-activemq-version/lib/web/jetty-all-9.2.22.v20170606.jar org.eclipse.jetty.util.security.Password passwordpassword
     ```
4. Shut down the ActiveMQ broker on each Data Collector:

   ```
   service activemq stop
   ```
5. Shut down the ActiveMQ broker on the Data Aggregator:

   ```
   service activemq stop
   ```
6. Start the ActiveMQ broker on the Data Aggregator:

   ```
   service activemq start
   ```

   If you do not, the Data Aggregator starts the broker automatically.
7. The Data Collectors automatically restart the ActiveMQ brokers. Use the following command to restart the brokers manually:

   ```
   service activemq start
   ```

Rehydrating Data in a Cloud Environment

If you have DX NetOps Performance Management set up in a cloud environment, you can patch operating systems from a common image instead of patching each operating system individually. The following procedures outline the necessary steps for rehydrating the DX NetOps Performance Management nodes with minimal data loss.

Verify the Prerequisites

Before rehydration, ensure your environment is in a good state.

Follow these steps:

1. Select **Administration**, **Data Source Settings**, and **System Status**.
2. Verify that the Data Aggregator and Data Repository are connected.
3. Verify that the Data Aggregator is up and running.
4. View the System Status page to verify there is no backed up or cached poll data.

   NOTE
   If the PRQ queue is not empty, the Data Collectors need to send the rest of the polled data to the Data Aggregator. The queue fills up when an outage occurs, which causes data to be cached on the Data Collectors. View the System Status page to verify that all the Data Collectors have a green status. The Polling Status column shows whether cached values exist on the Data Collector.
5. If you have DX NetOps Virtual Network Assurance in your environment, do the following steps:
   a. In , hover over **Administration**, and click **Monitored Items Management: VNA Gateways**.
   b. Set the **Administrative Status** to **Down**.

Rehydrate Each Data Collector

Rehydrate each Data Collector one at a time. Make sure each Data Collector recovers and starts polling before you rehydrate each Vertica node and the Data Aggregator. During this process, some polls are cached on the Data Collectors for a time.

Follow these steps:

1. Build the new operating system on the Data Collector container or virtual machine.
2. Copy the `DCM_ID` :
   ```
   grep "manager\-id\=" DC_Install_Directory/apache-karaf-<version>/etc/
   com.ca.im.dm.core.collector.cfg
   ```
3. Bring down the old container or virtual machine.
4. Give the new container or virtual machine a new IP address or name and bring it online.
5. Reinstall the Data Collector with the `DCM_ID` of the original Data Collector.
   ```
   export DCM_ID="Original_DC_Host:DCM_ID"
   cd /tmp;
   rm -rf install.bin;
   wget http://DA_Host:Port/dcm/InstData/Linux/VM/install.bin;
   chmod a+x install.bin;
   ./install -i silent
   ```
   The Data Collector installs, reconnects to the Data Aggregator, and starts polling.

Rehydrate Each Vertica Node

Rehydrate each Vertica node one at a time. Before you start, verify that all nodes are up and running:

```
/opt/vertica/bin/admintools -t list_allnodes
```

Follow these steps:

1. Bring down the Vertica node:
   ```
   /opt/vertica/bin/admintools -t stop_node -s IP_Address
   ```
2. Unmount the `data` directory and the `catalog` directory.
3. Create a new node with the same IP address and name.
4. Mount the `data` directory and the `catalog` directory to the new node.
5. Run the validation script:
   ```
   ./dr_validate.sh -n -p drinstall.properties
   ```

The script validates the system settings. Review and resolve any errors or warnings. You can run this script multiple times to verify that all system configuration options are set properly. The validation script may prompt you to reboot.

6. Install Vertica from an up and running node:
   ```
   /opt/vertica/sbin/install_vertica -u dradmin -l /export/dradmin -d /export/data -L ./
   resources/vlicense.dat -Y -r ./resources/vertica-<version>.rpm
   ```

   NOTE
   Values should match those in the properties files for `dr_install.sh` , and point to the same resources.
7. Start the node and verify that it is up and running:
   ```
   /opt/vertica/bin/admintools -t restart_node -s Host_Name -d DB_Name
   ```

   NOTE
   The state starts as DOWN, then changes to REBUILDING until it changes to UP.
8. Repeat this procedure for each node.
9. After all nodes are rehydrated, verify that all nodes are back up and running as the `dradmin` user:
   ```
   /opt/vertica/bin/admintools -t list_allnode
   ```

Rehydrate the Data Aggregator

During this Vertica refresh, the Data Aggregator should collect data from the Data Collectors. The Data Aggregator pushes data to Vertica the entire time on the up and running nodes. The speed of the ingestion is sometimes cut in half during this time.After you rehydrate the Data Collectors and Vertica, you can rehydrate the Data Aggregator.

Follow these steps:

1. Prepare a new node for the Data Aggregator.
2. Do one of the following steps:
   - Stop the Data Aggregator service:
     ```
     service dadaemon stop
     ```

     NOTE
     For RHEL 7.x, `service` invokes `systemctl` . You can use `systemctl` instead.
   - (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**
       ```
       service dadaemon maintenance
       ```
     - **RHEL 7.x, SLES, or OL:**
       ```
       DA_Install_Directory/scripts/dadaemon maintenance
       ```

   The Data Aggregator completes processing and the service stops.
3. Move the configuration files to the new node. For more information, see Back Up Data Aggregator.

   NOTE
   In environments with fault tolerant Data Aggregators, use the shared data directory and reattach it. For more information, see Fault Tolerance.
4. Do one of the following steps:
   - Start the Data Aggregator service:
     ```
     service dadaemon start
     ```
   - (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
     - **RHEL 6.x:**

```
service dadaemon activate
```

- **RHEL 7.x, SLES, or OL:**:

  DA_Install_Directory/scripts/dadaemon activate

The Data Aggregator consumes the queued polls and pushes them to Vertica.

> **NOTE**
> Depending on the total outage time, all cached data is consumed and ready for reporting in approximately two times the outage time. When the ActiveMQ consumption returns to normal, this indicates there is no longer a backlog. View the System Status page to verify that all the Data Collectors have a green status and that the system is receiving approximately the same number of polls as it was before the process started.

Rehydrate NetOps Portal

Finally, you can rehydrate NetOps Portal.

Follow these steps:

1. Prepare a node for NetOps Portal.
2. Bring down NetOps Portal:

   > **NOTE**
   > For RHEL 7.x and higher or OL, `service` invokes `systemctl` . You can use systemctl instead.

   ```
   service caperfcenter_console stop
   service caperfcenter_devicemanager stop
   service caperfcenter_eventmanager stop
   service caperfcenter_sso stop
   ```
3. Move the database to the new node. For more information, see Back Up Performance Center.
4. Start NetOps Portal:
   a. Start the SSO service:
      ```
      service caperfcenter_sso start
      ```
   b. Wait one minute, then start the event manager and device manager:
      ```
      service caperfcenter_eventmanager start
      service caperfcenter_devicemanager start
      ```
   c. Wait one minute, then start the console service:
      ```
      service caperfcenter_console start
      ```

Rehydrate DX NetOps Virtual Network Assurance

If you have DX NetOps Virtual Network Assurance in your environment, rehydrate it now.

Follow these steps:

1. Query the following REST URL to find the engine ID required later:
   http://*VNA_host*:8080/vna/rest/v1/admin/engines
2. Query the following REST URL for your plug-in configuration required later:
   http://*VNA_host*:8080/vna/rest/v1/admin/engines/*Engine_ID*/config
3. Stop WildFly using one of the following commands:
   ```
   service wildfly stop
   systemctl stop wildfly
   ```
4. Back up the existing database:
   VNA_Install_Directory/tools/bin/db_backup.sh *Backup_File_Name*
5. Install DX NetOps Virtual Network Assurance on the new server and restore the database from the backup:

```
VNA_Install_Directory/tools/bin/db_restore.sh Backup_File_Name
```

6. Reconfigure the plug-ins using the information from your original query.

   NOTE
   Use the same Domain ID from the original configuration.

7. In NetOps Portal, hover over **Administration**, and click **Monitored Items Management: VNA Gateways**. Change the new DX NetOps Virtual Network Assurance server ID. Set the **Administrative Status** to **Up**.

Reconnect an Existing DX NetOps Spectrum Data Source

If you rehydrate the DX NetOps Performance Management environment, and want to reconnect it to an existing Spectrum server, complete the following procedure.

Follow these steps:

1. Go to **Administration**, **Data Sources**, **Data Sources**.
2. Select the DX NetOps Spectrum data source, and click **Edit**.
3. Change the Status to Disabled, and click **Save**.
4. Remove the NetOps Portal entries:

```
cd Spectrum_Install_Directory/vnmsh
./connect
./show models | grep CAPC
```

5. Run the following command for every `CAPCIPDomain` and `CAPCTenant` model found.

```
./destroy model mh=0xXXXXX
```

6. Remove the NetOps Portal integration database from DX NetOps Spectrum:

```
bash -login
cd mysql
cd bin
./mysqladmin --defaults-file=../my-spectrum.cnf -unetqos -ppassword drop netqos_integ
```

7. Restart DX NetOps Spectrum tomcat:

```
cd Spectrum_Install_Directory/tomcat/bin
./stopTomcat.sh
./startTomcat.sh
```

8. Go to **Administration**, **Data Sources**, **Data Sources**.
9. Select the DX NetOps Spectrum data source, and click **Edit**.
10. Change the Status to Enabled, and click **Save**.

Rehydrate Network Flow Analysis

If you have Network Flow Analysis in your environment, rehydrate it now.

Follow these steps:

1. Go to **Administration**, **Data Sources**, **Data Sources**.
2. Select the Network Flow Analysis data source, and click **Edit**.
3. Change the Status to Disabled, and click **Save**.
4. Determine the database files to backup.
   - Customized data_retention database (Stand-alone or Harvester server): `data_retention`
   - harvester database (Stand-alone or Harvester server): `harvester`
   - reporter database (Stand-alone or NFA console): `reporter`
5. Copy each of the target directories or files to a remote location.

6. Back up the following databases to a remote location, using `mysqldump` . Back up the `reporter` database last, regardless of the deployment architecture.
   - Customized data_retention database (Stand-alone or Harvester server): `data_retention`
   - harvester database (Stand-alone or Harvester server): `harvester`
   - reporter database (Stand-alone or NFA console): `reporter`

   ```
   mysqldump --routines --events -u root dbname --skip-lock-tables > dbbackupname.sql
   ```
7. (Optional) Verify that the `mysqldump` was successful by checking that the size of the backup is over 1 KB.
8. Restore each of the target directories or files from its remote location to its original location.
9. Restore each of the databases. Restore the reporter database first, regardless of the deployment architecture.
   - reporter database: `reporter` (Stand-alone or NFA console)
   - Customized data_retention database: `data_retention` (Stand-alone or Harvester server)
   - harvester database: `harvester` (Stand-alone or Harvester server)

     IMPORTANT
     For best results, restore to a clean installation.

   ```
   mysql –e “drop database DB_Name;”
   mysql -e "create database DB_Name;"
   mysql -u root DB_Name dbbackupname.sql
   mysql -u root mysql > proc.sql
   ```
10. Go to **Administration**, **Data Sources**, **Data Sources**.
11. Select the Network Flow Analysis data source, and click **Edit**.
12. Change the Status to Enabled, and click **Save**.

Building

To provide data for dashboards and views, DX NetOps Performance Management collects data from devices in your network. Building includes information about device management, discovery, and self-certification, and other topics that relate to how DX NetOps Performance Management collects data.

Self-Certification

Self-certification is the process of updating or creating certifications to support new vendor devices and technology types. DX NetOps Performance Management uses metric families and vendor certifications to support devices. These components determine how DX NetOps Performance Management collects configuration and operational metrics for a device.

Out of the box, DX NetOps Performance Management supports the common vendors, metrics, and components in your network infrastructure. The Technology Certification Portal lists out-of-the-box certifications by data aggregator version, vendor certification, and metric families: http://serviceassurance.ca.com/im/

For unsupported devices, extend monitoring capabilities using self-certification.

TIP
When possible, use an extension instead of a new vendor certification or metric family. When CA Technologies updates the certification or metric family, extended certifications are also updated.

WARNING
Changes to metric families and vendor certifications apply to all tenants.

Types of Self-Certification

Basic Self Certification: Create a custom vendor certification in the UI, but with limitations. You cannot use basic self-certification after using another method. However, you can update vendor certification expressions that you created using the custom certification process in the UI.

Custom Certification: Create a custom vendor certification, metric family, or component.

Extend: Modify an out-of-the-box vendor certification or metric family. Extending a vendor certification creates an XML file, but keeps a backup of the factory certification. Changes to extended metric families or vendor certifications are maintained when the original metric family or vendor certification is updated.

Update: Apply changes to a custom certification. Updating a vendor certification completely replaces the existing XML file.

> **NOTE**
> Some UI features, such as configuring percentiles or projections, automatically extend or update the certification.

When to Self-Certify

Self-certification applies in the following situations:

- To support an existing metric family on a device that DX NetOps Performance Management does not yet support, create a custom vendor certification.
- To support a new vendor or device, create a custom metric family and a custom vendor certification.
- To support a new technology in DX NetOps Performance Management, create a custom component, custom metric family, or a custom vendor certification.
- To add a metric to an out-of-box vendor certification, extend the metric family or extend the vendor certification.
- To change the name of a metric, the calculation of a metric for an out-of-box vendor certification, or to extend the metric family.
- To add custom discovery filtering to an out-of-box vendor certification, extend the vendor certification.
- To change the OID that a device uses, extend the vendor certification.
- To change polled and baseline configuration for metrics in an out-of-box metric family, extend the metric family.

Self-Certification Prerequisites

To ensure a successful self-certification process, verify that you meet the following prerequisites:

- You have access to the MIB and OIDs from the device.
- You have a MIB browser, such as the free version of iReasoning.
- You have a test environment for the certifications.

> **WARNING**
> Metric families and vendor certifications cannot be deleted from your system. Test custom certifications before you implement the changes in your production environment.

The Data Model

Understanding the data collection model helps you understand what is required in the self-certification process.

Data Aggregator supports devices using the following configuration features:

- **Discovery Profile:** Determines which items Data Aggregator discovers in your environment, typically based on a range of IP addresses. The discovery process identifies the "type" for each item that it finds.
- **Device Collections:** Organizes your inventory into groups of related items. Items are automatically added to a device collection based on the item type and IP address.
- **Monitoring Profile:** Controls the polling rate for a device collection, and determines which metric families to poll. Monitoring profiles can poll one or more metric families. To poll the same metric family at different rates, and on different groups, add the same metric family to more than one monitoring profile.

  NOTE
  To ensure that the system is not overloaded with polling traffic, use monitoring profiles to adjust the polling rate for different sets of metrics.
- **Metric Family:** Controls which metrics are gathered for a monitoring profile. Metric families are associated with one or more vendor certifications, which are listed in priority order.
- **Vendor Certification:** Maps attributes from a vendor MIB to the metrics in a metric family. Also determines how metrics that are collected from an item are formatted. Metrics that are provided for an item can vary, depending on the item vendor. Mapping these values ensures that the metric values are reported consistently, regardless of the vendor. Multiple vendor certifications can be associated with a single metric family. In such cases, Data Aggregator maps metric values using a ranked list of vendor certifications. The data aggregator calculates a metric value using the highest-priority vendor certification that matches the polled item.

  NOTE
  MIBs can be imported into the system and compiled as part of building a vendor certification. Import MIBs only using the basic certification process. They are not required for polling.

Example: Support for a Router Device

When running your discovery profile, the data aggregator finds and identifies an item as a router. The router managed item is automatically added to the All Routers device collection. This device collection is associated with the Routers monitoring profile. This profile uses the CPU and Memory metric families to discover the CPU and Memory components on the device. These metric families also determine the vendor certification to use when calculating the metric values for these components. Based on this monitoring profile, the data aggregator polls the router every 5 minutes. The vendor certifications that are associated with a metric family determine how to calculate and format the raw metric data. DX NetOps Performance Management stores the collected metric data for your router, and uses the data in dashboards and reports.

Self-Certification Workflow

To successfully complete a self-certification, do the following procedures in the indicated order:

1. Create Custom Components.
   Skip this step if you have existing components.
2. Create or Extend Metric Families.
   Skip this step if you have existing metric families.
3. Create or Extend Vendor Certifications.
4. Manage Vendor Certification Priorities.

Create Custom Components

To support a new technology, create a custom component. You can create a custom component using REST Web Services. You can create an entry that lists all instances of your component in the Inventory menu and create a Context page by creating a custom component. Use a component to create a REST endpoint, or to create attributes that are shared between metric families.

NOTE
You cannot extend factory components.

WARNING
To avoid possible data loss, back up the certification directory before you create or update a custom component.

Create a Component XML Template

Use an existing component to create an XML template.

TIP
To retrieve a list of existing components, go to the following REST URL:
http://*da_hostname*:8581/typecatalog/components

Follow these steps:

1. Set up a REST client with a connection to the data aggregator server.
2. Select a component that is similar to the component that you require.
3. Enter the following URL to retrieve the template component:
   `http://da_hostname:8581/typecatalog/components/component_name`
   component_name specifies the name of the template component.
4. Select **GET** in the Method tab, and run the method.
   The REST client returns the XML information for the component.
   Use the XML as a template to create the custom component.

Edit the Component XML

To apply the necessary changes to the component, edit the XML file (the component XML). Make changes to the `<ItemSyncDefinition>` section to create an entry that lists all instances of your component in the Inventory menu and to create a Context page for your component.
For more information about the XML structure, see Component XML Structure.

Import the Component XML

To import the component, use a REST client.

Follow these steps:

1. Specify http://*da_hostname*:8581/typecatalog/components as the URL.
2. On the Method tab, Select **POST** for a new custom component, or select **PUT** to update a component.
3. In the Body settings, set **application/xml** as the **Body Content-type**.

   WARNING
   Failing to set the Content-type results in a 415 error.
4. Copy the component XML into the Body tab.
5. Run the method.
   Your custom component is imported. If no errors occur, the Status field in the HTTP Response section displays the following result:
   `HTTP/1.1 200 OK`

Create or Extend Metric Families

If an out-of-the-box metric family does not fit your monitoring needs, extend an existing metric family or create a custom metric family. If an existing metric family is close to what you need, extend that metric family. If you need something new, create a custom metric family. For an example, see Add a New Metric to an Existing Metric Family.

Use the following procedures to create, extend, or update metric families:

WARNING
To avoid possible data loss, always back up the certification directory anytime you extend, create, or update a metric family.

Create a Metric Family XML Template

For a new metric family, use an existing metric family to create an XML template. For an extension, get the XML for the target metric family.

TIP

To retrieve the name of the metric family in the UI, go to the Metric Families page. Click the downward arrow on any column, hover over **Columns**, and click **Internal Name**.

Follow these steps:

1. Set up a REST client with a connection to the Data Aggregator server.
2. Enter the following URL to retrieve the template metric family:
   - **New Metric Family:** `http://da_hostname:8581/typecatalog/metricfamilies/mf_name`
   - **Extension:** `http://da_hostname:8581/typecatalog/metricfamilies/mf_name` **mf_name** specifies the name of the template metric family.
3. Select GET in the Method tab, and run the method.
   The REST client returns the XML information for the metric family.
   Use the XML as a template to create the custom or extended metric family.

Edit the Metric Family XML

To apply the necessary changes to the metric family, edit the XML file. For complete information about the XML structure, see Metric Family XML Structure.

WARNING

If the Units attribute is not defined in the XML, the units label on reports is 'Units'.

NOTE

When you extend a metric family, include only the XML nodes that require changes.

Import a Metric Family

Select one of the following options to import a metric family:

Use a REST Client to Import a Metric Family

To import a metric family, you can use a REST client.

Follow these steps:

1. Specify one of the following URLs:
   - **Custom Metric Family:** `http://da_hostname:8581/typecatalog/metricfamilies/`
   - **Extend Metric Family:** `http://da_hostname:8581/typecatalog/metricfamilies/extension/mf_name`
2. On the **Method** tab, Select **POST** for a new custom metric family, or select **PUT** to update or extend a metric family.
3. In the **Body** settings, select 'application/xml' as the 'Body Content-type'.

WARNING
Failing to set the Content-type results in a 415 error.

4. Copy the metric family XML into the **Body** tab.
   Run the method.
   Your custom metric family is imported. If no errors occur, the Status field in the HTTP Response section displays the following result:
   ```
   HTTP/1.1 200 OK
   ```

Import a Metric Family in the UI

To import a metric family, you can use the UI.

Follow these steps:

1. Click **Metric Families** from the **Monitoring Configuration** menu for a Data Aggregator data source.

   NOTE

   Use the Search feature in any pane to locate specific information that is related to that pane. Alternatively, navigate between pages in a pane using the arrows.
2. Click **Import**.

   NOTE

   The Import button supports ZIP files. For example, you can import the downloaded ZIP file for a certification from the On-Demand Certification support page.
3. Click **Browse**, and select the metric family file.
4. Click **Open**, and then click **Import**.
   Your metric family is imported.

Update Metric Family Properties

To change attributes, such as the display name, update the metric family properties.

Follow these steps:

1. Specify the following URL:
   - **Extend Metric Family:** `http://da_hostname:8581/typecatalog/metricfamilies/extension/mf_name`
2. On the **Method** tab, select **PUT** to update or extend a metric family.
3. In the **Body** settings, select **application/properties** as the **Body Content-type**.
4. Specify updates with one line per property in the **Body** tab as illustrated in the following template and example.
   Template:

   NOTE

   The ***metricfamilyname*** *and* ***attributename*** variables in the following example are case-sensitive and are lowercase. These variables are a different case from their values in the XML. For example, **NormalizedPortInfo** from the XML is **normalizedportinfo** here and **PctDiscardsIn** in the XML is **pctdiscardsin** here.

```
im.ca.com.normalizer.metricfamilyname.displayname=DisplayName
im.ca.com.normalizer.metricfamilyname.documentation=Documentation text
im.ca.com.normalizer.metricfamilyname.attribute.attributename.attributedisplayname=AttributeI
```

```
im.ca.com.normalizer.metricfamilyname.attribute.attributename.documentation=Documentation
 text
```

Example:

```
im.ca.com.normalizer.normalizedportinfo.displayname=Interface
im.ca.com.normalizer.normalizedportinfo.documentation=Defines the identification
 information, configuration information, and polled metrics for interfaces.
im.ca.com.normalizer.normalizedportinfo.attribute.pctdiscardsin.attributedisplayname=Percent
 Discards In
im.ca.com.normalizer.normalizedportinfo.attribute.pctdiscardsin.documentation=The
 percentage of the frames (packets) received by the interface that were discarded.
```

5. Run the method.

Trigger Rediscovery

After you extend a metric family, the changes occur during the nightly automatic rediscovery. If the changes do not apply automatically, trigger the update manually.

WARNING

To avoid a severe impact on performance, do not trigger a rediscovery during normal business hours.

Follow these steps:

1. Navigate to the **Data Aggregator** data source.
2. Click **Monitoring Configuration**, **Metric Families**.
3. Select the metric family.
4. Click **Update Metric Family**.
   The Data Aggregator rediscovers components on all devices that support the selected metric family.

Verify the Metric Family Results

To ensure successful operation, verify the results of the import.

Follow these steps:

1. Log in to the UI, and navigate to the Data Aggregator data source.
2. Go to Monitoring Configuration, Metric Families.
3. Verify that the metric family in the list and that the Last Modified time has been updated.

Create or Extend Vendor Certifications

If you have a new vendor or device that you want to support, create a vendor certification. If you want to change the way that a metric is calculated, or to add custom discovery filtering for an out-of-box vendor certification, extend the vendor certification. To remove a vendor certification extension, import an unchanged vendor certification extension template.

WARNING

To avoid possible data loss, always back up the certification directory anytime you extend, create, or update a vendor certification. Metric families and vendor certifications cannot be deleted from your system. Test custom certifications before you implement the changes in your production environment.

Get a Vendor Certification XML Template

For a new certification, use an existing vendor certification for a similar device to create an XML template. For an extension, get the XML for the target vendor certification.

TIP

To find a suitable vendor certification to use as a template, look at the metric family you want to support with the new certification, and pick one that is similar to your device.

Follow these steps:

1. Set up a REST client with a connection to the Data Aggregator server.
2. Enter the following URL to retrieve the template vendor certification:
   - **New Certification:** *http://da_hostname:8581/typecatalog/certifications/snmp/cert_name*
   - **Extension:** *http:*
     cert_name specifies the name of the vendor certification, which is an attribute of the FacetType tag.
3. Select GET in the Method tab, and run the method.
   The REST client returns the XML information for the vendor certification.
   Use the XML as a template to create the custom or extended vendor certification.

Edit the Vendor Certification XML

To apply the necessary changes, edit the XML file. When you extend a vendor certification, include only the XML nodes that require changes. For complete information about the XML structure, see Vendor Certification XML Structure.

Import the Custom Vendor Certification

Import the vendor certification to the system.

TIP

Verify the vendor certification in a test environment before you import the certification to your production environment. You cannot delete a vendor certification.

Select one of the following options to import the vendor certification:

Use a REST Client to Import a Vendor Certification

To import a single vendor certification, you can use a REST client.

Follow these steps:

1. Specify one of the following URLs:
   - **Import Custom Vendor Certification:** *http://da-hostname:8581/typecatalog/certifications/snmp*
   - **Update Custom Vendor Certification:** `http://da-hostname:8581/typecatalog/certifications/snmp/cert_name`
   - **Extend Vendor Certification:** `http://da-hostname:8581/typecatalog/certifications/snmp/extension/cert_name`
2. On the **Method** tab, select **POST** to import a custom vendor certification, or select **PUT** to update or extend a certification.
3. In the **Body** settings, select 'application/xml' as the 'Body Content-type'.

WARNING
Failing to set the Content-type results in a 415 error.

4. Copy the vendor certification XML into the Body tab.
5. Run the method.
   Your vendor certification is imported. If no errors occur, the Status field in the HTTP Response section displays the following result:
   ```
   HTTP/1.1 200 OK
   ```

NOTE

To import an unchanged vendor certification extension template, use a file that is similar to the following template:

```
<?xml version="1.0" encoding="UTF-8"?>
<DataModel namespace="http://im.ca.com/certifications/snmp" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xsi:noNamespaceSchemaLocation="SNMPCertificationFacet.xsd">
  <Author>CA</Author>
  <Version>2.02</Version>
  <FacetType name="IfXTableMib"
 descriptorClass="com.ca.im.core.datamodel.certs.CertificationFacetDescriptorImpl">
    <FacetOf namespace="http://im.ca.com/core" name="Item" />
  </FacetType>
</DataModel>
```

Import Custom Vendor Certifications in the UI

After you create a custom vendor certification, you can share it with other Data Aggregator users who want to gather metrics for the same vendor.

WARNING

The **genericWS** format will be deprecated in a future release. Therefore, we recommend that you use the **typecatalog** format.

Custom vendor certifications can be shared between Data Aggregator users. Custom vendor certifications let users gather metrics for vendor devices when a factory certification is not yet available. To use a shared vendor certification, import it in XML format into your installation of Data Aggregator. You are not required to import the MIB.

Follow these steps:

NOTE

The metric family that is associated with the vendor certification must be available in CA NetOps Portal before importing. The import fails when the associated metric family is unavailable.

1. Click **Vendor Certifications** from the **Monitoring Configuration** menu for a Data Aggregator data source.
2. Click **Import**.

   NOTE

   The Import button supports ZIP files. For example, you can import the downloaded ZIP file for a certification from the On-Demand Certification support page.
3. Click **Browse**, and select the custom vendor certification file.
4. Click **Open**, and then click **Import**.
   Your custom vendor certification is imported. Data Aggregator immediately begins collecting metrics for the metric families that are associated with the newly imported custom vendor certification.

Verify the Vendor Certification Results

To ensure successful operation, verify the results of the import.

Follow these steps:

1. Log in to the UI, and navigate to the **Data Aggregator** data source.
2. Click **Monitoring Configuration**, **Vendor Certifications**.
3. Verify that the certification appears in the list and that the Last Modified time has been updated.
4. Click your metric family in the **Metric Families** view, and verify that the metric family appears.
5. Click the **Vendor Certification Priorities** tab.
   New custom vendor certifications are automatically added to the bottom of the priority list for the specified metric family. If necessary, modify the priority list and move the vendor certification to a higher priority.

Manage Vendor Certification Priorities

If the metric family for a device supports more than one vendor certification, the vendor certification with the highest priority is selected as the backing vendor certification. New custom vendor certifications are automatically added to the bottom of the priority list for the specified metric family. If necessary, modify the priority list and move the vendor certification to a higher priority. To use more than one vendor certification for the same device, group vendor certification priorities.

Prioritize the Vendor Certification Within the Metric Family

When you change the priority of the vendor certifications for a metric family, the metric family is updated on all affected devices. An event is generated on the metric family, indicating that the vendor certification priority on the metric family has changed. If the backing vendor certification changes on a device, an event is generated on the device. The event indicates that a vendor certification has changed. A second event is also generated, indicating the specific changes.

> **NOTE**
>
> To take advantage of any new vendor certifications that are part of an installation upgrade, manually change the vendor certification priorities. For example, F5 CPU vendor certifications are modeled as normal CPUs but are not discovered because F5 also supports Host Resources. After an upgrade, the Host Resources CPU priority entry will be higher than the F5 entries appended to the end of the priority list. To discover F5 CPU devices and components, update the vendor certification priority for the CPU metric family. A fresh installation does not have this issue.

Follow these steps:

1. Log in to the UI, and navigate to the **Data Aggregator** data source.
2. Click **Monitoring Configuration**, **Metric Families**.
3. Select a metric family, and click the **Vendor Certification Priorities** tab.
   The list of prioritized vendor certifications appears.
4. Click **Manage**.
5. Arrange the priority order as necessary, and click **Save**.
6. The metric family uses the new priority to determine which vendor certification to use for monitored devices.

Group Vendor Certification Priorities

Grouping vendor certification priorities lets you use more than one vendor certification for the same device. A single vendor certification priority can belong to as many priority groups as necessary for your application. When a device is discovered, all vendor certifications in the priority group are supported on the device.

WARNING

Do not update PriorityGroup and change the order of the vendor certifications in the same REST call. Changing both simultaneously may disrupt automatic rediscovery. For more information, see Automatic Rediscovery Does Not Run After Updating Vendor Group Priority.

To group vendor certification priorities, use the REST Web Services. You cannot group vendor certification priorities using the UI.

Follow these steps:

1. Run a GET operation on the following REST URL:
   `http://da_host:8581/rest/vendorpriorities/`
   The REST call returns a list of all the vendor certification priorities.
2. Determine the ID of your metric family in the list of vendor certification priorities.
3. Run a GET operation on the following REST URL:
   `http://da_host:8581/rest/vendorpriorities/ID`
   The XML of the vendor certification priority that you want to modify is retrieved.
4. To add a vendor certification priority to a group, add the `<PriorityGroup>` tag to the vendor certification.
   Example:
   In this example, the vendor certification priority is added to the group entitled "F5".

```
<CertificationOrder>
   <CollectionID>167</CollectionID>
   <VendorCertID>{http://im.ca.com/certifications/snmp}F5BigipMultihostCpu</
VendorCertID>
   <PriorityGroup>F5</PriorityGroup>
</CertificationOrder>
```

   WARNING

   Proper XML for the `<VendorCertID>` tag is written on a single line, and excludes spaces and carriage returns. Failure to follow this guideline causes the vendor certification priority to fail.

   NOTE

   To enabled recommended priority groups, replace the `<RecommendedPrioritiyGroup>` tag with the `<PriorityGroup>` tag.
5. (Optional) To add a single vendor certification priority to multiple groups, separate the group names using commas.
   Example:
   `<PriorityGroup>F5, Huawei</PriorityGroup>`
6. Remove the `<ID>` and `<MetricFamilyID>` tags from the vendor certification priority XML.
7. Run a PUT REST call on the following URL to import the new XML file:
   `http://da_host:8581/rest/vendorpriorities/ID`

   ID
   Specifies the ID of the vendor certification priority.
   DX NetOps Performance Management rediscovers all devices that support the metric family.

Verify Vendor Certification Priority Grouping

Verify that the vendor certification priorities are grouped as necessary.

Follow these steps:

1. Log in to the UI and navigate to the Data Aggregator data source.
2. Click **Monitored Inventory**, **Monitored Devices**.

3. Select a device from the Tree View.
4. Click the **Polled Metric Families** tab in the pane on the right.
   The vendor certifications that you grouped under the corresponding metric families appear on multiple rows in the **Vendor Cert** column.

Basic Vendor Self-Certification

For basic vendor certification, use the UI to apply simple changes to a vendor certification. This option is useful for limited changes that you need immediately.

Basic certification has the following limitations:

- Applies only to devices with a single MIB and a single MIB table.
- Cannot modify all aspects of the vendor certification.
- Does not apply to extended vendor certifications or custom certifications created with the advanced method.

Log in as the administrator to perform these tasks:

Create a Custom Vendor Certification in the UI

A vendor certification maps attributes from a vendor MIB to the metrics specified in a metric family. Vendor certifications also determine how metrics collected from an item are formatted for use in the UI and in reports. Metrics that are provided for an item can vary depending on the vendor of the item. Mapping these values ensures that the metric values are reported consistently, regardless of the vendor.

Different vendor certifications can apply to the same metric family. Data Aggregator maps metric values using a ranked list of vendor certifications. Data Aggregator calculates a metric value using the highest priority vendor certification that matches the polled item. If a vendor certification does not exist for a device, you can create one.

To determine if a device supports a vendor certification, the device is queried for each key attribute that is defined in the specified vendor certification. If a device supports an attribute, the device responds to an SNMP GET NEXT request on a given Object ID. A device supports a vendor certification only if all the key attributes are supported. For custom vendor certifications created with the Vendor Certification wizard, any attribute used in an expression is considered “key” and therefore the device supports it.

WARNING

To avoid possible data loss, back up the certifications directory each time that you create or update a vendor certification, metric family, or component.

Follow these steps:

1. Click **Vendor Certifications** from the **Monitoring Configuration** menu for a Data Aggregator data source.
2. Click **New**.
   The New Vendor Certifications wizard opens, guiding you through the following steps to define your vendor certification:
   - Selecting the MIB for your device.
   - (Optional) Importing a new MIB when one does not exist.
   - Selecting the metric family to which you want to map.

     NOTE
     Only scalar metric families or table metric families with a single index appear in the list.
   - Defining the expressions between the metrics in a selected metric family and the vendor certification variables from the selected MIB.

NOTE
The Names and Indexes metric names require an expression. For a custom vendor certification created with the Vendor Certification wizard, Data Aggregator automatically provides the Indexes metric expression for your selected MIB table.

3. Follow the prompts.
   The new vendor certification is created and automatically added to the end of the priority list for the selected metric family. The vendor certification is automatically associated with the All Manageable Devices device collection.

   NOTE
   (Optional) You can change the priority of the vendor certification within the metric family.
4. Run a discovery and verify that Data Aggregator is correctly polling the metric data for your devices.

   NOTE
   Data Aggregator only polls for metrics that have an expression defined in the vendor certification. If you try to report on metrics without a defined expression, your reports display a "no data available" message.

Import Custom Vendor Certifications in the UI

After you create a custom vendor certification, you can share it with other Data Aggregator users who want to gather metrics for the same vendor.

WARNING

The **genericWS** format will be deprecated in a future release. Therefore, we recommend that you use the **typecatalog** format.

Custom vendor certifications can be shared between Data Aggregator users. Custom vendor certifications let users gather metrics for vendor devices when a factory certification is not yet available. To use a shared vendor certification, import it in XML format into your installation of Data Aggregator. You are not required to import the MIB.

Follow these steps:

NOTE
The metric family that is associated with the vendor certification must be available in NetOps Portal before importing. The import fails when the associated metric family is unavailable.

1. Click **Vendor Certifications** from the **Monitoring Configuration** menu for a Data Aggregator data source.

   NOTE

   Use the Search feature in any pane to locate specific information that is related to that pane. Alternatively, navigate between pages in a pane using the arrows.
2. Click **Import**.

   NOTE

   The Import button supports ZIP files. For example, you can import the downloaded ZIP file for a certification from the On-Demand Certification support page.
3. Click **Browse**, and select the custom vendor certification file.
4. Click **Open**, and then click **Import**.
   Your custom vendor certification is imported. Data Aggregator immediately begins collecting metrics for the metric families that are associated with the newly imported custom vendor certification.

Edit a Custom Vendor Certification in the UI

You can edit existing custom vendor certifications to collect additional data for reporting. For example, you can edit the expression that maps to the normalized metric family variables.

This method applies only to custom vendor certifications that you created or edited in the UI.

WARNING

To avoid possible data loss, back up the certifications directory each time that you create or update a vendor certification, metric family, or component.

Follow these steps:

1. Click **Vendor Certifications** from the **Monitoring Configuration** menu for a Data Aggregator data source.
2. Select a custom vendor certification from the list.
3. Select a metric family, and click **Edit**.
4. Manually edit the expression.
   Common edits include the following changes:
   – Change a value that is assigned to the expression, such as an average.
   – Add multiple vendor certification variables to the expression.
   – Remove an expression from a metric family variable by clearing the Expression text box.

   NOTE
   The Names and Indexes metric names require an expression. For a custom vendor certification created with the Vendor Certification wizard, Data Aggregator automatically provides the Indexes metric expression for your selected MIB table.
5. Click **Accept Expression**.
   The expression is mapped, and the top table is populated with the updated values.
6. Click **Save**.
   The vendor certification details grid is updated with the changes to the metric family variables.

Create or Edit Vendor Certification Expressions

To modify the mapping of normalized metric family variables, edit the vendor certification expressions.

Consider the following information when you edit expressions:

- Use delimiters to separate vendor certification variables.
- MVEL functions and custom functions are valid.
- The Names and Indexes metric names require an expression. The remaining metric names are optional.

NOTE

For a vendor certification created with the Vendor Certification wizard, DX NetOps Performance Management automatically provides the Indexes metric expression for your selected MIB table.

Example: Change the Value for Averages

Cisco router CPU statistics are mapped to the normalized variable 'CPU Utilization', as shown in the following expression:

```
cpmCPULoadAvg5min+cpmCPUUseravg5min
```

You can change the 5-minute average to a 1-minute average by editing the expression as follows:

```
cpmCPULoadAvg1min+cpmCPUUseravg1min
```

Example: Use an Advanced Expression

The following expression verifies whether hrStorageSize < 0, and returns the value of hrStorageSize converted to an Unsigned value, and multiplied by 100. Otherwise, the expression returns the following value: hrStorageUsed/ hrStorageSize * 100.

```
(hrStorageSize &lt; 0) ? (hrStorageUsed/
convertSignedIntToUnsignedDecimal(hrStorageSize)) * 100 : hrStorageUsed/
hrStorageSize * 100
```

Functions and Global Variables

MVEL is the language that vendor certifications use to manipulate data from monitored devices. In vendor certification expressions, use MVEL to normalize data and perform calculations.

MVEL is a publicly available Expression Language for Java environments that can be embedded. MVEL supports expressions similar to Java expressions. You can build expressions using operators, use braces to control precedence, and terminate statements using semi-colons. For a detailed reference of the MVEL language, see the MVEL 2.0 Wiki.

Performing Calculations with MVEL

If your expression contains a calculation without at least one attribute variable, you might see unexpected results. Include at least one attribute in your expression that does not affect the calculation result. For example, the following expression might return unexpected results:

```
<Expression destAttr=”metric1”>15 * 15</Expression>
```

However, the following expression does not affect the result and does return the expected result:

```
<Expression destAttr=”metric1”>Index; 15 * 15</Expression>
```

- **Index**
  Specify an attribute variable that is defined in the **Attribute** or **AttributeGroup**.

The following certification shows the proper usage of MVEL functions for vendor certifications: MVEL Test Certification. The **assert** tag is used for internal testing purposes only, and is not used in creating vendor certifications.

> **WARNING**
>
> To ensure that you do not lose all the data from an expression that uses an assert tag, add a space before the semicolon at the end of the expression.

The following custom functions and global variables are available for use in vendor certification expressions:

availabilityWithSysUptime Function

This function calculates availability as a percentage using sysUptime and the poll duration, granting a grace period.

Syntax

This function has the following format:

```
Object availabilityWithSysUptime (Long sysUpTime, Long duration)
```

Parameters

- **sysUpTime**

The time (in centiseconds) since the network management portion of the system was last reinitialized.

- **duration**
  The poll duration time in seconds. Use the global variable _rspDuration. See the Advanced example for more information.

Return Values

Returns the availability as a percentage (0 - 100), or returns "null" when invalid data is passed.

Examples

The following expression produces the following result for a sysUpTime of 30000 and a poll duration of 300:

Expression:

```
availabilityWithSysUptime (sysUpTime, duration)
```

Result:

```
100
```

The same expression produces the following result for a sysUpTime of 6000 and a poll duration of 300:

Result:

```
20
```

The same expression produces the following result for a sysUpTime of 30005 and a poll duration of 300:

Result:

```
100
```

Advanced Example

The following expression is taken from “System Statistics” Vendor Certification:

```
Availability=availabilityWithSysUptime(sysUpTime,_rspDuration)
```

mapModel Function

This function uses the value of an objectID (sysObjectID) and maps the system OID to a model name string. Use this function to certify devices.

Syntax

This function has the following format:

```
String  mapModel ( ObjectID sysObjectID )
```

Parameters

- **sysObjectID**
  The object ID value to parse.

Return Values

Returns the string containing the mapped model name.

Examples

The following expression produces the following result for an OID value of 1.3.6.1.4.1.9.1.223:

Expression:

```
mapModel (oid )
```

Result:

```
Cisco7204VXR
```

The same expression produces the following result for an OID value of 1.3.6.1.4.1:

Result:

```
Unknown 1.3.6.1.4.1
```

Advanced Example

The following expression is taken from “System Statistics” Vendor Certification:

```
Model=mapModel (sysObjectID)
```

mapVendor Function

This function uses the value of an objectID (sysObjectID) and maps the system OID to a vendor name string. Use this function to find the vendor of a device.

Syntax

This function has the following format:

```
String mapVendor( ObjectID sysObjectID )
```

Parameters

- **sysObjectID**
  The object ID value to parse.

Return Values

Returns the string containing the mapped vendor name. If a vendor is not found, returns "".

Examples

The following expression produces the following result for an OID value of 1.3.6.2.1.2.2636.0:

Expression:

```
mapVendor (oid )
```

Result:

```
Juniper
```

The same expression produces the following result for an OID value of 1.3.6.2.1.2.1234567.0:

Result:

```
Unknown
```

Advanced Example

The following expression is taken from “System Statistics” Vendor Certification:

```
Model=mapVendor (sysObjectID)
```

mvelInfo Function

This function populates the INFO level of the karaf.log file with the input parameters. Use this function to log the polled values from a report that returns a result that you believe is incorrect.

The poll log of the Data Collector only shows the values of the polled attributes, while the report only shows the result of the calculation. The mvelInfo function allows you to view the input poll values to determine where the calculation went wrong.

Syntax

This function has the following format:

```
String mvelInfo (Array objects)
```

Parameters

- **objects**
  The object array is logged under the INFO level in the karaf.log file of the Data Collector.

Return Values

Null

Examples

The following expression logs cpmCPUTotal5minRev in the karaf.log file.

Expression:

```
mvelInfo({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev})
```

Result:

Null

Result (karaf.log):

MVEL info: cpmCPUTotal5minRev=15

Advanced Example

```
mvelInfo({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev, " cpmCPUTotal10minRev=",
 cpmCPUTotal10minRev}); cpmCPUTotal10minRev;
```

Result:

12

Result (karaf.log):

MVEL info: cpmCPUTotal5minRev=15 cpmCPUTotal10minRev=12

mvelWarn Function

This function populates the WARN level of the karaf.log file with the input parameters. Use this function to log the polled values from a report that returns a result that you believe is incorrect.

The poll log of the Data Collector only shows the values of the polled attributes, while the report only shows the result of the calculation. The mvelWarn function allows you to view the input poll values to determine where the calculation went wrong.

Syntax

This function has the following format:

```
String mvelWarn (Array objects)
```

Parameters

- **objects**
  The object array is logged under the WARN level in the karaf.log file of the Data Collector.

Return Values

Null

Examples

The following expression logs cpmCPUTotal5minRev in the karaf.log file.

Expression:

```
mvelWarn({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev})
```

Result:

Null

Result (karaf.log):

MVEL warn: cpmCPUTotal5minRev=15

Advanced Example

```
mvelWarn({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev, " cpmCPUTotal10minRev=",
 cpmCPUTotal10minRev}); cpmCPUTotal10minRev;
```

Result:

12

Result (karaf.log):

MVEL warn: cpmCPUTotal5minRev=15 cpmCPUTotal10minRev=12

mvelError Function

This function populates the ERROR level of the karaf.log file with the input parameters. Use this function to log the polled values from a report that returns a result that you believe is incorrect.

The poll log of the Data Collector only shows the values of the polled attributes, while the report only shows the result of the calculation. The mvelError function allows you to view the input poll values to determine where the calculation went wrong.

Syntax

This function has the following format:

```
String mvelError (Array objects)
```

Parameters

- **objects**
  The object array is logged under the ERROR level in the karaf.log file of the Data Collector.

Return Values

Null

Examples

The following expression logs cpmCPUTotal5minRev in the karaf.log file.

Expression:

```
mvelError({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev})
```

Result:

Null

Result (karaf.log):

MVEL error: cpmCPUTotal5minRev=15

Advanced Example

```
mvelError({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev, " cpmCPUTotal10minRev=",
 cpmCPUTotal10minRev}); cpmCPUTotal10minRev;
```

Result:

12

Result (karaf.log):

MVEL error: cpmCPUTotal5minRev=15 cpmCPUTotal10minRev=12

mvelDebug Function

This function populates the DEBUG level of the karaf.log file with the input parameters. Use this function to log the polled values from a report that returns a result that you believe is incorrect.

The poll log of the Data Collector only shows the values of the polled attributes, while the report only shows the result of the calculation. The mvelDebug function allows you to view the input poll values to determine where the calculation went wrong.

Syntax

This function has the following format:

```
String mvelDebug (Array objects)
```

Parameters

- **objects**
  The object array is logged under the DEBUG level in the karaf.log file of the Data Collector.

Return Values

Null

Examples

The following expression logs cpmCPUTotal5minRev in the karaf.log file.

Expression:

```
mvelDebug({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev})
```

Result:

Null

Result (karaf.log):

MVEL debug: cpmCPUTotal5minRev=15

Advanced Example

```
mvelDebug({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev, " cpmCPUTotal10minRev=",
 cpmCPUTotal10minRev}); cpmCPUTotal10minRev;
```

Result:

12

Result (karaf.log):

MVEL debug: cpmCPUTotal5minRev=15 cpmCPUTotal10minRev=12

mvelTrace Function

This function populates the TRACE level of the karaf.log file with the input parameters. Use this function to log the polled values from a report that returns a result that you believe is incorrect.

The poll log of the Data Collector only shows the values of the polled attributes, while the report only shows the result of the calculation. The mvelTrace function allows you to view the input poll values to determine where the calculation went wrong.

Syntax

This function has the following format:

```
String mvelTrace (Array objects)
```

Parameters

- **objects**
  The object array is logged under the TRACE level in the karaf.log file of the Data Collector.

Return Values

Null

Examples

The following expression logs cpmCPUTotal5minRev in the karaf.log file.

Expression:

```
mvelTrace({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev})
```

Result:

Null

Result (karaf.log):

MVEL trace: cpmCPUTotal5minRev=15

Advanced Example

```
mvelTrace({"cpmCPUTotal5minRev=", cpmCPUTotal5minRev, " cpmCPUTotal10minRev=",
 cpmCPUTotal10minRev}); cpmCPUTotal10minRev;
```

Result:

12

Result (karaf.log):

MVEL trace: cpmCPUTotal5minRev=15 cpmCPUTotal10minRev=12

snmpConstArrayMap Function

This function maps a value (index) to a set of constant values (array). If necessary, this function rounds the input value to nearest integer value. Then, it uses the integer value as an index to the set of constant values (array) that are shown as c0, c1, up to cn-1. The c values must be integers. This function checks these values when the expression is parsed and returns c*x*. If the value is not in the domain from 0 to n-1 (inclusive), the result is 0 (without an error message). Use this function to certify devices.

Syntax

This function has the following format:

```
Integer  snmpConstArrayMap(Double index, Integer[] array)
```

Parameters

- **index**
  A Double value, which is used as an index into the array.
- **array**
  Any range of integer values.

Return Values

Returns an integer value from the array. An index value of null returns null.

Examples

The following expression produces the following result for an index of 2 and an array of {5, 6, 7, 8, 9, 4}:

Expression:

```
snmpConstArrayMap (index, array)
```

Result:

```
7
```

The following expression produces the following result for an index of 4.88 and an array of {5, 6, 7, 8, 9, 4}:

Expression:

```
snmpConstArrayMap (value, array)
```

Result:

```
4
```

Advanced Example

The following expression is taken from “Generic Modem” Vendor Certification:

```
SpeedOut=snmpConstArrayMap(mdmCsFinalTxLinkRate,
{0,110,300,600,1200,2400,4800,7200,9600,12000,14000,16000,19000,38000,75,450,0,57000,21000,2400
```

snmpCounter64 Function

This function evaluates two 32-bit numeric values and returns a value containing the 64-bit representation. Use this function to certify devices. The hiVal is shifted 32 bits left and the lowVal is added and the result is placed in a 64-bit return variable.

Syntax

This function has the following format:

```
Object snmpCounter64 (Long hiVal, Long lowVal)
```

Parameters

- **hiVal**
  The 32-bit numeric value representing the high-order bits.
- **lowVal**
  The 32-bit numeric value representing the low-order bits.

Return Values

Returns the 64-bit representation of the two 32-bit numeric values, or returns "null" when either 32-bit value input is null.

Examples

The following expression produces the following result for a hiVal of 88 and a lowVal of 558.

Expression:

```
snmpCounter64 (hiVal, lowVal)
```

Result:

```
377957122606
```

Advanced Example

The following expression is taken from “Cisco CBQos ClassMap” Vendor Certification. This certification contains many snmpMax examples:

```
PrePolicyPackets=snmpMax(0,snmpCounter64(cbQosCMPrePolicyPktOverflow,cbQosCMPrePolicyPkt))
```

snmpGet

This function gets the value of an ObjectID on the polled device.

> **NOTE**
>
> This function issues extra SNMP requests. To avoid a negative performance impact, certifications that include this expression are moved to a potentially slower processing queue.

Syntax

This function has the following format:

```
<GetResponse> snmpGet (OID<string>)
```

Parameters

- **OID** The ObjectID of the polled device.

Functions

- **getError()** Returns the response error code**. Example:** SUCCESS
- **getIp()** Returns the IP address of the device.
- **getOid()** Returns the requested ObjectID.
- **getResult()** Returns the SNMP response object.
- **getValue()** Returns the value from the SNMP response object.
- **getType()** Returns the type of the SNMP response object, such as COUNTER32 or GAUGE.

Return Values

Returns the response object of an SNMP GET request.

Example

The following expression includes sample results for each function:

```
response = snmpGet('1.3.6.1.2.1.3.0');
response.getError() --- SUCCESS
response.getIp() --- 10.42.96.5
response.getOid() --- 1.3.6.1.2.1.3.0
value = response.getResult();
value.getType() --- TIMETICKS
value.getValue() --- 31528546
```

The following expression does a null check (.?) to avoid breaking the logic when the result is null:

```
response = snmpGet('1.3.6.1.2.1.3.0');
response.error --- SUCCESS
response.ip --- 10.42.96.5
response.oid --- 1.3.6.1.2.1.3.0
response.?result.type ---- TIMETICKS
 response.?result.value ---- 31528546
```

snmpGetTable

This function gets the values of all ObjectIDs that share the prefix ObjectID.

> **NOTE**
>
> This function issues extra SNMP requests. To avoid a negative performance impact, certifications that include this expression are moved to a potentially slower processing queue.

Syntax

This function has the following format:

```
<GetBulkResponse> snmpGetTable (OID<string>)
```

Parameters

- **OID**
  The ObjectID of the polled device.

Functions

- **getError()** Returns the response error code**. Example:** SUCCESS
- **getIp()** Returns the IP address of the device.
- **getOid()** Returns the requested ObjectID.
- **getResult()** Returns a list of SNMP response objects.
- **getValue()** Returns the value from the SNMP response object.
- **getType()** Returns the type of the SNMP response object, such as COUNTER32 or GAUGE.
- **getIndex()** Returns the SNMP instance index of the SNMP response object.

Return Values

Returns a table that contains a list of SNMP response objects.

Examples

The following expression includes sample results for each function:

```
response = snmpGetTable('1.3.6.1.2.1.2.2.1.10');
response.getError() --- SUCCESS
response.getIp() --- 10.42.96.5
response.getOid() --- 1.3.6.1.2.1.2.2.1.10
list = response.getResult();
list.size() --- 200
list.get(0).getType() --- COUNTER
list.get(0).getValue() --- 1849
list.get(0).getIndex() --- 1
item = list.get(199);
item.getType() --- COUNTER
item.getResult() --- 1855
item.getIndex() --- 200
for(int i =0; i < list.size(); i ++){
    instance = list.get(i);
    instanceType = instance.getType();
    instanceValue = instance.getValue();
    instanceIndex = instance.getIndex();
}
```

NOTE

The `instanceType = listget(i).getType()` method chain is unsupported. The result of `list.get(i)` must be stored in a variable first. Use the following expression instead:

```
instance = list.get(i);
instanceType = instance.getType();
```

snmpGetUpSinceTime Function

This function returns the time that the system was turned on based on the number of seconds since the current epoch.

Syntax

This function has the following format:

```
snmpGetUpSinceTime(Long upTime)
```

Parameters

- **upTime**
  The number of seconds since the beginning of the current epoch. You can get the system uptime from the following OID: 1.3.6.1.2.1.1.3.0. Convert it into centiseconds before you pass it in.

Return Values

Returns the time that the device was powered on in the form of total seconds since the current epoch.

snmpMax Function

This function returns the larger of two 64-bit values. Use this function to certify devices.

Syntax

This function has the following format:

```
Object snmpMax(BigInteger val1, BigInteger val2)
```

Parameters

- **val1**
  The first 64-bit BigInteger value.
- **val2**
  The second 64-bit BigInteger value.

Return Values

Returns the maximum of the two BigInteger values that are passed in, or returns "null" when either BigInteger value input is null.

Examples

The following expression produces the following result for a val1 of 2^32 and a val2 of 10:

Expression:

```
snmpMax (val1, val2)
```

Result:

```
2^32
```

The same expression produces the following result for a val1 of 5864 and a val2 of 134556890:

Result:

```
134556890
```

Advanced Example

The following expression is taken from “Cisco CBQos ClassMap” Vendor Certification. This certification contains many snmpMax examples:

```
PrePolicyPackets=snmpMax(0,snmpCounter64(cbQosCMPrePolicyPktOverflow,cbQosCMPrePolicyPkt))
```

snmpObjectIDToASCIIString Function

This function converts an SNMP OID value to its string representation. Any leading or trailing spaces are removed.

Syntax

This function has the following format:

```
snmpObjectIDToASCIIString( Object Id oid )
```

Parameters

- **oid**
  The object ID to convert to a string.

snmpOIDParser Function

This function uses the value of an objectID (OID) and parses out a subset of the OID based on the startIndex and endIndex values. The indexes are 1 based. If the endIndex is -1, then we go to the end of the OID. Use this function to certify devices.

Syntax

This function has the following format:

```
ObjectID snmpOIDParser( ObjectID OID, Integer startIndex, Integer endIndex )
```

Parameters

- **OID**
  The object ID (OID) value to parse.
- **startIndex**
  An integer value of the index at which to begin parsing.
- **endIndex**
  An integer value of the index at which to stop parsing.

Return Values

Returns the parsed subset ObjectID (OID).

Examples

The following expression produces the following result for an OID value of 1.2.3.4.5.6.7.8.9.10, a startIndex value of 1, and an endIndex value of 5:

Expression:

```
snmpOIDParser(oid, startIndex, endIndex )
```

Result:

```
1.2.3.4.5
```

The same expression produces the following result for an OID value of 1.2.3.4.5.6.7.8.9.10, a startIndex value of 6, and an endIndex value of -1:

Result:

```
6.7.8.9.10
```

Advanced Example

The following expression is taken from “Cisco CBQos ClassMap” Vendor Certification:

```
ItemUniqueIDs=snmpOIDParser(cbQosConfigIndex, 2, 2)
```

snmpOctetStringFloat Function

This function converts an SNMP octet string to a floating-point value. Use this function to certify devices. An SNMP octet string is a seven-bit ASCII string.

Syntax

This function has the following format:

```
Object snmpOctetStringFloat(byte[] octetString)
```

Parameters

- **octetString**
  The SNMP octet string.

Return Values

Returns the converted string value, or returns "null" when the function cannot convert the string.

Examples

The following expression produces the following result for an octetString of {0x33, 0x33, 0x2E, 0x33, 0x33}:

Expression:

```
snmpOctetStringFloat (octetString)
```

Result:

```
33.33
```

The same expression produces the following result for an octetString of {0x36, 0x36, 0x36}:

Result:

```
666.0
```

snmpProtectedDiv Function

This function divides two Double values and returns the result of the division as a Double. If the dividend or divisor is null or 0.0 the return value is 0.0. Use this function to protect the expression from dividing with null or 0. Data Repository can contain null or zero values, such as when a poll fails. In this case, you avoid a divide-by-zero exception by using this function.

Syntax

This function has the following format:

```
Double snmpProtectedDiv(Double val1, Double val2)
```

Parameters

- **val1**
  The dividend, which is a Double value (floating number) to be divided by val2. (Double is a Java data type.)
- **val2**
  The divisor, which is a Double value (floating number). (Double is a Java data type.)

Return Values

Returns the result of the division as a Double or 0.0 if the dividend or divisor is null or 0.0 (*Double* is a Java data type).

Examples

The following expression produces the following result for a val1 of 7.2 and val2 of 2:

Expression:

```
snmpProtectedDiv(val1, val2)
```

Result:

```
3.6
```

The following expression produces the following result for a val1 of 7.2 and val2 of null or 0.0:

Result:

```
0.0
```

Advanced Example

The following expression is taken from Vendor Certification:

```
Utilization=snmpProtectedDiv((cpuStatsUser + cpuStatsSys),(cpuStatsUser + cpuStatsSys +
 (isdef(cpuStatsWait)?cpuStatsWait:0) + cpuStatsIdle))*100
```

snmpRound Function

This function rounds a numeric value to the nearest integer value.

Syntax

This function has the following format:

```
Long snmpRound(Double dNumber)
```

Parameters

- **dNumber**
  A Double value (floating number) to be rounded (*Double* is a Java data type).

Return Values

Returns a Long value, which is the nearest integer value to the value provided in dNumber (*Long* is a Java data type).

Examples

The following expression produces the following result for a dNumber of 3.5:

Expression:

```
snmpRound(dNumber)
```

Result:

```
4
```

The same expression produces the following result for a dNumber of 3.4:

Result:

```
3
```

Advanced Example

The following expression is taken from “Cisco IPSLA Jitter Precision Statistics” Vendor Certification:

```
PathAvailability=snmpRound(rttMonJitterStatsNumOfRTT / (rttMonJitterStatsNumOfRTT
 + rttMonJitterStatsPacketLossSD + rttMonJitterStatsPacketLossDS +
 rttMonJitterStatsPacketOutOfSequence + rttMonJitterStatsPacketMIA +
 rttMonJitterStatsPacketLateArrival + rttMonJitterStatsError + rttMonJitterStatsBusies +
 1/100) * 100)
```

snmpStringParser Function

This function was written for internal use only. The function parses IP addresses that are received from a CA Application Insight Module (AIM). CA has only tested this function with an internal class. Another type of class may not be supported.

Syntax

This function has the following format:

```
snmpStringParser(Delimiter, Type to convert to, String to parse 1, String to parse 2)
```

Parameters

- **Type to convert to**
  The type of class to which to parse the supplied strings.
- **Strings to parse 1 and 2**
  The IP address to parse. Two strings enable you to provide addresses in IPv4 and IPv6 format.

Return Values

Returns the converted value of the string, or returns "null" when the function cannot parse the string.

snmpSvcs Function

This function takes the values from sysObjectOID, sysService, and ipForwarding MIB variables of an agent and determines what services the SNMP agent supports. For example, Router/Switch/Repeater/Host could be a supported service, as defined in the SNMP MIB RFC 1213.

The return from the function is evaluated as follows because custom device types have high precedence over system ones:

- If sysObjectID OID is mapped in the DeviceTypes file, then the return services is from the file.
- If sysObjectID OID is not mapped in the DeviceTypes file, then the sysServices and ipForwarding is used to return the supported services.

Syntax

This function has the following format:

```
DeviceService[] snmpSvcs(ObjectID sysObjectID, Integer sysServices,
 Integer ipForwarding)
```

Parameters

- **sysObjectID**
  The object ID value to parse.
- **sysServices**
  An integer where each bit represents a different service, such as switch/repeater/host.
- **ipForwarding**
  An integer indicating whether this entity is acting as an IP gateway or IP host regarding the forwarding of datagrams. This entity receives the forwarded datagrams, but the forwarded datagrams are not addressed to this entity. Possible values are 1 (Forwarding) and 2 (notForwarding).

Return Values

Returns a list of one or more of the following device services:

- ROUTER
- REPEATER
- SWITCH
- HOST
- UNKNOWN_TYPE

Example

The following expression produces the following result for a sysServices value of 8, an ipForwarding value of 0, and sysObjectID not found in the DeviceTypes file:

Expression:

```
snmpSvcs(sysObjectOID,sysServices,ipForwarding)
```

Result:

```
DeviceService[HOST]
```

Advanced Example

The following expression is taken from the "System Statistics" Vendor Certification:

```
Services=snmpSvcs(sysObjectID,isdef(sysServices)?sysServices:0,isdef(ipForwarding)?
ipForwarding:0)
```

storePortReconfig Function

This function returns a string containing XML representing the values of ifNumber, ifTableLastChange, ifStackLastChange. You can use XML to track device changes and to rediscover interfaces on a device, when needed.

Syntax

This function has the following format:

```
String storePortReconfig ( Integer ifNumber, Long ifTableLastChange,
 Long ifStackLastChange )
```

Parameters

- **ifNumber**
  The number of ports on the device.
- **ifTableLastChange**
  The date and time of the latest port table change in milliseconds, calculated from a start date and time of January 1, 1970 GMT.
- **ifStackLastChange**
  The date and time of the latest port stack change in milliseconds, calculated from a start date and time of January 1, 1970 GMT.

Return Values

Returns a string containing XML in the form that is shown in the following example.

Example

The following expression produces the following result for an ifNumber of 5, ifTableLastChange of 123456, and ifStackLastChange of 234567:

Expression:

```
storePortReconfig ( ifNumber, ifTableLastChange, ifStackLastChange )
```

Result:

```
<ReconfigData>
     <ReconfigValue name="ifNumber" value="5"/>
     <ReconfigValue name="ifTableLastChange" value="123456"/>
     <ReconfigValue name="ifStackLastChange" value="234567"/>
</ReconfigData>
```

Global Variables

Data Aggregator supports the following global variables:

- **_ rspDuration**
  A Long (Java data type) containing the duration of the current poll cycle in seconds.

NOTE
The “System Statistics” Vendor Certification contains an example of the use of _rspDuration.

- **_rspTimestamp**
  A Long (Java data type) containing the timestamp at which the current poll cycle started in milliseconds since January 1, 1970 GMT.
- **_context**
  Java class that contains the details of the polled item, such as the Device Item ID.

WARNING
_context is a reserved keyword and global variable that is intended only for system use. Do not use **_context** under any circumstance.

Vendor Certification Expression Operators

Use MVEL syntax in vendor certification expressions. You can build expressions using operators, use braces to control precedence, and terminate statements by semi-colons. The MVEL language has vendor certification utility functions and vendor certification global variables that you can also use in vendor certification expressions.

MVEL is a publicly available embeddable Expression Language for Java environments that has a syntax close to Java. MVEL supports expressions similar to Java expressions. For a detailed reference of the MVEL language, see https://en.wikibooks.org/wiki/Transwiki:MVEL_Language_Guide.

To study the use of functions, operators, and global variables, you can use the Vendor Certification tab in NetOps Portal.

The following table summarizes the available operators:

NOTE
In XML documents, use the XML Named Entities (XNE) presentation.

Operator	XML Named Entities	Description	Example
=	N/A	Assign	a = 1
==	N/A	Equals	"fred" == "fred"
!=	N/A	Not Equals	"fred" != "tom"
>	&gt;	Greater Than	1 > 0 is true
<	&lt;	Less Than	0 < 1 is true
>=	N/A	Greater Than or Equal	1 >= 0 is true
<=	N/A	Less Than or Equal	1 <= 1 is true
contains	N/A	Verify if the value on the left side contains the value on the right	"tomcat" contains "cat"
isdef	N/A	Tests whether a variable is defined	isdef a
+	N/A	Add	1 + 1
+	N/A	Concatenate	"one " + "two"
-	N/A	Minus	2 - 1
*	N/A	Multiply	2 * 2
/	N/A	Divide	4 / 2
%	N/A	Modulus	5 % 2
&&	&&	Logical AND	(x>-1) && (x<1)
||	N/A	Logical OR	(x<-1) || (x>1)

&	&amp;	AND bit operation	17 & 0xF
|	N/A	OR bit operation	4 | 1
^	N/A	Exclusive OR bit operation	5 ^ 1
!	N/A	Negate	! True
?	N/A	Ternary operator	age > 17 ? "allow" : "deny"

Self Certification XML

Vendor certifications, metric families, and components are defined in XML. To create, extend, or update certifications, update the associated XML files.

The following pages provide details about the XML attributes and structure:

Certification Schema Files and Examples

The schema files that are provided with Data Aggregator have detailed information about element types, occurrence, and allowed lengths. The files also contain annotations that provide more information, such as allowed characters and naming conventions.

Before you create custom metric family and vendor certification XML files, download and review the related schema XSD files. You need the schema to validate your XML files.

Download the schema and example XML files by entering the following URLs in your web browser Address field. *Hostname* is the Data Aggregator host, and the default *port* is 8581.

- http://*hostname*:*port*/resource/xsd/IMDBCertificationFacet.xsd
- http://*hostname*:*port*/resource/xsd/ComponentFacet.xsd
- http://*hostname*:*port*/resource/xsd/ItemSyncDefinition.xsd
- http://*hostname*:*port*/resource/xsd/SNMPCertificationFacet.xsd
- http://*hostname*:*port*/resource/xsd/CertificationFacet.xsd
- http://*hostname*:*port*/resource/xsd/webservices.xsd
- http://*hostname*:*port*/resource/xsd/basewebservices.xsd
- http://*hostname*:*port*/resource/xsd/datamodel.xsd

Example XML files are located in /opt/IMDataAggregator/examples.

Restricted XML Tags

You cannot use the following XML tags in custom and extended vendor certifications:

- AggregateToDevice
- SupportsDeviceAggregation

When you extend a vendor certification or metric family, you cannot modify the following XML tags:

- AlarmRules
- Author
- ComponentFacets
- descriptorClass
- DeviceType
- IsDynamicDiscoveryAttribute
- ItemFacets
- ItemRelationshipMappings
- Normalized
- ParentNodeList
- Protocol
- RollupExpression
- TableName
- type
- UsesDynamicIndex
- Variance
- VCSupportExpression
- WriteOnPoll

Vendor Certification XML Structure

A vendor certification uses XML to map vendor- and device-specific data to performance metrics and configuration data that are defined in a metric family. Mapping this data from various sources to the "normalized" metric family values helps Data Aggregator uniformly report on this data, regardless of the device vendor.

WARNING

When you extend a vendor certification, do not edit restricted tags or attributes. For more information, see Restricted XML Tags.

NOTE

You must list some properties in the XML in a particular order. The properties included in the XML example and listed in the following descriptions are presented in the recommended order.

Example:

This example of a custom vendor certification XML supports Frame-Relay PVC. The example custom metric family, frPVCInfo, is included in the ExpressionGroup section:

NOTE

If you view the vendor certification XML in a browser, certain tags are hidden. For this reason, copy and paste the vendor certification XML only from a REST client

```

Basic Properties

The basic properties of your custom vendor certification help to distinguish it from other custom vendor certifications you create. Also, these properties indicate from which vendor MIB you are collecting metric data.

Consider the following restrictions when you determine basic properties:

- The FacetType/name and FacetType/DisplayName properties must be unique for each vendor certification.
- The Protocol tag is either SNMP or EMS.
  - `/typecatalog/certifications/snmp` support only SNMP certifications. In this case, the only value that is supported is SNMP.
  - `/typecatalog/certifications/camm` support only CAMM certifications. In this case, the only value that is supported is EMS.
- Set the FacetType/descriptorClass property and all DataModel and FacetOf properties as shown in the example XML in the previous illustration.

The following list details basic vendor certification properties:

- **FacetType/name**
  Uniquely identifies a vendor certification.
  Recommendation: Conform to "<MibName><TableName>Mib."
  Can be updated: No
  Possible values: Alphanumeric and underscore. Dot and dash are not permitted.
  The FacetType section manifests a particular vendor certification. The same XML document can contain multiple FacetType sections when those vendor certifications expose various aspects of the vendor-specific device such as TCP and UDP statistics from a MIB-2 implementation.
  The FacetType section contains some basic properties. For example, this section contains the name of the vendor MIB, followed by one or more AttributeGroup sections. These AttributeGroup sections define which attributes this certification uses from the MIB. One or more ExpressionGroup sections map attributes from the AttributeGroup sections to the metrics specified in a metric family.

NOTE

All of the following items can be updated and support plain text.

- **FacetType/Documentation**
  Describes what is certified with the vendor certification.
  Recommendation: Include the details about the vendor, MIB name, and table name.
  Effect of updating: None

  NOTE

  This property should be listed first under the `FacetType/name` .
- **FacetType/DisplayName**
  Specifies the name of the vendor certification as it displays in NetOps Portal.
  Recommendation: Start with the vendor name and include the MIB and functionality information.
  Effect of updating: A change to the name in the Administrator user interface.
  When does the update take effect: Immediately
  Required actions for updates to take effect: Refresh the user interface.

  WARNING

  Ensure that the DisplayName property is unique to the vendor certification.
- **FacetType/MIB**
  Specifies the name of the MIB, which the DEFINITIONS clause defines in the ASN.1 file.
  Recommendation: Conform to "<MibName>”
  Effect of updating: Change to the “SNMP MIB Name” column in the Vendor Certification tab of the Administrator user interface.
  When does the update take effect: Immediately
  Required actions for updates to take effect: Refresh the user interface.
- **FacetType/Protocol**The Protocol tag is either SNMP or EMS.
  - `/typecatalog/certifications/snmp` support only SNMP certifications. In this case, the only value that is supported is SNMP.
  - `/typecatalog/certifications/camm` support only CAMM certifications. In this case, the only value that is supported is EMS.

AttributeGroup

The following example illustrates the AttributeGroup section of your custom vendor certification. This section identifies the attributes (variable OIDs) of a particular table in the vendor MIB that are used to map raw device data. This data is mapped to the performance metrics and the configuration data that is defined in a metric family.

You set the AttributeGroup/list and AttributeGroup/external properties to true, as shown in the example XML in the previous illustration. These properties specify that each attribute represents a list of values that is obtained from an external source (a MIB table). The following information summarizes the XML elements to customize.

NOTE

All of the following items can be updated and support plain text. The update does not affect performance.

- **AttributeGroup/name**
  Specifies the attribute group name.
  Recommendation: Conform to "<FacetType/name>Group."
- **Documentation**
  (Optional) Specifies the description for the attribute group.

NOTE

This property should be listed first under the `AttributeGroup/name` .

- **UseIndex**
  Specifies the name of the attribute to be used as the index for this attribute group for joining multiple MIB tables.

  NOTE

  When using MultiMIB Table Support, the AttributeGroup order must match the IndexTagList order.

  Recommendation: Set to the value of the AttributeGroup/name property.

  NOTE

  In the attributes list, the attributes used for calculating indexes and names should be listed first.

General Attributes

The general attributes for all vendor certifications are as follows:

NOTE

Unless specified otherwise, the update takes effect immediately and no actions are required to trigger the update. All entries in this list can be updated.

- **Attribute/name**
  Specifies the attribute name.
  Recommendation: Set to the MIB variable name, which the OBJECT-TYPE clause defines in the ASN.1 file.
  Possible values: Alphanumeric and underscore. Dot and dash are not permitted.
  Effect of updating: Update any expressions that reference this attribute.
- **Attribute/type**
  Specifies the data type of the attribute.
  Recommendation: Use the attribute type that best matches the variable type that the SYNTAX clause defines in the ASN.1 file.
  Possible values: Boolean, Int, Long, Double, BigInteger, String, DateTime, IPAddress, MACaddress, IPSubnet, OctetString, ObjectID
  Effect of updating: Polled SNMP data is converted to this type.
  When does the update take effect: Next poll
- **Documentation**
  (Optional) Specifies the description for the attribute, which documents the semantics (such as the unit) of the MIB variable.
  Recommendation: Use the descriptions that are taken from the MIB ASN.1 file.
  Possible values: Plain text
  Effect of updating: None

  NOTE

  This property should be listed first under the `Attribute/name` and `Attribute/type` .
- **IsKey**
  (Optional) Uses a flag to indicate whether the MIB variable is key for determining support for a table. When multiple fields are specified as keys, all of the fields are considered together as a compound key.

  NOTE

  You cannot use `IsKey` and `VCSupportExpression` in the same vendor certification. Vendor certifications that contain both `IsKey` and `VCSupportExpression` do not discover anything.

  Default: false

Recommendation: Set to true if it is a key MIB object for component discovery. If the contents of the MIB attributes are necessary to determine support, use `VCSupportExpression` instead.
Possible values: true, false
Effect of updating: Components could change to a new vendor certification.
When does the update take effect: After component rediscovery.
Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

- **IsIndex**
  (Optional) Uses a flag to indicate whether this variable is an index to the MIB table.
  Default: false
  Recommendation: Set to true for an index attribute.
  Possible values: true, false
  Effect of updating: Component indexing could change.
  When does the update take effect: After component rediscovery.
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **NeedsDelta**
  (Optional) Uses a flag to indicate whether to delta (that is, store the difference between current and last poll for Counters) the MIB variable.
  Default: false
  Recommendation: Set to true if the variable is defined as a Counter, Counter32, Counter64, or TimeTicks quantity in the MIB.
  Possible values: true, false
  Effect of updating: The polled data changes.
  When does the update take effect: Next poll

  NOTE

  This attribute can only be used during polling. This attribute cannot be used during the discovery phases. For example, this attribute cannot be used as part of the Name or Description.
- **Source**
  Specifies the ObjectID of the attribute.
  Recommendation: Set to the fully qualified MIB variable OID that the OBJECT-TYPE defines.
  Possible values: Dot-separated numbers (for example, 1.3.6.1.4.1…)
  Effect of updating: Data is polled from the specified OID.
  When does the update take effect: Next poll

  NOTE

  By default, the `Source` attribute specifies an OID to poll from the device. This default behavior is defined with `src='polled'`. You can set `src='mvel'` to process an MVEL expression using any polled attribute instead of an OID. For example, you could use the `src='mvel'` parameter to combine two 32-bit OIDs into a single 64-bit counter. You could also use the `src='mvel'` parameter to poll a counter that is not stored as a numeric type.

Example: The following example uses the `src='mvel'` parameter to combine two 32-bit OIDs into a single 64-bit counter:

```
<Attribute name="memberbitsout" type="Long">
     <NeedsDelta>true</NeedsDelta>
     <Source src='mvel'>snmpCounter64(memberbitsoutHi32,memberbitsoutLo32)</Source>
</Attribute>
```

NOTE

The `src='mvel'` parameter can only be used during polling. This parameter cannot be used during the discovery phases. For example, this parameter cannot be used as part of the Name or Description.

- **Version**
  Specifies the version of the vendor certification. Update this attribute when you update the certification. You cannot decrease the Version value.
  Possible values: Floating point or decimal number Example: 1.0 or 1.01
- **Author**
  Specifies the creator of the vendor certification.
  Default: "Custom"
  Possible values: Any alphanumeric string.
  Effect of updating: The author attribute is updated.
- **UsesDynamicIndex**(Optional) Enables dynamic ObjectID values for IPSLA polling.
  Default: False
  Possible values: true, false
- **IsDynamicDiscoveryAttribute**(Optional) Specifies whether the attribute should be used to discover the dynamic index.

  WARNING

  If this is not specified, the Data Collector chooses the first dynamic OID it encounters in the attribute group. The device might not support the OID that the Data Collector chooses, which can result in poll failure.

The list of attributes specifies the set of data that a metric family collects when supported by this vendor certification. Typically, this data falls into two categories:

- Configuration data of the device component (such as name or indexes) that is collected only at discovery time.
- Performance data that is collected every poll cycle.

Configuration Data Attributes

An attribute with the name INDEX and type ObjectID is mapped to the Indexes attribute of the target metric family. You can set the value for the Source tag to any variable OID. However, you typically use one of the variables that are listed in the INDEX clause of the table. For example, consider ifIndex in the interfaces table of MIB-2. This variable serves as the index for the other variables in the same MIB table. In addition, the IsIndex tag (and typically also the IsKey tag) for this attribute is set to true.

In this example, attributes such as ifDesc or ifType provide more configuration information about an interface. Therefore, these attributes are useful for the Names and Description attributes of the target metric family.

Performance Data Attributes

These attributes provide the raw data for performance metrics in the target metric family. Consider the following points:

- You can directly map one of these attributes to a metric family performance metric, or
- You can use the attribute in an expression with other attributes to compute a value for the metric.

IndexTagList

To poll attributes from multiple MIB tables, we need an attribute group per MIB table containing these attributes. The index tag list provides a mechanism to relate two attribute groups (or MIB tables) with different indexes. The groups are related such that one item (row) of one table is linked to a corresponding row in a second table.

NOTE

For these items, the following criteria apply to all:

    - All entries in this list can be updated.
    - The update changes indexing.
    - The update takes effect after component rediscovery
    - For the updates to take effect, update the metric family or change the vendor certification priority.

- **PrimaryTag**
  References the primary Attribute group (that is, the group that defines an index attribute with the ObjectID type). The value of this element must equal the 'UseIndex' tag of the attribute group for the primary group.
  Possible values: The ‘UseIndex’ tag of the attribute group corresponding to the primary attribute group.
- **IndexTag**
  Defines how to relate rows of the primary group (or MIB table) to rows in the secondary group. This element relates the rows by specifying attributes of both groups that must match.
- **IndexTag/Name**
  References the secondary group (or MIB table). The value of this element must equal the 'UseIndex' tag of the secondary attribute group that you are trying to relate with the primary one.
  Possible values: The ‘UseIndex’ tag of the secondary attribute group.
- **IndexTag/PrimaryKeyExpression**
  Specifies an MVEL expression containing attributes of the primary attribute group or an attribute group corresponding to any of the previously defined IndexTag. The calculated value is matched up with the 'ThisTagKeyExpression'. If there is a match, the rows of both attribute groups (or MIB tables) are linked. Then, these attributes can be used together in an 'Expression' backing a destAttr (or Metric).
  Possible values: A valid MVEL expression
- **IndexTag/ThisTagKeyExpression**
  Specifies an MVEL expression containing attributes of the secondary attribute group. The calculated value is matched up with the 'PrimaryKeyExpression'. If there is a match, the rows of both groups (or MIB tables) are linked. Then, these attributes can be used together in an 'Expression' backing a destAttr (or Metric).
  Possible values: A valid MVEL expression

ExpressionGroup

The ExpressionGroup maps attributes as follows:

- From the AttributeGroup (that defines how to get a metric from an SNMP MIB)
- To the metrics specified in a metric family (that defines how an attribute is stored in the database)

    NOTE

    The `Filter, VariableGroup, VCSupportExpression, Expression` , and `SetExpression` properties must be listed in this order in the XML.

You can store a MIB value in the database as it is received from the device or after some normalization operations are performed. For example, normalization operations include dividing or multiplying with 1024 to transform to/from kilobytes.

NOTE

Unless specified otherwise, the update takes effect immediately and no actions are required to trigger the update. All entries in this list can be updated.

- **ExpressionGroup/destCert**
  Specifies the metric family that contains the destAttrs to populate.
  Possible values: Any valid metric family
  Effect of updating: Changes the permissible expression destAttr.
- **ExpressionGroup/name**
  (Optional) Specifies the expression group name.
  Possible values: Plain text

Effect of updating: None

- **ExpressionGroup/Filter**
  (Optional) Specifies which components are discovered. Using the Filter reduces the number of components that are managed.

  WARNING

  The expression group filter *does not* exclude the specified components. The filter selects the specified components and excludes components that do not match the criteria.

  Possible values: Boolean MVEL expression using available Attributes
  Effect of updating: Changes which components are discovered.
  When does the update take effect: After component rediscovery.
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **VariableGroup**
  Defines variables that are used in the ExpressionGroup.

  NOTE

  Within a VariableGroup, variables are processed in the order listed.

  Possible Values: Calculated vendor certification values.
  Effect of updating: Changes which components are discovered.
  When does the update take effect: After component rediscovery.
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

  NOTE

  The Juniper and Cisco/Standard High Speed Interface vendor certifications include the UtilizationMaxPercent variable. This variable defines the percentage at which to drop the data for the utilization metric. Dropped data preserves the integrity of rollup data for the interface and results in a gap in views and reports.
- **VCSupportExpression**
  (Optional) Extracts and calculates the MIB attribute values to determine whether the VC is supported.

  NOTE

  You cannot use `IsKey` and `VCSupportExpression` in the same vendor certification. Vendor certifications that contain both `IsKey` and `VCSupportExpression` do not discover anything.

  Possible values: Boolean MVEL expression using available Attributes
  Effect of updating: Changes which components are discovered.
  When does the update take effect: After component rediscovery.
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **Expression**
  Converts vendor certification attribute values to normalized attribute values.
  Possible values: Normalized attribute value
- **SetExpression**
  Converts normalized attribute values to vendor certification attribute values.
  Possible values: Vendor certification attribute value
  Effect of updating: Changes which components are discovered.
  When does the update take effect: After component rediscovery.
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

ExpressionGroup Filter Examples

Filters limit the device components that a vendor certification discovers and polls. Discovery occurs only if all the criteria in the filter are true. If any of the specified attributes in the filter criteria cannot be evaluated for a given component,

the component is discovered because the complete filter criteria could not be evaluated. The most common reason an attribute cannot be evaluated is that the component has no value for that attribute.

Example 1:

```
<Filter>(ifType!=24) &amp;&amp; (ifType!=1)</Filter>
```

DX NetOps Performance Management does not poll the device component if the ifType value is 1 or 24. Interfaces with no value for ifType are discovered and polled.

Example 2:

> **NOTE**
>
> You must use .toString() when comparing OctetString attributes, as OctetStrings are not Strings.

```
<Filter> hrStorageType.toString() == "1.3.6.1.2.1.25.2.1.4" &amp;&amp;
         hrStorageSize != 0
</Filter>
```

DX NetOps Performance Management discovers and polls the device component if the the StorageType is hrStorageFixedDisk (1.3.6.1.2.1.25.2.1.4) and the size is not 0. However, if a component has no value for the hrStorageSize, that component is discovered. If this behavior is not intended, extend the filter to use the **isdef** function to verify that the attribute has a valid value.

```
<Filter> hrStorageType.toString() == "1.3.6.1.2.1.25.2.1.4" &amp;&amp;
         isdef (hrStorageSize) &amp;&amp; hrStorageSize != 0
</Filter>
```

DX NetOps Performance Management discovers and polls the device component if the StorageType is hrStorageFixedDisk and the size is not 0. Only components with a specified value for hrStorageSize are discovered and polled.

Example 3:

> **NOTE**
>
> You must use .toString() when comparing OctetString attributes, as OctetStrings are not Strings.

```
<Filter> (rttMonCtrlAdminRttType==9) &amp;&amp;
         ( !(rttMonCtrlAdminOwner.toString() contains "Network Health") )
</Filter>
```

DX NetOps Performance Management discovers and polls the device component if the rttMonCtrlAdminRttType is 9 and the rttMonCtrlAdminOwner.toString does not contain Network Health.

Expression/destAttr Metrics

The following information describes the Expression/destAttr metrics. You can update all of these metrics:

> **NOTE**
>
> Unless specified otherwise, the update takes effect immediately and no actions are required to trigger the update.

- **Indexes**
  Specifies to use the vendor certification attributes of the ObjectID to define the MVEL expression to provide the value for the Indexes metric family attribute.
  Recommendation: Set to INDEX.
  Possible values: Any attribute that has <IsIndex>true</IsIndex>.

Effect of updating: Component indexing could change.
When does the update take effect: After component rediscovery
Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

- **Names**
  Specifies to use the vendor certification attributes to collect configuration data. This configuration data helps define the MVEL expression to provide the value for the Names metric family attribute.
  Recommendation: Include as much information as necessary to identify an instance uniquely.
  Possible values: String MVEL expression using available Attributes
  Effect of updating: Component name change
  When does the update take effect: After component rediscovery
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **Descriptions**
  (Optional) Specifies to use the vendor certification attributes to collect configuration data. This configuration data helps define the MVEL expression to provide the value for the Descriptions metric family. Not all metric families support a Descriptions attribute.
  Recommendation: Include as much information that is available to describe an instance.
  Possible values: String MVEL expression using available Attributes
  Effect of updating: Component description change
  When does the update take effect: Component rediscovery
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **Other Metrics**
  Specifies to use the vendor certification attributes to collect configuration or performance data. This data is used to define the MVEL expression to provide the value for the metric family attribute.
  Can be added: Yes, if the destAttr exists in the metric family.
  Possible values: MVEL expression using available Attributes, producing a value that matches the type of the destination attribute.
  Effect of updating: Polled value changes
  When does the update take effect: Next poll

The metric family exposes URIs (such as, {http://im.ca.com/normalizer}*FamilyName.AttributeName*), which are separately referred to in the ExpressionGroup. The ExpressionGroup/destCert property is set to the URI (for example, {http://im.ca.com/normalizer}*FamilyName*), and the Expression/destAttr is set to *AttributeName*.

Speed Override

Vendor certifications for interfaces include variables in the ExpressionGroup that can override the SpeedIn and SpeedOut values. The SpeedInOverride and SpeedOutOverride variables let you override the SpeedIn and SpeedOut values in the UI. The following example shows how to use the override variables:

```
<VariableGroup>
   <Variable name="SpeedInOverride" providedBy="override"/>
   <Variable name="SpeedOutOverride" providedBy="override"/>
   <Variable name="RawIfSpeed">ifSpeed</Variable>
   <Variable name="CalculatedSpeedIn">
      isdef(SpeedInOverride) ? SpeedInOverride : RawIfSpeed
   </Variable><Variable name="CalculatedSpeedOut">
      isdef(SpeedOutOverride) ?  SpeedOutOverride : RawIfSpeed
   </Variable>
   <Variable name="CalculatedIfInOctets">ifInOctets <= 786432000 ? ifInOctets : null</
Variable>
   <Variable name="CalculatedIfOutOctets">ifOutOctets <= 786432000 ? ifOutOctets :
 null</Variable>
```

```
</VariableGroup>
```

HierarchyList

The following list defines the hierarchy behavior:

> **NOTE**
>
> For these items, the following criteria apply to all:
>
> - All entries in this list can be updated.
> - The update changes the hierarchy construction.
> - The update takes effect after component rediscovery
> - For the updates to take effect, update the metric family or change the vendor certification priority.

- **Hierarchy/ParentFacet**
  Specifies the QName of the facet that is used to find the candidate parent items.
  Possible values: Any valid facet
- **Hierarchy/ParentAttribute**
  Specifies the QName of the attribute that is used to identify the specific parent item.
  Possible values: Any valid attribute QName
- **Hierarchy/ChildAttribute**
  Specifies the QName of the attribute on the child item that is used to match the ParentAttribute on the parent item.
  Possible values: Any valid attribute QName

Multi-MIB Table Support

Some situations exist where you must collect the raw data for a particular metric family from two or more MIB tables. Custom certification includes support for multiple MIB tables. The XML structure is similar to a standard vendor certification, and uses a common key (index) to join data that is collected from multiple tables.

Example:

In this example, the Frame Relay PVCs can be named using a combination of the ifName MIB object in the ifXTable and the frCircuitDlci object that provides the data link connection identifier (DLCI) for this PVC. This kind of naming convention is useful for determining which Frame Relay interface the PVC is layered onto.

To support both MIB tables, add the following information to the XML:

- Add an attribute to the existing AttributeGroup to represent the frCircuitDlci MIB object.
- The ifName MIB object comes from a MIB that is not included in your custom vendor certification. Add an AttributeGroup (in this case, ifXTable), and then add the new attribute (ifName).

```
<?xml version="1.0" encoding="UTF-8" ?>

```

AttributeGroup

Each table must go into its own AttributeGroup section. Each Attribute on that table is added as a child of that AttributeGroup.

Refer to these sections for the following information:

- The AttributeGroup information
  Details about the XML elements that are used to define primary and secondary table attributes.
- The UseIndex and IndexTagList information
  Details about the XML elements that are used to join the primary and secondary attribute groups.

In the example, the primary attribute group represents the table that you want to “extend” with more information. The secondary attribute group contains the “extension” information for the primary one.

The primary AttributeGroup contains an Attribute identifying the MIB table variable serving as the common “key” into the secondary AttributeGroup.

The secondary AttributeGroup includes the Attribute definitions for all MIB table variables carrying the “extension” information for the primary table. In addition, there is an Attribute identifying the variable matching the common “key” from the primary AttributeGroup.

UseIndex

Each AttributeGroup is given a UseIndex tag. The UseIndex tag lets you group OIDs under a common name. This common name is associated with a given variable serving as the common key (index) into the respective MIB table.

The following information summarizes the XML elements to customize:

- **AttributeGroup/UseIndex**
  Uniquely identifies the primary and secondary tag name (respectively) that is used in the IndexTagList section.
  Recommendation: Set to the value of the AttributeGroup/name property.

IndexTagList

The IndexTagList section is a mechanism to relate two attribute groups (or MIB tables) with different indexes. When the groups are related, one item has multiple index IDs from multiple tables.

The IndexTagList section contains all the join information, including an IndexTag section for every secondary attribute group.

- **IndexTagList/PrimaryTag**
  Defines the primary attribute group (or MIB table). Set to the value of the UseIndex property of the primary AttributeGroup.
- **IndexTag/Name**
  Defines the secondary attribute group. Set to the value of the UseIndex property of the secondary AttributeGroup.
- **IndexTag/PrimaryKeyExpression**
  Specifies the expression to generate the common key in the primary table. Consider using the MVEL functions to derive a common key from the designated primary table index Attribute.
- **IndexTag/ThisTagKeyExpression**
  Specifies the expression to generate the common key in the secondary table. Consider using the MVEL functions to derive a common key from the designated secondary table index Attribute.

The multitable approach supports the chaining of more than two tables. Two types of relationships exist in multiple table joins:

- **Primary - > Secondary #1, Primary - > Secondary #2**
  Ordering of the secondary tables does not matter in an index tag list.
- **Primary - > Secondary #1 - > Secondary #2**
  List secondary table #1 before secondary table #2 because of the way tables are merged.

One or more rows in the primary table can legally map to the same row in the secondary table. Keys on the secondary table are searched in order, and the first match wins.

Metric Family XML Structure

A metric family uses XML to define the set of metrics to collect and report on for a given technology. These metrics are normalized so that reporting is uniform regardless of the vendor (data source). Metrics are "null" when the vendor does not provide a value. Any report views based on the null metrics are empty.

A metric family also defines attributes that are captured during discovery, like the item name and index. There can also be discovery rules defined that reconcile component matching. You include a metric family in a monitoring profile. The set of metric families in a monitoring profile determines which metrics to collect for the devices in each device collection that is associated with the profile.

WARNING

When you extend a metric family, do not edit restricted tabs or attributes. For more information, see Restricted XML Tags.

NOTE

You must list some properties in the XML in a particular order. The properties included in the XML example and listed in the following descriptions are presented in the recommended order.

Example:

This example metric family supports the vendor certification for Frame-Relay PVC:

> **NOTE**
>
> If you view the metric family XML in a browser, certain tags are hidden. For this reason, copy and paste the metric family XML only from a REST client

```

Basic Properties

The basic properties of your custom metric family help to distinguish it from other custom metric families you create.

Consider the following restrictions when you determine basic properties:

- The FacetType/name, DisplayName, and TableName properties must be unique for each metric family.
- The Protocol tag is always IMDB.
- The Normalized tag is always true.
- Set the FacetType/descriptorClass property and all DataModel and FacetOf properties.

The following list details basic metric properties:

NOTE

: Unless stated otherwise, all entries in this list can be updated.

- **FacetType/name**
  Specifies the metric family name. For each metric family, the name must be a unique name that identifies it internally within the system. Carefully select a name with a minimal possibility of naming conflicts with future similar metric families. For example, define a naming scheme that ensures that these metric family names are unique.

  NOTE
  This name is never exposed externally. To display a metric family name in the user interface, use the DisplayName element.

  Can be updated: No
  Possible values: Alphanumeric and underscore. Dot and dash are not permitted. The value must be unique across all metric families.
- **Documentation**
  Specifies the external description for the metric family. To make these comments useful, describe why and when you added or changed the metric family.
  Possible values: Plain text
  Effect of updating: None

  NOTE

  This property should be listed first under the `FacetType/name` .
- **FacetOf** Asserts that this metric family is an item.
  Possible values: namespace="http://im.ca.com/core" name="Item"
- **DisplayName**
  Specifies the metric family name that displays in the user interface.
  Possible values: Plain text

  WARNING

  Ensure that the DisplayName property is unique to the metric family.

  Effect of updating: Change to the name in the administrator user interface.
  When does the update take effect: Immediately
  Required actions for updates to take effect: Refresh the user interface.

  NOTE

  This property should be listed before the `AttributeGroup` property.
- **TableName**
  Specifies the database table name that is used to store the metrics that the metric family collects.
  Possible values: Uppercase alphanumeric and underscore. The value must begin with a letter. The value must be unique across all metric families.
  Example: PROCESS_STATS
  Effect of updating: Poll data is stored in a new set of database tables.

  WARNING
  When you update the TableName, the old poll data is lost. Old report views are broken.

  When does the update take effect: Immediately. Before new views can be created, there is a delay of up to 5 minutes while DX NetOps Performance Management loads the new MIB files.
  Required actions for updates to take effect: Views must be recreated.
- **Protocol**
  The Protocol tag is always IMDB.
- **Normalized**
  The Normalized tag is always true.
- **SupportsDeviceAggregation**
  Supports thresholding at the device level for some metrics.

WARNING

This attribute is not supported for custom or extended certification.

ComponentFacets

The ComponentsFacets section lists the facets that are created during discovery. Discovery identifies items as device components or creates a hierarchy relationship between items.

- **Facet**
  Specifies a facet that is attached to the component item during component discovery.
  Can be updated: Yes
  Possible values: QName of the facet
  Effect of updating: If the component facet is synchronized to CA NetOps Portal, the component is visible in CA NetOps Portal.
  When does the update take effect: Rediscover
  Required actions for updates to take effect: Delete the device and rediscover.

ItemFacets

WARNING
ItemFacets is a new section that will likely change to support future, complex metric family structures. Its use is discouraged.

ItemFacets lists the facets that are created during discovery that identify items as devices.

- **Facet**
  Specifies a facet that is attached to the item during discovery.
  Can be updated: Yes
  Possible values: QName of the facet
  Effect of updating: Component is visible on the REST service for the specified facet. If the component facet is synchronized to CA NetOps Portal, the component is visible in CA NetOps Portal.
  When does the update take effect: Rediscover
  Required actions for updates to take effect: Delete the device and rediscover.

Example:

```
<ItemFacets>
   <Facet>{http://im.ca.com/inventory}Host</Facet>
   <Facet>{http://im.ca.com/inventory}Device</Facet>
   <Facet>{http://im.ca.com/inventory}ConsolidatedAndDiscoveredMetricFamilyHistory</
Facet>
   <Facet>{http://im.ca.com/core}Syncable</Facet>
   <!-- The IPDomainID attribute will be filled in by discovery  -->
   <Facet>{http://im.ca.com/core}IPDomainMember</Facet>
</ItemFacets>
```

AttributeGroup (Metric Family)

An AttributeGroup is a collection of item discovery attributes and metric attributes. The item discovery attributes are set during discovery, like item descriptions. The metric attributes are collected during polling. The following information describes the elements that you use in the AttributeGroup section.

Set the AttributeGroup/list and AttributeGroup/external properties to true. These properties specify that each attribute represents a list of values that is obtained from an external source. Customize the following XML elements:

NOTE

All entries in this list can be updated using plain text. The update has no behaviorial impact.

- **AttributeGroup/name**
  Specifies the attribute group name. Conform to the "<FacetType/name>Group" naming scheme.
- **Documentation**
  (Optional) Specifies the description for the attribute group.

General Attributes (Metric Family)

The general attributes for all metric families are as follows:

NOTE

All entries in this list can be updated. Unless specified otherwise, the update takes effect immediately and no actions are required to trigger the update.

- **Attribute/name**
  Specifies the unique, internal name. For metrics, this name is also used for naming the database column.

  NOTE
  This name is never exposed externally. To display an attribute name in the user interface, use the AttributeDisplayName element. To change the AttributeDisplayName, see Create or Extend Metric Families and update the metric family properties.

  Possible values: Alphanumeric and underscore.
  Effect of updating: For metrics, the values for this attribute are stored in a new database column corresponding to the updated name. The user loses the historical data that is collected for this metric (with the older name). The custom reports reporting on this metric fails.
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **Attribute/type**
  Indicates the data type of this attribute. The most frequently used data types are Int, Long, Double, String, or ObjectID. The database stores metric attributes as a float. Therefore, these attributes must use a numeric type (we recommend a Double). Other types are used for item attributes.
  Possible values: Boolean, Int, Long, Double (floating-point), BigInteger, String, DateTime, IPAddress, MACaddress, IPSubnet, OctetString (hex representation), ObjectID, ItemID, QName (Qualified Name)

  NOTE
  The type names are case insensitive, for example, "boolean" is the same as Boolean.

  Effect of updating: For metrics, none. All metrics are stored in the database as a float. For item attributes, the device must be deleted and rediscovered.
  When does the update take effect: For metrics, next poll. For item attributes, on rediscover.
  Required actions for updates to take effect: For metrics, none. For item attributes, delete the device and rediscover.
- **Documentation**
  Displays the attribute description in the user interface. The documentation is also displayed in tool tips when you hover the cursor over the attribute name.
  Possible values: Plain text
  Effect of updating: Hovering the cursor over the attribute name shows the updated documentation.

  NOTE

  This property should be listed first under the `Attribute/name` and `Attribute/type`. This property and the `AttributeDisplayName` property must be listed before the other attribute properties in the XML.
- **AttributeDisplayName**

Specifies the name of the attribute in the UI. To change the AttributeDisplayName, see Create or Extend Metric Families and update the metric family properties.
Possible values: Alphanumeric, space, and underscore.
Effect of updating: The metric reflects the updated AttributeDisplayName in the Metric Families UI and custom reports.

NOTE

This property and the `Documentation` property must be listed before the other attribute properties in the XML.

- **AttributeAbbreviation**This parameter is not supported.
- **Polled**
  Indicates whether the attribute is polled. If it is set to false, it is only accessed during discovery.
  Possible values: true, false
  Effect of updating: If set to false, the OIDs corresponding to this attribute/metric are not polled when no other polled attribute/metric is using that OID in its expression. If set to true, the OIDs corresponding to this attribute/metric are polled.
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **IsDbColumn**
  Stores its value in the database table. IsDbColumn is used for metric attributes. Set the IsDbColumn value to true when Polled is set to true.
  Possible values: true, false
  Effect of updating: If set to false, the data for this attribute/metric is not stored in the database. If set to true, the data for this attribute/metric is stored in the database.

Discovery Attributes

For many attributes only the value that is retrieved during discovery is stored in the database. No further polling or processing, such as an evaluation of a baseline, is performed.

The Indexes and Names attributes must exist for all metric families. The Descriptions attribute is optional.

```
<Attribute name="Indexes" type="ObjectID[]"  />
<Attribute name="Names" type="String"  />
<Attribute name="Descriptions" type="String"  />
```

The metric families supporting Hierarchy must include these attributes:

```
<Attribute name="ItemUniqueIDs" type="String" />
<Attribute name="ParentUniqueIDs" type="String" />
```

Polled and Baseline Attributes

The following information describes the polled and baseline attribute elements:

NOTE

All entries in this list can be updated.

- **Baseline**
  Indicates whether to calculate a mean value for this attribute. If it is set to true, a corresponding BaselineList definition must be defined.

  NOTE
  The Baseline attribute requires that the StandardDeviation attribute is set to true.

Possible values: true, false
Effect of updating: Baseline values are calculated when true.
When does the update take effect: Next poll
Required actions for updates to take effect: None

- **Maximum**
  Indicates whether to calculate the maximum of this attribute during the rollup. Creates a 'max_' column in the database table. If RollupStrategy is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Maximum.”
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **Minimum**
  Indicates whether to calculate the minimum of this attribute during the rollup. Creates a 'min_' column in the database table. If RollupStrategy is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Minimum.”
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **StandardDeviation**
  Indicates whether to calculate the standard deviation of this attribute during the rollup. Creates a 'std_' column in the database table. If RollupStrategy is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Standard Deviation.”
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **DeviationFromBaseline**
  Requires that the Baseline attribute is set to true. Provides two extra reporting fields, “Average Baseline” and “Percent Deviation,” calculated using baseline data. These fields are not available for building custom views. No changes are made to the database table.
  Possible values: true, false
  Effect of updating: True provides the “Average Baseline” and “Percent Deviation” fields for the internal report development.
  When does the update take effect: Immediately
  Required actions for updates to take effect: None
- **Percentile**
  Indicates whether to calculate the 95th percentile of this attribute during the rollup. Creates a 'pct_' column in the database table. If RollupStrategy is defined, this attribute must also be defined.
  Possible values: 0, 95
  Effect of updating: A value of 95 provides a calculation of, and a reporting field for, “95th Percentile.” Zero specifies that no calculation is performed, and the reporting field is not available.
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **Percentile2**(Optional) Specifies the value of a user-configurable percentile.
  Possible values: 0-99
  Effect of updating: A non-zero value specifies the percentile to calculate. Zero specifies that no calculation is performed, and the reporting field is not available.
  When does the update take effect: Next poll
  Required actions for updates to take effect: None
- **Percentile3**(Optional) Specifies the value of a user-configurable percentile.
  Possible values: 0-99

Effect of updating: A non-zero value specifies the percentile to calculate. Zero specifies that no calculation is performed, and the reporting field is not available.
When does the update take effect: Next poll
Required actions for updates to take effect: None

NOTE

You cannot set two percentiles to the same non-zero value. You cannot set Percentile2 or Percentile3 to 95.

WARNING

Changes to **Percentile2** and **Percentile3** may cause discontinuity in the trend view depending on the time range.

- **ProjectionPercentile**
(Optional) Specifies the percentile to calculate for metric projection.
Possible values: 0-99
Effect of updating: Changes the percentile to use to calculate projections. Zero specifies that no calculation is performed.

WARNING

Changes to **ProjectionPercentile** cause inaccurate projections for up to 90 days. When you change the value of **ProjectionPercentile**, the percentile values for days before the change are not recalculated.

When does the update take effect: Next poll
Required actions for updates to take effect: None

- **AggregateToDevice**Supports thresholding at the device level for some metrics.

WARNING

This attribute is not supported for custom or extended certification.

- **RollupStrategy**
Specifies the operation that is performed every cycle during the rollup of the individually polled values. When Polled and IsDbColumn are set to true, this element is required.
Possible values: Sum (a summation for counters), Avg (an average for gauges)
Effect of updating: The specified strategy is used to perform rollup calculations.
When does the update take effect: Next poll
Required actions for updates to take effect: None

- **Rate**
Provides an extra reporting field, “Average Rate,” calculated as AVG (metric value / time). No changes are made to the database table.

NOTE
The Rate is available for reporting but not for use when monitoring the profile event rules.

Possible values: true, false
Effect of updating: Provides the “Average Rate” field for reporting.
When does the update take effect: Immediately
Required actions for updates to take effect: None

- **Units**
Specifies the name of the units label used in reports. The actual label that is displayed is translated according to the language setting of the report.

WARNING

If this attribute is not defined, the units labels on reports is 'Units'.

Possible values: Percent, Packets, PacketsPerSecond, DiscardedPackets, ErroredPackets, Bits, BitsPerSecond, Bytes, BytesPerSecond, Seconds, Microseconds, Milliseconds, UnixTime, Observations, FramesPerSecond, Frames, RequestsPerSecond, Requests
Effect of updating: The specified units label is displayed in reports. **When does the update take effect:** Immediately **Required actions for updates to take effect:** None

Example: Using polled and baseline attribute elements

```
<Attribute name="Utilization" type="double">
   <AttributeDisplayName>Utilization</AttributeDisplayName>
   <IsDbColumn>true</IsDbColumn>
   <Baseline>true</Baseline>
   <Minimum>true</Minimum>
   <Maximum>true</Maximum>
   <RollupStrategy>Avg</RollupStrategy>
   <StandardDeviation>true</StandardDeviation>
   <DeviationFromBaseline>true</DeviationFromBaseline>
   <Percentile>95</Percentile>
   <Polled>true</Polled>
   <Units>Percent</Units>
</Attribute>
```

SourceFacetTypes Attribute

A **SourceFacetTypes** attribute is required for discovery and must be defined.

Use these required values:

- Name: SourceFacetTypes
- Type: QName
- Cached: true
- Persistent: true
- List: true

Example: <Attribute name="SourceFacetTypes" type="QName" cached="true" persistent="true" list="true" />

Can be updated: No

Expressions

The Expressions section is composed of ExpressionGroup tags that are used for component discovery. During the component discovery, the values for the component item properties (such as the IndexList, Name, and Description) are calculated. The vendor certification expressions supporting the metric family expressions are used for this calculation.

NOTE
Do not confuse the metric family and vendor certification ExpressionGroup tags.

The ExpressionGroup tags for the following DestCert URIs must exist:

DestCert	DestAttr
{http://im.ca.com/core}Item	Name
{http://im.ca.com/core}Item	Description
{http://im.ca.com/inventory} DeviceComponent	IndexList

NOTE

All entries in this list can be updated.

- **ExpressionGroup/name**
  (Optional) Specifies the expression group name.
  Possible values: Plain text
  Effect of updating: None
- **ExpressionGroup/destCert**
  Specifies the component facet that contains the destAttrs to populate. The facet name typically comes from the ComponentFacets section, except the Item and DeviceComponent facets.
  Possible values: Facets that are defined in ComponentFacets, or the Item, DeviceComponent facet.
  Effect of updating: Changes permissible expression destAttr
  When does the update take effect: Component Rediscovery
  Required actions for updates to take effect: None
- **ExpressionGroup/Expression**
  Specifies the expression for the component facet attribute.
  Possible values: Any valid metric
  Effect of updating: Changes permissible expression destAttr
  When does the update take effect: Component Rediscovery
  Required actions for updates to take effect: None
- **ExpressionGroup/Expression/destAttr**
  Specifies the component facet attribute name.
  Possible values: Any valid attribute from that component facet.
  Effect of updating: Changes the attribute name
  When does the update take effect: Component Rediscovery
  Required actions for updates to take effect: None

Hierarchy

A hierarchy, or parent-child relationship, can be defined between items of different metric families, for example, Interface and CBQoS Classmap. In the metric family definitions, the Hierarchy must be specified in the child metric family with:

- The Hierarchy QName in the ComponentFacets
- The ItemUniqueID and ParentUniqueID destAttr values in the Hierarchy ExpressionGroup
- The ItemUniqueIDs and ParentUniqueIDs attributes in the AttributeGroup

The supporting expressions are defined in the vendor certifications.

The Hierarchy ExpressionGroup tags for the following DestCert URIs must exist:

DestCert	DestAttr
{http://im.ca.com/inventory}Hierarchy	ItemUniqueID
{http://im.ca.com/inventory}Hierarchy	ParentUniqueID

Example:

```
<ComponentFacets>
   <Facet>{http://im.ca.com/inventory}QoSClassMap</Facet>
   <Facet>{http://im.ca.com/inventory}Hierarchy</Facet>
</ComponentFacets>
<ExpressionGroup name="Hierarchy" destCert="{http://im.ca.com/inventory}Hierarchy">
   <Expression destAttr="ItemUniqueID">ItemUniqueIDs</Expression>
```

```
    <Expression destAttr="ParentUniqueID">ParentUniqueIDs</Expression>
 </ExpressionGroup>
 <AttributeGroup name="QosCosGroup" list="true" external="true">
      <Attribute name="ItemUniqueIDs" type="String" />
      <Attribute name="ParentUniqueIDs" type="String" />
      ...
 </AttributeGroup>
```

BaselineDefinitions

The BaselineDefinitions section contains the baseline definitions to calculate for this metric family. A baseline definition must be specified for each metric in the AttributeGroup section whose Baseline property is set to true.

You can define two types of baselines: Hourly (required) and Daily (optional). Hourly baselines are used both for event processing and for displaying baselines in reports. Daily baselines are used for displaying baselines in reports with a time frame of one month or greater.

The following information describes the baseline elements used:

- **Name**
  Specifies the type of baseline definition for a metric. The type is either hourly or daily.
  Can be updated: No
  Possible values: HourlyBaseline, DailyBaseline
- **ID**
  Specifies a value that is no longer used. However, the field must be specified as a positive integer and must be unique across all hourly and daily baseline definitions within this metric family.
  Can be updated: Yes
  Possible values: Any unique and positive integer.
  Effect of updating: None
- **PerformanceMetric**
  Specifies the name (case sensitive) of the metric for which the baseline is calculated. Set the Polled and Baseline properties for the metric attribute to true.
  Can be updated: Yes
  Possible values: A valid metric name (case sensitive).
  Effect of updating: Baseline calculations are performed for the metric.
  When does the update take effect: Next baseline calculation, either hourly or daily.
  Required actions for updates to take effect: None
- **Period**
  Specifies the type of baseline calculation, hourly or daily. Specify the value "1 Hour" for an HourlyBaseline Name or "1 Day” for a DailyBaseline Name.
  Can be updated: Yes
  Possible values: 1 Hour, 1 Day
  Effect of updating: Baseline calculations are performed either hourly or daily.
  When does the update take effect: Next baseline calculation, either hourly or daily
  Required actions for updates to take effect: None
- **ProjectionInterval**
  (Optional) Specifies the projection period in days for metric projection. Specify this expression in DailyBaseline.
  Can be updated: Yes
  Possible values: 0 or any positive integer
  Effect of updating: Changes the period that the system calculates projection values for. Zero specifies that no calculation is performed.
  When does the update take effect: Next baseline calculation.

Required actions for updates to take effect: PredicitionInterval requires that ProjectionPercentile is set to a non-zero value.

- **ProjectionInterval2**
  (Optional) Defines a second projection interval. For details, see ProjectionInterval.
- **ProjectionInterval3**(Optional) Defines a third projection interval. For details, see ProjectionInterval.
- **Window**
  Specifies a value that is no longer used. However, the field must be specified as “30 Days” for hourly baselines and “90 Days” for daily baselines.
  Can be updated: No
  Possible values: 30 Days, 90 Days
- **StartDate, EndDate, DaysOfWeek**
  Specifies more values that are not used, but they must be specified as 0 (zero).
  Can be updated: No
  Possible values: 0

ComponentReconciliation

The following information defines the component reconciliation logic that is used in component discovery. First, this information determines whether the system has already discovered this component or not. Then, the reconciliation logic determines whether to update an existing component or create a new one.

There can be multiple ordered algorithms per metric family. If a metric family does not define a reconciliation algorithm, a default one with match attribute Item.Name is applied.

ItemReconciliation

> **WARNING**
> ItemReconciliation is a new section that will likely change to support future, complex metric family structures. Its use is discouraged.

The following information defines the item reconciliation logic that is used in item discovery. The logic determines whether the system has already discovered an item or not. Based on this determination, an existing item is updated or a new item is created. Item reconciliation is similar to component reconciliation. However, item reconciliation is used for items that are not components, such as virtual hosts. The ItemFacets are added to any new items or to any matching items (if the facets do not exist).

Example:

```
<ItemReconciliation>
   <SourceAgentScopedReconciliation>
    <MatchAlgorithms>
       <ExactMatch>
          <MatchAttribute name="{http://im.ca.com/
inventory}SourceAgentInfo.SourceAgentIndexes" />
       </ExactMatch>
    </MatchAlgorithms>
   </SourceAgentScopedReconciliation>
   <GlobalScopedReconciliation matchDevices="true" />
</ItemReconciliation>
```

- **SourceAgentScopedReconciliation**
  Defines the match algorithms that are used to reconcile items.
  Can be updated: Yes
  Effect of updating: Changes the item reconciliation logic.

When does the update take effect: Rediscovery
Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

- **GlobalScopedReconciliation**
  Defines the match algorithms that are used when items could not be reconciled for the source agent. The GlobalScopedReconciliation algorithms are used to locate items that have been created for other agents but match the potential new items. If the matchDevices property is set to true, the system default (built-in, not visible in XML) ComponentReconciliationInfo match algorithm is used. The match algorithm is based on the device primary IP address and host name.
  Can be updated: Yes
  Effect of updating: Changes the item reconciliation logic.
  When does the update take effect: Rediscovery
  Required actions for updates to take effect: Update the metric family or change the vendor certification priority.

MatchAlgorithms

Component reconciliation and item reconciliation use match algorithms. Two match algorithms are supported:

- **ExactMatch**All specified attributes must be matched to say the item matches with the new data.
- **BestOfMatch**
  Users must specify the least number of attributes to be matched by using the "leastMatchCount" value. Also, each attribute has a "required" key property. If the required property is set to true, that attribute must be matched to be considered a match.

The algorithm has a match precedence when multiple algorithms are provided for a metric family. The order of the algorithms determines the precedence. The algorithm at the top has the highest precedence. The bottom one has the lowest precedence.

Each algorithm must have at least one matching attribute. When data matches to multiple items with the same algorithm, the item with the most matched attributes wins. When multiple matched items have the same number of matched attributes, the winner is picked at random from these items.

Examples: How the reconciliation works

Two match algorithms are provided for a metric family: alg1 and alg2. Alg1 has higher precedence than alg2. The metric family has three existing component items: 1, 2 and 3. Rediscovering the metric family finds three entries: A, B, and C. Now, we apply the two algorithms to determine which entry is new, changed, and unchanged.

```
    Reconciliation Meta Data                    New Data          Existing Components
 <ComponentReconciliation>                         A                   1
   <MatchAlgorithms>                               B                   2
     <MatchAlgorithm1>                             C                   3
       <MatchAttribute name="attr1"/>
       <MatchAttribute name="attr2"/>
     </MatchAlgorithm1>

     <MatchAlgorithm2>
       <MatchAttribute name="attr1"/>
       <MatchAttribute name="attr3"/>
       <MatchAttribute name="attr4"/>
     </MatchAlgorithm2>

   </MatchAlgorithms>
```

```
</ComponentReconciliation>
```

<MatchAlgorithm1> and <MatchAlgorithm2> can be either <ExactMatch> or <BestOfMatch>. The order of the two match algorithms tells us that MatchAlgorithm1 has a higher precedence than MatchAlgorithm2.

- **Case 1: Unique 1-to-1 Match**
  Entry A matches to item 1, and item 1 does not have any other match.

  ```
  A -----> 1
  ```

  This example is the simplest case. This match is unique, so it does not matter if it also matches alg1 or alg2. Entry A matches item 1.
  A good match algorithm produces more unique matches.
- **Case 2: One entry has multiple matches**
  Entry A matches to item 1 by alg1 and also matches to 2 by alg2.

  ```
             ---> 1 (alg1)  (1 wins)
       /
     A                    Since alg1 has higher precedence, item 1 wins the match.
       \
             ---> 2 (alg2)
  ```
- **Case 3: Multiple entries match to the same item with different algorithms**
  Entry A matches to 1 by alg1 and entry B also matches to item 1 by alg2.

  ```
  A ------> 1 (alg1)  (A wins)
  B ------> 1 (alg2)
  ```

  Since alg1 has higher precedence, entry A wins.
- **Case 4: Multiple entries match to the same item with same algorithm but different numbers of matched attributes**
  Both A and B match to 1 by alg1.

  ```
  A ------> 1 (alg1, # of matched attrs: 2)  (A wins)
  B ------> 1 (alg1, # of matched attrs: 1)
  ```

  Because A has more matched attributes, A wins.
  If the number of match attributes is the same, the winner is randomly picked and a warning is generated.
- **Case 5: Mixed match 1**

  ```
   alg1
    A ----------------------------------> 1
      /  alg2(match attr count: 3)
    B
      \  alg2(match attr count: 2)
             --------------------------------> 2
  ```

  A matches to 1 because it matches with a higher precedence algorithm.
  B matches to 2 because 1 has matched to A.
- **Case 6: Mixed match 2**

  ```
         ---------> 3
      /  alg1
    A                ==> A wins 3 because alg1 has a higher matching precedence
      \  alg2
         ---------> 1
      /  alg2
    B                ==> B wins 2 because alg1 has a higher matching precedence
      \  alg1
  ```

```
         ---------> 2
      /  alg2
   C                    ==> C has no match because 2 is matched to B and 3 is matched
  to A
      \  alg2
         ---------> 3
```

Entry C is treated as a new component. 1 is considered as an unmatched item.
The more match case 1 (unique match), the better the match algorithm is.
Can be updated: Yes
Effect of updating: Changes the component reconciliation logic.
When does the update take effect: Rediscovery
Required actions for updates to take effect: Update metric family or change vendor certification priority.

ReconfigDetectionAttr

This element defines a metric family attribute that is used for change detection. You can enable the change detection on a monitoring profile. Data Aggregator polls that attribute only to verify whether the target device has changed, instead of doing a complete rediscovery. This feature helps performance and helps reduce the network traffic.

- **Can be updated:** Yes
- **Possible values:** The full name of the metric family attribute. The specified metric family attribute flag must have the cached, persistent, and external flags set to true.
- **Effect of updating:** Change to component reconfiguration detection.
- **When does the update take effect:** After rediscovery
- **Required actions for updates to take effect:** Update metric family or change vendor certification priority.

Tags in Custom and Extended Metric Families

The following tags have restricted use in custom and extended metric families:

- **Variance**The value of this tag must be 'false'.
- **RollupExpression**
  Remove this tag or the value must be blank.
- The Normalized tag is always true.

Component XML Structure

A device component uses XML to define a class of component items that are associated with a device. Many factory-defined components are provided, but a custom component is typically defined for a custom metric family. Components can define an optional ItemSyncDefinition, which synchronizes component items to NetOps Portal. You can then view the components in Inventory lists, groups, and context pages.

NOTE

You must list some properties in the XML in a particular order. The properties included in the XML example and listed in the following descriptions are presented in the recommended order.

Example:

This example shows a custom component named frPVC:

NOTE

If you view the component XML in a browser, certain tags are hidden. For this reason, copy and paste the component XML only from a REST client

```
<?xml version="1.0" encoding="UTF-8"?>
<!--Auto-generated by the type catalog local manager.-->
<DataModel namespace="http://im.ca.com/inventory" xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xsi:noNamespaceSchemaLocation="ComponentFacet.xsd">
  <Author>Custom</Author>
  <Version>1.0</Version>
  <FacetType name="frPVC">
    <Documentation>A Frame Relay PVC</Documentation>
    <FacetOf namespace="http://im.ca.com/core" name="Item" />
    <Component>true</Component>
    <ItemSyncDefinition itemTypeName="component" itemSubtypeName="frpvc"
 itemTypeLabel="FrameRelayPVC" itemTypeLabelPlural="FrameRelayPVCs" categorize="false"
 groupBy="false" context="true">
    </ItemSyncDefinition>
  </FacetType>
</DataModel>
```

Set the context in the ItemSyncDefinition to “true” to enable a link to a custom context page. You can navigate to this page from the frPVC device component where it appears in the Inventory, Device Components list. Setting it to “true” also enables you to select the metric family as a “context,” which makes your custom metric family available in the Dynamic Trend chart type.

Basic Properties

The basic properties of your custom component help to distinguish it from other custom components that you create.

NOTE

In the following list, only the documentation property can be updated.

- **FacetType/name**
  Specifies the component name. Each component must have a unique name that identifies it internally within the system. Carefully choose a name with a minimal possibility of naming conflicts with future similar components. For example, define a naming scheme that ensures that these component names are unique.

  NOTE

  This name is never exposed externally. To display a component name in the user interface, use the `ItemSyncDefinition` , `itemTypeLabel` , and `itemTypeLabelPlural` elements.

  Possible values: Alphanumeric and underscore. Dot and dash are not permitted.
  - **Documentation**
    Specifies internal comments for the component. To make these comments useful, describe why and when you added or changed the component.
    Possible values: Plain text
    Effect of updating: None
    When does the update take effect: Immediately
    Required Actions for updates to take effect: None

NOTE

This property should be listed first under the `FacetType/name` . This property and the `FacetOf` property must be listed before the `Component` and `ItemSyncDefinition` properties in the XML.

- **FacetOf**Asserts that this component is an item.
  Possible values: namespace="http://im.ca.com/core" name="Item"

NOTE

This property and the `Documentation` property must be listed before the `Component` and `ItemSyncDefinition` properties in the XML.

- **Component**
  Asserts that this item is a component.
  Possible values: true

ItemSyncDefinition

The ItemSyncDefinition attribute is optional. This attribute specifies how the component items are synchronized and displayed in NetOps Portal. If the component items are not specified, they do not display in the NetOps Portal Inventory lists (for example, Device Components). But, they can still be reported on in custom views.

NOTE

Unless otherwise, there are no required actions for the updates to take effect.

- **ItemSyncDefinition/itemTypeName**
  Specifies the item type. For custom components, this value must be “component.”
  Can be updated: No
  Possible values: Component
- **ItemSyncDefinition/itemSubtypeName**
  Specifies the internal name of the component in NetOps Portal. This value must be unique for all components. Use a naming convention that avoids conflicts with future factory and custom components, such as using a prefix representing your organization, 'acmeFan'.
  Can be updated: No
  Possible values: Alphanumeric, unique for all components
- **ItemSyncDefinition/itemTypeLabel**
  Specifies the user interface label that is used when displaying a single component of this type. For example, this value is used in the Inventory, Device Components UI “Type” column.
  Can be updated: Yes
  Possible values: Plain text, unique for all components
  Effect of updating: Label is displayed in NetOps Portal Inventory user interfaces.
  When does the update take effect: Allow for resync to occur and up to 15 minutes to complete updates.
- **ItemSyncDefinition/itemTypeLabelPlural**
  Specifies the user interface label that is used when displaying multiple components of this type. Used by the Inventory menu (see groupBy) and the Group name (see categorize).
  Can be updated: Yes
  Possible values: Plain text, unique for all components
  Effect of updating: Label is displayed in NetOps Portal Inventory UIs.
  When does the update take effect: Allow for resync to occur and up to 15 minutes to complete updates.
- **ItemSyncDefinition/categorize**
  Instructs NetOps Portal to create an inventory group under Inventory, All Items. This group contains all items of this component type. The group is named '*{itemTypeLabelPlural}'.*

NOTE
The inventory group that is created cannot be used for reporting dashboards. Instead, this group is for inventory purposes only. If the group is selected for reporting, then no data displays. Other, device-based inventory groups (under Inventory, All Items) can be used for reporting, such as Routers and Servers. However, component-based inventory groups cannot, such as Device Components.

Can be updated: Yes
Possible values: true, false
Effect of updating: Creates or removes an Inventory group in NetOps Portal. For NetOps Portal group administrators, on the Manage Groups page, the group is created under Inventory, All Items, *{itemTypeLabelPlural}*.
When does the update take effect: Allow for resync to occur and up to 30 minutes to complete updates.
Required actions for updates to take effect: Items typically appear in the group within 30 minutes. If they do not, manually resync the Data Aggregator datasource. Select 'Perform a Full Resynchronization' before clicking the Resync confirmation button.

- **ItemSyncDefinition/groupBy**
  Instructs NetOps Portal to create an inventory menu item (under Inventory) for viewing all items of this component item type. The menu is named "*{itemTypeLabelPlural}*." This attribute also causes the component type show up in the Context Type drop-down list when setting a view context. When false, the components are listed in the Inventory, Device Components table with the type of "*{itemTypeLabel}*." The groupBy property does not create a group (see categorize).
  Can be updated: Yes
  Possible values: true, false
  Effect of updating: The menu item is created when true, or removed when false.
  When does the update take effect: Allow for resynchronization to occur and allow up to 15 minutes to complete updates.
- **ItemSyncDefinition/context**
  Makes each component item name a context hyperlink in the Inventory component views that, when clicked, navigate to the individual component context page.
  Can be updated: Yes/No
  Possible values: Plain text
  Effect of updating: Makes each component item name a context hyperlink in the Inventory component views.
  When does the update take effect: Allow for resynchronization to occur and allow up to 15 minutes to complete updates.

Remove an ItemSyncDefinition

Completely removing an ItemSyncDefinition requires a specific procedure.

Follow these steps:

1. Remove the ItemSyncDefinition section, including the <ItemSyncDefinition> start and end tags.
2. After you apply the component change to Data Aggregator, log in to NetOps Portal as the administrator.
3. Select the DataAggregator datasource on the Data Sources page.
4. Click the Resync button.
5. Check the “Perform a Full Resynchronization” option, then click the Resync confirmation button.
   The resync process begins. Allow between 15-30 minutes for the changes to synchronize.
   When this process completes, all NetOps Portal behaviors that the ItemSyncDefinition defined for the component are removed.

Unsupported Properties for Custom Components

The following properties are *not* supported for custom components and should not be present in your XML:

- Attribute
- WebService
- ItemSyncDefinition/isDeviceComponent
- ItemSyncDefinition/mapped
- ItemSyncDefinition/ItemProperty

Self-Certification Workflows

Self-certification workflows are examples of real use cases that you may encounter. Use the following workflows as a model to help you with self-certification:

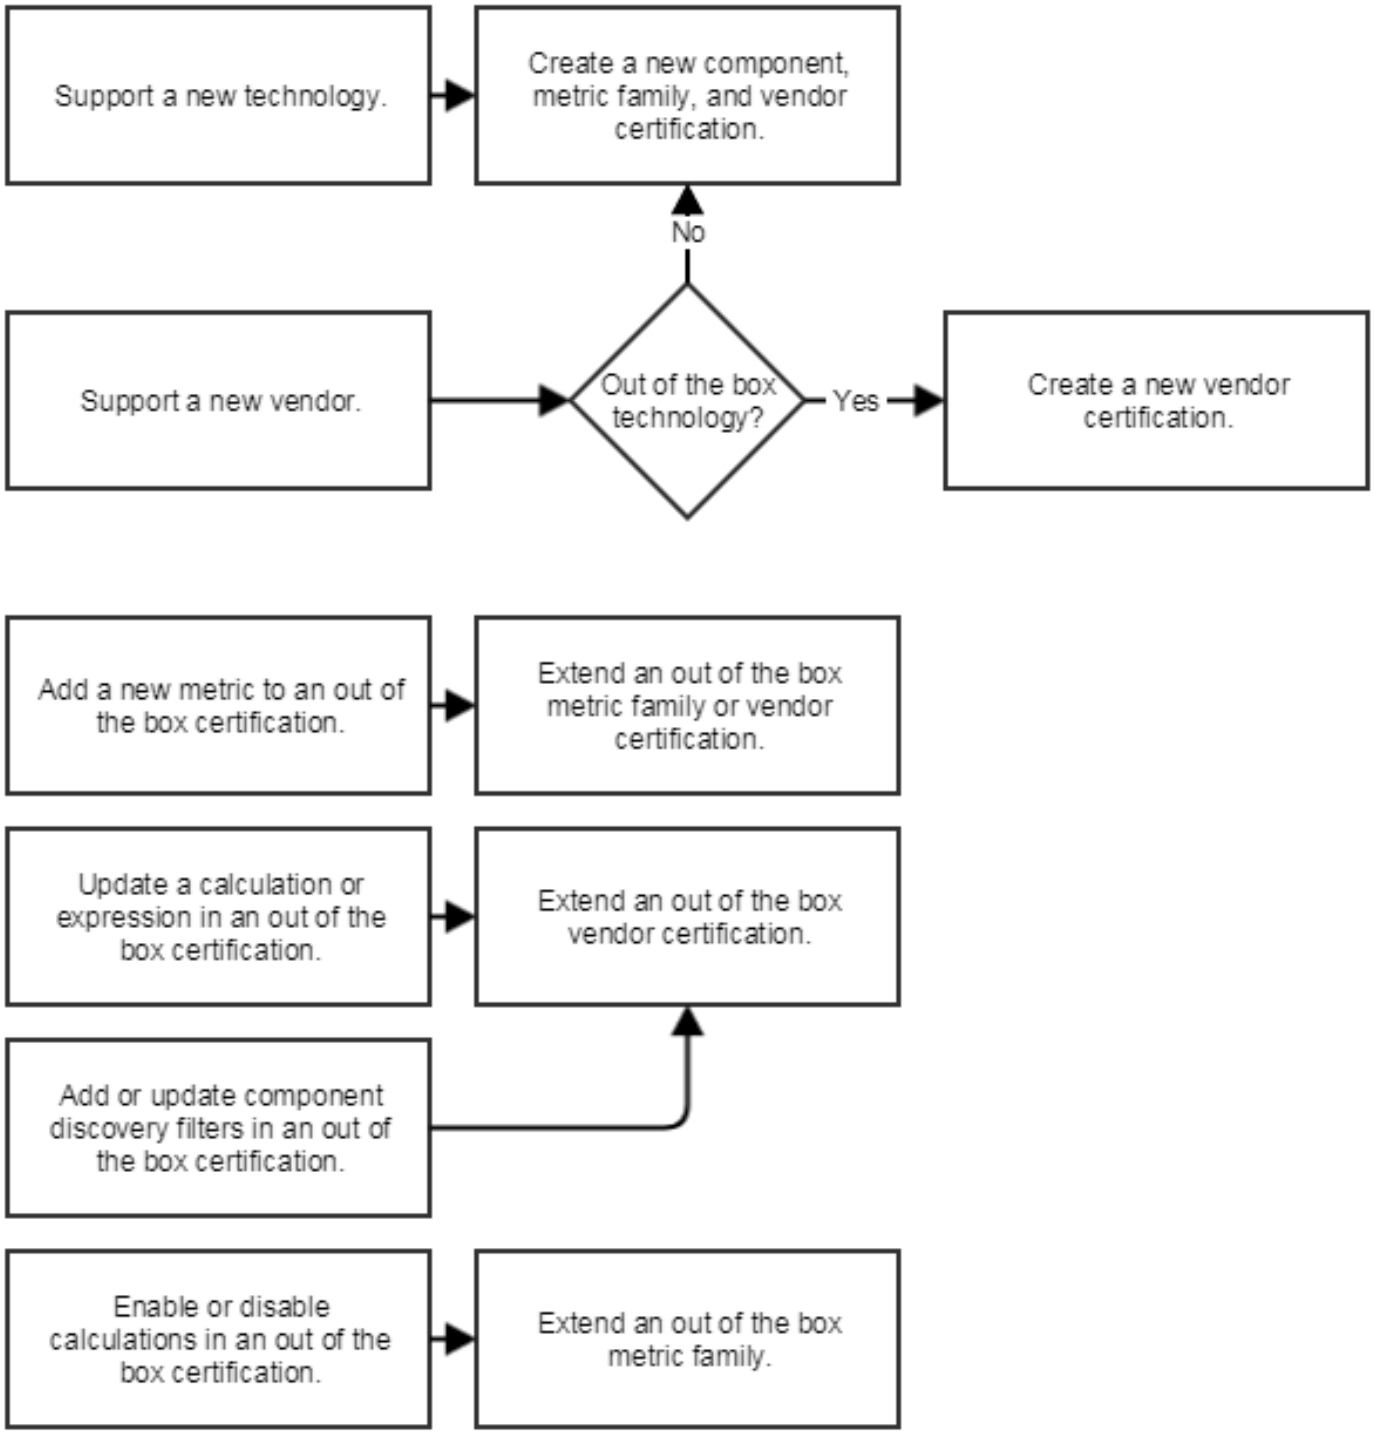
- Basic Self-Certification Workflow

Basic Self-Certification Workflow

You can create a vendor certification using the following basic self-certification workflow. This workflow covers the basic concepts and requirements to create a component, metric family, and vendor certification using the available REST services:

The following graphic provides a high-level overview of some common self-certification scenarios:

Figure 7: Self-Cert



NOTE
If you design a new vendor and technology certification containing only device-level metrics, a component definition is unnecessary (for example, see the Availability metric family).

For more information, see the following articles:

- Create Custom Components
- Create or Extend Metric Families
- Create or Extend Vendor Certifications

Create a New Component

You can introduce a new managed item type using the components XML. The components XML defines how a discovered component is synced over to NetOps Portal. The XML creates a component in your inventory and is required only when a component does not exist already.

Follow these steps:

1. Customize the following XML:

```
<?xml version="1.0" encoding="UTF-8"?>
<!--Auto-generated by the type catalog local manager.-->
<DataModel namespace="http://im.ca.com/inventory"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation="ComponentFacet.xsd">
  <Author>Custom</Author>
  <Version>Version</Version>
  <FacetType name="Name">
    <Documentation>Clear_Text_Description</Documentation>
    <FacetOf namespace="http://im.ca.com/core" name="Item" />
    <Component>true</Component>
    <ItemSyncDefinition itemTypeName="component"
itemSubtypeName="Internal_Name"
itemTypeLabel="External_Name"
itemTypeLabelPlural="External_Names_Plural"
categorize="false"
groupBy="false"
context="true">
    </ItemSyncDefinition>
  </FacetType>
</DataModel>
```

- **Version**
  Specifies the sequential number of the version definition. If you configure the version correctly, it should not change frequently.
  Example: `1.0`
- **Name** Specifies the component name. Each component must have a unique name that identifies it internally within the system. Carefully choose a name with a minimal possibility of naming conflicts with future similar components. For example, define a naming scheme that ensures that these component names are unique. This string is used in the Component Facet Definition in the Metric Family and cannot be updated.
  Possible values: Alphanumeric and underscore. Dot and dash are not permitted.

  NOTE
  This name is never exposed externally. To display a component name in the user interface, use the `ItemSyncDefinition` , `itemTypeLabel` , and `itemTypeLabelPlural` elements.
- **Clear_Text_Description**
  Specifies internal comments for the component. To make these comments useful, describe why and when you added or changed the component.
  Possible values: Plain text

Effect of updating: None
When does the update take effect: Immediately
Required Actions for updates to take effect: None

- **Internal_Name** Specifies the internal name of the component in NetOps Portal. This value must be unique for all components. Use a naming convention that avoids conflicts with future factory and custom components, such as using a prefix representing your organization, '`acmeFan` '.
  Can be updated: No
  Possible values: Alphanumeric, unique for all components
- **External_Name** Specifies the user interface label that is used when displaying a single component of this type. For example, this value is used in the Inventory, Device Components UI “Type” column.
  Can be updated: Yes
  Possible values: Plain text, unique for all components
  Effect of updating: Label is displayed in NetOps Portal Inventory user interfaces.
  When does the update take effect: Allow for resynchronization to occur and up to 15 minutes to complete updates.
- **External_Name_Plural**
  Specifies the user interface label that is used when displaying multiple components of this type. Used by the Inventory menu (see `groupBy`) and the Group name (see categorize).
  Can be updated: Yes
  Possible values: Plain text, unique for all components
  Effect of updating: Label is displayed in NetOps Portal Inventory UIs.
  When does the update take effect: Allow for resynchronization to occur and up to 15 minutes to complete updates.
- **categorize**
  Instructs NetOps Portal to create an inventory group under Inventory, All Items. This group contains all items of this component type. The group is named '*{*`itemTypeLabelPlural`*}'.*

  > **NOTE**
  > The inventory group that is created cannot be used for reporting dashboards. Instead, this group is for inventory purposes only. If the group is selected for reporting, then no data displays. Other, device-based inventory groups (under Inventory, All Items) can be used for reporting, such as Routers and Servers. However, component-based inventory groups cannot, such as Device Components.

  Can be updated: Yes
  Possible values: true, false
  Effect of updating: Creates or removes an Inventory group in NetOps Portal. For NetOps Portal group administrators, on the Manage Groups page, the group is created under Inventory, All Items, *{* `itemTypeLabelPlural}` .
  When does the update take effect: Allow for resynchronization to occur and up to 30 minutes to complete updates.
  Required Actions for updates to take effect: Items typically appear in the group within 30 minutes. If they do not, manually resync the Data Aggregator data source. Select **Perform a Full Resynchronization**, and then click **Resync confirmation**.
- **groupBy**
  Instructs NetOps Portal to create an inventory menu item (under Inventory) for viewing all items of this component item type. The menu is named "*{* `itemTypeLabelPlural` *}*." This attribute also causes the component type show up in the Context Type drop-down list when setting a view context. When false, the components are listed in the Inventory, Device Components table with the type of "*{* `itemTypeLabel` *}*." The `groupBy` property does not create a group (see categorize).
  Can be updated: Yes
  Possible values: true, false
  Effect of updating: The menu item is created when true, or removed when false.

When does the update take effect: Allow for resynchronization to occur and allow up to 15 minutes to complete updates.

- **context**
  Makes each component item name a context hyperlink in the Inventory component views that, when clicked, navigate to the individual component context page.
  Can be updated: Yes/No
  Possible values: Plain text
  Effect of updating: Makes each component item name a context hyperlink in the Inventory component views.
  When does the update take effect: Allow for resynchronization to occur and allow up to 15 minutes to complete updates.

  NOTE
  You can create a component without the `ItemSyncDefinition` tag. In this case, a component discovered in Performance Management for this managed item type is not synced over to NetOps Portal (like CPU, or memory). Although the component is not synced over, you can still report on these managed items at the device level.

2. Set up a REST client with a connection to the data aggregator server.
3. Use the following format for the URL in the REST client:
   http://DA_host:8581/typecatalog/components

   NOTE
   To update or extend a vendor component, use the following format for the URL in the REST client:

   `http://`*`DA_host`*`:8581/typecatalog/components/`*`component_name`*

   component_name Specify the name of the existing component.
4. Select `POST` for the **HTTP Method**.

   NOTE
   To update an existing component, select `PUT` .
5. Select **application/xml** as the **Body Content-type**.
6. Add the customized XML within the "Body" text section.
7. Run the method.

Create a New Metric Family

A metric family describes the metrics available for collection for a component. Different vendors can provide information for all or part of the metrics in a metric family. For each metric, a metric family defines the behavior of the system. For example, a metric family can define whether to calculate baselines, percentiles, minimum, maximum, or projections. They also define how to calculate rollups. Only some fields in the metric family XML require changes. The `Indexes` , `Names` , and `Description` attributes are required. You should add one or more metric attributes to reflect the number and type of metrics in the metric family.

Follow these steps:

1. Customize the following XML:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!-- Auto-generated by the type catalog local manager.  -->
<DataModel xmlns:xsi=http://www.w3.org/2001/XMLSchema-instance namespace="http://
im.ca.com/normalizer" xsi:noNamespaceSchemaLocation="IMDBCertificationFacet.xsd">
  <Author>Custom</Author>
  <Version>1.0</Version>
 <FacetType name="Internal_Metric_Family_Name"
descriptorClass="com.ca.im.core.datamodel.certs.NormalizedFacetDescriptorImpl">
```

```
<Documentation>Metric_Family_Description</Documentation>
    <FacetOf namespace="http://im.ca.com/core" name="Item" />
    <AttributeGroup name="AttributeGroup" external="true" list="true">
      <Documentation />
      <Attribute name="Indexes" type="ObjectID[]">
         <Documentation />
         <Polled>false</Polled>
         <Baseline>false</Baseline>
         <IsDbColumn>false</IsDbColumn>
         <Variance>false</Variance>
         <StandardDeviation>false</StandardDeviation>
         <Minimum>false</Minimum>
         <Maximum>false</Maximum>
         <WriteOnPoll>false</WriteOnPoll>
         <RollupStrategy />
         <AttributeDisplayName />
         <Percentile>0</Percentile>
       </Attribute>
       <Attribute name="Names" type="String">
 <Documentation>Element/Component_Name</Documentation>
         <Polled>false</Polled>
         <Baseline>false</Baseline>
         <IsDbColumn>false</IsDbColumn>
         <Variance>false</Variance>
         <StandardDeviation>false</StandardDeviation>
         <Minimum>false</Minimum>
         <Maximum>false</Maximum>
         <WriteOnPoll>false</WriteOnPoll>
         <RollupStrategy />
         <AttributeDisplayName />
         <Percentile>0</Percentile>

        <Normalized>true</Normalized>
       </FacetType>
     </DataModel>
```

– **Internal_Metric_Family_Name**
Specifies the metric family name. For each metric family, the name must be a unique name that identifies it internally within the system. Carefully select a name with a minimal possibility of naming conflicts with future similar metric families. For example, define a naming scheme that ensures that these metric family names are unique.

> **NOTE**
> This name is never exposed externally. To display a metric family name in the user interface, use the DisplayName element.

Can be updated: No

Possible values: Alphanumeric and underscore. Dot and dash are not permitted. The value must be unique across all metric families.

- **Metric_Family_Description** Specifies the external description for the metric family. To make these comments useful, describe why and when you added or changed the metric family.
  Possible values: Plain text
  Effect of updating: None
- **Element/Component_Name**
  The documentation is also displayed in tool tips when you hover the cursor over the attribute name.
- **Element/Component_Description** Displays the attribute description in the user interface. The documentation is also displayed in tool tips when you hover the cursor over the attribute name.
  Possible values: Plain text
  Effect of updating: Hovering the cursor over the attribute name shows the updated documentation.
- **Metric_Name**
  Specifies the unique, internal name. For metrics, this name is also used for naming the database column.

  NOTE
  This name is never exposed externally. To display an attribute name in the user interface, use the AttributeDisplayName element. To change the AttributeDisplayName, see Create or Extend Metric Families and update the metric family properties.

  Possible values: Alphanumeric and underscore.
  Effect of updating: For metrics, the values for this attribute are stored in a new database column corresponding to the updated name. The user loses the historical data that is collected for this metric (with the older name). The custom reports that report on this metric fails.
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **MIB_Metric_Type** Indicates the data type of this attribute. The most frequently used data types are `Int` , `Long` , `Double` , `String` , or `ObjectID` . The database stores metric attributes as a float. Therefore, these attributes must use a numeric type (we recommend a Double). Other types are used for item attributes.
  Possible values: `Boolean, Int, Long, Double` (floating-point), `BigInteger, String, DateTime, IPAddress, MACaddress, IPSubnet, OctetString` (hex representation), `ObjectID, ItemID, QName` (Qualified Name)

  NOTE
  The type names are case insensitive, for example, "boolean" is the same as Boolean.

  Effect of updating: For metrics, none. All metrics are stored in the database as a float. For item attributes, the device must be deleted and rediscovered.
  When does the update take effect: For metrics, next poll. For item attributes, on rediscover.
  Required Actions for updates to take effect: For metrics, none. For item attributes, delete the device and rediscover.
- **Metric_Description**
  Displays the attribute description in the user interface. The documentation is also displayed in tool tips when you hover the cursor over the attribute name.
  Possible values: Plain text
  Effect of updating: Hovering the cursor over the attribute name shows the updated documentation.
- **Baseline**
  Indicates whether to calculate a mean value for this attribute. If it is set to true, a corresponding `BaselineList` definition must be defined.

  NOTE
  The Baseline attribute requires that the StandardDeviation attribute is set to true.

  Possible values: true, false
  Effect of updating: Baseline values are calculated when true.
  When does the update take effect: Next poll

Required Actions for updates to take effect: None

- **Variance** This tag has restricted use in custom and extended metric families. The value of this tag must be 'false'.
- **Standard Deviation**
  Indicates whether to calculate the standard deviation of this attribute during the rollup. Creates a '`std` _' column in the database table. If `RollupStrategy` is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Standard Deviation.”
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **Minimum**
  Indicates whether to calculate the minimum of this attribute during the rollup. Creates a '`min` _' column in the database table. If `RollupStrategy` is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Minimum.”
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **Maximum**
  Indicates whether to calculate the maximum of this attribute during the rollup. Creates a 'max_' column in the database table. If `RollupStrategy` is defined, this attribute must also be defined.
  Possible values: true, false
  Effect of updating: True provides a calculation of, and a reporting field for, “Maximum.”
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **RollupStrategy**
  Specifies the operation that is performed every cycle during the rollup of the individually polled values. When Polled and `IsDbColumn` are set to true, this element is required.
  Possible values: Sum (a summation for counters), Avg (an average for gauges)
  Effect of updating: The specified strategy is used to perform rollup calculations.
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **Percentile**
  Indicates whether to calculate the 95th percentile of this attribute during the rollup. Creates a 'pct_' column in the database table. If `RollupStrategy` is defined, this attribute must also be defined.
  Possible values: 0, 95
  Effect of updating: A value of 95 provides a calculation of, and a reporting field for, “95th Percentile.” Zero specifies that no calculation is performed, and the reporting field is not available.
  When does the update take effect: Next poll
  Required Actions for updates to take effect: None
- **External_Metric_Family_Name** Specifies the metric family name that displays in the user interface.
  Possible values: Plain text

  > **IMPORTANT**
  > Ensure that the `DisplayName` property is unique to the metric family.

  Effect of updating: Change to the name in the administrator user interface.
  When does the update take effect: Immediately
  Required Actions for updates to take effect: Refresh the user interface.
- **DB_Table_Metric_Family_Name**
  Specifies the database table name that is used to store the metrics that the metric family collects.
  Possible values: Uppercase alphanumeric and underscore. The value must begin with a letter. The value must be unique across all metric families.
  Example: PROCESS_STATS
  Effect of updating: Poll data is stored in a new set of database tables.

WARNING
When you update the `TableName` property, the old poll data is lost. Old report views are broken.

When does the update take effect: Immediately. Before new views can be created, there is a delay of up to 5 minutes while DX NetOps Performance Management loads the new MIB files.
Required Actions for updates to take effect: Views must be recreated.

– **Component_Name**
Specifies a facet that is attached to the component item during component discovery.
Can be updated: Yes
Possible values: `QName` of the facet
Effect of updating: If the component facet is synchronized to NetOps Portal, the component is visible in NetOps Portal.
When does the update take effect: Rediscover
Required Actions for updates to take effect: Delete the device and rediscover.

2. Set up a REST client with a connection to the Data Aggregator server.
3. Use the following format for the URL in the REST client:
`http://DA_host:8581/typecatalog/metricfamilies`

NOTE
To update or extend a metric family, use the following format for the URL in the REST client:

`http://`*`DA_host`*`:8581/typecatalog/metricfamilies/`*`metric_family_name`*

metric_family_name Specify the name of the existing metric family.

4. Select `POST` as the **HTTP Method**.

NOTE
To update an existing component, select `PUT` .

5. Select **application/xml** as the **Body Content-type**.
6. Add the customized XML within the "Body" text section.
7. Run the method.

Create a New Vendor Certification

A vendor certification provides a link between the vendor MIB and the metrics in the metric family. A vendor certification specifies which MIB variables are used for the relevant metrics. A vendor certification also specifies the formulas or expressions that are used to calculate the relevant values. Some variables directly match a metric (for example, rate, errors, discards, and volume). Others variables require calculations (for example, utilization or free disk space).

NOTE
If scalar OIDs need to be polled in the vendor certification, the definition of attributes changes slightly. If you are grouping scalar OIDs for better organization within an `AttributeGroup` , set the list variable to false (list=”false”). Or, omit the variable in the `AttributeGroup` tag definition. `list=″true″` in a vendor certification appends the index to the OID when polling. When you define the attribute source, append a ‘.0’ to the end of the OID. You can also have scalar OIDs defined outside of an `AttributeGroup` .

Follow these steps:

1. Customize the following XML:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!-- Auto-generated by the type catalog local manager.-->
<DataModel namespace="http://im.ca.com/certifications/snmp"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="SNMPCertificationFacet.xsd">
  <Author>Custom</Author>
```

```
<Version>Version</Version>
  <FacetType name="Internal_Vendor_Cert_Name"
descriptorClass="com.ca.im.core.datamodel.certs.CertificationFacetDescriptorImpl">
    <Documentation>Vendor_Cert_Description</Documentation>
    <FacetOf namespace="http://im.ca.com/core" name="Item" />
    <AttributeGroup name="AttributeGroup" external="true" list="true">
      <Documentation />
      <Attribute name="INDEX" type="ObjectID">
      <Documentation />
    <Source>Index_OID</Source>
      <IsIndex>true</IsIndex>
      <IsKey>false</IsKey>
      <NeedsDelta>false</NeedsDelta>
    </Attribute>
    <Attribute name="Internal_Metric_Name" type="Data_Type_from_MIB">
      <Documentation />
<Source>MIB_Variable_OID</Source>
      <IsIndex>false</IsIndex>
      <IsKey>true</IsKey>
      <NeedsDelta>true</NeedsDelta>
    </Attribute>
</AttributeGroup>
  <Protocol>SNMP</Protocol>
<DisplayName>Vendor_Cert_Name</DisplayName>
  <Expressions>
 <ExpressionGroup destCert="{http://im.ca.com/normalizer}Metric_Family_Name"
 name="Metric_Family_Name">
      <Expression destAttr="Indexes">INDEX</Expression>
<Expression destAttr="Names">"Element_Name" + INDEX</Expression>
<Expression destAttr="Metric_Name">Internal_Metric_Name_or_MVEL_Expression</
Expression>
    </ExpressionGroup>
  </Expressions>
 <MIB>MIB_Name</MIB>
 </FacetType>
</DataModel>
```

- **Version**
  Specifies the vendor certificate version.
  Example: 1.0
- **Internal_Vendor_Cert_Name**
  Uniquely identifies a vendor certification.

  IMPORTANT
  Conform to "`<MibName><TableName>Mib` ."

  Can be updated: No
  Possible values: Alphanumeric and underscore. Dot and dash are not permitted.
- **Vendor_Cert_Description**
  Describes what is certified with the vendor certification.

TIP
Include the details about the vendor, MIB name, and table name.

Effect of updating: None

– **Index_OID** Specifies the `ObjectID` of the attribute.

TIP
Set to the fully qualified MIB variable OID that the OBJECT-TYPE defines.

Possible values: Dot-separated numbers (for example, 1.3.6.1.4.1…)
Effect of updating: Data is polled from the specified OID.
When does the update take effect: Next poll

NOTE
By default, the `Source` attribute specifies an OID to poll from the device. This default behavior is defined with `src='polled'` . You can set `src='mvel'` to process an MVEL expression using any polled attribute instead of an OID. For example, you could use the `src='mvel'` parameter to combine two 32-bit OIDs into a single 64-bit counter. You could also use the `src='mvel'` parameter to poll a counter that is not stored as a numeric type.

Example: The following example uses the `src='mvel'` parameter to combine two 32-bit OIDs into a single 64-bit counter:

```
<Attribute name="memberbitsout" type="Long">
     <NeedsDelta>true</NeedsDelta>
     <Source src='mvel'>snmpCounter64(memberbitsoutHi32,memberbitsoutLo32)</Source>
</Attribute>
```

NOTE
The `src='mvel'` parameter can only be used during polling. This parameter cannot be used during the discovery phases. For example, this parameter cannot be used as part of the Name or Description.

– **Internal_Metric_Name**
Specifies the attribute name.

TIP
Set to the MIB variable name, which the OBJECT-TYPE clause defines in the ASN.1 file.

Possible values: Alphanumeric and underscore. Dot and dash are not permitted.
Effect of updating: Update any expressions that reference this attribute.

– **Data_Type_from_MIB** Specifies the data type of the attribute.

TIP
Use the attribute type that best matches the variable type that the SYNTAX clause defines in the ASN.1 file.

Possible values: `Boolean, Int, Long, Double, BigInteger, String, DateTime, IPAddress, MACaddress, IPSubnet, OctetString, ObjectID`
Effect of updating: Polled SNMP data is converted to this type.
When does the update take effect: Next poll

– **MIB_Variable_OID** Specifies the `ObjectID` of the attribute.

TIP
Set to the fully qualified MIB variable OID that the OBJECT-TYPE defines.

Possible values: Dot-separated numbers (for example, 1.3.6.1.4.1…)
Effect of updating: Data is polled from the specified OID.
When does the update take effect: Next poll

NOTE
By default, the `Source` attribute specifies an OID to poll from the device. This default behavior is defined with `src='polled'` . You can set `src='mvel'` to process an MVEL expression using any polled attribute instead of an OID. For example, you could use the `src='mvel'` parameter to combine two 32-

bit OIDs into a single 64-bit counter. You could also use the `src='mvel'` parameter to poll a counter that is not stored as a numeric type.

Example: The following example uses the `src='mvel'` parameter to combine two 32-bit OIDs into a single 64-bit counter:

```
<Attribute name="memberbitsout" type="Long">
     <NeedsDelta>true</NeedsDelta>
     <Source src='mvel'>snmpCounter64(memberbitsoutHi32,memberbitsoutLo32)</Source>
</Attribute>
```

NOTE
The `src='mvel'` parameter can only be used during polling. This parameter cannot be used during the discovery phases. For example, this parameter cannot be used as part of the Name or Description.

- **Vendor_Cert_Name** Specifies the name of the vendor certification as it displays in NetOps Portal.

  TIP
  Start with the vendor name and include the MIB and functionality information.

  Effect of updating: A change to the name in the Administrator user interface.
  When does the update take effect: Immediately
  Required Actions for updates to take effect: Refresh the user interface.

  WARNING
  Ensure that the `DisplayName` property is unique to the vendor certification.
- **Metric_Family_Name**
  Specifies the metric family that contains the `destAttrs` to populate.
  Possible values: Any valid metric family
  Effect of updating: Changes the permissible expression `destAttr` .
- **Element_Name** Specifies to use the vendor certification attributes to collect configuration data. This configuration data helps define the MVEL expression to provide the value for the Names metric family attribute.

  TIP
  Include as much information as necessary to identify an instance uniquely.

  Possible values: String MVEL expression using available Attributes
  Effect of updating: Component name change
  When does the update take effect: After component rediscovery
  Required Actions for updates to take effect: Update the metric family or change the vendor certification priority.
- **Metric_Name**
  Specifies the metric name as defined in the metric family.
- **Internal_Metric_Name_or_MVEL_Expression**
  Specifies the internal metric name as defined in the attribute section. Or, specifies the relevant formula that is used to calculate the metric from the MIB variable represented by the internal metric name.
- **>MIB_Name**
  Specifies the name of the MIB, which the DEFINITIONS clause defines in the ASN.1 file.

  IMPORTANT
  Conform to "<MibName>”

  Effect of updating: Change to the “SNMP MIB Name” column in the Vendor Certification tab of the Administrator user interface.
  When does the update take effect: Immediately
  Required Actions for updates to take effect: Refresh the user interface.

2. Set up a REST client with a connection to the Data Aggregator server.
3. Use the following format for the URL in the REST client:
   `http://DA_host:8581/typecatalog/certifications/snmp`

   NOTE
   To update or extend a vendor certification, use the following format for the URL in the REST client:

`http://DA_host:8581/typecatalog/certifications/snmp/cert_name`

cert_name Specify the name of the existing certification.

4. Select `POST` for the **HTTP Method**.

   NOTE
   To update or extend a vendor certification, select `PUT` .
5. Select **application/xml** as the **Body Content-type**.
6. Add the customized XML within the "Body" text section.
7. Run the method.

Add a New Metric to an Existing Metric Family

Add a new BitsRateCustom metric that is based on collected MIB objects to the Interface metric family.

Update the Metric Family with a New Metric

Follow these steps:

1. Make the following GET REST call to export existing extensions for the Interface metric family:

   ```
   http://da_hostname:8581/typecatalog/metricfamilies/extension/NormalizedPortInfo
   ```

   The current extensions are returned. If you have not defined any extensions, the following XML is returned:

   ```
   <DataModel xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" namespace="http://im.ca.com/normalizer"
    xsi:noNamespaceSchemaLocation="IMDBCertificationFacet.xsd">
       <Author>CA</Author>
       <Version>2.03</Version>
       <FacetType name="NormalizedPortInfo"
    descriptorClass="com.ca.im.core.datamodel.certs.NormalizedFacetDescriptorImpl">
       <FacetOf namespace="http://im.ca.com/core" name="Item"/>
       </FacetType>
   </DataModel>
   ```

2. Define the BitsRateCustom attribute in the extension XML file.

   ```
   <DataModel xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" namespace="http://
   im.ca.com/normalizer" xsi:noNamespaceSchemaLocation="IMDBCertificationFacet.xsd">
       <Author>CA</Author>
       <Version>2.03</Version>
       <FacetType name="NormalizedPortInfo"
    descriptorClass="com.ca.im.core.datamodel.certs.NormalizedFacetDescriptorImpl">
       <FacetOf namespace="http://im.ca.com/core" name="Item"/>
       <AttributeGroup name="PortInfoPollable" list="true" external="true">
           <Attribute name="BitsRateCustom" type="Double">
               <Documentation/>
               <IsDbColumn>true</IsDbColumn>
               <Baseline>false</Baseline>
               <Minimum>true</Minimum>
               <Maximum>true</Maximum>
               <RollupStrategy>Sum</RollupStrategy>
               <StandardDeviation>false</StandardDeviation>
   ```

```
            <Variance>false</Variance>
            <Percentile>95</Percentile>
            <Percentile2>0</Percentile2>
            <Percentile3>0</Percentile3>
            <ProjectionPercentile>0</ProjectionPercentile>
            <Polled>true</Polled>
            <Units>BitsPerSecond</Units>
         </Attribute>
      </AttributeGroup>
      </FacetType>
   </DataModel>
```

3. Make the following PUT REST call to import the extensions for the Interface metric family:
   `http://da_hostname:8581/typecatalog/metricfamilies/extension/NormalizedPortInfo`

Update the Vendor Certification with the New Metric

Follow these steps:

1. Make the following GET REST call to export existing extensions for the vendor certification:

   TIP
   You can retrieve the name of the vendor certification in the user interface. Go to the Vendor Certifications page. Click the downward arrow on any column, hover over **Columns**, and click **Internal Name**.

   http://da_hostname:8581/typecatalog/certifications/snmp/extension/cert_name

2. Add an expression for calculating the new BitsRateCustom attributes.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--Auto-generated by the type catalog local manager.-->
<DataModel namespace="http://im.ca.com/certifications/snmp"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="SNMPCertificationFacet.xsd">
   <Author>CA</Author>
   <Version>2.02</Version>
   <FacetType name="IfTableMib"
 descriptorClass="com.ca.im.core.datamodel.certs.CertificationFacetDescriptorImpl">
   <FacetOf namespace="http://im.ca.com/core" name="Item" />
        <Expressions>
            <ExpressionGroup destCert="{http://im.ca.com/
normalizer}NormalizedPortInfo" name="PortNRMDS">
            <Expression destAttr="BitsRateCustom">((ifInOctets+ifOutOctets)*8)/
_rspDuration</Expression>
            </ExpressionGroup>
        </Expressions>
   </FacetType>
</DataModel>
```

3. Make the following PUT REST call to import the extensions for the Interface metric family:
   `http://da-hostname:8581/typecatalog/certifications/snmp/extension/cert_name`

After you import the vendor certification, the DX NetOps Performance Management resumes polling and uses the new extended vendor certification.

NOTE
The BitsRateCustom metric becomes available 10 minutes after you import the extension.

Validate in NetOps Portal

After you update the vendor certification with the new metric, verify that the BitsRateCustom metric appears in the Metric Families pane. Data that is polled for the BitsRateCustom metric appears in views after 3 poll cycles (15 minutes).

Follow these steps:

1. Click **Admin**, **Data Aggregator**.
   The Monitored Devices screen appears.
2. Click **Monitoring Configuration**, **Metric Families**.
3. Verify that the BitsRateCustom metric is added as needed.

TIP
You can report data on the metric that you added by creating a view for the metric.

Add a New Filter to a Vendor Certification

This self-certification workflow is an example of a real use case that you may encounter. Use this workflow as a model to help you with self-certification.

In this example, you add a filter to the IfTableMib vendor certification to prevent items with ifType 53 (propVirtual) from being discovered.

After the filter is applied, you can expect the following results:

- In NetOps Portal, if you go to **Administration**, **Monitored Devices**, **Polled Metric Families**, the interface appears as **Not Available** or **Not Present** and **Not Polled**.
- In NetOps Portal, if you go to **Administration**, **Monitored Devices**, **Filter Report**, the filter report is unaffected. The report shows only the filters from the monitoring profile. The report excludes the filter from the vendor certification.
- The interface is still available through REST on the Data Aggregator.
- The interface is unavailable through OpenAPI.

After the next sync, you can expect the following results in NetOps Portal:

- If you go to **Inventory**, **Interfaces**, the interface is removed.
- The interface is removed from all dashboards and context pages.

Follow these steps:

1. Make a GET REST call to export existing extensions for the vendor certification:
   `http://da-hostname:8581/typecatalog/certifications/snmp/extension/Vendor_Certification_Name`

   For example:
   `http://da-hostname:8581/typecatalog/certifications/snmp/extension/IfTableMib`

   TIP
   To retrieve the name of the vendor certification in the UI, go to the Vendor Certification page. Click the downward arrow on any column, hover over **Columns**, and click **Internal Name**.
2. Find the metric definition in the XML file.

```
<ExpressionGroup name="PortNRMDS" destCert="{http://im.ca.com/
normalizer}NormalizedPortInfo">
```

3. Enter the metric filtering expression inside a Filter tag:
   ```
   <Filter>(ifType!=24) &amp;&amp; (ifType!=1) &amp;&amp; (ifType!=53)</Filter>
   ```
4. Make a PUT REST call to import the new XML file:
   ```
   http://da-hostname:8581/typecatalog/certifications/snmp/extension/IfTableMib
   ```
   After you import the vendor certification, the Data Aggregator resumes polling using the new extended vendor certification.
5. Click **Update Metric Family** on the Metric Families page.
   The vendor certification no longer monitors interfaces of ifType 53.
6. To verify that the filter is added, click **Admin**, **Monitored Devices**.
7. >Click **Polled Metric Families**.
   In the list of Components, the Status of the filtered interfaces is changed to **Not Available** or **Not Present**, and the **SNMP Poll Rate** is changed to **Not Polled**.

Example

The following example shows how to define the metric filtering expression in the IfTableMib vendor certification:

```
<?xml version="1.0" encoding="UTF-8"?>

<!--Auto-generated by the type catalog local manager.-->

<DataModel namespace="http://im.ca.com/certifications/snmp" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="SNMPCertificationFacet.xsd">

  <Author>CA</Author>

  <Version>2.02</Version>

  <FacetType name="IfTableMib"
 descriptorClass="com.ca.im.core.datamodel.certs.CertificationFacetDescriptorImpl">

    <FacetOf namespace="http://im.ca.com/core" name="Item" />

    <Expressions>

      <ExpressionGroup destCert="{http://im.ca.com/normalizer}NormalizedPortInfo"
 name="PortNRMDS">

        <Filter>(ifType!=24) &amp;&amp; (ifType!=1) &amp;&amp; (ifType!=53)</Filter>

      </ExpressionGroup>

     </Expressions>

  </FacetType>
```

```
</DataModel>
```

Change the Calculation Method for an Existing Metric

You want to change how the Discards metric is calculated for the IfTableMIB vendor certification. Discards is an existing out-of-the-box metric.

1. Make a GET REST call to export the full IfTableMIB vendor certification.

   ```
   http://da_hostname:8581/typecatalog/certifications/snmp/IfTableMIB
   ```

2. Make a GET REST call to export existing extensions for the IfTableMIB vendor certification.
3. Find the metric expression that you want to change.

   ```
   <Expression destAttr="Discards"></Expression>
   ```

4. Enter the new calculation in the vendor certification extension file.

   ```
   <Expression destAttr="Discards">(ifInDiscards+ifOutDiscards+ifInErrors+ifOutErrors)</
   Expression>
   ```

5. Import the new extended vendor certification.

   ```
   http://da-hostname:8581/typecatalog/certifications/snmp/extension/IfTableMIB
   ```

   The DA resumes polling using the new extended IfTableMIB vendor certification. The new calculation for the Discards metric is applied.
6. After 3 poll cycles (15 minutes), verify the new calculation in a CAPC view.
   a. Create a view using the new extended IfTableMIB vendor certification.
   b. Verify in CA NetOps Portal that the new calculation for Discards is used.

Example

The following example shows how to define the new calculation in the vendor certification extension XML file:

```
<?xml version="1.0" encoding="UTF-8"?>

<DataModel xsi:noNamespaceSchemaLocation="SNMPCertificationFacet.xsd" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance" namespace="http://im.ca.com/certifications/snmp">

  <Author>CA</Author>

  <Version>100.0</Version>
```

```
  <FacetType
 descriptorClass="com.ca.im.core.datamodel.certs.CertificationFacetDescriptorImpl"
 name="IfTableMib">

    <Documentation>Supports interfaces new metrics</Documentation>

    <FacetOf namespace="http://im.ca.com/core" name="Item"/>

    <Expressions>

      <ExpressionGroup name="PortNRMDS" destCert="{http://im.ca.com/
normalizer}NormalizedPortInfo">

        <Expression destAttr="Discards">(ifInDiscards+ifOutDiscards+ifInErrors
+ifOutErrors)</Expression>

      </ExpressionGroup>

    </Expressions>

  </FacetType>

</DataModel>
```

Deploy a New Metric Family or Vendor Certification on the Production System

You have created a new metric family or vendor certification on your test environment. You want to deploy the new metric family or vendor certification to your production system. Do not experiment on the production system. Always develop metric families and vendor certifications on the test environment, and then deploy them to the production system.

1. Export the metric family or vendor certification from the test environment type catalog.
   Export a Metric Family

   ```
   GET http://da_testhostname:8581/typecatalog/metricfamilies/mf_name
   ```

   Export a Vendor Certification

   ```
   GET http://da_testhostname:8581/typecatalog/certifications/snmp/vc_name
   ```

2. Import the XML file that contains the metric family or vendor certification to the production system.
   Import a Metric Family

   ```
   POST http://da_hostname:8581/typecatalog/metricfamilies
   ```

   Import a Vendor Certification

   ```
   POST http://da_hostname:8581/typecatalog/certifications/snmp
   ```

Manage Missing Vendor Certifications

If you see views with no data, or views that have data for some fields and none for others, you might have missing vendor certifications. After discovery completes, you can view a list of metric families with missing vendor certifications and the affected devices.Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Monitored Devices**.
2. In the **Monitoring Configuration** section, click **Missing Vendor Certifications**. A list of metric families with missing vendor certifications appears.
3. Click one of the metric families. A list of the affected devices appears.
4. Go to the Technology Certification Portal to find the missing certification or to request a new one.

SNMP Profiles

Simple Network Management Protocol (SNMP) profiles contain the information necessary to enable secure queries of device management information bases (MIBs). SNMP profiles provide SNMP parameters to data sources and ensure data security. DX NetOps Performance Management supports SNMPv1, SNMPv2c, and SNMPv3. DX NetOps Performance Management encrypts community strings and credentials.

DX NetOps Performance Management uses SNMP profiles during inventory discovery to determine what credentials to use when accessing a device. Each profile is ranked for device access. During discovery, each profile is tried for device access. The profile with the highest rank that can access a device is used. If a device that uses an SNMPv1/SNMPv2c profile responds to SNMPv1 and SNMPv2c, DX NetOps Performance Management uses SNMPv2c.

Polling devices with SNMPv3 adds an extra load of about 30 percent to the CPU of Data Collectors.

> **NOTE**
> To limit the SNMP profiles that are used during discovery, use a specific list of assigned SNMP profiles. For more information, see Discovery Profiles.

CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor use SNMP profiles to query the MIBs of managed items for performance information. When you register one of these data sources, any profiles that were created in that data source are added to DX NetOps Performance Management. Naming conflicts are resolved automatically. Any changes to SNMP profile in NetOps Portal are propagated to these data sources during synchronization.

Users with the Administer SNMP Profiles role right can create, edit, and delete SNMP profiles. SNMP profiles are specific to tenants. The Default Tenant Administrator sees a list of SNMP profiles that are associated with the Default Tenant. In multi-tenant environments, each tenant administrator sees only the SNMP profiles for that tenant.

To view the list of SNMP profiles, hover over **Administration**, **Configuration Settings**, and then click **SNMP Profiles**. The list includes high-level information about the contents of each profile.

Create an SNMP Profile

To enable the system to query devices through SNMP, define SNMP profiles with communication credentials.

This procedure requires the Administer SNMP Profiles role rights.

Follow these steps:

1. Hover over **Administration**, **Configuration Settings**, and then click **SNMP Profiles**.
2. Click **New**.

3. Complete the fields, and change any default settings. Some fields apply only to SNMPv3.
   - **Profile Name**
     SNMP profile names must be unique, cannot be duplicated across SNMP versions, and are not case-sensitive.
   - **SNMP Version**
     Specifies whether the profile uses SNMPv1/v2c or SNMPv3.
   - **Port**
     The port that is used to make SNMP connections to devices associated with this profile.
     Default: 161

     NOTE
     This port can also be used to send SNMP traps to trap receivers associated with this profile through notifications. In this scenario, use 162 by default. For more information, see Configure Notifications.
   - **User Name**
     (SNMPv3 Only) Identifies the user for the profile, whose secret keys were used to authenticate and encrypt the SNMPv3 packets.
   - **Context Name**
     (SNMPv3 Only) Identifies the collection of management information that is accessible by an SNMP entity. An octet string that is necessary for providing end-to-end identification and for retrieving data from an SNMPv3 agent.

     NOTE
     The Data Aggregator does not use Context Name on the SNMPv3 profiles to communicate with the device.
   - **Community Name**
     (SNMPv1/v2c Only) Defines a secure string that lets the data source query the MIB of the associated device. The community that you supply must provide read access to the device MIB.

     NOTE
     In the default SNMP profile, the community is 'public'.
   - **Authentication Protocol**
     (SNMPv3 Only) Specifies the authentication protocol to use when contacting devices associated with this profile. The following algorithms for authenticating SNMPv3 packets are supported:
     - None
     - MD5 (Message Digest 5)
     - SHA (Secure Hash Algorithm)
   - **Authentication Password**
     (SNMPv3 Only) Specifies the password for authentication using SNMPv3 and the selected authentication protocol.
   - **Privacy Protocol**
     (SNMPv3 Only) Specifies the encryption protocol to use for data flows sent to any devices or servers:

     NOTE
     The privacy protocol option is enabled when authentication is enabled for the profile.

     - None
     - DES
     - AES 128
     - Triple DES
     - AES 256 with 3DES key
   - **Privacy Password**(SNMPv3 Only)
     Defines the password that is used when exchanging encryption keys.
   - **Use by default for new devices**

Specifies whether CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor use this profile to contact any new items. To stop these data sources from using this SNMP profile for discovery, disable this parameter.

– **Use for SNMP SET**
The profile provides write credentials on the discovered devices. Profiles with this property *do not* participate in device discovery. Associate this profile with devices which require SET authorization, for example, to configure RTT tests.
For more information, see Configure Round Trip Time (RTT) Tests.

4. Click **Save**.
The SNMP profile is added to the system and used for discovery and polling.
NetOps Portal automatically performs a global synchronization to send the profile information to registered data sources.

Change SNMP Profile Order

To determine the selection order of SNMP profiles for discovery and polling, change the priority order of the SNMP profiles. The **Order** parameter determines which profile DX NetOps Performance Management uses for polling when the device responds to multiple profiles.

Changes to the order do not affect existing polled devices. DX NetOps Performance Management continues to use the associated SNMP profile to poll those devices.

The new order takes effect in the following situations:

- A new device is discovered.
- An existing device becomes unreachable through SNMP for at least two poll cycles.
- The SNMP profile for a device is deleted.

Administrator users can modify the priority order of SNMP profiles.

Follow these steps:

1. Hover over **Administration**, **Configuration Settings**, and then click **SNMP Profiles**.
2. Click and drag or click **Move Up** and **Move Down** to change the order.
DX NetOps Performance Management uses the new order for unreachable devices.

SNMP Profile Changes

When the SNMP credentials on a polled device change, add the new SNMP profile information to DX NetOps Performance Management. When the device becomes unreachable with the deprecated SNMP profile for two poll cycles, DX NetOps Performance Management attempts to contact the device with other profiles. When DX NetOps Performance Management successfully contacts the device with an SNMP profile, that profile is assigned to the device for future polling.

NOTE
To see the SNMP profile that DX NetOps Performance Management uses to poll the device, go to the administration page for the device.
For more information, see Manage Devices.

Modify the Timeout and Retries Parameters

You can modify the timeout and retries parameters for each SNMP profile on your system using a REST client. If SNMP requests go across a WAN or across a slow network connection, they might time out. The timeouts can cause missing polled data or device discovery failure.

- **Timeout**

The amount of time a device is given to respond to an SNMP request per tryDefault: 3000 milliseconds

- **Retries**
  The number of times an SNMP query is reissued before it times out
  Default: 2 retries

For example, by default, an SNMP request is given the following amount of time:

- 3 seconds x (first attempt + 2 retries)= 3 seconds x 3 tries = 9 seconds to respond before it times outs

> **WARNING**
> Modifying these parameters without careful consideration can result in unintended consequences. For example, modifications could result in resource starvation (CPU/Memory) and unnecessary traffic on the Data Collector. Modify these parameters only if you have a basic understanding of SNMP communication.

Follow these steps:

1. Set up a REST client with a connection to the Data Aggregator server.
2. Specify the following URL:
   `http://da_hostname:8581/rest/profiles/profile_item_id`
3. PUT the XML for modifying the parameters:

```
<?xml version="1.0" encoding="UTF-8"?>
<CommunicationProfile version="1.0.0">
    <CommunicationFailurePolicy version="1.0.0">
        <Timeout>3000</Timeout>
        <Retries>2</Retries>
    </CommunicationFailurePolicy>
</CommunicationProfile>
```

Show Secure SNMP Data in Clear Text

By default, secure data is encrypted in the Add and Edit SNMP Profiles pages. To enable an administrator to troubleshoot issues with SNMP polling, allow that administrator to view secure data in clear text. By default, this role right is not assigned to any roles. Only the predefined Administrator role can have this role right. Only Administrator users can modify role rights.

By default, the predefined Administrator role is assigned only to the global administrator. To allow another user to view secure SNMP data, assign the Administrator role to another user account.

Follow these steps:

1. Hover over **Administration**, **User Settings**, and then click **Roles**.
2. Select the **Administrator** role, and click **Edit**.
3. Select **NetOps Portal**, and then click **Edit**.
4. Add the **SNMP Clear Text** role right to the **Selected Rights** list, and then click **OK**.
5. Click **Save**.
   Users with the Administrator role can now view secure SNMP data in clear text.

Discover Logical Devices Through SNMP Context

You can discover logical components on devices where you need to use alternate Simple Network Management Protocol (SNMP) contexts by adding Check Point Virtual Firewalls to managed devices.

Add Check Point Virtual Firewalls to Managed Devices

A new vendor certification and metric family are defined for Check Point Virtual Firewalls.

Follow these steps:

1. Use SNMPv3 profiles to discover the physical parent devices.
2. Attach the new Context System metric family to each device.
3. Wait for discovery to complete.
   The Check Point Virtual Firewalls are automatically discovered.

   NOTE
   All the Check Point Virtual Firewall items have the same IP address as the parent device. However, each Check Point Virtual Firewall item has its own context name. All the polling data for the Check Point Virtual Firewall item (CPU, Memory, Interfaces, and so on) appear under the context name.

IP Domains

IP domains resolve IP address conflicts by separating monitored devices from different networks. For example, you monitor two networks and each network includes a separate device with the same IP address.

As a service provider, use IP domains to monitor multiple discrete networks that belong to different customers. Each customer, or tenant, contains one or more IP domains. The data collectors associate managed items and data with the assigned IP domain. Customer user accounts see only the relevant IP domains. Service provider administrators see the data from all IP domains.

Administrators and Designers can create custom dashboards to monitor activity on a specific domain or group of domains.

To view IP domains, go to **Administration**, **IP Domains**.

In this article:

IP Domains and Other Data Sources

Network Flow Analysis, CA Application Delivery Analysis, and CA Unified Communications Monitor data sources can use IP domains. To apply domains to the data sources, register the data source with NetOps Portal. When you create IP domains in NetOps Portal, the domain identifiers become visible in the registered data sources after synchronization.

You can associate the following managed item types with an IP domain:

- Devices
- Interfaces and interface addresses
- Networks
- VoIP Locations

Data sources report a domain identifier that associates monitored items with a specific IP domain. Items that are not assigned to a custom domain in the data source are associated with the default domain.

Add or Edit an IP Domain

IP domains are required for monitoring multiple tenants or environments with overlapping IP addresses. Create custom IP domains so the data sources can associate monitored items with specific domains and tenants.

The Default Domain is automatically created. This domain includes any items that are not assigned to a custom domain in the data source.

The procedure requires the Administer IP Domains role right.

Follow these steps:

1. Select **Administration**, **IP Domains**.
2. Click **New**.
3. Specify a name and description.
4. (Optional) Configure a device name alias or interface description override. Click **Browse**, select the file, and then click **Open**.
   Use a CSV or TXT file with the following format:
   ```
   IP_Address,name,description,alias/alternate_description
   ```
   Use the primary IP address of the associated devices. To find the primary IP address, look at the Address column of the Inventory Devices list.
   You can use the same alternate interface descriptions for more than one interface.
   Example:
   ```
   172.24.36.107,ethernet_7,vmxnet3 Ethernet Adapter,Connection to Dallas
   ```

   NOTE
   To change or remove an alternate description or device name alias, import a new file. To remove the alias or alternate description, leave the final column blank. When you remove the alias or alternate description, the original name or description reappears. If you change or remove alternate descriptions or device name aliases from a file using a spreadsheet program, include a column heading for that column.

   Updates to device name aliases and interface descriptions can take up to 5 minutes to appear.

   TIP
   The preferred method to apply device name aliases and alternate interface descriptions is through REST. For more information, see Set the Alias Name for a Device and Set Interface Name Aliases.

   To update multiple device aliases, use the script that is included with DX NetOps Performance Management. For more information about this script, see Set Alias Names For Multiple Monitored Devices.
5. (Optional) To assign a primary and secondary DNS address for the domain in Network Flow Analysis, select **DNS Settings**, and then specify the required values.

   NOTE
   Only Network Flow Analysis uses the DNS settings. DX NetOps Performance Management does not directly use the DNS settings.
6. Click **Save**.
   The IP domain appears in the list immediately, and the changes apply to the data sources in the next synchronization. If you edit an IP domain, historical data for monitored items remains unchanged.

Assign Items to an IP Domain

To add items to an IP domain, associate a data collector with the IP domain and create a discovery profile that uses the IP domain. Each data collector associates managed items with a single IP domain. To enable multi-tenant deployments, assign an IP domain to each data collector. Before you install a data collector, create the tenants and IP domains that you require. You can associate multiple data collectors with a single IP domain.

NOTE
You cannot move items from one IP domain to another.

To assign items from other data sources to an IP Domain, see the documentation for that data source or see the following pages:

- Assign CA Network Flow Analysis Items to an IP Domain
- Assign CA Application Delivery Analysis Items to an IP Domain
- Assign CA Unified Communications Monitor Items to an IP Domain

TIP
DX NetOps Spectrum determines which models are synchronized with DX NetOps Performance Management using IP domains.
For more information, see the DX NetOps Spectrum documentation.

This procedure requires the Administer Data Sources role right, and the Administrator product privilege for the data aggregator data source.

Follow these steps:

1. Select **Administration**, and then click the data aggregator data source.
2. Expand **System Status**, and then click **Data Collectors**.
3. Select an IP domain and a tenant for each data collector in the list, and then click **Assign**.
   You cannot assign a data collector that is monitoring devices other than itself to a different IP domain.
4. Create a Discovery profile that is associated with the IP domain and run discovery.
   For more information, see Discovery.

Delete an IP Domain

When you delete an IP domain, all monitored items in that IP domain are deleted, including historical data. The items are also deleted from registered data sources that use IP domains, such as Network Flow Analysis, CA Application Delivery Analysis, and CA Unified Communications Monitor. DX NetOps Spectrum devices in the IP domain are removed from DX NetOps Performance Management, but DX NetOps Spectrum continues to monitor the devices.

When you delete an IP domain, the associated data collectors and discovery profiles become inactive. Assign another IP domain to continue polling or discovery.

IMPORTANT
To retain associated data, do not delete an IP domain. You cannot recover deleted data.

Assign Network Flow Analysis Items to an IP Domain

Interfaces and CVIs inherit their initial tenant-domain setting from the parent router and Harvester. The setting is inherited when the parent Harvester is added and the router and interfaces first become active. If the Harvester is not associated with a custom domain, the routers and interfaces are assigned to the Default Domain as they become active.

You can edit the settings for interfaces and CVIs to associate them with any tenant and domain at any time. The setting does not have to match the parent router or Harvester.

Changing this setting can affect which operators have access to interface data. The setting does not affect which Simple Network Management Protocol (SNMP) profiles you are using for polling. The router tenant determines the set of SNMP profiles for polling.

NOTE
You can also change the tenant-domain setting for Harvesters and routers.

Follow these steps:

1. Open the Active Interfaces page:
   a. Select **Administration** from the Network Flow Analysis console menu.
   b. Select Interfaces: Physical & Virtual from the Administration menu.
2. Select one or more interfaces that you want to associate with a tenant and domain.
3. • To search for parent routers, interfaces, or CVIs, enter all or part of a router IP address, a router or interface name, or an interface description in the **Search** field, and then click **Search**. Expand the router details.
   • To navigate to an interface or CVI manually, go to the page that contains the parent router, and click the arrow next to the router name. The router details expand to show the interfaces and CVIs.
4. Click **Edit**.

The Domain selection list is included in the dialog only if multiple domains exist.
5. Select a tenant/domain option from the Domain list.
6. Click **Save**.
The changes are shown on the Active Interfaces page.

Assign Application Delivery Analysis Items to an IP Domain

CA Application Delivery Analysis can observe duplicate Internet Protocol (IP) traffic, which occurs in a managed service provider environment. The provider can host an application on a single server for multiple customers whose environments contain overlapping client IP addresses.

You enable CA Application Delivery Analysis to identify separate IP traffic during data collection setup. As you verify and modify data collection parameters, assign the same IP domain to the appropriate:

- Monitor feeds
- Client networks
- Servers or server subnets

With the same IP domain assignments for these feeds, CA Application Delivery Analysis reports on the application traffic between a client and a server by domain.

Applications are domain-independent. Therefore, you are not required to define the same application twice, such as Exchange Company A and Exchange Company B, to enable CA Application Delivery Analysis to report on application performance across domains. However, to set different thresholds for application performance, performance operational level agreements (OLAs), and availability OLAs, create an application for each IP domain.

If you do not need to separate duplicate IP traffic, you can use the DNS settings in the Default Domain to query Domain Name System (DNS) and resolve the hostname of a CA Application Delivery Analysis server. Otherwise, CA Application Delivery Analysis uses the monitor feed that is assigned to the server to resolve the hostname.

View a List of Domains in CA Application Delivery Analysis

You can view a list of domain definitions and current domain associations in the Administration section of the CA Application Delivery Analysis management console.

Follow these steps:

1. Click the Administration tab in the management console.
2. Click **Data Monitoring**, **Domains** in the Show Me menu.
The Domains page opens.
3. (Optional) View the DNS settings for a domain by clicking the magnifying glass in the View column.
The Domain Properties page opens.
4. Verify the properties.
5. Click **OK** when you have finished.
The Domains page appears.

Assign a Domain to a Monitor Feed

You can instruct each Standard Monitor to associate the items that it monitors with a custom domain as part of CA Application Delivery Analysis collection device setup.

Follow these steps:

1. Click the **Administration** tab in the management console.
2. Click **Data Monitoring**, **Monitoring Devices** in the Show Me menu.
3. Click **Edit** to edit a multifunction monitoring device, such as a Standard or Multi-Port Monitor.

4. Scroll down to the Monitor Feeds list.
5. Click to edit a monitor feed.
6. Select a custom IP domain.
7. Click **Update**.
   All items detected by this monitor feed are automatically associated with the selected IP domain.

Assign a Domain to a Client Network

After you add a client network, you cannot change its IP domain association. If you need to change the assigned IP domain, first delete the network, and then add it to the correct domain.

Follow these steps:

1. Click the **Administration** tab in the management console.
2. Click **Data Monitoring**, **Networks** in the Show Me menu.
3. Select the IP domain from the list.
4. Click **Add Network**.
5. Enter the required information to add the network.
6. Click **OK**.
   The network is added to the domain.

Assign a Domain to a Server or Server Subnet

After you add a server or server subnet, you cannot change its IP domain. If you add a server or server subnet to the wrong IP domain, first delete it, and then add it to the correct domain.

Follow these steps:

1. Click the **Administration** tab in the management console.
2. Click **Data Monitoring**, **Servers** in the Show Me menu.
3. Select the IP domain from the list.
4. Enter the required information to add the Server or Server Subnet.
5. Click **OK**.
   The Server or Server Subnet is added.

Assign CA Unified Communications Monitor Items to an IP Domain

In the CA Unified Communications Monitor management console, you can instruct collectors to associate the items that they discover with custom domains in NetOps Portal. The act of creating a single custom domain in NetOps Portal enables domain associations for locations, voice gateways, and call servers in any registered data sources.

Items appear with domain designations when they are discovered from call traffic. Previously discovered items do not receive retroactive associations.

Locations are automatically associated with IP domains by the subnets that they contain. To preserve the flow of data collection and the appropriate association of data with IP domains, take care when moving Locations to new IP domains. Follow the procedure in the CA Unified Communications Monitor online Help to change IP domain assignments.

Instruct collectors to associate items with custom IP domains.

Follow these steps:

1. Click Administration, Data Collection, Collectors.
2. Edit each collector to select its domain for the IP Domain parameter.
3. Reload the collectors to send them the domain information.
   Domains are populated with managed items after the next product synchronization.

Discovery

Discovery is the process that DX NetOps Performance Management uses to identify the devices on your network. Devices are identified using the IP domain, IP addresses, IP ranges, and hostnames that you specify in discovery profiles.

Attempts to discover devices are made through SNMP and ICMP protocols. If a device does not respond to SNMP but *does* respond to ICMP, a pingable device is created.

Inventory Discovery

Inventory discovery, or device discovery identifies the following information about devices:

- Which protocols the device responds to, SNMP or ICMP
- The classification of the device, such as router or switch
- The device vendor, such as Cisco or Juniper
- The device type, such as 7700 or 8200

Discovered devices and monitored components take up to 5 minutes to begin synchronizing with NetOps Portal.

Discovered devices are automatically added to device collections depending on the rules that control each device collection membership. During the first synchronization between Data Aggregator and NetOps Portal *after* devices are discovered, the devices are added to collections.

You can use two methods to discover devices:

- Run discovery through DX NetOps Performance Management.
- Discover devices from other data sources.
  For more information, see Discovery From Other Data Sources.

The following workflow offers a best practice to use as a quick reference when performing a discovery of your inventory.

Perform this process as either a user with the Administrator role or as the tenant administrator.

1. To enable the Data Collector to perform queries of device MIB tables that use SNMP, create SNMP profiles.
   For more information, see SNMP Profiles.
2. Create discovery profiles. For more information, see Discovery Profiles.
3. Run discovery and view the results. For more information, see Run Discovery.

Metric Family Discovery

Metric family discovery, also known as component discovery, is a separate process that determines whether a specific metric family is supported for a device.

A metric family defines the set of metrics to collect and report on for a given technology. The values of the metrics are normalized so that reporting is uniform regardless of the data source.

Polling begins automatically after metric family discovery completes. Operational metrics are collected and retained at regular polling intervals for reporting. Examples of operational metrics include error rate, utilization, and bytes in. Configuration data represents or identifies a component or the component configuration, such as port type or component index.

For more information, see Configure Monitoring Profiles.

Quickly Discover SNMP Devices

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in your network. You can quickly discover SNMP devices without having to configure SNMP profiles and discovery profiles manually.

For more information, see Discovery.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Quick Device Discovery**.
2. Select **SNMP devices**.
3. Select the SNMP protocol to use.
4. Complete the following fields:
   - **IP Domain**
     If you have multiple IP domains, select the IP domain for discovery.
   - **Community Name** (SNMPv1/v2c Only)
     Specify a secure string that lets the data source query the MIB of the associated device. The community that you supply must provide read access to the device MIB.
   - **Verify Community Name**
     Specify the Community Name again for verification.
   - **Port**
     Specify the port that is used to make SNMP connections to your devices.
     Default: 161

     NOTE

     This port can also be used to send SNMP traps to trap receivers associated with this profile through notifications. In this scenario, use 162 by default. For more information, see Configure Notifications.
   - **IPs/Host**
     Specify the IP address ranges that you want to discover for IPv4. Range discovery is not supported for IPv6 addresses.
5. Click **Discover**.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.

Quickly Discover Virtual Network Devices

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in your network. You can quickly discover Virtual Network devices without having to configure discovery profiles manually.

For more information, see Discovery.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Quick Device Discovery**.
2. Select **Virtual Network Devices**.
3. Select a technology.
4. Complete the following fields for the selected technology:
   - **Viptela SD-WAN**
     - **IP Address**
     - **Protocol**
       The HTTP security scheme for vManage
     - **Port**
     - **User Name**
     - **Administrator Password**
     - **Re-enter Administrator Password**
   - **Cisco ACI**
     - **APIC Host IP Address**

The IP address of the APIC controller host
- **Protocol**
  The communication protocol with the APIC controller
- **Port**
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

– **128T**
- **Host Conductor IP Address/Name**
  The IP address of the 128T Conductor
- **Protocol**
  The HTTP security scheme for 128T SD-WAN
- **Port**
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

– **Nuage**
- **VSD Host IP Address**
  The Virtualized Services Directory (VSD) host
- **Protocol**
  The communication protocol with the VSD
- **VSD Port**
  The port that the VSD UI/API server listens on
- **Stats Host IP Address**
  The IP address of the stats server
- **Stats Protocol**
  The communication protocol with the stats server
- **Stats Port**
  The port the stats server is listening on for REST requests
- **Nuage Organization**
  The name of the Nuage enterprise to manage
- **Time Zone**
  The time zone of the system, which must match the VSD time zone
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

– **SilverPeak**
- **Host Orchestrator IP Address/Name**
  The Unity Orchestrator Management host
- **Protocol**
  The communication protocol with the Orchestrator
- **Port**
- **User Name**
- **Administrator Password**
- **Re-enter Administrator Password**

5. Click **Discover**.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.

Discover Devices

If you do not use quick discovery, you can configure SNMP profiles and discovery profiles manually.

The following video shows the detailed discovery process starting with the required setup:

Follow these steps:

1. Configure SNMP Profiles.
2. Configure IP Domains.
3. Configure Discovery Profiles.
4. Run Discovery.

Discovery Profiles

Discovery profiles specify how discovery operates. Discovery profiles determine the IP domain, IP addresses, IP address ranges, and host names for discovery. You can only specify one IP domain for each discovery profile. Newly discovered devices are created in the selected IP domain. When multiple Data Collectors are deployed in one IP domain, each Data Collector issues a discovery request to each device as specified by the discovery profile. When more than one Data Collector can contact a device, a specific Data Collector is randomly selected to monitor the device. Review the capacity of the Data Collectors and rebalance as required. For more information, see Rebalance the Load on Data Collector. Discovery profiles are only accessible to users in the tenant space where the discovery profile was created. Users that are assigned to the Default Tenant can access discovery profiles in the Default Tenant space. Log in to the correct tenant *before* you create a discovery profile.

Administrators can manage discovery profiles through the UI or through the Data Aggregator REST web services. Log in as a tenant administrator to perform these tasks.

The following video walks through a single device discovery:

Create Discovery Profiles

To specify how inventory discovery operates in your environment, create discovery profiles. To optimize discovery and reduce SNMP traffic, set up granular discovery profiles:

- Use separate discovery profiles for each group of devices that share an SNMP profile.
- Use separate discovery profiles for groups of devices that require different rediscovery schedules.

Follow these steps:

1. Select **Administration**, and click the Data Aggregator data source.
2. Click **Discovery Profiles** from the Monitored Inventory menu.
3. Click **New**.
4. Specify a name and select an IP Domain.
   The following characters are not permitted:
   – Single quotes
   – Double quotes
   – Backward slashes
   – Forward slashes
   – Ampersands
5. Select the IPs/Hosts tab and do one or more of the following actions:
   – (Optional) Navigate to and import a CSV file of IP addresses. The CSV file can contain a comma-separated list of IPv4 addresses, IPv6 addresses, IPv4 address ranges, and hostnames. Browse to select the file and click **Open**.

NOTE
To apply Chinese characters to the alias name, save the CSV file in UTF-8 format.

– Specify IP address ranges, individual IP addresses, and host names. Comma-delimited values are accepted.

NOTE
If an IP range includes multiple IP addresses, and one of the IP addresses maps to the hostname, discovery always uses the hostname IP as the primary IP address.

6. (Optional) To regularly update information for discovered devices and discover new devices, configure a schedule for the discovery profile. Select the **Schedule** tab, and specify a schedule.
7. (Optional) To use specific SNMP profiles, select the **SNMP** tab, and complete the following steps:
   a. Select **Use specific list of assigned SNMP profiles**.
   b. Move one or more SNMP profiles from the list of available profiles to the assigned list.

TIP

Using a subset of SNMP profiles reduces SNMP traffic.

8. Select the Advanced tab, and configure advanced options:
   – **Naming Order**
   Change the attribute priority, which the system uses to name the discovered devices. Any device item that the discovery profile creates is named with the highest available naming convention. If a higher priority attribute is unavailable for the device, DX NetOps Performance Management uses the next highest priority attribute. For virtual machines, DX NetOps Performance Management ignores the naming order and uses the names from vCenter.

NOTE

If you use host name to name devices, the device name is updated automatically when the hostname changes. If you use another attribute, such as system name, the change to the device name occurs when the discovery profile runs again. Run discovery manually or configure a schedule for the discovery profile.

   In some unusual configurations, the network might not have unique DNS host names. To reconcile devices by the IP address and system name only, select **Exclude Host Name**.
   – **ICMP Discovery**
   To determine if a device can respond to ICMP, select **Use ICMP**.
   To create pingables for devices that respond to ICMP but not SNMP, select **Create Pingables**.
9. Click **Save**.
   The discovery profile is created and is displayed in the Discovery Profiles list. If the profile has a schedule, discovery runs at the scheduled time.

Discovery Profile IP Ranges

In a discovery profile, you can specify the IP address ranges that you want to discover for IPv4. Range discovery is not supported for IPv6 addresses.

When you specify IP ranges in the discovery profile, the following rules apply:

- An IPv4 range can contain wildcards (*). A wildcard represents a full range for an IP octet: 0-255
- An IPv4 range can contain hyphens (-). A hyphen can exist between the lower IP address and upper IP address. A hyphen can also be in the IP octets in the lower IP address.

Examples: Valid IP Ranges

- Both of the following examples attempt to discover devices at every IP address from 10.25.1.0 to 10.25.1.190:

```
10.25.1.0-10.25.1.190
```

OR

```
10.25.1.0-190
```

- Both of the following examples attempt to discover devices at every IP address from 10.25.0.0 to 10.25.255.255:

  ```
  10.25.*.*
  ```

  OR

  ```
  10.25.0.0 - 10.25.255.255
  ```

- Both of the following examples attempt to discover devices at every IP address from 10.25.0.3 to 10.25.0.40 and from 10.25.1.3 to 10.25.1.40:

  ```
  10.25.0-1.3-40
  ```

  OR

  ```
  10.25.0.3 - 10.25.0.40, 10.25.1.3 - 10.25.1.40
  ```

- Both of the following examples attempt to discover devices at every IP address from 10.25.0.0 to 10.25.0.5, from 10.25.1.0 to 10.25.1.5, and so on, up to 10.25.255.0 to 10.25.255.5:

  ```
  10.25.*.0-5
  ```

  OR

  ```
  10.25.0.0 - 10.25.0.5, 10.25.1.0 - 10.25.1.5 ... 10.25.255.0 - 10.25.255.5
  ```

Examples: Invalid IP Ranges

- The following example is invalid because the upper IP address is incomplete:

  ```
  10.25.1.0 - 10.23
  ```

- The following example is invalid because when a hyphen (-) is used in an octet in the lower IP address, the upper IP address cannot be present:

  ```
  10.25.1.0-190 - 10.25.1.255
  ```

- The following example is invalid because when a wildcard (*) is used in an octet in the lower IP address, the upper IP address cannot be present:

  ```
  10.25.*.0 - 10.25.255.255
  ```

- The following example is invalid because it is unclear whether the wildcard octet (1*) implies 10.25.10-19.0 or 10.25.10-199.0:

```
10.25.1*.0
```

Run Discovery

Inventory discovery finds devices as specified by a discovery profile. Run discovery manually, or schedule the discovery.

If discovery hangs for more than 10 minutes, the discovery is aborted. A discovery is considered to be hanging when no new devices are discovered within 10 minutes and the state for the discovery profiles have not changed within 10 minutes. An audit event is generated on the Data Aggregator device. If no devices were discovered, the state of the discovery profiles indicates FAILURE. If at least one device was discovered, the state indicates PARTIAL_FAILURE.

The discovered devices and monitored components can take up to 5 minutes to synchronize with NetOps Portal. When the synchronization is complete, the devices and components appear in the **Inventory** tab.

Manual Discovery

An administrator or a tenant administrator can run manual discovery. To run a discovery as the administrator, first configure the Data Collector for the Default Tenant domain.

Follow these steps:

1. Go to **Administration**, and click the Data Aggregator data source.
2. Click **Discovery Profiles** from the Monitored Inventory menu.
3. Select one or more discovery profiles, and then click **Run**.
   The state of the selected profiles must be READY or SCHEDULED.
4. Click **Yes** in the confirmation dialog.
   Discovered devices are added to device collections, which initiates component monitoring and polling.

Scheduled Discovery

You can configure a discovery to run on a daily or weekly schedule. When the discovery is scheduled, the State for the discovery profile is SCHEDULED and the next scheduled run time appears.

To run schedule discoveries, configure the options in the **Schedule** tab when you create or edit a discovery profile.

View Discovery Results

The discovery results show the number of devices that were discovered during a specific discovery instance. You can view specific details about these discovered devices, including the IP address, model, type, vendor name, location, and protocols.

Follow these steps:

1. From the **Discovery Profiles** list, select a discovery profile, and click **History**.
2. Select a Discovery instance.
3. (Optional) Filter the **Discovered Devices** table by device type or state.
   The discovery results appear in the Discovered Devices table.
   The SNMP Profile column shows the highest ranked SNMP profile that the device responded to.
   The State column indicates one of the following states:
   - **New**
     Indicates a device that was discovered for the first time when this discovery profile was run.
   - **Changed**
     Indicates that a device type has changed from a previous discovery. For example, a previously discovered pingable device is now discovered as a manageable device. Or a previously manageable device with the

device type of Switch has now changed to the device type of Router. Devices with only attribute changes, such as hostname, or system description are not classified as Changed.

- **Unchanged**
  Indicates that existing devices have not changed. Existing devices with only attribute changes are also classified as Unchanged. Existing devices that show different IP addresses were discovered and are being monitored with a different IP address. Many devices can respond to multiple IP addresses. DX NetOps Performance Management maintains the full set of IP addresses for each device.
- **Deleted**
  Indicates that the device was deleted from Data Aggregator since the discovery was run.

  NOTE
  If a single IP address or hostname that was specified in the discovery profile is not found, the device type indicates Inaccessible. DX NetOps Performance Management does not report inaccessible devices from IP ranges.

Get a List of Unreachable Devices

If discovery fails for any of your devices, you can access a list of the unreachable devices using the `discoveryinstances` rest service.

NOTE
This method works only when you specify each IP address or host in your discovery profile. This method does not provide a list when you specify an IP range in your discovery profile.

Follow these steps:

1. View a list of the discovery instances available at the following location:
   `http://DA_HOST:8581/rest/discoveryinstances/`

2. Find the discovery instance that corresponds to when you ran your discovery.
   Example:
   ```
   <DiscoveryInstance version="1.0.0">
        <ID>6508</ID>
        <IPSweepStartTime>Mon Sep 18 15:44:31 2017 -0400</IPSweepStartTime>
   ```

3. Note the discovery instance ID.
4. View the results for your discovery instance at the following location:
   `http://DA_HOST:8581/rest/discoveryinstances/DISCOVERY_INSTANCE_ID`

5. View the `<UnreachableDevicesList>` section.
   Example:
   ```
   <DiscoveryInstance version="1.0.0">
        <ID>6508</ID>
        <IPSweepStartTime>Mon Sep 18 15:44:31 2017 -0400</IPSweepStartTime>
        <TestedCommProfilesList>
             <TestedCommProfiles>4657</TestedCommProfiles>
             <TestedCommProfiles>4603</TestedCommProfiles>
             <TestedCommProfiles>4656</TestedCommProfiles>
        </TestedCommProfilesList>
        <ProgressPercentage>100</ProgressPercentage>
        <PingResponseDeviceCount>0</PingResponseDeviceCount>
        <StartTime>Mon Sep 18 15:44:31 2017 -0400</StartTime>
   ```

```
        <CompletionTime>Mon Sep 18 15:44:39 2017 -0400</CompletionTime>
        <IPSweepCompletionTime>Mon Sep 18 15:44:39 2017 -0400</IPSweepCompletionTime>
        <CompletionStatus>SUCCESS</CompletionStatus>
        <ProfileID>6507</ProfileID>
        <IPSweepTotalSuccess>0</IPSweepTotalSuccess>
        <UnreachableDevicesList>
              <UnreachableDevices>10.255.255.255</UnreachableDevices>
              <UnreachableDevices>192.168.0.0</UnreachableDevices>
              <UnreachableDevices>172.31.255.255</UnreachableDevices>
              <UnreachableDevices>192.168.255.255</UnreachableDevices>
              <UnreachableDevices>10.0.0.0</UnreachableDevices>
              <UnreachableDevices>169.254.0.0</UnreachableDevices>
              <UnreachableDevices>169.254.255.255</UnreachableDevices>
              <UnreachableDevices>172.16.0.0</UnreachableDevices>
         </UnreachableDevicesList>
        <NewAccessibleOnlyButDeletedDevicesCount>0</
NewAccessibleOnlyButDeletedDevicesCount>
        <Item version="1.0.0">
             <CreateTime>Mon Sep 18 15:44:31 2017 -0400</CreateTime>
        </Item>
 </DiscoveryInstance>
```

Rediscovery

Rediscovery updates information about existing devices and discovers new devices. When you run a discovery profile that includes existing devices, DX NetOps Performance Management detects the following changes to the device:

- System name
- System contact
- Device type
- Location
- Vendor
- Device description
- Device model

Changes to device attributes can result in changes to the groups and device collections that a device is in. Changes to groups and device collections can potentially add or remove monitoring profiles. Running the discovery profile does not evaluate or update the metric families for the device.For information about how to update metric families for the device, see Rediscover Metric Families.

Rediscover a Device

To update a single monitored device, run rediscovery for that device.

Follow these steps:

1. Select **Administration**, and click the Data Aggregator data source.
2. Click **Monitored Devices** from the Monitored Inventory menu.
3. Select the device.

4. Click **Rediscover**.
   DX NetOps Performance Management runs device discovery and metric family discovery for the device. Changes in the device attributes can take up to 5 minutes to be seen in inventory or dashboards views.

Discovery From Other Data Sources

You can configure whether all new inventory from a data source contributes to the Data Aggregator.

To enable this option, edit a data source and select **Contribute inventory to the Data Aggregator**. If unselected, the existing inventory remains the same, and no new data source inventory contributes to the Data Aggregator.

Automatic synchronization includes only devices that are discovered after you select this option. To discover previously discovered devices, perform a full synchronization of the Data Aggregator. DX NetOps Performance Management creates a discovery profile that includes the IP addresses of the devices. This discovery profile attempts discovery 1 minute after new IP addresses are pushed into the IP domain discovery profile for the Data Aggregator. Otherwise, the discovery profile attempts discovery once per day. For more information, see Configure a Data Source and Synchronize Data Sources.

Discovery and Polling in VMware Environments

DX NetOps Performance Management can discover and monitor your VMware virtual machines and ESX hosts. The discovery and monitoring process for these devices and components differs to accommodate the collection of data from vCenter. You can discover the VMs and ESX Hosts directly with SNMP, and you can collect vCenter data through the vCenter Server Application Insight Module (VCAIM).

DX NetOps Performance Management discovers ESX hosts and virtual machines in the following ways:

- Through ICMP
- Through SNMP, if the servers have an SNMP agent deployed
- Through discovery of a server running systemEdge with the VCAIM

Only one device item is created for each ESX host or virtual machine.

By default, the change detection rate for virtual machines is 15 minutes. The change detection rate for ESX hosts is 24 hours.

> **NOTE**
>
> Any virtual device (Virtual Machine or ESX), discovered with systemEdge is not polled for its vCenter statistics when the device lifecycle state is Retired.

systemEdge Discovery

When discovery runs for a server running systemEdge with the VCAIM, DX NetOps Performance Management uses the following logic during discovery of the vCenter Server:

The VMware ESX Host monitoring profile discovers all ESX hosts, and DX NetOps Performance Management uses the following rules to create devices:

- DX NetOps Performance Management creates SNMP devices for each device with an IP address that is used by another discovered device. The device type is ESX Host and Server.
- DX NetOps Performance Management creates pingable devices with the ESX Host device type in the following situations:
  - A device does not have an IP address.
  - The IP address of a device is not used by another device.

The VMware Virtual Machine monitoring profile discovers all virtual machines, and DX NetOps Performance Management uses the following rules to create devices:

- DX NetOps Performance Management creates SNMP devices for each device with an IP address that is used by another discovered device. The device type is Virtual Machine and Server.
- DX NetOps Performance Management creates pingable devices with the Virtual Machine device type in the following situations:
  - A device does not have an IP address.
  - The IP address of a device is not used by another device.

Groups

Groups determine the data that you see in dashboards when you log in. The group that is applied as a filter to the current dashboard is the group context for that dashboard. When you log in to CA NetOps Portal, the pages reflect the context of your default permission group. You can change the default group for your user account to view data from another group in the dashboards.

Groups are organized into a hierarchical tree structure. The Groups tree helps you define relationships, policies, and dependencies among services, devices, applications, locations, and users within your organization. Organize your group structure according to business and reporting needs. To create a regional structure that represents regions, countries, and locations, use site groups. Use custom groups for other types of organizations, such as customers, services, or technologies.

Threshold profiles apply threshold rules to all items in a group. The group hierarchy requirements for thresholding are probably different from the requirements for reporting. Create separate groups that address both sets of requirements. Consider the different layers of the network and how to create thresholds for components in those layers. For example, you might threshold on CPU, memory, and interface metrics on the core network differently to the distribution layer. Create multiple groups to apply threshold rules appropriately.

Tenants include special types of system groups to maintain separation among customer deployments. Tenants can also contain entire custom grouping structures.

NOTE

The lock icon that appears on a group icon, such as System Groups, indicates that a group cannot be edited.

System Groups

System Groups are read-only groups that are automatically created based on information from data sources. System groups can be viewed, applied as permission groups to user accounts, or copied to custom or site groups.

Inventory Group

The Inventory group includes all managed items that are discovered by all registered data sources. This group also organizes data sources, IP domains, and managed items in subgroups. The Inventory group contains its own system subgroups to organize managed items by their type.

WARNING

DataSource@Hostname groups, such as DataAggregator@mydahost.ca.com, are not synced to data sources. These groups cannot be used for reporting, or as default user groups. Using these groups causes synchronization errors.

The following system groups appear under the Inventory node:

- **All Items**

Includes subgroups of managed items, which are categorized by type.
  - **All Pingable Devices**
    Includes all discovered devices that cannot be contacted using SNMP.
  - **ESX Hosts**
    Includes all VMware servers that host virtual machines.
  - **Interfaces**
    Includes router and switch interfaces from all data sources.
  - **Routers**
    Includes all routers from all data sources.
  - **Servers**
    Includes all servers from all data sources.
  - **CA Application Delivery Analysis**
    Includes all networks that CA Application Delivery Analysis (ADA) has observed. A ADA network consists of an IP address and mask.
  - **Switches**
    Includes switches from all data sources.
  - **Virtual Machines**
    Includes all virtual machines running on all ESX servers.
- **Data Sources**
  Includes all registered data sources. Each data source has a dedicated group under this node. Some data sources have their own system subgroups, which appear when you expand the data source group.

  WARNING

  Some data sources, such as Data Aggregator and Event Manager, do not have groups. The groups are not designed as reporting groups and might not provide data when selected as the context.

- **IP Domains**
  Includes all custom IP domains that are created by the administrator. Also includes the Default Domain, which contains all items that are not explicitly assigned to a custom domain. For more information, see IP Domains.
- **VNA Domains**
  These groups contain hierarchically organized items from DX NetOps Virtual Network Assurance. The structure groups the items into logical reporting groups. Use these groups for reporting. The highest level groups under this node are user configurable in DX NetOps Virtual Network Assurance.

Custom Collections

The Custom Collections group represents the collections of devices. Collections are groupings of devices that are monitored using the rules that are specified in monitoring profiles. The factory collections are not visible in the Groups tree. Collections include only devices.

This group lets you create custom collections. Any subgroup that you add to the Collections group is synchronized to the Data Aggregator as a collection.

Custom Groups

Custom groups create hierarchical levels and organize items into logical relationships within the Groups tree. Custom groups at the top level of the Groups tree represent geographical, topological, or functional divisions within your organization. Lower-level custom groups, or subgroups, typically represent one of the following options:

- Applications
- Devices
- Job functions of IT staff
- Services

Only users that have the "Administer Groups Owned by You" role right can create and edit custom groups, which filter the data in dashboards and views. The group context for a dashboard or view determines the data that is presented.

Custom groups are used to monitor and manage your system. Creating custom groups lets you organize data and assign operator permissions to access data.

You can use group rules to add items to groups automatically as they are discovered. Setting up rules makes it easier to populate and maintain groups. You can also populate custom groups by manually adding specific items, such as routers or interfaces that are logically or geographically related.

Site Groups

Site groups are special custom groups that are based on sites, such as branch offices, or on physical locations, such as regions or cities. Site groups let you create navigation functions within dashboards to present views across all sites. They include a Time Zone and a Business Hours parameter to let you see prioritized data from business-critical times of day.

Site groups also provide a granular context to apply to dashboards. For example, after you create a site group for each of your sites, a single dashboard can individually report on each site. Create a site group for each data center within your enterprise, and for other major infrastructure locations.

Groups for Multi-Tenant Deployments

When the administrator for the Default Tenant creates at least one tenant, features to support multi-tenancy are enabled. Multi-tenant deployments consist of multiple discrete enterprises with IP addresses that might overlap. More groups appear in the Groups tree to let the administrator organize tenant inventories and allocate permissions:

- **Tenants**
  The Tenants group includes all tenants. Tenants are used with IP domains to monitor separate customer environments with a single CA NetOps Portal instance. Each tenant can contain multiple subgroups of items that are not shared among tenants.
  Tenant administrators can create custom groups within their tenant. For the global administrator, tenant groups appear under the Tenant node in the Groups tree.
- **Global Tenant Groups**
  Global Tenant Groups contain groups of items that help the global administrator manage tenant environments. These groups let the administrator visualize and organize shared items, which are not explicitly associated with a tenant IP domain. The groups that allocate access to data from shared items appear under each tenant.
  When you expand the top-level Inventory group, the following group appears in a multi-tenant deployment:
- **IP Domains**
  Includes all custom IP domains that are used to associate managed items with tenants. Also includes the Default Domain, which contains all items that are not explicitly assigned to a custom domain. For more information, see IP Domains.

In a multi-tenant deployment, each tenant has its own groups. Tenant users cannot see items outside of the tenant group unless the global administrator grants access with Service Provider groups.

- **Groups (Tenant)**
  Lets the global administrator or tenant administrator create custom groups. Select this node to enable the Add Group button.
- **Inventory (Tenant)**
  Includes all managed items that are associated with the tenant IP domains. Items from all registered data sources might appear in this group.

Each tenant also has the following system subgroups in its Inventory group:

- **IP Domains**

The IP Domains subgroup represents the IP domains that are associated with this tenant. Any managed items that have been discovered are associated with this tenant through its IP domains. To see the managed items of the tenant, click a tenant IP domain in the Groups tree.

- **Global Tenant Groups**
  The Global Tenant Groups include groups that the global administrator has populated with shared items that this tenant can access. Use these groups to grant access to data from shared devices to selected tenant user accounts.
  For example, a router that the service provider owns handles traffic from multiple tenant domains. Using Service Provider Defined groups, the global administrator can allocate tenant access to data from that router. The tenant can then independently monitor and verify system performance.
- **Global Tenant Items**
  Items that are not explicitly associated with a tenant IP domain are automatically placed in the Service Provider Items group. The global administrator can place these items into Service Provider Defined Groups to allocate tenant access to data from shared items.

Device Collections

Device collections are logical groupings of monitored devices. Custom device collections provide granular control over polling. Most deployment require custom device collections. Collections include *only* devices.

Custom Device Collections

The factory device collections are mostly for use in a lab or in a demo setting. In a real production deployment, the best practice is to design and configure custom device collections to have granular control over what is being polled. For example, disable polling of a device by disassociating the device from any other device collection that has monitoring profiles that are associated to it. If you are associating monitoring profiles to the factory device collections (such as All Routers), then you cannot stop a single device from being polled. Devices cannot be removed from factory device collections, so you disassociate the monitoring profiles instead to disable polling. You then create custom device collections that contain devices that you want to apply the same polling policy to. Associate monitoring profiles (or custom monitoring profiles) to those custom device collections to begin polling.

Create custom device collections in NetOps Portal, then either synchronize them immediately with Data Aggregator, or wait for the automatic synchronization. Upon synchronization, Data Aggregator creates the corresponding device collections for use in monitoring devices.

Access the Monitoring Configuration menu to see a list of device collections and to see the monitoring profiles that are applied to each. Administrators can view the device collections for the tenant they are administering. A tenant administrator can view its own list of device collections.

> **NOTE**
>
> Only users with the Administrator role can create or edit collections because collections control polling. Collections can significantly impact system load and performance.

Consider the following best practices for organizing devices into collections for monitoring:

- Create custom collections that match the monitoring requirements in the environment.
  - Consider the different layers of the network, access, distribution, and core. Devices in different layers might require different levels of monitoring.
  - Consider which technologies and metric families are required. Metric families that would be applied to all devices, such as CPU and memory, apply to broad collections. Targeted monitoring, such as QoS and IPSLA, apply to limited collections.
- Create collections that enable the flexibility to break out monitoring.

- Some devices are included in multiple collections so that specific metric families are polled at different rates.
- Devices in different collections have different filtering criteria.
- Different monitoring requirements depending on importance of device

Factory Device Collections

Several factory (out-of-the-box) device collections are provided to get data into your system quickly and test the product. Devices that are detected during discovery are added to these device collections depending on their type. For example, routers are added to the factory All Routers device collection. Upon synchronization, these monitored devices are added to the corresponding device collections in NetOps Portal.

Factory monitoring profiles are then automatically applied to factory device collections, allowing data to be collected immediately without any intervention on your part. Once this data has been collected, you can run reports on the data to gain a better understanding of your network.

The following factory device collections are provided:

> **NOTE**
> The factory device collections are mostly for use in a lab or in a demo setting. In a real production deployment, the best practice is to design and configure custom device collections to have granular control and optimal data collection.

Access the Monitoring Configuration menu to see a list of device collections and to see the monitoring profiles that are applied to each. Administrators can view the device collections for the tenant they are administering. A tenant administrator can view its own list of device collections.

All Devices

The All Devices device collection is a factory device collection. Manageable and pingable devices that are detected during a discovery are automatically placed into the All Devices device collection. Inaccessible devices are not included in the All Devices device collection.

> **WARNING**
> Do not associate monitoring profiles with the All Devices device collection. Doing so can cause extra SNMP requests being made to pingable-only devices, and can result in sporadic metric family support.

All Routers

The All Routers device collection is a factory device collection. Routers that are detected during a discovery are automatically placed into the All Routers device collection.

> **NOTE**
> Routers can appear in both the All Routers device collection and the All Switches device collection.

All Servers

The All Servers device collection is a factory device collection. Physical and virtual servers (hosts) that are detected during a discovery are automatically placed into the All Servers device collection. Network devices such as routers and switches are not included in the All Servers device collection.

All Switches

The All Switches device collection is a factory device collection. Switches that are detected during a discovery are automatically placed into the All Switches device collection.

> **NOTE**
> Switches can appear in both the All Routers device collection and the All Switches device collection.

All Manageable Devices

The All Manageable Devices device collection is a factory collection. Manageable devices collect advanced performance statistics and are monitored with a protocol such as SNMP. Manageable devices that are detected during a discovery are automatically placed into the All Manageable Devices device collection.

Pingable devices can only be monitored for availability and do not provide any additional performance metrics. Therefore, pingable devices are not included in the All Manageable Devices device collection.

Note: Manageable devices can appear in both the All Devices device collection and the All Manageable Devices device collection.

All ESX Hosts

The All ESX Hosts device collection is a factory device collection. ESX hosts that are detected during discovery are placed into the All ESX Hosts device collection automatically.

All Virtual Machines

The All Virtual Machines device collection is a factory device collection. VMware virtual machines that are detected during discovery are placed into the All Virtual Machines device collection automatically.

All VMware vCenters

The All VMware vCenters device collection is a factory device collection. All servers that are running systemEdge with the VCAIM that are detected during discovery are placed into the All VMware vCenters device collection automatically.

Manage Groups

Before you create a group, consider the types of access permissions that users require to perform their monitoring duties. If you are deploying business hours, create a site group. Site groups are custom groups that are based on physical locations, such as a city, region, office, or campus. They include Time Zone and Business Hours parameters to let you precisely filter data from business-critical times of day.

> **NOTE**
> You can apply business hours filters only in whole hour increments. Only site groups that have time zones with only whole hour offsets are available for selection.

Create groups under the **All Groups** node in the Groups tree, or within an existing custom or site group. You cannot add groups to system groups, which appear locked in the Groups tree. However, while the Collections group appears locked, it can contain child groups, but cannot be modified. To keep reporting times within reasonable limits, a maximum of 2000 child groups is recommended for any parent group.

By default, only users with the Administrator or Tenant Administrator role can administer groups that other users create. To administer groups that other users created, you require the Administer Groups Owned by You and Others role right. With this role right, you can modify child groups that other users created if you have the rights to administer the parent group.

> **WARNING**
> If you create a group for a data aggregator data source, limit the group membership to 10,000 items, including the children of managed items. Limiting the number of items keeps reporting times within reasonable limits.

> **NOTE**
> For optimal performance, collapse the **Items** section until you need to manage items. Likewise, collapse each managed item type until you need to manage a specific item type.

Create or Edit a Group

Follow these steps:

1. Log in as an Administrator or as a user with the My Custom Groups functionality enabled.
2. Do one of the following tasks:
   - Hover over **Administration**, and click **Group Settings: Groups**.
   - Click the name of your user account in the upper-right corner, and then click **My Custom Groups**.

     NOTE

     The groups that you can see are groups that the administrator selected for you, based on your responsibilities. The custom groups that the administrator created cannot be edited within the My Custom Groups interface. These read-only groups appear as group references; their properties tab shows a path to the original group.
3. Do one of the following tasks:
   - To add a group, select a location for the new group in the **Groups** tree, and click **Add Group**.
   - To edit a group, select the group from the **Groups** tree.
4. Specify or edit the values for the following parameters:
   - **Group Name**
     Use a strategic naming convention. You can use all special characters in the group name except the vertical bar (|), the forward slash (/), and the backslash (\).

     NOTE
     Groups that are synchronized from DX NetOps Spectrum retain restricted characters except the backslash (\). This character is removed from synchronized group names.
   - To create a custom group, select **Custom** from the **Group Type** list. To create a site group, select **Site**.
     To create a site group, optionally specify the following parameters:
     - Latitude
     - Longitude
     - Location
     - Elevation
     - Time zone
     - Business hours
   - **Description**
5. Confirm the setting for the following parameter:
   - **Include the children of managed items**
     Adds the children of managed items automatically when the items are added to this group. If you disable this option and you add a router to the group, the interfaces on that router are not included. Therefore, their data is not visible in drilldown views.
     Default: Selected
6. Click **Save**.
   The new group appears in the Groups tree. To configure views or on-demand reports with the group, wait for the group to be synchronized to the data sources.
   The group is empty until you add items. You have two options for adding items to a custom group:
   - Manually populate the group by adding items in the **Manage Groups** interface.
   - Create rules to manage the group membership.

Add Managed Items to a Group Manually

To populate custom groups manually, add managed items to groups.

NOTE
System groups with a lock symbol in the **Groups** tree are read-only. You cannot add items to or remove items from system groups. Custom groups that are created by the administrator are also locked.

Follow these steps:

1. Select the group to which you want to add managed items from the **Groups** tree.
   Managed items that have already been added to this group appear in the right pane.

   NOTE
   Managed items that are manually added directly to a group appear as **Direct Items** in the **Group Properties** pane. Managed items that are added to a group as children of a managed item are **Inherited Items** in the Group Properties.
2. Scroll to the managed item type in the **Items** section.
   The available items depend on the item type, the data sources that are registered, and the items that are discovered. To see more pages of items, click the links below the list. You can also search for an item in the list using the Quick Filter.
3. Click to add a managed item.
4. Select items by selecting their checkboxes. To select all items on a page, select the checkbox in the table header row.
5. Click **Add**, and then **Save**.
   The new items are added to the group.

View Group Membership

View a sortable list of all items that have been added to a system group or custom group on the **Manage Groups** page. You can verify group rules, or whether custom scripts have created and populated groups appropriately. You can also view a list of items in a selected group.

Use filters to select the types of items that you want to see, such as all items that were added to the group manually. By default, the list on the Items tab only shows items that are added directly to the group. The items are added either manually or by the application of a rule (Direct Items membership). If you report on a dashboard in the context of a group, all items in the subgroups of the group appear in the dashboard. The items in the subgroups do not appear on the **Group Administration** page.

Follow these steps:

1. Select the group for which you want to view membership details from the **Groups** tree.
2. Scroll to the **Items** section.
3. To specify the items to display, select a filter from the **Show Items** drop-down list.
   The following membership types are applicable, depending on the type of group that you selected:
   - **Direct Items**
     Includes the items that were added directly to the group, either manually or by the application of a rule. You can add or remove items only when **Direct Items** is selected. The **Added By** column indicates whether the item was added manually or by a group rule.
   - **Direct and Inherited Items**
     Includes all items in the group, whether they were added directly or inherited as the children of items that were added directly.
     The checkbox next to **Options** on the Properties tab determines the ability to inherit items. Excluded items are not inherited.
   - **Inherited Items**
     Includes only the children of managed items in the group. When you enable inheritance for this group and add a router, all interfaces that are associated with the router are added to the group.
     You can remove inherited items only by removing the parent item.
   - **Excluded**

Items in this list are not added to the group by group rules. To prevent groups rules from adding an item to the group, add the item to the **Excluded** list.
This list also includes manually-deleted items if a group rule originally added that item. To add an excluded item to the group, remove the item from the **Excluded** list, and run group rules.

4. Select an item type from the list.
   A list of all items of the selected type that are included in the group appear.

Manage Group References

A group reference is a copy of another group. Any group that is referenced in the Groups tree has a **References** section at the bottom of the page.

To view and remove references to that group, scroll to the **References** section.

To delete group references, scroll to the **References** section for the original group. While deleting a group that has been referenced deletes all of its references, deleting a group reference does not affect the original group. Deleting a subgroup that is a reference does not affect the original group or its parent group. To prevent problems when deleting a group that contains subgroup references, delete all the references before deleting the group.

Delete Groups

The global administrator can delete custom groups, including groups that belong to any tenants. A tenant administrator can also delete custom groups that belong to that tenant definition. The subgroups of the deleted group are also deleted. You cannot delete system groups. Likewise, you cannot delete the Default Domain group.

Manage Subgroups

After you have created custom groups, you can populate them by adding subgroups that contain managed items.

Add Subgroups to a Group

To create a hierarchical structure, you can create new groups within custom groups that you previously created. You can also add an existing group to another group to create a subgroup.

Follow these steps:

1. Navigate to the **Manage Groups** page.
   The current groups appear in a tree structure.
2. Right-click the parent group, and select **Add Group**.
   The Add Group dialog appears.
3. Specify the parameters.
   The Groups tree appears.
4. Click **Save**.
   The existing group and all of its subgroups are added to the selected parent group as reference groups.

Copy a Subgroup into a Group

You can copy system groups or other custom groups into high-level groups to create subgroups. When you copy a group, you create a group reference, which cannot be modified but can be removed. When you copy a group, the original group displays the References section at the bottom of the page. Scroll to the **References** section to view the locations where copies of the group have been placed. Any changes that you make to the original group are reflected in all the references of the group. Removing a group also deletes all of its references.

Follow these steps:

1. Navigate to the **Manage Groups** page.
   The current groups appear in a tree structure.
2. Select the group that you want to copy. All its subgroups are automatically included in the selection.
3. Right-click, and select **Copy Group**.
4. Select the parent group where you want to add the subgroup.
5. Right-click, and select **Paste Group**.
   The existing group and all its subgroups are copied to the selected parent group.
   The group icons indicate that they are read-only group references.

Manage Group Rules

Use rules to keep custom groups up-to-date when systems and networks change. Newly discovered items that meet rule specifications are added to groups. Similarly, if the items do not meet rule requirements, or if the items are no longer monitored, items are removed. After you create a rule, you can modify it by deleting filters or adding subrules.

> **NOTE**
> If you remove an item from a group manually, the group rule cannot add the item to the group again.

In this article:

The following default restrictions apply to group rules:

- Maximum 50 rules per group
- Maximum 50 conditions per rule
- Maximum 50 'OR' matches in a condition
- Maximum 20 'AND' subrules

Create Group Rules

Follow these steps:

1. Log in as an Administrator or as a user with the My Custom Groups functionality enabled.
2. Do one of the following tasks:
   – Hover over **Administration**, and click **Group Settings: Groups**.
   – Click the name of your user account in the upper-right corner and click **My Custom Groups**.
   The My Custom Groups page shows a tree view of group structure and a tabbed view of group properties.
3. Select the group to which you want to add managed items.
   Items that have already been added to this group appear in the right pane.
4. Scroll to the **Rules** section, and then click **New Rule**.
5. Type a name for the rule.
6. Select the type of managed item that you would like to add to the group from the **Add** drop-down list.
   The list might include item types that have not been synchronized to your system. These item types let you create rules that are applied later when you discover these items. To view the existing item types on your system, see the Inventory menu.
7. Click **Add Condition**.
   A row of drop-down lists and fields appears.

   > **NOTE**
   > By default, a condition that filters added items to your top-level permission group exists in the list of conditions. You can adjust the filter to a group of your choice. Filter to the group with the fewest items to improve rule processing.
8. Select a method for identifying managed items. For example, select **Device Type**.

The remaining lists are updated to match the type of selected item.

NOTE

If you select a string field like Device Context Type, the 'is equal to' operator returns only *exact* string matches (for example, '`server,WirelessController` '). Use the 'is like' operator to return matches on a portion of the string (for example, '`server,WirelessController` ', '`device,WirelessController` ', and '`router,WirelessController` '). Do not use spaces.

9. Select an operator from the second list. For example, select 'is equal to'.

   WARNING
   Use CIDR notation for the IP addresses that you specify for the 'is in subnet' and 'is not in subnet' options. Use dot-decimal notation for the IP addresses that you specify for the 'is between' and 'is not between' options.

10. (Optional) Enter a text string to match in the remaining condition field. For example, to add all routers and servers in the Southwest region, enter a string with the appropriate naming convention, such as "sw*".

    NOTE
    The * wildcard character is accepted in this field for a multicharacter match.

    WARNING
    Some methods have a limited list of acceptable condition values. For example, when the method for identifying managed items is device alarm state, the text value must match one of the actual device alarm states. Acceptable values are discussed further on this page.

11. (Optional) To add 'OR' matches, click + at the end of the condition.
12. (Optional) To add 'AND' matches, click **Add Condition**.
13. Click **Save**.
14. Click **Preview Results** to confirm that the new rule includes the correct items.
    The results are shown in the Preview section. You can scroll to each item type to view the specific items that were added.
15. (Optional) Click **New Rule** to add other item types to the group.
    Each item type requires its own rule.
16. When you have finished creating rules, click the following options:
    - **Save**
      Saves the rules without running them. The group is populated during the next global synchronization, which occurs approximately every 5 minutes.
    - **Run Rules**
      Populates the group immediately.

Edit Group Rules

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Navigate to the **Manage Groups** page.
   The current groups appear in a tree structure.
3. Expand the **All Groups** node in the Groups tree.
4. Select the group that contains the rule that you want to modify.
5. Scroll to the **Rules** section.
6. Click a rule in the list.
7. Click **Edit Rule**.
8. Edit existing filters, add filters or subrules, or remove filters or subrules as needed.
9. Click **Save**.
10. Click **Preview Results** to confirm that the modified rule adds the appropriate items the group.

11. When you have finished editing the rules, click the following options:
    - **Save**
      Saves the rules without running them. The group is populated during the next global synchronization. Global synchronization occurs approximately every 5 minutes.
    - **Run Rules**
      Populates the group immediately.

Delete Group Rules

You can delete the rules that you have created. Deleting a group rule removes any items in the group to which the rule is applied immediately. The items are not deleted from the inventory. They are no longer available on the Items tab for the affected group.

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Navigate to the **Manage Groups** page.
   The current groups appear in a tree structure.
3. Select the group with the rule that you want to delete in the Groups tree.
4. Scroll to the **Rules** section.
5. Click a rule in the list.
6. Click **Remove Rule**.
7. Click **Yes**.
   The rule is no longer applied to the group.

View Groups Change Log

Changes that are made to groups are logged in the Groups Change Log. You can use this log to troubleshoot unwanted changes. The log shows the username of the user who made the change, the time, and the nature of the change. The log provides a high-level summary of changes without specific details, such as the old name of a group when the name is changed. To view the Groups Change Log, a user needs the View Groups Change Log role right. By default, the Administrator and Tenant Administrator have this role right.

To view the Groups Change Log, click **Administration**, **Groups Change Log**. The Owner column specifies the username of the group creator. The Tenant column specifies the tenant under which the group was created. Customize the groups change log as follows:

- To change the Group context, click **[change]** next to 'All Groups'.
- To change the time selection, click **[change]** next to 'Last Hour'.
- To enable or disable tracking changes for groups, or to set the tracking duration, reach out to CA Support.

Organize Group Items Geographically

As an IT Manager, you have administrator-level access to NetOps Portal. You have registered a data source to monitor infrastructure usage, status, and performance enterprise-wide. You need to set up NetOps Portal groups to organize infrastructure monitoring and reporting. For example, place routers and switches in groups according to their data centers. Group managed items according to their country, region, state, or city.

Geographical Grouping Strategy

Consider a global enterprise, Mod-Lex Corporation, with the following major branch offices:

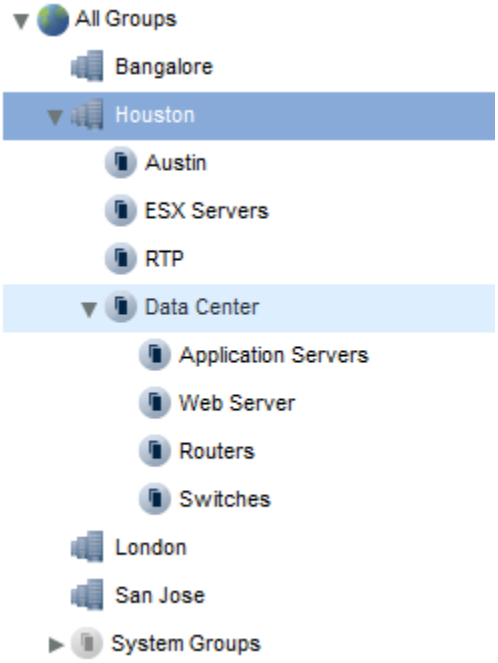
- Bangalore
- Houston, TX
- London
- San Jose, CA

Mod-Lex has a significant data center at each of these offices. Data centers support branch office operations and smaller Sales offices nearby.

Mod-Lex also has small branch offices in Austin, TX and Research Triangle Park, NC. The Austin office does not have a dedicated data center. Its three application servers are connected by a T3 line to the Houston data center. The RTP office is also connected to the Houston data center. All of its application servers are virtual machines, running on an ESX server in Houston.

Most IT staff are located at Mod-Lex corporate headquarters in London. The staff have user accounts for NetOps Portal, most with user-level access. The NetOps Portal server is running in the data center in London. Dedicated IT staff are assigned to each of the major data centers. Staff charged with monitoring Houston are also responsible for Austin and RTP.

Here is an example of a grouping strategy that takes geography and logical network structure into account:



To monitor the Research Triangle Park (RTP) site effectively, place a copy of the 'Houston\ESX Servers' group into the RTP group. Metrics from the critical application server are then reflected at the RTP group level. You can ensure that a user is monitoring that group.

Bangalore, Houston, London, and San Jose are site groups, which can contain subgroups. The Houston Data Center group contains subgroups to break out different types of infrastructure items to be monitored separately. Individual users can be granted access to data based on entire sites or on subgroups.

For example, the Network Managers for Houston, Austin, and RTP can access the entire Houston site group, or they can access the Data Center subgroup. The Austin Network Manager also needs access to the Austin group. Ensure that any Austin-specific items are added to that group. In this example, the RTP site does not have a dedicated Network Manager.

Create a Custom Group

NetOps Portal site groups are useful in a geographical grouping strategy. Site groups contain items and subgroups of items that are grouped by location. Adding site groups to other custom groups in your tree structure allows you to build geographically and logically organized reports.

Before you create groups, consider the types of access permissions that operators require to perform their monitoring duties.
Create the site groups:

- London
- San Jose
- Houston
- Bangalore

Create the custom groups:

- Austin
- RTP

To create the grouping structure, copy the Austin and RTP groups into the Houston site group as subgroups. Problems that affect users in Austin or Research Triangle Park are visible in dashboard views for the Houston site group. You can drill down into event or performance information for those specific subgroups. You can quickly pinpoint the source of the issue.

After you have created custom groups, you can populate groups by adding subgroups that contain managed items. When you copy a group, you create a group reference. You cannot modify a group reference, but you can remove it. Groups that have been copied display an extra tab in the right pane. Any changes that you make to the original group are reflected in all of its references of the group. Removing a group also deletes all of its references.

Add Managed Items to a Group

Add managed items to the subgroups in the Austin and RTP custom groups. For the Austin subgroups, add the three application servers. For the RTP custom groups, add the virtual machines that run on the ESX server in Houston.

Use Group Rules to Manage Items

Use group rules to keep the Austin and RTP groups up-to-date when systems and networks change. Newly discovered items that meet rule specifications are added to groups. Similarly, if the items do not meet rule requirements, or the items are no longer monitored, items are removed.

Mod-Lex consistently uses a geographical prefix to identify the location of devices and servers as they are purchased and brought into service. For example, the main router that is dedicated to ESX servers in Houston is named 'hou-esx-rtr'. This naming convention lets us use group rules to group items automatically.

Create a rule to populate the following parent group: 'Houston\Data Center\Application Servers'. Select the parent group in the group hierarchy to add it as a condition automatically. Add a second condition that prevents routers and switches with the 'hou' prefix in their names from being placed in the Application Servers group.

Use Groups and Group Rules to Organize Devices

You want to organize your devices into logical groups that Data Aggregator can monitor. Create a group that lets you discover and monitor your end-user switches separately. You want to monitor those switches separately because the uplink interfaces on those end-user switches have a significant impact on your network. Separate monitoring lets you report on the inventory that is related to that device collection for better troubleshooting. This scenario shows how REST web services can be used to configure device groups in NetOps Portal and Data Aggregator. This configuration

also provides the framework to write proprietary automation scripts that integrate with your third-party or proprietary management system.

> **NOTE**
> This workflow does not explain the configuration of monitoring profiles in Data Aggregator, which is done after group configuration is complete. Monitoring profiles are associated with device collections and are used to keep discovered inventory up-to-date.

To execute web service calls manually, use a REST client editor or an HTTP tool that sends requests and gets responses. In this scenario, we refer to the REST client editor to perform these procedures.

> **NOTE**
> To automate, write your own application or script that leverages the web services that are described in this documentation.

To create custom groups and group rules for organizing devices and component items using REST web services, follow these steps:

> **NOTE**
> Perform steps 1-2 using NetOps Portal REST web services. Perform step 3 using the Data Aggregator REST web services.

Create a Custom Group and Group Rules

This scenario involves creating a custom group for end-user switches only. Factory (out-of-the-box) device collections do not exist for specific switches in Data Aggregator. Instead, there is a factory device collection for *all* switches, named "All Switches". Since your uplink interfaces have significant performance impact in your network, you want to monitor these specific switches for uplink interfaces separately for better troubleshooting.

You first create a custom monitored group in NetOps Portal. Upon synchronization, Data Aggregator creates a corresponding device collection for use in device monitoring.

Add rules to your custom group so that the corresponding the device collection is kept up-to-date with discovered end-user switches. Newly discovered devices that meet rule specifications are added to device collections. Similarly, if they do not meet rule requirements or they are no longer monitored, devices are not included or removed. For this scenario, we assume that your end-user switches are easily identifiable with the word "EndUser" at the end of their descriptions.

Follow these steps:

1. Open a REST client editor that has a connection to the NetOps Portal web server.
2. Set the Content-type to application/xml.
3. Provide a valid Username and Password in the request header for a user account that has Administrator access to NetOps Portal.
4. Enter the Body text in a REST client and modify the attributes as needed:
   - **Group Name**
     Specifies a name for the group. For this scenario, type the name **My End-User Switches**.

     > **NOTE**
     > Do not use the following special characters in group names: /&\,%.
   - **Group Tree Path**
     Specifies the path where the monitored group is created. Type the path **All Groups/Collections,** which is required for the device collection to show up in the Data Aggregator administration UI.
   - **Rules**
     Specifies the rules that automatically group the devices. In this case, create a rule that groups the end-user switches that have the value "EndUser" at the end of their descriptions.
   - **type**

Indicates the type of group.

– **inherit**
Indicates whether the group includes child items of group members. In this case, set the "inherit" attribute to **true** so that the device interfaces become group members when the devices are added to the group.

Example:

```
<GroupTree path="/All Groups/Collections">
 <Group inherit="true" name="My End-User Switches" desc="" type="user group">
  <Rules allowDeletes="true" saveRules="true">
   <Rule add="Device" name="Add Devices">
    <Match>
     <Compare readOnly="true" using="MEMBER_OF">
      <Property name="ItemID" type="Device"/>
      <Value reference="/All Groups">1</Value>
     </Compare>
     <Compare readOnly="false" using="LIKE">
      <Property name="DisplayName" type="Device"/>
      <ValueList>
       <Value>EndUser</Value>
      </ValueList>
     </Compare>
    </Match>
   </Rule>
  </Rules>
 </Group>
</GroupTree>
```

5. POST the following URL:
   `POST http://pc_host:8181/pc/center/webservice/groups/false/true`
   The 'false' and 'true' values refer to the following parameters:
   – **useIds**
   Indicates that the groupId parameter is used to identify the group. In this example, the XML does not contain a group ID, so the value is 'false'.
   – **allowDeletes**
   Enables deletion of the group that you are creating.
   The My End-User Switches device collection is created. After synchronization, Data Aggregator adds all discovered end-user switches automatically to the My End-User Switches device collection.

Verify the Group Was Added to the Group Tree

Verify that the group was added to the group tree.

Follow these steps:

1. Enter the following URL:
   http://PC_host:8181/pc/center/webservice/groups/groupPath/All%20Groups%2FCollections
2. Look for the group "My End-User Switches".
   This group change in the web service corresponds to the group change in the NetOps Portal user interface.

Verify the Device Collection Appears in Data Aggregator

After automatic synchronization occurs between NetOps Portal and Data Aggregator, verify that the new device collection appears in Data Aggregator.

Follow these steps:

1. Enter the following URL: `http://da_host:8581/rest/groups`
2. Look for the device collection (group) "My End-user Switches".
   This change in the web service also appears on the Data Aggregator user interface administration pages.

You have successfully configured a custom group and group rules. You can proceed to create your own automation script with your third-party or proprietary software to populate information in Data Aggregator.

Configure Monitoring Profiles

The monitoring profile determines which metric families are collected for all devices in associated device collections and how often polling occurs. The metric families in the monitoring profiles determine which components are added to the system for devices in assigned device collections and which metrics are collected for those components.

Monitoring profiles are global across all tenants.

The relationship of monitoring profiles to device collections governs monitoring. Monitoring can be triggered in the following ways:

- A monitoring profile is associated with a device collection.
- A device is added to a device collection that has an associated monitoring profile.
- A metric family is added to a monitoring profile with an associated device collection.
- A new vendor certification is added for an existing metric family that is polled in a monitoring profile.
- The vendor certification priority changes for a metric family.
- A change occurs on a device. If **Automatically Update Metric Families** is selected, the change to monitoring occurs automatically according to the change detection rate. If **Automatically Update Metric Families** is cleared, the change to monitoring occurs when you click **Update Metric Family** on the **Polled Metric Families** tab of the **Monitored Devices** view.

Monitoring Profile Best Practices

Consider the following best practices for creating monitoring profiles:

- Before you configure monitoring profiles, see Determine Monitoring Requirements.
- Copy default monitoring profiles to create customer-specific monitoring profiles. Remove the collections that are applied to the default monitoring profiles. This model makes it easier to customize and manage device polling.

  NOTE

  Do not modify the DA Health Fast, Normal, and Slow monitoring profiles. These profiles are used for self-monitoring of the DX NetOps Performance Management components.
- For monitoring flexibility, use multiple monitoring profiles. Do not add all metric families that you monitor in your network to a single monitoring profile.
- Some metric families, such as CPU and Memory, apply broadly to all devices. You can apply a monitoring profile with these metric families to all-encompassing collections, such as All Routers or All Managed Devices.

- Monitoring profiles control the poll rate. To poll the same metric family on different devices at different rates, create monitoring profiles with different poll rates. Apply the faster poll rate to a collection that includes only the devices that require fast polling.
- Monitoring profiles control filtering. If different filtering criteria is required for different sets of devices, create a monitoring profile for each set of requirements.
- Apply only metric families that are applicable to the items in the associated collections. For example, do not apply a monitoring profile that contains the VMWare metric families to a collection of routers. Unnecessary metrics add processing to the Data Aggregator at every change detection period.

Create Monitoring Profiles

To specify which metrics to gather from which devices and components, create monitoring profiles. For example, create a custom Systems monitoring profile and configure the profile to poll resource utilization counters only from SNMP.

Monitoring profiles are available in all tenant work spaces. For example, create a "Service Router Monitoring" monitoring profile and use the profile for all tenants. You do not have to create a *separate* "Service Router Monitoring" monitoring profile for each tenant. Device collections that are associated with the monitoring profiles are tenant-scoped.

TIP

To create basic monitoring profiles, copy the out of the box monitoring profiles. Custom profiles provide flexibility.

Only Administrator users in the default tenant can modify monitoring profiles. In an MSP environment, all changes to monitoring profiles apply to all tenants.

Follow these steps:

1. Go to **Administration**, and click the Data Aggregator data source.
2. Expand **Monitoring Configuration**, and then click **Monitoring Profiles**.
3. Click **New**.
   To use an existing profile as a template, select the profile, and then click **Copy**. The copy function does not copy event rules.
4. Specify a unique profile name and description.
5. Select a poll rate.
   – Polling occurs at the fastest rate for all the monitoring profiles that are associated with a device collection.
   – Changes to the poll rate take up to two cycles to apply.
   – When you use the 60-minute rate for an existing device, a **No Data To Display** message appears in views with a time range of Last Hour. If you change the dashboard setting to a prior hour, you can see earlier data. However, the view does not display the latest data until the new poll cycle completes.

   WARNING
   One-minute polling on large device collections or devices with many components can affect the performance of the system.

   NOTE
   To poll critical interfaces at a faster rate, use a separate monitoring profile with a filter.
   For more information, see Poll Critical Interfaces Faster than Non-critical Interfaces.
6. (Optional) To detect when the components on a device change, select **Enable Change Detection**. This option is enabled by default. If you select this option, configure the behavior:
   – Specify the change detection rate. The change detection rate determines how often the system identifies changes to component items on monitored devices. If a device is associated with multiple monitoring profiles, change detection occurs as the fastest specified rate. To determine the configuration changes, DX NetOps Performance Management uses reconciliation algorithm that is defined in the metric family.

NOTE
Consider how frequently the monitored components on the devices are likely to change. Avoid setting change detection rates that are more frequent than necessary. Some metrics, such as availability, never or rarely change. Because change detection uses some system resources, do not enable change detection for such metrics.

– (Optional) To automatically start monitoring newly detected components, select **Automatically Update Metric Families**. To manually control when changes to monitoring occur, clear this option.

NOTE
Clearing this option does not automatically apply the changes to monitoring. The Events Display dashboard displays configuration events for the detected changes. To apply the changes to the devices, go to the Data Aggregator administration menu, **Monitored Devices** view, and open the **Polled Metric Families** tab. Select the appropriate metric family, and click **Update Metric Family**.

When monitoring changes are applied to devices, components that are no longer detected on the devices are marked "Not Present".

7. Assign metric families to the **Selected Metric Families** list.

TIP
By default, all metrics in each selected metric family are collected. To select a limited set of metrics, see Configure Metric Filtering.

8. Click **Save**.
The monitoring profile is applied to any assigned collections during the next poll cycle. To start monitoring with a new monitoring profile, assign the profile to device collections.

Add Event Rules to Monitoring Profiles

Event rules set conditions to trigger Threshold Violation events. Each rule is based on a single metric family and contains criteria to raise or clear the violation. The event rules apply to each component on all devices in collections that are assigned to the monitoring profile.

You cannot add event rules to factory monitoring profiles. Only Administrator users in the default tenant can modify event rules on monitoring profiles.

TIP
For best performance and granular control, configure event rules on threshold profiles instead of monitoring profiles. For more information, see Configure Threshold Profiles.

Follow these steps:

1. Select a custom monitoring profile.
2. Click the **Event Rules** tab.
3. Click **New** to create a rule, or click **Edit** to modify an existing rule.
For more information about how to create event rules, see Configure Threshold Profiles.
Events are raised and cleared when the devices in associated collections satisfy the event rule conditions.

Configure Monitoring Profile Filters

Monitoring profile filters specify criteria that governs which components are monitored. Only the component items that match the filter criteria are polled for the associated metric family. Filtering limits SNMP traffic and ensures that the system monitors only relevant components. The filters of each monitoring profile are assessed independently.

WARNING
DX NetOps Performance Management monitors device components if any of the monitored components pass the filter criteria of any associated monitoring profile.

NOTE
Monitoring profile filters apply after discovery. The system creates the component items but does not send SNMP requests to monitor the items. Monitored components are reassessed according to the change detection interval. *Vendor certification filters* prevent the creation of component items that do not match the filter criteria. Vendor certification filters might not recognize changes at the component level. Both filter types reduce SNMP traffic to the same level. Use vendor certification filters only when the monitoring profile filter cannot filter component item.

Example: Multi-Rate Polling

You want to monitor all interfaces with 5-minute polling, and one type of interface with 1-minute polling. One monitoring profile has a poll rate of 5 minutes. This monitoring profile is associated with a device collection. A second monitoring profile has a poll rate of 1 minute. The interface metric family on that profile has a filter that specifies the type of interface to poll at a 1-minute interval. This monitoring profile is also associated with the same device collection. DX NetOps Performance Management polls the specified interface type at a 1-minute rate and all other interfaces at a 5-minute rate.

Example: How and When Filters Are Combined

You want to apply multiple filter profiles to multiple devices. You want to exclude an attribute from one of the filters. However, the product Poll filters are not *exclusion* filters. They are *inclusion* filters. The product behavior is to poll as much as you can, as fast as you can. So, if two filter criteria conflict, the product *includes* interfaces in the polling rather than *exclude* them. The following example explains how filtering works and how you can achieve your goal.
For example, you have two filters with the following configuration:

- **Filter 1**:
  (Description contains "Virtual-Access" or Description contains "Tunnel")
- **Filter 2**:
  Name does not contain "Internal"

This situation means that Filter 1 and Filter 2 are OR'ed. Only components that meet the previously mentioned criteria are polled.
However, if you want to *exclude* any interfaces that contain "Internal" in the Name attribute, add that filter criteria to each monitoring profile as an AND. Filter 1 should appear as follows:

- **Filter 1**:
  (Description contains "Virtual-Access" or Description contains "Tunnel") AND (Name does not contain "Internal)

When you have the same devices that are associated to two monitoring profiles, the two profiles must have filter criteria. In this scenario, effectively, you combine the two filters by stating exclusion criteria in both. Otherwise, the monitoring profile without the filter causes all components on the device to be polled. Therefore, Filter 2 should appear as follows:

- **Filter 2:**
  (Description contains "Virtual-Access" or Description contains "Tunnel") AND (Name does not contain "Internal)

Configure Profile Filters

Only Administrator users in the default tenant can add or edit monitoring profile filters.

Follow these steps:

1. Select a custom monitoring profile.
2. In the Metric Families tab, select a metric family.
3. Click **Edit Filter**.
4. Click the existing AND condition, then click a logic button, such as New AND or New OR.
5. Select an attribute and an operation, and specify a value for the filter condition.
6. Click **Add Condition**.
7. Create all required filter conditions.

8. Click **Save**.
   The filter applies to the selected metric family on the next poll cycle.
   When you view metric families the assigned filters, an asterisk (*) appears next to each metric family that does not have any assigned filters.

   NOTE
   To clear a filter, select the metric family, and click **Clear Filter**. The filter is removed on the next poll cycle.

Associate Monitoring Profiles and Collections

To apply the polling behavior of a monitoring profile to devices, associate the profile with a device collection. When multiple monitoring profiles are associated with a device collection, Data Aggregator uses the fastest specified poll rate.

WARNING

Do not associate monitoring profiles with the All Devices device collection. Doing so can cause extra SNMP requests being made to pingable-only devices, and can result in sporadic metric family support.

Metric families such as QoS, MPLS, and various Response Path Test metric families can contribute to significant SNMP requests. For more information about the implications and restrictions of SNMP requests to your network devices, see the vendor documentation or contact the vendor.

Administrators and Tenant Administrators can modify associations between monitoring profiles and device collections. Administrators see only the associated device collections for the current tenant.

Assign Collections to Monitoring Profiles

Follow these steps:

1. From the **Monitoring Profiles** page, select the monitoring profile, and click the **Collections** tab.
2. Click **Manage**.
3. Select collections for the **Assigned Collections** list, and click Save.
   The monitoring behavior that is defined in the monitoring profile is applied to the assigned device collections.

Assign Monitoring Profiles to Collections

Follow these steps:

1. From the **Collections** page, select a collection, and click the **Monitoring Profiles** tab.
2. Click **Manage**.
3. Select monitoring profiles for the **Assigned Monitoring Profiles** list, and click **Save**.
   The monitoring behavior that is defined in assigned monitoring profiles is applied to the device collection.

Factory Monitoring Profiles

Factory monitoring profiles let you start monitoring devices in the environment quickly. Factory monitoring profiles are automatically associated with factory device collections. For example, the Router monitoring profile is associated with the All Routers device collection.

NOTE
You cannot edit or delete factory monitoring profiles.

The following factory monitoring profiles can have a significant performance impact:

- CBQoS
- MPLS
- Network Interface
- Response Path

Configure Threshold Profiles

Threshold profiles let users monitor specific devices or components, such as interfaces and IPSLA tests. Different components often require different threshold configuration. Creating threshold profiles lets users determine a threshold for a given metric or set of metrics. Failing to meet the threshold produces a violation event, and returning to acceptable operation produces an event which indicates that the violation has been cleared.

Example

You want to monitor the utilization of an interface, and trigger a violation when the utilization is above 75 percent. When the utilization drops below 75 percent, you want the violation to clear.

- **Event Rules**
  Event rules let users define logic, which uses metric data to determine when a violation of a threshold occurs. Each event rule uses metrics from a single metric family, and various operators that compare the threshold to the actual value. Up to five conditions can be added to an event rule, and a violation is produced when the threshold is exceeded. In the example on this page, at least two rules are needed. One rule determines when the violation occurs, while the other determines when it is cleared.
- **Event Condition**
  Event conditions automatically appear in a view when all the conditions in a certain event rule are met. Conditions include "Violation" and "Cleared".

The following video shows the threshold profile configuration process:

Threshold Best Practices

Consider the following best practices when you configure thresholding:

- Apply threshold profiles to groups with specific components instead of devices. This group structure increases the granularity and flexibility of thresholding.
- Expand threshold monitoring slowly. Start with a small group of components and verify that the monitoring engine does not become degraded. For more information, see Threshold Event Processing Self-Monitoring Metrics.
- Thresholds on components with 1-minute polling have a high resource cost to the system.
- Threshold evaluations might slow down after a Data Aggregator restart while cached poll data from the the Data Collectors is processed.

Create Threshold Profile

Log in as a user or administrator to create a threshold profile. Users with the Create DA Threshold Profile or the Administer DA Threshold Profile role right can create threshold profiles.

You can edit or delete exiting threshold profiles.

Follow these steps:

1. Hover over **Administration**, **Data Sources**, and click the data source.
2. Expand **Monitoring Configuration**, and click **Threshold Profiles**.
3. Create a folder, or select an existing folder.
4. Click **New Profile**.
5. Specify the required information.
6. (Administrator Only) Select an owner. Only the owner or a user with the Administer DA Threshold Profile role right can edit the profile.

7. Add event rules to the profile.
8. Click **Save**.
   The threshold profile is added to the system. To generate events, assign the profile to a group.

Add Event Rules

Each event rule is based on a single metric family, and determines the conditions that cause or clear a violation. Each threshold profile requires at least one event rule.

You can edit or delete existing event rules.

> **TIP**
>
> To use an existing event rule as a template, select an event rule, and click Copy.

Follow these steps:

1. Create or edit a threshold profile.
2. In the Event Rules pane, click **New**.
3. Specify the required information for the event rule. The following fields require explanation:
   - **Duration**
     Specifies the total amount of time a given condition must be true within the specified Window to generate an event. The poll cycles that trigger the condition do not need to be consecutive.
   - **Window**
     Specifies the overall range of time to evaluate the rule condition.
   - **Aggregation**
     Specifies whether the threshold applies to an aggregate value of all components for the device. This field appears only when you select a supported metric family.

     > **NOTE**
     >
     > Currently, only the Utilization (%) Metric for the CPU and Memory metric families are supported for aggregation. When you select this option, the event rule must use Fixed Value for the Condition Type.
4. Save the event rule.
5. Save the threshold profile.

Duration and Window Example:

A monitored device has a poll rate of 5 minutes. An associated threshold profile has an event rule with a duration of 600 (10 minutes) and a window of 3600 (1 hour). An event does not occur when the conditions are triggered for a single poll result because the 5-minute poll does not reach the 10-minute duration. The event occurs only if the conditions of the rule are triggered for a second poll result within one hour of the first triggering poll.

> **NOTE**
>
> When a threshold is breached, an alarm is created. When the event clears, the threshold is rechecked with the next poll cycle. If the threshold is breached again, a new alarm is created.

Standard Deviation Event Conditions

Event rules that use standard deviation compare the poll results to the baseline for the device or component. The baseline and the standard deviation value are calculated for the specific hour of the day of the week. For more information about these calculations, see Baseline Calculations.

Standard deviation rules are triggered when the value of the metric differs from the baseline by the specified number of standard deviations. For rules with the Above operator, the rule is triggered when the value of the metric exceeds the baseline value plus the number of standard deviations. For rules with the Below operator, the rule is triggered when the value of the metric is lower than the baseline value minus the number of standard deviations.

Example

The baseline is 65% and the standard deviation is 10%. The rules states that an event triggers when CPU utilization is above 2 standard deviations. This condition triggers when the CPU utilization is greater than 85%.

Percent of Baseline Event Conditions

Event rules that use Percent of Baseline compare the poll results to the calculated baseline plus or minus a percentage of the calculated baseline for the device or component. An event is triggered when the qualifying poll data meets the criteria that are specified for a Percent of Baseline event rule condition. Percent of Baseline event conditions are useful when there is a lot of or very little variation in the metric values. Consider using Percent of Baseline conditions when the standard deviation is above 3 or extremely low like 0.1 or 0.0.

Examples

The calculated baseline is 60 degrees and the specified Percent of Baseline is 50%. The rule states that an event triggers when the temperature rises above 50% of the baseline. This condition triggers when the temperature is higher than 90 degrees.

Math: 60 + (+50%*60) = 60 + 30 degrees = 90 degrees

The calculated baseline is 60 degrees and the specified Percent of Baseline is -50%. The rule states that an event triggers when the temperature falls below -50% of the baseline. This condition triggers when the temperature is lower than 30 degrees.

Math: 60 + (-50%*60) = 60 - 30 degrees = 30 degrees

Assign Groups to Threshold Profile

To generate violation events, associate groups to the threshold profile. Assigning groups to a profile identifies the devices or components that the profile monitors. When a device is in the group, the threshold profile applies to each component of the device that supports the selected metric family.

> **NOTE**
>
> Threshold profiles that are assigned to collections apply the event rule only to devices in the collection. Components and interfaces in the collections are not analyzed. Use custom groups to generate events for components and interfaces.

Follow these steps:

1. Select a threshold profile from the Folder View or Table View.
2. Click the **Groups** tab in the right-hand pane.
3. Click **Manage** at the bottom of the screen.
4. Select the groups from the **Available Groups** tree, and click the right arrow to add it to the Selected list.
5. Click OK.
   The groups in the Selected list are assigned to the threshold profile.

View Threshold Profile Events

Event rules that you create trigger events when a threshold is violated and when the violation is cleared. The Threshold Profiles screen shows events that have occurred as a result of specific event rules. In contrast, the Events Display dashboard shows threshold events that relate to all event rules in all threshold profiles.

Follow these steps:

1. (Administrator) Select **Administration**, **Threshold Profiles**.
   (User) Click the name of your user account in the upper-right corner and click **Manage Threshold Profiles**.
2. Select a threshold profile.

3. Click the **Events** tab.
4. (Optional) Click the **Details** button.
5. (Optional) Click **Change** next to the time range, and select a default time range.
   You can also select **Custom Time Range** to set a different time range.

Create Custom Attributes

You can add custom attributes to items such as devices or interfaces. Populate these items using REST Web Services. Custom devices and interfaces are then available in reports, dashboards, and group rules. Custom devices, device components, and interfaces are also available for OpenAPI queries with some delay due to ETL job scheduling.

Custom attributes for devices and interfaces appear in the Information section of the Details tabs in a context page for an item. For more information, see Context Pages.

> **WARNING**
>
> After custom attributes are created, you cannot delete them.

Define Custom Attributes

To define custom attributes for items such as devices or interfaces, POST the XML using a REST client.

By default, the maximum number of custom attributes is 5 for string and 5 for integer for each supported item type. If you attempt to exceed the maximum number of attributes, the Data Aggregator returns an error.

Follow these steps:

1. Set up a REST client with a connection to the Data Aggregator server.
2. Specify the following URL:
   `http://da_hostname:8581/rest/customattributedefinition`
3. POST the XML for defining your custom attributes.
   The following example defines a **CustomerID** attribute for all devices.

```
<CustomAttributeDefinition version='1.0.0'>
   <Label>Customer ID #</Label>

   <Description>Customer account number</Description>

   <Hidden>true</Hidden>

   <Storage>

      <AttributeName>CustomerID</AttributeName>
      <Type>String</Type>
      <ItemType>Device</ItemType>

   </Storage>

</CustomAttributeDefinition>
```

- **<Label>**Specify a label that can be displayed in the NetOps Portal user interface for the custom attribute.**Limit:** 64 characters
- **<Hidden>**Specify whether to hide the property by default from the NetOps Portal user interface. If this tag is set to "true," you can manually display the custom attribute in the user interface. This tag impacts whether custom attributes appear by default in the NetOps Portal user interface only. They are available by default in other areas, such as the OpenAPI QueryBuilder.
  Default: "true"

  NOTE

  If this tag is set to "true", custom attributes are hidden from context pages and cannot be manually shown in the user interface. If you want custom attributes to appear on context pages, you must set this tag to "false."
- **<Description>**Specify a description for the attribute.
- **<AttributeName>**Specify an internal reference name for the custom attribute. Use this name to set a value for the custom attribute in the following procedure.
  Limit: 26 characters
- **<Type>**Specify whether the custom attribute is a string or an integer.**Valid entries:** "String" and "Integer"
- **<Item Type>**Specify whether the custom attribute is for a device, component, or interface ("Port")**.Valid entries:** "Device", "DeviceComponent", and "Port"

  NOTE

  Custom device component attributes are available only for OpenAPI queries with some delay due to ETL job scheduling. They are *not* available in reports, dashboards, and group rules.

The POST returns an ID for the definition of the custom attribute.

Set Values for Custom Attributes

To set values for your custom attributes, PUT the XML using a REST client.

Follow these steps:

1. Specify one of the following URLs:
   - `http://da_hostname:8581/rest/devices/customattributes/itemID`
   - `http://da_hostname:8581/rest/devices/components/customattributes/itemID`
   - `http://da_hostname:8581/rest/ports/customattributes/itemID`
     - **devices**
       If the custom attributes are for devices, specify this item type in your URL.
     - **devices/components**
       If the custom attributes are for device components, specify this item type in your URL.
     - **ports**
       If the custom attributes are for interfaces, specify this item type in your URL.
     - ***itemID***
       Specify the device or interface ID.
2. PUT the XML for setting your custom attributes.
   String attributes support up to 255 characters. Integer attributes support up to 64-bit integers.
   The following example sets the **CustomerID** attribute from the previous example.

```
<DeviceCustomAttributes version='1.0.0'>
     <CustomerID>CustomAttributeValue</CustomerID>
</DeviceCustomAttributes>
```

The following example sets the custom attributes for a device component:

```
<DeviceComponentCustomAttributes version='1.0.0'>
     <AttributeName>CustomAttributeValue</AttributeName>
</DeviceComponentCustomAttributes>
```

The following example sets the custom attributes for a port:

```
<PortCustomAttributes version='1.0.0'>
     <AttributeName>CustomAttributeValue</AttributeName>
</PortCustomAttributes>
```

Change the Maximum Custom Attributes

By default, the maximum number of custom attributes is 5 for string and 5 for integer for each supported item type. However, you can increase or decrease these values.

TIP

Consider the performance impact of increasing the maximum number of custom attributes for each supported item type. For example, the NetOps Portal user interface allows only a defined number of custom attributes to display. We recommend that you avoid exceeding a maximum of 30 attributes total for string and integer combined.

Follow these steps:

1. Create the following file:
   DA_install_directory/apache-karaf-*version*/etc/
   com.ca.im.item.custattr.CustAttrColumnCache.cfg
2. Add new limits.
   Example:

```
MaxStringColumnsPerItemType=7

MaxIntegerColumnsPerItemType=2
```

   A message appears logged in the `karaf.log` file.
   Example:

```
INFO | AttrColumnCache) | 2016-07-29 09:46:34,464 | CustAttrColumnCache |
 tem.custattr.CustAttrColumnCache 80 | ository.webservices.impl | | Max Integer
 custom attributes per item type:2

INFO | AttrColumnCache) | 2016-07-29 09:46:34,465 | CustAttrColumnCache |
 tem.custattr.CustAttrColumnCache 93 | ository.webservices.impl | | Max String custom
 attributes per item type:7
```

Configure Business Hours Filtering

Business hours represent the times of the day and week during which business is normally conducted. These hours are relevant for capacity planning. You can filter data to these hours for investigation purposes by applying a business hours filter to a dashboard or view.

Business hours definitions apply to views that report data from the data aggregator. They apply to all the devices and components in a site group. Site groups are custom groups that are based on physical locations, such as a city, region, office, or campus. They include Time Zone and Business Hours parameters so that you can precisely filter data from business-critical times of day. When you select the associated group in the context, business hours apply to all applicable views as you navigate between dashboards. The subtitle of each view indicates whether business hours apply to the view.

Alternatively, you can apply a business hours filter to a custom view.

For more information, see Customize Views.

You can also apply a business hours filter to a view on a context page.

For more information, see Context Pages.

Subgroups do not directly inherit business hours and time zone filters from site groups. Associate the business hours definition with each relevant subgroup. However, when rendering views, these filters apply to all items based on the selected site group. The filters of the selected site group apply to all items in that group and in any subgroups. When you change the selected site group to a subgroup, the filters of the parent group are not applicable.

Reference groups inherit associated business hours and time zone filters from the original site group.

In this article:

Business Hours Support and Limitations

Business hours filtering can apply to the data in the following view types:

- Gauge chart
- Pie chart
- Table grid

> **NOTE**
> You can apply a business hours filter to the data in a group scorecard trend view only when the resolution is As Polled or Hourly. The subtitle on the view indicates whether the filtering is applied.

Trend views and heat charts apply shading to show business hours. Shading appears only in the following circumstances:

- A site group with a business hours filter is specified at the page level.
- A site group with a business hours filter is specified at the view level.
- A business hours time filter is specified at the view level.

> **NOTE**
> The data in these views is not limited to the business hours.

You cannot apply business hours filters to the following metrics, data, views, dashboards, and charts:

- Baseline and projection metrics
- Daily rollup data and any view that shows daily resolution
- Table views in On-Demand reports
- Dashboards with views created with a device or interface context
- Trend charts where the option to enable events is selected

Configure a Business Hours Definition

Before you can apply business hours filters to views, create a business hours definition and associate the business hours with a site group. Each definition includes the times of day and days of the week. Select the hours and days that reflect periods of increased activity. Create definitions for every distinct location in your enterprise.

Applying a business hours filter that is associated with a site group to a view applies the filter to that group. Otherwise, apply the business hours filter to the view by associating the business hours definition with a site group.

Only users with the Administer Business Hours role right can add, edit, or delete business hours.

Follow these steps:

1. Hover over **Administration**, and then click **Business Hours**.
2. Click **New**.
3. Specify a name and description.
   The name appears when you associate business hours with site groups. The description appears only on the Manage Business Hours Definitions page.
4. Select the days of the week to include.
5. Select the start time and end time for the business hours from the drop-down lists.
   Half-hour increments are not supported. The same hours are applied to all selected days.
6. Associate the business hours definition with a site group:
   a. Click **Select Site Groups to Associate**.
   b. Add one or more site groups to the **Selected Sites** list.

      NOTE
      You can select only site groups that already have a time zone. Because you can apply business hours filters only in whole hour increments, only site groups that have time zones with only whole hour offsets are available for selection.
      You can assign time zones and business hours when you create or edit site groups.

   c. Click **OK**.
7. Click **Save**.

Schedule Maintenance Indicators

Maintenance indicators represent times when maintenance is occurring. After you schedule maintenance indicators, views indicate maintenance with shading.

Maintenance indicators apply to all the devices and components in a site group. When the associated site group is selected in the context, maintenance indicators appear in applicable views as you navigate between dashboards. The subtitle of each view indicates whether maintenance indicators apply to the view.

Subgroups do not directly inherit maintenance indicators from the site groups. Associate the maintenance indicators with each relevant subgroup. However, when rendering views, these filters apply to all items based on the selected site group. The filters of the selected site group apply to all items in that group and in any subgroups. When you change the selected site group to a subgroup, the filters of the parent group are no longer applicable.

Reference groups inherit associated maintenance indicators from the original site group.

Maintenance Indicators Support and Limitations

Maintenance indicators can apply to the data in the following view types:

- Trend charts
- Calendar heat charts

Trend views and calendar heat charts apply shading to show maintenance indicators. Shading appears only in the following circumstances:

- A site group with maintenance indicators is specified at the page level.
- A site group with maintenance indicators is specified at the view level.

NOTE

The data in these views is not limited to the maintenance indicators.

Maintenance indicators are not supported for the following cases:

- Maintenance hours longer than 24 hours
- Daily rollup data and any view that shows daily resolution
- Table views in On-Demand reports
- Views on context pages

Schedule Maintenance Indicators

To apply maintenance indicators to views, create maintenance indicators and associate the maintenance indicators with a site group. Each definition includes the times of day and day of the week. Select the hours and day that reflect maintenance periods. Create definitions for every distinct location in your enterprise.

Only users with the Administer Maintenance Indicators role right can add, edit, copy, or delete maintenance indicators.

1. Select **Administration**, and click **Maintenance Indicators**.
2. Click **New**.
3. Specify a name and description.
   The name appears on views displaying maintenance indicators. The description appears only on the Manage Maintenance indicators page.
4. Select the days of the **Maintenance Date**.
5. Select the start time and end time for the maintenance indicators from the drop-down lists.
   Half-hour increments are not supported. The same hours are applied to all selected days.
6. Add one or more site groups to the **Selected Sites** list.

   NOTE

   You can only select site groups that already have a time zone. The Maintenance Indicators feature currently supports filtering only in whole hour increments. Therefore, the feature offers only whole hour offsets. Time zones with offsets of 30 or 45 minutes are unsupported.
7. Click **Save**.
   If you associated the maintenance indicators with a site group, the maintenance indicators apply to that group.

Manage Devices

You can view details for monitored devices and can view their associations with device collections, components, monitoring profiles, and metrics. You can also view a Filter Report. This information helps you see information in context, such as which monitoring profiles are being used to poll device components.

NOTE
Some features require administrator privileges.

Monitored devices are manageable or pingable (accessible). Inaccessible devices are not monitored devices.

The following device types are supported:

- **Routers**
- **Switches**
- **Servers**
- **Pingable Devices**

In this article:

Manage the Device Details

To do any of the following tasks, go to the Details tab of the Monitored Devices page:

- View and edit device details.
- Rediscover a device.
- Reconfigure components for any configuration updates.

Follow these steps:

1. Hover over **Administration**, and then click **Monitored Items Management: Monitored Devices**.
2. Do one of the following tasks and select a specific device:
   - On the Tree View tab, select **Device by Collection** or **Device by Monitoring Profile** from the drop-down. Select a specific device from the corresponding tree view.
   - On the Search tab, search by host name, device name, or IP address. You can enter a partial name or IP address to return a list of devices that contain that partial match. Wildcards and regular expressions are not supported.
3. Select the **Details** tab. View details for the selected monitored device.
4. Edit any of the following fields:
   - **IP address**
     For more information, see Change the Primary IP Address for a Device.
   - **Data Collector host**
   - **SNMP profile**
   - **SNMP version for the device**
5. To rediscover the device, click **Rediscover**. The following set of attributes can be updated as a result of this discovery:
   - System name
   - Hostname
   - Device type (as it appears in CA NetOps Portal)
   - Location
   - Vendor
   - Device description
   - Device model

   NOTE
   You cannot rediscover CAMM devices.
6. To verify that the device was rediscovered, look for the event that the rediscovery triggered.
7. To pause polling of the device, click **Stop Polling**. Automatic change detection is disabled. You can manually update metric families or run the rediscovery.

   NOTE
   You cannot stop the polling of CAMM devices.
8. To resume polling, click **Start Polling**.
9. To reconfigure components for any configuration updates, see Device Reconfiguration.

View the Polled Metric Families for a Device

To view the components of monitored devices, go to the **Polled Metric Families** tab of the **Monitored Devices** page. View the total set of metric families that are polled on a device and their poll rates. This total set is based on the consolidation of all the monitoring profiles on the device.

Follow these steps:

1. View the Polled Metric Families table. This table includes the following columns:
   - **Metric Family**
     View the metric families polled on the device.
   - **Vendor Cert**
     View the vendor certifications that are used for each metric family. When Vendor Cert Priority Grouping is occurring on a device, more than one row appears on this tab. One row appears for each vendor certification that is used for a metric family.
   - **Status**
     View whether the device supports the metric family.
   - **Last Discovered**
2. View the Components table. This table shows the polling status on the components for a metric family component that was previously discovered. One of the following values displays in the Status column:
   - **Active**
     The component is being polled.

     NOTE
     CAMM devices show Not Polled in the SNMP Poll Rate column. DX NetOps Performance Management does not poll CAMM devices.
   - **Inactive**
     Polling has stopped on the component because the metric family is no longer monitored for the device.
   - **Not Present**
     The component no longer exists on the physical device. Polling is stopped on the component. You can view historical data for reporting purposes. By default, these components are not synchronized with CA NetOps Portal. To enable this option, select **Synchronize items that are no longer present** in the **Edit Data Source** dialog on the **Manage Data Sources** page in NetOps Portal.
3. To reconfigure components for any configuration updates, see Device Reconfiguration.

View More Device Details

To view more device details, go to one or more of the following tabs:

- **Monitoring Profiles**
  Select a device collection to view the associated profiles names. Hover over a profile to see the description.
- **Threshold Profiles**
  View the threshold profiles that are applied to the selected device due to the groups to which the device belongs.
- **Metrics**
  View a list of metrics that this device supports. Select a metric family to view the following details:
  - The backing vendor certification.
  - The vendor source (the MIB table source is displayed if it is an SNMP vendor certification).
  - Whether the metric is collected.
  - The expression that is used to calculate each metric.
- **Filter Report**
  View which interface filter criteria were used during the component monitoring. The tab also shows a report of all of the interfaces that are identified on the device. The tab shows whether the interfaces matched the specified filter criteria. If you change the rules on a custom monitoring profile, the Interface Filter Criteria pane does not reflect those changes.

If you disassociate the monitoring profile from a group, the Interface Filter Criteria pane does not reflect those changes. Rediscover the device to filter the interfaces using the changes made to the filter criteria and monitoring profile.

- **Events**
  View the events that have occurred on the selected device.

Change the Primary IP Address for a Device

The primary IP address is the IP address that DX NetOps Performance Management uses to monitor a device. When a device is first discovered with the IP ranges discovery profile, DX NetOps Performance Management tries to use the IP address that maps to the hostname as the primary IP address.

If the primary IP address on a devices item changes, an event is generated on that device item.

Automatic Change Detection

By default, when the IP address that maps to a hostname on the physical device changes, the primary IP on the device item does not change. To update the primary IP automatically, enable IP change detection. DX NetOps Performance Management tries to detect the IP address change only after two consecutive polling failures. The data collector uses a reverse hostname lookup to find the new IP address.

NOTE

If your DNS is not up to date, automatic change detection may cause errors.

Use the following REST to enable or disable IP change detection:

URL: http://{da-host}:8581/rest/discoverydefaultconfig/{itemID}**Method:** PUT
Body:

- **Enable:**

```
<DiscoveryDefaultConfig  version="1.0.0">

   <DetectIPChange>true</DetectIPChange>

</DiscoveryDefaultConfig>
```

- **Disable:**

```
<DiscoveryDefaultConfig  version="1.0.0">

   <DetectIPChange>false</DetectIPChange>

</DiscoveryDefaultConfig>
```

Change the Primary IP Address

Situations may arise when you want to change the primary IP address of a device. For example, you want to change the hostname IP address to the loopback IP address, or the IP address is no longer reachable on the device.

Follow these steps:

1. Click Monitored Devices from the Monitored Inventory menu for a Data Aggregator data source.
   The Tree View tab displays.

2. Select **Device by Collection** or **Device by Monitoring Profile** from the drop-down list, and select a specific device.

   NOTE
   Alternatively, select the Search tab to search by host name, device name, or IP address. You can enter a partial name or IP address to return a list of devices that contain that partial match. Wildcards and regular expressions are not supported.
3. Change the primary IP address by taking one of the following steps:
   – Edit the IP Address field and then click Save.
   – Right-click an IP address in the IP Addresses table, select **Set this IP as the device's primary IP**, and click Save.

   The primary IP address is changed.

Change the Primary IP Address Through REST

If you change the primary IP address of a device to an IP address that another devices uses, the REST call returns and error.

To change the primary IP address of a device with a REST client or HTTP tool, enter the following criteria:

- **URL:** http://*da-hostname*:8581/rest/devices/*deviceitemID*
  deviceitemID specifies the target device.
- **Method:** PUT
- Enter the changed primary IP address in the Body tab of the HTTP Request pane.
  For example:

```
<Device version="1.0.0">

      <PrimaryIPAddress>IP</PrimaryIPAddress>

</Device>
```

- **IP** specifies the new primary IP address of the device.

Example: In this example, you change the primary IP address on the device to 1.2.3.4:

```
<Device version="1.0.0">

      <PrimaryIPAddress>1.2.3.4</PrimaryIPAddress>

</Device>
```

Delete Components That Are Not Present

Data Aggregator includes a script to delete components that are not present. These components are components that no longer exist on physical devices. The presence of excessive numbers these components can impact user interface performance.

Follow these steps:

1. Open a command prompt and access the /opt/IMDataAggregator/scripts directory.
2. Type the following command:
   `./remove_not_present_items.sh`
   The script usage is described.

NOTE

- If you filter the components by IP domain name or IP domain ID, also specify a specific IP address to return correct results.
- If your filter criteria return too many components, the REST interface does not return a response. Use other filtering options to narrow the results. More filter criteria are available at http://*hostname*:*port*/rest/retired/xsd/filterselect.xsd.

Automate the Removal of Components That Are Not Present

As an administrator, you can automate the removal of components that are not present from your network. For example, you can set up a weekly cron job to delete the components that are a month old.

The remove_not_present_items script that is included with Data Aggregator is comprised of two parts. The first part of the script identifies and returns data about the components, which is based on the filter that you set. The second part of the script issues the delete of the component list. To automate the process, understand how this script was built.

Example: Filter the List of Components By a Device IP Address

In this example, you want to find all of the components for a device that has a primary IP address of 10.252.1.1. Filtering by IP address is a two-step process because no direct component filter by IP address is available. To filter the components, first make note of the IP address for the device that the components are associated with. With the IP address information, you will determine the device item ID for the device. Then, using the device item ID, you will determine what the components are. Finally, you delete the components.

NOTE
This example uses the curl command, but you can use any command that you are familiar with.

1. Create the filterDeviceIP.xml file. You will use this file to return the device item ID for the device that has a primary IP address of 10.252.1.1. The file must look like the following example:

```
<FilterSelect xsi:noNamespaceSchemaLocation="filter.xsd" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance">
  <Filter>
    <And>
     <Device.PrimaryIPAddress type="EQUAL">10.252.1.1</Device.PrimaryIPAddress>
    </And>
  </Filter>
</FilterSelect>
```

2. Run the following command:
   curl -X http://*hostname*:*port*/rest/devices/filtered -H "Content-Type: application/xml" -T "filterDeviceIP.xml" > returnedDeviceID.xml
   - **-X**
     Creates the filter that you indicate.
   - ***hostname*:*port***
     Specifies the Data Aggregator host name and the port number.
     Default port: 8581
   - **-H**
     Indicates the content type of the file that you are posting.
   - **-T**
     Indicates the file that you are posting.

   The following result is returned as an HTTP response:

```
<?xml version="1.0"?>
<DeviceList>
```

```
 <Device version="1.0.0">
   <ID>107881</ID>
   <PrimaryIPAddress>10.252.1.1</PrimaryIPAddress>
   <supportsOnDemandMFDiscovery>true</supportsOnDemandMFDiscovery>
   <SupportedProtocolsList>
     <SupportedProtocols>ICMP</SupportedProtocols>
   </SupportedProtocolsList>
   <DiscProfileID>107503</DiscProfileID>
   <HostName>rtp003723rts.ca.com</HostName>
   <RelatesTo>
     <MonitoredGroupIDList relatesURL="relatesto/monitoredgroups"
rootURL="monitoredgroups">
       <ID>509</ID>
     </MonitoredGroupIDList>
     <GroupIDList relatesURL="relatesto/groups" rootURL="groups">
       <ID>547</ID>
       <ID>530</ID>
       <ID>509</ID>
     </GroupIDList>
   </RelatesTo>
   <IsAlso>
     <IsA name="MetricFamilyDiscoveryHistory" rootURL="devices/mfdiscoveryhistory"/>
     <IsA name="AccessibleDevice" rootURL="devices/accessible"/>
     <IsA name="Syncable" rootURL="syncable"/>
     <IsA name="IPDomainMember" rootURL="ipdomainmember"/>
   </IsAlso>
   <DataCoectionMgrId version="1.0.0">
     <DcmID>dcname.ca.com:8f53bc55-f442-42fc-9bd5-a907d0261421</DcmID>
   </DataCollectionMgrId>
   <Syncable version="1.0.0">
     <SyncID>-1</SyncID>
   </Syncable>
   <Item version="1.0.0">
     <DisplayName>router.ca.com</DisplayName>
     <CreateTime>Wed Feb 05 10:20:26 EST 2014</CreateTime>
     <Name>router.ca.com</Name>
   </Item>
   <IPDomainMember version="1.0.0">
     <IPDomainID>2</IPDomainID>
   </IPDomainMember>
   <DeviceMonitoringProfile version="1.0.0">
     <ConsolidatedMonitoringProfile>2509</ConsolidatedMonitoringProfile>
   </DeviceMonitoringProfile>
 </Device>
</DeviceList>
```

Device item ID 107881 is returned. The results also display detailed information about the device.

3. Create the filterNotPresent.xml file. You will use this file to return the components that are not present and are associated with the device whose device item ID is 107881. This file must look like the following example:

```
<FilterSelect xsi:noNamespaceSchemaLocation="filter.xsd" xmlns:xsi="http://
www.w3.org/2001/XMLSchema-instance">
  <Filter>
    <And>
        <DeviceComponent.DeviceItemID type="EQUAL">107881</
DeviceComponent.DeviceItemID>
    </And>
  </Filter>
  <Select use="exclude">
    <Item use="exclude">
      <DisplayName use="include"/>
    </Item>
  </Select>
</FilterSelect>
```

4. Run the following command:
   curl -X post http://*hostname*:*port*/rest/retired/filtered -H "Content-Type: application/xml" -T "filterNotPresent.xml" > returnedNotPresentItems.xml
   The following result is returned as an HTTP response:

```
<?xml version="1.0"?>
<RetiredList>
  <Retired version="1.0.0">
    <ID>128452</ID>
    <Item version="1.0.0">
      <DisplayName>GigabitEthernet0/239 - GigabitEthernet0/239</DisplayName>
    </Item>
  </Retired>
  <Retired version="1.0.0">
    <ID>128451</ID>
    <Item version="1.0.0">
      <DisplayName>GigabitEthernet0/238 - GigabitEthernet0/238</DisplayName>
    </Item>
  </Retired>
</RetiredList>
```

   Two components that fit the filter criteria are returned. The item IDs for the components are 128452 and 128451.
5. Create the deleteNotPresentList.xml file. You will use this file to delete the returned list of components. The file must look like the following example:

```
<DeleteList>
  <ID>128452</ID>
  <ID>128451</ID>
</DeleteList>
```

6. Run the following command:
   curl -X post http://*hostname*:*port*/rest/retired/deletelist -H "Content-Type: application/xml" -T "deleteRetiredList.xml" > deletelistreponse.xml
   The following result is returned as an HTTP response:

```
<?xml version="1.0"?>
```

```
<DeleteListResult>
  <DeleteResult>
    <ID>128452</ID>
    <Error>SUCCESS</Error>
  </DeleteResult>
  <DeleteResult>
    <ID>128451</ID>
    <Error>SUCCESS</Error>
  </DeleteResult>
</DeleteListResult>
```

The components are successfully removed.

Example: Delete a Large Number of Retired Components

You can easily delete all of the retired components where the total exceeds 100,000:

- To review all of the retired components where the total exceeds 100,000, type the following command:
  ```
  ./remove_not_present_items.sh -h host_name  -o ouputfile
  ```
  – **-o *outputfile***
  Is the output of all of the retired components. The output is a .csv file.

  For example, the following command outputs a list of all of the retired components. The .csv file format includes the device item ID, the device display name, the retired component ID, and the retired component display name:
  ```
  ./remove_not_present_items.sh -h my_host_name  -o myretired.csv
  ```
- To delete all of the retired components where the total exceeds 100,000, and to log the information to a .csv file, type the following command:
  ```
  ./remove_not_present_items.sh -h host_name  -o ouputfile  -c Yes
  ```
  – **-o *outputfile***
  Is the output of all of the retired components. The output is a .csv file.
  – **-c Yes**
  Confirms the deletion of all retired components.

  For example, the following command deletes all of the retired components:
  ```
  ./remove_not_present_items.sh -h my_host_name  -o myretired.csv  -c Yes
  ```

Delete Devices

To remove a device item, all associate components, and historic data from the system, delete the device.

When you delete a device, the following results occur:

- All the associated device components are deleted.
- Historical data on the deleted devices and device components is no longer accessible.

If discovery finds a deleted device, DX NetOps Performance Management creates a *new* device item. The new device item has no association with the old device item.

TIP

To stop polling the device and retain historical data, edit the device life cycle state. For more information, see Manage Device Life Cycles.

Follow these steps:

1. Go to Administration, and click the Data Aggregator data source.
   The Monitored Devices page opens.

2. (Optional) Open the Search tab, and search for the device to delete.

   NOTE
   Do not use the global Search box at the top of the page.
3. Select the devices to delete, and click **Delete**.
4. In the confirmation dialog, click **Yes**.
   The devices are deleted and are removed from the Monitored Devices inventory. Historical data for the devices is deleted from the database. After the next synchronization cycle, the devices are removed from inventory and groups in NetOps Portal.

   NOTE

   If another data source is managing these devices, the devices continue to appear in the Inventory view and in groups.

Device Reconfiguration

Device reconfiguration includes changes to physical device components and the software configuration, such as monitoring response path tests for protocols. Data Aggregator uses the same method to monitor both types of reconfiguration. To keep device components up-to-date, you can monitor and update device reconfiguration changes in Data Aggregator.

Additional examples of reconfiguration changes include:

- Adding a board to a device, which adds more ports.
- Adding memory, CPUs, physical interfaces, or any metric family to a discovered device.
- Reconfiguring a virtual switch.
- Changing the configuration of a device to include a discovered device in routing protocols.

When a change is detected, Data Aggregator generates reconfiguration events and can update its representation of the metric family to reflect the changes to device components. View reconfiguration events by selecting Dashboards, Operations, Events Display.

Understanding how change detection works in Data Aggregator helps you to select the options that are best suited to monitoring device reconfiguration in your environment. For example, you can set the frequency for change detection monitoring.

How to Manage Change Detection

Change detection management planning helps ensure that Data Aggregator detects and monitors device reconfigurations in your environment according to your needs. You can plan ahead for any device reconfiguration when you first set up Data Aggregator to discover new devices. You can also edit these options at any time after devices are discovered.

Refer to the following guidelines when planning change detection:

- Likelihood of change.
- Frequency of change.
- Tolerance for outdated data.

Monitor metric families, such as CPUs, for reconfiguration infrequently. For dynamic metric families, such as virtual systems, choose a more frequent rate.

Follow this process:

1. Create or edit a custom monitoring profile. (You can also copy a factory monitoring profile and edit the copy.)
2. Select **Enable Change Detection** and set the **Change Detection Settings**, **Rate** in the monitoring profile.

The Change Detection Settings, Rate option is used to set the frequency at which Data Aggregator checks for changes. The rate of detection can be set in minutes or hours. By default, the rate is set to 24 hours.

3. Update the Data Aggregator representation of the metric families.
   After you set the change detection rate, you have two options for correcting the Data Aggregator configuration: automatic or manual update of the metric families. Manual Update updates the representation of the metric families by ensuring the correct set of components is being monitored.
   – To avoid having to make changes when a reconfiguration is detected, select **Automatically Update Metric Families** (selected by default). Data Aggregator automatically starts monitoring any new components, and marks any components that are no longer detected as Not Present.
     View the Events Display dashboard to see reconfiguration events:
     • If the components have changed for a device, an event is generated on the associated device. This event describes that a component change has been detected and will be applied after a short period.
     • After component reconciliation is applied, another event is generated. This event describes how many components were added, how many are not present, and how many remained unchanged.
   – To stop the Data Aggregator from automatically monitoring new components or Not Present components, deselect **Automatically Update Metric Families**.
     View the Events Display dashboard to see reconfiguration events:
     • If the components have changed for a device, an event is generated on the associated device. This event describes a component change that has occurred without reconciliation.

     To have the reconfiguration changes applied, manually click **Update Metric Family** on the Polled Metric Families page for a device.
4. To enable the monitoring profile, assign the custom monitoring profile to a device collection.

TIP

- If your environment is undergoing major maintenance, turn off the automatic update until the maintenance is complete. For small, regular changes, enable the automatic update feature to ensure that your Data Aggregator stays up-to-date.
- Monitoring profiles are assigned to device collections. If you want to monitor special devices differently, create a custom device collection and assign a custom monitoring profile with the desired change detection settings. For example, you can monitor critical core routers more frequently than other routers by creating a device collection and assigning a custom monitoring profile that performs change detection hourly. Other routers remain in the 'All Routers' device collection using the factory monitoring profile (with no change detection), or a custom monitoring profile that you set to less frequent change detection.

Update Device Reconfiguration Automatically

Reconfiguration changes to a discovered device can affect the metric families that are associated with the device. The device reconfiguration can update automatically in the monitoring profile to which the metric families are assigned, which applies to any metric families that the monitoring profile includes. This option is set by default when you create a custom monitoring profile, but it can also be edited at any time.

When the metric family is updated, Data Aggregator has an accurate representation of the device configuration. Reports that you generate reflect accurate information.

Follow these steps:

1. Select the monitoring profile that you want to update automatically and click **Edit**.
2. Select **Enable Change Detection**.
3. Set the **Change Detection Settings, Rate** to a value that is greater than zero.

NOTE
Consider how frequently the metric family is likely to change, and how many devices the monitoring profile is applied to. Avoid setting change detection rates that are more frequent than necessary.

4. Select **Automatically Update Metric Families**.
5. Click **Save**.
   When you make a configuration change to a device that is associated with this monitoring profile, the device configuration is updated automatically.
   When a device configuration is updated, Data Aggregator does the following steps:
   – Generates an event on the monitored device.
   – Identifies new components and creates them.
   – Identifies components that are no longer present and marks them as Not Present.
   By default, components that are not present are not synchronized with NetOps Portal. To enable this option, select **Synchronize items that are no longer present on the device** on the Manage Data Sources page.
   – Identifies existing components that have changed from a previous discovery. The Name column changes, if applicable.
   Historical data is accessible and can be reported on.

Update Device Reconfiguration Manually

Reconfiguration changes to a discovered device can affect the metric families that are associated with the device. The device reconfiguration can be updated manually when **Automatically Update Metric Families** is not selected in the associated monitoring profile. View the event logs to identify reconfiguration events for which you want to update the metric families.

When the metric family is updated, Data Aggregator has an accurate representation of the device configuration. Reports that you generate reflect accurate information.

Follow these steps:

1. View the event logs to identify reconfiguration events for which you want to update the metric families.
2. Click **Monitored Devices** from the Monitored Inventory menu for a Data Aggregator data source.
   The Tree View tab appears.
3. Select **Device by Collection** from the drop-down list, and select the monitored device that was updated from the corresponding tree view.
   The Polled Metric Families tab shows the consolidated monitoring profiles that are associated with a device. Devices only have one consolidated monitoring profile. Each consolidated monitoring profile lists every metric family that can be polled on the device, and whether the device supports the metric family.
4. Select the metric family for which you want to update the configuration and click **Update Metric Family**.
   Your device configuration is updated, and Data Aggregator does the following steps:
   – Generates an event on the monitored device.
   – Identifies new components and creates them.
   – Identifies components that are no longer present and marks them as Not Present.
   – Identifies existing components that have changed from a previous Discovery. The Name column changes, if applicable.
   Historical data is accessible and can be reported on.

Reconfiguration Detection of Ports

Reconfiguration changes to a discovered device may cause ports to be reconfigured. The new port and the old port are identical if either of the following is true for the Interface metric family after the reconfiguration:

- The PortType and Description attributes in the Interface metric family remain the same.
- The PortType and at least two of the following remain the same:

- Alias
- Description
- MacAddress
- Index

For all other metric families, the new component and the old component are identical if both Name and Index remain the same after the reconfiguration.

Manage Device Life Cycles

Life cycle states define the monitoring behavior for devices. Life cycle management enables you to define the usage state of SNMP and ICMP devices. Components inherit the life cycle state of the associated device.

NOTE
Life cycle management does not apply to devices from DX NetOps Mediation Manager.

You can manage the device life cycle state using the Manage Device Life Cycle user interface in NetOps Portal or the NetOps Portal API. To use the NetOps Portal API, see Update the Device Life Cycle State.

You can also manage the device life cycle state from the device inventory. You can change the life cycle state of a device to Active or Maintenance from an alarms view.

Life Cycle States

- **Active**
  The normal operating status of a device.
- **Retired**
  Specifies that the device is no longer in use and that no monitoring occurs. This state disables polling, threshold monitoring, notifications, and change detection. The system does not update the SNMP Profile or change the hostname.

  NOTE
  Virtual devices (Virtual Machine or ESX) discovered with systemEdge are not polled for its vCenter statistics when the device lifecycle state is "Retired".
- **Maintenance**
  Specifies that the device is temporarily under maintenance. The behavior of this state is configurable.

Change Life Cycle Status

To define when a device is active, retired, or in maintenance, change the life cycle state.

Prerequisite: You have the Administer Life Cycle role right.

Follow these steps:

1. Do one of the following steps:
   - Go to **Administration**, **Device Life Cycle**.
   - Go to **Inventory**, **Devices**.
   - Go to an alarms view.

     NOTE
     You can change the life cycle state of a device only to "Active" or "Maintenance" from an alarms view. You cannot change the life cycle state to "Retired" from an alarms view.
2. Select the devices, and then click **Manage Life Cycle**.
3. Select the **Life Cycle State**, and then click **OK**.
   The system applies the selected state to the device and logs a life cycle event that marks the change.

NOTE
When a change to the life cycle state stops polling a device, if the data is within the rollup time frame, the polled data is included in rollups. For example, the system stops polling at 9:20 am. The data is included in rollups for the 9:00-10:00 hour, but not for the 10:00-11:00 hour. Baselines use data up to 90 days in the past, even if the device is no longer polled.

Configure Maintenance Behavior

To define the behavior for devices in the "Maintenance" state, specify the life cycle behavior.

WARNING
Changes to maintenance behavior do not apply to devices already in the "Maintenance" state. The changes apply only to devices set to "Maintenance" after you change the maintenance behavior.

Follow these steps:

1. Go to **Administration, Life Cycle Behavior**.
2. Under **Maintenance State**, specify the behavior:
   - **Polling**
     Specifies whether DX NetOps Performance Management polls the device.
   - **Threshold Evaluation**
     If polling is enabled, specifies whether DX NetOps Performance Management analyzes event rules for the device.
   - **Event Notification**
     Specifies whether DX NetOps Performance Management sends notifications for the device.
3. Click **Save**.
   DX NetOps Performance Management applies the defined behaviors to devices that you put in the "Maintenance" state.

DX NetOps Spectrum Integration

For systems with an integrated instance of DX NetOps Spectrum, you can configure DX NetOps Spectrum to control the life cycle state of devices in DX NetOps Performance Management. Changes in DX NetOps Spectrum trigger changes in DX NetOps Performance Management. If you change the state of a device in DX NetOps Performance Management, the state does not change again unless the state changes in DX NetOps Spectrum. With this option enabled, DX NetOps Performance Management uses the following behavior:

- Active devices in DX NetOps Spectrum are Active in DX NetOps Performance Management.
- Devices in Maintenance in DX NetOps Spectrum, have the Maintenance state in DX NetOps Performance Management.
- The state of the device in DX NetOps Spectrum overwrites the state in DX NetOps Performance Management.

To manage the life cycle state of a device from DX NetOps Spectrum, edit the DX NetOps Spectrum data source and select the **Synchronize device life cycle state from Spectrum** checkbox.

The following video explains the DX NetOps Spectrum integration behavior:

For more information, see Configure a Data Source.

Retirement Consolidation

The DX NetOps Performance Management user interface now supports supports the co-existence of "Retired" and replacement devices coming from Network Flow Analysis.

NOTE
You must upgrade to Network Flow Analysis 10.0 and DX NetOps Performance Management 3.7 to leverage this functionality.

In the earlier versions of DX NetOps Performance Management, it was not possible to have multiple devices with the same IP address. With this enhancement to the device life cycle, you can now have multiple devices with the same IP address displayed in DX NetOps Performance Management. When a device is "Retired", Network Flow Analysis retires the old device and creates a new device with an interface. The new and the retired device show in DX NetOps Performance Management after synchronization. A new device can be discovered using the same IP. You can now report on the new and retired device in the same or separate group. If you want to report on the new and old device together, we recommend that you place them in the group.

When Network Flow Analysis 10.0 detects a flow from a different device with the same IP , the existing device is marked as retired. Network Flow Analysis then creates a new entry for the new device with new set of interfaces.

NOTE
If you upgrade DX NetOps Performance Management to 3.7 before upgrading Network Flow Analysis to 10.0, a full Synchronization of Network Flow Analysis data source will be required when you upgrade Network Flow Analysis.

NOTE
When a device has been set to "Retired" state and a new device has been created, as with any new device, you can choose to configure and manage the new device accordingly.

Manage Hostname Changes

When the hostname of a monitored device changes, DX NetOps Performance Management detects the change and updates the hostname for the device item. If the device item name uses the hostname, DX NetOps Performance Management updates the device name. The default detection rate for hostname changes is 24 hours. However, the change might not appear in the system for up to twice the detection period. For example, with the default reevaluation rate of 24 hours, changes to the hostname are updated within 48 hours.

NOTE

DX NetOps Performance Management only looks for hostname changes on devices with defined hostnames. If the device did not have a DNS hostname when discovery created the device item, DX NetOps Performance Management does not detect changes. To add the hostname to the device item, run the discovery profile again. For more information, see Run Discovery.

Modify the Hostname Change Detection Rate

The default hostname change detection rate is 24 hours. To reduce DNS traffic or to detect changes faster, modify the reevaluation interval. Each Data Collector has a separate evaluation interval. To change the interval for a specific device or group of devices, apply the changes to each Data Collector individually.

Follow these steps:

1. Log in to the Data Collector host that monitors the device.
2. Locate the Data Collector configuration file:
   `APACHE_KARAF/etc/com.ca.im.dm.core.collector.cfg`
3. Add or modify the following line:
   `hostname-reevaluation-interval-in-hours=`*`number`*
   number specifies the length in hours of the reevaluation interval.
4. Save the file.
   The Data Collector uses the new interval for hostname reevaluation. Changes to the hostname take up to twice the interval to appear in the system.

Override Device Types

Based on the device service information, the Data Aggregator automatically classifies manageable devices. Classifications include Router, Switch, Server, Firewall, Load Balancer, Wireless Controller, and Wireless Access Point. During synchronization, the Data Aggregator inspects each device and its classification. The Data Aggregator designates a primary device type, and forwards any additional types as context types. The associated context types, including the primary device types, appear listed in a column within the device inventory tables in NetOps Portal.

The following list describes more device type classifications:

- **Pingable**
  The device is not manageable.
  Example: The device does not respond to SNMP requests and its device type cannot be determined.
- **Manageable**
  The device type is classified as 'Manageable' when the following criteria are true:
  – The manageable device cannot be classified as Router, Switch, or Server.
  – The manageable device *can* be classified as Firewall, Load Balancer, Wireless Controller, or Wireless Access Point.
- **Other**
  The device type is classified as 'Other' when the following criteria are true:
  – The manageable device cannot be classified as Router, Switch, or Server.
  – The manageable device cannot be classified as Firewall, Load Balancer, Wireless Controller, or Wireless Access Point.

Override Device Types

If the device types of some SNMP manageable devices were not classified as expected, you can fully override the device types.

Scenarios:

- An existing device is discovered as 'Other'. However, you want the device to be classified as 'Router' instead. To override the existing 'Other' classification, you can add 'Router' to the DeviceTypes.xml.
- An existing device is discovered as 'Switch'. The SNMP agent advertised the wrong type. The device should have been advertised as 'Router' and it is also a 'Firewall'. To override the incorrectly discovered types, you can add 'Router' and 'Firewall' to the DeviceTypes.xml.

Map the device `sysObjectID` MIB value explicitly to the correct device type in the following file on the Data Aggregator host:

```
DA_install_directory/data/custom/devicetypes/DeviceTypes.xml
```

In a fault tolerant environment, a shared directory (example: `/DASharedRepo`) is defined to help limit data loss. Therefore, in a fault tolerant environment the file would be located in the following directory:

```
DASharedRepo/custom/devicetypes/DeviceTypes.xml
```

For more information, see Fault Tolerance.

> **NOTE**
> You cannot add new device types to the DeviceTypes.xml file.

The DeviceTypes.xml file contains a template to map the `sysObjectID` to appropriate device types. By default, the file does not contain any `sysObjectID` -to-type mapping entry. To classify a device type with a particular `sysObjectID` , modify the template to add the `sysObjectID` -to-type entries into the file. Before you add a `sysObjectID` , uncomment the section where you are adding the `sysObjectID` .

NOTE
Updates to the DeviceTypes.xml file can take up to one minute to apply.

A device can be classified into multiple device types. However, the type, Device, is mutually exclusive to other device types. For example, if you add a `sysObjectID` to one or more of the Router, Switch, or Server device types and you also add that `sysObjectID` to the 'Device' device type, the 'Device' device type is dropped and is not recognized.

Fully override the device types when the following criteria are true:

- No automatically discovered device types were found or the discovered device types are wrong.
- You want to override the types discovered during device discovery.
- You want to assign the correct types manually.

Example: Map a Device sysObjectID to Another Device Type

WARNING

The `sysObjectID` -to-type mappings in the following example override any already discovered device types.

Follow these steps:

1. Open the following file:
   DA_install_directory/data/custom/devicetypes/DeviceTypes.xml
   In a fault tolerant environment, the file would be located in the following directory:
   DASharedRepo/custom/devicetypes/DeviceTypes.xml
2. Enter the following information:

```
<DeviceType>
     <Routers>
          <sysObjectID>1.3.6.5.1.34</sysObjectID>
     </Routers>

     <Switches>
          <sysObjectID>1.3.6.5.5.3</sysObjectID>
          <sysObjectID>1.3.6.5.1.34</sysObjectID>
     </Switches>

     <Servers>
          <sysObjectID>1.3.6.5.567.1</sysObjectID>
     </Servers>

     <Devices>
          <sysObjectID>1.3.6.5.49.1</sysObjectID>
     </Devices>
</DeviceType>
```

3. Run discovery on the discovery profile that contains the devices.

   NOTE
   The changes that you make to the DeviceTypes.xml file do not take effect on existing devices until you rerun discovery.

   When discovery is run, the following results occur:

- All devices that have a `sysObjectID` of 1.3.6.5.1.34 are classified as a device type of Router and Switch.
- All devices that have a `sysObjectID` of 1.3.6.5.5.3 are classified as a device type of Switch.
- All devices that have a `sysObjectID` of 1.3.6.5.567.1 are classified as a device type of Server.
- All devices that have a `sysObjectID` of 1.3.6.5.49.1 are classified as a device type of Device.

4. To verify your changes, go to the following locations:
   - Hover over **Administration**, and click **Monitored Items Management: Device Life Cycle**.
   - Hover over **Inventory**, and click **Devices**.

Preserve Device Types

Sometimes, a device might have an incomplete classification. For example, a device that is discovered as a Router may be a Firewall too. In this case, you want to preserve the discovered Router classification. You also want to augment the classification with one or more manually assigned device types (in this example, Firewall).

Scenarios:

- An existing device is discovered automatically as a 'Server'. You want the device to be classified as a 'Firewall' too. To preserve the discovered 'Server' classification, add 'Firewall' to the DeviceTypes.xml with the `sysServiceOverride` tag attribute set to 'false'.
- An existing device is discovered automatically as a 'Router'. You want the device to be classified as a 'Firewall' and 'Switch' too. To preserve the existing 'Router' classification, add 'Firewall' and 'Switch' to the DeviceTypes.xml with `ysServiceOverride` tag attribute set to 'false'.

The `sysServiceOverride` tag attribute provides a way to disable the default override behavior. You can assign a `sysObjectID` to one or more device types in the DeviceTypes.xml (for example, Firewall) in addition to the types that the system automatically discovers (for example, Router). To preserve the device types, use the `sysServiceOverride` tag attribute and set it to 'false' for the `sysObjectIDs` or device types.

Use the `sysServicesOverride` tag attribute when the following criteria are true:

- You want to preserve the type that is discovered during device discovery.
- You accept the automatically discovered device type as correct and do not want to lose it.
- You want to add more types.

Example: Preserve the device types already mapped to the sysObjectIDs

Follow these steps:

1. Open the following file:
   DA_install_directory/data/custom/devicetypes/DeviceTypes.xml
   In a fault tolerant environment, the file would be located in the following directory:
   DASharedRepo/custom/devicetypes/DeviceTypes.xml
2. Enter the following information:

```
<DeviceType>
     <Routers>
          <sysObjectID sysServicesOverride="false">1.3.6.5.1.34</sysObjectID>
     </Routers>

     <Firewalls>
          <sysObjectID sysServicesOverride="false">1.3.6.1.4.1.8072.3.2.10</
sysObjectID>
     </Firewalls>

     <Firewalls sysServicesOverride="false">
```

```
            <sysObjectID>1.3.6.1.4.1.9.1.522</sysObjectID>                <!--
    cat6500FirewallSm -->
            <sysObjectID>1.3.6.1.4.1.2620.1.6.123.1.56</sysObjectID>      <!-- Check
    Point 21800 -->
            <sysObjectID>1.3.6.1.4.1.2620.1.6.123.1.16</sysObjectID>      <!-- Smart-1
    150 -->
        </Firewalls>

        <WirelessAccessPoints>
            <sysObjectID>1.3.6.1.4.1.2620.1.6.123.1.48</sysObjectID>
        </WirelessAccessPoints>

        <WirelessControllers>
            <sysObjectID>1.3.6.1.4.1.9.1.770</sysObjectID>
        </WirelessControllers>

        <LoadBalancers>
            <sysObjectID>1.3.6.1.4.1.6527.1.6.1</sysObjectID>
        </LoadBalancers>

    </DeviceType>
```

3. Run discovery on the discovery profile that contains the devices.

   NOTE
   The changes that you make to the DeviceTypes.xml file do not take effect on existing devices until you rerun discovery.

   When discovery is run, the following results occur:
   - All devices that have a `sysObjectID` of 1.3.6.5.1.34 are classified as a device type of Router. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.8072.3.2.10 are classified as a context type of Firewall. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.9.1.522 are classified as a context type of Firewall. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.2620.1.6.123.1.56 are classified as a context type of Firewall. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.2620.1.6.123.1.16 are classified as a context type of Firewall. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.2620.1.6.123.1.48 are classified as a context type of Wireless Access Point. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.9.1.770 are classified as a context type of Wireless Controller. The device types that are already mapped to the `sysObjectID` are preserved.
   - All devices that have a `sysObjectID` of 1.3.6.1.4.1.6527.1.6.1 are classified as a context type of Load Balancer. The device types that are already mapped to the `sysObjectID` are preserved.
4. To verify your changes, go to the following locations:
   - Hover over **Administration**, and click **Monitored Items Management: Device Life Cycle**.
   - Hover over **Inventory**, and click **Devices**.

Set Alias Names For Multiple Monitored Devices

To set aliases for multiple monitored devices simultaneously, use a script that is included with DX NetOps Performance Management. The alias appears in the inventory lists for devices and interfaces. An alias that you set using this script takes precedence over the alias that is set by importing a CSV file when you add an IP domain.

The script returns a list of device item IDs and device names in CSV format. Add the alias names that you want to set on each monitored device to the CSV file. The script reads the updated CSV file and sets the alias names for the monitored devices.

Follow these steps:

1. Open a command prompt and access the following directory:
   `Performance_Center_installation_directory/PerformanceCenter/Tools/bin`
2. To set alias names for monitored devices, type the following command:
   `./update_alias_name.sh`
3. To return a complete list of monitored devices, type the following command:
   `./update_alias_name.sh -h host_name -u username -p password [-T item_type] [-o output_filename]`
   - **-h host_name**
     Specifies the NetOps Portal host name.
   - **-u username**
     Specifies the username of the administrator who sets the alias names.
   - **-p password**
     Specifies the password for the CA NetOps Portal administrator who sets the alias names.
   - **-T item_type**
     Specifies the type of item for which you want to set alias names.
     Acceptable values: device, interface, or component.
     Default: device
     Keep the default value.
   - **(Optional) -o output_filename**
     Creates a CSV file with the total number of monitored devices by itemID and Device Name. Use this command to specify to override the default file name. If you do not enter a value for this parameter, DeviceList.csv is used for the .csv file.
     The CSV file has the following format: Device ItemID, Device Name.
     Examples:
     - `560, MyRouter1`
     - `561, MyRouter2`
   - Modify the CSV file as needed. Take note of the alias name that you want to set for each monitored device. This file has the following format: Device ItemID, Device Alias Name.
     If the Item IDs in your CSV file are invalid, the entries are ignored.
     Examples:
     - `560, MyRouter1AliasDisplayName`
     - `561, MyRouter2AliasDisplayName`

     NOTE

     For devices, the Alias Name value must be URL-encoded. Commas are allowed in the Alias Name field of the .csv file. Spaces must be URL-encoded as “%20”.
     For interfaces and components, the Alias Name value must be XML-encoded. Commas and spaces are allowed in the Alias Name value of the .csv file. The ampersand character must be encoded “&”. The less-than character must be encoded “<”. The greater-than character must be encoded as ">".
   - Type the following command:
     `./update_alias_name.sh -h host_name -u username -p password [-T device] -i input_file`

     -i input_file

Specifies the name of the CSV file.The alias names are set for monitored devices. If this parameter is not specified, the script finds all the item IDs that are required for the specified type, and creates a CSV file with item IDs and item names.

– (Optional) To control the workload when you set alias names for many monitored devices, type the following command, which adjusts the batch size and creates pauses between batches:

```
./update_alias_name.sh -h host_name -u username -p password -T device -i input_file -b batch_size -
t time_in_seconds
```

- **–b batch_size**
  Indicates the number of items to process in each batch.
  Default: 10000
  Default with the -i parameter unspecified: 150
- **–t time_in_seconds**
  Indicates the time, in seconds, to pause between batches.
  Default: 1
  Default with the -i parameter unspecified: 1
  Example:

```
./update_alias_name.sh -h host_name -u username -p password -T device -
i input_file -b 20 -t 2
```

Device Deduplication

Without deduplication, a single physical device is modeled as multiple device items when it is discovered from multiple sources (Simple Network Management Protocol (SNMP), DX NetOps Mediation Manager, DX NetOps Virtual Network Assurance, or another source). Deduplication models a single device in DX NetOps Performance Management.

The following general rules apply to deduplication. Exceptions to these rules are covered in the following sections.

- DX NetOps Performance Management deduplicates devices only when they are in the same IP domain.
- DX NetOps Performance Management successfully deduplicates devices regardless of discovery order.
- When the deduplication criteria of a device (IP address, hostname, and so on) from one source matches an existing device item from another source, DX NetOps Performance Management does not create a new device item. Instead, the same existing device item is used for both sources.
- If attributes conflict and SNMP is a source, the attributes from SNMP take precedence.

SNMP Deduplication

New SNMP devices are not created in the following scenarios:

> **NOTE**
>
> The primary IP address is the IP address that DX NetOps Performance Management uses to monitor a device. When a device is first discovered with the IP ranges discovery profile, DX NetOps Performance Management tries to use the IP address that maps to the hostname as the primary IP address.

- The primary IP address matches an existing device. The existing device could be a DX NetOps Mediation Manager (CAMM) or DX NetOps Virtual Network Assurance (VNA) device with the same primary IP Address.
- The hostname matches an existing device.
- The primary IP address for a new device is in the IP address list of an existing device, and the primary IP address of the existing device is in the IP address list of the new device. If the primary IP address of the new device is listed as a single IP address in the discovery profile, `sysName` is verified. If the `sysName` of the new and existing device match, the new device is not created.
- For devices that support the Device Unique Identifier metric family, the `UniqueID` matches an existing device.

SNMP and DX NetOps Mediation Manager Deduplication

DX NetOps Mediation Manager (CAMM) monitors devices that do not support SNMP or provides metrics that are not accessible through SNMP polling. CAMM injects data into the Data Aggregator through one of the Data Collectors. When the CAMM device pack provides an IP address or hostname that matches another device in the system, DX NetOps Performance Management deduplicates the devices to a single item.

The following table illustrates that DX NetOps Performance Management deduplicates SNMP and CAMM devices when the IP address or hostname match:

IP Address Match	Hostname Match	Deduplication
Yes	Yes	Yes
Yes	No	Yes
No	Yes	Yes
No	No	No

To deduplicate devices by the IP address only, edit the discovery profile to exclude hostname. For more information, see Discovery Profiles.

The following criteria must be met for deduplication to occur:

- Both the Data Collector and the CAMM Local Controller are in the same IP domain and poll the same device.
- Either a matching IP address or a matching hostname is present in both SNMP and CAMM.
- The CAMM device pack supports deduplication.

  WARNING

  Deduplication with CAMM devices occurs only for device packs that support deduplication. To determine which device packs support deduplication, see the information file of each device pack.
- For multiple devices packs, the device names on each device pack match.
- CAMM and SNMP discovery is successful.

DX NetOps Performance Management deduplicates devices only when the Data Collector and CAMM Local Controller and are in the same IP domain. However, the Data Collector and CAMM Local Controller can reside on different servers. The following server configurations are supported:

- Data Collector server for SNMP polling
- Local Controller server for CAMM polling
- Data Collector and Local Controller on the same server for SNMP and CAMM polling

If the combined workload is manageable, the CAMM Local Controller can be installed on the same server as the Data Collector for SNMP polling. However, ensure that your servers have enough capacity to continue operating with the normal SNMP polling load and the CAMM requirements.

For new installations, install the CAMM Local Controller on a Data Collector in the same IP domain with the devices that you want to monitor. Devices that are discovered through CAMM and through SNMP are deduplicated.

For existing installations, rediscover the devices with SNMP or CAMM. CAMM deduplication does not delete any existing duplicated device items. The historical data is still available on the existing device items. Historical data that was captured with the device model from an old IP domain still exists, but is unconnected to the newly reconciled device. We recommend that you delete or retire the device from the old IP domain to avoid double polling from CAMM. If the device from the old IP domain is not deleted, or the historical data is not aged out, DX NetOps Performance Management continues to have two devices.

CAMM components and SNMP components from the same Metric Family are not reconciled with each other. SNMP component discovery is delayed until the next change detection. An error occurs when all the following conditions are true:

- SNMP and CAMM polled devices in the same IP domain.
- The SNMP and CAMM devices were polled by the same Data Collector.
- The SNMP and CAMM device packs contribute to the same Metric Family.
- One of the two contributors (CAMM or SNMP) have late arriving data (greater than 30 minutes after the rollup period ends). Late arriving data is more likely to happen with CAMM data, especially with a 15-minute polling interval.

When the load on the Data Collectors is rebalanced, CAMM and VNA devices are not rebalanced. Therefore, deduplicated SNMP, CAMM, and VNA devices are not rebalanced. For more information, see Rebalance the Load on Data Collector.

Manage Metric Families

Viewing a metric family shows its associations with device collections, vendor certifications, and monitoring profiles. Understanding the relationships between metric families, device collections, and device types helps you control how to monitor your devices. Also, you can determine whether you need more metric families to monitor your environment sufficiently.

Follow these steps:

1. Hover over **Administration**, and click the Data Aggregator data source.
2. Expand **Monitoring Configuration**, and click **Metric Families**.
   Click the heading columns to sort the Metric Family columns, as needed.
3. Select a metric family from the list.
4. Click a tab to get more information:
   - **Metrics tab**
     View the metrics that are included in the selected metric family and various properties for each metric.
     - **Name**
     - **Polled**
     - **Min**
     - **Max**
     - **Percentiles**
     - **Projections (Days)**
     - **Projections Percentile**
     - **Baseline**
     - **Rollup Strategy**
     - **Standard Deviation**
   - **Vendor Certification Priorities tab**
     View a list of device collections that are associated with the selected metric family. Typically, a metric family is associated with a single device collection. When you select a device collection, a prioritized list of MIB sources (vendor certifications) appears. This information shows the order in which the vendor certifications are applied to that device collection for the metric family.
   - **Monitoring Profiles tab**
     View a list of the associated monitoring profiles and their poll rates.

Configure Metric Filtering

Metric filtering reduces the storage footprint of collected performance data by limiting the metrics collected from a metric family for a particular monitoring profile. For devices in associated collections, only the selected metrics are loaded.

The following example helps to describe the behavior for multiple monitoring profiles.

Example:

- One monitoring profile (A) has no metric filtering.
- Another monitoring profile (B) has some metric filtering to collect only BitsIn, BitsOut.
- Each monitoring profile is associated with a different collection.

Result:

- If a device ends up in both collections, the configuration from (B) takes priority. The system only collects BitsIn, BitsOut.

  WARNING

  If a device is associated with multiple monitoring profiles, all selected metrics from all monitoring profiles are collected and saved for the device at the fastest rate among all monitoring profiles.

Storage savings are not linear. To estimate the storage savings, use the Configure Data Retention Rates.

Metric filtering can only be applied to custom monitoring profiles. You cannot apply metric filtering to a monitoring profile with a lock icon.

NOTE

Metric filtering does not reduce SNMP traffic. Filtered metrics are still polled. Metric filtering applies only to metrics collected through SNMP.

Filtered metrics are still available for selection when building dashboards or configuring event rules for thresholds. Consider dashboard and threshold requirements before you filter a metric.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Monitoring Profiles**.
2. Select the monitoring profile, and click the **Metric Families** tab.
3. Select the metric family, and click **Edit Collected Metrics**.
4. Move the metrics to collect to the **Selected** pane.

   TIP

   By default, all metrics are selected. To pick a limited set of metrics, select all metrics, and move the metrics to the **Available** pane. Then move the metrics to collect to the **Selected** pane.
5. Click **Save**.
   Only the selected metrics are loaded to the Data Repository for devices in collections associated with the monitoring profile.

   WARNING

   If the collection is associated with another monitoring profile that includes the same metric family, or if the devices are in another collection associated with a monitoring profile with the same metric family, the metrics are still collected.

To view the metrics that are collected for a particular device, go to the device administration page, click the **Metrics** tab, and select a metric family. A column in the right pane indicates where the metric is collected.

NOTE

This tab represents consolidated information across all monitoring profiles associated with all collections the device belongs to. If you see a metric that you do not want to collect, view the metric families associated with each monitoring profile for each collection.

Edit a Metric

Use the UI to edit metric properties for any metric in a specific metric family. When you edit a metric, the metric family is extended automatically with the new values.

For complete information about how to extend metrics and metric families through REST services, see Create or Extend Metric Families.

> **NOTE**
>
> You can only edit a metric that is being polled. If the value in the Polled column on the Metrics tab is False, then you cannot edit the corresponding metric.

Follow these steps:

1. Click Metric Families from the Monitoring Configuration menu for a Data Aggregator data source.
   A list of metric families appears, including factory and custom metric families.
2. Select a metric family from the list.
3. Click a metric in the Metrics tab, and then click the Edit button.
   The Edit Metric dialog opens.
4. Enter the desired values in the Percentile, Projection, and Projections Percentile fields. Acceptable values for the fields in the Edit Metric dialog are as follows:
   - **95th Percentile:** Enabled or Disabled
   - **Percentiles 2 and 3**: 0-99, except 95
   - **Projections 1-3**: 0-730
   - **Projection Percentile:** 0-99

     > **WARNING**
     >
     > Changes to **Projection Percentile** cause inaccurate projections for up to 90 days. Changes to **Percentile 2** and **Percentile 3** cause a gap in the trend view. When you change the values in these fields, the percentile values for days before the change are not recalculated.

   For more information, see Percentiles and Metric Projection.
5. Click the Save button.
   The selected metric is updated in the parent metric family. The metric family is marked as extended and the Last Modified and Last Modified By fields are updated.
   The new data is available for reporting within several poll cycles.

Populate Components List for Response Path Metric Family

The Monitored Devices page can display a Supported status for a response path metric family on the Polled Metric Families tab, but the Components list for that metric family can be empty. To populate the Components list, update the Metric Family.

Follow these steps:

1. Verify that the device is configured to run the test that is associated with the metric family.
   For example, if the "Response Path Test DHCP" metric family shows no components, verify that the device is configured to run the DHCP test.
2. Select the row for the metric family, and click Update Metric Family.

Rediscover Metric Families

To ensure that you have the latest metric family and component support information for your devices, rediscover metric families.

NOTE
Log in as a tenant administrator to perform this task.

Follow these steps:

1. Select **Administration**, **Data Sources**, and click a Data Aggregator data source.
2. Click **Monitored Devices** from the Monitored Inventory menu.
3. Select a device for which you want to rediscover metric families from the Tree View tab.
   The device information displays in the Polled Metric Families view.
4. Click the **Update Metric Families** button.
   The Update Metric Families dialog opens asking you to confirm whether to update all metric families.
5. Click **Yes**.
   The status of each polled metric family is updated, such as whether it is newly or no longer supported. This status includes updating the Last Discovered time.
   The Components view is also updated for each polled metric family. Components that are no longer found during the rediscovery get a status of Not Present.

Manage Interfaces

Interfaces represent monitored communications ports, such as Ethernet or serial ports. DX NetOps Performance Management includes the following options for managing interfaces:

Poll Critical Interfaces Faster than Non-critical Interfaces

As the Administrator, you need frequent data about your most critical systems while maximizing the overall performance of your performance management systems. One way to accomplish your goal is by polling only critical interfaces at a high rate, while polling noncritical interfaces at a normal or slow rate. You can poll at differing rates by using a filter on the Interfaces metric family that is associated with your monitoring profile. By fast-polling interfaces sparingly, you can reduce unnecessary network traffic and performance management system load while still sufficiently monitoring the health of your network system.

For example, your data center access switch connects many application servers to only two aggregation switches. You decide to poll the interfaces supporting these aggregation switches at a higher rate. These links are critical, because they support network traffic to all other connected switches. However, polling *all* interfaces at a higher rate would cause unnecessary network traffic, wasting system resources and possibly causing network performance issues. After consulting with your network operations and engineering teams, you decide that a normal polling rate is sufficient for the interfaces connecting each attached server. To apply different polling rates, you implement two monitoring profiles for interfaces.

NOTE
Filters that you set on metric families are ignored when event rules that are applied to monitoring profiles trigger events.

View Your Monitoring Profiles

As the CA NetOps Portal Administrator, you decide to poll critical interfaces as often as possible. However, you want to minimize unnecessary network traffic that polling *all* interfaces at this fast rate can produce. You decide to create two monitoring profiles for interfaces -- one with normal polling, and one with fast polling.

Before you create a monitoring profile, you review the existing monitoring profiles to find one that closely matches your needs.

Follow these steps:

1. Click Monitoring Profiles from the Monitoring Configuration menu for your Data Aggregator data source.
   A list of monitoring profiles is populated.

2. Select a monitoring profile.
   Details for the selected monitoring profile populate the tabs:
   – Metric Families tab -- Displays a list of metric families that are associated with that specific monitoring profile. Metric families contain the metrics that are used for polling devices and components.
   – Collections tab -- Displays a list of device collections that are associated with that specific monitoring profile.

Copy a Factory Monitoring Profile

As the CA NetOps Portal Administrator, you find that the factory Network Interfaces monitoring profile closely matches your needs and requires only minor changes. Therefore, you create a copy and use it to poll only critical interfaces at a faster polling rate.

NOTE
Log in as the administrator to perform this task.

Follow these steps:

1. Navigate to the list of all monitoring profiles in CA NetOps Portal.
2. Select the Network Interfaces monitoring profile and click Copy.

   NOTE
   Factory monitoring profiles cannot be edited or deleted. All monitoring profiles, including custom, are global.

   The Create/Edit Monitoring Profile dialog opens.
3. Enter the following information for your monitoring profile:
   – **Name:** Uplink Interfaces
   – **Description** (optional)**:** Monitors performance of interfaces in all critical Uplink devices.
   – **SNMP Poll Rate:** 1 minute

   NOTE
   We recommend that you rename the profile. Unique naming is enforced across all tenants.

   Consider the following information about poll rates:
   – When the poll rate is changed, it takes up to two cycles for the new poll rate to take effect. When the 60-minute rate is used to poll an existing device, a 'No Data To Display' message appears in the dashboard view given the default time range of Last Hour. If you change the dashboard setting to a prior hour, it is possible to see earlier data. However, the view does not display the latest data until the new poll cycle completes.
   – Interfaces that are assigned to multiple monitoring profiles with different poll rates are polled at the fastest assigned rate.
4. Leave the Change Detection Settings, Rate value at 24 Hours.
   Consider the following information about change detection rates:
   – The *change detection rate* is how often Data Aggregator checks whether any components on a device have been reconfigured. Changes can include new components that have been created or existing components that have been retired.

     NOTE
     The reconciliation algorithm specified in the metric family defines the configuration changes to watch for.
   – The Change Detection Settings, Rate option is used to set the frequency at which Data Aggregator checks for changes. The rate of detection can be set in minutes or hours. By default, the rate is set to 24 hours.
   – Changes are detected at the fastest rate you specified for all of the monitoring profiles that are associated with a collection of devices.
5. Leave the 'Automatically Update Metric Families' check box selected.

This option controls the Data Aggregator response once a change or reconfiguration is detected. Selecting this option automatically causes Data Aggregator to start monitoring new components or to stop monitoring retired components. When this option is not selected, you can manually control monitoring of components, as follows:

a. Manually check the Events Display dashboard to watch for configuration events.
b. Navigate to the Data Aggregator administration menu, Monitored Devices, Polled Metric Families view.
c. Select the appropriate metric family, and click Update Metric Family to help ensure that Data Aggregator picks up the latest device reconfiguration.

NOTE
If an interface filter is applied, Data Aggregator monitors only the interfaces that pass the filter conditions after reconfiguration.

6. Leave the Interfaces metric family as the only metric family in the Selected Metric Families list.
7. Click Save.
   Your copied monitoring profile is added to the Monitoring Profiles list. However, this monitoring profile is not active until you assign it to a device collection.

Set an Interface Filter

By default, the factory network interface monitoring profile includes a filter to prevent modeling interfaces that are administratively down. In addition, interfaces with a type (ifType) of 1 (Other) or 24 (Loopback) are not modeled, regardless if those interfaces are administratively up or down. IPSLAs with the rttMonCtrlAdminOwner MIB object that contains the string “Network Health" are not modeled either.

Filtering reduces the number of interfaces that are monitored, which reduces unwanted data collection and network traffic.

In addition to polling only administratively up interfaces, you also want to poll the most critical interfaces more frequently. To isolate and poll only these interfaces faster, you add a second filter condition to the interface filter associated with your custom monitoring profile. This second filter condition isolates the critical interfaces by finding only interfaces that contain "uplink" in their description.

NOTE
Log in as the administrator to perform this task.

Follow these steps:

1. Select your interfaces monitoring profile (called "Uplink Interfaces") from the Monitoring Profiles page.
2. Click Interface metric family row on the Metric Families tab and click Edit Filter.

   NOTE
   Do not click directly on the metric family name, because it is linked to take you to the metric family definition. Instead, click the row the metric family name is in to activate the Edit Filter option.
3. Click the Add Condition button.

   NOTE
   Multiple conditions are connected with an "and" operation. That is, all conditions must be met to satisfy the filter.
4. Configure the filter conditions with the following options and click Save:
   – Attribute: Description
   – Operation: Contains
   – Filter Value: uplink

   NOTE
   The Filter Value field is case-sensitive.

   Consider the following details about additional attributes you can use for filtering:

- For Speed In and Speed Out, you can use a decimal in the text field (such as 1.544) and can specify bps, Kbps, Mbps, or Gbps.
- For more information about configuring Type (that is, ifType), see the iana web site: .
- For Description and Alias, you can use a regular expression for filtering only when you select the Matches Regex or the Does Not Match Regex operation.
- When you save your changes, the filter criteria display on the Metric Families tab. You can now apply this monitoring profile to the appropriate device collection to begin polling your selected interfaces.

NOTE
Data Aggregator applies filtering after discovery. Interface components that do not match the filter criteria are not polled. If you add or edit an Interface filter *after* you run a discovery, polling on these components stops. These interface components are *not* displayed in CA NetOps Portal dashboards and data views.

Considerations for Interface Filters and Multiple Monitoring Profiles

When multiple monitoring profiles are assigned to a device collection, the filter matching criteria follows the "or" rule. So, Data Aggregator monitors all interfaces that satisfy the criteria for any of the monitoring profiles in the group.

Some of the monitoring profiles may have filters and some may not. Plus, these profiles can specify differing poll rates. In this case, Data Aggregator monitors the interfaces that match any monitoring profile, but the polling rates can differ. If more than one monitoring profile applies to an interface, Data Aggregator polls the interface once, and polls it at the fastest polling rate:

- Monitoring Profile 1 -- Filter: Description contains "X," Poll Rate: 1 minute
- Monitoring Profile 2 -- Filter: None, Poll Rate: 5 minutes
- Monitoring Profile 3 -- Filter: Description contains "Y," Poll Rate: 10 minutes

In this example, interfaces that match Monitoring Profile 1 are polled every minute. All other interfaces are polled every 5 minutes. Interfaces that match Monitoring Profile 3 also match Monitoring Profile 2, which does not include a filter. The fastest poll rate applies, so no interfaces are polled at 10-minute intervals.

In this case, if one monitoring profile has no filter, the result is that many interfaces may be polled more frequently than necessary. Therefore, after you set a filter, remove associations from other monitoring profiles to make sure that only components matching the specified filter are monitored.

Assign Your Monitoring Profile to a Device Collection

As the administrator or a tenant administrator, you associate the new Uplink Interfaces monitoring profile with a device collection to begin polling. In this case, you associate the profile with the Switches device collection, which is the same device collection that is associated with the factory Network Interfaces monitoring profile. Polling rates are applied to the interfaces in this device collection, as follows:

- Fast polling: Interfaces that satisfy the filter criteria of the Uplink Interfaces monitoring profile.
- Normal polling: All other interfaces that the Network Interfaces monitoring profile discovers.

WARNING
All custom monitoring profiles are global and visible to tenant administrators. However, the association of a monitoring profile with a specific device collection can be scoped to a tenant.

Follow these steps:

1. Click Collections from the Monitoring Configuration menu for your Data Aggregator data source.
   A list of device collections displays. Administrators can view the device collections for the tenant they are administering. A tenant administrator can view its own (tenant) list of device collections.
2. Select the All Switches device collection and click the Monitoring Profiles tab.

A list displays the monitoring profiles that are associated with the selected device collection. The Network Interface device collection exists in this list.

3. Click Manage.
   The Assign Collection Monitoring Profiles dialog opens.
4. Select the Uplink Interfaces monitoring profile and click Add.
   The selected monitoring profile moves to the Assigned Monitoring Profiles list.
5. Click Save.
   Your changes are saved.

View Monitored Devices to Verify Results

After you set up your monitoring profiles, review the monitored devices and the Filter report to verify that only your critical devices are polled at the higher rate. This information helps you to see information in context, such as which monitoring profiles are being used to poll device components. Verifying the results can help you identify any necessary adjustments to help you achieve the polling results that you want.

Note: Monitored devices are manageable devices and pingable (accessible but not manageable). Inaccessible devices are not monitored devices. Components of monitored devices can be viewed from the Polled Metric Families tab.

Follow these steps:

1. Run an on-demand discovery.

   NOTE
   If your discovery profile runs automatically, you can wait for the next scheduled discovery.
2. Click Monitored Devices from the Monitored Inventory menu for a Data Aggregator data source.
3. Select one of these options from the drop-down list to locate one of your aggregation switch devices in the corresponding tree view:
   - Device by Collection -- Your devices appear under the All Switches device collection.
   - Device by Monitoring Profile -- Your critical interfaces appear under Devices under the Uplink Interfaces monitoring profile.

     NOTE
     Alternatively, select the Search tab to search by host name, device name, or IP address. You can enter a partial name or IP address to return a list of devices that contain that partial match. Wildcards and regular expressions are not supported.

   The Polled Metric Families tab shows the consolidated monitoring profiles that are associated with the switch device. Devices have only one consolidated monitoring profile. Each consolidated monitoring profile lists every metric family to poll on the device and whether the device supports the metric family.
4. Select the Interface metric family.
   The Components table for the Interfaces metric family shows one of the following polling statuses for the discovered Interface components:
   - **Active**
     Indicates that the component is being polled.
   - **Inactive**
     Indicates that polling has stopped on the component because the metric family is no longer monitored for the device.
   - **Not Present**
     Indicates that the component no longer exists on the physical device. Polling is stopped on the component. You can view historical data for reporting purposes. By default, retired components are not synchronized with CA NetOps Portal.
   - **Filtered (interface components only)**
     Indicates that the component does not pass the filter criteria and polling on the component is stopped.

NOTE

Filtered interfaces are not displayed in CA NetOps Portal dashboards and data views.

5. (Optional) Select the Interface metric family and click Update Metric Family.
   Data Aggregator reconfigures components for any configuration updates. For example, if you add a disk drive on a server, you can use the Update Metric Family button to rediscover the configuration update. The configuration update creates a disk component.
6. Click the Filter Report tab and follow these steps:
7. Look at the filters on each of the other Interface monitoring profiles to see if they are monitoring the same device collection that you want to filter.
8. Remove any relationships between other Interface monitoring profiles and device collections that will block your filter criteria. For example, if your new Interface monitoring profile is associated with the All Routers device collection, remove the relationship between *other* Interface monitoring profiles and the All Routers device collection.
9. Run another discovery and review the updated Filter report to verify that the new filter criteria is active. If the Filter report shows that an unwanted monitoring profile was included, repeat the previous steps until you are monitoring only the interfaces that you want.
   The Filter Report tab shows which interface filter criteria have been used during component monitoring. The tab also shows a report of all of the interfaces that are identified on the device and whether they matched the specified filter criteria.

   NOTE
   If you change the rules on a custom monitoring profile, the Interface Filter Criteria pane does not reflect those changes. If you disassociate the monitoring profile from a group, the Interface Filter Criteria pane does not reflect those changes. Rediscover the device to filter the interfaces that are based on the changes you made to the filter criteria and monitoring profile.

Interface Components Naming Convention

The naming convention for interface components that the Interface vendor certification or the High Speed Interface vendor certification backs is based on the following logic:

- If the ifName attribute exists and has a value, the interface uses this value for its name.
- If the ifName attribute does *not* exist or does *not* have a value, the interface uses the value of ifDescr for its name.

  NOTE
  New certifications for the Interface metric family can provide a different expression for the interface name.

Override Speed In and Speed Out Values on Interfaces

Data Aggregator provides a means for overriding the Speed In and Speed Out values for any interface to ensure utilization calculations use the appropriate values. For example, you could use the bandwidth command to configure ifSpeedIn and ifSpeedOut on your router interfaces to affect routing decisions. In this case, provide an override speed with Data Aggregator to ensure that utilization is calculated correctly.

The settings that you make on the device can change the value to one that is higher or lower than the actual available data rate. So, the utilization calculations that are made for the interface can appear inaccurate, due to this manipulation of the bandwidth. To ensure that interface utilization is calculated correctly, you want to provide an override speed on the interface within Data Aggregator.

By default, utilization is calculated using the Speed In and Speed Out values that the device, which the interface is a component of, reports. However, you can override these speed values. Reporting on interface utilization can then be more accurate.

Follow these steps:

1. Click Monitored Devices from the Monitored Inventory menu for a Data Aggregator data source.
   The Tree View tab displays.
2. Select Device by Collection or Device by Monitoring Profile from the drop-down list. Select the device that you want to override the Speed In and Speed Out values for an interface on and select the appropriate interface metric family on the Polled Metric Families tab.
   The interface components that are monitored on the device appear in the Interface Components table.
3. Select the interface component that you want to override the Speed In and Speed Out values for and click Edit.
   The Edit Interface dialog appears. The dialog displays the default discovered Speed In and Speed Out values.
4. Enter Speed In and Speed Out values in bits per second and click Save.

   NOTE
   You can remove overrides by clicking Clear and clicking Save. Going forward, bandwidth utilization charts in NetOps Portal for the interface display utilization using the speed values that the device reports. An event is generated on the interface, indicating that the speed overrides have been removed. The event can be seen in the Events Display dashboard in NetOps Portal.

   The dialog closes. The overridden Speed In and Speed Out values on the interface appear in the Interface Components table with asterisks.
   An event is generated on the interface, indicating that the Speed In and Speed Out values have been overridden on an interface. The event can be seen in the Events Display dashboard in NetOps Portal.
   Going forward, bandwidth utilization charts in NetOps Portal for the interface display utilization using the speed values that you specified.

Configure Counter Behavior

SNMP uses counters to record data points. The Data Collector polls the counters, and reports the differences in the counters over time. When the counter hits a preset limit, the counter resets to zero. The Data Collector assumes that the rollover happens no more than once per poll. If a rollover happens more than once, the resulting data is inaccurate. To resolve the issue of inaccurate data, take one of the following actions:

- Poll more often to ensure that the data is accurate
- Use a 64-bit counter instead of a 32-bit counter
- Show gaps in the data and leave out the inaccurate data

A counter can also go backwards, which indicates that the data is incorrect. The Data Collector interprets the backward behavior as a large spike in data, and discards the data point.

Bad Counter Deltas

The delta value for counters is calculated by comparing one poll cycle to the previous poll cycle. When Data Collector receives bad delta values, the values are discarded for calculation purposes. Occasionally, the counter value receives a bad poll result, and the value decreases. When the counter value shows a decrease, Data Collector skips the bad value.

When showGapsOnCounterRollover=true, the Data Collector discards the previous delta baseline. As a result, the Data Collector cannot calculate the delta for the next poll cycle.

The following table shows an example of the delta behavior when showGapsOnCounterRollover=true:

Poll Cycle	Counter Value	Delta Baseline	Delta Value	Utilization
Poll1	96	95	1	normal
Poll2	97	96	1	normal
Poll3	**30 (bad value)**	97	**null (drop)**	**gap**

Poll4	99	**reset**	**null (drop)**	**gap**
Poll5	100	99	1	normal

Show Gaps in Data

To show gaps in the data, change the default behavior. Repeat this procedure on each Data Collector.

WARNING

The following global settings apply to all devices that a particular Data Collector polls.

Follow these steps:

1. Create the following file on the Data Collector host:

   ```
   DC_install_directory/apache-karaf-<vers>/etc/
   com.ca.im.dm.snmp.collector.SnmpCollector.cfg
   ```

2. Add the following line to the file:

   ```
   showGapsOnCounterRollover=true

   showGapsOnCounterRollover32=true
   ```

   Default:
   - showGapsOnCounterRollover=false
   - showGapsOnCounterRollover32=false
3. Save the file.
   The new behavior takes effect immediately.

When you hide gaps, the following logic continues to protect against some spikes in the data:

- If a 64-bit counter appears to wrap at the 32-bit mark, the SNMP agent on the device is likely using the 32-bit counter. If the counter goes from an initial value below the maximum value of a 32-bit counter to a lower value, DX NetOps Performance Management computes the delta at the counter wrap as a 32-bit counter.
- If the delta exceeds a certain limit for either a 32-bit or a 64-bit counter, the data point is dropped.

Limit Delta Values

For 32-bit or 64-bit counters, the delta value is likely an error when both of the following criteria apply:

- A counter rollover occurs
- The delta is greater than the maximum allowable delta value
  Default: 2^32 for 32-bit; 2^63 for 64-bit

If an error occurs, the value is discarded for calculation purposes, and the report data shows a gap of one poll cycle. You can configure the behavior to increase or decrease the maximum allowable delta value. Repeat this procedure on each Data Collector.

Follow these steps:

1. Open the following file:

   ```
   DC_install_directory/apache-karaf-<vers>/etc/
   com.ca.im.dm.snmp.collector.SnmpCollector.cfg
   ```

2. To set a non-default threshold, add the following line to the file:

```
largeDeltaValueThreshold=integer

largeDeltaValueThreshold32=integer
```

Integer
Specifies the threshold for delta values.

3. **Default:**
   - largeDeltaValueThreshold32=2147483648 (0x80000000, or 2^31)
   - largeDeltaValueThreshold=9223372036854775807 (0x7fffffffffffffff, or 2^63-1)

   When a counter rollover occurs, DX NetOps Performance Management ignores delta values at or above the threshold.

Counter Rollover Log

The counter rollover log tracks detailed information about each counter rollover for all devices on a Data Collector. Use this log to verify counter behavior and troubleshoot counter issues.

Locate the log on the Data Collector that polls the relevant device:

```
/opt/IMDataCollector/apachxxxx/data/log/CounterRollover.log
```

The log contains currently applied configuration values, rollover events, IP addresses, and OIDs.

Example:

```
2016-03-07 12:54:13,480 | INFO  | ecutor-thread-58 | CounterRollover
      | .dm.snmp.rdp.impl.SnmpDeltaCache  327 | 186 - com.ca.im.data-collection-
manager.core.interfaces - 2.8.0.SNAPSHOT |  | Delta calculated is greater than or
 equal to 2147483648; dropping response: previous=1 / current=0 for ip 10.42.96.32, OID
 1.3.6.1.4.1.9.9.42.1.3.5.1.39.2222, itemID 906, in poll group 211.
```

Manage Interface Polling Behavior

If you have the Modify Component Polling role right, you can disable or enable polling capability on specific interfaces from the UI. This feature allows for more granular polling control than monitoring profile filters alone. Monitoring profile filters are limited because they can apply only to common attributes.

> **NOTE**
>
> When polling is disabled, polling is turned off and polling cannot occur. When polling is enabled, polling can occur, but this feature does not turn on polling. For polling to occur, the appropriate monitoring profiles and life cycle states must be set. For more information, see Configure Monitoring Profiles and Manage Device Life Cycles.

Disabling or enabling polling generates administrative events. For more information, see Event Types.

You can also use a Data Aggregator REST web service to disable or enable polling on other components. For more information, see Manage Polling Behavior for Components.

By default, polling is enabled for all new components. You can use a Data Aggregator REST web service to disable polling for all new components that are associated with specific metric families. For more information, see Manage Default Polling Behavior.

Follow these steps:

1. Hover over **Inventory** and click **Interfaces**.
2. Select the desired interfaces.
3. Click the **Select Polling State** drop-down and select **Disable** or **Enable**.
4. Click **OK**.
   The polling state changes.

Manage Network Flow Processing

You can enable and disable network flow processing for your Network Flow Analysis interfaces. You can also delete interfaces.

> **NOTE**
> From Network Flow Analysis v10.0.3, you can enable/ disable the interface/ device. From Network Flow Analysis v10.0.5, all the features are supported.

Perform the desired operation on the target routers or interfaces.

Navigate to the Network Flow Processing UI

Follow these steps:

1. Log in as an Administrator.
2. Hover over **Administration**, click **Data Sources**, and select the Network Flow Analysis data source.

Enable or Disable Interface

Follow these steps:

1. In the right pane, click the **All Interfaces** tab, and select the desired interfaces.
   Select multiple interfaces to perform bulk action.
2. Click **Enable** or **Disable**.
3. Click **Yes** at the prompt.

Edit an Interface

Follow these steps:

1. In the right pane, click the **Active Interfaces** tab, and select the desired interfaces.
   Select multiple interfaces to perform bulk action. However, only a few fields are editable in the bulk edit option. To edit all allowed fields, select only one interface.
2. Click **Edit Interface**.
3. Set the desired interface parameter values.
4. Click **Save**.

Delete an Interface

Follow these steps:

1. In the right pane, click the **Active Interfaces** tab, and select the desired interfaces.
   Select multiple interfaces to perform bulk action.
2. Click **Delete**.
3. Click **Yes** at the prompt.

SNMP Refresh

Follow these steps:

1. In the left pane, select the desired router.
   NOTE
   You can refresh only one router at a time.
2. Click **SNMP Refresh**.
3. Click **Yes** at the prompt.

Enable or Disable Devices (Router)

Follow these steps:

1. In the left pane, select the desired router.
   Select multiple devices to perform bulk action.
2. Click **Enable** or **Disable**.
3. Click **Yes** at the prompt.

Edit a Device (Router)

Follow these steps:

1. In the left pane, select the desired router.
   Select multiple routers to perform bulk action. However, only a few fields are editable in the bulk edit option. To edit all allowed fields, select only one router.
2. Click **Edit**.
3. Set the desired router parameter values.
4. Click **Save**.

Delete a Device (Router)

Follow these steps:

1. In the left pane, select the desired router.
   Select multiple devices to perform bulk action.
2. Click **Delete**.
3. Click **Yes** at the prompt.

Configure Round Trip Time (RTT) Tests

To enable round-trip time tests, configure the tests using the Data Aggregator REST API. DX NetOps Performance Management supports the following test types:

- **DNS**
  Measures the DNS lookup time.
- **ICMP Echo (Ping)**
  Measures the round-trip delay for the full path.
- **ICMP Path Echo**
  Measures the round-trip delay and hop-by-hop round-trip delay.
- **ICMP Jitter**
  Measures the hop-by-hop jitter, packet loss, and delay measurement statistics in an IP network.
- **HTTP**

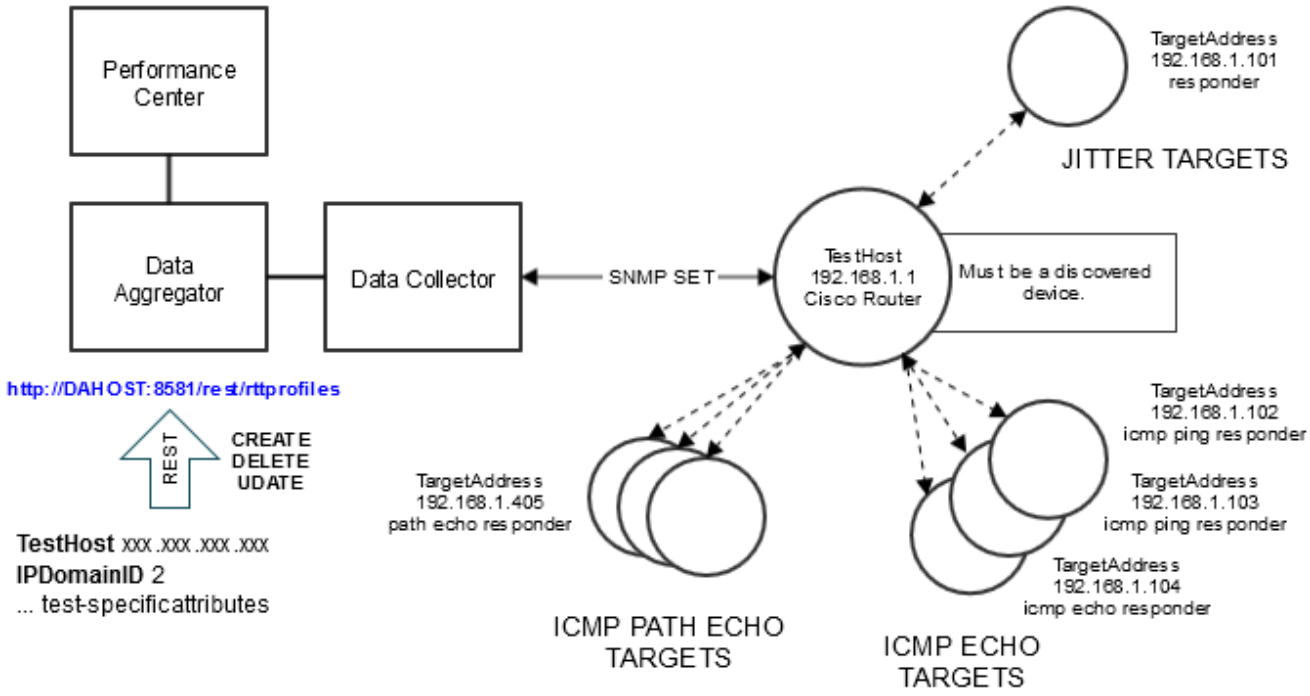
Measures the round-trip time to retrieve a web page.

- **TCP Connect**
  Measures the time to connect to a target device with TCP.
- **UDP Jitter**
  Measures the round-trip delay, one-way delay, one-way jitter, and one-way packet loss. Codec simulation is provided for MOS and ICPIF voice quality scoring capability.

RTT Test Architecture

The following diagram shows how the various components participate in the RTT test feature:

Figure 8: RTT Test Architecture



Configure the Tests

To configure RTT tests, complete the following steps:

Gather Required Information

The following information is required to configure a test:

- Required for all RTT tests in your environment:
  - DA host/address
  - IpDomainId

    NOTE

    To determine the IpDomainId, use the Data Aggregator REST API.
- Required for the specific test:
  - TestHost

The IP address of the device where DX NetOps Performance Management creates the test.

– Depending on the test type, one of the following targets is required:
  - TargetAddress
    The device that receives the test probes.
  - (DNS) TargetAddressString
    IP address or hostname of the target that receives the probes. Use this string instead of TargetAddress.
  - (HTTP) Url
    The URL that the HTTP probe communicates with.

Create an SNMP "SET" Profile

Create an SNMP profile and specify **Yes** for **Use in SNMP SET**.

For more information, see SNMP Profiles.

Discover Devices Capable of Running RTT Tests

Apply a monitoring profile with the IPSLA-related metric families that you want to monitor to the target devices. Then, run discovery for those devices.

For more information, see IPSLA Polling.

Associate SET Profiles with the Devices

For each device, associate the SET profile to the device item.

Through the UI:

1. Go to **Administration**, and click the Data Source.
2. Select the monitored device.
3. Select the SNMP SET Profile and the SNMP SET Version.
4. Click **Save**.
   You can now use DX NetOps Performance Management to configure RTT tests on the device.

Through the Data Aggregator API:

Documentation: `http://DA_HOST:8581/rest/devices/manageable/documentation`
PUT URL: `http://DA_HOST:8581/rest/devices/manageable/<device item id>`
Headers: [Content-Type=application/xml]
Body Syntax:

```
<ManageableDevice version="1.0.0">
  <RWSNMPProfileID>DA_RWSNMP_PROFILE_ID</RWSNMPProfileID>
  <RWSNMPProfileVersion>SNMP_VERSION</RWSNMPProfileVersion>
</ManageableDevice>
```

TIP

To find the Item ID of an SNMP profile, go to the following REST URL: `http://DA_HOST:8581/rest/profiles/snmpv1`

Example: This example associates the SNMP Profile identified by Item ID 736 with device 1144:

PUT URL

```
http://DA_host:8581/rest/devices/manageable/1144
```

Body

```
<ManageableDevice version="1.0.0">

  <RWSNMPProfileID>736</RWSNMPProfileID>

  <RWSNMPProfileVersion>SNMPV1</RWSNMPProfileVersion>

</ManageableDevice>
```

Configure the Tests

Use a REST client to create RTT profiles. DX NetOps Performance Management uses the RTT profiles to configure the tests on the target devices. Each profile initiates the specified action type to create, update, or delete a test on the device. The profile is not used again after DX NetOps Performance Management performs the specified action. Old RTT profiles are deleted.

For information about how to configure the RTT profiles, see RTT Configuration Examples.

RTT Configuration Details

Use a REST client to issue REST POST requests to create, delete, or update tests.

Endpoints

```
http://DA_host:8581/rest/rttProfiles/TestType
```

The following example shows the basic structure of the POST REST request:

```
<RTT_Profile version="1.0.0">
   <Item version="1.0.0">
    <Name>...</Name>
   </Item>

   <AttrGroupList>
     <AttrGroup>
       <ActionType>...</ActionType>
       <TestHost>...</TestHost>
       <IPDomainID>...</IPDomainID>
       <OptionalAttribute0>...</OptionalAttribute0>
       <OptionalAttribute1>...</OptionalAttribute1>
     </AttrGroup>
  </AttrGroupList>

</RTT_Profile>
```

RTT_Profile specifies the test type and determines which attributes are required and optional. Use one of the following values:

- DNSRoundTripTestProfile
- IcmpEchoRoundTripTestProfile
- IcmpPathEchoRoundTripTestProfile
- ICMPJitterRoundTripTestProfile
- HTTPRoundTripTestProfile
- TCPRoundTripTestProfile
- JitterRoundTripTestProfile

Action Types

The following table provides details about the operations that you use to configure the tests:

Logical Operation	REST Operation	Action Type	Endpoint	Description
Create	POST	CREATE	/rest/rttprofiles /<*TestType*>	Creates a test profile.
Force Create	POST	FORCE_CREATE	/rest/rttprofiles /<*TestType*>	Creates a test profile, but does not verify uniqueness.
Delete	POST	DELETE	/rest/rttprofiles /<*TestType*>	Deletes a test profile, including all the associated test instances.
Update	POST	UPDATE	/rest/rttprofiles /<*TestType*>	Deletes a test profile, and creates a new test profile that uses the same underlying MIB object index.
Get all test profiles	GET	GET	/rest/rttprofiles /<*TestType*>	Fetches all profiles of the specified test type.
Get specific test profile	GET	GET	/rest/rttprofiles /<*TestType*>/<*ID*>	Fetches a profile with the specified type and ID.

TestType specifies the RTT test type. Use one of the following values:

- dns
- icmpecho
- icmppathecho
- icmpjitter
- http
- tcp
- jitter

CREATE

This operation creates an instance of a test profile of the specified type with ActionType equal to CREATE. The created profile conceptually represents a background job to perform an SNMP set to create an RTT test on a device. The test is created permanently.

The create operation succeeds only if:

- The TestHost is a discovered device.
- The attributes of the requested test do not match an existing test in DX NetOps Performance Management.
- The attributes are semantically correct. The TargetHost does not reject the attributes because values are incorrect or the combination of attributes is invalid.

The result of a CREATE request is reflected in the read-only <Result> attribute of the created test. Perform a GET to view the result.

FORCE_CREATE

This operation is similar to CREATE, but creates the test even if an existing test has the same attribute values.

DELETE

This operation deletes a test that is identified by ItemIDs or by supplied attributes.

Deletes all tests that match the supplied attributes or the specific tests that matches the ItemIDs.

ItemIDs supersede attributes.

UPDATE

This operation re-applies attributes to an existing test. The operation deletes the test, and creates a test with new attributes. UPDATE changes only the supplied attributes. UPDATE runs DELETE, then CREATE. To preserve the relationship between the test configuration and the discovered Response Path Test components, the new test reuses the underlying MIB object index.

Attributes

NOTE

Depending on the Cisco IOS, some attributes may not apply to your device.

The following attributes apply to all test types:

- **ActionType** The action type of RTT test.
- **TestHost**
  The address of the device on which the test runs.
- **ItemID**
  Specifies the ID of the target test for DELETE and UPDATE actions. To get the ItemID, see Get the ItemID for a Test
- **IPDomainID** Specifies the IP Domain of the test. IP Domain is required for all actions that do not include ItemID.
  - CREATE always requires IPDomainID.
  - DELETE requires IPDomainID to delete a test without specifying the ItemID.
  - UPDATE never requires IPDominID.
- (Optional) **Owner**
  Specifies the test owner.
- (Optional) **Tag**
  A short string that identifies the test in logging and notification.
- (Optional) **Threshold**
  Specifies that the test generates a threshold event if test takes longer than specified milliseconds.
- (Optional) **Frequency**
  Duration in seconds between initiating each RTT test.
- (Optional) **Timeout**
  Duration in milliseconds to wait for an RTT operation completion.
- (Optional) **VrfName**

Specifies the VPN name where the RTT operation is used . The agent uses this field to identify the VPN routing table for the operation.

- (Optional) **Persist**
  Indicates whether this test configuration should be saved when persisting agent configuration to non-volatile storage. If left unspecified, the default is true.

  NOTE

  Cisco recommends persisting the tests. If the configuration is lost on the device, DX NetOps Performance Management does not re-provision the test.

This table summarizes the attributes that are associated with each IPSLA test. R indicates Required, and O indicates Optional:

Parameter	Description	ICMP Echo (Ping)	ICMP Path Echo	ICMP Jitter	UDP Jitter	UDP Jitter (VoIP)	DNS	TCP	HTTP
SourceAddress	The address of the device on which the test runs.	O	O	O	O	O	O	O	O
SourcePort	Specifies the source address port number. If the port is unspecified, the system selects a port.	N/A	N/A	N/A	O	O	O	O	O
TargetAddress	The destination IP addresses of the RTT test.	R	R	R	R	R	N/A	R	N/A
TargetPort	The destination port to which test probes are sent.	N/A	N/A	N/A	R	R	N/A	R	N/A
RequestSize	The request probe payload size.	(28)	(28)	N/A	(32)	(32)	N/A	N/A	N/A
ResponseSize	The response probe payload size.	N/A	O	N/A	O	O	N/A	N/A	N/A

TypeOfService	The type of service octet in an IP header.	O	O	O	O	O	N/A	O	O
Interval	The inter-packet delay in milliseconds between packets.	N/A	N/A	N/A	O	O	N/A	N/A	N/A
NumPackets	Number of packets to transmit.	N/A	N/A	N/A	O	O	N/A	N/A	N/A
CodecType	The codec type to use with jitter probe.	N/A	N/A	N/A	N/A	O	N/A	N/A	N/A
CodecInterval	The inter-packet delay in milliseconds between packets. Valid only for jitter probe which uses CodecType.	N/A	N/A	N/A	N/A	O	N/A	N/A	N/A
CodecPayload	Number of octets to place into the Data portion of the message. Valid only for jitter probe which uses CodecType.	N/A	N/A	N/A	N/A	O	N/A	N/A	N/A
CodecNumPackets	Number of packets to transmit . Valid only for jitter probe which uses CodecType.	N/A	N/A	N/A	N/A	O	N/A	N/A	N/A
ICPIFAdvFactor	Used while calculating jitter ICPIF values.	N/A	N/A	N/A	N/A	O	N/A	N/A	N/A

TargetAddressString	Specifies the address of the target. This string can be an IP address or a hostname.	N/A	N/A	N/A	N/A	N/A	R	N/A	N/A
NameServer	Specifies the IP address of the name-server.	N/A	N/A	N/A	N/A	N/A	R	N/A	N/A
Url	Specifies the URL that the HTTP probe targets.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	R
Operation	Specifies the HTTP operation that represents the specific type of RTT operation.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	R
HTTPVersion	Specifies the version number of the HTTP server.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	O
String1	Stores the content of a raw HTTP request. If the request cannot fit into String1, use more String attributes. *Required only if **Operation** is set to **httpRaw (2)**.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	R*
String2	Continues the raw HTTP request from **String1**.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	O

String3	Continues the raw HTTP request from **String2**.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	O
String4	Continues the raw HTTP request from **String3**.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	O
String5	Continues the raw HTTP request from **String4**.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	O

NOTE

When you specify an attribute value that has an associated enumerated name as defined by the MIB, only the numeric value is recognized.

Result

The result attribute is a read-only attribute that indicates the outcome of the request:

Meaning	<Result> value
The operation is in progress.	PENDING
The operation succeeded.	SUCCESS
The TestHost is not discovered.	FAILURE: Unable to identify device at 192.168.96.1
The requested test is already configured.	ALREADY_EXISTS: Existing Count = 1
TestHost is unreachable. Get the ItemID for a Test

The UPDATE and DELETE operations use ItemID to identify tests. To get the ItemID, use a filtered REST endpoint:

- *http://DA_HOST:8581/rest/responsepathtest/filtered*
  Searches all test types.
- *http://DA_HOST:8581/rest/responsepathicmp/filtered*
  Searches ICMP Echo tests.
- *http://DA_HOST:8581/rest/responsepathecho/filtered*
  Searches ICMP Path Echo tests.
- *http://DA_HOST:8581/rest/responsepathjitter/filtered*Searches UDP Jitter tests.
- http:// *DA_HOST:8581*/rest/responsepathicmpjitter/filtered
  Searches ICMP Jitter tests.
- http://*DA_HOST*:8581/rest/responsepathhttp/filtered
  Searches HTTP tests.
- http://*DA_HOST*:8581/rest/responsepathtcp/filtered
  Searches TCP Connect tests.
- *http://DA_HOST:8581/rest/responsepathdns/filtered*
  Searches DNS tests.

Example Request

This example shows a filtered request for tests with the specified target:

```
<FilterSelect xmlns:xsi='http://www.w3.org/2001/XMLSchema-instance'
 xsi:noNamespaceSchemaLocation='filter.xsd'>
  <Filter>
    <ResponsePathTest.Target type='EQUAL'>10.42.94.250</ResponsePathTest.Target>
  </Filter>
  <Select use="exclude"/>
</FilterSelect>
```

TIP

To exclude all attributes except ItemID, the following statement:

```
Select use="exclude"
```

Example Response

This example shows the response to a filtered request:

```
<ResponsePathIcmpList>
    <ResponsePathIcmp version="1.0.0">
        <ID>955</ID>
    </ResponsePathIcmp>
    <ResponsePathIcmp version="1.0.0">
        <ID>956</ID>
    </ResponsePathIcmp>
</ResponsePathIcmpList>
```

RTT Configuration Examples

Use these examples to help configure your tests:

RTT REST Configuration Example Script

The following script creates an example POST. Use the example as a template to create, delete, and modify RTT tests.

rtt_rest_configuration_examples.py

```
$ ./rtt_rest_configuration_examples.py
Usage: rtt_rest_configuration_examples.py [--quiet] [--dry-run] <DA host> create|delete
 ping|jitter [<attribute_name> <attribute_value> ...]

Options
      --quiet      Suppress output
      --dry-run    Construct REST request, but do not send

    Test     Attributes
    --------
 ------------------------------------------------------------------------------------------
    icmpecho DeviceIp IpDomainId Owner Threshold Tag Frequency Timeout TargetAddress
 RttTestName SourceAddress
    jitter   DeviceIp IpDomainId Owner Threshold Tag Frequency Timeout TargetAddress
 RttTestName SourceAddress

Examples
    % ./rtt_rest_configuration_examples.py testda1.ca.com create icmpecho DeviceIp
 10.165.170.222 IpDomainId 2 TargetAddress 10.132.159.140 SourceAddress 10.117.139.209
 Frequency 180
    % ./rtt_rest_configuration_examples.py testda1.ca.com delete jitter DeviceIp
 10.103.224.132 IpDomainId 2 TargetAddress 10.132.159.140

(See script comments for more examples)
```

Example RTT Configurations

ICMPECHO CREATE

This example creates an ICMP Echo test:

```
<IcmpEchoRoundTripTestProfile version="1.0.0">
   <Item version="1.0.0">
    <Name>Example ICMP Echo Test</Name>
   </Item>

   <AttrGroupList>
     <AttrGroup>
       <ActionType>CREATE</ActionType>
       <TestHost>10.250.134.47</TestHost>
       <IPDomainID>2</IPDomainID>
       <TargetAddress>10.0.63.106</TargetAddress>
       <Frequency>62</Frequency>
       <Timeout>5000</Timeout>
       <Threshold>5000</Threshold>
       <Owner>tedison</Owner>
       <Tag>ECHO02</Tag>
       <RequestSize>40</RequestSize>
     </AttrGroup>
  </AttrGroupList>

</IcmpEchoRoundTripTestProfile>
```

ICMPECHO DELETE

This example deletes three ICMP Echo test with the specified ItemIDs:

```
<IcmpEchoRoundTripTestProfile version="1.0.0">
   <Item version="1.0.0">
    <Name>Delete ICMP Echo Test</Name>
   </Item>

   <AttrGroupList>
     <AttrGroup>
       <ActionType>DELETE</ActionType>
       <ItemId>800<ItemId>
     </AttrGroup>
     <AttrGroup>
       <ActionType>DELETE</ActionType>
       <ItemId>2311<ItemId>
     </AttrGroup>
     <AttrGroup>
       <ActionType>DELETE</ActionType>
       <ItemId>1021<ItemId>
     </AttrGroup>
  </AttrGroupList>

</IcmpEchoRoundTripTestProfile>
```

ICMPECHO UPDATE

This example updates the TargetAddress and Owner for the ICMP Echo test with the specified ItemID:

```
<IcmpEchoRoundTripTestProfile version="1.0.0">
   <Item version="1.0.0">
    <Name>Update ICMP Echo Test</Name>
   </Item>

   <AttrGroupList>
     <AttrGroup>
       <ActionType>UPDATE</ActionType>
       <ItemID>921</ItemID>
       <TargetAddress>10.52.217.32</TargetAddress>
       <Owner>admin_andy</Owner>
     </AttrGroup>
  </AttrGroupList>

</IcmpEchoRoundTripTestProfile>
```

ICMPPATHECHO CREATE

This example creates an ICMP Path Echo test:

```
<IcmpPathEchoRoundTripTestProfile version="1.0.0">
   <Item version="1.0.0">
    <Name>Example ICMP Path Echo Test</Name>
   </Item>

   <AttrGroupList>
```

```
      <AttrGroup>
        <ActionType>CREATE</ActionType>
        <TestHost>10.250.134.47</TestHost>
        <IPDomainID>2</IPDomainID>
        <TargetAddress>10.40.29.130</TargetAddress>
        <Owner>att</Owner>
        <Tag>seattle1</Tag>
        <Frequency>180</Frequency>
        <Timeout>7777</Timeout>
        <Threshold>6666</Threshold>
      </AttrGroup>
   </AttrGroupList>

 </IcmpPathEchoRoundTripTestProfile>
```

ICMPPATHECHO DELETE

This example deletes an ICMP Path Echo test with the specified attributes:

```
 <IcmpPathEchoRoundTripTestProfile version="1.0.0">
    <Item version="1.0.0">
     <Name>Example ICMP Path Echo Test</Name>
    </Item>

    <AttrGroupList>
      <AttrGroup>
        <ActionType>DELETE</ActionType>
```

```
        <TestHost>10.250.134.47</TestHost>
        <IPDomainID>2</IPDomainID>
        <TargetAddress>10.0.63.106</TargetAddress>
      </AttrGroup>
   </AttrGroupList>

</IcmpPathEchoRoundTripTestProfile>
```

JITTER CREATE

This example creates two Jitter tests:

```
<JitterRoundTripTestProfile version="1.0.0">
    <Item version="1.0.0">
     <Name>Create Jitter Test</Name>
    </Item>

    <AttrGroupList>
      <AttrGroup>
        <ActionType>CREATE</ActionType>
        <TestHost>10.188.72.48</TestHost>
        <IPDomainID>2</IPDomainID>
        <TargetAddress>10.16.75.221</TargetAddress>
        <TargetPort>33333</TargetPort>
        <Owner>admin_dan</Owner>
        <Tag>JITTER022</Tag>
      </AttrGroup>
```

```
      <AttrGroup>
        <ActionType>CREATE</ActionType>
        <TestHost>10.84.206.153</TestHost>
        <IPDomainID>2</IPDomainID>
        <TargetAddress>10.42.96.10</TargetAddress>
        <Owner>admin_steve</Owner>
        <Tag>JITTER023</Tag>
        <Frequency>120</Frequency>
        <Timeout>10000</Timeout>
        <CodecType>1</CodecType>
        <CodecInterval>20000</CodecInterval>
        <CodecPayload>172</CodecPayload>
        <CodecNumPackets>100</CodecNumPackets>
      </AttrGroup>

   </AttrGroupList>

 </JitterRoundTripTestProfile>
```

JITTER DELETE

This example deletes a Jitter test with the specified attributes:

```
 <JitterRoundTripTestProfile version="1.0.0">
    <Item version="1.0.0">
     <Name>Example Jitter Test</Name>
```

```
    </Item>

    <AttrGroupList>
      <AttrGroup>
        <ActionType>DELETE</ActionType>
        <TestHost>10.250.134.47</TestHost>
       <IPDomainID>2</IPDomainID>

        <TargetAddress>10.237.30.166</TargetAddress>
      </AttrGroup>
   </AttrGroupList>

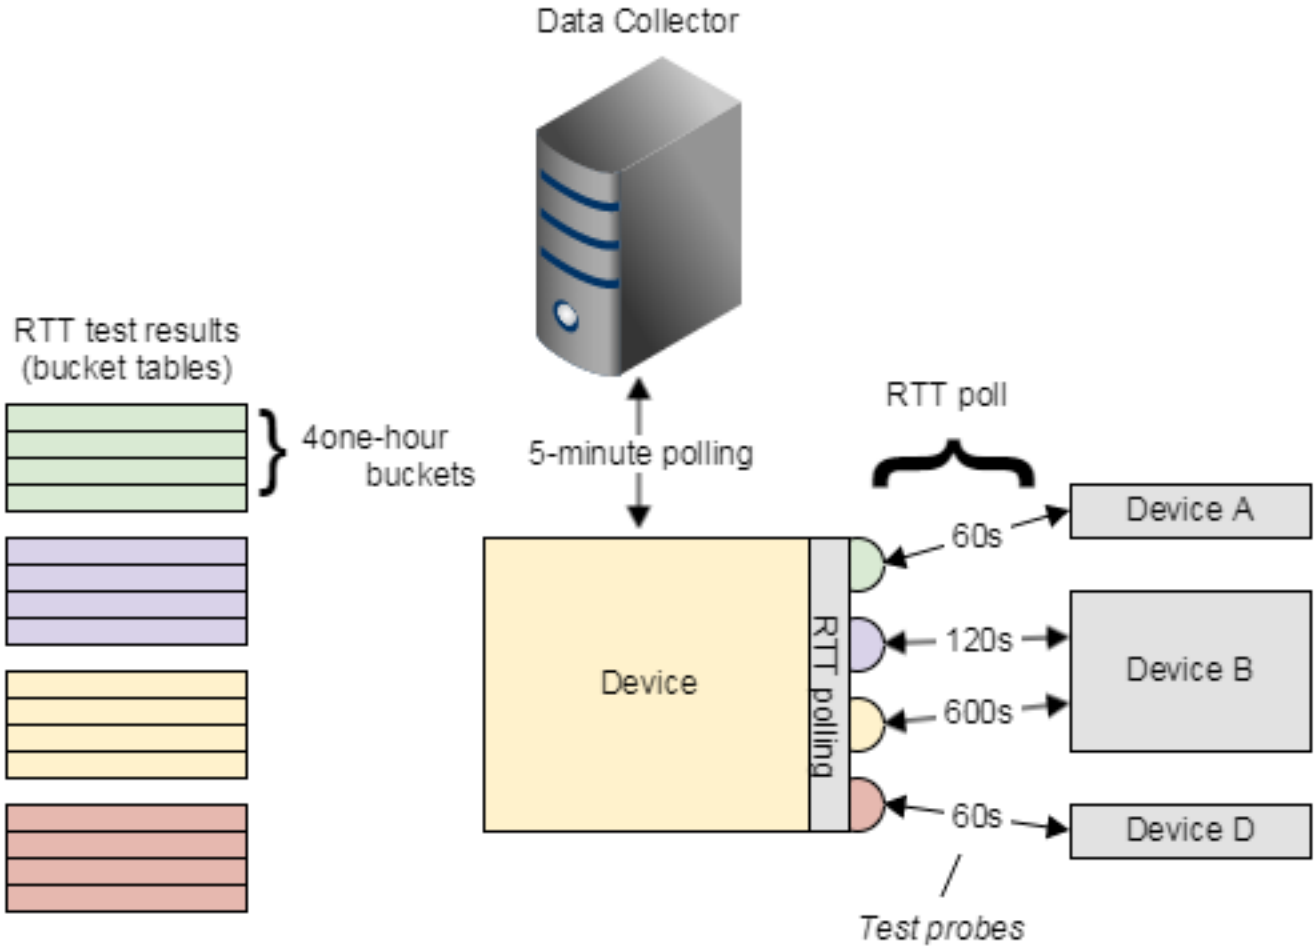
 </JitterRoundTripTestProfile>
```

IPSLA Polling

The Data Aggregator and Data Collectors poll IPSLA-enabled devices, which can run RTT tests. An RTT test frequency controls how often an active test runs (for example, every 60 seconds). While a test is active its results are stored in a statistics table. Each row represents one hour of results for a specific test. Test result metrics (for example, `rttMonStatsCollectTimeouts`) are stored as counters and increment after each execution of the test. At the end of an hour a new bucket is created. When the maximum number of buckets is reached, the oldest bucket is dropped. Metrics for new buckets are reset to zero and begin to increment. Disabled tests stop counting. The DX NetOps Performance Management poll rate controls how often the Data Collector requests these statistics. Each time the Data Collector polls the counter, it subtracts the last value from the current to produce a delta value for a given metric. For more information about setting the poll rate, see Configure Monitoring Profiles.

The following diagram illustrates IPSLA polling:

Figure 9: IPSLA Polling



Using

DX NetOps Performance Management monitors the health of your environment, including networks, applications, and devices. To display the relevant data, DX NetOps Performance Management uses dashboards and context pages. Both types of pages include views that show different information about your infrastructure.

Launch NetOps Portal

NetOps Portal is the web user interface for DX NetOps Performance Management. Use NetOps Portal to view infrastructure data, configure, collect, and perform administrative tasks.

NetOps Portal is supported in modern web browsers.

The following video shows the login process and provides more information about the authentication process:

Follow these steps:

1. Open a web browser.

2. In the address field, enter the following address: `http://PC_host:8181`
   - **PC_host** The IP address or hostname of the NetOps Portal host
   - **8181**
     The default port number for NetOps Portal
3. Specify your NetOps Portal username and password.
4. (Optional) Select **Remember me on this computer** to save your login session for 15 days. This option prevents your session from being deleted when you log out, time out, or you close the browser.
5. Click **Log In**.
   The NetOps Portal console opens to your home dashboard.

Search and Filter in Performance Center

Global search locates items in DX NetOps. For high scale environments, you can limit the scope and improve performance using the search controls that DX NetOps includes.

In this article:

Global Search

Global searches return lists of the items in the inventory that match the search string. The lists are sorted by item type (such as devices, interfaces, device components).

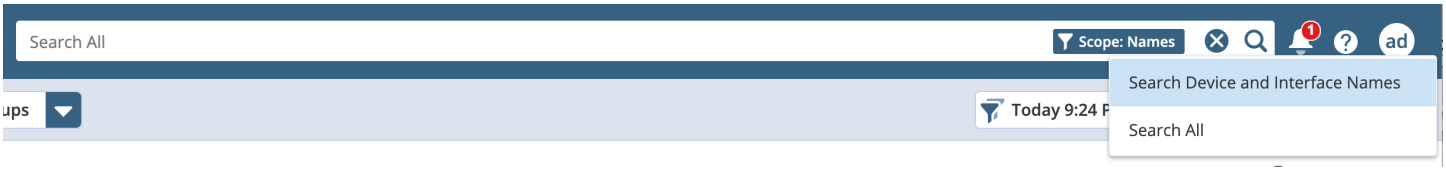
To perform a global search, click **Search** (the magnifying glass) at the top of any page. The following image shows an example of the global search bar:

Figure 10: Global_Search_bar

By default, the global search is set to search only device and interface names that contain the search string (Scope: Names).

To widen the search scope and search all managed items (for example, to search for tunnels) or search across other identifying information about an entity (for example, to search for ip-addresses) by selecting **Scope** in the search box, and then selecting **Search All** (Scope: All) from the drop-down. The following image shows the drop-down:

Figure 11: Global_Search_dropdown



Limit Global Search

You can limit the search scope in the **Search All** context using filter expressions. In the most basic form, the filter expression uses the following syntax:

```
ViewName:ColumnName=value
```

To search multiple views or columns, use the following syntax:

```
ViewName1:Column1;ColumnN&ViewName2:Column1;ColumnN=value
```

Filter Expression Examples

The following are examples of filter expressions you can use to limit the search scope:

Example: Search Devices Containing the String ‘foo’ Anywhere in the ‘Name’ Column

Use the following search expression:

```
Devices:Name=foo
```

Example: Search Interface Names or Descriptions and Devices that Include ‘foo’

Use the following search expression:

```
Interfaces:Interface Name;Description&Devices:Name=foo
```

Example: Search All Views

Use the following search expression:

```
Name;Description=foo
```

If the view does not include these columns, the expression searches all columns of this view.

Example: Search All Columns for a View

Use the following search expression:

```
Interfaces:*=foo
```

Use Wildcards in Filter Expressions

By default, global search searches for text that is contained in an item string. For example, searching for 'foo' or 'oo' returns ‘Foo’ as a result. To narrow or broaden your search, for example, to locate column names, add the asterisk (*) wildcard character to the filter expression.

You can search within interfaces view columns that contain ‘Name’--such as “Name Alias”, “Interface Name”, “Device Name Alias”--using the following filter expression:

```
Interfaces:*Name*=value
```

Using asterisks at the beginning and end of a keyword (‘contains’ searches), for example ‘*Name*’, is equivalent to entering ‘Name’ as the search string.

> **NOTE**
> ‘Starts with’ searches can return quicker results than ‘contains’ searches. For example, ‘foo*’ (starts with ‘foo’) executes faster than the ‘*foo*’ (contains ‘foo’) search.

To narrow the search, add multiple search words. For example, searching for devices using the ‘server 192.168*’ search string returns all servers on the 192.168.0.0/16 network.

Other Wildcard Examples

- Return all rows with entries that start with 'serv':
  `serv*`
- Return all rows with entries that end in ‘erver’:
  `*erver`
- Return all rows with entries that start with ‘fo’ and end with ‘200’. For example, the following filter expression returns ‘Foo_5976_10.92.200.200’, but it does not return ‘Foo_5976_10.92.200.201’:
  `fo*200`
- Return all rows with entries that:

- Start with ‘fo’
- Contain at least one character following 'fo'
- Contain '200'
- End with any character

```
fo*200*
```

Quick Filter

You can limit the contents of many table views to only those items that contain the search criteria that you enter using the quick filter. Quick filtering a table (for example, an inventory table that shows devices) is similar to performing a global search and looking at the results for that kind of managed item.

The following image shows an example of a quick filter:

Figure 12: Global_Search_bar

To quick filter a table view, type the search string into the quick filter box, and then either click filter (the funnel icon) or press the Return key on the keyboard.

To clear a quick filter, delete the search term, and then click filter (the funnel icon) or press the Return key on the keyboard.

Customize Your User Settings

You can customize your user account's default dashboard and personal settings.

In this article:

Set a Dashboard as Your Home Page

To log in to your preferred dashboard, set that dashboard as your home page. By default, the first dashboard in your first menu is your home page.

> **TIP**
> To return to your home page from any other page, click the logo in the upper left corner.

The following video shows how to set your default dashboard:

Follow these steps:

1. Navigate to the dashboard that you want to set as your home page.
2. (Optional) To set a specific context as your default, click the **[change]** link, and then select the group context for the dashboard. The home page saves the context.

   > **NOTE**
   > If the selected group is removed from your permission set, your default permission group is used for the dashboard context.
3. Click **More**, and then click **Set as Home Page**.
4. In the confirmation dialog, click **Yes**.

The selected dashboard is now your home page.

Customize your User Account Settings

User accounts include settings that you can customize, such as the preferred language and the time zone. Your role rights determine the settings that you can customize. If your user account has the required role right, you can change the settings.

Follow these steps:

1. Click the name of your user account in the upper-right corner, and then click **User Settings**.
2. Modify your user account settings:
   - **Preferred Language**
     Specify a language for the NetOps Portal user interface (UI). NetOps Portal displays the selected language regardless of the language selected for the operating system or for the browser language.

     NOTE
     For a language to display appropriately, the relevant fonts must be installed.

     For more information about the languages that DX NetOps Performance Management supports, see Language Support.
   - **Email Address**
   - **Time Zone**
     The default time zone is UTC (Coordinated Universal Time).

     NOTE
     Changing the time zone after email schedules are set up in NetOps Portal can cause incorrect times to appear in the Scheduled Emails UI.
   - **Time Display Format**
     Select the default time format, either 12 hours or 24 hours.
   - **Default Group**
     This group is the default context when you log in. The list only includes groups from your permission groups.
   - Select one of the following options from the **View Suppression** drop-down:
     View suppression hides views when the required data source is not registered or when a required technology is not configured. Similar behavior applies to context tabs and custom menus. Menus and tabs that include only suppressed views are hidden. View suppression applies to the default views on out-of-the-box dashboards. View suppression does not hide views from administrators when they use the view categories to edit a dashboard.
     When the data source that populates a view is registered, that view is no longer hidden.
     - **Suppress Views**
       View suppression is enabled and views are hidden by default. You can disable it for troubleshooting purposes, or to help you decide whether to deploy another data source.
     - **Display All Views**
       View suppression is disabled and all views appear.
   - Select one of the following options from the **Item Name Display Setting** drop-down:
     This option determines whether device and interface names appear as the display name or as the alias in dashboards and views. By default, all users see the display name.

     NOTE
     This option does *not* control how devices and interfaces appear in the device or interface inventory lists.

     To modify this option, your user account requires the View Item Display Name or Name Alias role right.
     - **Use Display Name**
     - **Use Item Name Alias**
3. Click **Save**.

Change User Password

You can change the password for your user account.

By default, user passwords must meet the following requirements:

- Be different than the username
- Minimum length of 8 characters
- Maximum length of 30 characters
- Contain at least 3 of the following types of characters:
  - Special characters
  - Uppercase letters (A-Z)
  - Lowercase letters (a-z)
  - Numbers (0-9)

If desired, you can disable these requirements.

Follow these steps:

1. Click the name of your user account in the upper-right corner and click **Change Password**.
2. Enter the old password.
3. Enter the new password.
4. Confirm the new password.
5. Click **Save**.

Auto Refresh

You can turn on (enable) and off (disable) auto refresh using the option in the upper-right corner of the NetOps Portal UI. Enabling auto refresh displays the most recent data. Auto refresh defaults to refresh every 60 seconds, however, you can adjust this setting. For example, if you set the poll cycle to 5 minutes, you can work with CA Support to set auto refresh to 5 minutes.

> **NOTE**
> You can set auto refresh only to a rate that is higher than the poll cycle.

Share Data with Other Users

You can create or access reusable On-Demand report templates, and download a report for sharing. You can also access a dashboard and download it for sharing.

> **NOTE**
> When you generate CSV output, the following leading characters are removed from cells: (+, -, @, =).

Multiple options let you share dashboards and views. To share dashboards and views:

- Export a dashboard to a static report in PDF format. The PDF includes only the information currently visible in your dashboard.
- Set up schedules to send reports automatically.
- Export individual views. Publish views on a web page, such as an intranet site.
- Export data from a view to a file in CSV format. The CSV includes only the information up to the row limit (1,000 for custom views and 5,000 for common views).

For all data-export options, certain user account role rights are required.

When you send or schedule a report by email, you can choose the following format options:

- **PDF**
  - Select **Portrait** or **Landscape** to specify the page layout of the PDF document.
  - Select whether to run the report on only the **First Page** or **All Pages**.

For **First Page**, only the first page is attached and sent in an email message. For **All Pages**, an email message is sent with a time-sensitive link to the report containing all pages.

- **CSV**
  Select **Scaled** or **Unscaled** to specify whether the values in the exported dashboards are scaled.
  For **CSV**, a file is attached that contains all the data for each view based on the limit for the view.

NOTE

By default, each metric in a trend view appears as its own table in the CSV output. CSV reports can support having a column for each metric included in a trend view. To include a column for each metric in a trend view of a CSV report, reach out to CA Support.

WARNING

Running reports on All Pages can significantly impact performance. To minimize the performance impact, adhere to our best practices.

The following best practices apply to running reports on All Pages:

- Before you schedule reports on All Pages, ensure all your servers, especially the Data Repository, meet the minimum requirements and sizing guidelines.For information about the sizing requirements, see the DX NetOps Performance Management Sizing Tool.
- Schedule reports on All Pages to run during non-business hours.
- Run reports on All Pages only as a user *without* the High Resolution role right.
- Running reports on All Pages for As Polled data can be problematic especially for trend views and group scorecard trend views.
- Do not run reports on All Pages for the context page of a site group.
- Before you schedule a report to run on All Pages, try running it in isolation to understand its performance impact.

If a report on All Pages times out, when you click the link for the report, the PDF contains a "Query failed" error message. If a report times out, see Report on All Pages Times Out.

The System Status page includes details about the Report Generation Services. For more information, see View the Health of the System

Print a Report to PDF or CSV

If your user account has the required role right, you can export the current dashboard contents as a printed report. The Print feature lets you preview the current dashboard page in PDF or CSV format.

NOTE

When exporting Chart/Table views, the PDF does not show the gauge or chart that is associated with the currently selected row in the table.

Follow these steps:

1. Do one of the following tasks:
   - Hover over **Reports**, and click **On-Demand Report Templates**, and run an existing report template.
   - Hover over **Dashboards**, and select a dashboard.
2. Click the **Print** icon on the toolbar.
3. Click **Print PDF** or **Print CSV**:
   - **Print PDF**
     Select **Portrait** or **Landscape** to specify the page layout of the PDF document.
   - **Print CSV**
     Select **Scaled** or **Unscaled** to specify whether the values in the exported dashboards are scaled.

Scaled values appear with larger units, for example, 1 KB. Unscaled values appear in the raw form for the metric, for example, 1000 bytes.

4. Save the file to the local computer using the options that you selected.

Send or Schedule a Report by Email

If your user account has the required role right, you can export dashboard contents as a report attached to an email message. The Email feature lets you specify the email address of the recipient and the subject of the message. For CVS and single-paged PDF, the file is attached and sent in an email message. For full-paged PDF, an email message is sent with a time-sensitive link to the report. Download and save the report as soon as possible. Reports sent or scheduled by email include only the information up to the row limit. For example, the limit for the IM Table (Top) view is 2,500 by default.

When an IM Table (Top) view contains a mix of core and baseline metrics, the results might be capped at 1,000 rows. This reduced row limit depends on the number of queried items. The following warning message appears, “Selected metric has a sum roll-up strategy. Detailed projections support only averaged metrics.”

You can send a report by email immediately, or you can create a schedule for recurring report emails. For example, you can email interface utilization reports to the IT department each week for capacity planning.

NOTE

By default, up to 5 email tasks can run concurrently.

To send reports by email, your user account must have the 'Send Reports by Email' role right.

To set up a recurring email schedule, your user account needs the 'Send Reports by Email' and 'Send Reports on a Schedule' role rights.

NOTE
The administrator must specify an email server to enable this feature.

Follow these steps:

1. Do one of the following tasks:
   - Hover over **Reports**, and click **On-Demand Report Templates**, and run an existing report template.
   - Hover over **Dashboards**, and select a dashboard.
2. Click the **Email/Schedule Report** icon on the toolbar.
3. Complete the following fields:
   - **Dashboard**
     A read-only field that identifies the name of the dashboard. The dashboard name appears in the filename of the report that is attached to the email. The dashboard name also appears in the Dashboard column in the list of email schedules on the Manage Scheduled Emails page.
   - **Send To**
     Specifies the email addresses of the recipients. Use the standard format:
     `<name>@<domain>`
   - **Subject**
     Describes the emailed report.
     Example: The dashboard title and any components for which data is included in the report.
   - **Message**
     (Optional) Message that accompanies the emailed report.
   - **Security** Specifies whether to require a login to view the report.
4. Select one of the following formats from the **Format** drop-down list:
   - **PDF**
     - Select **Portrait** or **Landscape** to specify the page layout of the PDF document.
     - Select whether to run the report on only the **First Page** or **All Pages**.

For **First Page**, only the first page is attached and sent in an email message. For **All Pages**, an email message is sent with a time-sensitive link to the report containing all pages.

- **CSV**
  Select **Scaled** or **Unscaled** to specify whether the values in the exported dashboards are scaled.

5. Specify a frequency for running the report with a start time, time zone, and time range for the report:
   - **Send Now**
     Runs the report and sends the email message immediately.
   - **Run Daily**
     Runs the report and sends the email message once per day. If selected, reveals checkboxes where you can select the day of the week when the report is run.
     Default: Run the report every weekday (Monday - Friday) at 00:30 hours in the time zone of the logged-in user. The data in the report reflects the previous 24 hours.
   - **Run Weekly**
     Runs the report and sends the email message once per week. If selected, lets you select the day that the report is run.
     Default: The report is run every Sunday at 01:00 in your time zone. The data in the report reflects the previous seven days (Saturday - Sunday).
   - **Run Monthly**
     Runs the report and sends the email message once per month. If selected, lets you select the day of the month to run the report.
   - **Run Quarterly**
     Runs the report and sends the email message once per quarter. If selected, lets you specify a starting month and day of the month to run the report.
   - **Run Yearly**
     Sends the email message once per calendar year. If selected, lets you specify a starting month. Reports are run on the first day of the specified month.
6. Click **OK**.
   The report is sent immediately, or according to the schedule that you selected. For CVS and single-paged PDF, the file is attached and sent in an email message. For full-paged PDF, an email message is sent with a time-sensitive link to the report. Download and save the report as soon as possible.

Manage Scheduled Reports

Users with the required role rights can set up schedules to email reports on a recurring basis. Selected dashboard data is exported in report format and sent to designated users according to a regular schedule.

If you have the role right to schedule emails, you can manage your own report schedules. Only users with the Administrator role can manage report schedules that belong to other users.

Follow these steps:

1. Log in as a user with the 'Send Reports by Email' role right.
2. Do one of the following tasks:
   - Hover over **Administration**, and click **Configuration Settings: All Scheduled Reports**.

     NOTE
     Tenant administrators only see the items that are associated with their tenant.
   - Hover over **Reports**, and click **Scheduled Reports**.

   The Manage Scheduled Reports page opens, and a list of scheduled reports appears.
3. Select the report schedule that you want to change, and click **Edit**.
4. View or change the settings for report schedules.
5. Click **Save**.
   The new report schedule settings are saved.

Generate a URL for a View

To share a view with users who do not have access to a dashboard, generate a URL for the view. The URL recreates the selected view on demand. The URL lets you add the view to a web page or intranet site to share performance data.

A security token is included with each URL. This token is based on the user who is logged in at the time of URL generation. Any user who accesses the exported view sees the same data as the user who exported the URL.

This procedure requires the Generate URLs from Views role right.

Follow these steps:

1. Open the dashboard that contains the view for which you want to generate a URL.
2. Click the **Edit** (gear) icon on the view, and select **Generate URL**.
   The Generate URL dialog opens. The URL is displayed in the URL field.
3. Enable or disable the following required parameters for the exported view:
   - **View Container**
     Displays the chart or graph with a surrounding container. The container includes the title of the view and a black outline around the chart or graph.
   - **Copyright**
     Shows the copyright information for the web page in the view.
   - **Drill Down**
     Lets users drill down from the view into the underlying data source for more detailed data. To use this feature, users must have access to the data source and the Drill into Data Sources role right.
   - **Detailed View Logging**
     If you encountered an issue with this view, enable logging. You can use this method to provide the necessary details to CA Support.
4. Select from the following time frame options:
   - **Time Options**
     Specify the time range for the data in the view.
   - **Token Expiration Options**
     Control view expiration. The default, 'Never' expires, lets the exported view display indefinitely.
     If you want the view to expire, select a timeout period from the **Token Expiration** list. The URL includes an encrypted token that causes the view to expire after the specified timeout period.
     The token does not enable the user who interacts with the generated view to drill down for more data.
5. (Optional) Click **Preview** to see how the view looks with the options that you have selected.
6. Copy the URL displayed at the top of the page to the clipboard.
7. Click **OK**.
8. Paste the URL to the destination where you want to display the view.
   The URL provides access to the selected view.

Export a View to a CSV File

You can export the contents of a view to a file in comma-separated values (CSV) format. The CSV file format is compatible with spreadsheet applications, such as Microsoft Excel. When you export a view, all view contents are exported as raw data.

> **NOTE**
> Limits of managed items are enforced for CSV export (1,000 for custom views and 5,000 for common views). Items that exceed the limit are not exported from the database.

Follow these steps:

1. Log in as a user with the 'Export to CSV' role right.
2. Navigate to the report that contains the view that you want to export.

3. Click the gear icon on the view, and select **Export to CSV (scaled)** or **Export to CSV (unscaled)**.
   The browser prompts you with options to open or save the exported file.
4. Select **Save** if you want to supply a filename.
5. Browse to the location where you want to save the file, and click **Save**.
   The view is saved as a file in CSV format.

Inventory Pages and Views

The Inventory pages show lists of managed items from all data sources. The **Inventory** menu shows only categories of items currently available to the product from the registered data sources. This menu is also limited to items types that are members of the groups in your user account permission set.

Some dashboards and context pages show relevant inventory list views. These views show the same information as inventory pages.

Inventory lists provide minimal information to identify each item, such as device hostnames or IP addresses.

Based on the device service information, Data Aggregator automatically classifies manageable devices as Router, Switch, and Server types. Also, where applicable, managed devices are associated with context types (Firewall, Load Balancer, Wireless Controller, and Wireless Access Point). The associated context types, including device types, appear listed in a column within device inventory tables.

The following list describes more device type classifications:

- **Pingable**
  The device is not manageable.
  Example: The device does not respond to SNMP requests and its device type cannot be determined.
- **Manageable**
  The device type is classified as 'Manageable' when the following criteria are true:
  – The manageable device cannot be identified as Router, Switch, or Server.
  – The manageable device *can* be identified as Firewall, Load Balancer, Wireless Controller, or Wireless Access Point.
- **Other**
  The device type is classified as 'Other' when the following criteria are true:
  – The manageable device cannot be identified as Router, Switch, or Server.
  – The manageable device cannot be identified as Firewall, Load Balancer, Wireless Controller, or Wireless Access Point.

If the type of some SNMP manageable devices were not identified as expected, override the device or context types. For more information, see Override Device Types.
The following procedures are common to the inventory views:

- To drill down to the context page for an item, click the item in the list.
- To sort by a column, click the column heading.
- To add or remove columns, hover over a column heading, and click the gear icon. Expand **Columns**, and select or clear columns.
- To run and On-Demand report, select an item, and click **On Demand**.
  For more information, see On-Demand Reports.
- To retire a device, or mark it for maintenance, select the device, and click **Manage Life Cycle**.
  For more information, see Manage Device Life Cycles.
- To enable or disable polling on specific interfaces, select the interfaces, and click **Select Polling State**.
  For more information, see Manage Interface Polling Behavior.

Device Inventory with Alarm States

If you have DX NetOps Spectrum configured as a data source, you can view alarm states from the device inventory.For more information, see Integrate CA Spectrum, Integrate CA Spectrum with CA Performance Management, and Customize Event Integration.The following columns in the device inventory contain alarm state information:

- **Current Alarm State**
  View the current alarm state of the device. This column is displayed by default.
- **Last Alarm State Change**
  View the date the alarm state last changed. This column is hidden by default.

The following alarm states are displayed:

- Normal
- Minor
- Major
- Critical
- Maintenance
- Suppressed
- Initial

If the device is not synchronized over from DX NetOps Spectrum, the alarm state information is blank.

Inventory Hierarchy View

The inventory hierarchy view shows the group tree, devices, and components or interfaces. The group tree is pinned to the current group context for the dashboard or context page.

- Select a group to filter the devices, components, and interfaces to the members of that group.
- Select a device in the top pane to filter the interfaces or components in the bottom pane.

  NOTE

  The filter only shows results for a single device. If you select multiple devices, the bottom pane is not filtered.

Configure an Inventory Hierarchy View

For standard view configuration details, see Customize Views.

The inventory hierarchy view can show devices, components, and interfaces. To configure which item types appear, configure the following properties:

- Select whether to show devices, components, or both.
- If the view shows components, select the Component Context type. This property determines the type of components that appear in the view.

Dashboards

Dashboards contain sets of views that let you see the polled data as meaningful information. You can also generate reports from dashboards. In addition to custom dashboards that the administrator has created, several out-of-the-box dashboards are available. When you log in, all dashboards that are assigned to your user account are accessible.

When you register a new data source, you can use the out-of-the-box dashboards and views that are associated with it. With the required role rights, you can edit dashboards, and can save the changes to your own user account.

DX NetOps Performance Management includes two categories of pages:

- **Dashboard Pages**

Provide high-level information, such as average performance of monitored items in a group. Dashboards often provide a drill-down path to more detailed, related pages from a selected context.

- **Context Pages**
  Provide focused performance and status data that is scoped to a specific item, such as a single router or server. These pages are available as drill-down links or tabs from dashboard pages.

To drill down to a context page from a dashboard, take one of the following steps:

- Right-click a hyperlink on an item and select a context page tab
- Click a hyperlink on an item to open the default context page tab.

NOTE
The drill-down feature requires the Drill into Views role right.

Custom Dashboards

All dashboards can be customized with different set of views, context, and layouts. Custom dashboards can be used to troubleshoot issues or long term to monitor categories of items.

Examples:

- A regional manager uses a dashboard that pins views to each site group in that region.
- A systems administrator uses a dashboard to monitor all servers.
- A network engineer uses a dashboard with views pinned to problematic routers or critical interfaces.

Change the Context

The dashboard context filters the data appears in views on the dashboard. When you select a group for a standard dashboard, you apply a filter to all views on the page. When you select a group context, items from all subgroups that are available to you appear in views on the dashboard. However, the same subgroups might not appear on the Items tab in Group administration. For more information on administering groups, see Groups.

You can also view dashboards in multiple windows, and apply a different data context to each dashboard.

Follow these steps:

1. Click the [change] link under the title of the dashboard.
2. Select a group from the group hierarchy.
3. Click OK.
   All views on the page with dynamic context are refreshed to reflect the new data context. The change applies until you log out.

Change the Time Range

To filter data based on specific time periods, specify time ranges for dashboards. Changing the time range is useful for troubleshooting performance issues. For example, you can change the time range to show data from the last seven days. In this case, the time range helps you to determine whether an issue is occurring regularly.

You can select a precise time range for the performance data shown in the current dashboard. Use the time period selectors to select the day, the start time, and the end time. When you change the time range for a dashboard, the change applies to all dashboards in that window. To compare content in different time ranges, open the dashboard in multiple browser windows or modify specific views to show a fixed custom time range.

Follow these steps:

1. Click **Change** in the upper-right corner of the dashboard page.
2. Select a default time period from the list or specify a custom time range.
   The selected time range is applied to the dashboard.

Apply Business Hours to a Dashboard

Business hours filtering is supported for some views on a dashboard. Business hours filtering is not supported for trend charts where the option to enable events is selected. For more information, see Configure Business Hours Filtering.

Business hours override other business hour settings in the following priority order:

1. Business hours configured and associated with a site group. For more information, see Configure Business Hours Filtering.
2. Business hour filters assigned to a view. For more information, see Customize Views.
3. Business hours applied to a dashboard.

Follow these steps:

1. Click **Apply Business Hours**.
2. Apply the business hours to a site listed in the **Site to apply** drop-down.
3. Click **Apply**.
   The business hours for the specified site are applied to the dashboard. The business hours remain applied when you switch between tabs, change time ranges, and so on. If you go to a top-level dashboard or you change the context, the business hours filtering is removed.

Manage Dashboards

To add a page with a custom set of views, create a custom dashboard. To modify the views or layout, edit an existing dashboard. To use an existing dashboard as a template, copy the dashboard.

Create a Dashboard

To add a new dashboard to the dashboard menu, create a dashboard. This procedure requires the Create a Dashboard role right.

Follow these steps:

1. Click the **Dashboards** tab.
   A list of available dashboards appears. Each pane on the page corresponds to a menu.
2. Click **Add Dashboard** next to the menu where you want the new dashboard to appear.
3. Complete the following fields:
   - **Dashboard Menu**
     The menu where the dashboard appears
   - **Menu Item**
     The name of the dashboard in the menu
   - **Dashboard Title**
   - The name that appears at the top of the dashboard
4. Select a layout template for the dashboard. Each layout treats the page as a table with rows and columns for views. The Layout buttons indicate the number of views in each column and row on the page. Select a layout before you add views.

   TIP

   Some views, such as scorecards, MultiView, and MultiTrend views, include a lot of detail and require more screen space. These views do not render well in layouts with more than one column.
5. Click and drag views to the page layout. The maximum number of views per dashboard is 25.
   To customize the view settings, click the Edit (gear) icon for the view.
   For more information about configuring views, see Customize Views.

TIP

To limit the list of views, click **Select Context**, and select a group, item, or device. Views that you add to the layout are pinned to the selected context.

6. Click **Save**.
   The dashboard is saved, and is added to the selected menu.
   The dashboard page refreshes to reflect your changes. The changes persist across login sessions.

Edit a Dashboard

To add or remove views, or rearrange views, edit a dashboard.

This procedure requires one of the following role rights:

- Administer Shared Dashboards
- Create a Dashboard

Follow these steps:

1. Use the **Dashboards** tab to access the dashboard that you want to edit.
2. Click the **More** menu in the upper right corner, and select **Edit Dashboard**.
3. Edit the dashboard as required.
4. Click **Save**.
   The dashboard reloads and shows the new settings.

Copy a Dashboard

To use an existing dashboard as a template for a new dashboard, copy the dashboard.

This procedure requires the Create a Dashboard role right.

NOTE

Dashboards in your My Dashboards menu can be copied only within your My Dashboards menu. You cannot copy a dashboard from your My Dashboards menu to another menu.

Follow these steps:

1. Open the dashboard that you want to copy.
2. Click **More** in the upper right corner, and click **Copy Dashboard**.
3. Select the dashboard menu where you want the copied dashboard to appear.
4. Specify the name for the dashboard in the dashboard menu.
5. Specify the title that appears at the top of the dashboard page.
6. Click **Save**.
   A copy of the dashboard is created. The new dashboard opens.

Organize Dashboards in Menus

Dashboards are organized in customizable menus. You see a list of available dashboards and menus when you hover on the Dashboards tab. Before you add custom menus, only predefined menus are included in the list. The user account role determines the menus that each user can access. Custom menus are defined for each tenant. Only the factory menus are shared among tenants.

Users with the required administrative role rights have the following options to manage menus:

- Create custom menus.
- Add or remove dashboards from menus.
- Associate menus with role.
- Reorganize menus for a role.

To access the **Manage Menus** page, hover over **Administration**, and click **User Settings: Menus**.

My Dashboards

With the required role right, you can add, move, or copy dashboards to a menu. Dashboards in the My Dashboards menu are not visible to other users. Users can copy and customize a dashboard from another menu to the My Dashboards menu.

> **TIP**
>
> To edit the My Dashboards menu for another user, proxy that user account. The action requires the Proxy User role right.

Add a Menu

Custom menus let you organize dashboards and make them available to users with specific roles. Administrators and designers can create custom menus, and can select dashboards for each menu. Custom menus are not available to any users until the administrator adds the menu to a role. All users with that role see the menu.

Follow these steps:

1. Hover over **Administration**, and click **User Settings: Menus**.
2. Click **New**.
3. Specify a name and description for the menu.
4. Add dashboard to the **Available** list for the menu.
5. Click **Save**.

Delete a Menu

You can delete a menu that is no longer in use, which removes it from the Dashboards tab. Any dashboards that are assigned to the menu are not affected, and remain available to other menus. Deleting a user account that is associated with a custom menu does not delete that menu.

Out-of-the-Box Dashboards

Out-of-the-box dashboards provide data immediately after you run discovery and begin collecting metrics from your environment. These dashboards show you examples of dashboards that you can build to monitor your environment. The dashboards provide views for different users across your organization. Use these dashboards as a starting point to create your own dashboard.

> **NOTE**
>
> Many out-of-the-box dashboards include views with data from CA Application Delivery Analysis or Network Flow Analysis. These views appear only if these data sources are installed in your monitoring system and register in NetOps Portal. For dashboards without a listed data source, the data comes from the Data Aggregator in DX NetOps Performance Management.

- **Infrastructure Overview Dashboard**View key health metrics across multiple technologies in the environment.
  User: Operations, Network Engineer

Data Source: Data Aggregator, CA Application Delivery Analysis, Network Flow Analysis

- **Server Device Health Dashboard**View consumption and status-related metrics specific to servers. **User:** Operations, System Administrator
- **Server Performance Dashboard**
  View server performance metrics.**User:** Operations, System Administrator**Data Source:** CA Application Delivery Analysis
- **Network Device Health Dashboard**View performance and consumption metrics for routers, switches, and interfaces.**User:** Operations, Network Planner**Data Source:** Data Aggregator, Network Flow Analysis
- **Network Performance Dashboard**View network, site, and component performance and health metrics for network devices.**User:** Operations, Capacity Planner**Data Source:** Data Aggregator, CA Application Delivery Analysis, Network Flow Analysis
- **Management Overview Dashboard**View availability, reachability, and flow.**User:** Operations
  Data Source: Data Aggregator, Network Flow Analysis
- **Network Overview Dashboard** View high-level key health metrics across multiple technologies in the environment.**User:** Operations, Network Engineer **Data Source:** Data Aggregator, Network Flow Analysis
- **Interfaces Display Dashboard**View interface utilization and traffic health.**User:** Operations, Network Engineer **Data Source:** Data Aggregator, Network Flow Analysis
- **Server Overview Dashboard**View a multitechnology focus on server consumption metrics.**User:** Operations
- **Data Source:** Data Aggregator, CA Application Delivery Analysis
- **CPU/Memory Display Dashboard**View top utilized CPU and memory for all devices in the monitoring environment.**User:** Operations, Capacity Planner
- **Interface Trends Dashboard**View interface utilization, errors, discards trend graphs.**User:** Capacity Planner, Network Engineer
- **Anomaly Detector Dashboard**View anomalies in network flow data. **User:** Operations, Capacity Planner, Network Engineer**Data Source:** Network Flow Analysis
- **Interface Capacity Watch Lists**View interfaces with the top utilization and baseline deviation.**User:** Capacity Planner
- **Router/Switch Capacity Watch Lists**View device level flow and consumption metrics.**User:** Capacity Planner, Network Engineer **Data Source:** Data Aggregator, Network Flow Analysis
- **Server Capacity Watch Lists**View server consumption metrics and baseline deviation.**User:** Capacity Planner, System Administrator

Technology-Specific Dashboards

The following dashboards are associated with specific technologies. The views on each dashboard are customized to fit the needs of each technology.

CBQoS Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

CBQoS Overview Dashboard and Device Views

Use the CBQoS Overview dashboard and device views to analyze the performance of your class-based quality of service policies. CBQoS policies help you manage bandwidth. For example, policies can determine the handling of VoIP and video conferencing data to minimize packet loss.

Some views let you gauge the effects of policies on packet discards. You can discover disparities in the discard rates of prepolicy and postpolicy data for a device. A view such as the Top CBQoS Policing Packets Transmitted view shows the number of packets that violated or exceeded the rate limits set by Class-Based Policing on the device. This information helps you to pinpoint the problem.

DS1 Interface Statistics Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Firewall Statistics Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

IP Statistics Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Mobile Wireless Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Modem Statistics Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

MPLS Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

MPLS Overview Dashboard and Device Views

Use the MPLS Overview dashboard and device views to see the status of the Multi-Protocol Label Switching (MPLS) environment. This information lets you gain a broad sense of overall MPLS performance for the enterprise or a specific device.

QoS Statistics Device Components

View the overall status of a device component and determine if the component is causing an issue.

Response Path Tests Overview Dashboard and Device Views

This dashboard and device views help you see the overall status of response tests for devices that support service level agreements (SLA) using various protocols. This information lets you gain a broad sense of overall SLA performance for the enterprise or a specific device.

For example, as a network infrastructure manager, you can identify which protocols are experiencing the highest latency and slowest response times from the dashboard. You can then look at the device-level views to determine which devices are experiencing the problems. This information can help determine if the cause is increased activity, a device that is down, or some other cause.

Response Path Device Component Views

Use these views, for any supported protocol, to see the overall status of a device component and determine if the response path tests are causing an issue.

Sonet/SDH Device Component Views

View the overall status of a device component and determine whether the component is causing an issue.

Vendor-Specific Dashboards

The following dashboards are associated with specific vendors. The views on each dashboard are customized to fit the needs of each vendor.

Cisco UCS Overview Dashboard and Device Views

The Cisco UCS platform integrates networking, virtualization, storage access, and management of the UCS components chassis, blade server, and Fabric Interconnect (a FCoE switch).

The Cisco UCS Overview dashboard provides performance and status information about Cisco UCS blade servers, chassis, and fabric interconnects. From the Overview page, you can drill down to the Blade, Chassis, and Fabric Interconnect Overview pages. From these Overview pages, you can drill down to component-level views that allow you to view trends.

All these views exploit the capabilities of the Cisco UCS manager that is integrated within Cisco UCS. A malfunctioning component such as a memory module or a fan can be easily identified and replaced before it becomes a severe problem.

Engineers can use this information to troubleshoot problems with the blade chassis physical components, including power supplies, fans, CPUs, and memory modules.

Cisco UCS Blade Overview Dashboard and Device Views

The Cisco Unified Computing System (UCS) Blade Overview dashboard provides performance and status information about Cisco UCS blade servers. From the Overview page, you can drill down to component-level views that allow you to view trends.

For example, a single blade can have up to 24 memory modules. Using this view, an overheated memory module can easily be identified. You can also a spot a malfunctioning fan at a single glance.

Cisco UCS Chassis Overview Dashboard and Device Views

The Cisco Unified Computing System (UCS) Chassis Overview dashboard provides performance and status information about Cisco UCS chassis. From the Overview page, you can drill down to component-level views that allow you to view trends.

For example, a single chassis can have up to eight blades. Using this view, an overheated power supply can easily be identified. You can also spot a malfunctioning fan at a single glance.

Cisco UCS Fabric Interconnect Overview Dashboard and Device Views

The Cisco Unified Computing System (UCS) Fabric Interconnect Overview dashboard provides performance and status information about Cisco UCS fabric interconnects. From the Overview page, you can drill down to component-level views that allow you to view trends.

Use this view to identify CPU consumption of a heavily loaded fabric interconnect. You can also a spot a malfunctioning fan or power supply at a single glance.

Citrix VDI Overview Dashboard and Device Views

The Citrix VDI Overview dashboard provides performance and status information on the Citrix VDI Management Servers and Desktops. Citrix Virtual Desktop Infrastructure (VDI) is the market leading technology for providing virtualized desktops using Hypervisor technologies. Currently, DX NetOps Performance Management supports VMware vSphere Hypervisors. From the Overview page, you can drill down to device-level views to isolate a problem.

Engineers can use this information to troubleshoot problems. Capacity planners can use this information to see which services are overloaded and plan for more VDI servers.

The CPU and Memory reports available in both the Citrix VDI Overview dashboard and the Citrix VDI Server Overview dashboard can display metrics that are not explicit to the Citrix VDI metric family. To avoid this problem, we recommend that you edit the view and save its context to a particular group to ensure the dashboard only reports on Citrix VDI controllers.

Desktop information provided includes:

- Number of desktops
- Desktops that are showing exceptional utilization
- Content of desktop groups
- Available VMs in the VDI catalog

Engineers can use this information to get a quick overview of the infrastructure and its utilization.

Infrastructure servers (called desktop controllers) information provided includes:

- State
- CPU
- Memory
- Storage
- Network utilization

Engineers can use this information to identify bottlenecks on the controllers before they become problems.

Citrix VDI Desktop Overview Dashboard and Device Views

The Citrix VDI Desktop Overview dashboard provides performance and status information on the Citrix VDI Desktops. Citrix Virtual Desktop Infrastructure (VDI) is the market leading technology for providing virtualized desktops using Hypervisor technologies. Currently, DX NetOps Performance Management supports VMware vSphere Hypervisors. From the Overview page, you can drill down to device-level views to isolate a problem.

Desktop information provided includes:

- The number of desktops
- The desktops that are showing exceptional utilization
- The content of desktop groups
- Available VMs in the VDI catalog

Engineers can use this information to get a quick overview of the infrastructure and its utilization.

Citrix VDI Server Page

The Citrix Server page contains the following views:

- Citrix VDI Controller - Registered Desktops (Table)
- Citrix VDI Controller - Services Health (Table)
- Citrix VDI Controller - State (Time Chart)
- Citrix VDI Controller - Configuration (Table)
- Top Citrix VDI Desktop - CPU/Latency/Logon Time (Table)
- Citrix VDI Desktop Group - Used Desktops/Group Enabled (Table)
- Citrix VDI Desktop Group - Desktops Available/Connected (Table)
- Citrix VDI Catalog - Used VMs (Table)
- Citrix VDI Catalog - Assigned VMs (Table)

On the Citrix Server page all metrics are in the scope of its controller, except for desktop group and catalog metrics.

IBM LPAR Overview Dashboard and Device Views

Use the IBM LPAR Overview dashboard and device views to see the status of overall LPAR performance for the enterprise or a specific device.

IBM LPAR Device Component Views

The IBM LPAR Device dashboard lets you view the overall status of a device component and determine if the component is causing an issue.

Microsoft Hyper-V Overview Dashboard and Device Views

Use the Hyper-V Overview dashboard and device views to see the status of overall Microsoft Hyper-V performance for the enterprise or a specific device.

Microsoft Hyper-V Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Microsoft Exchange Server and Active Directory Overview Dashboard and Device Views

This overview dashboard helps you see the overall status of the monitored devices in your Exchange 2007, Exchange 2010, and Active Directory 2008 environments. This information includes directory domain services as well as mailbox and hub-transport mail services.

For those services you can identify the key performance metrics, which includes mail traffic and directory traffic metrics. You can then access device-level views to isolate a problem.

Engineers can use this information to troubleshoot problems. Capacity planners can use this information to see which services are overloaded and plan for more domain and mail servers.

Microsoft Exchange Server and Active Directory Device Component Views

View the overall status of a specific device component and determine whether the component is causing an issue.

Microsoft Cluster Service Overview Dashboard and Device Views

To see the overall status of the monitored devices that are part of your Microsoft Cluster Service (MSCS), use the Microsoft Cluster Service Overview Dashboard.

You can identify which devices are the top offenders for:

- Resource failures
- Crypto and registry checkpoint restoration and saves
- CPU and memory usage
- Node traffic
- Time spent in various states.

You can then access device-level views to isolate a problem.

Engineers can use this information to troubleshoot problems. Capacity planners can use this information to see which MSCS devices are nearing their utilization capacity and plan for more resources.

Microsoft Cluster Service Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Solaris Zones Overview Dashboard and Device Views

Use the Solaris Zones Overview dashboard and device views to see the status of overall Solaris Zones performance for the enterprise or a specific device.

Solaris Zones Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

VMware Overview Dashboard and Device Views

The VMware Overview dashboard shows the overall status of monitored devices in your VMware environment, such as virtual centers, virtual machines, ESX hosts, and other supported devices. Use this information to identify which devices are the top offenders for attributes such as CPU and memory usage, bytes in/out, capacity, and the percentage of time that was spent in various states. You can then access device-level views to isolate a problem.

Engineers can use this information to troubleshoot problems. Capacity planners can use this information to see which virtual devices are maximizing their CPU shares and plan for more resources.

To access this dashboard, select Dashboards, VMware Overview. Drill down from the dashboard view to a specific device, and then select a VMware related tab for more detail about that device. To access the device pages directly, select Inventory, Devices, and select a supported device. Then select either the VMware, VMware ESX Host, or VMware Virtual Machine tab.

VMware Device Component Views

View the overall status of a device component and determine whether the component is causing an issue.

IWF Statistics Device Component Views

View the overall status of a device component and determine if the component is causing an issue.

Context Pages

You can often access more information about individual managed items from dashboards. Most dashboards are composed of views of summary data, such as hourly rollups or averages from a group of items. If additional data is available from the data source, with the Drill into Views role right, you can click a link on the dashboard page to drill down into the context pages.

The views on context pages show filtered data from a narrow context, such as a view of data from a single managed item. Drill down into specific data to determine the source of a performance problem using the links.

You can right-click the name of an item in some table views to access a menu. For example, right-click the link that corresponds to an item name in the Inventory section. In the menu, you can select a related context page, containing more granular data.

In this article:

Extended Flow Views

You can drill down Network Flow Analysis data for an interface within NetOps Portal without having to navigate to Network Flow Analysis. The interface context page supports the following views:

- **IP Performance**
  Provides a broad summary of information for the selected interface extracted from the flow data such as Top N Protocols, Top N Hosts, Top N Conversations and Top N ToS values. The interface also provides the interface utilization and discards details for the same interface provided through the data aggregator.
  To navigate to the context page of the protocol or host and so on, you can select the required protocol or host and so on from any of the views.

  NOTE
  If the data source is Network Flow Analysis 10.x and higher, the links in the charts and tables in the IP Performance page open the corresponding network flow pages within DX NetOps Performance Management. If the data source is Network Flow Analysis 9.x and earlier, the links open the corresponding pages in the Network Flow Analysis console.
- The following interface pages are available only if the data source is Network Flow Analysis 10.x and higher:
  - **Network Flow Protocol**
    Provides trends and next level drill downs (hosts and conversations) for the selected Protocol in the table. Host and conversation trend tables provide utilization information in the context of the selected Protocol.
  - **Network Flow Host**
    Provides host trends and protocol stacked trends for the selected Host in the table.
  - **Network Flow Conversation**
    Provides host trends and protocol stacked trends for the selected Conversation in the table.
  - **Network Flow ToS**
    Provides trends and next level drill downs (hosts and conversations) for the selected Type of Service(ToS) in the table. Host and conversation trend tables provide utilization information in the context of the selected ToS.

For all context pages, selecting a row in the top table view sets the corresponding context for the other views in the page. You can change the measurement (Rate/Bytes/Utilization) and direction (In/Out) in the settings for each of the views.

NOTE
You can send or schedule these views in a report by email. By default, the first row is selected in the Top table and the data for the following views are of the first-row selection.
For more information, see Share Data with Other Users.

Pick a Context

You can pick a context using the context picker that is available next to the name of the managed item. Context pickers are also available for the children of the managed item.

To pick a different context, click **Change**, select the context, and then click **OK**.

Reachability Status

Some context pages, such as routers and servers, include the reachability status of the device. The reachability status indicates whether DX NetOps Performance Management is able to reach the device during the selected time range of the context page.

For more information, see Reachability Status and Contact Status.

Edit a Context Page

Prerequisite: You have the Edit Context Pages and Drill into Views role rights.

> **NOTE**
> The predefined Administrator and Designer roles have these role rights by default.

Unlike standard dashboard pages, item context pages are clustered in sets of tabbed pages. You can edit the predefined tabs and can change the views that are displayed on those tabs. You can add tabbed pages. You can also rearrange the tabs in an item context to change their order.

Based on the device service information, the data aggregator automatically classifies manageable devices as Router, Switch, and Server primary device types. Also, where applicable, managed devices are associated with context types (Firewall, Load Balancer, Wireless Controller, and Wireless Access Point). The associated context types, including primary device types, appear listed in a column within device inventory tables.

When you add or edit tabs for a device context page, you can associate them with a primary device type or context type. Tabs that are associated with a primary device type or context type appear on the device context pages that are associated with the specified types.

Examples:

- If you add or edit a tab and associate it with the server type, it appears for all server types.
- If you add or edit a tab for a server type and associate it with firewall, it appears only for all server, firewall types.
- If you add or edit a tab for a router type and associate it with wireless access point, it appears only for all router, wireless access point types.
- If you add or edit a tab for a server type and associate it with wireless controller, it appears only for all server, wireless controller types.

> **TIP**
> Associating a tab with a primary device type or context type impacts all manageable devices that are associated with the primary device type and context type. For change control, minimize edits to the tab after you associate it with a primary device or context type.

Revert changes to all tabs in the current context by selecting **Restore Tabs to Defaults** from the **Edit Tab** menu.

Modifications apply to the current tenant.

Follow these steps:

1. Log in as a user with the Edit Context Pages and Drill into Views role rights.
2. Navigate to the item context whose page you want to edit. For example, click the link for a router on any dashboard to open the Router context pages.
   The tab that is selected includes an **Edit** icon so that you can access the Edit menu.
3. Select the tab that you want to modify.
   The Edit icon appears.
4. Click the **Edit** icon, and then select the **Add** or **Edit** tab.
5. (Optional) Select one of the default tab templates from the menu. Each template populates the page with the default views for that type of page.
6. Change the tab title. A title is required.
   The tab title determines the name that appears at the top of the tabbed context page.
7. (Optional) To associate the tab with a primary device type or context type, select a context page type.
8. Select a layout template for the page from the layout buttons.
9. Remove unwanted views from the page if desired. In the **Layout** pane, click one of the following:

- **Clear Layout:** Changes the positioning of all views on the page.
- **[X]:** Removes an individual view from the page.

10. The views that you can add to the page are shown in categorized lists. The lists are filtered by the selected group or item context.
    All registered data sources are represented. However, the available views are limited to those views that are applicable to the context.

    NOTE
    The item context for the page is preselected for the present context.
11. Click to expand the categories of views.
12. Select a view, drag it to the Layout pane, and drop it where you want it to appear.
13. Click **Save**.
    The context page refreshes to reflect your changes. The changes persist across login sessions, but they are only applied to the current tenant.

Edit Item Properties

You can edit the fields (item properties) that are listed for an item in the Information section of the **Details** tabs in a context page.

Prerequisite: You have the following role rights:

- Modify Device Alias
- Modify Interface Alias
- Modify Device IP Address
- Modify Interface Speed Overrides

Follow these steps:

1. Select the **Details** tab.
2. Click the **Edit** icon in the **Information** section.
3. Edit the available details as desired.
   If **Alias**, **Speed In (bps)**, or **Speed Out (bps)** are not set, they appear blank.
   If you edit an interface that does not exist on the data aggregator, the following fields are unavailable:
   - **Speed In (bps)**
   - **Speed Out (bps)**
4. Click **Save**.
   If you cleared **Speed In (bps)** or **Speed Out (bps)**, the change takes a few minutes to appear.

Apply a Business Hours Filter to a Context Page

You can apply a business hours filter to most views on context pages. Business hours filtering is not supported for trend charts where the option to enable events is selected. For more information, see Configure Business Hours Filtering.

Follow these steps:

1. Click **Apply Business Hours**.
2. Apply the business hours to a site listed in the **Site to apply** drop-down.
3. Click **Apply**.
   The business hours for the specified site are applied to the context page. The business hours remain applied when you switch between tabs, change time ranges, and so on. If you go to a top-level dashboard or you change the context, the business hours filtering is removed.

Rearrange Context Tabs

Each item context consists of sets of tabbed pages. In addition to modifying individual tabbed pages, you can rearrange the tabs in an item context. Modifications are only saved to the current tenant.

Prerequisites: You have the Edit Context Pages and Drill into Views role rights.

> **NOTE**
> The predefined Administrator and Designer roles have these role rights by default.

Follow these steps:

1. Click the **Edit** icon on the selected tab, and select **Reorder** tabs.
   A list of Current Context Page Tabs appears. The list reflects the current ordering of tabs, from left to right.
2. Select a tab to move, and then drag it to another location in the list.
3. Click **Save**.
   The context page refreshes to reflect your changes. The tabs are displayed in a new order from left to right.
   If too many tabs are available for the context to display without horizontal scrolling, an arrow appears on the right. Click the arrow to see additional tabs.

Views

Dashboards and context pages render views. Views report collected data in a chart and/or a table format. Depending on the view, the data comes from the various registered data sources.

Views that show data for a group contain collated and aggregated data from data sources. Views that show data for individual items provide a drilldown path to the context page for the item.

View Contexts

View contexts act as filters that determine the nature of the data that views display. The context of a view is either in "Fixed" or "Dynamic" mode:

- A Dynamic context indicates that the context of the view changes with the context of the dashboard page.
- A Fixed context indicates that the view uses a specified group, device, or component as a context for the data.

If the context of a view is Fixed, changing the dashboard context does not affect the Fixed view.

Views on a context page default to the context of an item. However, from a context page, you can dynamically change the filter to view the context of another item.

The context level of a view determines which data appears in the view:

- **Group**
  Group context level views show data for devices and component items that belong to the selected group. Views that show a single value aggregate the results to the group level.
- **Device**
  Device context level views show data for a specific device. Views that show a single value aggregate the results to the device level.
- **Component / Interface**
  Component or interface context level views show data only for the individual selected device component or interface. Because this context shows only a single item, no aggregation occurs.

Out-of-the-box and Custom Views

Out-of-the-box views show data for a preselected metric or a limited set of metrics. These views include only limited customization options. Each registered data source includes an array of associated out-of-the-box views.

Custom views use the information from the Data Aggregator to provide flexible configuration options. These views let you select from many collected metric in multiple graphical and tabular formats. To add a custom view to a dashboard or page, expand the **Custom View - Infrastructure Management** in the **Views** pane, and drag the view to the **Layout** pane.

Customize Views

Customize view options determine the method that is used to filter the data reported in views. The icons in the upper right of a view let you collapse views, modify view settings, and access context-sensitive documentation.

By default, all views on a dashboard page show data from the same group and for the same time frame. You can change the data context for a particular view to show a specific group. You can select custom time range for views to compare data that was collected at different times.

For some types of views, you can customize the table or chart format. You can also select the data that is reported in custom views.

For more information:

- About how to add a view to a dashboard, see Manage Dashboards.
- About how to add a view to a context page, see Context Pages.

In this article:

Set the Scope for View Settings

To determine which users see view changes, set the scope when changing the view settings. Select the scope from the **Apply Changes** drop-down list whenever you edit a view. The options are scoped according to permissions:

- **My Current Session**
  Save the changes to the current session. Changes do not persist after the logged in session ends. Values set at this level supersede settings at the **My User Account** and **For All Tenant Users** levels during the logged in session. This option is available only after a view has been configured and added to a dashboard page.
- **My User Account** (Default)
  Save the changes to the current user account rendering the view. Changes persist after the logged in session ends and the user logs back in. Values set at this level supersede settings at the **For All Tenant Users** level for the user account.
- **For All Tenant Users**
  Save the changes to all user accounts associated with the tenant rendering the view. Values set at this level supersede the out of the box default settings for all user accounts associated with tenant.

Restore Defaults

To return views setting to default values, click **Use Defaults**. The view reverts to the default options. These changes apply only to the selected scope when you save the view.

Expect the following behavior for each scope:

- **My Current Session**
  Restoring defaults clears the settings set at the **My Current Session** level. Views use values set at the **My User Account** level, values set at the **For All Tenant Users** level, or the out of the box default settings.
- **My User Account**
  Restoring defaults clears the settings set at the **My User Account** level. Views use values set at the **For All Tenant Users** level or the out of the box default settings.
- **For All Tenant Users**
  Restoring defaults clears the settings set at the **For All Tenant Users** level. Views use the out of the box default settings.

NOTE
New configuration options added to a view during and upgrade do not appear in views. To use new configuration options, reset the view to the default options.

Set the Resolution for a View

Trend charts and related views show data as a time series. Time series data shows values for multiple time points across the time range of the report. The resolution setting of a trend view determines the amount of time that each data point in the chart represents.

Table views also include data resolution settings. For table views, the resolution represents the data rollup level to show: as polled, hourly rollup, or daily rollup.

The **Use default resolution** option uses the time range to determine the appropriate resolution automatically.

When you set a custom resolution, the view shows that resolution only if the following conditions are true:

- The user can view report data at that resolution for that time range.
- The data resolution is within the data retention policy of the data source.

If the data is unavailable or the time range is too great, the system overrides the specified resolution automatically. The system returns the closest permissible resolution for the time range.

For trend views, the *chart* subtitles indicate the data resolution.

For tables views, the *view* subtitle indicates the data resolution. The following examples describe some table view subtitles:

- **Resolution: Hourly Roll-Up (Overridden)** Hourly resolution is requested for the selected time range for the current user.
- **Resolution: Hourly Roll-Up (Overridden) Resolution Returned: Daily Roll-Up** Hourly resolution is requested for the selected time range for the current user. The data source does not have hourly data for the entire time range, so the view provides daily resolution.

For more information, see Data Resolution.

Metric Filtering and Baseline Metrics

To include a metric in a view, select a metric from the **Metric Value** list. Metrics fall into two profile types: counter or gauge and are reported in several categories, such as bytes, and percentages, such as utilization.

Metrics with a counter profile type are summed up overtime and rolled up as such. Metrics with a gauge profile type are averaged overtime.

The following options impact the available metrics in the **Metric Value** list:

- **Metric Family**
  The selected **Metric Family** populates the **Metric Value** list with the metrics associated with the **Metric Family**. A metric family is a normalized categorization of metrics associated with device collections, vendor certifications, and monitoring profiles. The metric family contains information about the supported units and rollup strategy for when an associated metric is populated.
- **Metric Filtering**
  Select to limit the **Metric Value** list to only the metrics that are appropriate to the metric profile type (counter or gauge). Clear this option to make available the metrics for the selected **Metric Family**. If you select a metric that is inconsistent with the metric profile type, the metric is flagged with a warning.
- **Baseline Metrics**
  Select to add baselines to the **Metric Value** list. Baseline data helps to characterize past performance for selected monitored parameters, assess present performance, and estimate future performance.
  For more information, see Baseline Calculations.

Set the Custom Time Range

To filter data based on specific time periods, select a custom time range for the views. A custom time range on a view overrides the time range that is set for the dashboard.

You can specify a custom time range for all views except the Calendar Heat Chart view an On-Demand Report Templates.

Follow these steps:

1. Click the View Settings (gear) icon on the view, and then select **Edit** from the menu.
2. Select **Enabled** for **Custom Time Range**.
3. Select the custom time range from the **Time Range** drop-down list.
4. Click **Save**.
   The custom time range is indicated in the subtitle of the view.

Assign a Time Zone and Apply a Business Hours Filter to a View

To show data for particular business hours in a view, assign a time zone and apply a business hours filter to the view. Only items in site groups with the selected business hours filter appear in the view with this filter. If the group context does not include groups with the assigned time zone and business hours, the view shows no data. The subtitle of the view indicates which time zone and business hours filters apply to the view.

> **NOTE**
> Trend views and heat charts apply shading to show the selected business hours, but the data is not limited to the business hours.

Time filtering provides the following options:

- Select a time zone filter without a business hours filter. The view shows data from devices in site groups associated with that time zone.
- Select a time zone and a business hours filter. The view shows data for devices in sites groups associated with that time zone for the selected business hours.
- Select **All Time Zones** and a business hours filter. The view shows data for devices in site groups with the selected business hours.

  > **WARNING**
  > This option loads slowly.

> **NOTE**
> For views with an applied business hours filter, if the time frame is entirely outside the business hours, the view displays the following message:
> `No data is within business hours for this time frame`

For more information, see Configure Business Hours Filtering.

Follow these steps:

1. Click the View Settings (gear) icon in the view, and then click **Edit**.
2. Select **Enable** for **Time Filtering**.
3. Select a **Time Zone**.
   The list contains only time zones that are associated with site groups for the current tenant.
4. Select a **Business Hours** filter.
   The list contains only business hours that are associated to site groups for the current tenant.
5. (Optional) To show a particular site group in the view, select a fixed context. If you select a group context that does not have the selected time zone and business hours, the view shows no data.
6. Click **Save**.
   The view filters data to the selected business hours according to the view type.

Change the Data Context for a View

View contexts act as filters that determine the nature of the data that views display. The context of a view is either in Dynamic or Fixed mode:

- A Dynamic context indicates that the context of the view changes with the context of the dashboard page. For more information, see Dashboards.
- A Fixed context indicates that the view uses a specified group, device, or component as a context for the data.

To show data from a specific item or group in an individual view, set a fixed context for the view.

Follow these steps:

1. Click the **View Settings** (gear) icon in the view, and then click **Edit**.
2. For **Context**, select **Fixed**.
3. Select the context according to the view type.
4. Click **Save**.
   The view shows data only from the selected item or group. The view subtitle indicated the selected context and includes a lock icon.

Data Resolution

Some view types, such as table views and trend views, provide the option to set the resolution for the reported data.

For trend views, the resolution specifies the amount of time that each data point represents. The granularity ranges from minutes to daily resolution depending on the time range.

For table views, the resolution specifies the granularity of the reporting data: as polled, hourly rollup, or daily rollup.

The time range for a view determines the default data resolution:

- **As Polled Data**
  Less than, or equal to, 24 hours
- **Hourly Resolution**
  Greater than 24 hours to less than 14 days
- **Daily Resolution**
  14 days to less than one year
- **Weekly Resolution**
  One year or longer

When you edit a view, the current selected time range determines the possible resolution options. The following values show the maximum time range for each data resolution:

- **As Polled Data**
  Less than, or equal to, 24 hours
- **Hourly Resolution**
  Less than 30 days, and more than 24 hours
- **Daily Resolution**
  More than, or equal to, 30 days

Users with the Run Dashboards at Higher Resolution role right use the following maximum time ranges:

- **As Polled Data**
  Less than, or equal to, 31 days
- **Hourly Resolution**

More than 31 days
- **Daily Resolution**
  More than three months

To view the report resolution settings, select **Administration**, **Report Resolution**. The resolution settings cannot be modified on the Report Resolution page.

When you set a custom resolution, the view shows that that resolution only if the following conditions are true:

- The user can view report data at that resolution for that time range
- The data resolution is within the data retention policy of the data source

If the data is unavailable or the time range is too great, the system overrides the specified resolution automatically. The system returns the closest permissible resolution for the time range. For trend views, the *chart* subtitles indicates the data resolution. For tables views, the *view* subtitle indicates the data resolution.

Alarms View

If you have DX NetOps Spectrum configured as a data source, an alarms view lets you view and manage DX NetOps Spectrum alarms. For more information, see Integrate CA Spectrum, Integrate CA Spectrum with CA Performance Management, and Customize Event Integration.

NOTE

The DX NetOps Spectrum data source now requires a user name and password.

An alarms view provides a prioritized list of DX NetOps Spectrum alarms, which helps you quickly focus on resolving the most impactful problems. The alarms view also provides visibility into other, potentially related, issues on the same device, or connected to a device.

Each device context page includes an Alarms tab. For more information, see Context Pages.

NOTE

The Alarms tab was added to all device-level context pages in the DX NetOps Performance Management 3.6 release.

The following role rights are associated with an alarms view:

- **Allow Alarm Modification Actions**
  Lets users acknowledge, clear, or assign a troubleshooter to alarms.
- **Allow Alarm Triage Actions**
  Lets users perform alarm triage actions.
- **Allow Alarm Filter Creation**
  Lets users create and manage alarm filters.
- **Allow Alarm Filter Management**
  Lets users manage and assign alarm filters to other users.

For more information, see Data Source Role Rights.

NOTE

When you sort, search, or filter an alarms view, the returned results show only the alarms up to the maximum alarms retrieved, which is specified in the view settings.

Standard View Concepts

An alarms view includes standard view configuration options, such as time filters and context settings. For standard view configuration details, see Customize Views.

By default, all views on a dashboard page show data from the same group and for the same time frame. You can change the data context for a particular view to show a specific group. You can select a time range for views to compare data that was collected at different times.

Context Settings

In DX NetOps Spectrum, you can select a particular Global Collection to view all the alarms asserted on it.

Group filters in the upper-left corner of NetOps Portal behave similarly. You can select a particular group, which can correspond to your Global Collections, to view all the alarms asserted on it.

If you select a custom group for reporting, the alarms view is scoped to the elements within that custom group. NetOps Portal groups can include DX NetOps Spectrum Landscapes and Global Collections. Landscapes and Global Collections are available under All Groups, Inventory, Data Sources, and *your DX NetOps Spectrum data source*. If the group context includes Landscapes or Global Collections, an alarms view can show alarms for devices that are not synced to NetOps Portal. For more information, see Manage Groups.

Time Filters

In the WebClient Alarms tab in DX NetOps Spectrum, time filters display the alarms that occurred in the last few hours. The options available under this filter are: 1, 2, 4, 6, 12, 24 hours.

Example: Suppose, four alarms were generated an hour and a half ago, and two alarms were generated 30 minutes ago in your DX NetOps Spectrum environment. In this case, selecting the **2-hours** option displays six alarms. If you select the **1-hour** option, two alarms are displayed.

Time filters in the upper-right corner of NetOps Portal behave similarly. However, you can also specify custom time ranges. We recommend that you specify a time range that includes the latest list of alarms.

> **WARNING**
>
> Only alarms that are raised within the specified time range appear in an alarms view. After an alarm is cleared, it does not appear regardless of the selected time filter.
>
> **TIP**
>
> Ensure the specified time range is large enough to include all active alarms.

Alarms View Panes

An alarms view shows alarms data from DX NetOps Spectrum in the following available panes:

> **TIP**
>
> We recommend that you turn auto-refresh off when you view alarms. If you have auto-refresh turned on while looking at an alarms view, any selected alarms are cleared when the page refreshes.

- **Alarms**
  View a list of the latest DX NetOps Spectrum alarms and their severity.
- **Alarm Details**
  View the details of the selected alarm. You can add or remove the attributes to display in the Alarm Details pane. By default, the Alarm Details pane displays the following attributes.

  - Severity
  - Date/Time
  - Item Name
  - IP Address
  - Model Type
  - Acknowledged
  - Contact Person
  - Troubleshooter
  - Trouble Ticket ID
  - Number of Occurrences
  - Impact
- **Impact: Management Lost**
  View the devices that this alarm impacts.
- **Impact: Symptoms**
  View the alarms leading up to this alarm.
- **Neighbor Topology**
  View all the neighboring models that are connected to the device of the selected alarm.
- **Interfaces**
  View the interfaces associated with the selected alarm.
- **Events**
  View the events associated with the selected alarm. If you have the Export to CSV role right, you can click the gear icon to export the events list to CSV. You can also filter and search the events list.

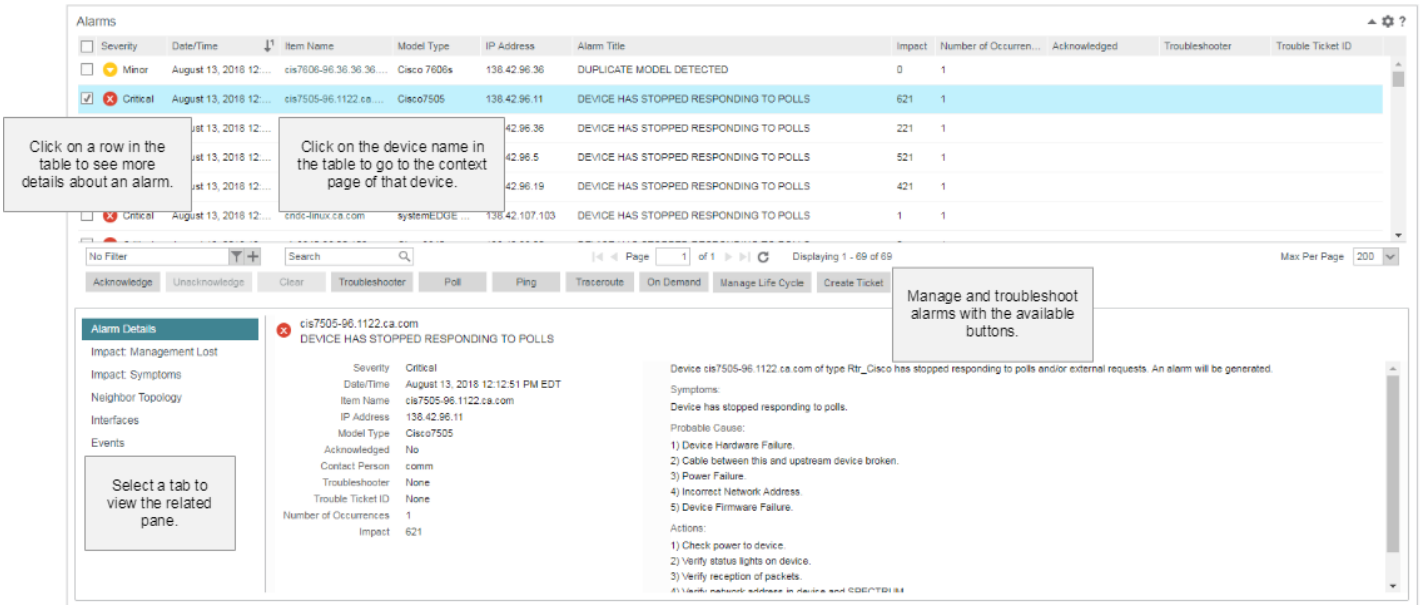
NOTE

The Events tab is available only with DX NetOps Spectrum 10.3.0 or higher.

Alarms View Elements

The following example shows the important elements of an alarms view:

Figure 13: Alarms_Views



Sort Multiple Columns

You can sort by up to three columns in an alarms view.

Follow these steps:

1. In the column header to sort first, click the Gear icon.
2. Select **Sort First**, and click one of the following options:
   - **Sort Acsending**
     Sort the column in ascending order.
   - **Sort Descending**
     Sort the column in descending order.
   - **Remove Sort**
     Remove the sort order from the column.

     NOTE

     You can CTRL+Click on a column heading to remove the sort order.
3. In the column header to sort second, click the Gear icon.
4. Select **Sort Second**, and click a sort option.

   NOTE

   You can SHIFT+Click on a column heading to add it as a secondary sort.
5. In the column header to sort third, click the Gear icon.
6. Select **Sort Third**, and click a sort option.

Create an Alarm Filter

If you have the Allow Alarm Filter Creation role right, you can create alarm filters.

You can filter by the the following attributes:

- **Acknowledged**
  Indicates whether the alarm is acknowledged
  Attribute ID: 0x11f4d
  Type: BOOLEAN
- **Cause Code**
  Identifies the cause of the alarm
  Attribute ID: 0x11f50
  Type: HEX
- **Clearable**
  Indicates whether the alarm is clearable
  Attribute ID: 0x11f9b
  Type: BOOLEAN
- **Contact Person**
  The person to contact when device problems occur
  Attribute ID: 0x23000c
  Type: STRING
- **IP Address**
  The IP address for the item
  Attribute ID: 0x12d7f
  Type: ADDRESS_RANGE
- **Location**

The location of the device
Attribute ID: 0x23000d
Type: STRING

- **Manufacturer**
  The manufacturer of the device
  Attribute ID: 0x10032
  Type: STRING
- **Model Class**
  The model class of the item
  Attribute ID: 0x11ee8
  Type: ENUM
- **Name**
  The device or model name
  Attribute ID: 0x1006e
  Type: STRING
- **Number of Occurrences**
  The number of times that the alarm occurred
  Attribute ID: 0x11fc5
  Type: INTEGER
- **Severity**
  The severity of the alarm
  Attribute ID: 0x11f56
  Type: ENUM
- **Show Symptoms**
  Indicates whether the alarm is the result of symptoms
  Attribute ID: 0x12a07
  Type: BOOLEAN
- **Symptom Count**
  The number of symptoms for the alarm
  Attribute ID: 0x12a06
  Type: INTEGER
- **System Name**
  The system name of the device
  Attribute ID: 0x10b5b
  Type: STRING
- **Troubleshooter**
  The troubleshooter assigned to the alarm
  Attribute ID: 0x11fc6
  Type: ENUM
- **Trouble Ticket ID**
  The Trouble Ticket ID assigned to the alarm
  Attribute ID: 0x12022
  Type: STRING

An administrator can also use web services to manage alarm filter attributes. For more information, see Use Web Services to Manage Alarm Attributes.

Follow these steps:

1. To the right of the filter drop-down, click the plus icon.
   The Create Filter dialog opens.
2. Complete the fields and specify the conditions for the filter.
3. Click **Save**.
   The new filter appears in the filter drop-down.

Manage Alarm Filters

If you have the Allow Alarm Filter Management role right, you can manage and assign alarm filters to other users.

When you create or edit a filter from the Manage Filters dialog, you can set the scope to one of the following options:

- **For My Use**
  The filter is available only for your user account.
- **For All Users With My Role**
  The filter is available only for users with your role.
- **For All Tenant Users**
  The filter is available for all the tenant users.

  NOTE

  If a new role is added, users with that new role do not have access to the shared filter. You can assign the filter to the new role.
- **For Specific Users or Roles**
  The filter is available for selected users or roles.

Follow these steps:

1. Click the filter drop-down.
2. Click **Manage Saved Filters**.
3. **Add**, **Edit**, **Copy**, or **Delete** filters as necessary.

Assign Filters to Specific Users or Roles

If you have the Allow Alarm Filter Management role right, you can assign shared filters to specific users or roles.

Follow these steps:

1. Click the filter drop-down.
2. Click **Manage Saved Filters**.
3. Select a filter to assign to users or roles.
4. Click **Users** or **Roles**.
5. Select the users or roles to assign the filter.
6. Click **Save**.

Manage Alarms

An alarms view contains the following alarm management buttons:

- **Acknowledge**
  Acknowledge the selected alarms. "Yes" appears in the Acknowledge column in the top Alarms pane.
- **Unacknowledge**
  Unacknowledge the selected alarms. This button removes "Yes" from the Acknowledged column in the top Alarms pane.
- **Clear**

Remove the selected alarms from the top Alarms pane. This option is available only for clearable alarms. To determine whether an alarm is clearable, show the Clearable column.

- **Troubleshooter**
  Manage the troubleshooter assignment for the selected alarms.
- **Poll**
  Poll the devices for the selected alarms. The poll is initiated from the SpectroSERVER.
- **Ping**
  Send an ICMP ping to the devices for the selected alarms. The ICMP ping is initiated from the SpectroSERVER.
- **Traceroute**
  Determine the route (path) to the device of the selected alarm over a maximum of 30 hops. The round-trip time of packets that are received from each hop is also measured. Traceroute is initiated from the SpectroSERVER. This option is unavailable when you select multiple alarms.
- **On Demand**
  Launch On-Demand reports for the selected alarms. Alarms and items that are not synchonized to NetOps Portal are filtered out. For more information, see On-Demand Reports. This option is available when you have the Create On-Demand Report Templates role right and the Run On-Demand Report Templates role right.
- **Create Ticket**
  Create a service desk ticket for a single alarm that is selected in the table. To launch the trouble ticket system from an alarms view, a trouble ticket management system at your organization must be set up with DX NetOps Spectrum. For more information, see the Alarms Tab Preferences in the CA Spectrum documentation. This option is available when you have either the Allow Alarm Modification Actions role right or the Allow Alarm Triage Actions role right.
- **Manage Life Cycle**
  Change the life cycle state of a device to Active or Maintenance. This option is available when you have the Administer Life Cycle role right. The **Synchronize device life cycle state from Spectrum** option should be selected for the DX NetOps Spectrum data source. For more information, see Manage Device Life Cycles.

Configure an Alarms View

To display an alarms view, go to the **Alarms Console** dashboard or add the **Alarms** view available from the **Alarms and Events** section. An Alarms view is also available from device, router, server, switch, and interface context pages.

Configure the following alarms view settings:

- **Max Alarms to Retrieve**
  Specify the maximum number of alarms to retrieve from DX NetOps Spectrum starting with the most recent.
  Default: 20,000
  Maximum: 20,000
- **Ping Count**
  Specify how often to send an ICMP ping to each device. You can specify a value of 1 through 5.
  Default: 3
- **Grid Height**
  Specify the height of the Alarms grid.
  Default: 300
- **Sort First**
  Select a column on which to sort first.
  Default: Date/Time
- **Sort Second**
  Select a column on which to sort second.
  Default: None
- **Sort Third**
  Select a column on which to sort third.

Default: None
- **Sort Direction**
  Select whether to sort the selected column in **Ascending** or **Descending** order.
  Default: Descending
- **Customize Panels**
  Select the panes to enable or disable.
- **Attributes to Show**
  Add or remove the attributes to display in the Alarm Details pane.
- **Filter Selection**
  Select whether to pin an alarm filter to the view. If enabled, select the filter to pin to the view.

Browser Views

The browser view lets you show the content of a web page directly in NetOps Portal. The browser view also lets you update internal and external data dynamically.

Configure a Browser View

To show a web page or application, configure a browser view.

Follow these steps:

1. Specify a URL for the view.

   WARNING
   Use a URL for a web page that supports being an embedded iFrame.
2. (Optional) Customize the URL parameters.

   TIP

   Use URL parameters to add NetOps Portal data to the URL. These parameters support adding context-sensitive information, such as time range or group, to the URL. Use these parameters to provide specific information to OpenAPI applications.
3. Set a height for the view, in pixels.
4. Click **Save**.
   The web page or application that the URL references appears in the browser view window.

Customize URL Parameters

You can customize a browser view to your preference. When you configure a browser view, select parameters to add to the URL of the view. Each parameter is defined when the URL is accessed.

TIP

Add an identifier to the URL before each property. The identifier helps you to determine the meaning of each property in the URL.

The parameters that are available from the user interface appear in a drop-down with two columns. The first column shows the property. The second column shows the current values for the logged in user. The second column values are based on the current context and time on the system. The properties resolve in the following manner:

- **{Culture}**
  Culture of the logged in user
- **{ItemDesc}**
  Description of the item or group of the current context

The context is specified at the top of the page or within the dashboard builder.

- **{ItemId}**
  NetOps Portal item ID of the current item or group
- **{ItemIdDA}**
  Data Aggregator item ID of the current item or group
  This parameter appears only when you have a Data Aggregator data source.
- **{ItemName}**
  Name of the current item or group
- **{ItemSubType}**
  Subtype of the current item or group
- **{ItemSubTypeName}**
  Subtype name of the current item or group
  The subtype name is usually the same as the subtype, but not always.
- **{ItemType}**
  Type of the current item or group
- **{ItemTypeLabel}**
  Singular form of the item type label
- **{ItemTypeLabels}**
  Plural form of the item type label
- **{ItemTypeName}**
  Item type name
- **{Locale}**
  Locale of the logged in user
  The locale is similar to culture, but has a slightly different format.
- **{ModelHandleSpectrum}**
  Model handle from DX NetOps Spectrum for the device or interface
  This parameter is unavailable for groups. This parameter appears only when you have a DX NetOps Spectrum data source.
- **{PageSize}**
  Number of items that are specified to display in the view
- **{Resolution}**
  Data resolution in seconds
- **{ResolutionLabel}**
  Data resolution in a descriptive text
- **{ServerName}**
  NetOps Portal server name or IP address
- **{ServerNameDA}**
  Data Aggregator server name or IP address
  This parameter appears only when you have a Data Aggregator data source.
- **{ServerPort}**
  NetOps Portal server port
- **{ServerPortDA}**
  Data Aggregator server port
  This parameter appears only when you have a Data Aggregator data source.
- **{TimeEndUTC}**
  Number of seconds of the end of the time range (based on Unix time) at the top of the page
- **{TimeEndUTCExpanded}**
  Expanded form of the end of the time range
- **{TimeSpan}**

Description of the time range that is specified at the top of the page
- **{TimeStartUTC}**
  Number of seconds of the start of the time range (based on Unix time) at the top of the page
- **{TimeStartUTCExpanded}**
  Expanded form of the start of the time range
- **{UserEmailAddress}**
  Email address of the logged in user (if specified)
- **{UserId}**
  NetOps Portal ID of the current user
- **{UserName}**
  Current user name
- **{UserRoleId}**
  NetOps Portal role ID of the current user
- **{UserRoleName}**
  Role name of the current user
- **{UserSsoToken}**
  SSO token for the current user
  This token can be used to log in to other data sources that honor SSO (for example, Network Flow Analysis).
- **{UserTimeZone}**
  Time zone of the current user

Example:

If you want aspects of your browser view to adjust dynamically, use custom URL parameters.

For this example, you want to display the content at the following URL:

`http://PC_host:port/pc/apps/user/appsubdirectory/MyPageFile.html`

You can append the URL with the following URL parameters:

`?id={ItemIdDA}&startTime={TimeStartUTC}&endTime={TimeEndUTC}`

- **{ItemIdDA}**
  This parameter resolves to the ID of the interface for the selected context page.
- **{TimeStartUTC}**
  This parameter resolves to the start time selected in the time picker for the context page.
- **{TimeEndUTC}**
  This parameter resolves to the end time selected in the time picker for the context page.

Follow these steps:

1. Select a URL parameter from the drop-down list, and click the Append to URL button.
   The URL parameter is added to the end of the current URL in the URL field.
2. Click the URL field, and enter an identifier before each parameter.
   Enter a '?' before the first parameter. Enter a '&' before each subsequent parameter.

Bar Chart Views

Bar charts, also known as horizontal bar charts, show a comparative visualization of data. These charts are useful to compare items in a small group when the expected value of the metric is similar for all items. The visualization enables you to identify which item differs from the others. Bar charts can be useful for capacity planning.

Business hours filtering can apply to the data in bar chart views. The applied business hours filter appears in the subtitle. For more information, see Configure Business Hours Filtering.

For standard view configuration details, see Customize Views.

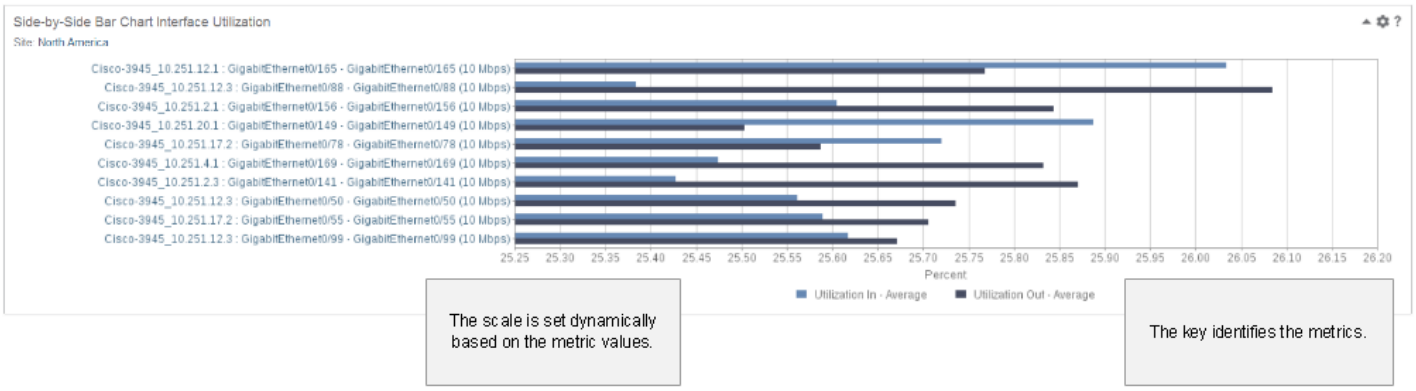
Side-by-Side Bar Charts

Side-by-side bar charts compare pairs of related metrics for interfaces.

For the out-of-the-box views, select the Metric Value to display on the view: Percentage, Rate, or Volume.

The following example shows the important elements of a side-by-side bar chart:

Figure 14: Side-by-Side Bar Chart Elements

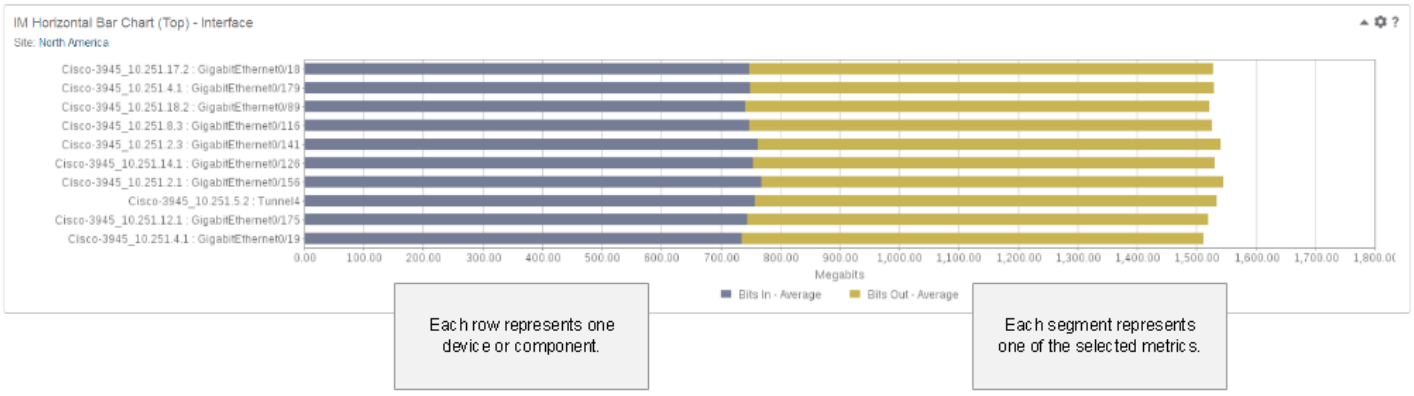


Stacked Bar Charts

Stacked bar charts show a horizontal bar with segments representing each selected metric.

The following example shows the important elements of a horizontal bar chart with the stacked chart type:

Figure 15: Stacked Bar Chart Elements



Configure a Horizontal Bar Chart View

The IM Horizontal Bar Chart is a custom view that lets you select the metrics to display. The chart can display multiple metrics for each device or component in the view context.

Follow these steps:

1. Select the metrics to show in the chart.
   Each selected metric appears as different colored bar in the chart.

TIP

The custom bar chart is best used to compare a few similar metrics for a small group of items. If you select too many items or too many metrics, the view is difficult to read.

Select metrics with consistent unit types (bits, percentage, and so on) for more valuable comparisons.

Also, select metrics with a consistent rollup or aggregation strategy. For example, compare two sets of averages for two different metrics. This comparison is more valuable than comparing the total for one metric and the average for another metric.

2. Select the sort order for the view.
   The metric that you select from the Metric Sort list represents the first bar on the bar chart.
3. Select the Metric Calculate Level.
   This option determines what level of aggregation each row in the view represents: a device, or a component.
4. Select the chart type:
   - **Stacked Chart**
     For each device or item, this chart type shows a horizontal bar with segments representing each selected metric.
   - **Side-by-Side Chart**
     For each device or item, this chart type shows a horizontal bar representing each selected metric.

Bar Chart Tables

Some out-of-the box table views show a column with a bar graph. These tables display a bar chart column for metrics with percentage values. For more information about these views, see Table Views.

Calendar Heat Chart Views

Calendar heat chart views provide a month-long overview with hourly intervals that are color coded based on custom thresholds. The calendar shows one month with a colored block to show the status for each hour.

NOTE
If the hourly data retention is less than 1 month, the calendar heat chart still shows hourly data.

This view helps network engineers identify patterns in percentage-based metrics such as utilization, latency, and loss metrics. Identifying patterns can be a critical step in locating the source of performance issues that might appear to be intermittent. Usage patterns also aid in capacity planning.

You can limit the data that appears in the view by applying one of the following pattern-matching filters:

- **Busy Hour**
  View the hour each day with the highest value for the selected metric.
- **Business Week Pattern**
  View patterns where the same hours have similar values on three or more days in the business week.
- **Calendar Week Pattern**
  View patterns where the same hours have similar values on four or more days in the calendar week.
- **Repeating Hours by Business Day**
  View patterns where the same hour on the same day of the business week has a similar value for three or more times in the month.
- **Repeating Hours by Calendar Day**
  View patterns where the same hour on the same day of the calendar week has a similar value for three or more times in the month.

Maintenance indicators apply to all the devices and components in a site group. When you have selected the associated site group in the context, maintenance indicators appear as shaded cells in the calendar heat chart.

For more information, see Schedule Maintenance Indicators.

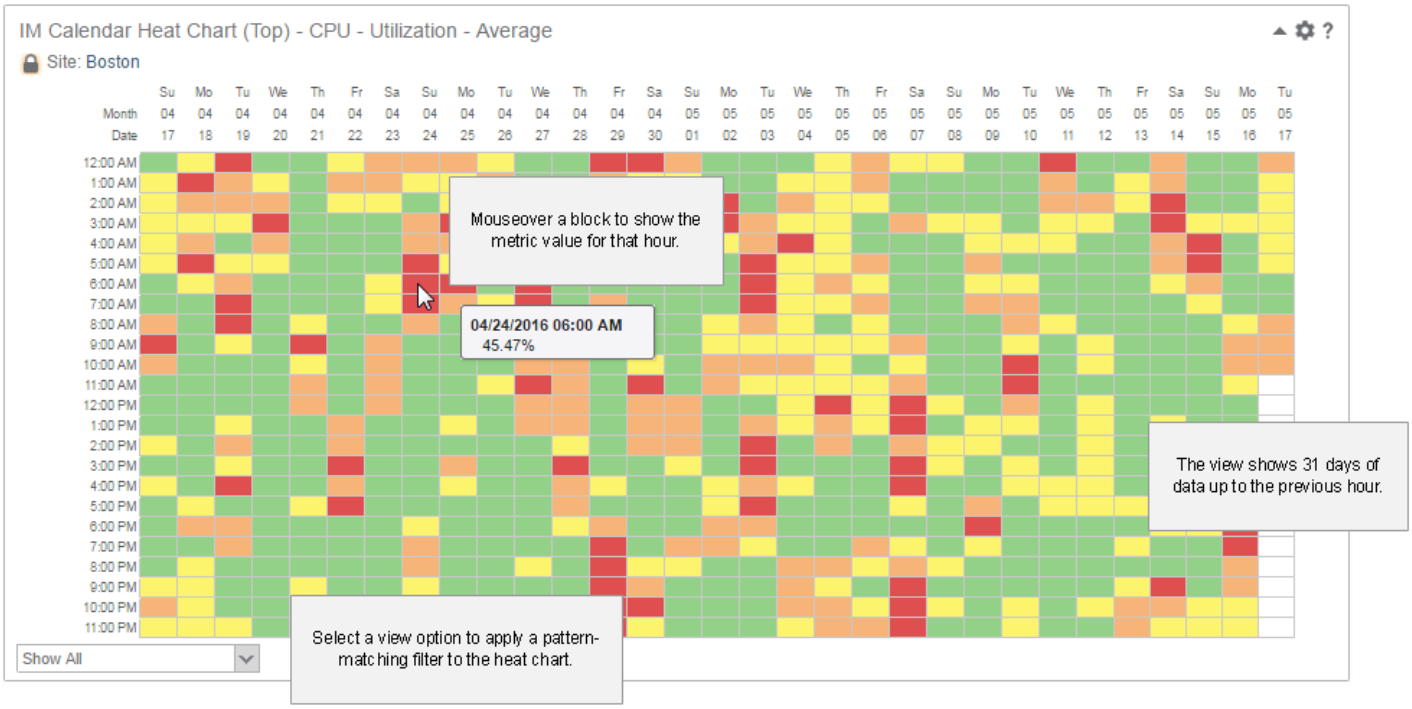
Applying a business hours filter to a calendar heat chart view displays the same data in the view, but the periods outside of the business hours are shaded.

For more information:

- About business hours filtering, including how to define business hours definitions, see Configure Business Hours Filtering.
- About how to apply a business hours filter to views on a dashboard, see Dashboards.
- About how to apply a business hours filter to views on a context page, see Context Pages.

The following example shows the important elements of a calendar heat chart:

Figure 16: Calendar Heat Chart Elements



Configure the Behavior of Calendar Heat Chart Views

Calendar heat charts include configuration options to set the threshold values for the colors to show in the chart. The view also lets you change the starting day and time display formats.

> **TIP**
> Because the color status thresholds are set in integers, this view works best with metrics that are gradable by integer, such as utilization. Metrics that have narrow ranges in value, such as percent errors, do not provide meaningful visualizations.

The IM Calendar Heat Chart lets you select the metric to show in the view. The built-in calendar heat charts on context pages have fixed metric selections.

For standard view configuration details, see Customize Views.

Specify the following properties:

- **Business Week Start**
  Define the start of the five-day business week for the pattern-matching filters.
- **Time Display Format**

Specify whether the hours are identified with 12-hour or 24-hour time.

- **Green Zone Start**
  Specify the threshold for the metric to show a normal status indicated with green.
- **Yellow Zone Start**
  Specify the threshold for the metric to show a minor status indicated with yellow.
- **Orange Zone Start**
  Specify the threshold for the metric to show a major status indicated with orange.
- **Red Zone Start**
  Specify the threshold for the metric to show a critical status indicated with red.

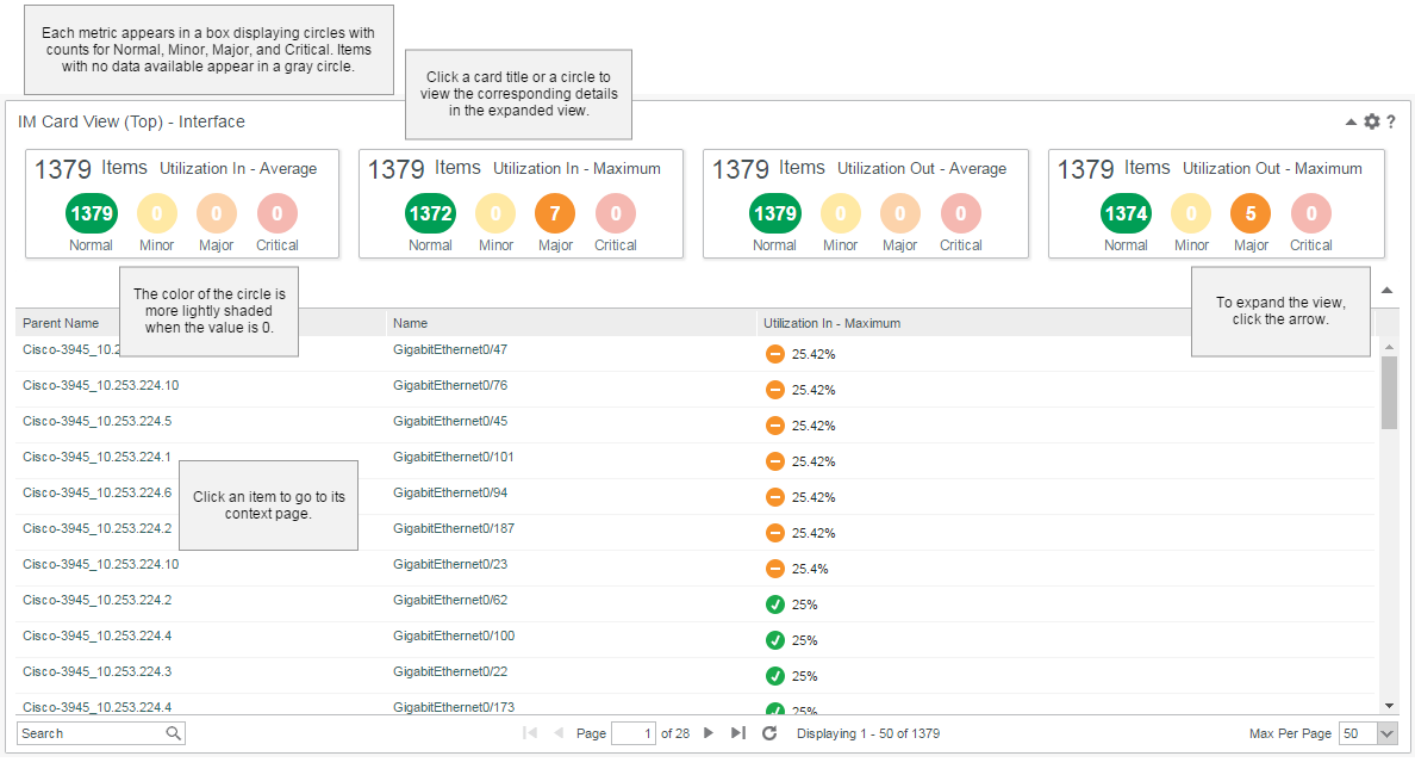
TIP
You can configure calendar heat chart views to reflect reverse value severity. For metrics where low values are bad and high values are good, set Green highest and Red lowest. To omit a severity level, set the threshold value to zero. For example, setting Orange to zero removes the major severity when profiling metric thresholds.

Card Views

Card views display cumulative counts of groups, devices, or components for the threshold ranges of each specified metric. The counts appear within green, yellow, orange, and red circles. The color of each circle is based on a set of user-defined thresholds. You can specify separate thresholds for each metric.

The following image shows the important elements of a card view:

Figure 17: Card_Views



Configure the IM Card View

To display a card view, add the IM Card view. Card views include standard view configuration options, such as time filters and context settings. For standard view configuration details, see Customize Views.

Follow these steps:

1. Select the metrics to show in the card view.
   Each selected metric appears as a box in the view.
2. Select the **Metric Calculate Level**.
   This option determines what level of aggregation for the cumulative counts: by groups, devices, or components.
3. For each metric, specify the thresholds for the status indicators.
   If the value for the metric is at or above the specified value, the icon indicates the status by color.
   Green indicates normal, yellow indicates minor, orange indicates major, and red indicates critical.
   To remove the status indicators, set the threshold values for all status levels to zero.
   You can specify thresholds with up to two decimals places with the lowest value being 0.01. Values with more than two decimal places are rounded.

   TIP

   For metrics where low values are bad and high values are good, set Minor highest and Critical lowest. To omit a severity level, set the threshold value to zero.

Dynamic Trend Views

Dynamic trend views combine data from multiple managed items, or groups of items, in a single view. You can add this view to a dashboard or context page. You can compare the data from hundreds of managed items, or groups of managed items, in one or more charts. You can select display units and determine how data is plotted using the view settings.

NOTE
Dynamic trend views support only the data aggregator data source.

You can create a trend chart for a selected metric using the dynamic trend view. The view is termed "dynamic" because it has the following options:

- Display an individual chart for the selected metric for each item that you select.
- Display a single chart for all the selected items, for a single metric.
- Display a single trend line for a selected metric that reflects aggregated data from all the selected items.

NOTE
Percentile metrics appear as dashed lines.

Use dynamic views during advanced troubleshooting. These views let you build a complex comparison of data from multiple groups, or a temporary grouping of items. You can quickly select items from across a wide range of possibilities, without creating a group in advance.

For example, you can use dynamic views to analyze data from any of the following items:

- Multiple interfaces in a group
- The interfaces in your inventory with the worst performance metrics
- The interfaces on a single device

A dynamic view is empty until you edit the view settings that you want to apply.

Trend data in dynamic views represents averages of metric values across all items that are included.

TIP
Dynamic trend views require more page space than other types of views. To add a dynamic trend view to a dashboard, add it to a single-column area in the layout. Do not add a dynamic trend view to a small section on a dashboard layout.

Dynamic trend views also require more space for the PDF output.

Maintenance indicators apply to all the devices and components in a site group. When the associated site group is selected in the context, maintenance indicators appear as shading in dynamic trend views.

For more information, see Schedule Maintenance Indicators.

Applying a business hours filter to a dynamic trend view displays the same data in the view, but the periods outside of the business hours are shaded.

For more information:

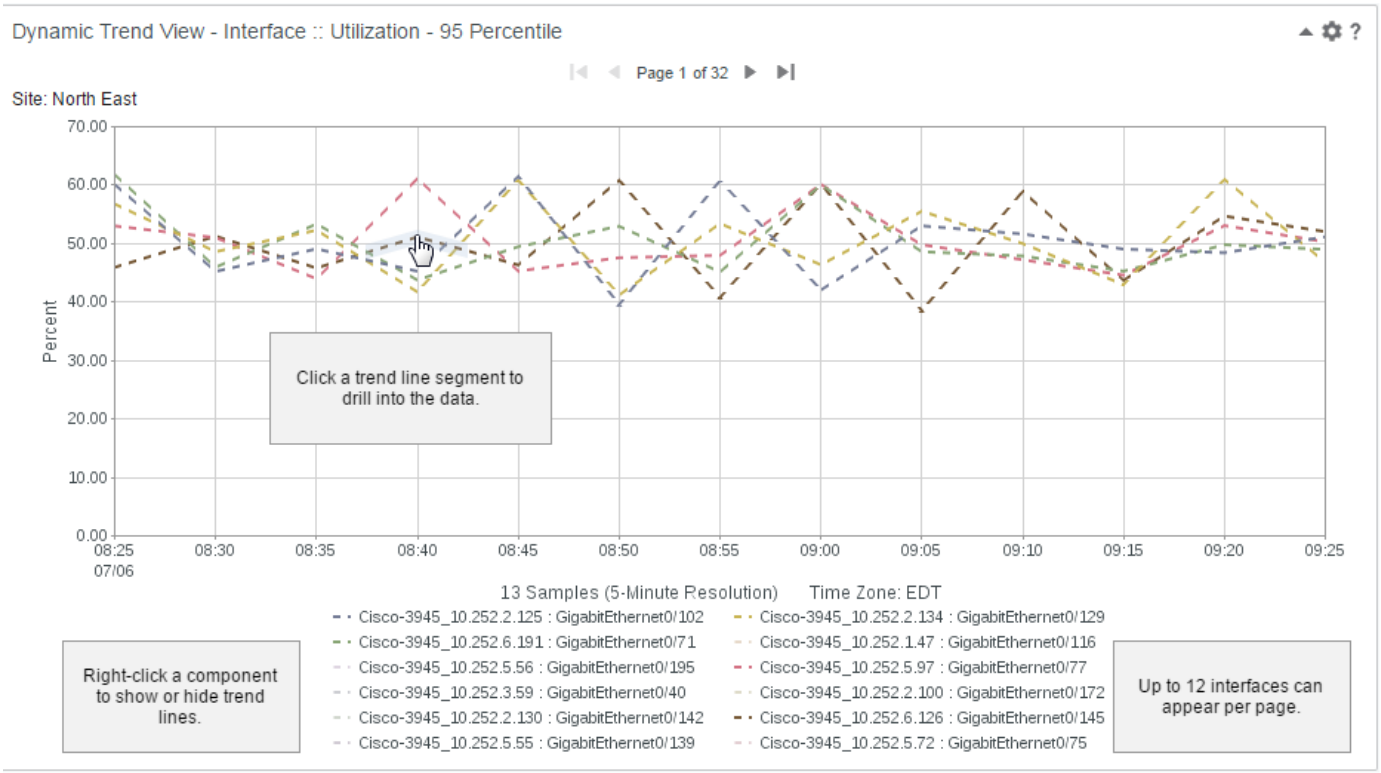
- About business hours filtering, including how to define business hours definitions, see Configure Business Hours Filtering.
- About how to apply a business hours filter to views on a dashboard, see Dashboards.
- About how to apply a business hours filter to views on a context page, see Context Pages.

In this article:

Elements of a Dynamic Trend View and Dynamic Trend MultiView

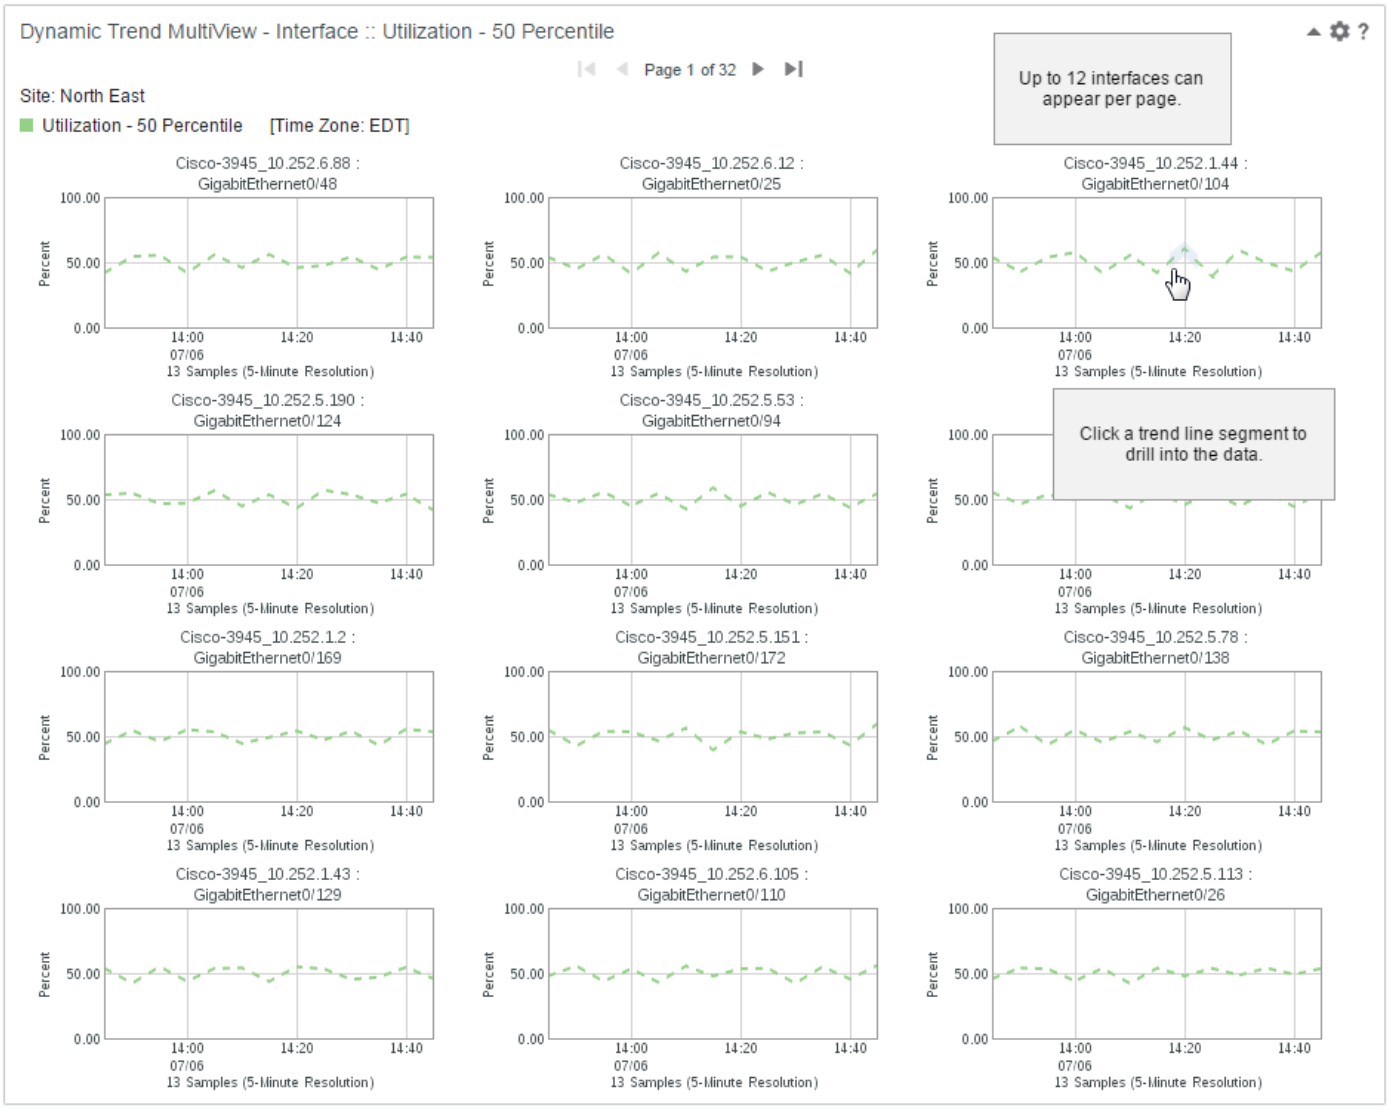
The following image shows the important elements of a dynamic trend view:

Figure 18: DynamicTrendView



The following image shows the important elements of a dynamic trend MultiView:

Figure 19: DynamicTrendMultiView



Configure a Dynamic Trend View

To configure a dynamic trend chart, customize or edit a dynamic trend view. Dynamic trend views contain no data until you edit them to select settings.

For standard view configuration details, see Customize Views.

Follow these steps:

1. Select one of the following Chart Type options:
   - **Trend Chart**
     View a traditional trend line for each device, component, or metric.
   - **Stacked Chart**
     View a stacked line on top of each other for each device, component, or metric.
2. Select one of the following **Standardized Axis** options for the Y-axis of each trend chart:
   - **Fixed at 0 to 100**

Maintain a static range, 0 through 100, for the Y-axis.
  - **Calculated**
    Let the Y-axis adjust dynamically, based on the range of metric values that are included. The calculated setting is applied to all charts in the view.
  - **Scale per Chart**
    Let the Y-axis adjust dynamically, based on the range of metric values for each chart in the view. The Y-axis scaling of one chart in a view does not affect the scaling of any other chart.
3. Optionally, enable **Baseline Metrics**.
   You can determine whether utilization trends are changing using the baseline trend line. The baseline data that is plotted in many views shows statistical deviations from "normal" performance for a given statistic.
   For more information, see Baseline Calculations.
4. If you are adding the dynamic trend view to a dashboard, set the **Context** to one of the following:
   - **Dynamic:** A Dynamic context indicates that the context of the view changes with the context of the dashboard page.
   - **Fixed:** A Fixed context indicates that the view uses a specified group, device, or component as a context for the data.

Gauge Views

Gauge views highlight where the value of a metric differs from the expected value. The out of the box gauge views display percentage metrics. However, custom gauge views do allow for configuring metric values that are not of type percentage.

Business hours filtering can apply to the data in gauge views. The applied business hours filter appears in the subtitle. For more information, see Configure Business Hours Filtering.

Gauge View Elements

The gauge shows the minimum, maximum, and average values in the time range. The gauge needle shows the average value. The gray inner arc shows the minimum and maximum range of the metric value.

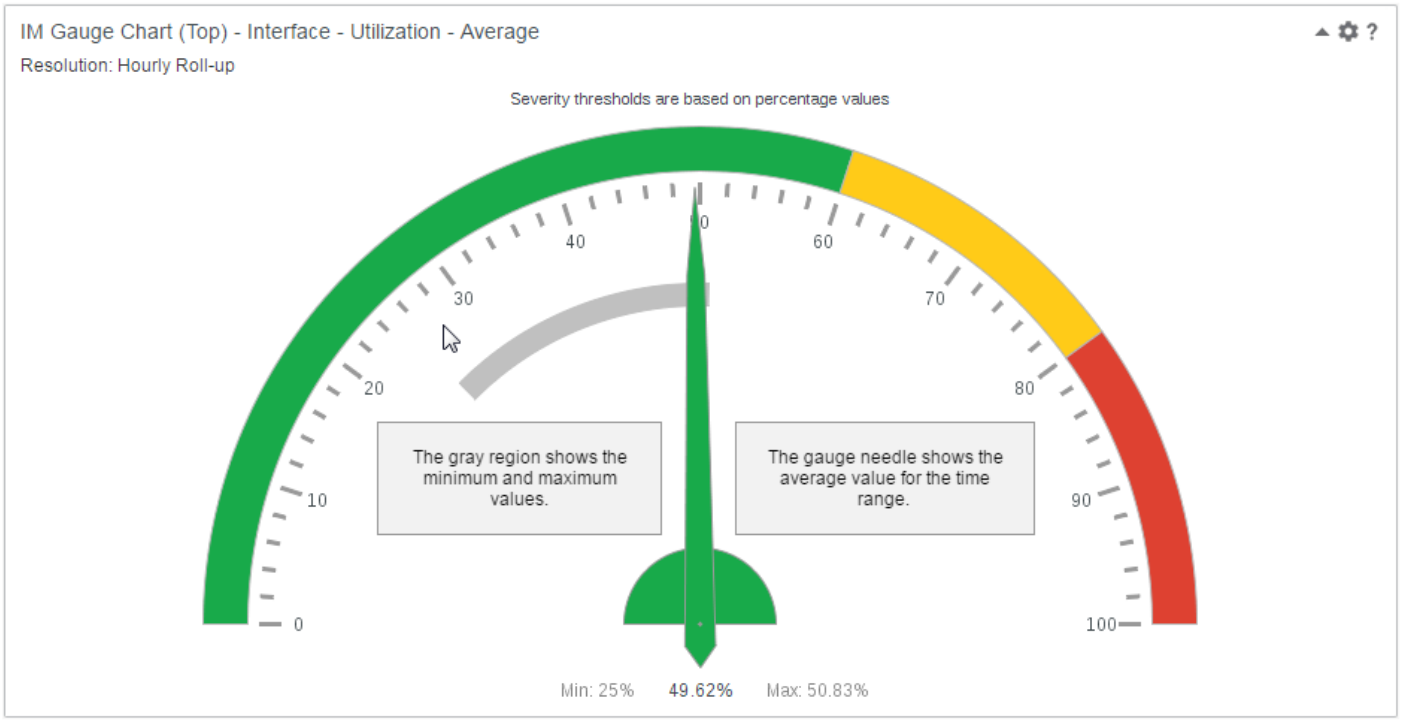
The outer arc uses the following colors to show customizable threshold ranges:

- **Green** The normal status range
- **Yellow** The moderate status range
- **Red** The critical status range

The gauge chart legend shows the resolution, which specifies the granularity of the reporting data: as polled, hourly rollup, or daily rollup. For custom views, the minimum and maximize thresholds are based on this resolution. For out of the box views, the minimum and maximum thresholds are based on the as polled resolution.

The following example shows the important elements of a gauge view:

Figure 20: Gauge View Elements



Configure Gauge Views

All gauge views let you customize the threshold values for metric status. The IM Gauge Chart custom view provides more configuration options.

For standard view configuration details, see Customize Views.

Follow these steps:

1. Select the **Metric Needle** from the list of metrics for the selected metric family. This option determines the selected metric for the view.
2. Do one of the following tasks:
   - If you are configuring a custom view, select whether **Gauge End Points** are calculated or fixed. This option determines the range of the gauge.
     - If fixed, define the minimum and maximum values.
     - If calculated, the view determines the gauge end points based on the minimum and maximum values of the data from the appropriate item level.
   - If you are configuring an out of the box view, the gauge end points are fixed. Define the minimum and maximum values.
3. If you are configuring a custom view, select whether **Determine Threshold** is by percentage value or by numeric value.
   - **By Percentage Value**
     The status start values are a percentage of the range between the gauge endpoints.
   - **By Numeric Value**
     The status start values are fixed numeric values.
4. Define the thresholds for the gauge:

- **Moderate Status Start** The gauge shows yellow for this zone.
- **Critical Status Start**
  The gauge shows red for this zone.

  TIP

  For metrics where low values are bad and high values are good, such as availability, set Moderate Status Start higher than Critical Status Start.

5. If you are configuring a custom view, select **Scaled** or **Unscaled** to specify whether the values in the view are scaled. Scaled values appear with larger units, for example, 1 KB. Unscaled values appear in the raw form for the metric, for example, 1000 bytes.

Gauge/Table Views

Gauge/table views highlight where the value of one metric differs from the expected value when compared to other metrics. The gauge shows the minimum, maximum, and average values for one item in the time range. The table lets you see the values for all items and select an item to show on the gauge. For more information about these views, see Table Views.

Group Scorecard Trend Views

Group scorecard trend views display performance metrics by subgroup, device, or component for the selected group. Group scorecard trend views provide line-of-business owners a group-level summary of how key metrics perform over time. Performance is based on a set of user-defined thresholds. These views incorporate red, orange, yellow, and green icons as visual indicators of performance levels.

Group scorecard trend views show the average, minimum, and maximum utilization, or the selected metric at different time intervals for a group. Each interval length is equal to the time range selected for the dashboard. Out-of-the-box views show either the utilization average or the 95 percentile. The IM Group Scorecard Trend view shows any selected metric.

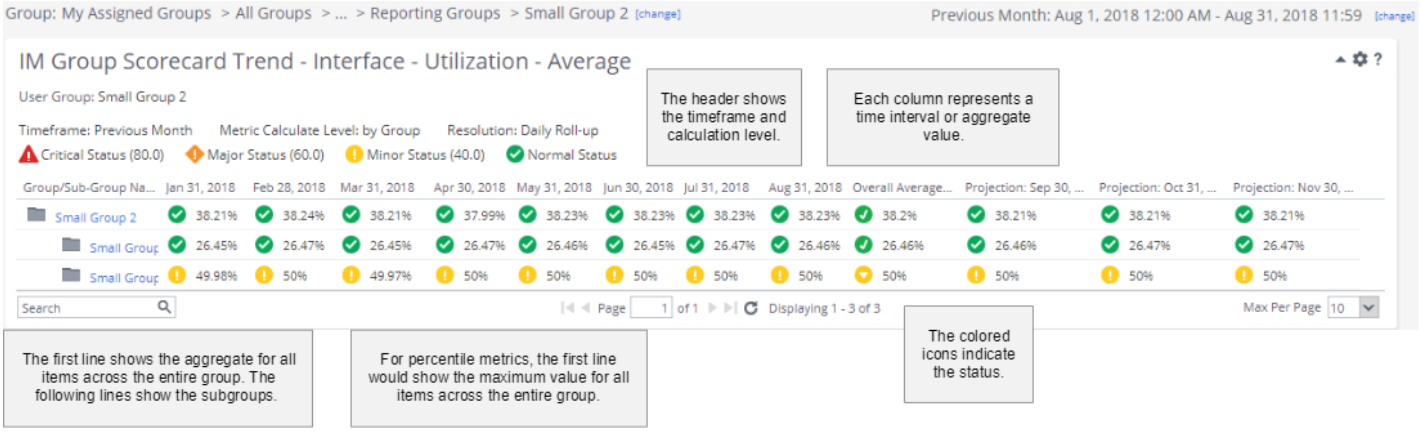
You can select counter metrics (for example, Bits Out - Total). However, group scorecard trend view thresholds are intended for gauge metrics (for example, Bits Out - Average Rate).

Group scorecard table views are also available, which let you view multiple metrics in the same scorecard. For more information, see Group Scorecard Table Views.

The following images show the important elements of a scorecard view.

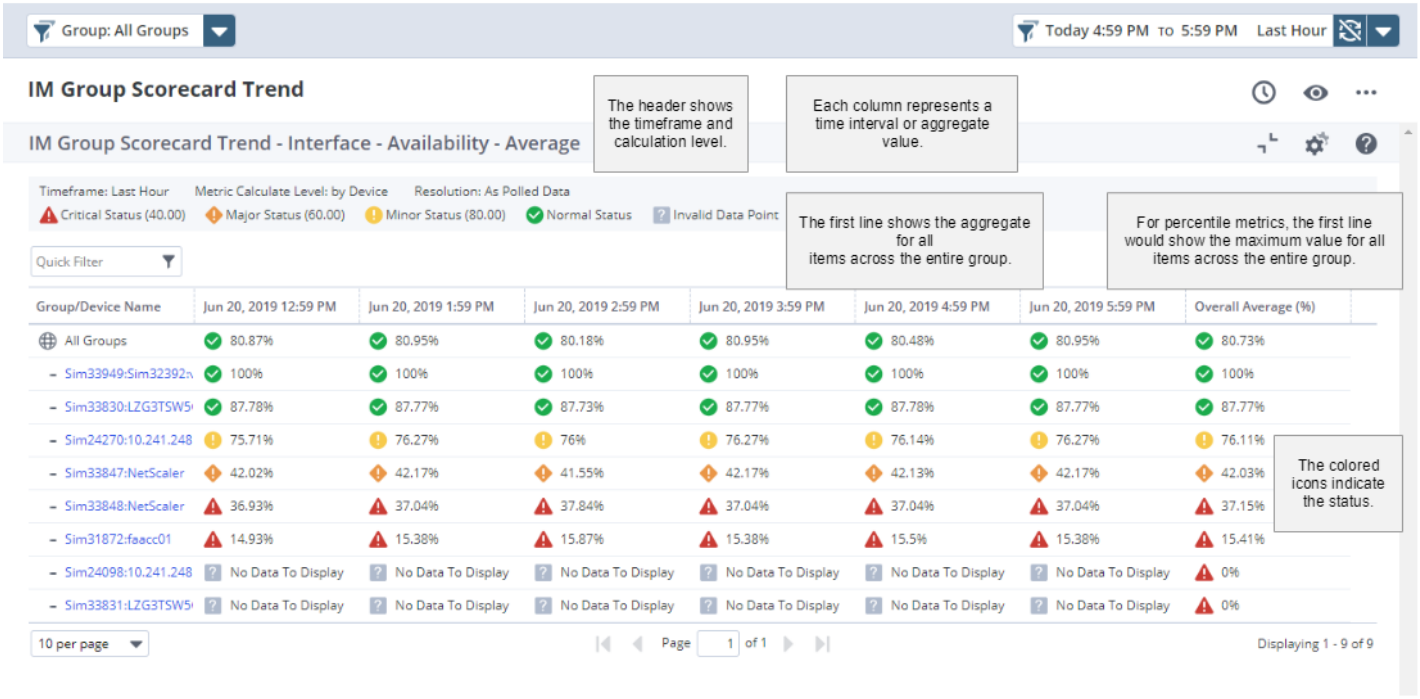
The Metric Calculate Level in the following image is set to Group:

Figure 21: Group Scorecard Trend



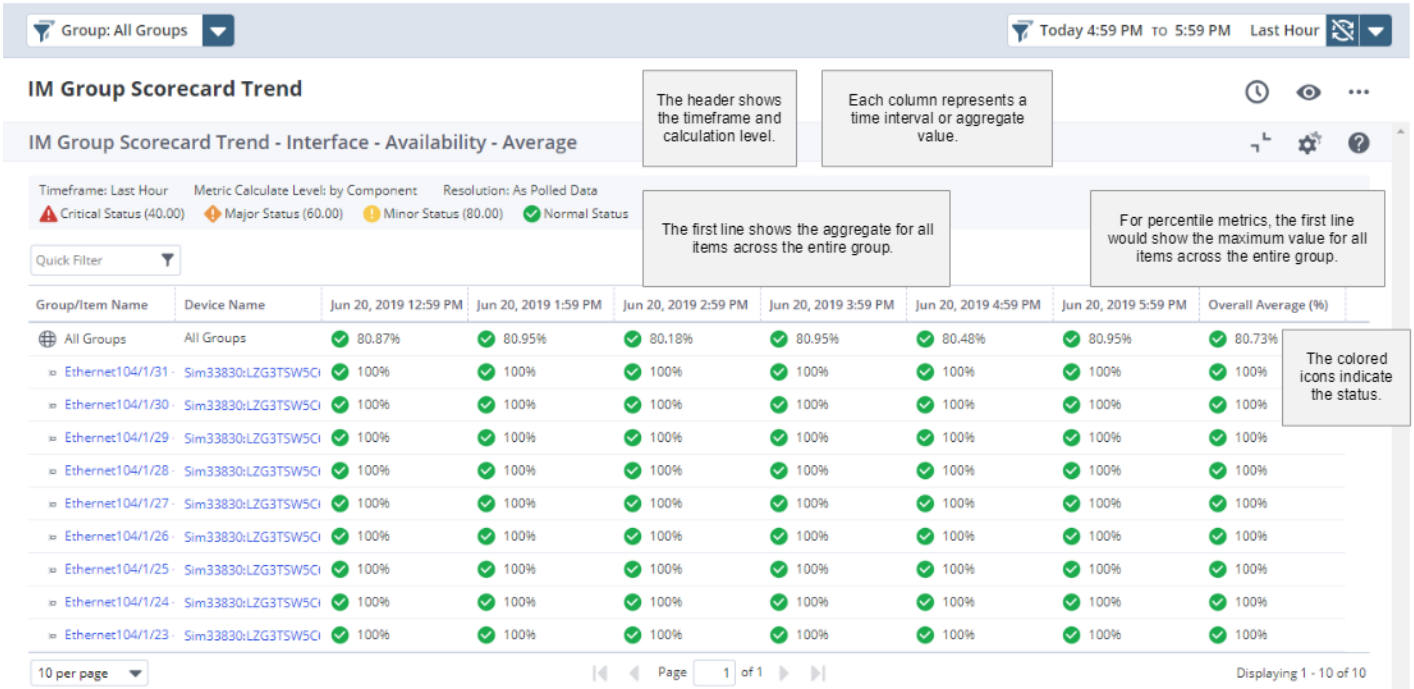
The Metric Calculate Level in the following image is set to Device:

Figure 22: Group Scorecard Trend Device



The Metric Calculate Level in the following image is set to Component:

Figure 23: Group Scorecard Trend Component



NOTE

If a time period renders nonnumeric value for the reporting metric, the scorecard view and header contains a gray icon. This icon indicates that the data for that timeframe includes an invalid data point.

Group scorecard trend views calculate and display projected values as follows:

- For monthly intervals, the first projection is the last day of the following month.
- For weekly intervals, the first projection is midnight on the following Sunday.
- For daily intervals, the first projection is the following midnight.
- For hourly intervals, the first projection is the top of the following hour.

IM Group Scorecard Trend View

The IM Group Scorecard Trend view is a fully customizable scorecard. This scorecard displays historical time intervals for any metric, and up to three projected values. The projected values are calculated from the trend of historical data in the time range of the view. The items in a group determine the metrics that are available in this view.

Interface 95th Maximum Percentile Trend Scorecard View

Most group scorecard trend views always attempt to use daily data unless your data retention policy prevents it. However, the Interface 95th Maximum Percentile Trend Scorecard view uses polled data for accuracy.

When you select larger time ranges (for example, Previous Month), you can easily surpass the configured data retention rate, which limits the number of columns available for comparison.

Configure Group Scorecard Trend Views

Group scorecard trend views include standard view configuration options, such as time filters and context settings. For standard view configuration details, see Customize Views.

TIP

On dashboards, scorecards render best in single-column layouts. Scorecards with fewer columns also render well in two-column layouts. Do not use scorecards in three-column layouts.

The following configuration options apply only to scorecard views.

Follow these steps:

1. (Trend and Custom Scorecard Views Only) Select the number of time intervals.
   Each time interval is one column on the view.

   NOTE

   This setting directly relates to the Time Range setting for the view. The time range for the view determines the length of each time interval. For example, if you select Last 30 days for the Time Range, each interval equals 30 days.
2. (Custom Scorecard View Only) Configure scorecard projection.
   - Select the number of projections to display.
     Each projection is a column on the view.
   - Select the calculation method for the projection.

   For more information, see Scorecard Projection.
3. Select the Metric Calculate Level.
   This option determines what level of aggregation each row in the scorecard view represents: a subgroup, a device, or a component.
4. Specify the thresholds for the status indicators.

If the value for the metric is at or above the specified value, the status icon in the view indicates the status by color. Red indicates critical, orange indicates major, yellow indicates minor, and green indicates normal.
To remove the status indicators, set the threshold values for all status levels to zero.

TIP

For metrics where low values are bad and high values are good, set Minor highest and Critical lowest.

5. Set the results limit.
   This limit determines the number of items included in the data results shown on each page of the scorecard.
   Default: 10

Scorecard Projection

Scorecard projections use a customizable set of data points to predict future values for metrics. Projected values are calculated when the view is rendered, and are based on the historical time frame of the view. You can add the projected values to IM Custom View Group Scorecards.

TIP

Do not use scorecard projections for error metrics. Each error is a discrete event that is not affected by historical errors.

The scorecard view includes two methods to calculate projections:

- **Approximation**
  The Approximation method uses the average from each time frame in the view to calculate the projection values. DX NetOps Performance Management calculates a least squares regression on the averages, then uses the line equation to project future values. This calculation method is faster than the Detailed Data method.
- **Detailed Data**
  The Detailed Data method uses the polled data for the entire time frame of the view. DX NetOps Performance Management calculates a least squares regression for the entire set of data points. This calculation is more statistically accurate than the Approximation method, and provides extra columns in the view.

NOTE

Detailed data scorecard projections are supported only for gauge metrics (for example, Bits Out - Average Rate). Detailed data scorecard projections are *not* supported for counter metrics (for example, Bits Out - Total). Projection values are calculated on the As Polled (rate) data to ensure precision.

These columns are hidden by default:

- **Slope**
  Indicates the slope of the line equation.
- **Intercept**
  Indicates the intercept of the line equation.
- **Degrees**
  Degrees of freedom, which indicates the sample size.
- **Linear Fit**
  Indicates the confidence level of the projected values as related to the sample data.
- **Days to Threshold**
  Indicates the projected number of days before the specified critical threshold is reached.

Group Scorecard Table Views

Group scorecard table views let you view multiple metrics in the same scorecard. Group scorecard table views display the metrics by subgroup, device, or component for the selected group. These views incorporate red, orange, yellow, and green icons as visual indicators of performance levels. The color of the status icons is based on a set of user-defined thresholds. You can specify separate thresholds for each metric.

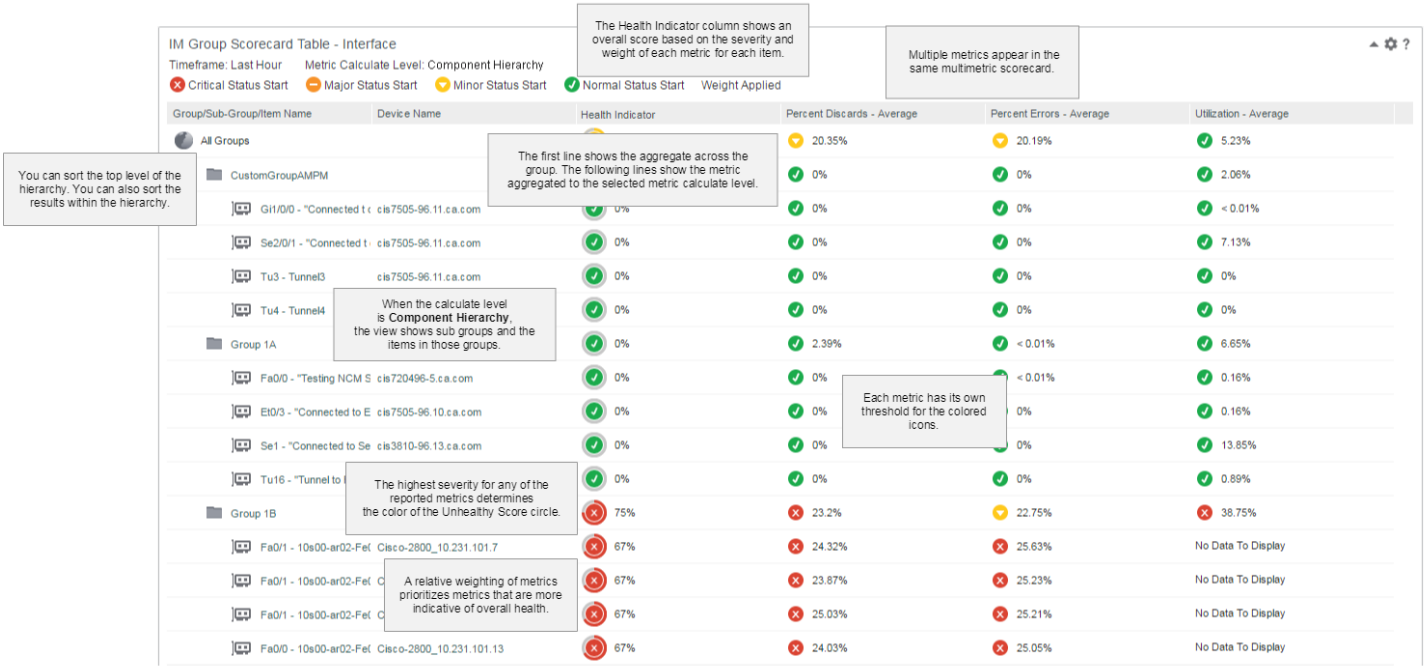
You can select counter metrics (for example, Bits Out - Total). However, group scorecard table view thresholds are intended for gauge metrics (for example, Bits Out - Average Rate).

Group scorecard trend views are also available, which provide line-of-business owners a group-level summary of how key metrics perform over time. For more information, see Group Scorecard Trend Views.

The following images show the important elements of a group scorecard table view. The Health Indicator column is shown.

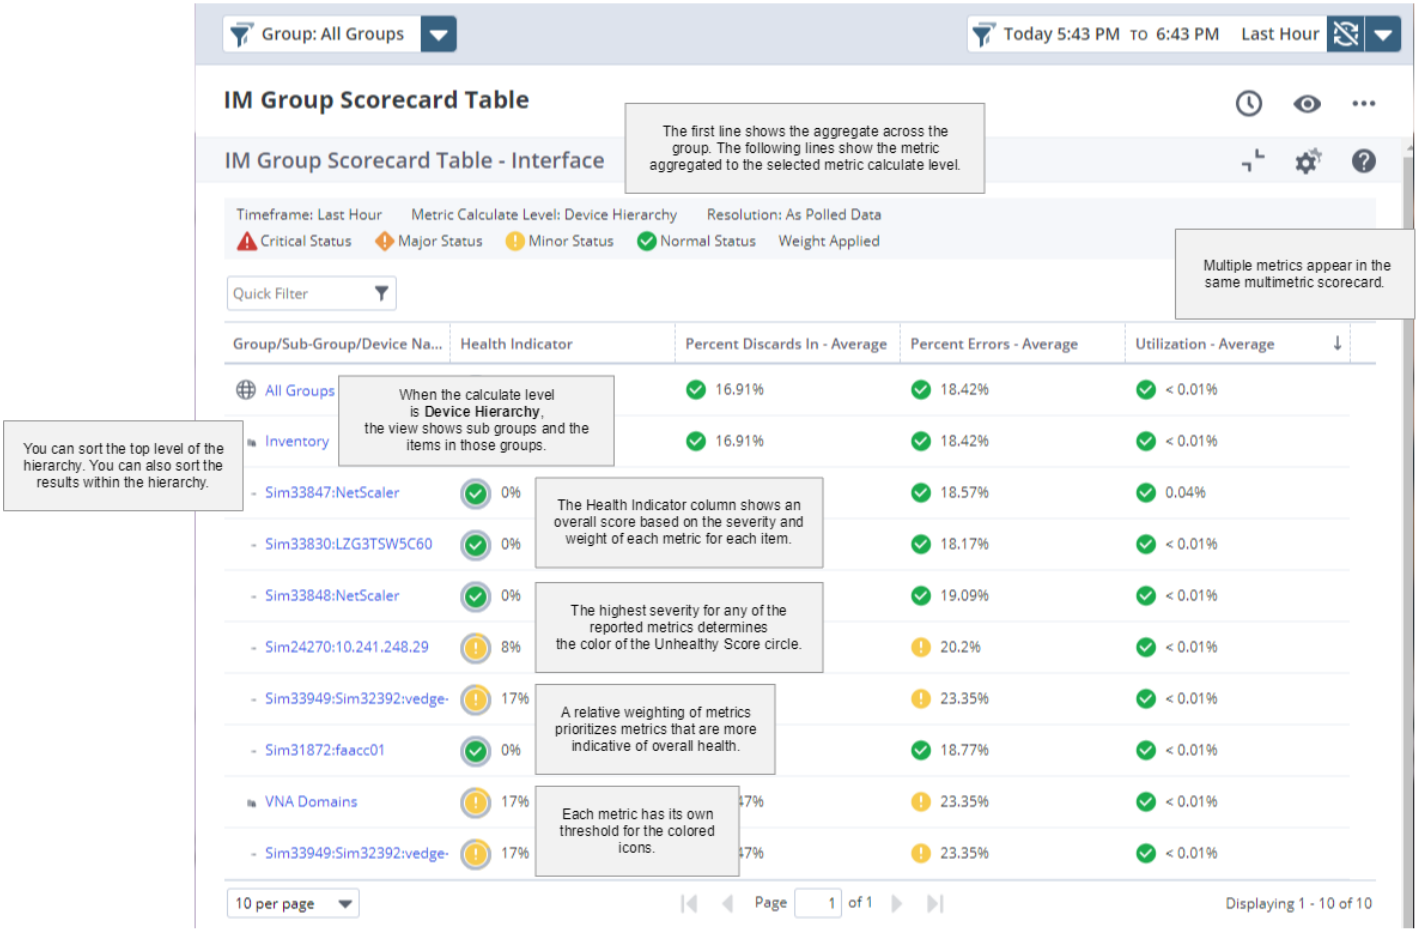
The Metric Calculate Level in the following image is set to Component Hierarchy.

Figure 24: Group Scorecard Table Component Hierarchy



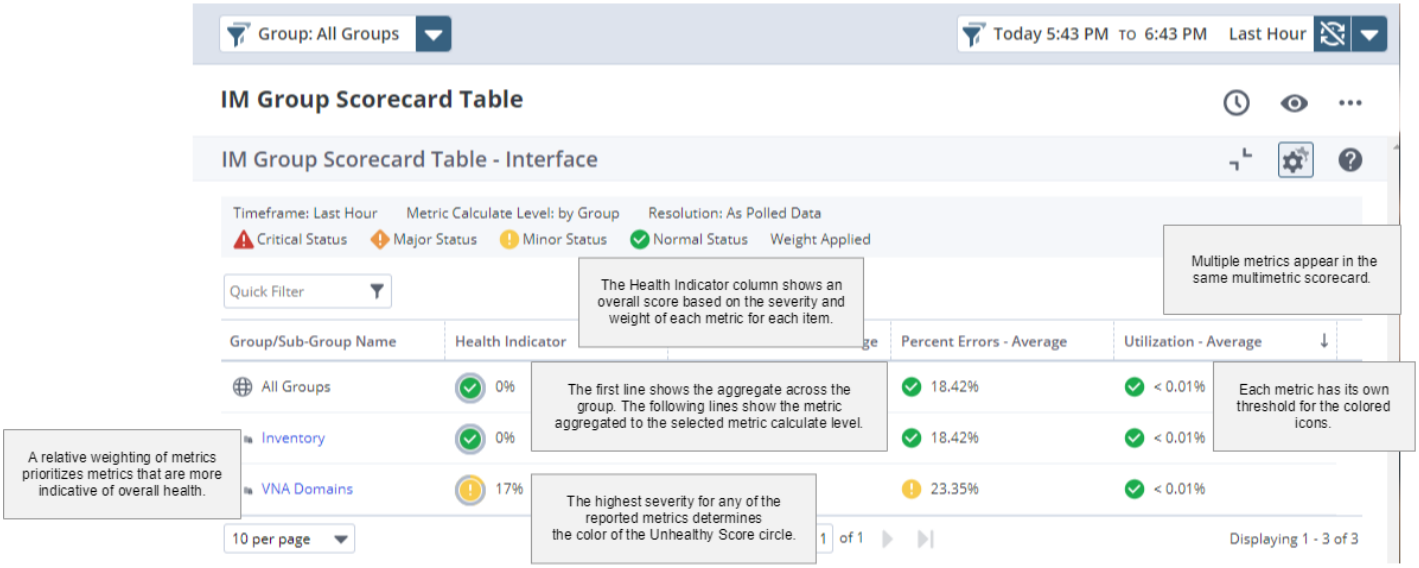
The Metric Calculate Level in the following image is set to Device Hierarchy:

Figure 25: Group Scorecard Table Device Hierarchy



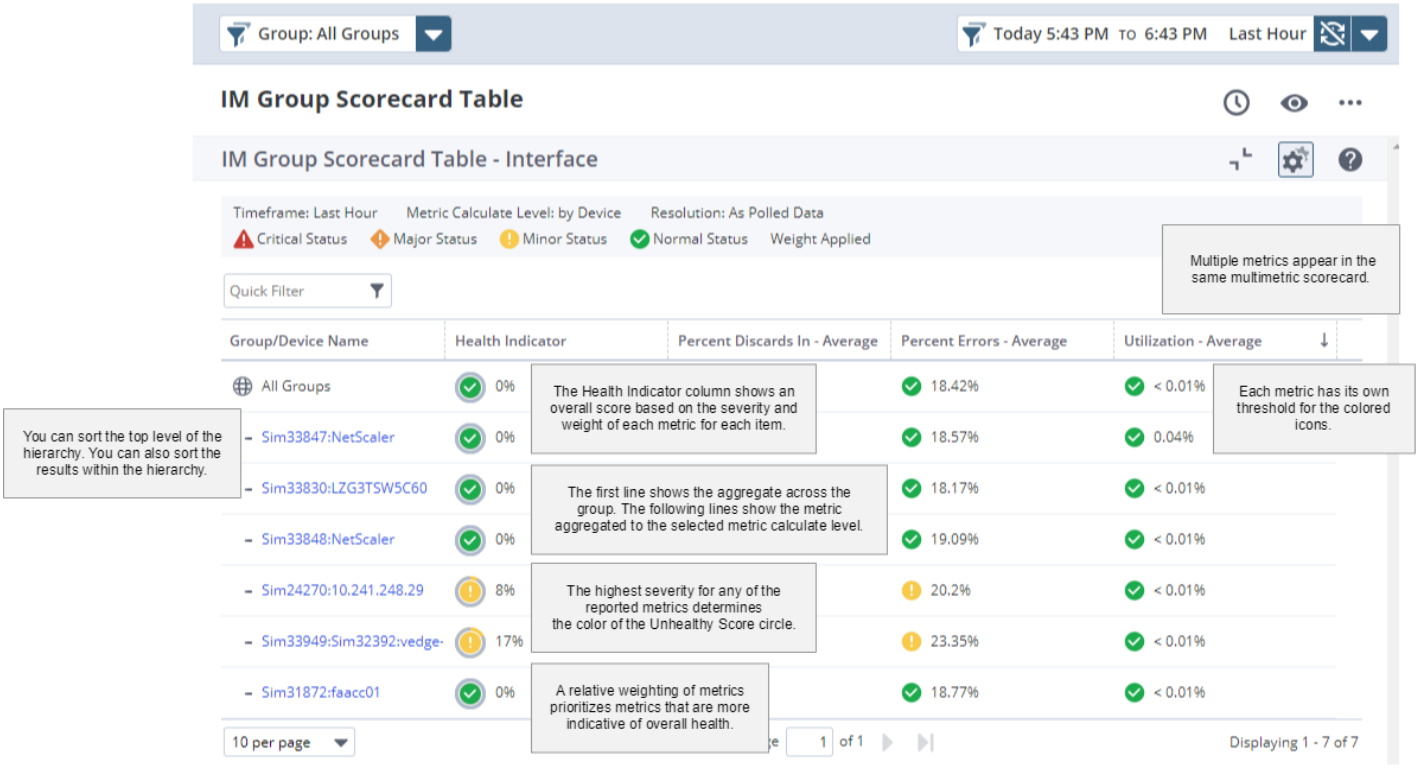
The Metric Calculate Level in the following image is set to Group:

Figure 26: Group Scorecard Table Group



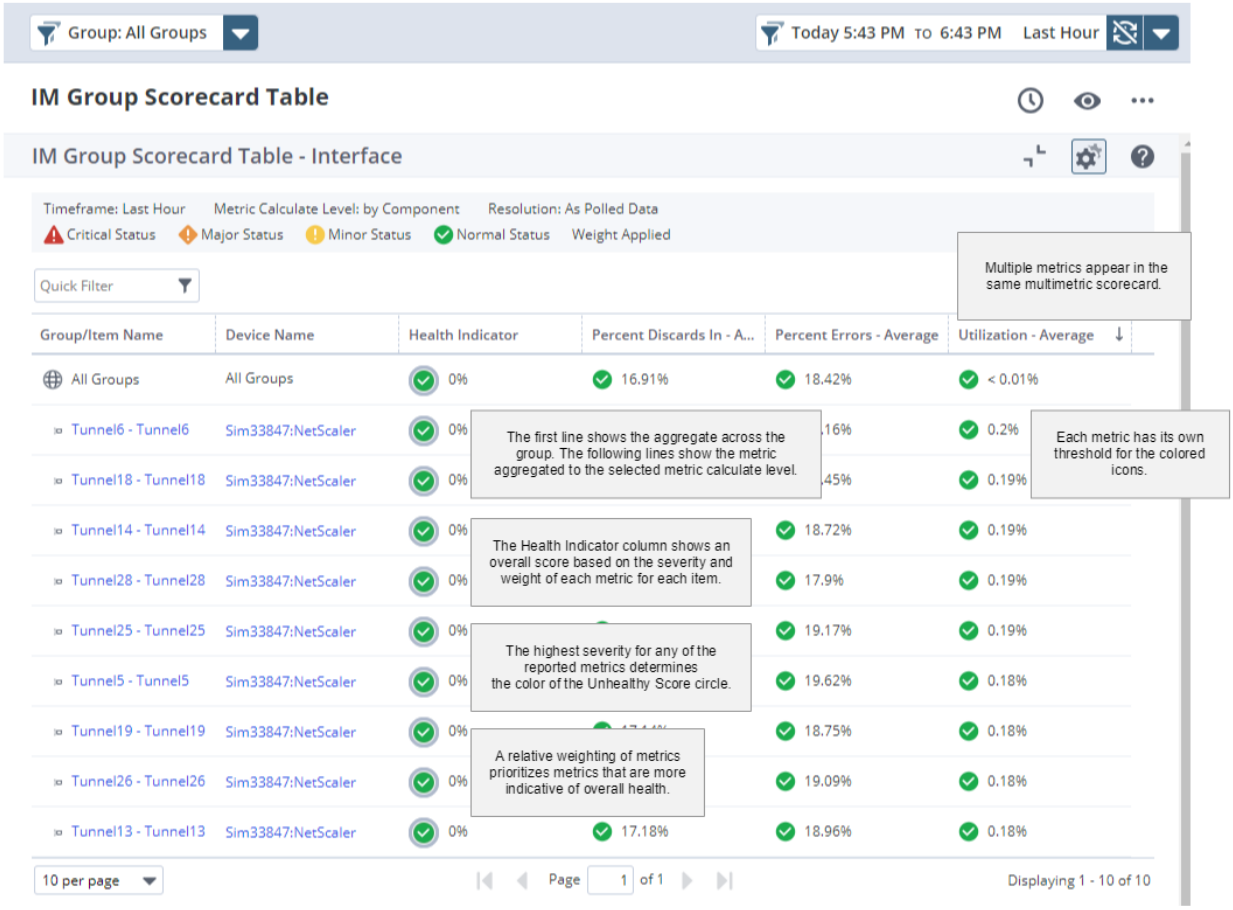
The Metric Calculate Level in the following image is set to Device:

Figure 27: Group Scorecard Table Device



The Metric Calculate Level in the following image is set to Component:

Figure 28: Group Scorecard Table Component



Configure a Group Scorecard Table View

To display a group scorecard table view, add the IM Group Scorecard Table view. Group scorecard table views include standard view configuration options, such as time filters and context settings. For standard view configuration details, see Customize Views.

TIP

On dashboards, group scorecard tables render best in single-column layouts. Group scorecard tables with fewer columns also render well in two-column layouts. Do not use group scorecard tables in three-column layouts.

Follow these steps:

1. **Show** or **Hide** the Health Indicator column.
2. Select the **Metric Calculate Level**.
   This option determines what level of aggregation each row in the scorecard view represents: a group, a device, a component, a device hierarchy, or a component hierarchy.
   Component Hierarchy shows aggregation to the current group and to each group that is a child of that group.
3. Set the **Results Limit**. This limit determines the number of items that are included in the data results shown on each page of the scorecard.

NOTE

If the **Results Limit** is less than the child item count, only the data results within the limit are aggregated. For accuracy, we recommend the **Results Limit** exceed the child item count. However, your child item count might exceed the supported maximum limit to meet performance expectations. In this scenario, we recommend that each parent group contain a smaller set of child items.

4. For each metric, specify the thresholds for the status indicators.
   If the value for the metric is at or above the specified value, the icon indicates the status by color.
   Red indicates critical, orange indicates major, yellow indicates minor, and green indicates normal.
   To remove the status indicators, set the threshold values for all status levels to zero.
   You can specify thresholds with up to two decimals places with the lowest value being 0.01. Values with more than two decimal places are rounded.

   TIP

   For metrics where low values are bad and high values are good, set Minor highest and Critical lowest. To omit a severity level, set the threshold value to zero.
5. If the Health Indicator column is shown, for each metric, specify a weight:
   - **0**
     This weight shows the metric in the table, but does not factor the metric into the Health Indicator.
   - **1**
     This weight applies a standard weight to the metric when calculating the Health Indicator.
   - **2**
     This weight doubles the metric value when calculating the Health Indicator.
   - **3**
     This weight triples the metric value when calculating the Health Indicator.

Map Views

Map views are available for SD-WAN tunnels and application/SLA paths only. Map views show the location of each site for the selected group. You must select a DX NetOps Virtual Network Assurance-based site. Sites with no data appear as gray icons. In previous versions, sites with no data were excluded from the Map view. Map views show only a single level below the selected group

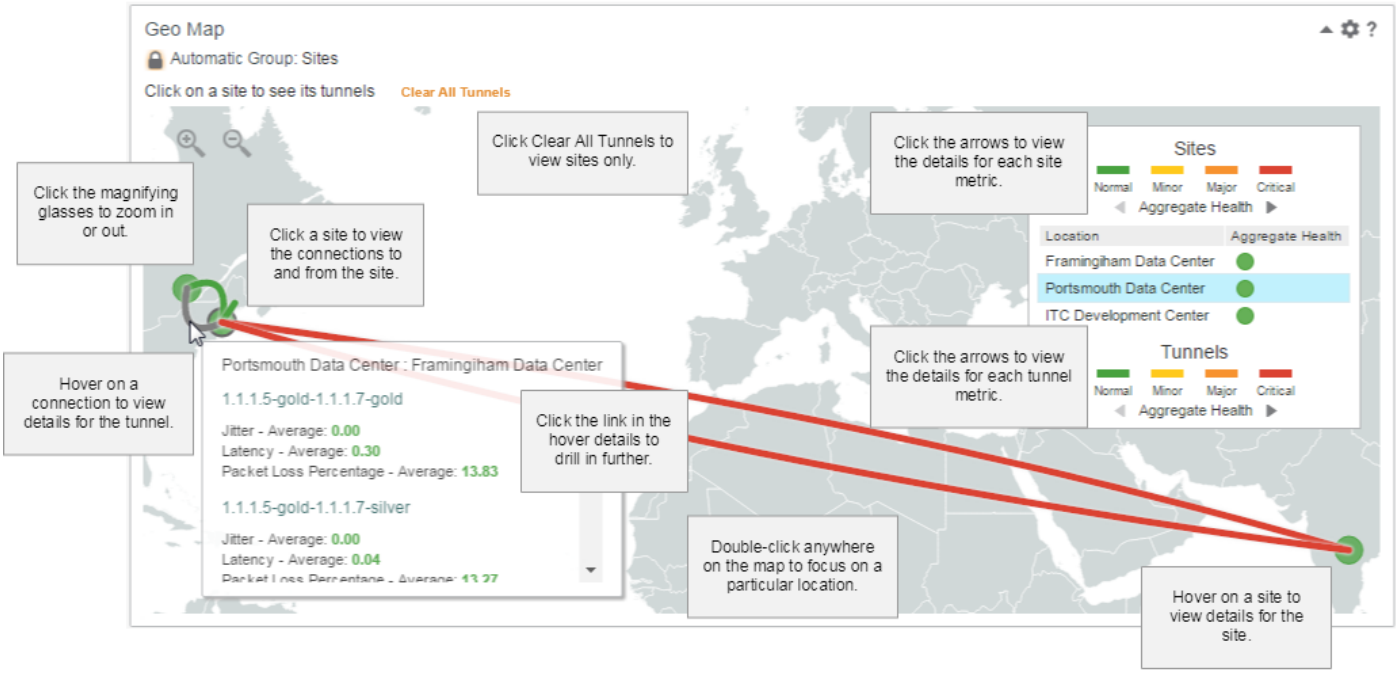
Example: A USA site group contains site groups for states. The site groups for states contain site groups for cities. If you select USA, the map view shows the site groups for states, but not for cities. If you select a state, the map view shows the site groups for cities within the state.

When a site is selected, the connections to and from other sites appear. The connection lines are color-coded based on health metrics. Site router details appear when you hover over a site. Tunnel or application/SLA path details appear when you hover over a connection.

For more information about monitoring SD-WAN, see Monitor SD-WAN.

The following example shows the important elements of a map view for tunnels:

Figure 29: Map_View



Configure a Map View

Map views include standard view configuration options, such as time filters and context settings. For standard view configuration details, see Customize Views.

> **NOTE**
>
> Map views are available only for SD-WAN tunnels and application/SLA paths. Other managed item types are unsupported.

Follow these steps:

1. Specify the thresholds for each site metric (CPU utilization, memory utilization, and virtual interface utilization).
   If the value for the site is at or above the specified value, the icon indicates the status by color.
   Green indicates normal, yellow indicates minor, orange indicates major, and red indicates critical.
   You can specify thresholds with up to two decimals places with the lowest value being 0.01. Values with more than two decimal places are rounded.

   > **TIP**
   >
   > For metrics where low values are bad and high values are good, set Minor highest and Critical lowest. To omit a severity level, set the threshold value to zero.
2. Specify the thresholds for each tunnel or application/SLA path metric.

Pie Chart Views

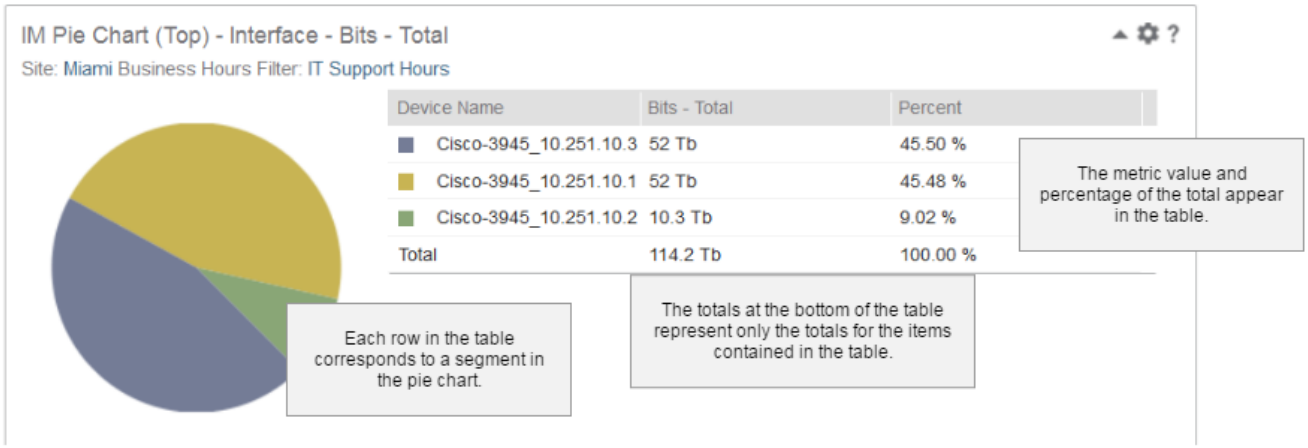
Pie charts show the relative values of a metric. Use pie charts to view metric values that represent parts of a whole. Pie charts are best used for small groups of items. This view includes a table that shows the metric value and the percentage of the total value for each item.

You can apply a business hours filter to the data in pie chart views. The applied business hours filter appears in the subtitle.

For more information about how to configure business hours definitions, see Configure Business Hours Filtering.

The following example shows the important elements of a pie chart view:

Figure 30: Pie Chart Elements



To set up a pie chart, configure the following properties:

- **Metric Label**
  The selected attribute (Device Names, Item name, or Description) appears as the first column of the table. When the selected attribute is Device Name, the metrics are aggregated at the device level.
- **Sort Direction**
  The pie chart includes the items for the selected metric in descending or ascending order.
- **Max Rows**The maximum number of table rows determines the maximum segments that appear in the pie chart.

For more information about how to configure a standard view, see Customize Views.

Pie/Table Views

For more information about pie/table views, see Table Views.

Table Views

Table views are the most useful way to show vertically and horizontally dense data, include multiple metrics, many items, or many properties. Tables let you sort the data according to any metrics, so you can view the best and worst results for each metric.

Business hours filtering can apply to the data in table views. The applied business hours filter appears in the subtitle. For more information, see Configure Business Hours Filtering.

Table View Options

Table views provide the following functionality:

- To drill down to detailed data for individual items, click the item name.
- To sort by a particular column or reverse the sort order, click the column heading. An arrow icon indicates the sorted column.

When you sort by a different column, DX NetOps Performance Management queries the data source to get new results for the table that match the top values for the new sorted column. The sort order applies only to the currently rendered view. The sort order does not persist and cannot be saved on the view.

- For column options, mouseover column heading and click the gear icon. Use the following options to manage columns:
  - **Sort Ascending/Sort Descending**
    Sort the entire data set from the data source.
  - **Sort Results Ascending/Sort Results Descending**
    Sort the already retrieved and rendered result set.
  - **Add/Hide Columns**
    Expand the Columns menu, and select or clear columns for the table. This list includes the selected metrics from the view configuration and more details about the items, such as Alias and Life Cycle State.
  - **Move**
    Click and drag the column header to the desired location.
  - **Resize**
    Hover over the separator line between two columns in the grid header, and click and drag the column to be wider or narrower.
  - **Save**
    Save the column settings for the view at the tenant, user, or session level. The save operation is applied only to the column selection and the order of columns.

    NOTE

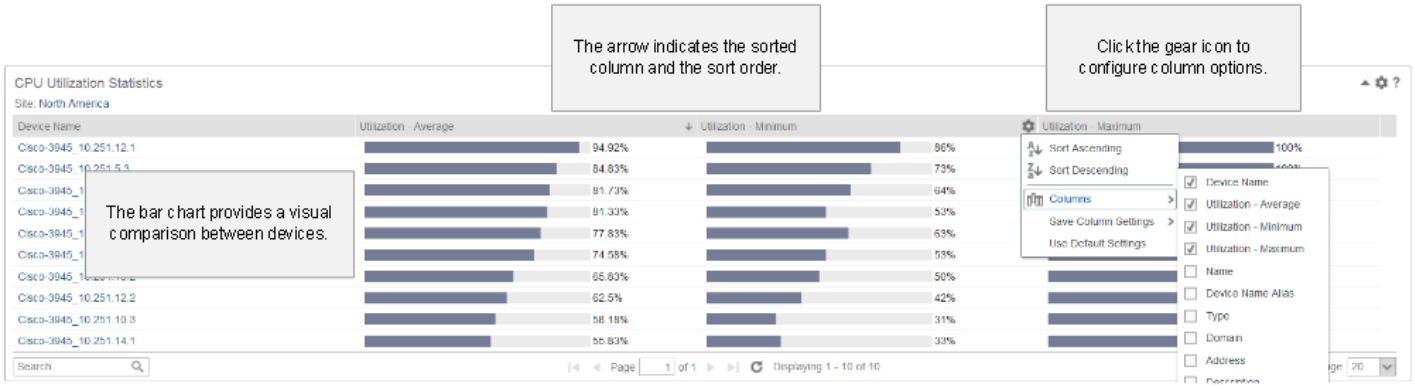
    Save does not preserve column sort order.
  - **Use Default Settings**
    Revert any custom changes applied to the view column settings.
- By default, **Enable Scrolling** is selected and the Search bar is locked in place when you display more than 20 rows. To change this setting, click the **Max Per Page** drop-down in the lower-right corner, and change **Enable Scrolling**.

Bar Chart Table Views

Some out-of-the-box views, show tables with a bar chart column. These views show metrics with percentage values. Use these views to identify problematic devices quickly.

The following example shows the important elements of a bar chart table:

Figure 31: Table Bar Chart Elements



Deviations from Normal Table Views

The Top Deviations from Normal views compare actual values from the selected time frame to a calculated baseline value. Use these views to identify places where performance has changed. These views display the items that deviated the most from that normal value. The way the baseline is calculated varies by data source.

The table shows the following information:

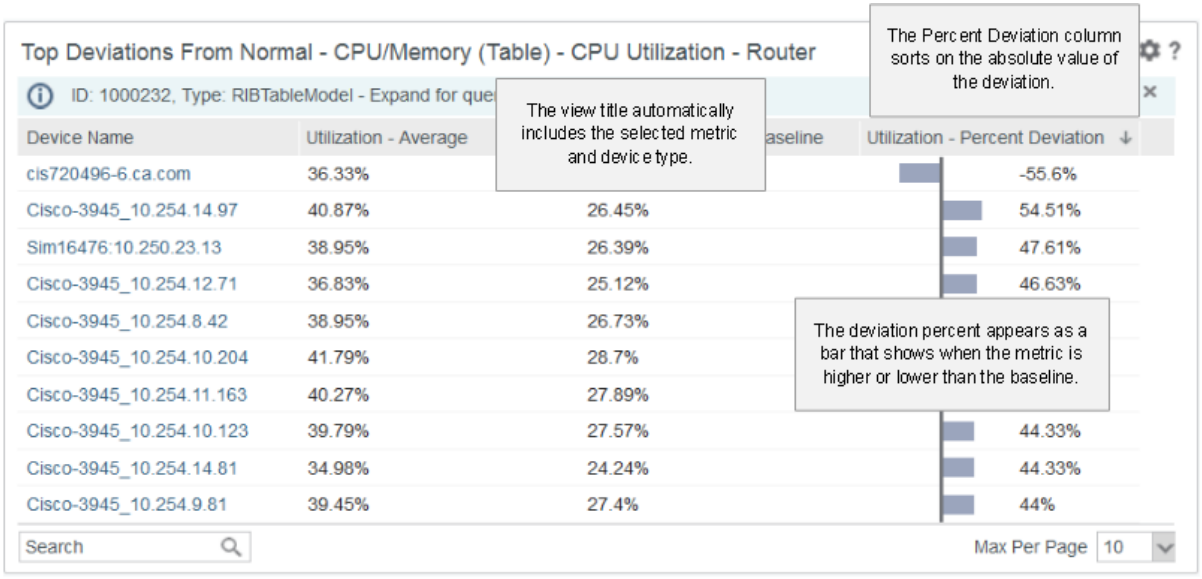
- The average for the selected metric
- The average baseline for the selected metric
- The percent divination with a relative visualization sorted by absolute value

Edit the view to specify the following information:

- The type of device: router, server, or switch
- The selected metric

The following example shows the important elements of a deviations from normal table:

Figure 32: Deviations from Normal Table Elements



Chart/Table Views

Chart/table views combine aspects of other visualizations with table views. These views support only percentage type metrics.

> **NOTE**
>
> When you print a combi-view, only the table portion of the view appears in the PDF.

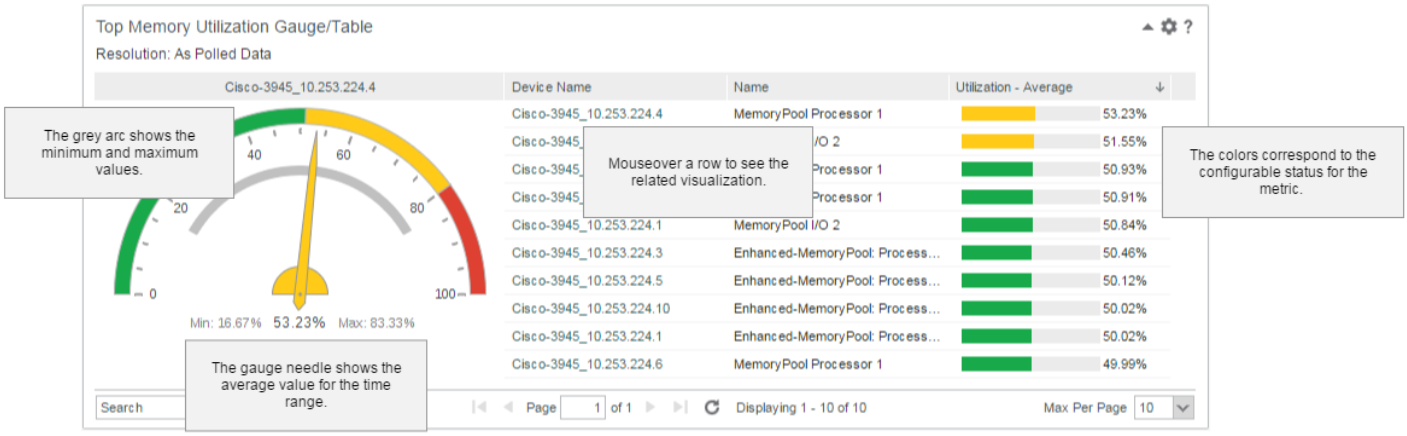
Gauge/Table Views

Gauge/table views highlight where the value of one metric differs from the expected value when compared to other metrics. These views are good for metrics where the value is a percentage. The gauge shows the minimum, maximum, and average values for one item in the time range. The table lets you see the values for all items and select the item to show on the gauge.

The gauge chart legend shows the resolution, which specifies the granularity of the reporting data: as polled, hourly rollup, or daily rollup. For customized views, the minimum and maximize thresholds are based on this resolution. For out of the box views, the minimum and maximum thresholds are based on the as polled resolution.

The following example shows the important elements of a gauge/table view:

Figure 33: Gauge Table Elements



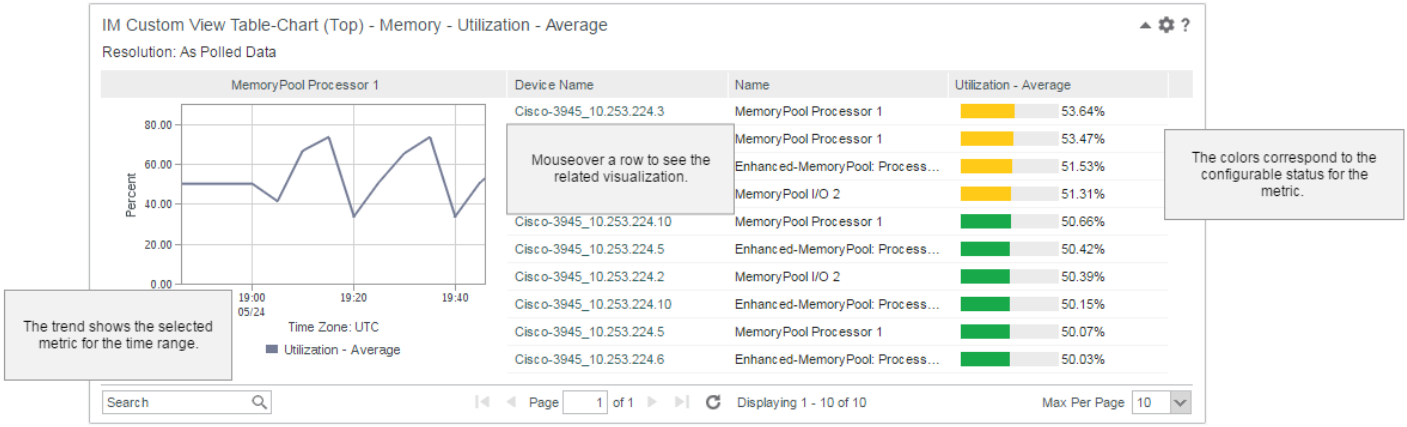
Trend/Table Views

Trend/table views provide the flexibility of table data and use the trend view to show the change in a metric over time. The trend shows the value over the time range for one item. The table lets you see the values for all items and select the item to show on the trend. Percentage-based metrics are represented with a bar.

Most trend/table views have a trend chart that shows the value of a single metric. Some trend/table views have a trend chart that shows the value of multiple metrics. Each metric is represented with its own trend line.

The following example shows the important elements of a trend/table view:

Figure 34: Trend Table Elements

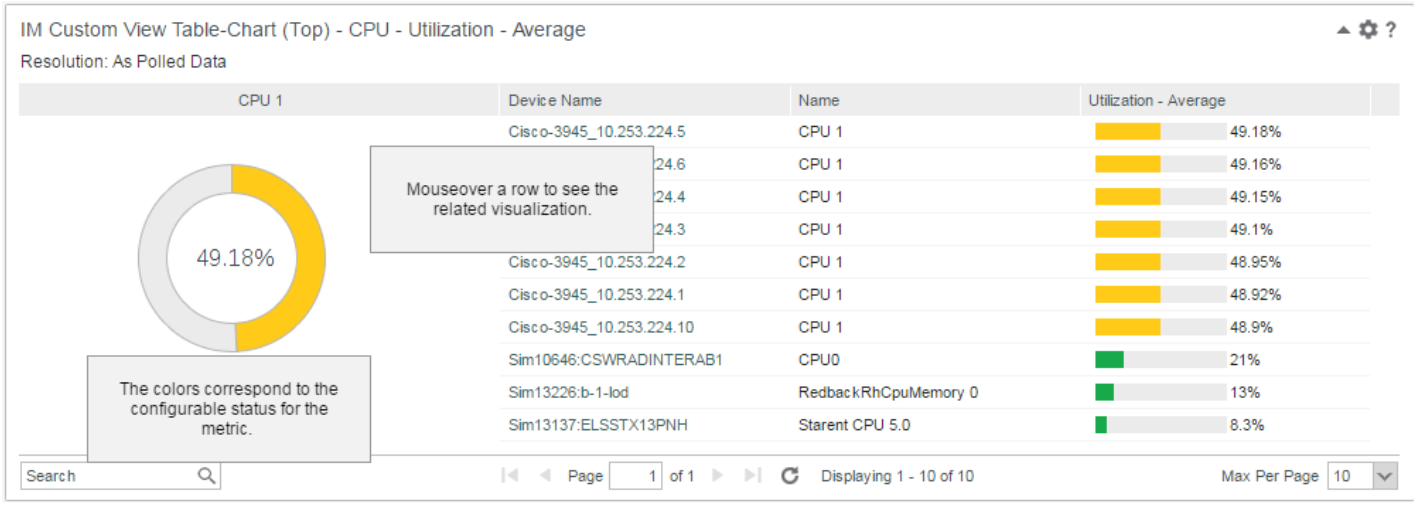


Radial Bar/Table Views

Radial bar/table views show percentage values within a circular bar.

The following example shows the important elements of a radial bar/table view:

Figure 35: Radial_Bar

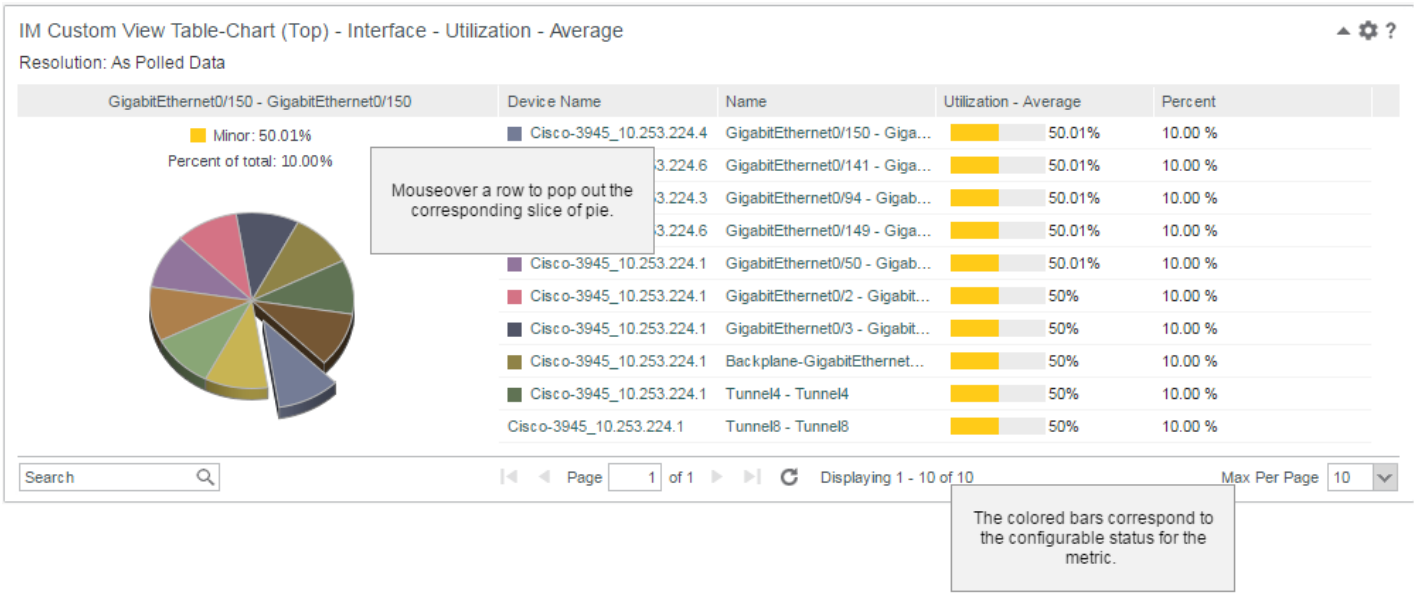


Pie/Table Views

Pie/table views show the relative values of a metric. When you hover over the corresponding item in the table, the corresponding slice of pie pops out. Use pie charts to view metric values that represent parts of a whole. Pie charts are best used for small groups of items.

The following example shows the important elements of a pie/table view:

Figure 36: Pie_Table_View



Configure Chart/Table Views

The IM Custom Chart-Table view is a custom view that reports data from the data aggregator data source.

Not all settings are available for all table view types. For standard view configuration details, see Customize Views.

Follow these steps:

1. Select a **Chart Type**.
2. Select the **Metric Name** from the list of metrics for the selected metric family. This option determines the selected metric for the view.
3. If you are configuring a custom view, select the **Metric Calculate Level**.
   This option determines what level of aggregation each row in the view represents: a device, or a component.
4. Change definitions for the status levels:
   - **Minor Status Start**
     Metrics before this value have a normal status indicated with green.
     Metrics at or after this value have a minor status indicated with yellow.
   - **Major Status Start** Metrics at or after this value have a major status indicated with orange.
   - **Critical Status Start**
     Metrics at or after this value have a critical status indicated with red.

     NOTE

     Some out-of-the-box views show **Moderate Status Start**. For these views, moderate status is yellow and orange is unavailable.

     TIP

     You can configure chart/table views to reflect reverse value severity. For metrics where low values are bad and high values are good, set Green highest and Red lowest. To omit a severity level, set the threshold value to zero. For example, setting Orange to zero removes the major severity when profiling metric thresholds.
5. Select the **Max Rows**. This limit defines the total number of rows that the table can display. If the number of results exceeds the max rows, the table shows the top metrics according to the sorted column.

Configure Table Views

The IM Table (Top) view is a custom view for data from the Data Aggregator data source.

Not all settings are available for all table view types. For standard view configuration details, see Customize Views.

Follow these steps:

1. Select the **Metric Fields** from the selected metric family to display in the table. Each selected field is a column in the table.

   NOTE

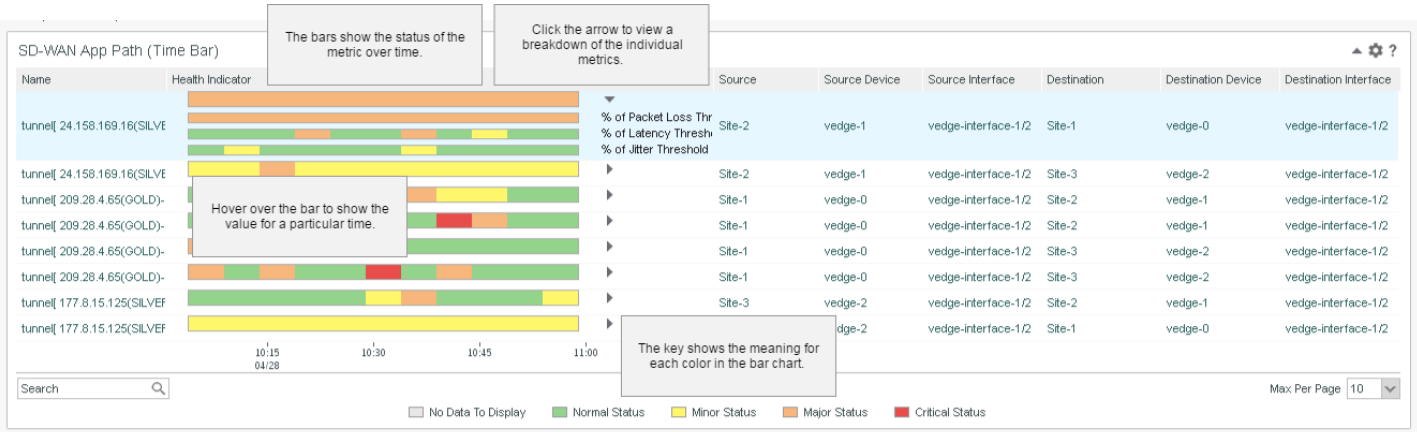
   If you select Device Name without Name, the metrics are aggregated to the device level. If you select Name or Description with or without Device Name, the metrics are aggregated to interface or component level.
2. Select the **Metric Sort**, which defines the column to use to sort the table by default.
3. Select the default **Sort Direction** for the **Metric Sort** column.
4. Select a requested resolution. For more information, see Data Resolution.
5. Select the **Max Rows**. This limit defines the total number of rows that the table can display. If the number of results exceeds the max rows, the table shows the top metrics according to the sorted column.

Time Bar Chart Views

These views use a bar to show the status of percentage metrics by color over the selected time range. Time bar views show threshold values within a time series. The time slices represent the statuses as bars of colors. Hover over a section of the time range to view a tooltip with the corresponding value.

The following example shows the important elements of a time chart:

Figure 37: Time Chart Elements



Sort a Time Bar Chart

Time bar views report only percentage metrics. Percentage values range inclusively from 0% to 100%. Values that are outside that range are marked as invalid, shown as a gray bar, and excluded from the sort order.

Use the Sort Direction in the view settings to sort the highest and lowest items based on the maximum rows across the entire time range. This also sorts the colored bars within the time bar itself.

You can also click the gear icon in the table heading to sort as follows:

- **Sort Ascending/Sort Descending**
  Sort the already retrieved and rendered result set.

Configure a Time Bar Chart

The IM Time Bar Chart is available on dashboards, device context pages, and group context pages. This view is not available on interface or component context pages. For standard view configuration details, see Customize Views.

> **TIP**
>
> On dashboards and in context pages, time bar charts render best in single-column or two-column layouts.

To configure the behavior of a custom time bar chart, specify the following properties:

- **Metric Value**
  Select a specific metric to include in the view. To view a time bar chart aggregating the associated metrics, select the following option:
  - **Health Indicator**
    You can click to expand and view a time bar chart for each metric.
- **Metric Calculate Level**
  This option determines what level of aggregation each row in the view represents: a device, or a component.
- Define the thresholds for the bar:
  - **Critical Status Start**
    The bar shows red for metrics with this value for this time.
  - **Major Status Start**
    The bar shows orange for metrics with this value for this time.
  - **Minor Status Start**
    The bar shows yellow for metrics with this value for this time.

Time Bar/Table Views

For more information about these views, see Table Views.

Trend Views

Trend views show the value of a metric across time. Trends show spikes or dips in activity and help identify whether a metric is increasing or decreasing. Trend views provide one or more of the following chart types:

- **Trend Chart**
  View a traditional trend line for each device, component, or metric.
- **Stacked Chart**
  View a stacked line on top of each other for each device, component, or metric.

  NOTE
  Trend views displaying data up to the present moment might contain dips or spikes for the present moment as data is processed.

Maintenance indicators apply to all the devices and components in a site group. When the associated site group is selected in the context, maintenance indicators appear as shading in trend views.
For more information, see Schedule Maintenance Indicators.

Applying a business hours filter to a trend view displays the same data in the view, but the periods outside of the business hours are shaded.
For more information:

- About business hours filtering, including how to define business hours definitions, see Configure Business Hours Filtering.
- About how to apply a business hours filter to views on a dashboard, see Dashboards.
- About how to apply a business hours filter to views on a context page, see Context Pages.

In this article:

Trend View Options

Trend views let you quickly change the trend lines that are displayed on the graph. The following options also apply to MultiTrend views:

- To remove a metric from the chart temporarily, right-click the metric in the legend, and click **Hide**.
- To add a metric back into the chart, right-click the metric in the legend, and click **Show**.
- To hide all other metrics, right-click a metric in the legend, and click **Focus**.
- To narrow the view on a precise time frame, click and drag across the time frame in the chart.

  NOTE
  Select a time frame of at least 30 minutes. For MultiTrend views, you must drill into an individual trend view before you can select a time frame. If non business hours compression is enabled, zooming is not supported.
- To apply the precise time frame to the entire dashboard, click **Apply to Dashboard** at the bottom of the chart.
- To revert the view to the default settings, click **Undo** in the lower-left corner.

Trend View Element Examples

Trend views can include the following elements:

NOTE
A specific trend view might or might not include the following elements. A specific trend view might include elements in addition to following elements.

- **Baselines**
  If available, the baseline trend line lets you determine whether utilization trends are changing. The baseline data that is plotted in many views shows statistical deviations from "normal" performance for a given statistic.
  For more information, see Baseline Calculations.

  NOTE
  Baseline metrics are processed up to hourly and daily increments. When the resolution is less than an hour, data points are interpolated between known hourly data points.
- **Events**
  If available, events appear as flags indicating the times that the events occurred.

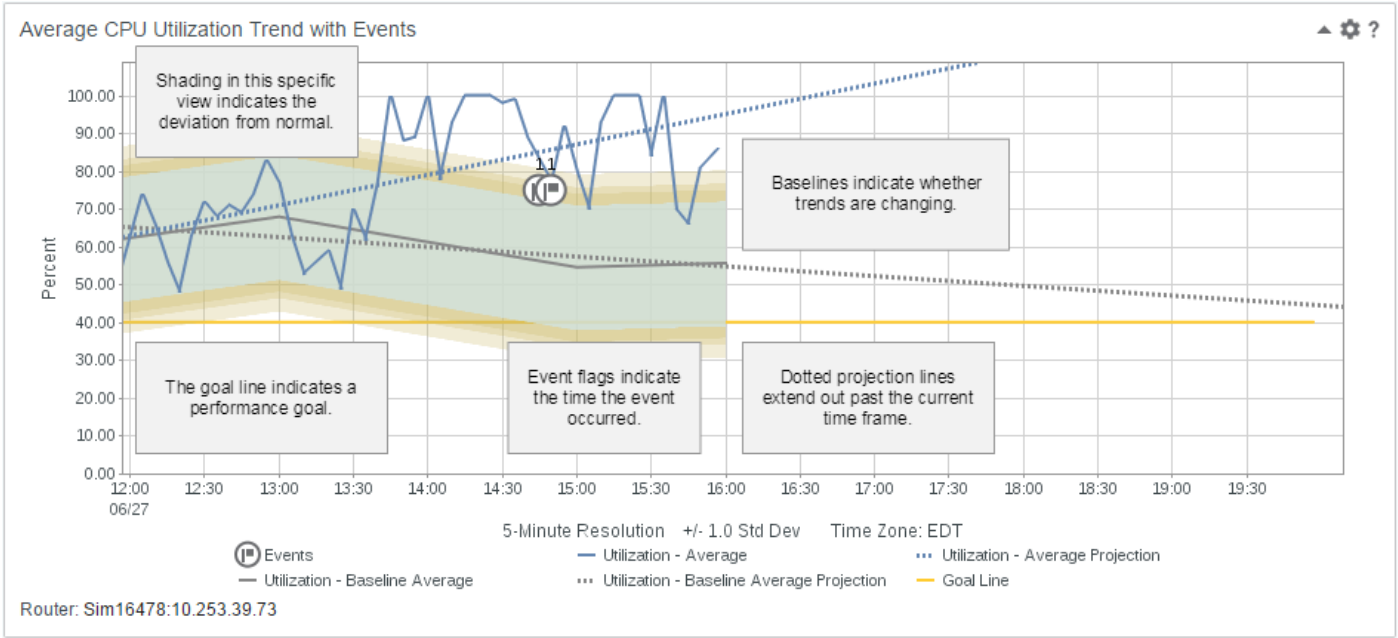
  NOTE
  Events are based on as-polled data. If a rollup is applied to the trend line, a threshold event might appear outside the trend line.

  Trend charts with events are disabled when the time range is greater than 3 months.
- **Trend Projections**
  If available, projections on charts appear as dashed trend lines that predict future performance of metrics. Each projection is based on trends in recent values in the time frame of the chart. Projections help determine whether current performance is within normal bounds.
  By default, each projection includes a future time frame equivalent to one time beyond the current time frame. For example, if the time frame is the Last Hour, the projection shows values for the next hour.
  For views that support projections, you can show or hide the projection data by editing the view settings.

The following image shows the important elements of a trend view:

NOTE
Percentile metrics appear as dashed lines.

Figure 38: TrendView

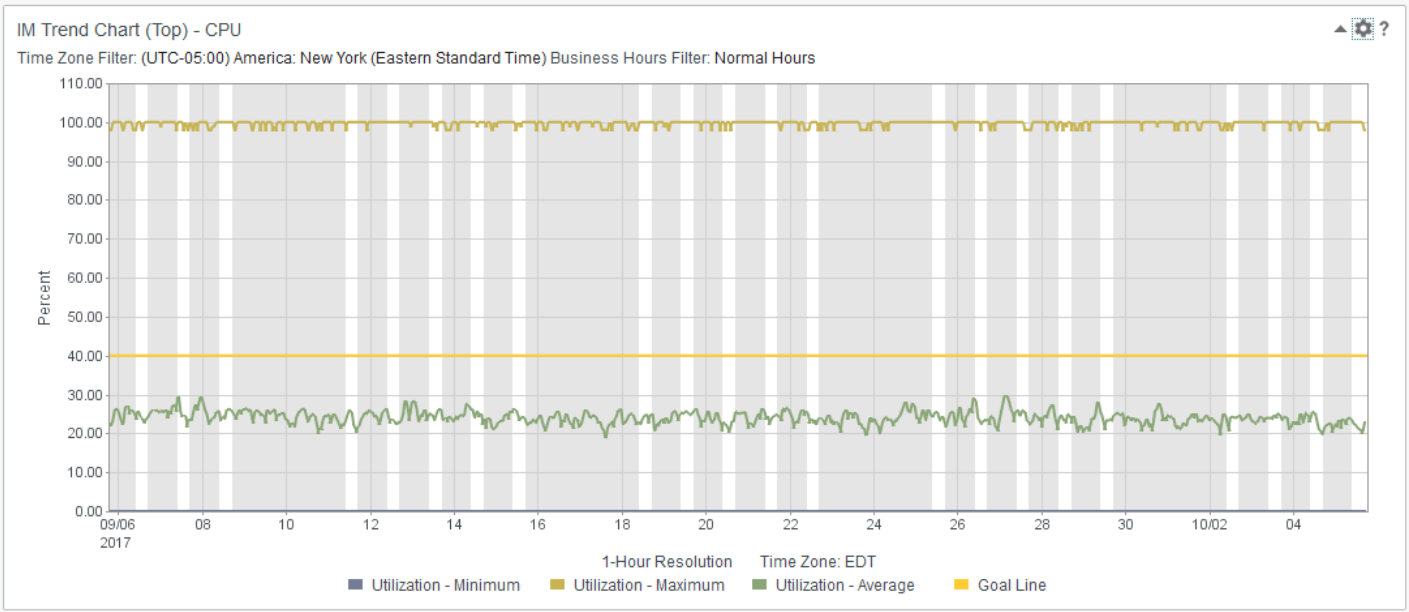


Compress Non Business Hours in a Trend View

If the resolution is less than one day and business hours filtering is configured, trend views apply shading. The shading differentiates between the selected business hours and non business hours.
For more information about how to configure business hours definitions, see Configure Business Hours Filtering.

The following image shows a trend view with shaded non business hours:

Figure 39: Non_Business_Hours

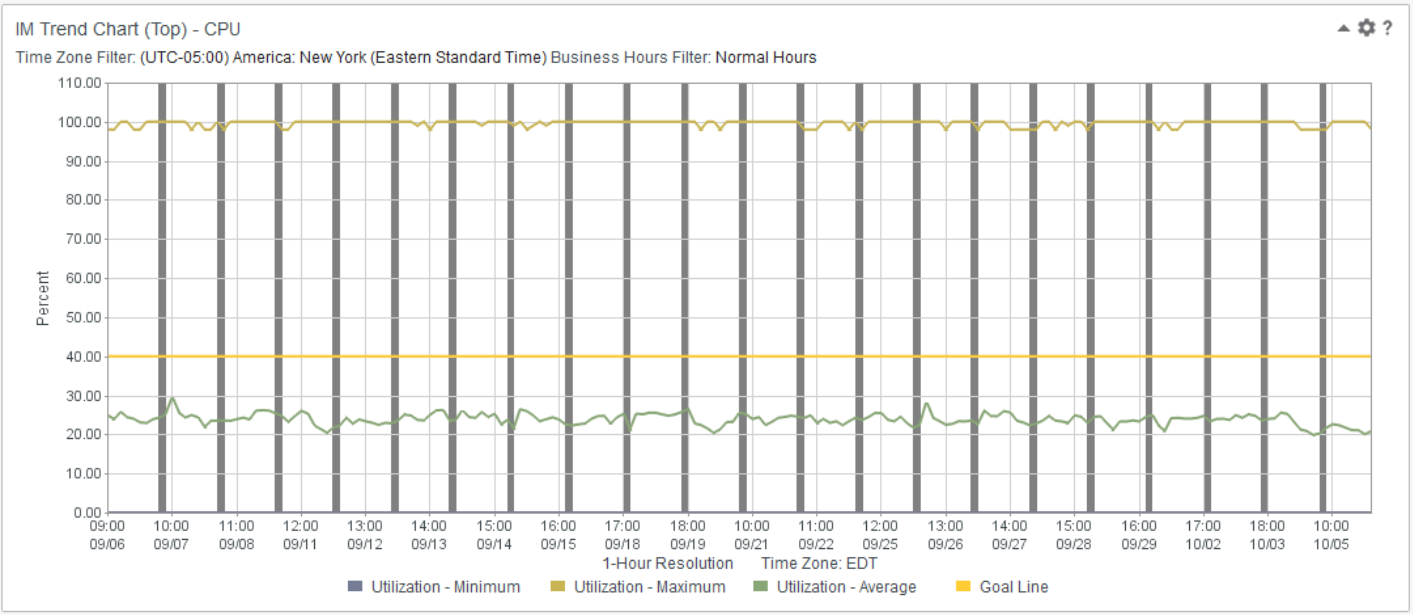


You can also configure a trend view to compress non business hours. If you compress non business hours, the shaded regions are compressed into a single region equal to the resolution period. The resolution is listed at the bottom of the chart.

> **NOTE**
> If non-business hours compression is enabled, you cannot zoom.

The following image shows a trend view with compressed non business hours:

Figure 40: Compressed_Non_Business_Hours



Configure a Trend View

To configure a trend chart, customize or edit a trend view. For standard view configuration details, see Customize Views.

Follow these steps:

1. Select **Show** or **Hide** from the drop-down list to control any of the following trend lines or data points:
   - **Projection**
     The line that plots projected average values for twice the current time period.
   - **95th Percentile**
     The line that plots the values in the top 5 percent of measurements that were taken during the reporting interval.
   - **Events**
     The data points that show when events were reported during the reporting interval.
   - **Goal Line**
     The line that plots the value that you selected as the goal for the metric in this view. This option is available only for some of the trend views.

     NOTE
     Not all trend line options are available for all trend chart types.
2. Set a value for the **Goal Line** if you selected to show it.
   Goal lines serve as visual indicators of fixed metric values. For example, select a value within a critical threshold range to determine whether performance is approaching a degraded level quickly.
3. Supply a label for the goal line to identify the value that you selected.
4. Select whether to **Compress Non Business Hours**.

MultiTrend Views

MultiTrend views let you combine trend data from multiple components in a single-line trend chart. You can compare the data from up to 12 components in a single MultiTrend view. You can use MultiTrend views to view data from the following interfaces:

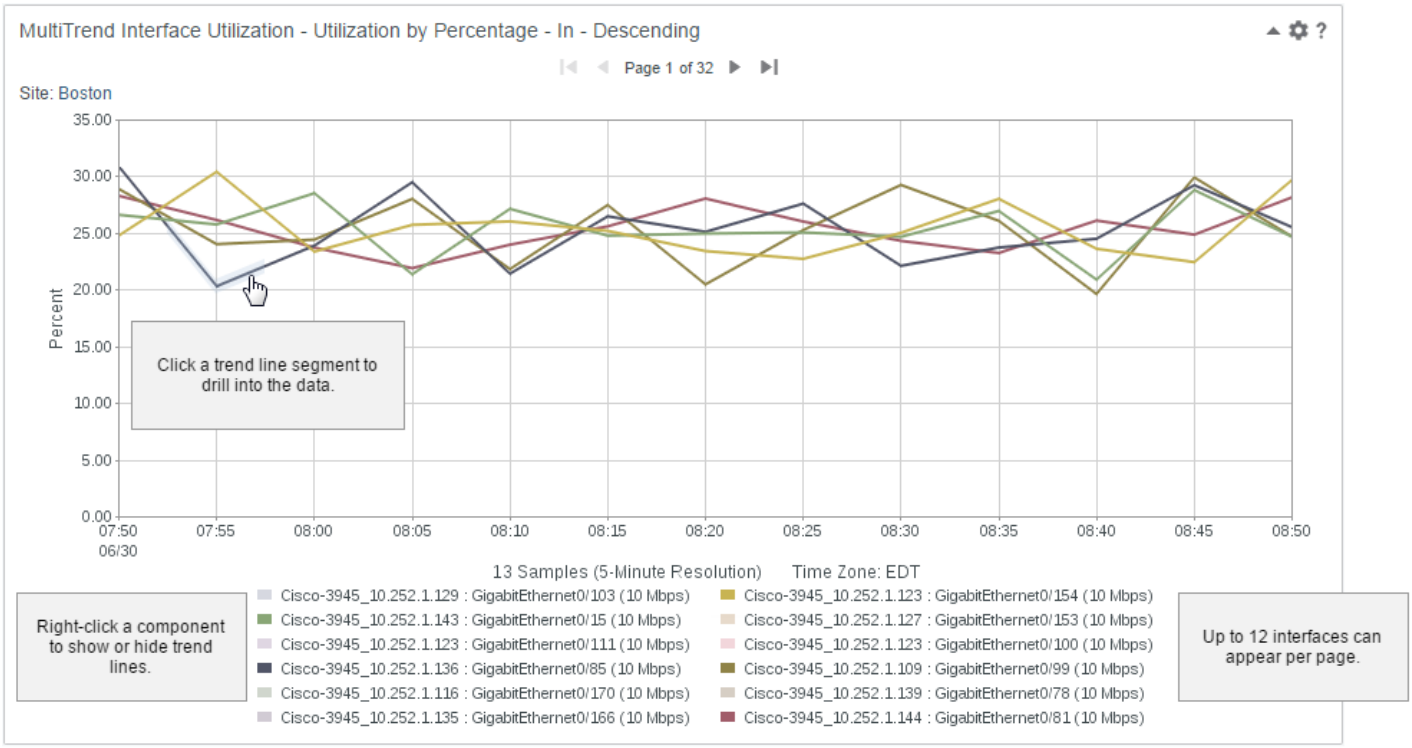
- Multiple interfaces in a group
- Interfaces in your inventory with the worst performance metrics
- Interfaces on a single device

TIP
MultiTrend views require more page space than other types of views. To add a MultiTrend view to a dashboard, add it to a single-column area in the layout. Do not add a MultiTrend view to a small section on a dashboard layout.

MultiTrend views also require more space for the PDF output.

The following image shows the important elements of a MultiTrend view:

Figure 41: MultiTrendView



MultiViews

MultiViews let you combine statistics from multiple interface charts in a single view. Use MultiViews to diagnose performance issues on a device. For example, you can compare the recent performance of all interfaces on a card in a single view. More MultiViews that query for different types of metrics are available in the Device category when you edit a dashboard.

TIP
MultiViews require more page space than other types of views. To add a MultiView to a dashboard, add it to a single-column area in the layout. Do not add a MultiView to a small section on a dashboard layout.

MultiViews also require more space for the PDF output.

The following image shows the important elements of a MultiView:

Figure 42: MultiView

Configure a MultiTrend View

To configure a MultiTrend chart, customize or edit a MultiTrend view. For standard view configuration details, see Customize Views.

Follow these steps:

1. Specify the **Sort Direction**, which is Descending order (highest values first) by default. The sort direction determines which interfaces are reflected in the first pages of trend charts.
2. Select one of the following **Standardized Axis** options for the Y-axis of each trend chart:
   - **Fixed at 0 to 100**
     Maintain a static range, 0 through 100, for the Y-axis.
   - **Calculated**

Let the Y-axis adjust dynamically, based on the range of metric values that are included. The calculated setting is applied to all charts in the view.
- **Scale per Chart**
  Let the Y-axis adjust dynamically, based on the range of metric values for each chart in the view. The Y-axis scaling of one chart in a view does not affect the scaling of any other chart.

3. Select one of the following options for the **Chart Display Order**:
   - **Display by Metric**
     Sort the interface charts by metric value, with the highest (most severe) values shown first, top to bottom.
   - **Display by Name**
     Sort the interface charts in alphanumeric order, by interface name.

Configure a MultiView

To configure a MultiView, customize or edit a MultiView. For standard view configuration details, see Customize Views.

Follow these steps:

1. Select a **Metric Family**. From the **Metrics Fields Available** list, select up to 10 metrics to display in the report. You can select multiple metrics from only one metric family. You can use the arrows to specify an order for the selected metrics and the order is saved.
2. Select the **Metric Sort**, which defines the metric for the primary Y-axis.
3. Specify the **Sort Direction**, which is Descending order (highest values first) by default. The sort direction determines which interfaces are reflected in the first pages of trend charts.
4. Select one of the following options for the **Chart Display Order**:
   - **Display by Metric**
     Sort the charts by metric value, with the highest (most severe) values shown first, top to bottom.
   - **Display by Name**
     Sort the charts in alphanumeric order, by device name and then item name. If the **Metric Calculate Level** is **by Device**, the charts are sorted only by device name.
5. To determine the level of aggregation for metrics, select the **Metric Calculate Level**:
   - **by Component**
   - **by Device**
6. Select one of the following **Standardized Axis** options for the Y-axis of each trend chart:
   - **Fixed at 0 to 100**
     Maintain a static range, 0 through 100, for the Y-axis.
   - **Calculated**
     Let the first Y-axis adjust dynamically, based on the range of metric values that are included. The calculated setting is applied to all charts in the view.
   - **Scale per Chart**
     Let the Y-axis adjust dynamically, based on the range of metric values for each chart in the view. The Y-axis scaling of one chart in a view does not affect the scaling of any other chart.
7. Specify a 1, 2, or 3-column layout.
8. Specify up to 48 charts per pages.
9. Specify a **Maximum Number of Charts** up to 1200.

Trend/Table Views

Trend/table views provide tables with data. As you hover over each metric, a related trend chart displays. The trend chart shows the metric value over the selected time range for each item. The table lets you see the values across the entire time range for each item being charted. Some out-of-the box trend/table views show a column with a line graph.
For more information about these views, see Table Views.

On-Demand Reports

On-demand reports retrieve data sets from specific sets of items or groups without building a dashboard. To view the same data in different ways, change the view type of the report.

You can add on-demand reports to group and device context pages. For group context pages, the reports use the selected group as the context for the view. For device context pages, the reports use the device as the context.

The following role rights apply to on-demand reports:

- **Create On-Demand Report Templates**
  Allows users create on-demand report templates.
- **Run On-Demand Report Templates**
  Allows users run on-demand report templates.

  NOTE
  On-demand reports do not show data for the SD-WAN Tunnel metric family.

Applying a business hours filter to trend views on on-demand reports displays the same data in the view, but the periods outside of the business hours are shaded.

For more information:

- About business hours filtering, including how to define business hours definitions, see Configure Business Hours Filtering.
- About how to apply a business hours filter to views on a dashboard, see Dashboards.
- About how to apply a business hours filter to views on a context page, see Context Pages.

In this article:

On-Demand Report View Types

On-demand report view types determine the chart format. For options that require aggregation, the system determines the aggregation method. For example, Bits has the counter metric profile type and uses sum. The Rate metric is profiled as type gauge and uses average.
Many view types provide more configuration options, such as Number of Charts on Page and Maximum Number of Charts.

TIP
To change the visualization of the data, edit the report and change the view type. The summary table view shows only aggregate metrics. If you change to this view type, the view editor does not remove selected nonaggregate metrics. However, the view shows only the aggregate values. For example, you can you configure a Chart with Multiple Metrics to show the CPU Utilization maximum. When you change the view type to the summary table, the view shows the CPU Utilization average.

Chart with Multiple Metrics

This view consists of one chart that displays a trend line for each selected metric. The trend line is an aggregate for all the selected groups or items.

Figure 43: ChartWithMultMet

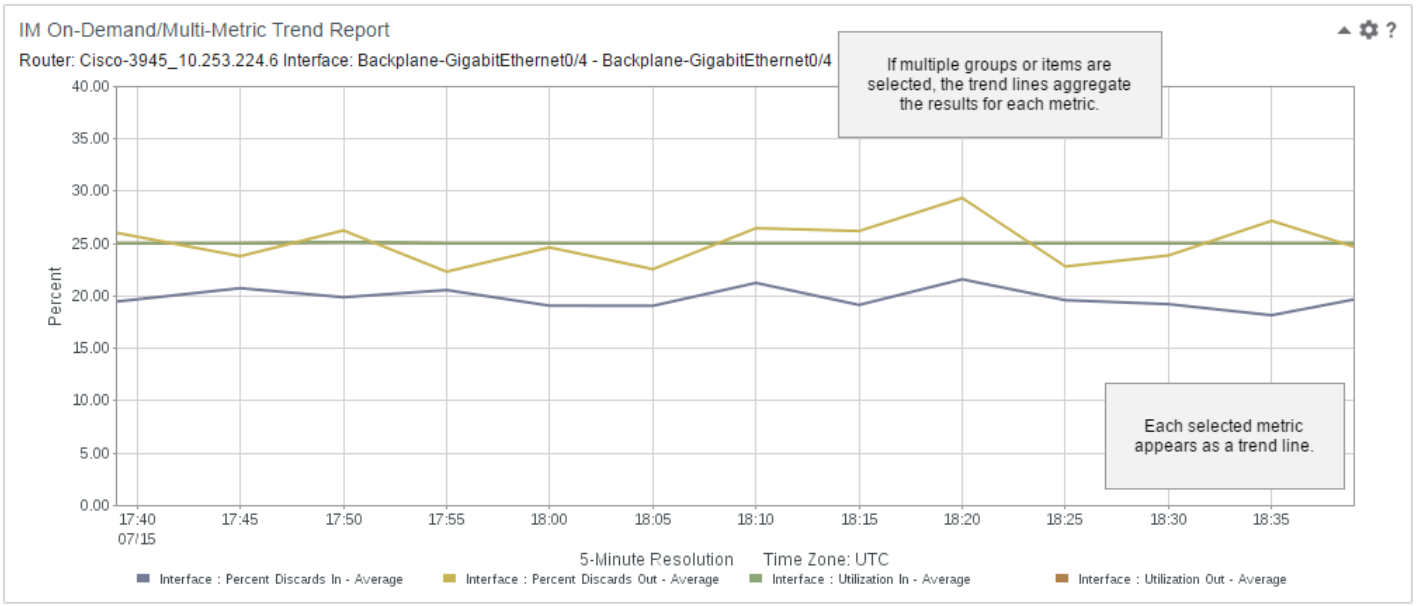


Chart Per Metric

This view consists of one chart for each selected metric. Each chart displays a trend line for the metric. The trend line is an aggregate for all the selected groups or items.

Figure 44: ChartPerMet

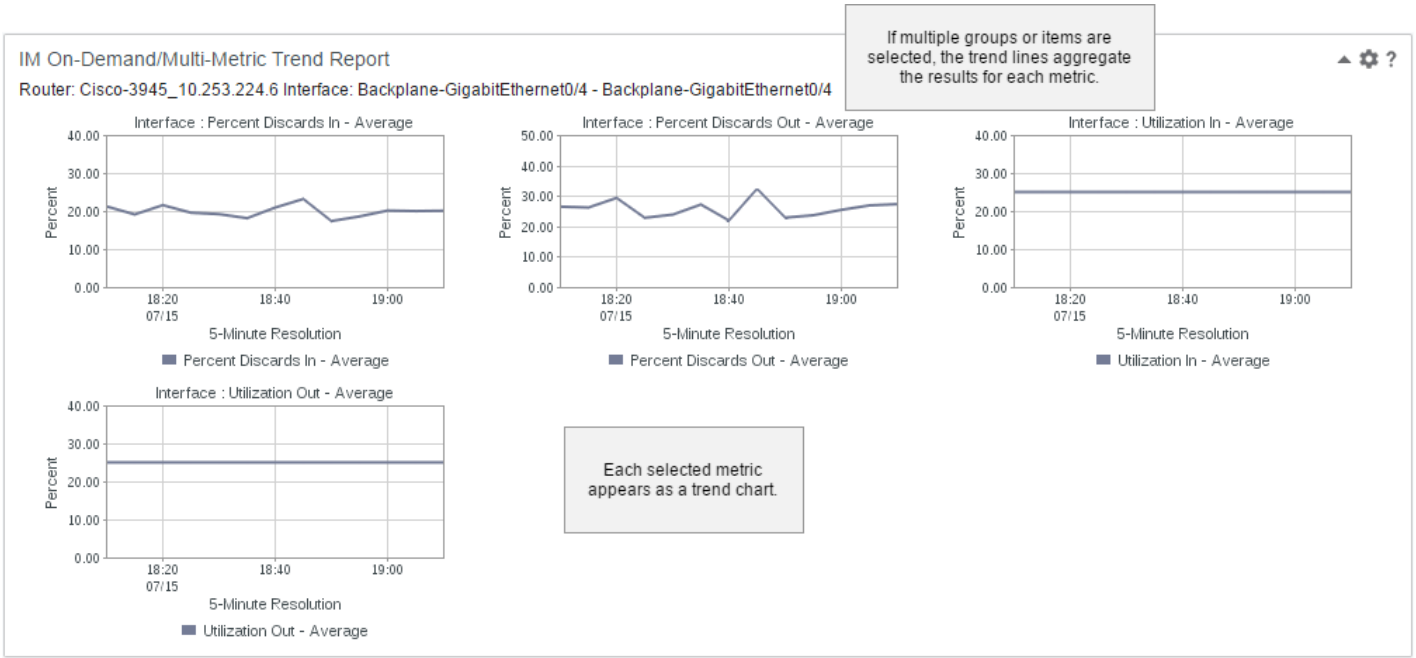

Chart Per Item with Multiple Metrics

This view consists of one chart for each selected item or group. Each chart displays trend lines for each selected metric.

Figure 45: ChartPerItemWithMultMet

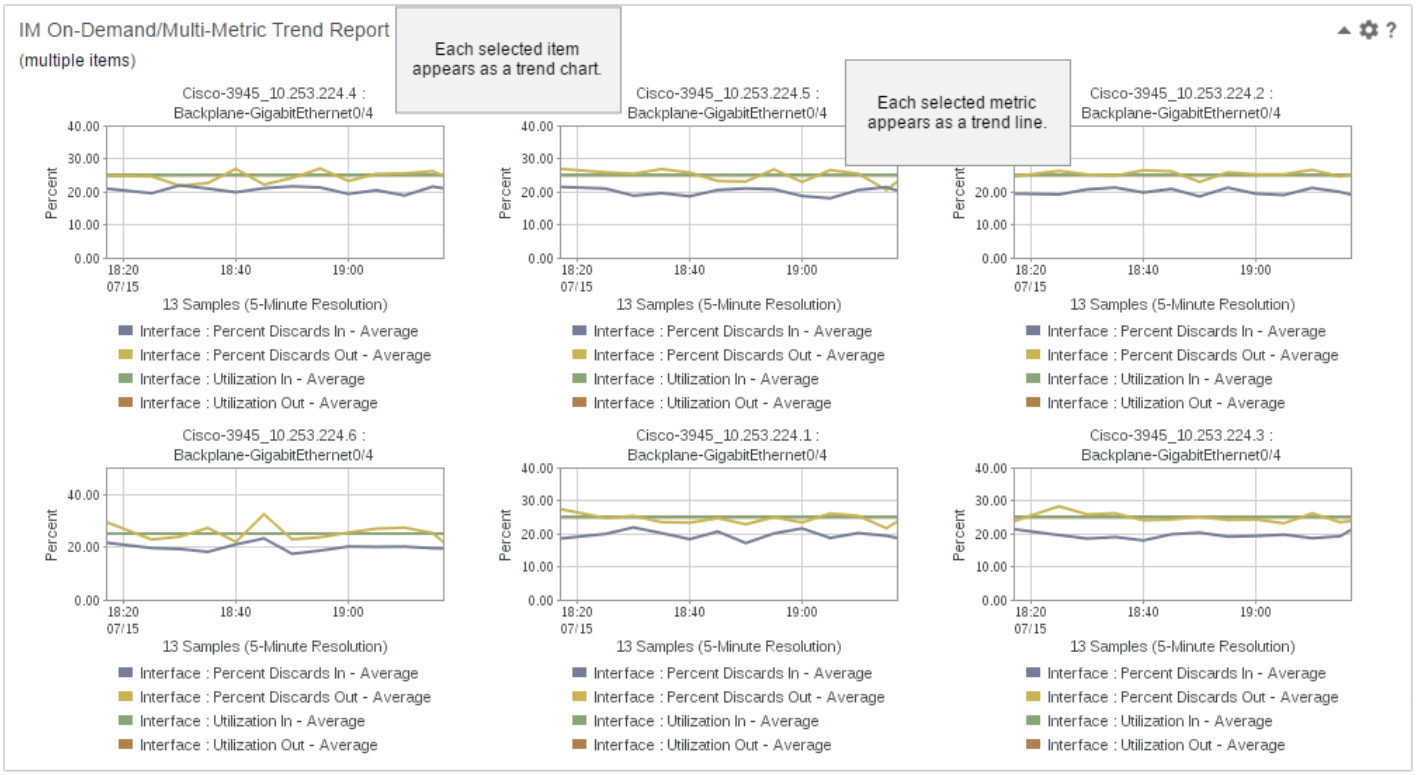

Chart Per Metric with Multiple Items

This view consists of one chart for each selected metric. Each chart displays trend lines for every selected item or group.

Figure 46: ChartPerMetWithMultItems

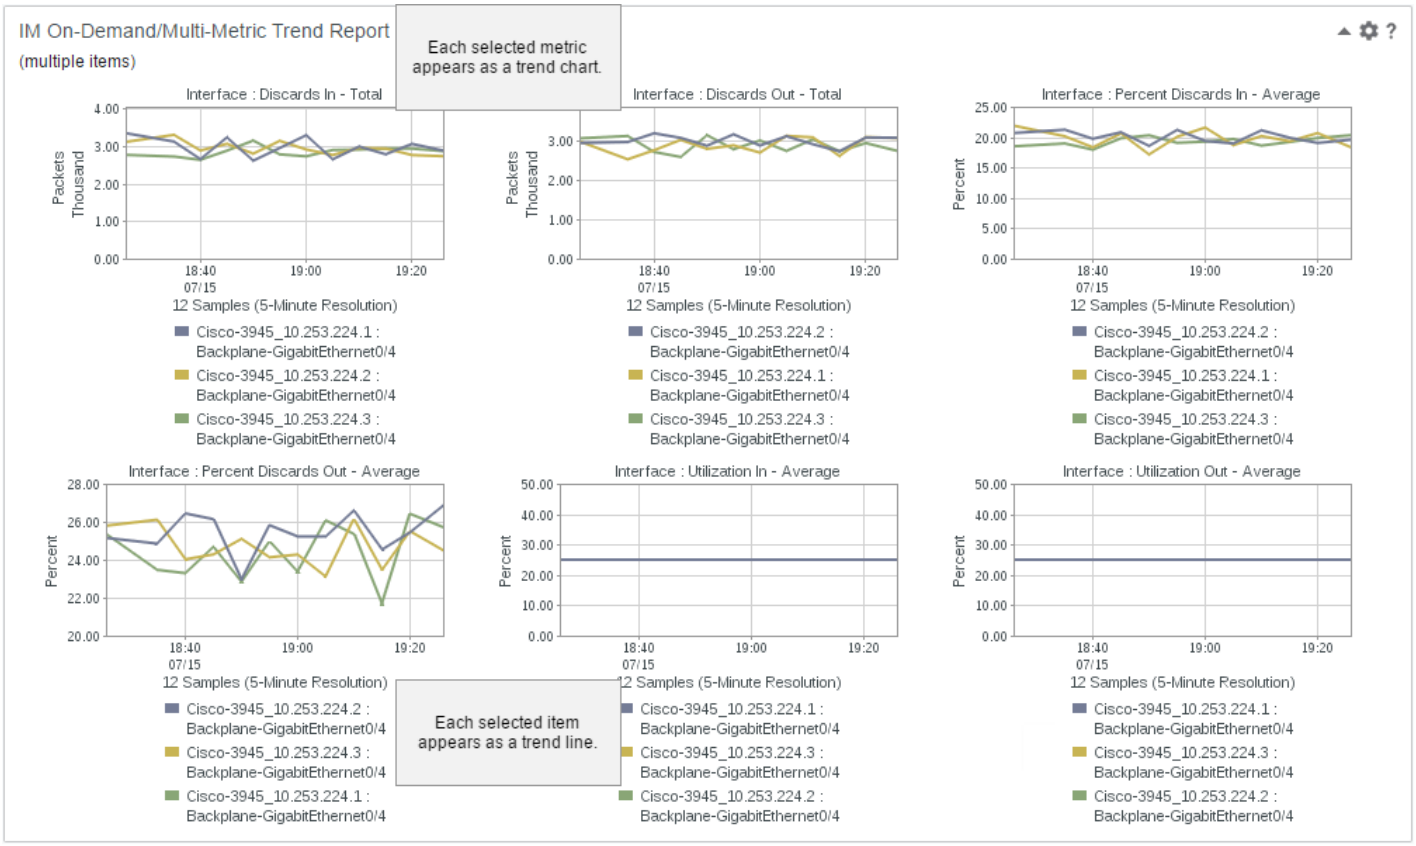

Chart per Metric by Single Item

This view consists of chart groupings for each selected item or group. Each chart grouping consists of one chart for each selected metric.

Figure 47: ChartperMetricbySingleItemReport

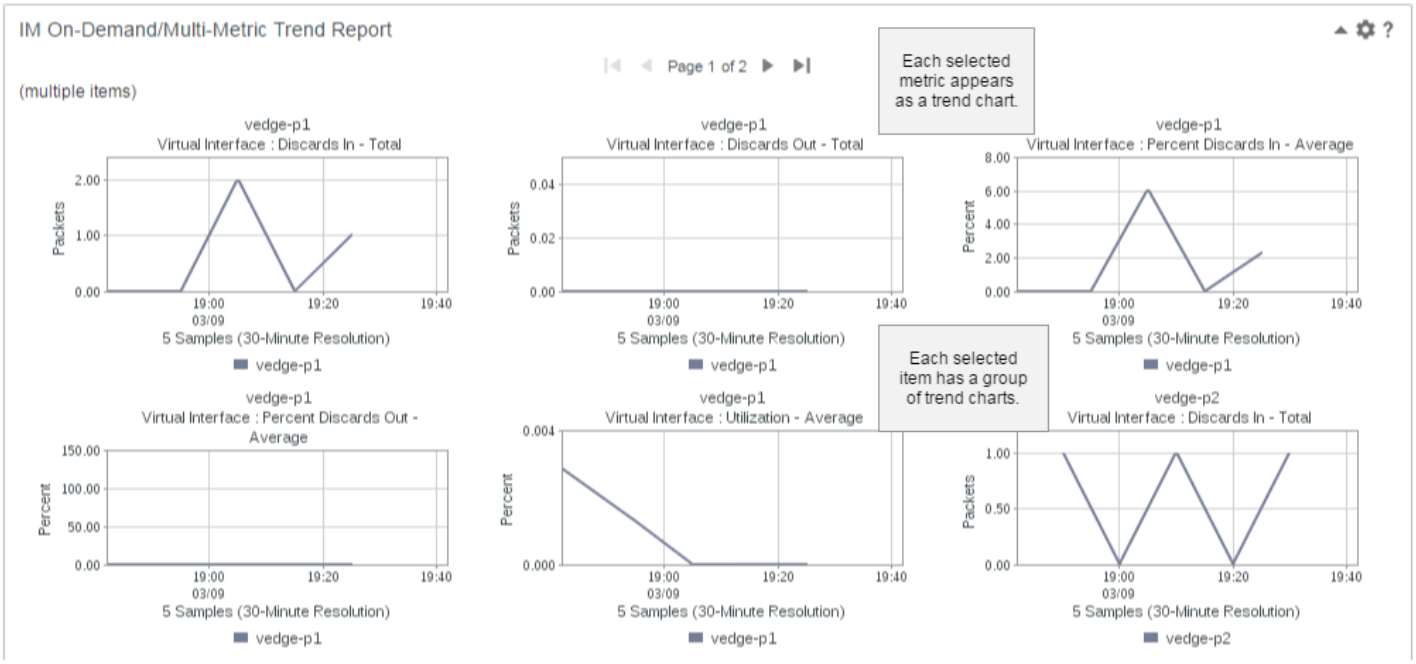

Table with Multiple Metrics

This view consists of one table that displays a list of the selected metrics. The table shows aggregate values for all the selected groups or items.

Figure 48: TableWithMultMet

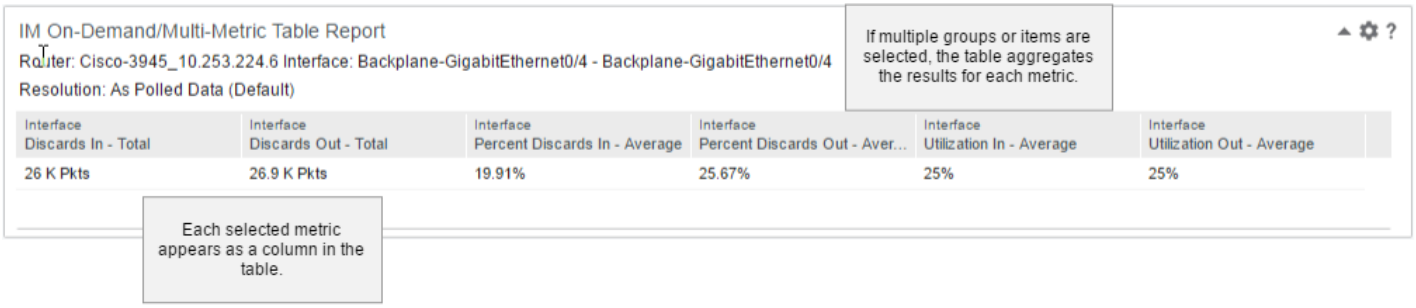

Table Per Item with Multiple Metrics

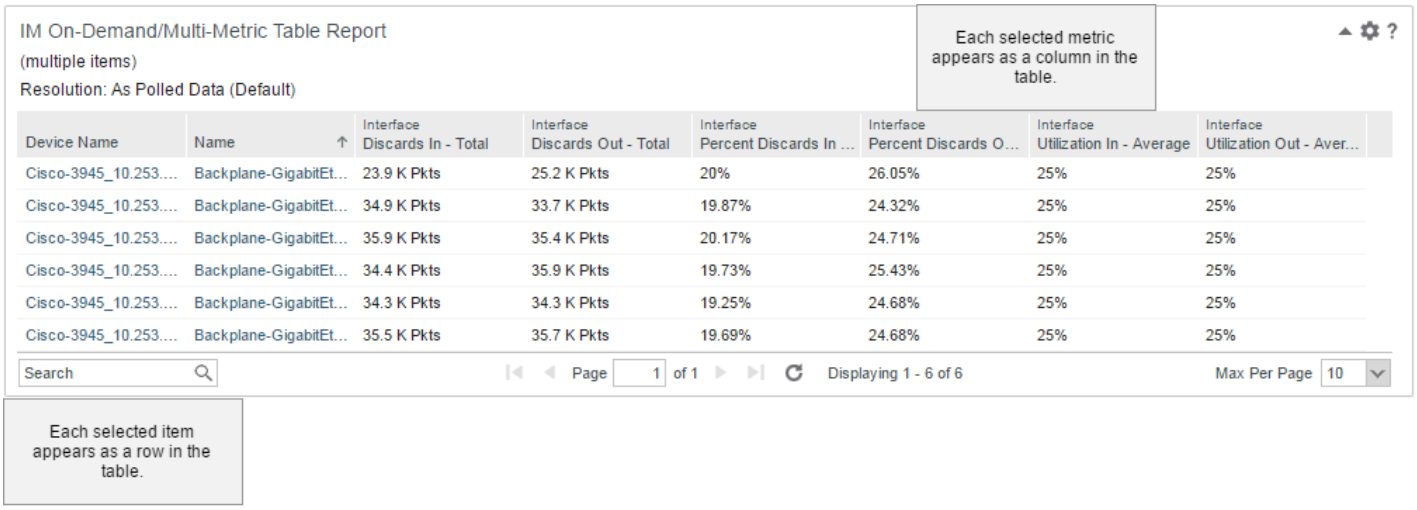
This view consists of one table that displays a list of the selected metrics. Each row in this table represents a single item.

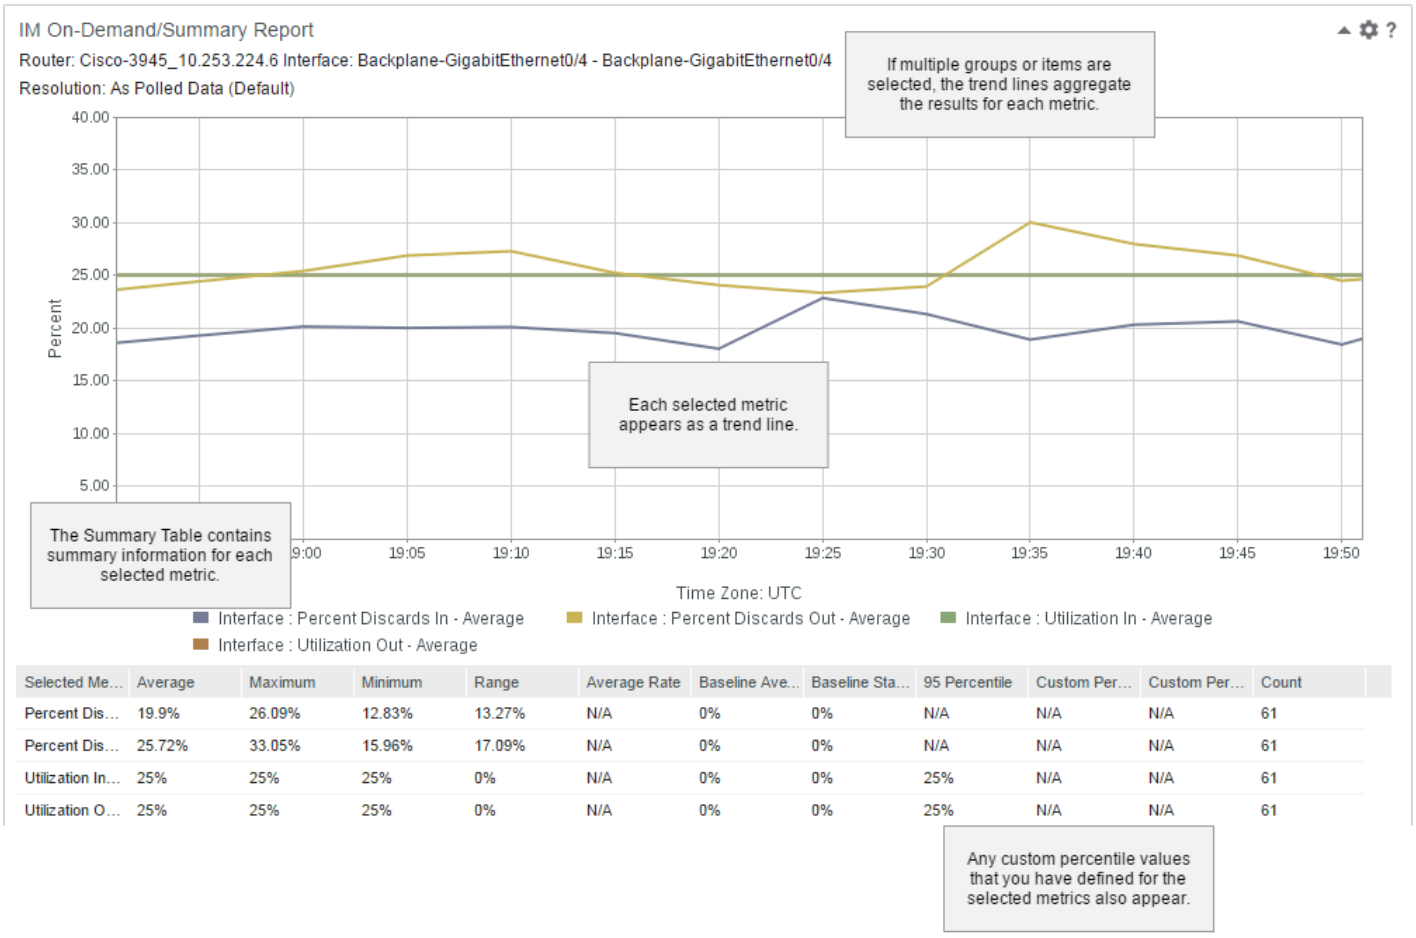
Figure 49: TablePerItemWithMultMet



Summary Table/Chart by Metrics

This view consists of one trend graph that represents one or more items and multiple metrics. The trend graph aggregates all items for each selected metric. The summary table below the graph is sorted by metric. Any custom percentile values that you have defined for the selected metrics also appear in the summary table.

Figure 50: SummaryTableChartByMet

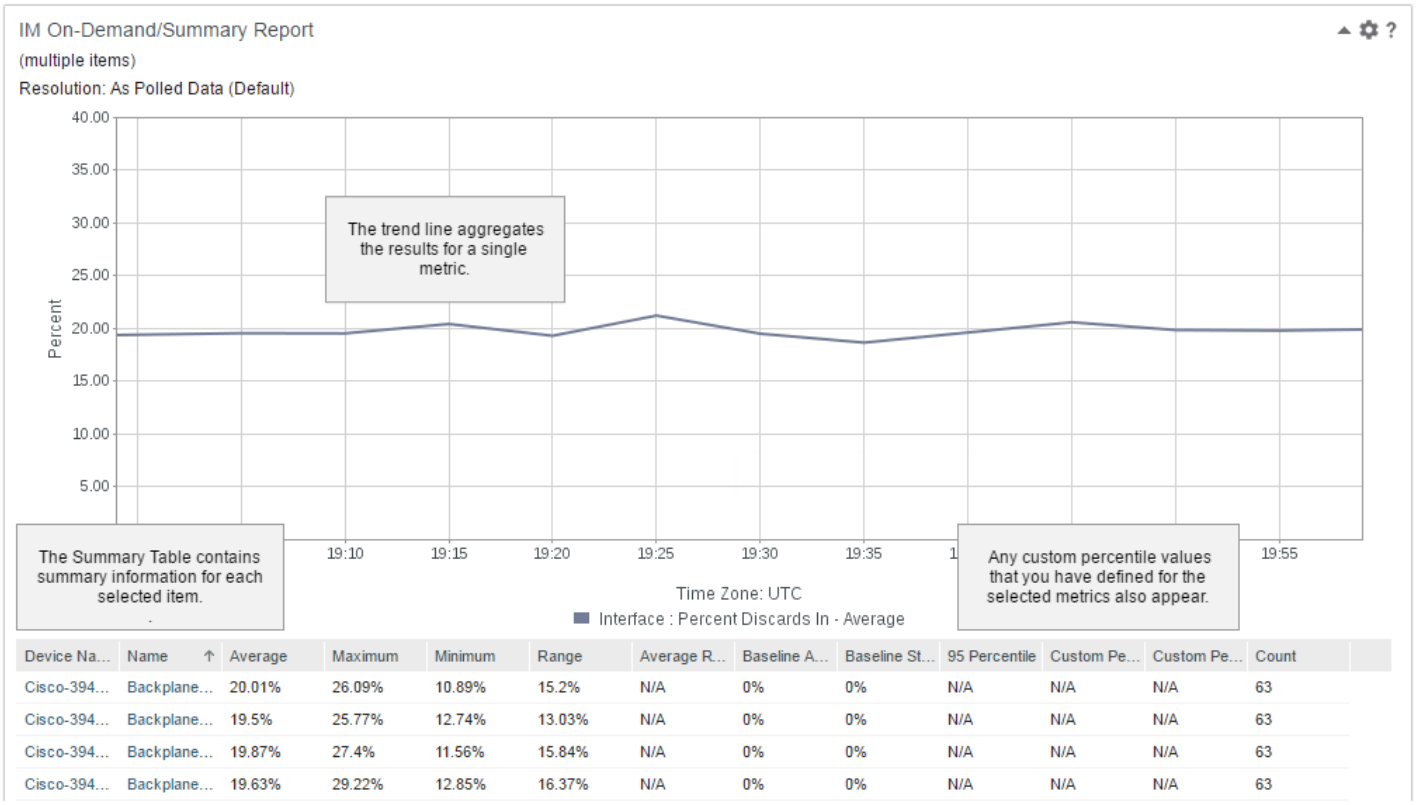


Selected Me...	Average	Maximum	Minimum	Range	Average Rate	Baseline Ave...	Baseline Sta...	95 Percentile	Custom Per...	Custom Per...	Count
Percent Dis...	19.9%	26.09%	12.83%	13.27%	N/A	0%	0%	N/A	N/A	N/A	61
Percent Dis...	25.72%	33.05%	15.96%	17.09%	N/A	0%	0%	N/A	N/A	N/A	61
Utilization In...	25%	25%	25%	0%	N/A	0%	0%	25%	N/A	N/A	61
Utilization O...	25%	25%	25%	0%	N/A	0%	0%	25%	N/A	N/A	61

Summary Table/Chart by Items

This view consists of one trend graph that represents multiple items and a single metric. The trend graph aggregates all items for the metric. The summary table below the graph is sorted by item. Any custom percentile values that you have defined for the selected metrics also appear in the summary table.

Figure 51: SummaryTableChartByItems



View the Report Templates

You can view a list of reusable report definitions on the **Manage On-Demand Report Templates** page. Users see only the report templates that are associated with the current tenant. The global administrator sees only reports that are associated with the Default Tenant.

Prerequisite: You have the Administer Reports or Run Reports role right.

Follow these steps:

1. Log in as a user with either the Administer Reports or Run Reports role right.
2. Select **Reports**, and then click **On-Demand Report** Templates.
   The **Manage On-Demand Report Templates** page opens, and the current list of reports appears.
3. (Optional) To filter the list to show only your reports, click **My Reports**.
   Use this page to view, add, edit, delete, or generate the reports in your tenant.

Generate an On-Demand Report

Generate an on-demand report to view a static data set from a narrow context. Use on-demand reports to investigate and troubleshoot issues.

Select managed items and metric families that complement each other. Changing the item context can clear the original selections. For example, if you select three routers for reporting, and then add interfaces, the routers are cleared. The report reflects interface data, but no rollups to the router level.

Different device types and components are compatible for reporting in a single on-demand report. For example, routers and servers can be included in the same report.

Use one of the following methods to generate an on-demand report:

- Select an item on an inventory page, and then click **On-Demand**.
- Go to **Reports**, **On-Demand Report Templates**, and then click **New**.
- Go to **Reports**, **On-Demand Report Templates**, select an existing report template, and then click **Edit**.
- Add the **IM On-Demand/Multi-Metric Trend Report** to a dashboard or context page.

> **TIP**
> On dashboards and in context pages, this report renders best in single-column layouts.

Follow these steps:

1. Specify the **Title**, **Name**, and **Description**.
   The title appears on the view and in the report.
   The name identifies the report in the **On-Demand Report Templates** list and appears as a title for the report.
2. Select the **View Type**.
3. Select a **Resolution** option. For more information, see Customize Views.

   > **NOTE**
   > On-Demand reports that were configured before release 2.6 cannot use the 'As Polled Data' resolution option. To enable this option, delete the template, and recreate the report.
4. To add baseline metrics to the metric value drop-down list or item selector, select the **Baseline Metrics** checkbox. Baseline data helps characterize past performance for the selected monitored parameters, assess present performance, and estimate future performance.
5. If you are adding the IM On-Demand/Multi-Metric Trend Report to a dashboard, set the **Context** to one of the following:
   - **Dynamic**
     A Dynamic context indicates that the context of the view changes with the context of the dashboard page.
   - **Fixed**
     A Fixed context indicates that the view uses a specified group, device, or component as a context for the data.
6. If you select **Dynamic** as the context, skip this step. Otherwise, select whether to **Add Items** or **Add Groups**:
   - If you selected **Add Items**, click **Add / Remove Items**, select a **Context Type**, and add up to 15 items.
   - If you selected **Add Groups**, click **Add / Remove Groups**, and add up to 15 groups.

     > **NOTE**
     > Only the groups and items that are included in your permission groups are displayed.

     > **WARNING**
     > You cannot include any groups that are in the Collections category in reports.

   The **Metrics to Include** list is populated with the available metric families and metrics for the selected items or groups.
7. To determine the level of aggregation for metrics, select the **Metric Calculate Level** to one of the following:
   - **by Group**
   - **by Device**
   - **by Component**

   This option is available only when you select one of the following view types:
   - Chart per Item with Multiple Metrics
   - Chart per Metric with Multiple Items
   - Table per Items with Multiple Metrics
   - Summary Table/Chart by Items
8. In the **Metrics to Include** list, expand from the list of available metric families, and select up to 15 metrics to display in the report. You can select metrics from multiple metric families. You can use the arrows to specify an order for the selected metrics and the order is saved.

NOTE
For SD-WAN metric families (Tunnels and Application Paths), percentile and projection metrics are available, but unsupported and the views render incorrectly.

9. If the view supports business hours, select whether to **Compress Non Business Hours**.
10. (Optional) To preview the report, click **Run**.
    A preview dashboard shows the view format that you have selected.

    NOTE
    If the metric families that you selected do not apply to the selected components, N/A appears in the report.
11. From the preview, click **Save Template**.
12. Click **Save**.
    The report template is added to the **Manage On-Demand Report Templates** page. Run, email, or print the report as required.

Share On-Demand Report Results

After you generate the on-demand report, select an output format to share the results. Role rights to print reports and send them by email are required.

Performance Metrics

Data sources collect, process, and aggregate performance data that is shown in NetOps Portal dashboards. However, it is helpful to understand how NetOps Portal handles data and rolls up values for display in views. In some cases, views in NetOps Portal are rollups of more granular data that is available in the data source interfaces, or by drilling down into details from the main dashboard pages.

We also offer some guidance for interpreting the metrics you see in NetOps Portal dashboards and context pages.

Baseline Calculations

Some views include baseline data as a basis for comparison. The baseline calculation method varies by the registered data source. The baseline data that is plotted in many views shows statistical deviations from "normal" performance for a given statistic. Metrics are considered to be "normal" based on the calculated baseline average. The Standard Deviation is used to gauge the statistical validity of the baseline values. Baseline values are included in charts to help you see places where performance values are changing rapidly.

Baseline data helps to characterize past performance for selected monitored parameters, assess present performance, and estimate future performance. For example, comparing current CPU utilization to a known baseline average level helps to determine whether current utilization is within a typical range. A monitored parameter that exceeds a baseline can indicate additional load on the server from a new application process, an increase in the number of users or sessions, or an increase in the amount of data being processed.

Baseline Averages

Depending on the amount of polled data that is collected, *baseline averages* are calculated in two ways:

- Initially, averages are calculated for the same hour regardless of the day.
- After enough data is collected, averages are calculated for the same day of the week and the same hour.

Baseline averages help to characterize past performance for selected monitored metrics, and helps to assess present performance. Baseline averages and related standard deviations are continually calculated as each hour passes. The standard deviation provides a statistical indicator of how much variability exists in the population data that factored into the baseline average calculations.

In Data Aggregator, "normal" for a specified duration within a window of time is based on the calculated baseline average.

Baseline Average Calculations

When a limited amount of data is first collected, the baseline average is calculated for the same hour for every preceding day of the week. For example, after two days worth of history, a baseline average value for the 9:00 AM to 10:00 AM time period is calculated by averaging the hourly rollups for the same time periods for two consecutive days.

Eventually, when more data is available, a switchover in the calculation method occurs automatically and Data Aggregator establishes "normal" by averaging hourly samples across available preceding same days of the week. This method, then, considers the day of the week patterns in utilization. This method produces a better approximation of what is "normal", which can lead to a reduction in the number of missed violations and false positive events that are generated. In the same example as above, after three weeks of history, a baseline average is calculated by averaging the 9:00 AM to 10:00 AM hourly rollups for the three Mondays within the three-week period.

NOTE

By default, this automatic switchover occurs when at least three same day of the week, same hour data samples are available for the past 12 weeks. Data Aggregator switches back to the every day, same hour calculation method automatically when the required number of data points is no longer available. These default settings are configurable. For more information, see Configure Data Retention Rates.

Baseline averages are calculated for event and report generation purposes.

Standard Deviation Calculations

The standard deviation is calculated from the baseline average for rollups, threshold events, and report generation purposes.

Rollups:

- For hourly rollups, the standard deviation is calculated for the polled values.
- For daily rollups, the standard deviation is calculated for hourly averages.
- For weekly rollups and beyond, the standard deviation is calculated for the daily averages.

Threshold Events:

- The standard deviation provides a statistical indicator of how much variability exists in the population data that factored into the baseline average calculations.

Reporting:

- For hourly reporting, the standard deviation is calculated for the polled values.
- For daily reporting, the standard deviation is calculated for hourly averages.
- For weekly reporting and beyond, the standard deviation is calculated for the daily averages.

The formula for calculating this standard deviation is:

```
population deviation = Square root of (Sum ( X - population mean)/number of data
points)
```

- **X**
  The data point value in the population
- **Population**
  The set of potential values that includes observed cases and potentially observable cases

Example: Calculate the Same Hour Average and Population Standard Deviation for CPU Utilization

The following example shows how the "same hour" average (mean) and population standard deviation are calculated for CPU utilization on a specific device, when there are three points of data for 2:00 AM on Monday, Tuesday, and Wednesday.

1. Collect three points of data.

```
Day:                                Monday      Tuesday     Wednesday
Mean (Average) CPU utilization:     76          65          10
```

2. Calculate the population mean.
   The formula for calculating the population mean is as follows:

```
The population mean = sum of data point values in population/number of data points.
```

   The equation for this example is as follows:

```
(76+65+10)/3
The population mean= 50.33
```

3. Calculate the difference of each data point from the mean.
   The differences for this example are:

```
25.67    14.67    -40.33
```

4. Calculate the square of the difference for each data point.
   The squares for this example are:

```
658.78     215.11    1,626.778
```

5. Calculate the sum of the squares:
   The sum of the squares for this example is 2,500.67.
6. Calculate the sum of the squares, divided by the number of data points in the population.
   The result for this example is 833.56.
7. Calculate the square root of the sum of squares of data point value from the population mean.
   The square root for this example is 28.87.
   The standard deviation for this example is 28.87.

The following table depicts the hourly averages (mean) of rate data by day, the average (mean) of hourly averages, and the population standard deviation of the hourly averages for the same hour:

Time	Monday	Tuesday	Wednesday	...	Mean	Standard Deviation
2:00 AM	76	65	10	...	50.33	28.87
3:00 AM	87	18	32	...	45.67	29.78
4:00 AM	10	56	40	...	35.33	19.07
5:00 AM	60	45	19	...	41.33	16.94
Hour...	...	...	...	...	...	...

Example: Calculate the Same Day of the Week Same Hour Average and Population Standard Deviation for CPU Utilization

The following example shows how the average (mean) and population standard deviation are calculated for CPU utilization on a specific device, when there are three points of data for three Mondays at 2:00 AM.

1. Collect three points of data.
   ```
   Monday of Week:                      1       2       3
   Mean (Averages) CPU utilization:    76       4       6
   ```

2. Calculate the population mean.
   The formula for calculating the population mean is as follows:
   ```
   The population mean = sum of data point values in population/number of data points.
   ```

   The equation for this example is as follows:
   ```
   (76+4+6)/3
   The population mean = 28.67.
   ```

3. Calculate the difference of each data point from the mean.
   The differences for this example are:
   ```
   47.33    -24.67    -22.67
   ```

4. Calculate the square of the difference for each data point.
   The squares for this example are:
   ```
   2,240.44    608.44    513.78
   ```

5. Calculate the sum of the squares.
   The sum of the squares for this example is 3,362.67.
6. Calculate the sum of the squares, divided by the number of data points in the population.
   The result for this example is 1,120.89.
7. Calculate the square root of the sum of squares of the data point value from the population mean.
   The square root for this example is 33.48.
   The standard deviation for this example is 33.48.

The following table depicts the hourly averages (mean) of rate data by day, the average (mean) of hourly averages and the population standard deviation of the hourly averages for the same day of the week, same hour:

Time	Week 1		Week 2		Week 3	Monday			
	Monday	...	Monday	...	Monday	...	Mean	Standard Deviation	
2:00 AM	76	...	4	...	6	...	28.67	33.48	
3:00 AM	87	...	71	...	56	...	71.33	12.66	
4:00 AM	10	...	27	...	58	...	31.67	19.87	
5:00 AM	60	...	3	...	32	...	31.67	23.27	
Hour	...	...	...	...	...	...	...	...	

Example: Deviation from Normal using the Same Day of the Week Same Hour Average and Population Standard Deviation for CPU Utilization

Assume that Data Aggregator is polling CPU utilization data at a 5-minute interval. You define an event rule to generate an event when CPU utilization is greater than one standard deviation above the mean for a single 5-minute poll interval.

In this example, event rule duration and window are both set to 5 minutes.

The formula for calculating when an event is raised is as follows:

```
CPU utilization = mean value + 1(standard deviation value)
```

Therefore, substituting mean and standard deviation values from the preceding same day of the week, same hour for Monday at 2:00 AM is as follows:

```
CPU utilization = 28.67 + 1 (33.48)
CPU utilization = 62.15
```

As a result, if CPU utilization were to exceed 62.15 for a single 5-minute poll interval between 1:05 AM and 2:00 AM on Monday, an event would be raised. This event indicates that the CPU utilization deviated from normal for that timeframe.

Example: Examine CPU Utilization Events in a Trend Chart View

Assume that Data Aggregator is polling CPU utilization data at a 5-minute interval. In this example, you want to be alerted whenever CPU utilization on one of your business critical servers drops below the expected level. You define an event rule to generate an event when CPU utilization is one standard deviation below the mean for a single 5-minute poll interval.

For illustrative purposes only, assume that CPU utilization is 50 percent from Monday, 12:00 AM to Sunday, 12:00 AM. From Sunday, 12:00 AM to Monday, 12:00 AM, CPU utilization drops to 10 percent. You expect this drop in utilization. However, when Data Aggregator begins to calculate the baseline average, an event is raised when the CPU utilization drops to 10 percent. The event clears when the CPU utilization goes back up to 50 percent. The erroneous event is raised because, initially, when a limited amount of data is collected, the baseline average is calculated for the same hour for every day, not taking into account the difference in utilization across days of the week. Data Aggregator is expecting the CPU utilization to be 50 percent *always*.

After three weeks pass, three same days of the week, same hour data samples are available, and the baseline average calculation method changes. Data Aggregator establishes "normal" by averaging hourly samples across same days of the week. Data Aggregator is now expecting the CPU utilization to be 10 percent every Sunday at 12:00 AM to Monday at 12:00 AM. The erroneous event that was raised previously every Sunday at 12:00 AM is no longer raised.

Rate Metrics

The Dynamic and Custom view types let you select metric families and metrics to display for the selected managed item or group. For some metrics, two additional options are available: Average Rate and Total Rate. These Rate variants represent a “per second” value for the metric, achieved by dividing the raw sample value by the number of seconds in the sample’s poll period.

The “Average Rate” and “Total Rate” variants are aggregated differently across managed items when a group is selected for reporting. They are also aggregated differently when a selected device has child items that are monitored, or when the selected time period requires aggregation. For example, in a table, a single value can be shown that represents the aggregated result of one hour of samples: 12 samples from five-minute polling are aggregated into a single value. In this case, using “Average Rate” would average out the “rate” values for the 12 samples, where “Total Rate” would simply sum them.

The following calculations illustrate the difference:

Average Rate (AvgRate) = ((sample1/duration1) + (sample2/duration2) + (sample3/duration3)) / numberOfSamples

Total Rate (TotalRate) = ((sample1/duration1) + (sample2/duration2) + (sample3/duration3))

For most situations, Average Rate is the preferable metric to use.

Examples

Particularly for the Composite Trend view type, selecting the more useful rate metric option can yield more revealing results. Average Rate is adequate for most situations. But if you select Total Rate for a view that reports on groups, you can see the total for all devices of a similar type, or for all devices in the same region, for example.

The Total Rate metric lets you see metrics for a device across all of its interfaces. For a device with child interfaces, you can see an average across all of its interfaces, or you can see totals per interface. Select trend chart settings that display data from each interface as a separate line.

In cases where you are reporting on subinterfaces, consider that each one has a rate of N bytes/sec. The rate per interface is an aggregation of rate data from all subinterfaces. Typically, you would select Total Rate to see a metric such as Bytes/second per interface. To see data from all subinterfaces, use Total Rate to see a Bytes/second total for all interfaces.

If you do an aggregation of the 12 samples from an hour time period, those samples would be averaged to get the Average Rate. They would be added together to get the Total Rate.

Interface Reporting

Digital network interfaces use serial transmission to send data from the transmission port to the receive port on the other end of the communications channel or circuit. Some transmission channels, such as copper Gigabit Ethernet, aggregate serial data across multiple channels to establish their overall circuit capacity. For copper Gigabit Ethernet, 4 channels of 250 Mbps are used to establish the 1-Gbps Ethernet circuit.

Most digital interfaces are *full-duplex.* The term means that they can transmit outbound data at the same moment that they are receiving inbound data. Because data transmission and data reception are independent interface tasks, they are reported separately.

Interface Utilization represents the average amount of data that is transmitted by the interface in a single direction (In or Out), divided by the interface bandwidth, or capacity. Interface utilization can be expressed as a percentage or as a transmission rate in bits per-second (bps).

Interface utilization rates can contribute to network performance issues. For a given interface, monitor whether it is transmitting frames at or below the rate at which it is receiving them. Acceptable interface utilization rates also depend on various SLAs and failover scenarios within your network. For example, two interfaces use a load-sharing algorithm to balance outbound traffic to the next hop. The average interface utilization must remain low enough that a failure of one link does not saturate the remaining available link, which now transmits all data.

Interface Utilization

Interface utilization refers to the transmission and reception of data and associated framing of device interfaces. Interface utilization is commonly referred to as "network utilization," "circuit utilization," or "uplink utilization."

The interface utilization percentage metric is calculated from average data because an instantaneous reading of individual interface utilization is either 100% (actively transmitting or receiving a frame) or 0% (not actively transmitting/receiving a frame). The average utilization percentage value includes the amount of time that the interface was in use over the given interval.

The interface utilization rate metric takes into account the interface speed, or its available bandwidth. For a physical interface, the available bandwidth of an interface is defined as the actual clockspeed rate at which the interface is capable

of transmitting data. For example, 1536 Kbps, 44.728 Mbps, 100 Mbps, 1 Gbps, and 10 Gbps describe clockspeed rates. For logical interfaces, such as subinterfaces, the available bandwidth is defined as the bandwidth value assigned to the interface by a network administrator. However, the total amount of real bandwidth available to the logical interfaces cannot exceed the physical interface capacity in terms of actual transmission rates.

Full-duplex interfaces have the capability to transmit data independently at the same time that they can receive data. This capability requires independent hardware dedicated in the transmit direction and the receive direction of the interface. Accordingly, the average utilization of an interface is reported separately in either the inbound or outbound direction. For example, separate views show "Average Utilization Out" and "Average Utilization In".

The network utilization can be derived from interface utilization values averaged over time from interfaces that are in use or not in use.

Interface Errors and Discards

Elevated interface error rates usually indicate a problem with the transmission medium. For example, the cable, fiber, or interface hardware can cause errors. Each error indicates that the associated packet was dropped during the attempt to transmit or receive it.

When detected in the inbound direction, errors typically indicate problems with the transmission medium (for example, cable or fiber). Outbound errors indicate problems with the interface hardware. The acceptable rate of errors for any given interface is typically zero (0) errors.

Interface discards typically occur when interface buffers no longer have the capacity to store packets (because, for example, buffer memory is exhausted). Buffer congestion often indicates that the rate at which packets are arriving at the interface exceeds its transmission rate.

Each reported discard is a packet that the reporting interface threw out. The sending host must retransmit such packets if a reliable protocol such as TCP is used to send the data end-to-end. Interface discards are typically the result of congested queues serving the interface. Discards frequently occur in bursts. Elevated discard rates may be the result of either microcongestion or chronic congestion issues.

Acceptable discard rates depend on the applications being served, the transmission protocols, and the SLAs established within your organization. Views of interface error and discard totals use a "k" to indicate thousands. Units labeled 'kErrors' or 'kDiscards' therefore refer to thousands of packet errors or thousands of packet discards.

Interface Bandwidth

The term "bandwidth" generally refers to the available capacity of an interface to transmit data at a given bit rate. The bandwidth associated with an interface depends on the type of interface.

For a physical interface, the bandwidth is the physical clock rate that the interface uses to transmit data. The clock rate is also typically a function of the type of interface. The following list shows the clock rates for common physical interfaces:

- DS-0: 64 Kbps
- DS-1: 1.536 Mbps
- E-1: 2.048 Mbps
- E-3: 34.368 Mbps
- DS-3: 44.278 Mbps
- OC-3: 155 Mbps
- Fast Ethernet: 100 Mbps
- Gigabit Ethernet: 1000 Mbps
- Ten Gigabit Ethernet: 10 Gbps

CPU Utilization

The CPU utilization metric is based on average CPU usage over the time period selected for the view.

Utilization percent is a term applied to the portion of a time period that a component is doing work, divided by the total amount of time in the time period. The result is multiplied by 100 to obtain a percentage.

For a CPU, the busy time is spent processing program instructions. Here is an example of how to interpret a utilization rate of 70% for a 5-minute time period: "For 70% of the 5 minutes, the CPU was fully utilized."

High rates of CPU utilization can indicate poor application performance. With high CPU utilization, processes must wait in the processor queue for a previous process to complete execution.

Memory Utilization

In addition to utilization, the data sources send information about memory capacity and usage to NetOps Portal. The Memory Utilization metric is an average utilization statistic derived from the percentage of available memory in use at a given moment, averaged over the reporting interval.

High rates of memory utilization may indicate that processes are paging instruction sets into and out of virtual memory. Such paging leads to slower memory read times, and may require the CPU to be interrupted to manage the paging process. The result is decreased performance for the associated application processes.

In addition, a steady increase in memory utilization over time may indicate a 'memory leak' condition. Such a condition exists where memory is allocated by processes as they start, but is not being released as the processes end. Memory leaks degrade device performance over time. Typically, the device becomes unresponsive when memory is no longer available.

Device Availability and Reachability

Availability measures system uptime and reachability measures device connectivity to DX NetOps Performance Management.

Availability is a percentage of time that the device is powered on and capable of processing data. DX NetOps Performance Management uses system uptime to calculate the percentage of time within a poll cycle that the device was available. The metric value is recorded as up (100), or down (0), or a percentage of the poll cycle.

If DX NetOps Performance Management is unable to reach a device for a particular timeframe, availability is backfilled when the device sends a poll response. DX NetOps Performance Management uses the system uptime to calculate which poll cycles to mark as available. If the device was restarted, or if a counter rollover for uptime occurred, DX NetOps Performance Management backfills only from the 0 to the current system uptime value. Poll cycles before the rollover or restart, where no poll responses were received, remain blank. Hourly and daily rollups reflect the backfill data only if the data is received before the rollup occurs. Availability is the only metric that DX NetOps Performance Management backfills.

A device that is available might be unreachable because of a network or communications failure by another device.

Reachability refers to whether a device is reachable from the data source. Typically, data sources use ICMP (ping testing) to communicate regularly with the target device. Any communication failures, including the loss of the network path or routing, affect the reachability statistics. If ICMP is blocked, DX NetOps Performance Management uses SNMP to determine reachability.

Reachability data comes from regular ping testing of all devices that support ICMP. The reachability value is the percentage ping responses that are received from the device during each reporting interval.

Reachability Status and Contact Status

Reachability status and contact status indicate whether DX NetOps Performance Management can communicate with a device. These states appear on various pages, such as the device details page and context pages.

Reachability Status

Some context pages, such as routers and servers, include the reachability status of the device. The reachability status indicates whether DX NetOps Performance Management can reach the device during the selected time range of the context page. The value is based on the polled reachability metric for the device at the last poll cycle of the time range.

- **Reachable** indicates that the device reachable during the last poll cycle of the time range.
- **Unreachable** indicates that the device was unreachable during the last poll cycle of the time range.
- **Unknown** indicates that the device was not polled during the last poll cycle of the time range. This status may indicate that the device is retired or offline for maintenance.

Contact Status

The Details tab on the Monitored Device page shows the device Status. Status indicates the live status of a pingable or manageable device and is based on the outcome of active polling.

- **Up** indicates that the device is being successfully polled or pinged.
- **Down** indicates that at least two polls failed to receive a response. The managed item cannot be reached by SNMP or ping.
- **Lost Connection to Data Collector** indicates that the Data Collection that is associated with the device is no longer network reachable or was shut down.
- **Not Monitored** indicates that polling has been administratively disabled, for example by using the Stop Polling button.
- **Management Lost** indicates that the device is still pingable, but SNMP is no longer responding to poll requests. This status often indicates incorrect details in a recently changed SNMP profile.
- **Unknown** indicates an unexpected condition. The details are written to the Data Aggregator or Data Collector logs.

Scorecard Projections

Scorecard projections use a customizable set of data points to predict future values for metrics. Projected values are calculated when the view is rendered, and are based on the historical time frame of the view. You can add the projected values to IM Custom View Group Scorecards.

> **TIP**
>
> Do not use scorecard projections for error metrics. Each error is a discrete event that is not affected by historical errors.

The scorecard view includes two methods to calculate projections:

- **Approximation**
  The Approximation method uses the average from each time frame in the view to calculate the projection values. DX NetOps Performance Management calculates a least squares regression on the averages, then uses the line equation to project future values. This calculation method is faster than the Detailed Data method.
- **Detailed Data**
  The Detailed Data method uses the polled data for the entire time frame of the view. DX NetOps Performance Management calculates a least squares regression for the entire set of data points. This calculation is more statistically accurate than the Approximation method, and provides extra columns in the view.

NOTE

Detailed data scorecard projections are supported only for gauge metrics (for example, Bits Out - Average Rate). Detailed data scorecard projections are *not* supported for counter metrics (for example, Bits Out - Total). Projection values are calculated on the As Polled (rate) data to ensure precision.

These columns are hidden by default:

- **Slope**
  Indicates the slope of the line equation.
- **Intercept**
  Indicates the intercept of the line equation.
- **Degrees**
  Degrees of freedom, which indicates the sample size.
- **Linear Fit**
  Indicates the confidence level of the projected values as related to the sample data.
- **Days to Threshold**
  Indicates the projected number of days before the specified critical threshold is reached.

Percentiles

A percentile is the value of a variable below which a certain percent of observations fall. For example, the 95th percentile is the value (or score) below which 95 percent of the observations are found. Percentiles are calculated for rollups, dashboards, and report generation purposes.

Percentile monitoring is useful in measuring throughput data. This statistic more accurately reflects the required capacity of the monitored link for applications that are bandwidth sensitive. The 95th percentile says that 95 percent of the time, the bandwidth usage is below this amount. The remaining 5 percent of the time, the bandwidth usage is above that amount.

Metric values are aggregated during rollups.

By default, DX NetOps Performance Management calculates the 95th percentile for some metrics. Metric families can include up to two more configurable percentile calculations.

Metric Property	Default	Values
Percentile	Disabled or 95	0 or 95
Percentile2	Disabled	0-99
Percentile3	Disabled	0-99

A value of 0 disables the percentile calculation.

Changes to these properties generate Administration events. After you update the metric family, the percentile data is available for reporting within several poll cycles. For trend views, changes cause a gap in the trend line. For table views, changes affect the value of the percentile for time ranges when the change occurred. For example, in a daily time range, the value is inaccurate for one day.

TIP

When you disable a percentile, modify views that include the percentile to avoid an error in the view.

WARNING

Calculate only percentiles that you need. Each percentile that you calculate might significantly affect system performance.

Three percentile values appear in the Metric Families table under the Monitoring Configuration menu for a Data Aggregator. A dash in the Percentiles column indicates that all three percentile values are equal to zero.

Percentile Calculations

Percentile calculations use the Microsoft Excel method.

Hourly and daily rollup uses the polled rate data. Weekly rollup performs the percentile calculation on the results of the daily rollups.

Percentiles are calculated in the database and exposed to the reports and dashboards.

Metric Projection

To calculate future values based on historical metric data, use metric projection. Metric projection is useful for capacity planning. For example, to verify that the interface bandwidth is sufficient for a specific time in the future, calculate the projected interface utilization.

To see future trends, metric projection supports up to three configurable intervals. For example, you can project to 20, 60, and 180 days in the future for the metric. Projection shows an overall trend. Typically, the longer the projection interval, the less accurate the exact value.

Scorecard Projections

- Scorecard views provide line-of-business owners a group-level summary of how key metrics perform over time. Performance is based on a set of user-defined thresholds.
- The scorecard view displays historical time intervals, and up to three projected values.
- Projected values are calculated when the view is rendered, and are based on the historical time frame of the view.

Metric Projections

- Metric projection is designed for network and capacity planners that want the system to calculate and store projections.
- Projections are configured for individual metrics. Up to three projection intervals can be specified per metric.
- Projected values are based on up to 90 days of historical data. Once configured, projected metric values can be included in custom table views.

For more information, see Scorecard Projections.

You can add the projection values to custom table views.

> **TIP**
>
> Table views are useful for capacity planning.

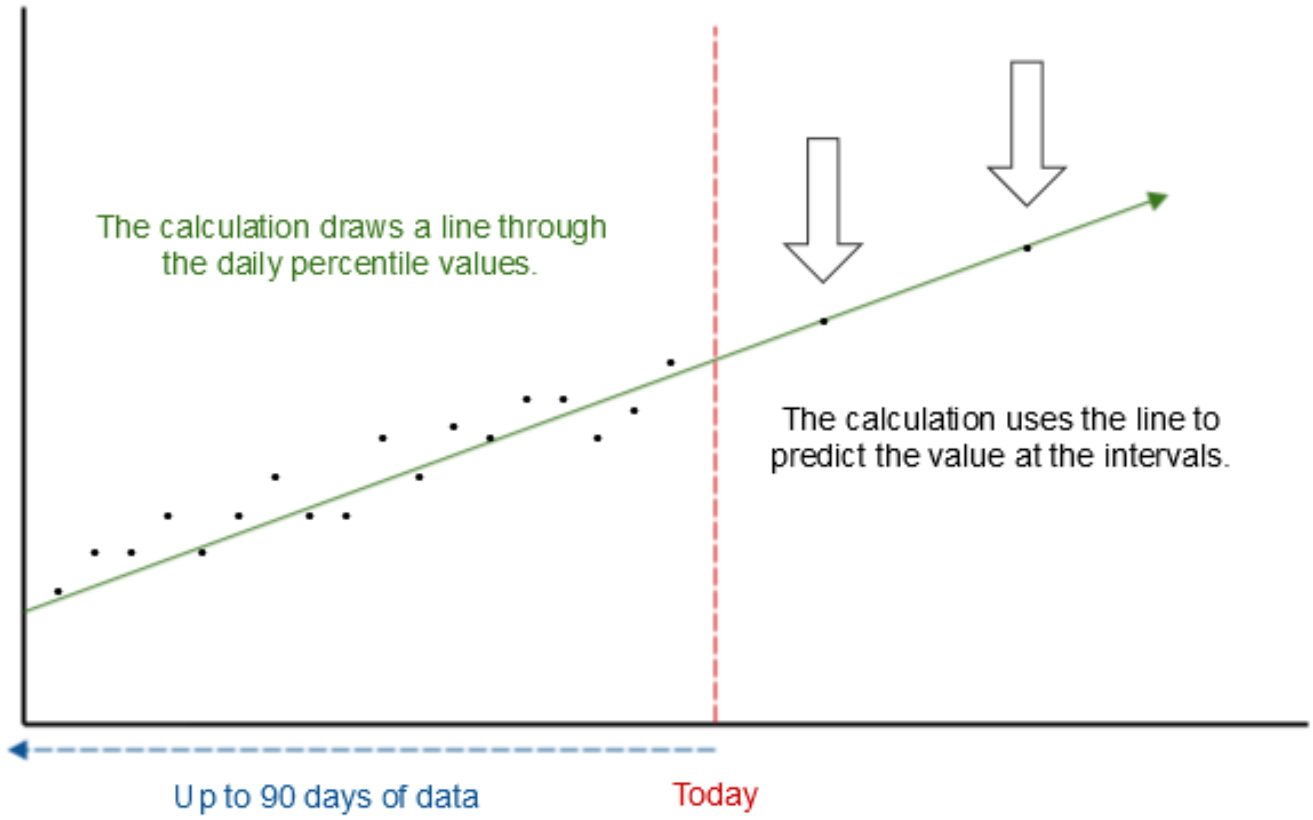
Metric Projection Calculations

Projection values are calculated for a specified interval and are based on a configurable daily percentile calculation on the metric. For capacity planning, 95 percent is a typical percentile value. The system uses the following process to calculate the projection:

1. Calculates and stores the daily percentile value using the Microsoft Excel method from the as polled data.
2. Calculates a linear regression line from the daily percentile values. The calculation uses a simple linear regression (least squares regression).
   The calculation uses all the available daily percentile values from the last 90 days as input data. Projection requires at least two days of daily percentile values. The accuracy of the projection typically increases with the available data points.
3. Calculates the future value for the interval from the linear equation.

The following diagram illustrates the calculation method:

Figure 52: Metric Projection Calculation



Configure Metric Projection

To configure metric projection, edit the metric through the UI. For more information, see Edit a Metric.

TIP

When you disable a projection, modify views that include the projection to avoid an error in the view.

WARNING

Calculate only projections that you need. Each projection that you calculate may significantly affect system performance. For more information, see the DX NetOps Performance Management Sizing Tool.

To configure metric projection using REST web services, execute a PUT operation on the target metric. Configure **ProjectionPercentile** and **ProjectionInterval** for the metric. For more information, see Metric Family XML Structure.

WARNING

Changes to ProjectionPercentile cause inaccurate projections for up to 90 days. When you change the value of ProjectionPercentile, the percentile values for days before the change are not recalculated.

Changes to these properties generate Administrative events.

Example:

This example shows the XML for interface utilization. This projection is calculated based on the 95th percentile. The projection is calculated for 20, 30, and 90 days.

Total, Average, Minimum, and Maximum Values

The total, average, minimum, and maximum values are calculated for rollups and for reporting purposes. These values let you observe the upper and lower bounds of performance across a given time interval.

A *rollup* is the process during which metric values are aggregated. In an hourly rollup, the 1 minute, 5 minute, 15 minute, 30 minute, and 60 minute polled values for metrics are aggregated every hour. In a daily rollup, as-polled values

for metrics are aggregated once a day. In a weekly rollup, daily values for metrics are aggregated once a week. A given metric is aggregated by either averaging or summing data points during the rollup (not both) based on the "RollupStrategy" configured for that metric.

Hourly rollups:

- Total: Sum of all the as-polled data points for the hour.
- Average: Sum of all the as-polled data points divided by the number of data points for the hour.
- Minimum: The lowest single poll value of the hour.
- Maximum: The highest single poll value of the hour.

Daily rollups:

- Total: Sum of all the as-polled data points for the day.
- Average: Sum of all the as-polled data points for the day divided by the number of data points.
- Minimum: The lowest single value of the hourly minimums.
- Maximum: The highest single value of the hourly maximums.

Weekly rollups and beyond:

- Total: Sum of all the daily data points for the week.
- Average: Sum of all the daily data points divided by the number of data points for the week.
- Minimum: The lowest single value of the daily minimums for the week.
- Maximum: The highest single value of the daily maximums for the week.

Five-minute resolution reporting:

- Total: Sum of all the as-polled data points for the 5 minute increment.
- Average: Sum of all the as-polled data points divided by the number of data points for the 5-minute increment.
- Minimum: The lowest single poll value of the five-minute increment.
- Maximum: The highest single poll value of the five-minute increment.

One hour resolution reporting:

- Total: Sum of all the as-polled data points or the hourly rollup value for the hour.
- Average: Sum of all the as-polled data points divided by the number of data points or the hourly rollup value for the hour.
- Minimum: The lowest single value of the as-polled data or hourly rollup minimum for the hour.
- Maximum: The highest single value of the as-polled data or hourly rollup maximum for the hour.

Day resolution reporting:

- Total: Sum of all the hourly data points or the daily rollup value for the day.
- Average: Sum of all the hourly data points divided by the number of data points or the daily rollup value for the day.
- Minimum: The lowest single value of the hourly data or daily rollup minimum for the day.
- Maximum: The highest single value of the hourly data or daily rollup maximum for the day.

Events

An event is a message that provides information about what is happening in DX NetOps Performance Management. Events provide information for monitoring the health and status of your system and your environment. All events include basic information, such as related devices and the time of the occurrence that triggered the event.

TIP

You can integrate the Event Manager with CA Spectrum. In CA Spectrum, you can configure the events to generate alarms. For more information, see the CA Spectrum documentation.

View Events

Events View

This view displays all the events that occurred in the selected time range for the dashboard. This view can be filtered for a specific group. This view is the default view in the Events Display dashboard.

Filtered Event Views

This view includes filters for data source, severity, event type, event subtype, and threshold profile.

> **TIP**
>
> To see the complete event properties, select an event in any view, and click **Details**.

Using Events

Some typical reasons to view events include the following scenarios.

Troubleshoot Performance Issues

To troubleshoot performance issues with a specific device, you can filter the events to that device. The Events view filters the complete list of events to display only events for the selected device.

Monitor Thresholds

Thresholds are configured to generate events for specified devices, components, or groups. Use these events to track when the monitored devices do not meet operating requirements.

Track Configuration Changes

When Automatically Update Metric Families is not selected for a custom monitoring profile, view the events log to configuration changes. Reconfiguration events with the Detected subtype indicated detected changes on the monitored devices. Reconfiguration events with the Changed subtype indicate changes to device items.

Audit Changes to the System

Administration events provide useful information about changes to the system configuration, such as the time of a change.

Event Types

The event type determines what information the event contains. Each event has an event type and many events have an event subtype. Events can be categorized as the following types:

> **NOTE**
>
> More event types might appear when DX NetOps Performance Management is integrated with other products.

Administration Events

Administration Events include system status notifications and audit events. These events include the following event subtypes:

- **ActiveMQ Status**
  Occurs when the ActiveMQ status changes.
- **Administration Message**Several administrative tasks that are related to discovery and tenants can trigger this event type.
- **Certification Change**
  Occurs when a vendor certification or metric family is extended or updated.
- **Data Collector Status**

Occurs when the status of a data collector changes.
- **Monitoring Profile**
  Occurs when the monitored metrics selected for a monitoring profile are modified.
- **Percentile Change**
  Occurs when percentile calculations are changed for a metric family. When the percentile is changed in the UI, the event includes the user.
- **Projection Change**
  Occurs when projection calculations are changed for a metric family. When the projection is changed in the UI, the event includes the user.
- **Threshold Monitoring Status**
  Provides information about the threshold monitoring engine. For more information, see Threshold Monitoring and Threshold Limiter Behavior.
- **Vendor Certification**
  Occurs when the vendor certification priority order is modified for a metric family.

Data Collection

Data collection events provide information about contact with monitored devices. These events include the following subtypes:

- **Contact Established**
  Occurs when the data collector established contact with a device.
- **Contact Lost**
  Occurs when the data collector loses contact with a device.
- **Management Established**
  Occurs when the data collector established contact with the management protocol of the device, such as SNMP.
- **Management Lost**
  Occurs when the data collector loses contact with the management protocol of the device, such as SNMP.
- **Polling Disabled**
  Occurs when polling for a device stops.
- **Polling Enabled**
  Occurs when polling for a device starts.

Data Repository State

Data Repository State events provide information about the status of the data repository. All Data Repository State events include information about the data repository host. These events include the following subtypes:

- **Connected**
  Occurs when the data aggregator connects to a data repository node after another node goes down. The event includes information about the connection.
- **Data Repository Failover**
  Occurs when the data repository cluster changes the primary host. The event includes the new host name and the previous host name.
- **Data Repository Failure**
  Occurs when a data repository cluster fails. The event includes the name of the host that failed.
- **Degraded**
  Occurs when the data repository node response time to the data aggregator heartbeat is over 20 seconds.
- **Down**
  Occurs when a data repository node is down.
- **Start Up**

Occurs when a data repository node starts up. The event includes availability information about all the data repository nodes.

Life Cycle

Life Cycle events track changes to the device life cycle. These events include the following subtype:

- **State Change**
  Occurs when the life cycle state of a device changes. The event includes the current state, the previous state, and the user who changed the state.

Override

Override events provide information about manual changes to metric values. These events include the following subtypes:

- **Override Cleared**
  Occurs when a user clears the override for the Speed In and Speed Out values for an Interface.
- **Override Set**
  Occurs when a user manually updates the Speed In and Speed Out values for an Interface.

Polling State

Polling State events track whether polling is disabled or enabled on an interface. The events include the following subtypes:

- **State Change**
  Occurs when the polling state of an interface changes. The event includes the current state, the previous state, and the user who changed the state.

Reconfiguration

Reconfiguration events provide information about change detection. These events include the following subtypes:

- **Changed**
  Occurs when the system applies a change to a component item.
- **Detected**
  Occurs when the system detects a change to a component.
- **Rebooted**
  Occurs when the system detects that a devices has rebooted.

Threshold Violation

Threshold Violation events occur when monitored groups or devices violate the configured criteria in assigned threshold profiles. These events include the following subtypes:

- **Cleared**
  Occurs when a device or group that is in violation of a threshold clears the violation. The event includes detailed information about the violation and the reason the violation was cleared.
- **Raised**
  Occurs when the monitored device or group violates the event rule in an assigned threshold profile. The event includes detailed information about the violation.

For more information about thresholds, see Configure Threshold Profiles and Use Events to Monitor Device Performance.

Change Event Properties

To change the properties of the Event Manager, update the `em.properties` file.

For example, you can modify the `Event.Retention` property to change how long the event manager stores events. By default, the Event Manager database retains events for 30 days.

You can also modify the `em.notification.script_notification_execution_time` property to change the maximum time (in seconds) that a script can take to complete execution before it is killed. For more information about notification scripts, see Configure Notifications.

Follow these steps:

1. Open the Event Manager properties file:
   `/opt/CA/PerformanceCenter/EM/webapps/EventManager/WEB-INF/em.properties`
2. Edit the properties as desired:

```
db.driverClassName=com.mysql.jdbc.Driver
db.timeout=120
db.maxActive=40
rib.queryTimeout=100
em.ws.maxqueue=50

Event.Retention=45
db.url=jdbc\:mysql\://localhost\:3306/em?useUnicode\=true&characterEncoding\=UTF-8
em.notification.trap.eventmanager_trap_use_new_format=false
em.event.analysisThreshold=10000
em.notification.notification_pool_size=10
db.username=netqos
nqevents.dbHost=
em.ws.queuetimeout=180
em.notification.notification_max_pool_size=20

em.notification.script_notification_handler_max_pool_size=1

em.notification.script_notification_handler_pool_size = 1

em.notification.script_notification_handler_queue_size=5000

em.notification.script_notification_execution_time=300

em.web.port=8281
db.password=netqos
```

3. Save the changes.
4. Stop the Event Manager service using the command line:
   `service caperfcenter_eventmanager stop`
5. Restart the Event Manager service using the command line:
   `service caperfcenter_eventmanager start`

The Event Manager starts and uses the new value to determine the retention period.

Use Events to Monitor Device Performance

DX NetOps Performance Management can be configured to generate events when devices deviate from normal performance expectations. These events help you monitor the health of your network and react to correct performance issues.

DX NetOps Performance Management generates events using monitoring profiles. Monitoring profiles contain a set of event rules. Using metrics, these rules define the conditions that trigger events. To implement your event rules, associate the monitoring profile with a device collection.

Example:

An organization recently virtualized several business critical applications. The IT Architect and the Operations Center Manager want to monitor their virtual servers to ensure that the servers can handle the load from these applications. They create a monitoring profile, and they add event rules to find over-utilized CPUs and virtual memory issues for the collection of virtual devices. They associate the collection that includes the virtual servers with the monitoring profile. DX NetOps Performance Management automatically evaluates all the devices in the collection after every poll for each device. If needed, DX NetOps Performance Management raises or clears events when the devices trigger event rule conditions.

NOTE
You can generate user-visible alarms in CA Spectrum from events that are processed and logged in DX NetOps Performance Management. For more information, see the CA Spectrum documentation.

To monitor device performance against specific thresholds, complete the following process:

Create a Custom Device Collection

The device collection defines which devices DX NetOps Performance Management monitors with a monitoring profile. To create a device collection that includes the target devices, create a custom group and add the devices to the group. Use group rules, or manually add the devices to the group

Create a Monitoring Profile and Add Event Rules

To specify the conditions that generate an event, create a monitoring profile and add event rules to the profile.

Example:

The IT Architect and the Operations Center Manager define the threshold criteria. You add the following event rules:

- Add a VMware memory utilization rule, as follows:
  - Violation occurs when memory utilization is above 80 percent for 300 seconds (5 minutes) within a 900-second (15-minute) window.
  - Clear the violation when the memory utilization is equal to or below 75 percent for 300 seconds within a 900-second window.
- Add a VMware CPU utilization rule, as follows:
  - Violation occurs when both of the following conditions are met:
    - Condition 1: CPU utilization is above 70 percent.
    - Condition 2: CPU utilization is above one standard deviation.
  - These conditions occur for 300 seconds within a 900-second window.

Assign the Monitoring Profile to the Custom Device Collection

To begin monitoring the devices, and to activate event rules, assign the monitoring profile to the custom device collection.

Follow these steps:

1. Navigate to the Data Aggregator data source.
2. Click **Monitoring Configuration**, **Collections**.
3. Select the device collection, and click the **Monitoring Profiles** tab.
4. Click **Manage**.
5. Click and drag the monitoring profile to the **Assigned Monitoring Profiles** list.
6. Click **Save**.
   DX NetOps Performance Management begins monitoring this collection of devices using the monitoring profile and event rules. Events that are generated appear in the Events Display dashboard.

TIP

You can configure notifications for the threshold events.

Threshold Monitoring and Threshold Limiter Behavior

The threshold limiter monitors how long the evaluation engine takes to process rules in the Data Aggregator. If the threshold monitoring exceeds the specified percentage of the poll cycle, the evaluation engine enters a DEGRADED state. In the DEGRADED state, the evaluation engine waits for the monitoring to drop below the specified percentage. After a specified time, the threshold monitoring engine reassesses whether to suspend threshold evaluations. If threshold violations continue to exceed the percentage during the time period, the evaluation engine is suspended. Threshold evaluations will not resume, even if you restart the Data Aggregator. If the threshold violation does not exceed the specified percentage, the evaluation engine returns to normal operation.

WARNING
Do not modify the threshold limiter settings. The default settings provide protection against potential polled data loss. For any changes to the limiter settings, contact CA Support.

View the Threshold Monitoring Dashboard

The Threshold Monitoring dashboard provides information about the state of the threshold monitoring engine. Use this dashboard to see changing trends over time. This dashboard includes two views:

- **The Number of Event Rules Evaluated - Total**
  This view displays the number of actual rule evaluations that have occurred for an associated set of polled items.
- **Percentage of Poll Cycle to Complete Event Processing**
  This view displays the percentage of the poll cycle that the threshold monitoring engine takes to complete event processing.

Follow these steps:

1. Navigate to **Administration**, and click a Data Aggregator data source.
2. In the Tree View tab, expand the **All Data Aggregators** collection, and select the same Data Aggregator data source.
3. Click the name of the Data Aggregator on the Details tab.
4. Click the **Threshold Monitoring** tab in the Data Aggregator Pages view.

Threshold Monitoring Engine Status Events

Threshold monitoring engine status events describe the status of threshold evaluations. You can see these events in the Data Aggregator Events tab. The following table shows the possible Threshold monitoring engine status events:

Event Type	Event Subtype	Description
Administration event	Threshold monitoring engine status	Threshold evaluations have been enabled.
Administration event	Threshold monitoring engine status	The Threshold Monitoring Engine has transitioned to a degraded state. This means that threshold evaluations are taking longer than the configured threshold {X} and will be suspended in {X} minutes if this condition persists.
Administration event	Threshold monitoring engine status	Threshold evaluations have been disabled by the System Administrator.
Administration event	Threshold monitoring engine status	Threshold evaluation operations are still taking longer than the configured threshold {X}. The system is suspending threshold evaluations. Please contact the System Administrator to evaluate the monitoring configuration.
Administration event	Threshold monitoring engine status	The Threshold Monitoring Engine is no longer degraded and is functioning normally.
Administration event	Threshold monitoring engine status	The Threshold Monitoring limiter has been disabled.
Administration event	Threshold monitoring engine status	The Threshold Monitoring limiter has been enabled.
Administration event	Threshold monitoring engine status	Threshold evaluation operations are longer than the configured maximum threshold {X}. The system is suspending threshold evaluations. Please contact the System Administrator to evaluate the monitoring configuration.

Take Action If Threshold Evaluations Are Suspended

If threshold evaluations are suspended, consider the following options before you resume evaluations:

- Try to correlate the change in performance to configuration changes in the system.
- Reduce the overall number of active event rules. Turn off event rules one at a time. Check the performance after you turn off each rule before turning off another rule.
- Reduce the overall number of active event rules that have windows greater than 300 seconds.
- Reduce the number of Violation event conditions within event rules.
- Reduce the number of event rules that use a condition type of Standard Deviation.
- Verify that only *required* collections are applied to the monitoring profile or threshold profiles that contains event rules.
- Verify that only *required* devices are contained within collections that are associated with these monitoring profiles or threshold profiles.

Threshold Limiter Behavior

To determine whether to suspend threshold evaluations, the limiter looks at how long the engine takes to evaluate thresholds as a percentage of the poll cycle time.

Percentage of Poll Cycle Threshold specifies the percentage of the poll cycle that can be used to monitor thresholds. By default, the Percentage of Poll Cycle Threshold attribute value is 80 percent.

For example, 4 minutes for items that are polled at a 5-minute rate. The threshold monitoring engine becomes DEGRADED when the engine takes more than 240 seconds to complete threshold evaluations. An event is generated on the Data Aggregator item when the threshold monitoring engine becomes DEGRADED.

Recovery Interval specifies how long the threshold monitoring engine remains in the DEGRADED state. By default, the Recovery Interval attribute is 15 minutes. If the processing time does not drop below the specified percentage with the recover interval, threshold evaluations are suspended. An event is generated on the Data Aggregator item when threshold evaluations are suspended.

Resume Threshold Evaluations

Threshold evaluations are not resumed automatically after they are suspended. Resume them manually.

WARNING

If threshold evaluations are suspended frequently, contact CA Support.

Follow these steps:

1. Enter the following information in a web browser:
   ```
   URL: http://DA_host:port/rest/thresholdmonitoring/config
   ```

2. Take note of the ID value of the ThresholdMonitoringConfiguration item.
   Example:
   ```
   <ThresholdMonitoringConfigurationList>
      <ThresholdMonitoringConfiguration version="1.0.0">
         <ID>16</ID>
        <ThresholdMonitoringEnabled>true</ThresholdMonitoringEnabled>
        <PercentOfPollCycleThreshold>80</PercentOfPollCycleThreshold>
        <ThresholdMonitoringLimiterEnabled>true</ThresholdMonitoringLimiterEnabled>
        <RecoveryIntervalInMinutes>15</RecoveryIntervalInMinutes>
      </ThresholdMonitoringConfiguration>
   </ThresholdMonitoringConfigurationList>
   ```

3. Open a REST client editor or HTTP tool that sends requests and gets responses.
4. Set the Content-type to application/xml.
5. Enter the following filter criteria:
   - URL: http://*DA_host*:*port*/rest/thresholdmonitoring/config/*ID*
     - ***ID***
       The identification number that is assigned to the ThresholdMonitoringConfiguration item.
   - HTTP method = PUT
   - Resume threshold evaluations on the Body tab of the HTTP Request pane:
     ```
     <ThresholdMonitoringConfiguration version="1.0.0">
          <ThresholdMonitoringEnabled>true</ThresholdMonitoringEnabled>
     </ThresholdMonitoringConfiguration>
     ```

   Threshold evaluations resume.

Change the Default Behavior of the Threshold Limiter

In some situations, CA Technologies may recommend that you modify the behavior of the threshold limiter.

Follow these steps:

1. Navigate to the following URL:
   `http://DA_host:port/rest/thresholdmonitoring/config`
2. Note of the ID value of the ThresholdMonitoringConfiguration item.
3. Open a REST client editor or HTTP tool that sends requests and gets responses.
4. Set the Content-type to application/xml.
5. Enter the following filter criteria:
   - URL: http://*DA_host*:*port*/rest/thresholdmonitoring/config/*ID*
     - ***ID***
       The identification number that is assigned to the ThresholdMonitoringConfiguration item.
   - HTTP method = PUT
   - Increase the Percentage of Poll Cycle Threshold value on the Body tab of the HTTP Request pane.

     ```
     <ThresholdMonitoringConfiguration version="1.0.0">
          <PercentOfPollCycleThreshold> percent </PercentOfPollCycleThreshold>
          <RecoveryIntervalInMinutes> minutes </RecoveryIntervalInMinutes >
     </ThresholdMonitoringConfiguration>
     ```

     - **percent** specifies the percentage value.
     - **minutes** specifies the number of minutes to wait before reassessing the threshold monitoring engine.

   The threshold limiter runs with the updated values.

Disable the Limiter

In rare situations, CA Technologies may recommend that you disable the threshold limiter.

Follow these steps:

1. Navigate to the following URL:
   `http://DA_host:port/rest/thresholdmonitoring/config`
2. Note of the ID value of the ThresholdMonitoringConfiguration item.
3. Open a REST client editor or HTTP tool that sends requests and gets responses.
4. Set the Content-type to application/xml.
5. Enter the following filter criteria:
   - URL: http://*DA_host*:*port*/rest/thresholdmonitoring/config/*ID*
     - ***ID***
       The identification number that is assigned to the ThresholdMonitoringConfiguration item.
   - HTTP method = PUT
   - Disable the limiter on the Body tab of the HTTP Request pane:

     ```
     <ThresholdMonitoringConfiguration version="1.0.0">
          <ThresholdMonitoringLimiterEnabled>false</ThresholdMonitoringLimiterEnabled>
     </ThresholdMonitoringConfiguration>
     ```

   The limiter is disabled and the evaluation engine cannot enter a DEGRADED state.

Threshold Event Processing Self-Monitoring Metrics

To determine if you are doing too much eventing, monitor the key performance indicators in Data Aggregator. Eventing in Data Aggregator is performed in batches, for example, events are simultaneously evaluated and generated for large groups of items. Several metrics provide self-monitoring to assess the health of the Data Aggregator system.

To view these metrics, add a custom IM Device MultiTrend view to a dashboard. Edit the dashboard, using the following metrics from the metric family **Data Aggregator Event Calculation Times**:

- **Event Process Queue Size** shows the size of the event processing queue. An increase in queue size without a subsequent recovery (trending downward) indicates that eventing is backed up.
- **Count of Cleared Events** indicates the number of cleared events that are in the reporting resolution window.
- **Count of Created Events** indicates the number of raised events that are in the reporting resolution window.
  A continuously large number of events that are raised or cleared can affect the Event Manager database. These metrics can indicate when your system has exceeded the recommended event generation rate. Event generation/clear bursts are acceptable.
- **Count of Processed Event Rule Evaluations** indicates the sum of event rules multiplied by the number of items those rules are applied to. The higher the number of evaluations, the more work your system is doing. Some evaluations are more expensive than others. For example, evaluations with more conditions, more standard deviation conditions, or longer duration and window are more expensive. The total acceptable number of evaluations depends on your event rules.
- **Total Time to Calculate Events** indicates the total amount of time that was spent processing events for this metric family. If the value of this metric exceeds the number of seconds in the reporting resolution window, the eventing was delayed or backlogged at that point in time.

In general, steady values for these self-monitored metrics indicate a healthy system. Some intensive database jobs cause fluctuation in these self-monitoring metrics. Typically, these jobs run between 2 AM and 4 AM UTC. Turn on eventing slowly and judge the system health before moving forward with different rules. Monitor the health of the system over 24 hours after each subsequent change.

Errors in the Karaf log on the Data Aggregator system may also indicate that your system is under stress.

Modern Network Monitoring

DX NetOps Virtual Network Assurance (VNA) provides modern network monitoring for software-defined architectures and hybrid cloud platforms. DX NetOps Virtual Network Assurance enables comprehensive coverage with monitoring that is scalable and heterogeneous across the greatest number of technology stacks in the following architectures:

- Traditional
- SDN
- SDDC
- SD-WAN
- NFV
- Hybrid-cloud

To show you both virtual network data and traditional physical infrastructure performance information, DX NetOps Virtual Network Assurance collects data from these architectures and delivers that information to DX NetOps Performance Management.

For more information, see the DX NetOps Virtual Network Assurance documentation.

Load VNA Data

To populate dashboards with VNA data, load the inventory and performance data. For more information, see Manage Data from CA Virtual Network Assurance.

VNA Domains

DX NetOps Performance Management uses DX NetOps Virtual Network Assurance domains as reporting groups.

Modern Network Monitoring Dashboards

NetOps Portal provides various dashboards for viewing VNA data related to the relevant technologies and architectures of your environment.

Manage Data from Virtual Network Assurance

To display data for software-defined networking (SDN) and network functions virtualization (NFV) controllers and orchestrators, connect to DX NetOps Virtual Network Assurance (VNA). VNA includes the Gateway component, which delivers SDN/NFV data to DX NetOps Performance Management. After you configure the connection, VNA sends the inventory data to DX NetOps Performance Management. VNA sends updates to inventory information and performance data as that information is collected from the virtual network.

> **NOTE**
> To load performance data, VNA must be configured to collected data from the virtual network. For more information, see the DX NetOps Virtual Network Assurance documentation.

The data collector can support multiple Gateways, however, only one Gateway can be active at a time. You can delete a Gateway and its associated inventory. This action deletes the associated VNA items on DX NetOps Performance Management and deletes the historical performance data. Alternatively, to preserve the inventory and performance data, you can edit the lifecycle state of the Gateway. With a lifecycle state set to `Retired` , the data collector does not process data from the Gateway.

The following video shows the configuration process:

Configure the Connection in NetOps Portal

Follow these steps:

1. Hover over **Administration**, and then click **Monitored Items Management: VNA Gateways**.
2. Click **New** or **Edit**.
3. Specify the VNA host and port, and then select the data collector that receives VNA data.
   Default Port: 8080
4. Select the **Administrative Status**.
   With the Administrative Status set to `Up` , the data collector registers VNA to receive inventory and performance data.
5. Select the **Life Cycle State**.
6. Click **Save**.

Configure the Connection Through REST

Use the following REST information configure the connection:

URL: `http://`*`da_host`*`:8581/rest/tenant/`*`tenantID`*`/sdnGateways`

- **tenantID** is the ID of the tenant to which the data collector belongs. For the default tenant, the tenant ID is usually 1.

  > **TIP**
  > To get the tenant ID, use the following REST URL: `http://`*`da_host`*`:8581/rest/tenant`

Method: POST

Body:

```
<SDNGateway version="1.0.0" >
   <Item version="1.0.0">
     <Name>GatewayName</Name>
     <MDRItemID>DC_ItemID</MDRItemID>
   </Item>
   <AdminStatus>status</AdminStatus>
   <LifeCycleState>state</LifeCycleState>
   <Hostname>host</Hostname>
   <Port>8080</Port>
 </SDNGateway>
```

- **Name** assigns a name to the Gateway item.
- **MDRItemID** specifies which Data Collector the SDN Gateway connects to.
- **AdminStatus** determines whether the data collector receives inventory and performance data from the Gateway.
  Values: `UP` or `DOWN`
- **LifeCycleState** determines whether the data collector processes data from the Gateway. Only one Gateway can be active at a time.
  Values: `ACTIVE` or `RETIRED`
- **Hostname** is the hostname of the SDN Gateway.
- **Port** is the port for the SDN Gateway.
  Default: 8080

Example:

```
<SDNGateway version="1.0.0" >
  <Item version="1.0.0">
    <Name>SDN GW 2</Name>
    <MDRItemID>762</MDRItemID>
  </Item>
  <AdminStatus>UP</AdminStatus>
  <LifeCycleState>ACTIVE</LifeCycleState>
  <Hostname>sdn-gw2</Hostname>
  <Port>8080</Port>
</SDNGateway>
```

If the AdminStatus set to `UP` , the data collector registers the Gateway to send it inventory and performance data.

Monitor Virtual Inventory

In SDN and NFV environments, your virtual inventory changes according to the requirements of your services. Modern network monitoring provides insight into the trends in virtual inventory. Inventory metrics provide assurance that the programmatic processes that manage the network are functioning properly. These metrics also highlight anomalies in provisioning.

The SDN/NFV Virtual Inventory Overview dashboard shows your virtual inventory.

The SDN/NFV Virtual Inventory Overview dashboard provides the following information:

- VNF count by type over time as a trend chart and a stacked chart
- Service chain and virtual network inventory trends
- VNF inventory trends by type

NOTE

The Other VNFs Count view shows VNFs where DX NetOps Performance Management cannot determine the type.

Monitor SDN/NFV Virtual Resource Usage

To investigate performance degradation and for capacity planning, monitor the resource usage of your virtual environment.

DX NetOps Performance Management provides two dashboards that show resource utilization:

SDN/NFV Virtual Compute Usage Overview Dashboard

This dashboard shows virtual CPU and memory usage for VNFs. The views use different visualizations to show aggregated and individual resource utilization. By default, views show the VNFs with the highest utilization.

SDN/NFV Virtual Storage Usage Overview Dashboard

This dashboard shows virtual storage, reads, and writes for VNFs. The views use different visualizations to show aggregated and individual resource utilization. By default, views show the VNFs with the highest utilization.

The following video highlights the key capabilities of this dashboards:

Monitor SDN/NFV Physical Host Resource Usage

To investigate performance degradation and for capacity planning, monitor the physical resource usage of your virtual environment. In a virtual network, all virtual network functions (VNF) run on physical hosts. If the load on the physical hosts is too high, the VNFs compete for resources, leading to performance degradation.

DX NetOps Performance Management provides the SDN/NFV Physical Server Usage Overview dashboard which shows the status of the physical infrastructure that supports the virtual environment.

This dashboard includes the following information:

- Aggregated CPU, memory, and disk utilization for physical servers
- Availability and Reachability information
- Individual servers with the highest CPU, memory, and disk utilization
- Inventory of all servers in the SDN/NFV environment

The following video highlights the key features of this dashboard:

Monitor Service Chains

In an SDN/NFV environment, services are delivered dynamically through virtual network functions (VNF). The service chain represents the required VNFs and the stack of physical and virtual building blocks that support the VNF.

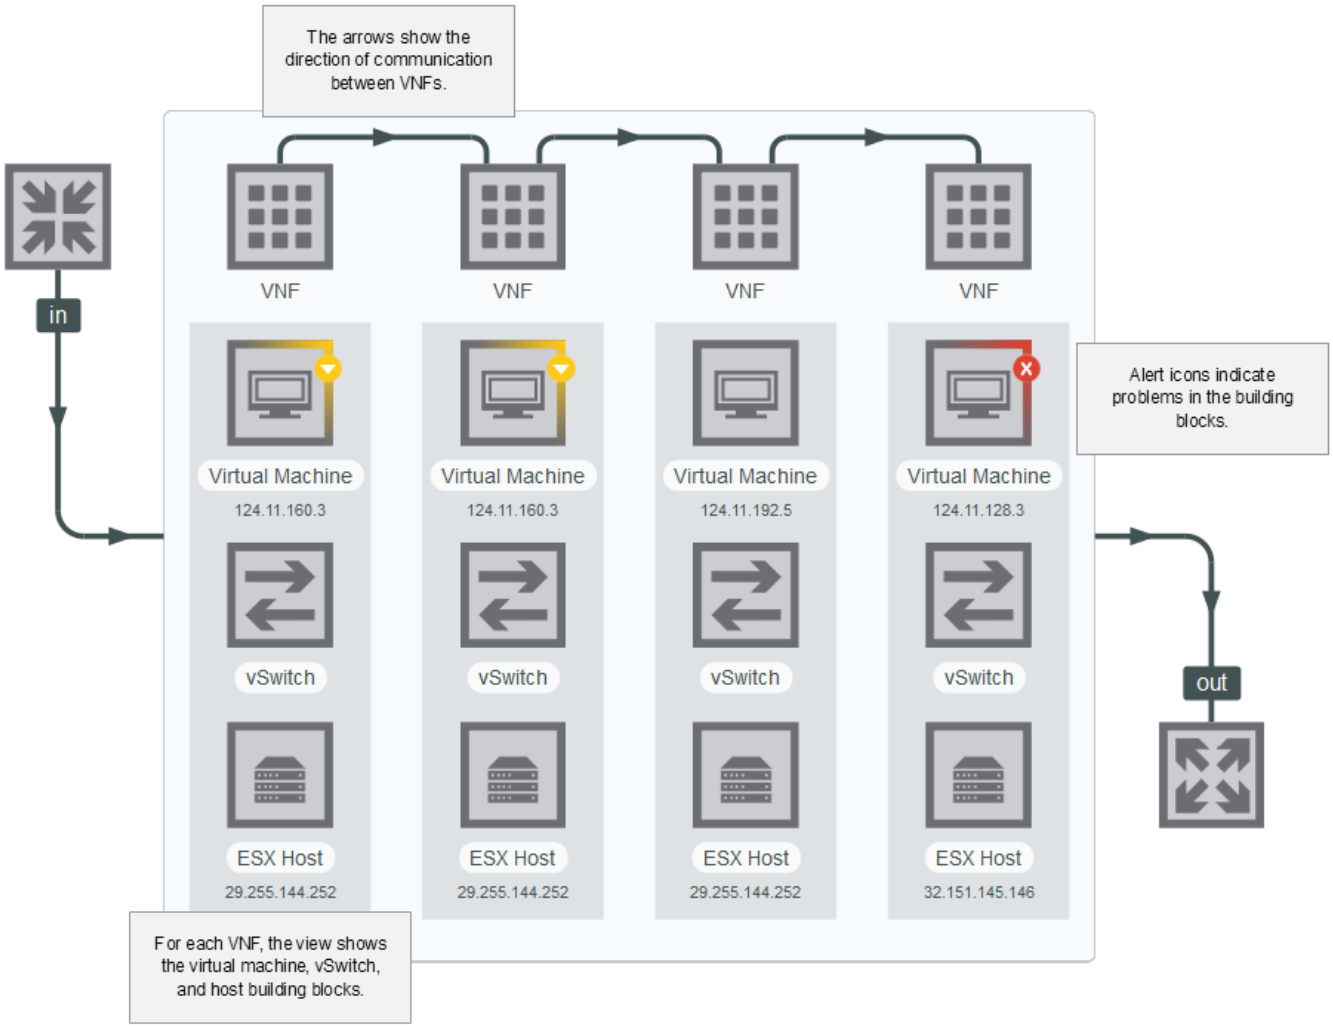
The Service Chain page provides information about the status of service chains. The main view shows the VNFs in the service chain and includes the virtual and physical building blocks. The view indicates the type of each VNF with an abbreviation. The arrows show whether communication is one-way or bidirectional.

To access the Service Chain page, go to **Inventory**, **Service Chains**, and click a service chain in the list. The view provides the following functionality:

- To show name, type, IP address, and performance information, hover over a building block in the service chain.
- Alert icons indicate problems in the building blocks. Hover over the icon for information about the violated threshold.
- To load the detailed context page for a building block, right-click a building block, and select a context.

The following image shows the important elements of the service chain visualization:

Figure 53: Service Chain Details Elements



Service Chain Thresholds

To configure the thresholds for the alert icons, click the **View Settings** (gear) icon, and click **Edit**. Assign Critical (red), Major (orange), and Minor (yellow) threshold for the following metrics:

- CPU utilization
- Memory utilization

VNF Types

The view uses the following abbreviations to identify the currently defined VNF types:

- **vFW** Firewall
- **vLB** Load Balancer
- **vNAT** NAT
- **vOPT** Optimizer
- **vCMF** Content Filter
- **vDPI** DPI
- **vWOL** WAN Accelerator
- **vADC** ADC
- **vCACHE** Cache
- **vROUTER** Router
- **Other**

Monitor vSwitch Performance

To identify bottlenecks in your SDN or NFV environment, monitor vSwitch performance. Because vSwitches connect VNFs to each other and to physical interfaces, the performance of the vSwitch determines the overall bandwidth of the connected VNFs. With the transition from physical to virtual networking, the generalized architecture of the x86 box replaces the highly specialized hardware of the physical switch. Because this architecture is not optimized for switch performance, vSwitch performance is an important indicator of overall virtual network health.

The following video highlights this feature:

NOTE

In DX NetOps Performance Management, vRouters appear as vSwitches.

SDN/NFV vSwitch Performance Overview Dashboard

The SDN/NFV vSwitch Performance Overview dashboard lets you analyze the overall performance of vSwitches in your environment. This dashboard uses different visualizations to show the following information about vSwitches:

- The inventory of vSwitches in the virtual network
- The vSwitch throughput in bits and packets
- The minimum, maximum, and average throughput in bits and packets
- The vSwitch utilization and throughput in bits and packets aggregated to the device level
- The CPU and memory utilization of vSwitch service

TIP

The views that show vSwitch network performance, such as throughput, errors, and discards, show the top vSwitches for these metrics. Use these views to drill in to the vSwitch context page for more details.

vSwitch Context Page

The vSwitch context page provides detailed information about a specific vSwitch. To access the vSwitch context page, click a vSwitch in the inventory, in another view, or in the service chain visualization.

Details Tab

The Details tab shows basic information about the vSwitch, a list of events, and availability information. Use this tab for basic troubleshooting.

Network Tab

The Network tab shows network performance information for the vSwitch. Use this tab to identify network performance bottlenecks that are related to the vSwitch. The tab includes the following information:

- Average interface utilization
- Errors and discards for interfaces on the vSwitch
- Aggregated throughput in bits and packets
- Interface throughput in bits and packets
- Inventory of the virtual interfaces

High dropped packets might indicate that the vSwitch service is overburdened.

Resource Tab

The Resource tab shows resource use for the vSwitch service. Use this tab to ensure that the vSwitch is not consuming too much of the host resources. The tab includes the following information:

- Current CPU and memory utilization

  NOTE

  CPU and memory utilization for the vSwitch service are compared against the total resources available to the host.
- Trend chart for CPU and memory utilization

High utilization for the service means that other VMs on the host might have insufficient resources.

Virtual Interface Context Page

The virtual interface context page provides performance information for interfaces on your vSwitches. To access the virtual interface context page, click an interface in the inventory or in another view.

Details Tab

The Details tab shows basic information about the interface and a list of events for to the interface.

Health Tab

The Health tab shows performance information for the virtual interface, such as the following information:

- Discards
- Errors
- Interface utilization
- Throughput in bits and packets

Monitor Cisco ACI

Cisco Application Centric Infrastructure (ACI) uses Nexus 9000 switches to create a dynamic virtual environment that hosts and serves applications. Monitor the Cisco ACI environment to verify that everything is operating as expected and to highlight problem areas. DX NetOps Performance Management provides dashboards and context pages that support Cisco ACI monitoring.

ACI Console

The ACI Console provides a searchable inventory list that shows relationships between items in the Cisco ACI environment. Where relevant, the inventory shows the most recent ACI health score.

- To limit the list to a particular node in the hierarchy, double-click that node.
- To return to a higher level of the hierarchy, click the breadcrumb links.
- To filter the inventory by a health-score threshold, use the slider at the top of the pane. The inventory shows nodes with children with health scores equal to or lower than the threshold.

The ACI Console also provides relationship diagrams for various aspects of the ACI inventory. The diagrams show alert icons on items that exceed customizable thresholds. Use the diagrams to understand how particular problems with the ACI infrastructure affect your applications. The ACI Console includes diagrams for the following inventory item types:

- **Application Profile Diagram**
  Shows the relationships between endpoint groups (EPGs) that support the application profiles (APs). Provider EPGs are connected to contracts connected to consumer EPGs. The diagram also shows the underlying leafs that support the endpoints in the EPGs.
- **EPG Diagram**
  Shows the AP parent and each end point. For each endpoint, the diagram shows the associated leaf.
- **Endpoint Diagram**
  Shows the EPG parent. If the endpoint is a vLAN, the diagram shows the connection to the leaf. If the endpoint is an application, the diagram shows the full supporting technology stack.
- **Leaf Diagram**
  Shows application profiles that contain endpoints which are connected to the leaf.
- **APIC Diagram**
  Shows leafs that are connected to the APIC controller.

  NOTE

  Because each spine is connected to each leaf and has no other relationships, the ACI console does not include a diagram for spines.

All diagrams share common functionality:

- To open a diagram, click an item in the inventory.
- To show more details for an item in the relationship map, hover over the icon for the item.
- To show which thresholds are exceeded, hover over the alert icon in the relationship map.
- To open the relationship map for another item, click the icon for an item in the current relationship map. The previous relationship map becomes a breadcrumb link on the right side of the diagram.
- To open the context page for an item, click the item name in the relationship map.
- To go to the ACI Health dashboard or the Switches Overview dashboard, click links in the upper left corner of the dashboard.

ACI Console Thresholds

To configure the thresholds for the alert icons, click the **View Settings** (gear) icon, and click **Edit**. Assign Critical (red), Major (orange), and Minor (yellow) threshold for the following metrics:

- CPU utilization
- Health score
- Interface utilization
- Memory utilization

The following image shows the important elements of the ACI Console:

Figure 54: ACI Console Elements

ACI Health Dashboard

The ACI Health dashboard provides focused information about your Cisco ACI environment. To highlight problem areas, the dashboard focuses on health scores and faults. To narrow the area of troubleshooting, change the context of the dashboard:

- To find problematic switches, scope to the fabric.
- To find a problem in a tenant, scope to a tenant.
- To find a problem in an application, scope to an AP.

This dashboard shows the following information:

- Counts of items in the Cisco ACI environment
- Count of critical faults
- ACI health scores for items in the environment
- Aggregated fault trends by severity
- AP and EPG inventory

Switches Overview Dashboard

The Switches Overview dashboard provides information about the status of switches. If you select the appropriate group of Nexus 9000 switches, you can monitor the infrastructure behind an ACI environment. For example, you can analyze critical faults, CPU, memory, and interface utilization for these switches.

NOTE

Most metrics on this dashboard require SNMP data collection from the Nexus 9000 switches through DX NetOps Performance Management.

This dashboard shows the following information:

- Switches with the highest CPU and memory utilization
- Switches with the highest interface utilization
- Switches with the highest policy CAM utilization
- Switches with the most critical faults

ACI Workflows

The ACI dashboards are designed with the following role-based workflows:

- An **ACI System Administrator** is responsible for maintaining the Cisco ACI environment.
  a. Use the ACI Console to look at the fabric and VMs:
     - View the relationship of the fabric to APs and EPGs.
     - View the relationship of fabric nodes to compute resources.
     - View the relationship of VMs to APs and EPGs.
     - View the relationship of VMs to fabric nodes and compute resources.
  b. Use the ACI inventor to track the number of entities in the ACI environment.
  c. Track the performance of APs and EPGs on context pages.
- A **Tenant Administrator** is responsible for managing tenants in the ACI environment.
  a. Scope the ACI Console to the tenant, and look at VM relationships to APs, EPGs, compute resources, and the fabric.
  b. Use the ACI Health dashboard to look at the health score and faults within the tenant.
  c. Track the performance of APs and EPGs on context pages.
- An **Application Owner** is responsible for a single application that is hosted in the ACI environment.
  a. Scope the ACI Console to the AP, and look at VM relationships to the AP, EPGs, compute resources, and the fabric.
  b. Use the AP context page to monitor computer and storage utilization by VM and in aggregate and top VM utilization.
- A **Fabric Administrator** is responsible for maintaining the health of the network in the ACI environment.
  a. Scope the ACI Console to the fabric, and look at fabric relationships to APs and EPGs and the relationships of fabric nodes to compute resources.
  b. Use the ACI Health dashboard to look at the health score and faults within the fabric.
  c. Track the performance of the Nexus 9000 switches on the Switches Overview dashboard and the context pages for the switches.

Monitor SD-WAN

SD-WAN solutions, like Viptela and Cisco IWAN, route traffic according to predefined performance requirements. DX NetOps Performance Management provides dashboards and context pages that support SD-WAN monitoring. Dashboards and context pages allow you to monitor the following items:

- **Tunnel**
  Represents the connection between two devices and has polled statistics (jitter, latency, and packet loss).
- **Application/SLA path**
  Represents a tunnel in relation to service level agreements (SLAs) thresholds. The measured SLA metrics (jitter, latency, packet loss) are reported as percentages of the related SLA thresholds. Rather than reporting tunnel traffic, application/SLA paths show the ability of a tunnel to meet the SLAs for different types of traffic (for example, voice or video). These traffic types are referred to as SLA classes.

  NOTE

  Viptela sites map to site groups in NetOps Portal. If desired, you can manage the site groups in NetOps Portal to update the site name. For more information, see Manage Groups.

For information about the metrics that Viptela collects including the VNA metrics, SNMP metric families, and NFA metrics, see the CA Virtual Network Assurance documentation.

The following video examines how DX NetOps Performance Management supports the Viptela SD-WAN technology:

SD-WAN Tunnel and Application Paths Dashboards

View the SD-WAN Tunnel Statistics dashboard or the SD-WAN App Path Statistics dashboard to view the health of your SD-WAN tunnels or application/SLA paths. The SD-WAN App Path Statistics dashboard lets you easily identify issues impacting your delivering of services and applications according to service level agreements (SLAs).

The SD-WAN Tunnel Statistics dashboard reports the following metrics:

- Jitter
- Latency
- Packet loss

The SD-WAN App Path Statistics dashboard reports the following metrics:

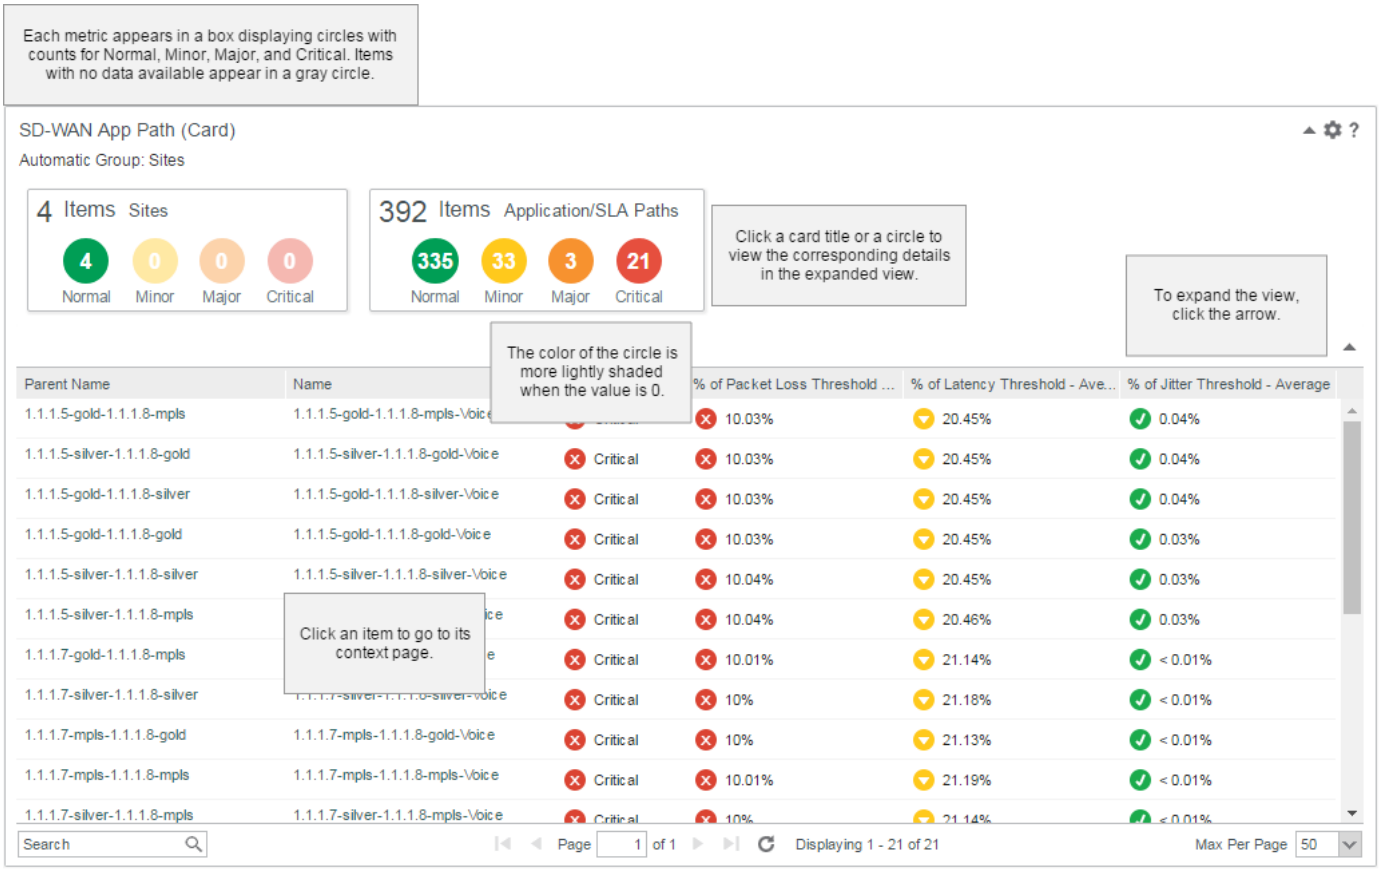
- Percentage of Jitter SLA Threshold
- Percentage of Packet Loss SLA Threshold
- Percentage of Latency SLA Threshold

The following details appear in these dashboards:

- **Health Counts**
  View the aggregated health counts of the following items:
  - Sites
  - Edge Routers
  - Application Paths
  - Applications
  - Tunnels

  Counts appear in color-coded circles for each threshold range. To expand the view, click the arrow in the lower-right corner. Click a card title or a circle to view the corresponding details in the expanded view.

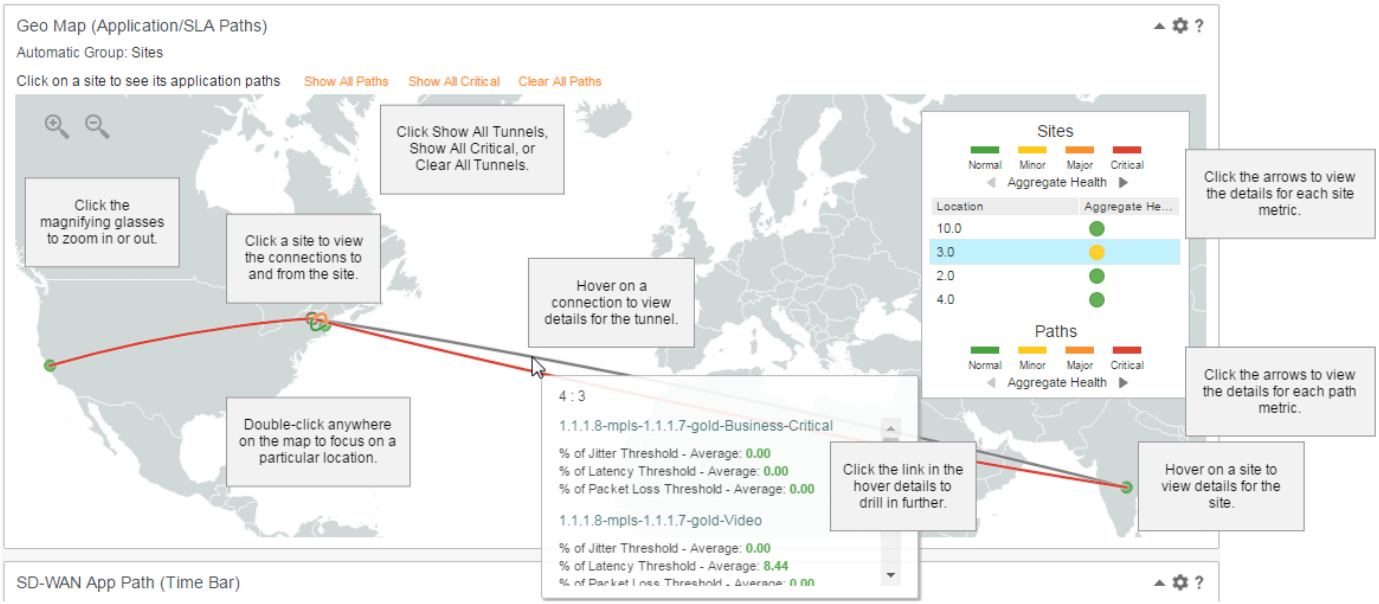
Figure 55: SD-WAN Card



- **Geographic Map**
  View the location of each site. When a site is selected, the connections to and from other sites appear. The connection lines are color-coded based on health metrics. Site router details appear when you hover over a site. Tunnel or application/SLA path details appear when you hover over a connection.

  NOTE
  Only sites within the page-level Group context are shown even when a tunnel or application path runs between an included and excluded site.

Figure 56: SD-WAN Map



- **Timeline**
  View time bar charts aggregating packet loss, latency, and jitter metrics and time bar charts for each metric.

  NOTE
  Only sites within the page-level Group context are shown even when a tunnel or application path runs between an included and excluded site. The selected site in the Map view filters this view.

Figure 57: SD-WAN Timebar

- **Scorecard**
  View tunnel or application/SLA path metrics by subgroup and component for the selected group. Subgroups and the items in those groups appear in a hierarchical format. Colored icons indicate performance levels for metrics and an overall health indicator.

Figure 58: SD-WAN Scorecard

- **Statistics**
  View tunnel or application/SLA metrics in a table with color-coded bars for percentage metrics.
- **Gauge**
  In the SD-WAN Tunnel Statistics dashboard, view packet loss in a gauge/table view.
- **Trend**
  View packet loss, latency, and jitter in a trend/table view.
- **Traffic**
  View latency and jitter metrics side by side for comparison and in a trend chart.
- **Inventory**
  View the source and destination end points of your tunnels or application/SLA paths.
- **Errors and Discards**
  In the SD-WAN Tunnel Statistics dashboard, view SD-WAN virtual interface errors in one table and SD-WAN virtual interface discards in another table.

SD-WAN Context Pages

From the inventory or the SD-WAN dashboards, you can navigate to context pages containing more details for the following SD-WAN items:

- **Devices**
  View the typical device context page for any of your SD-WAN devices.
- **Application/SLA Paths**
  On the Details tab, view the details for the selected application/SLA path. View its statistics, packet loss in a gauge, heat chart, and trend chart, and its traffic.
  On the Class Health tab, view the percentage of packet loss, percentage of jitter, and the percentage of latency. These metrics appear in gauges, heat charts, side-by-side bar charts, trend charts, and a bar chart table.
- **Tunnels**
  On the Details tab, view the details for the selected tunnel. View its statistics, packet loss in a gauge, heat chart, and trend chart, and its traffic.
- **Virtual Interfaces**
  On the Details tab, view the details for the selected virtual interface with its event list.
  On the Health tab, view trend charts for discards, utilization, errors, packet rate, and bit rate.

SD-WAN Workflows

The following video examines SD-WAN application/SLA paths and why CA Network Operations Analytics monitoring is so important to delivering a reliable digital experience:

The following workflows illustrate how an Operations Engineer can use the SD-WAN dashboards and context pages for SD-WAN monitoring:

1. One of the following events drives you to the relevant SD-WAN dashboard:
   – For an event impacting site connectivity, go to the SD-WAN Tunnel Statistics dashboard.
   – For an event that could impact service level agreements (SLAs), go to the SD-WAN App Path Statistics dashboard.
2. Use the Health Counts to view the site connections or application/SLA paths with issues.
3. Use the Geographic Map and Scorecard to view site details.
4. Review the remaining trend data.
5. Drill into edge devices.

Monitor AWS

CA Virtual Network Assurance monitors the AWS Cloud environment to verify that everything is operating as expected and to highlight problem areas. DX NetOps Performance Management provides custom dashboards and context pages that support AWS cloud monitoring. the dashboards and context pages allow you to monitor the following items:

- **Tunnel**
  Represents the connection between two devices and has the following polled statistics:
- – TunnelState
  – TunnelDataIn
  – TunnelDataOut
- **Ec2**
  Represents a virtual machine and has the following polled metrics:
  CPU
- – Utilization
  – Aggregated Network Incoming Bytes
  – Aggregated Network Outgoing Bytes
  – Aggregated Network Incoming Packets
  – Aggregated Network Outgoing Packets
  Disk
- – Disk IOPS
  – Disk Read Bytes
  – Disk Write Bytes
  – Disk Capacity

AWS Context Pages

From the inventory, you can navigate to context pages for more information on the the following AWS items:

- **Devices**
  View the typical device context page for any of your AWS devices.
- **Tunnels**

Context page for AWS tunnel does not include any AWS cloud metrics. You must create custom dashboards to view tunnel performance metrics.

- **EC2s**
  In the Summary tab, you can view the details for the selected EC2 with the corresponding event list.
  In the VMware Virtual machine tab, you can view trend charts for CPU Usage, Active Memory Usage, Power State Connection state, and so on. You must create custom dashboards to view all supported EC2 performance metrics.
- **Virtual Interfaces**
  In the Details tab, you can view the details for the selected virtual interface with its event list.

Configure Notifications

Configure notifications for events that come from a data source to Event Manager. The incoming events are evaluated against the conditions that you configure for the notification criteria. Only when the criteria are met does Event Manager take a notification action. If an event does not trigger a notification, you can still display the event in the Event List.

A user only configures and receives notifications for events for an item in a group to which the user has access.

Consider the following information:

- Users cannot see the notifications of other users.
- The action to delete event notifications does not affect the actual or future events.

Notification Actions

When you configure notifications, you can specify the following actions.

Email

Send email notifications to one or more recipients when an event is raised or cleared. The email provides a link to the context page for the device or component that triggered the alarm.

> **NOTE**
> To use the hostname in the URL instead of the IP address of the NetOps Portal host, configure the **Web Site Host**. For more information, see Update Performance Center Website Settings.

Supported roles: Users with a role that contains the Create Notifications role right and Event Manager access can configure email notifications. However, the Administrator role must first specify an SMTP server.
In the Email tab, select Enable, and configure the email notification settings.

Trap

Send trap notifications to fault or network management system (NMS) in your environment, such as DX NetOps Spectrum.

> **NOTE**
> While DX NetOps Spectrum can receive traps, this method is not the preferred method to integrate with DX NetOps Spectrum. For more information, see the CA Spectrum documentation.
>
> **IMPORTANT**
> Create an SNMP profile with the outgoing trap port (typically 162) before creating the notification.

Supported roles: Users with the Administrator role (global administrators) can configure trap notifications. Administrators must also have product privileges to Event Manager and data sources that create events.

The trap receivers must be preconfigured to receive traps. Each destination can have its own configuration regarding SNMP community and IPV4 destination. To receive and decrypt SNMPv3 traps, the SNMP profile for the trap receiver

should match this notification configuration. For more information, see SNMP Profiles. For more information about trap formats, see the corresponding NMS documentation for your trap receiver.

Script

Define a script. Scripts can store events to a database, forward notifications to multiple systems, send specific types of notifications to some specific system, and so on. You can log output from scripts that you own. Script return codes are logged in the standard PC log file. Script notification actions are executed serially to ensure that sets are processed before clears. If the queue of unprocessed script notification actions exceeds a certain size (5000 by default), any new incoming script notification actions are dropped. An event is generated when events start dropping and when the processing of new script notification actions restarts. If a script takes too long to complete execution (300 seconds by default), it is killed and an event is generated. The script notification action events are generated on the Data Aggregator item in NetOps Portal.

For moreinformation about how to change event properties that are related to script notification actions, see Change Event Properties.

> **NOTE**
> Store scripts in the `/opt/CA/PerformanceCenter/NotificationScripts` directory.

The following video examines automatic script execution:

The following parameters are automatically passed to script notification actions:

- `CAPM_EventDataSource`
- `CAPM_EventCategory`
- `CAPM_EventType`
- `CAPM_EventSubType`
- `CAPM_EventState`
- `CAPM_EventSeverity`
- `CAPM_EventOccurredOn`
- `CAPM_EventDesc`
- `CAPM_ItemParentName`
- `CAPM_ItemName`
- `CAPM_ItemNameAlias`
- `CAPM_ItemDesc`
- `CAPM_IPAddress`
- `CAPM_ItemUrl`
- `CAPM_ItemType`
- CAPM_ItemSubtype
- CAPM_ItemId
- CAPM_ItemParentId

> **NOTE**
> Event-specific properties are also available and prefixed with "`CAPM_EvProp_` ". The `CAPM_ItemId` and `CAPM_ItemParentId` parameters are NetOps Portal IDs. The script parameters and notifications are always in English regardless of the NetOps Portal language.

Supported roles: Users with a role that contains the Create Notifications role right can create or edit script notification actions.

Examples:

You can define a script that prints environment variables to a file and a CPU utilization threshold event can trigger the script.

1. Define the following `printenv.sh` script in the `/opt/CA/PerformanceCenter/NotificationScripts/` directory by running the following command:
   ```
   printenv > /opt/CA/PerformanceCenter/NotificationScripts/out.txt
   ```
2. Make the script executable by running the following command:
   ```
   chmod u+x printenv.sh
   ```
3. Configure notifications so that a CPU utilization threshold event triggers the `printenv.sh` script.
   The script creates the following output:
   ```
   CAPM_EventCategory=PERFORMANCE
   CAPM_EvProp__Severity=1
   CAPM_IPAddress=10.253.223.1
   CAPM_ItemNameAlias=cisco2621-10.253.223.1
   CAPM_EvProp_AlarmRuleID=5,313
   CAPM_EvProp_AlarmAggregationMethod=No Aggregation
   CAPM_ItemId=118
   CAPM_EvProp_AlarmProfileName=Test cpu
   CAPM_ItemDesc=Cisco Internetwork Operating System Software ^M
   IOS (tm) C2600 Software (C2600-IK9O3S3-M), Version 12.3(9), RELEASE SOFTWARE (fc2)^M
   Copyright (c) 1986-2004 by cisco Systems, Inc.^M
   Compiled Fri 14-May-04 14:37 by dchih
   CAPM_EventState=OPENED
   CAPM_EventType=ThresholdViolation
   PWD=/opt/CA/PerformanceCenter/EM/bin
   CAPM_EventDesc=A Threshold Violation event has been raised. (Profile Name: Test cpu,
    Rule Name: test cpu)
   CAPM_ItemName=CPU 2
   CAPM_ItemParentId=118
   CAPM_EvProp_ThresholdProfileFolderId=5,311
   CAPM_EvProp_AlarmDuration=60
   CAPM_EvProp_AlarmProfileId=5,314
   CAPM_EvProp_AlarmViolationRuleDetail=Utilization > 50.0
   SHLVL=1
   CAPM_EvProp__Alarm_ID=1500
   CAPM_ItemType=DEVICE
   CAPM_ItemParentName=cisco2621-10.253.223.1
   CAPM_EventSeverity=MAJOR
   CAPM_EvProp_AlarmMetricFamilyName=CPU
   CAPM_EventOccurredOn=Thu May 24 10:39:00 EDT 2018
   CAPM_EvProp_AlarmRuleName=test cpu
   CAPM_EventDataSource=Data Aggregator@fergi04-dev-da
   CAPM_ItemUrl=http://10.237.15.180:8181/pc/desktop/page?
   pg=r&DeviceID=118&timeRange=-1&startTime=2018-05-24+10%3A09+America
   %2FNew_York&endTime=2018-05-24+11%3A09+America%2FNew_York
   CAPM_ItemSubtype=router
   CAPM_EvProp_AlarmWindow=60
   ```

```
CAPM_EventSubType=Raised
_=/usr/bin/printenv
```

NOTE
If an error occurs during the script execution, the errors are logged in the *PC_Install_Directory*/PerformanceCenter/EM/logs/EMService.log file. For example, if the script does not exist or the script is not executable, an error is logged. The exit code of the script is also logged.

You can define a script that prints environment variables to a file and any device life cycle change can trigger the script.

1. Define the following `printenv.sh` script in the `/opt/CA/PerformanceCenter/NotificationScripts/` directory by running the following command:
   ```
   printenv > /opt/CA/PerformanceCenter/NotificationScripts/env.txt
   ```
2. Make the script executable by running the following command:
   ```
   chmod u+x printenv.sh
   ```
3. Configure notifications so that any device life cycle change event triggers the `printenv.sh` script.
   The script creates the following output:
   ```
   CAPM_EventCategory=CONFIG
   CAPM_EvProp__Severity=Unknown
   CAPM_IPAddress=138.42.96.2
   CAPM_ItemNameAlias=138.42.96.2 - alias
   CAPM_EvProp_User=admin
   CAPM_ItemId=110
   CAPM_EvProp_CurrState=RETIRED
   CAPM_EvProp_PrevState=ACTIVE
   CAPM_ItemDesc=RS 38000 - Riverstone Networks, Inc. Firmware Version: 9.4.1.1 PROM
    Version: prom-2.0.1.8
   CAPM_EventState=CLOSED
   CAPM_EventType=LifeCycle
    PWD=/opt/CA/PerformanceCenter/EM/bin
   CAPM_EventDesc=LifeCycle - Change
   CAPM_ItemName=rs38000-96.2
   CAPM_ItemParentId=110
   SHLVL=1
   CAPM_ItemType=DEVICE
   CAPM_ItemParentName=rs38000-96.2
   CAPM_EventSeverity=
   CAPM_EventOccurredOn=Mon Dec 18 16:20:58 EST 2017
   CAPM_EventDataSource=CA Performance Center
   CAPM_ItemUrl=http://10.237.10.219:8181/pc/desktop/page?
   pg=r&DeviceID=110&timeRange=-1&startTime=2017-12-18+15%3A50+America
   %2FNew_York&endTime=2017-12-18+16%3A50+America%2FNew_York
   CAPM_ItemSubtype=router
   CAPM_EventSubType=Change
   _=/usr/bin/printenv
   ```

NOTE
If an error occurs during the script execution, the errors are logged in the *PC_Install_Directory*/PerformanceCenter/EM/logs/EMService.log file. For example, if the script does not exist or the script is not executable, an error is logged. The exit code of the script is also logged.

Configure Notifications

To send a message that is related to events automatically, configure a notification.

Follow these steps:

1. Do one of the following tasks:
   - Hover over **Administration**, and then click **Configuration Settings: Notifications.**
   - Click the name of your user account in the upper-right corner and click **Manage Notifications**.
2. Click **New**.
3. Specify a name and description, and then click **Next**.
4. Select the groups that generate events to trigger the notification, and then click **Next**.
5. Select conditions for the notification, and then click **Next**.
6. Specify the notification actions:
   - **Email**
     Send email notifications.

     NOTE
     To include the device name for events that are triggered on components, use the `Item Parent Name` property.

     TIP
     To create or update a notification email template, select **Save** or **Update Email Template**. Changes to templates do not affect existing messages.
   - **Trap**
     Send trap notifications. Multiple destinations are supported, but the first destination is required.
     Two MIB choices are available in the Notifications wizard to provide compatibility for existing customers.
   - **Script**
     Specify the script file name. All scripts must be executable.
     You can use a script in another language like Python or Perl.

     NOTE
     Store scripts in the `/opt/CA/ PerformanceCenter/NotificationScripts` directory.
7. Click **Next**.
   DX NetOps Performance Management saves the notification and sends messages when the selected conditions occur.

Manage Notifications

Administrators can view, create, or delete notifications from **Administration**, **Configuration Settings: Notifications**. The **Notifications** option only appears when Event Manager is enabled and in the Available synchronized state.

NOTE
As a default tenant administrator, you can work in a real-user context to create a notification for a tenant administrator or tenant user. Log in as a tenant administrator or tenant user. The default tenant administrator can also administrate the tenant, and then create a tenant-scoped notification by proxying to the user.

Users can create email notifications by clicking the name of their user account in the upper-right corner, and then clicking **Manage Notifications**.

Traps Usage

The follow information describes traps usage information in DX NetOps Performance Management:

Get the SNMPengineID

The trap receiver (for example, DX NetOps Spectrum), using SNMPv3, uses the `SNMPengineID` to allow encrypted traps from a specific sender for decryption. Use the following REST endpoint to get the `SNMPengineID` :

URL: `http://<pc_host>:<port>/EventManager/webservice/notifications/engineId`

- **port** is the port for the Event Manager.
  Default: 8281

Method: GET

Return:

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>

<EngineID>

   <ID>
80:00:13:70:01:8a:2a:f8:41
</ID>

</EngineID>
```

The ID string is the `SNMPengineID` .

EventManager Format Usage

The EventManager MIB is supported for trap notifications. If needed, the MIB files can be found in:

```
InstallLocation/PerformanceCenter/PC/webapps/pc/mibs/netqos-em-mib
```

- ***InstallLocation***
  Is the directory where CA NetOps Portal was installed.

When the EventManager format choice is selected, the trap will be sent out with the following variables:

- **netQosEventId**
  Specifies an identifier that Event Manager assigned to the event.
- **netQoSEventType**
  Specifies the type of event.
- **netQoSEventCategory**
  Categorizes the event.
  Values: 0 Unknown, 1 Fault, 2 Config, 3 Accounting, 4 Performance, 5 Security
- **netQoSEventSeverity**
  Specifies the severity of the event.
  Values: 0 Normal, 1 Unknown, 2 Minor, 3 Major, 4 Critical, 5 Unavailable
- **netQoSEventDescription**
  Describes the event.
- **netQoSEventState**

Specifies the current state of the event. Each state has its own notification.
Values: 0 opened, 1 acknowledged, 2 closed, 3 cleared

- **netQoSEventOpenTime**
  Specifies the UTC timestamp (from the eventState timestamp).
- **netQoSEventMapURL**
  No value is available. The "" string will be sent.
- **netQoSEventDetailsURL**
  No value is available. The "" string will be sent.
- **netQoSEventAssociatedItemURL**
  Specifies the URL to the item web page.
- **netQoSEventItemName**
  Specifies the item name. There is one notification per item.
  Maximum length: 127 bytes
- **netQoSEventItemType**
  Specifies the item type.
  Maximum length: 32 bytes
- **netQoSEventItemSubtype**
  Specifies the item subtype.
  Maximum length: 32 bytes
- **netQoSEventItemIpAddress**
  Specifies an IP address for the item or an empty string.
- **netQoSEventPropertyName**
  Specifies one name set for each property. A PropertyName exists for each property in the event. (The properties vary by the event type.)
  Maximum length: 128 bytes
- **netQoSEventPropertyValue**
  Specifies the property value for the event. A PropertyValue exists for each property in the event. (The properties vary by the event type.)

nhLiveAlarm Format Usage

The nhLiveAlarm MIB is supported for trap notifications. If needed, the MIB files can be found in:

```
InstallLocation/PerformanceCenter/PC/webapps/pc/mibs/concord-diagmon.mib
```

- ***InstallLocation***
  Is the directory where CA NetOps Portal was installed.

When using the nhLiveAlarm format for trap notifications, be aware of the following restrictions. Many of the variable values described by the CA eHealth trap MIB have changed from integrations with earlier versions of CA PC.

- **nhServerIp**
  No value is available. The "" string is sent.
- **nhServerName**
  No value is available. The "" string is sent.
- **nhServerPort**
  No value is available. The "" string is sent.
- **nhElementIp**
  Specifies the IP address of the item or "" if no IP address exists.
- **nhElementName**
  Specifies the item name.
- **nhElementId**

Specifies the item CA PC ID (global ID).
- **nhStartTime**
  Specifies the timestamp from the event.
- **nhDisplayStr**
  Specifies the value for the MaxThresholdValue variable from the event.
- **nhGroup**
  No value is available. The "" string is sent.
- **nhGroupList**
  No value is available. The "" string is sent.
- **nhExceptionType**
  No value is available. The "" string is sent.
- **nhVariable**
  Specifies variables in the event profile rule.
- **nhSeverity**
  Specifies the severity of the event.
- **nhOpenViewSeverity**
  No value is available. The "" string is sent.
- **nhProfile**
  Specifies the event profile name.
- **nhExceptionId**
  Specifies the event ID.
- **nhTechType**
  No value is available. The "" string is sent.
- **nhEventCarrier**
  No value is available. The "" string is sent.
- **nhElementAlias**
  No value is available. The "" string is sent.
- **nhComponent**
  No value is available. The "" string is sent.
- **nhDescription**
  Contains the event description.
- **nhAlarmOccurId**
  Specifies the alarm ID.
- **profileId**
  Specifies the event profile ID.
- **nhElementBaseType**
  Specifies the item type.

Administrating

Administrating includes information about monitoring and maintaining the system components, managing users, roles, and tenants, and system configuration options. This section also includes information about the APIs for the product.

For information about how to configure data collection, see Building.

Onboard a New Product Operator

As an administrator, you want to give a coworker with a unique role in the IT organization permissions to use the product.

The administrator creates a custom user account for each person who uses the product. Usually, predefined menus and roles are assigned to the new user accounts. However, to create a new user with a unique organizational role, custom menus, and roles are also required.

Custom user accounts are best deployed in a well-planned system that includes custom groups. Custom groups are assigned as permissions to let product operators view only the data, menus, and dashboards that they use to perform their daily tasks. Before you onboard a new product operator, set up custom groups for your organization.

Log in to Test the New User Account

To test a new user account, log in to the account. The Proxy feature lets you test user accounts while logged in as the administrator. However, user account proxying does not let you test roles or role rights.

Follow these steps:

1. Log in using the username and password that you assigned to the new user account.
2. Click the Inventory tab.
3. Click item links to verify that the user can see monitored items in the inventory.
4. Select a few dashboards, and verify that the views are populated with data.
5. Test your ability to select a new group or item context for a dashboard by taking the following steps:
   a. Click the [change] link above the time period selectors.
      A dialog opens with filtering options.
   b. Click to select another managed item.
   c. Expand nodes in the Groups tree to select a group context.
   d. Click OK.
6. Verify that the user can see data from the new item or group.
7. Test any special role rights that you assigned to the user, such as saving changes to views.
8. Log out when you are satisfied that the user account meets the requirements of the intended operator.

You are now ready to contact the new product operator and provide the username and password.

Set up a Unique Operator

As an administrator, you want to give a coworker in the IT organization permissions to use the product. You want to create a custom menu for this new operator to reflect this person's organizational responsibilities.

Onboarding a unique operator involves creating a menu and populating the menu with either predefined or custom dashboards. You also create a custom role for the new user, and assign the role to a new user account.

Finally, you log in to the new user account to test account permissions and determine whether adjustments are required.

Add a Menu for a New Product Operator

Custom menus let you organize dashboards and make them available to users with selected roles. Administrators and designers can create custom menus, and can select dashboards for each menu. A custom menu is available to any whose role to includes the menu.

Create a Custom Dashboard for a New Operator

Users with the necessary role right can create a custom dashboard. They can select views for the dashboard and their location on the page. They can also select the menus in which the dashboard appears so that it can be shared with other operators.

The views in a custom dashboard can also be customized. For example, you can select a group context, or you can specify a custom view title.

You can customize the predefined dashboard pages, or you can add new dashboards. You can select the views and data context for custom dashboards.

Create a Dashboard

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Click the **Dashboards** tab.
   A list of available dashboards appears. Each view on the page corresponds to a menu.
3. Click **Add Dashboard** next to the menu where you want the new dashboard to appear.
   The Add Dashboard page opens.
4. Complete the following fields:
   - **Dashboard Menu**
     The menu where you want the dashboard to appear.
   - **Menu Item**
     The name of the dashboard as you want it to appear in the menu.
   - **Dashboard Title**
     The name that you want to appear at the top of the new dashboard.
5. (Optional) Select a layout template for the dashboard.
   Each layout treats the page as a table with rows and columns for views. The Layout buttons indicate the number of views in each column and row on the page. We recommend selecting a layout before adding views.
6. (Optional) Apply a group or context filter to the views. Views with a selected context always display data for that context; they do not inherit the context of the dashboard.
   For example, if you set the context filter to Group A and add a view to the dashboard, that view will always display data for Group A, even after you change the dashboard context to Group B.

   NOTE

   By default, the context is Summary. With the Summary context setting, the available views display summary data for the current group context of the dashboard. The Summary setting does not require you to select a specific group or item. Summary views dynamically update the context when you change the context of the page.

Select a Context

Follow these steps:

1. Click **Select Context**.
2. Select a Context Type, such as a type of managed item. Select **Group** to see the Groups tree.
   By default, the list is filtered to show only items and item types to which you have access. For example, if you are not monitoring any servers, the Context Type list does not include the Servers option. Select **Show All Context Types** to see all context options.
3. Select a specific context item or a group context.
4. Click **OK**.
   The new context filter is saved.
   - Expand the categories of views in the left pane. Select the 'Display suppressed views in list' option only if you want to see views from data sources that you have not registered. This check box disables View Suppression.
   - Select a view that you want to add to the page from one of the expanded lists.

Select a View

Follow these steps:

1. Click and drag a view to the page layout, and drop it where you want it to appear.
2. (Optional) Click **Revert** to discard your changes.
   The layout returns to the settings that you last saved.
3. Click **Save**.
   The dashboard is saved, and is added to the selected menu.
   The dashboard page refreshes to reflect your changes. The changes persist across login sessions.

   NOTE

   : The maximum number of views per dashboard is 25.

Edit the Menu to Add the New Dashboard

Administrators and designers can customize menus to meet the requirements of each operator. When you edit custom or factory menus, you can add new dashboards, remove dashboards, and change the order of the dashboards in the menu.

Add a Custom Role

You can add a custom user role for each product operator. The user account roles let product operators perform their job responsibilities. Assign new roles to any menus that you have customized for the intended product operator. Roles are disabled until they are assigned to user accounts.

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Select **Administration**, **User Settings**, and click **Roles**.
   The Manage Roles page displays the current list of roles.
3. Click **New**.
   The Add Role dialog opens.
4. Enter the required information and make selections in the fields provided. The default value for Role Status is Enabled.
   A table indicates that no role rights have been selected for the role.
5. Select **Menu Set**, and click **Edit**.
   The Edit Role dialog opens.
6. Select the new menu in the **Available Rights** list, and click the right arrow.
   The menu moves to the **Selected Rights** list.
7. Select **NetOps Portal** , and click **Edit**.
   The Edit Role Rights dialog opens. Role rights that are listed under **Available Rights** can be added to the role.
8. Click an item on the left that you want to add to the role, and then click the right arrow.
   Use Shift + Click or Ctrl + Click to select multiple items in the list.
   The selected item moves from the **Available Rights** list to the **Selected Rights** list.
9. (Optional) Use the Up and Down arrows to move items around in the list. The order of role rights determines their priority when rights overlap.
10. Click **Save**.
    The Add Role page appears.
11. Click **Save**.
    The new role is created and appears in the Role List.

Add a Custom User Account

Add a user account for each operator. For security purposes, do not share user accounts with multiple people.

NOTE
You can create user accounts with basic parameters, and then edit them as a separate step to assign permissions. This workflow lets you carefully consider the groups that each operator must access.

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Navigate to the Manage Users page.
3. Click New.
   The Add User wizard opens.
4. Specify information for the account parameters.
   The Authentication Type field identifies the authentication method that applies to this user account. The method must match Single Sign-On configuration. Select one of the following options:
   – **NetOps Portal:** The default authentication scheme
   – **External:** A third-party authentication scheme, such as LDAP or SAML
5. Advance the wizard to the Permission Groups page.
6. Assign permissions to the user account.
7. Advance the wizard to the Product Privileges pages.
8. Click Save.
   The new user account appears on the Manage Users page.

Assign Permissions to the User Account

Individual operators require data access permissions to monitor data, which are based on groups. You can assign access permissions according to your plan for custom groups.

NOTE

Do not assign the 'Collections' group as part of a user's access permissions. Do not use this group for reporting.

To assign permissions, edit user accounts. Make sure that all operators see only the data that they require for their role.

Follow these steps:

1. Log in as a user with administrative privileges.
2. Select **Administration**, **User Settings**, and click **Users**.
   The Manage Users page opens.
3. Select a user account that you want to change, and click **Edit**.
   The Add User wizard opens.
4. Click **Access Permissions**.
   The Access Permissions page appears.
5. Add permission groups to the user account, as follows:
   a. Expand the groups in the **Available** groups tree in the left pane.
   b. Select a group or subgroup.
   c. Click the right arrow button to add it to **Selected** groups tree on the right.
6. Select a group from the drop-down list.
   By default, My Assigned Groups is selected.
   When the user logs in, data from the default group appears in dashboards by default.
7. Click **Save**.

Manage Data Sources

Data sources are the products and components that provide performance and configuration data.

The Data Aggregator data source administration is integrated into NetOps Portal. CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor collect and aggregate data independently. However, once these data sources are registered in NetOps Portal, DX NetOps Performance Management controls many administrative functions. DX NetOps Performance Management does not administer DX NetOps Spectrum.

Synchronization status is included in the table on the Manage Data Sources page. Failures and detailed statuses are included in the Data Source Log.

The System Health icon at the top of the page indicates when a synchronization failure occurs. To view more information about the failure, click the icon. Review the information in the Global Synchronization Status section and the Data Sources section. For more information, see Synchronize Data Sources.

Maximum Data Source Instances Supported

The following limits apply to the number of data sources for each type that you can register:

- 10 CA Application Delivery Analysis data sources
- 10 Network Flow Analysis data sources
- 4 CA Unified Communications Monitor data sources
- 1 CA Application Performance Management data source
- 1 CA Catalyst Connector data source
- 1 Event Manager data source
- 1 DX NetOps Spectrum data source
- 1 CA Business Intelligence data source

Configuration Data from Data Sources

For CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor, the monitoring parameters, user accounts, and other definitions are shared with DX NetOps Performance Management and other registered data sources after registration.

During registration, DX NetOps Performance Management imports shared monitoring data, such as user accounts, SNMP profiles, and other administrative data from the data sources. DX NetOps Performance Management resolves conflicts and eliminates duplication. At the next synchronization, DX NetOps Performance Management sends updated administrative data to registered data sources.

The registration process includes a "binding" step that prevents further modifications to shared administrative data in individual data sources. As a result, the data source administrator can only modify shared monitoring parameters after registration.

For user accounts and SNMP profiles, NetOps Portal uses the following processes to handle conflicts or duplicates:

Redundant User Accounts

A user can have two different accounts with the same name in different data source products. The resulting user account retains the password of the first account that is synchronized. The unique role rights and permissions from other accounts are added to the account as you register more data sources.

While multiple user accounts sometimes share a username in different data sources, some account parameters differ. Manual editing is required in this situation.

Example

A user who is named Robert uses Network Flow Analysis, and a different user, also named Robert, uses CA Application Delivery Analysis. In this case, DX NetOps Performance Management creates one account that is named Robert. The role

rights and permissions from both data sources are merged into a single new account. To preserve the distinct role rights of the two accounts, create an account with a unique username.

Redundant SNMP Profiles

Registering a data source that contains SNMP profile definitions automatically adds the profiles to DX NetOps Performance Management. The profiles are distributed to the other registered data sources during the next synchronization.

When a data source is added, DX NetOps Performance Management minimizes duplication of SNMP profiles by comparing the following values to existing profiles:

- User for SNMPv3
- Community String for SNMPv1 and SNMPv2

If the compared values match, the SNMP profile with the most recent timestamp is retained.

If the compared values do not match, DX NetOps Performance Management appends a number to duplicate profile names. For example, the first profile that is named Boston remains Boston. The second profile becomes Boston(1).

Synchronization with DX NetOps Spectrum

After an integration with DX NetOps Spectrum is configured, consider the following guideline whenever you restore the SpectroSERVER or OneClick database:

- If DX NetOps Spectrum exists as a data source in NetOps Portal, whenever you restore another data source, restart Tomcat.

  WARNING
  You must follow the correct procedures to enable data to synchronize correctly between DX NetOps Spectrum and NetOps Portal. For the correct procedures, see Integrate CA Spectrum with CA Performance Management .

Configure a Data Source

NetOps Portal represents each source of information as a registered data source. To load performance data, configure the data sources.

These procedures require the Administrator role:

Register a Data Source

To view collected data on the NetOps Portal dashboards, register your data sources.

Follow these steps:

1. Go to **Administration**, **Data Sources**, **Data Sources**.
2. Click **Add**.
3. Select the type of data source from the **Source Type** list.
   This list includes all possible data sources. The list does not show data sources that already have reached the registration limit.
4. (Optional) To delay synchronization with the data source, select **Disabled** for the **Status**.
5. Specify the hostname and port for the data source:
   - For the Data Aggregator data source, specify the IP address or hostname of the Data Aggregator host.
   - For other data sources, specify the IP address or hostname of the management console.
6. Select the communication protocol. For secure communication, select **https**.

NOTE

: Before you select HTTPS, verify that your system is configured for SSL. Single Sign-On supports secure communications between NetOps Portal and the data source products. For more information, see Single Sign-On .

7. (Optional) Specify a display name for the data source.
   By default, the data source type and the hostname are combined to create the display name. You can specify another name here. For example, instead of NetworkFlowAnalysis@192.168.10.22, you could name the data source NFA_NewYork.
8. (Optional) Select **Contribute inventory to the Data Aggregator**. If selected, all new data source inventory contributes to the Data Aggregator. If unselected, the existing inventory remains the same, and no new data source inventory contributes to the Data Aggregator.
   Automatic synchronization includes only devices that are discovered after you select this option. To discover previously discovered devices, perform a full synchronization of the Data Aggregator. DX NetOps Performance Management creates a discovery profile that includes the IP addresses of the devices. This discovery profile attempts discovery once per day.
9. (Optional) If the Web Console is on a different system than the data source, clear the **Same as data source** check box. Specify another hostname and port for the data source console.

   NOTE
   Use this parameter in cases when network address translation is deployed.
10. (Data Aggregator only) Configure the Data Aggregator settings:
    – **Synchronize component items that are not currently present on the monitored device**
    When the Data Aggregator finds a device component that is no longer present in the environment, that status of the component is set to **Not Present**. By default, the Data Aggregator does not synchronize these items because data can no longer be collected for the item. Historical data that has not reached the data retention limit is still available for these items.

      WARNING

      If the properties of an active component match the identifying properties of the not present component, the components are indistinguishable. Data from the old component might contribute to group based dashboards instead of data from the active component. Enable this feature only under the following circumstances:

      - You want to report on historical data for items that are no longer present in the environment.
      - You can ensure that the not present item does not conflict with an actively monitored item.
      - You can identify the not present items so that you can exclude the items from groups.
11. (DX NetOps Spectrum only) To enable DX NetOps Spectrum to control the life cycle state of items in DX NetOps Performance Management, select **Synchronize device life cycle state from Spectrum**. For more information, see Manage Device Life Cycles.
12. Click **Save**.
    If the data source is enabled, data appears in NetOps Portal after the next synchronization.

Test Data Source Connections

If data source registration does not complete successfully, use the test feature to determine the reason for the failure. The test validates version compatibility, and verifies that the data source is not registered with a different instance of the NetOps Portal.

To confirm the proper registration and connection of a data source, select the data source, and click **Test** .

If the test fails, verify that the server name or IP address is accurate for the source type. For more information, see Data Source Test Fails.

Edit a Data Source

When you edit a data source, changes apply to the system after the next synchronization.

Delete a Data Source

WARNING

When you delete a data source, the deletion does not remove everything from the system. If you register the same data source, unexpected behavior might occur. To remove a data source temporarily, edit the data source, and set the status to disabled.

A data source that you delete can be registered to another NetOps Portal instance.

Only users with the Administrator role and the Delete Data Sources role right can delete a data source. This role right is not granted by default. To delete a data source, assign this role right to the Administrator role.

NOTE

If View Suppression is enabled, views that are associated with the deleted data source are suppressed. As a result, deleting a data source might cause some menus and dashboards to become unavailable. A dashboard, context tab, or custom menu must contain at least one view that is not suppressed. Otherwise, the menu item does not appear in NetOps Portal.

Synchronize Data Sources

NetOps Portal periodically synchronizes with registered data sources to send configuration information and to retrieve data. NetOps Portal incrementally replicates information to the data sources. Data sources receive group configuration, authentication settings, SNMP profiles, users, and roles. The data sources send inventory to NetOps Portal. NetOps Portal uses the inventory data to request performance metrics from the data sources.

To determine whether items from multiple data sources are the same item, NetOps Portal runs global synchronization. During global synchronization, NetOps Portal reconciles devices and interfaces.

Devices are reconciled in the following scenarios:

NOTE

The primary IP address is the IP address that DX NetOps Performance Management uses to monitor a device. When a device is first discovered with the IP ranges discovery profile, DX NetOps Performance Management tries to use the IP address that maps to the hostname as the primary IP address.

- The primary IP addresses match.
- The name of a device without an IP address matches another device regardless of whether the other device has an IP address.
- The primary IP address for a new device is in the IP address list of an existing device, and the primary IP address of the existing device is in the IP address list of the new device.

After devices are consolidated, interfaces are reconciled in the following scenario:

- The parent device and the `ifIndex` match.

Reconciled items are a single item in NetOps Portal. If the reconciled item has different properties in different data sources, NetOps Portal uses the value from the data source with the highest priority. The Data Aggregator has the highest priority by default. First, the item type priority determines priority. Then the data source priority determines priority. Last, the data source assigned `SourceID` determines priority.

Incremental synchronization occurs 5 minutes after the previous synchronization completes. Incremental synchronization also occurs each time an SNMP profile is created. Only the records that are new or changed as of the last synchronization timestamp are included. The Last Polled On column shows the completion time of the last successful

synchronization for each data source. If this timestamp shows a time more than 5-10 minutes, synchronization for that data source has not completed successfully. Changes might not be reflected in the system.

A full synchronization occurs when a data source is first registered to NetOps Portal. NetOps Portal receives information about all managed items in that data source. This type of synchronization does not recur automatically. After the initial data source registration, this type of synchronization is not typically required.

These procedures require the Administrator role:

Synchronize a Data Source

Synchronization occurs regularly every 5 minutes with all registered data sources. To propagate a configuration change immediately, manually run synchronization. For example, if you add a group, you can send the change to the data sources immediately. If synchronization is in progress, the process is not interrupted and new changes are not applied until the next synchronization cycle. A new synchronization begins immediately once the in-progress synchronization is complete.

WARNING

Initiate full synchronization, only when requested by CA Support.

Follow these steps:

1. Go to **Administration**, **Data Sources**, **Data Sources**.
2. Select the data source.
3. Click **Resync**.
4. (Optional) Select **Perform a full resynchronization**.
5. In the dialog, click **Resync**.NetOps Portal collects inventory data and sends configuration changes to the selected data source. Only the records that are new as of the last synchronization timestamp are included.

View Synchronization Status

Synchronization status is included in the table on the Manage Data Sources page. Failures and detailed statuses are included in the Data Source Log.

The System Health icon at the top of the page indicates when a synchronization failure occurs. To view more information about the failure, click the icon. Review the information in the Global Synchronization Status section and the Data Sources section.

WARNING
If the Last Run Status in the Global Synchronization Status section displays Failed, contact CA Support.

The Data Sources section displays the status of all registered data sources. The following messages describe possible data source status conditions:

- **Awaiting Poll**
  The data source has never been contacted, and is waiting for the Device Manager to poll it. The data source is polled quickly unless the Device Manager is busy performing another poll.
- **Awaiting Bind**
  Inventory data has been retrieved from the data source. The data source is waiting for NetOps Portal to transmit configuration information, and to lock corresponding administrative features.
- **Available**
  The data source is available for reporting. Registration has succeeded.
- **Polling**
  The Device Manager is in the process of retrieving inventory data.
- **Registering**
  The Device Manager is in the process of registering the data source.
- **Binding**

The device manager is locking the users, roles, and groups that are defined in the data source. For some data sources, binding prevents further changes to configuration within the data source.

- **Synchronizing**
  The device manager is in the process of synchronizing with the data source.
- **Polling Failure**
  A failure occurred during polling.
- **Synchronization Failure**
  A failure occurred during synchronization.
- **Registration Failure**
  A failure occurred during registration.
- **Bind Failure**
  A failure occurred during the binding of users, groups, and roles.
- **Unable to Contact**
  NetOps Portal is unable to contact the data source due to communication problems.
- **Version Incompatible**
  The version of the data source is not compatible with NetOps Portal.
- **Requires Upgrade**
  The data source requires a software upgrade. Contact CA Support.
- **Requires Registration**
  The data source is waiting for registration.
- **Requires Migration**
  The data source requires migration and is waiting for the Device Manager.
- **Under Maintenance**
  The data source is under maintenance.
- **Disabled**
  The administrator has disabled the data source.

View the Data Source Log

Only the initial synchronization and any failures that occur during subsequent synchronizations are recorded in the Data Source Log. To determine when the last synchronization occurred, view the Last Polled On date on the Manage Data Sources page.

Use the Data Source Log to investigate suspected errors with the data source synchronization. Use this information to find events in the device manager logs. For more information, see Logs.

Follow these steps:

1. Go to **Administration**, **Data Sources**, **Data Sources**.
2. Select the data source.
3. Click **Log**.
   The Data Source Log page opens. The log shows only events that are related to synchronization for the selected data source.

Manage Roles and User Accounts

Manage user access with rights assigned to roles. Then refine access by assigning roles, access permissions, administer groups, and product privileges to each specific user account.

Roles

Roles are assigned to user accounts to control user access to the product features and dashboard pages. Based on job functions, roles grant administrative access to product configuration using role rights. Roles let users access data and product features that they require to perform their duties. Roles restrict access to features that they do not require.

Roles are shared with registered data sources. Roles determine what users can access in the data source interface when following a drilldown path to a data source. When you add a user, you select a role for the user account. You can edit roles to include new role rights. You can also disable roles to prevent users with those role assignments from using NetOps Portal. A set of predefined, or "factory," roles help you to add new users quickly while determining the required customizations.

User Accounts

Custom user accounts let operators view the data, menus, and dashboards that they require to perform their daily tasks. Operators with the administrator role rights can create user accounts and can manage existing accounts. Tenant administrators can manage user accounts only for their own tenant.

Before you create or edit user accounts, create the custom groups and roles that you require. Groups and roles are among the required parameters for each user account.

Create and Configure a User Account

Place managed items in custom groups before creating user accounts. Assign custom groups to user accounts as "permission groups," which determine the data that each user can view. You can grant selected ownership of a single branch of the Groups tree to a user account with administered groups.

Create any custom roles that you require before creating user accounts. Typically, the predefined roles provide starting points for customization.

We recommend the following process for creating a user account:

1. Log in as an administrator user.
2. Confirm that the appropriate groups exist, or create them if necessary.

   NOTE
   User account parameters include all the groups that the user can *view.* They also include one or more groups that the user can *manage*. The Administer Groups role right lets users without full administrative rights manage a specific branch of the Groups tree.
3. Confirm that the appropriate roles exist, or create them if necessary.
4. Add a user, and specify its user information.
5. Assign a role.
6. Assign permission groups.

   NOTE
   New user accounts have access to no groups by default. Their dashboards contain no data until you assign at least one permission group.
7. Assign group ownership so that the user can create and modify groups in one branch of the Groups tree.

   NOTE
   Only user accounts with the Administer Groups role right are eligible for this selective group ownership.
8. Assign product privileges to grant access to the data sources you have registered.
9. Test the user account by temporarily proxying it.

New User Account Example

To understand user account parameters, consider an example. A Data Center Manager at your company is responsible for data centers, staff, and infrastructure in the Southwest region.

Follow these steps:

1. Create a group named 'Southwest'.
2. Add managed items to this group.
   Include all the routers, switches, applications, and servers that comprise the Southwest region.
3. Create a custom role that includes the product features and menus that the Data Center Manager requires.
   The Data Center Manager is not a network engineer. This user does not drill in to detailed data in the data sources. To manage the team, this user wants to create dashboards and assign them to the roles of the team members.
   This user only wants to see menus containing high-level Management and Operations dashboards.
4. Add the user account.
5. When adding the user account, select the following items:
   - The custom 'Data Center Manager' role
   - The permission groups containing the managed items within the Southwest group that the Data Center Manager wants to monitor.

Role Rights

Role rights determine the types of views that users can see, the administrative features that they can change, and whether they can export data.

Administrators can grant rights to users by editing their role. The Edit Role dialog lists role rights that are currently assigned to roles. The Manage Users page shows the role that is assigned to each user.

Role rights also include menus. You can grant access to selected custom and predefined menus by editing role rights.

> **NOTE**
>
> Do not remove the administrative role rights from your primary administrator account. Administrative access to the console is required.

Administrative Role Rights

The following role rights give users access to administrative features. Limit the number of users with these role rights for increased security.

> **WARNING**
>
> Several role rights are limited to the Administrator role. Copying the Administrator role does not give the same role rights to the new role.

- **Create DA Threshold Profiles**
  Lets users define and configure threshold profiles. Users can only edit the profiles that they created. Unlike the Administer DA Threshold Profiles role right, this role right does not allow users to configure profiles that other users created, or to transfer ownership of profiles.
- **Administer Data Sources**
  Lets users register new data sources, test data source connections, view data source status, change data source parameters, and remove data sources. Also lets users view the data source log.
- **Administer Groups Owned by You**
  Lets users without full administrative rights manage a specific branch of the Groups tree. With this role right, users can create, change, and delete groups only in the specified branch. The Administrator role and the Tenant Administrator role have this role right by default, allowing administration of All Groups and the Tenant root group, respectively.

Only the Administrator and the owner (creator) of the groups in the administered branch can delete and modify groups in that branch. When an administered group is a child of another group, the administered group is deleted when the parent group is deleted. Administered groups are not deleted when the user account of the owner is deleted.

NOTE

Assign this role right to users who should not have full administrator rights to the Groups tree, but instead require limited, branch-specific administrator rights. In some organizations, this user is a 'power user' or a 'super user.'

Do not confuse the 'Administer Groups Owned by You' role right with the 'My Custom Groups' feature, which is simply a tool that lets users organize the groups to which an administrator has granted them access. 'My Custom Groups' does not provide administrative rights to a specific branch of the Groups tree.

- **Administer Groups Owned by You and Others**
  Lets users without full administrative rights manage the branch of the Groups tree that they have the rights to administer. With this role right, users can create, change, and delete groups in the branch that they or other users created. The Administrator role and the Tenant Administrator role have this role right by default, allowing administration of All Groups and the Tenant root group, respectively.
- **Administer IP Domains**
  Lets the user manage IP domains.
- **Administer Life Cycle**
  Lets the user change the state of devices.
- **Administer Maintenance Indicators**
  Lets users manage maintenance indicators.
- **Administer Menus**
  Lets users create, edit, and delete menus. This role right is required to assign new dashboards to menus. To assign menus to user accounts, the 'Administer Roles' role right is required.
- **Administer Roles**
  Lets users create, edit, and delete user account roles. Lets users assign new menus to user accounts by editing roles.
- **Administer Shared Dashboards**
  Lets users manage their own dashboards and the dashboards of other users. Users with this role right can edit an existing dashboard page and can save changes that are visible to other users.
  – To create a dashboard, the 'Create a Dashboard' role right is required.
  – To assign a dashboard to a menu, the 'Administer Menus' role right is required.
- **Administer SNMP Profiles**
  Lets the user manage SNMP profiles.
- **Administer Tenants**
  Grants users administrative rights over the tenants that are selected in the user wizard. Users with this role have the rights to administer certain tenants, but have limited access to the default tenant. This role is only used in multi-tenant environments. Tenant administration includes the ability to manage:
  – Users
  – Menus
  – Dashboards
  – Views
- **Administer Users**
  Lets users create, edit, and delete user accounts. Lets users assign new roles to user accounts.
- **Create DA Threshold Profiles**
  Lets users define and configure threshold profiles. Users can only edit the profiles that they created. Unlike the Administer DA Threshold Profiles role right, this role right does not allow users to configure profiles that other users created, or to transfer ownership of profiles.
- **Create a Dashboard**

Lets users create new dashboards and populate them with views. Other users cannot see these dashboards. To create dashboards for other users, the 'Administer Shared Dashboards' role right is required.

- **Create Notifications**
  Lets users configure email notifications using the Create/Edit Notifications wizard from the Administration, Notifications menu. Notifications are not supported for all data sources.

  NOTE

  To create notifications, the user also requires access to the Event Manager data source.
- **Create On-Demand Report Templates**
  Lets users create, edit, and delete on-demand report templates. This role right is always assigned together with the Run On-Demand Report Templates right. Users can save on-demand report templates at the user level, which allows only the user to view the templates.
- **Save On-Demand Report Templates for All Users**
  Lets the user save On-Demand report templates that are visible to all users. This role right is always assigned together with the Create On-Demand Report Templates and Run On-Demand Report Templates right.
- **Delete Data Sources**
  Lets a user with the Administrator role delete (unregister) a data source. This role right is not assigned to any user or role by default, and can only be assigned to the Administrator role.
- **Drill from Views into DA Admin Page**
  Lets a user access the Data Aggregator administrator page directly from a page that is associated with the Data Aggregator. For this role right to work properly, the user must also have the Administer Data Sources right. The ability to access the Data Aggregator administrator page is limited to views for Data Aggregator devices, interfaces, and components. Selecting a Data Aggregator interface or component causes the administrator page for the associated parent device to appear when clicking the gear button and Device Admin.
- **Edit Context Pages**
  Lets users edit, delete, add, or reorder tabs on context pages. A context is a managed item, such as a device, router, switch, or an interface. A context page resembles a dashboard with a fixed context. Only the Designer and Administrator roles have this right by default.
- **Modify Device Alias**
  Lets users modify the alias property for devices.
- **Modify Interface Alias**
  Lets users modify the alias property for interfaces.
- **Modify Device IP Address**
  Lets users modify the IP address property for devices.
- **Modify Interface Speed Overrides**
  Lets users modify the speed override properties for interfaces.
- **Proxy Users**
  Lets users log in as a selected user to view and verify user account settings.
- **Save Changes to Shared Views**
  Lets users save edits that they have made to the views on a shared page. Other users who can see these views can see the changes if they are applied as a 'Default for All Users'. The changes can also be saved to the user account so that they persist after logout.
- **SNMP Clear Text**
  Lets users troubleshoot SNMP profiles and view security information that is typically masked in clear text.

Role Rights for Dashboard and View Access

The following role rights give users access to reporting features. Most user accounts require these rights.

- **Drill into Data Sources**
  Lets users navigate to the data source interface during drilldown to see detailed data from a selected item.
- **Drill into Views**

Lets users drill in to a context view to see detailed data from a selected item. This role right is required to enable the 'Edit Context Pages' role right.

- **Edit Shared Views**
  Lets users edit the views on a shared page. Other users can see these views, but cannot see the changes. The changes can only be applied to the current login session or saved to the current user account.
- **Edit Time Zone**
  Lets users edit their own time zone setting for data that are displayed in dashboards.
- **Run On-Demand Report Templates**
  Lets users run on-demand report templates. This role right is always given together with the Create On-Demand Report Templates right. However, if the Create On-Demand Report Templates right is taken away, users do not lose the ability to edit and delete their on-demand dashboards. Users who have this right without the Create On-Demand Templates right can run on-demand report templates on the tenant level.
- **Run Dashboards at Higher Resolution**
  Lets users select higher resolutions when viewing dashboards. No roles are given this role right by default. Users with this role right can set and save the resolution to higher values than are typically allowed when reporting for longer time ranges. When users save the higher resolution at the tenant level, it is only visible to users with this role right. To view the current report resolution settings, select **Administration**, **Report Resolution**. The resolution settings cannot be modified on the Report Resolution page.
  The following resolutions apply when a user has the Run Dashboards at Higher Resolution role right:
  – **As Polled Data** Less than, or equal to, 31 days.
  – **Hourly Roll-Up** More than 31 days.
  – **Daily Roll-Up** More than 3 months.
  The following resolutions apply to a user without the Run Dashboards at Higher Resolution role right:
  – **As Polled Data** Less than 24 hours.
  – **Hourly Roll-Up** Less than 30 days, and more than, or equal to, 24 hours.
  – **Daily Roll-Up** More than, or equal to, 30 days.
- **View Conversations**
  Lets users see specific client conversations.
- **View Groups Change Log**
  Lets users see the table view that shows changes that are made to groups.
- **View Hosts**
  Lets users see specific client host information.
- **View Item Display Name or Name Alias**
  Lets users see the display names or the aliases for items.

  NOTE
  Users who are given this role right can select the name that appears in their dashboards and views in the My Settings, Display Settings menu item.
- **View Item Name Alias Only**
  Lets users see only the aliases for items.
- **View Inventory and Search**
  Determines whether users can access the Inventory tab and Search field to find items.
- **View Protocols**
  Lets users view protocol information, where available.
- **View System Health Dashboards**
  Lets users view system health dashboards that show information about the performance of DX NetOps Performance Management.
- **View ToS**
  Lets users view the Type of Service information in applicable views.

Role Rights to Export and Print

The following role rights allow users to export dashboard data in various formats:

- **Export to CSV**
  Lets users export the contents of a selected view to a file in comma-separated values (CSV) format.
- **Generate URLs for views**
  Lets users share views externally with a URL.
- **Print a Dashboard**
  Lets users export a dashboard page as a PDF, and to send it to a selected printer. This role right also lets users export a dashboard page to a CSV file.
- **Send Reports by Email**
  Lets users export dashboards as reports, and to send them to other users in email messages from the console.
- **Send Reports on a Schedule**
  Lets users set up schedules to export dashboards as reports, and to send them by email on a recurring basis automatically.

  NOTE
  This right also requires the 'Send Reports by Email' role right.

Data Source Role Rights

Each registered data source has its own set of roles with unique rights that let users access features and data within that interface. Administrators can assign rights for a role within that data source. These data source rights apply when users follow a drilldown path from a data view to that particular data source. However, any rights that are granted in this manner are specific to a data source instance. For example, if more than one CA Application Delivery Analysis (CA ADA) data source is registered, the rights for each management console are managed separately.

For example, an administrator can grant the right to generate reports in a CA Network Flow Analysis (CA NFA) data source, but withhold the right to edit dashboards in CA NetOps Portal. The individual data source Administrator Guides provide detailed information about the application of role rights.

Individual data source administrators can create user accounts and grant users role rights to access features within that data source. After registration, those rights are synchronized with CA NetOps Portal. The rights are then displayed in NetOps Portal when data source administrators edit a role.

NOTE

Role rights to individual data sources are distinct from rights to access DX NetOps Performance Management features, but they frequently have the same names.

Data Aggregator Role Rights

- **Drill from Views into DA Admin Page**
  Drill down from Data Aggregator views to the Monitored Devices Admin page to troubleshoot a view that does not display data.
- **Administer Tenants**
  Administer tenants, including user accounts, discover and delete devices for Data Aggregator.
- **Administer DA Threshold Profiles**
  Administer Data Aggregator threshold profiles, including creating threshold profiles, editing any threshold profiles, and changing the ownership of all threshold profiles.
- **Create DA Threshold Profiles**
  Create Data Aggregator threshold profiles, where you can create and manage event profiles. Event profiles contain event rules, and are associated with groups. You can create reports on the events that are generated with these profiles. This role allows you to create threshold profiles, edit your own profiles, and view all threshold profiles.

CA Network Flow Analysis Role Rights

The following role rights are applicable to the CA NFA (formerly CA ReporterAnalyzer) console:

- **View ToS**
  View Type of Service data
- **Manage Reports**
  Create, modify, delete, and execute reports
- **Run Reports**
  Execute defined reports
- **View Conversations**
  View conversation data
- **View Hosts**
  View host data
- **View Protocols**
  View protocol data

CA Application Delivery Analysis Role Rights

The following role rights are applicable to the CA ADA (formerly NetQoS SuperAgent) management console:

- **Engineering**
  Navigate the Engineering section and create Engineering reports
- **Operations**
  Navigate to the Operations section and create Operations reports
- **Management**
  Navigate the Management section and create Management reports
- **Incidents**
  Navigate the Incidents section and view Incidents reports
- **Investigations**
  Launch Investigations and drill into data from Investigations

Role rights do not give a CA ADA user:

- Permission to access the Administration page of the CA ADA management console.
  To give a user access to the Administration page, give the user the Administrator or Power User product privilege on the CA ADA data source.
- Access to actual report data in the CA ADA management console.
  To enable a user to see report data, assign the appropriate groups to the user.

CA UC Monitor Role Rights

The following role rights are applicable to the CA UC Monitor management console:

- **Call Details**
  Export call details to a CSV file
- **Call Performance**
  Access Call Performance reports
- **Call Quality and Volume**
  Access Call Quality and Volume reports
- **Call Watch**
  Access Call Watch reports
- **Call Watch Setup**

Set up and launch a Call Watch on a selected phone
- **Collector Incidents**
  Access Collector Incident reports
- **Incidents**
  Access Incident reports
- **Investigations**
  Access Investigation reports
- **Launch Investigation**
  Launch an investigation and view the resulting data
- **Phone Details**
  Access Phone Details reports
- **Quality**
  Access Quality reports
- **Trunk Groups**
  Access Trunk Group reports
- **Voice Interface**
  Access Voice Interface reports
- **Midstream Devices**
  Access midstream device and midstream legs reports

Manage Roles

NetOps Portal includes a set of predefined roles that you can assign to a custom user account. You can access summary information about these roles on the Manage Roles page.
For more information, see Role Rights and Data Source Role Rights.

Any custom roles that you create are also listed on this page.

If the predefined user roles that come with NetOps Portal do not fit your requirements, add custom roles. When you have finished creating a role, assign it to a user account as a separate step. Roles are inactive until they are assigned to user accounts. Only users with the 'Administer Users' and 'Administer Roles' role rights can assign roles to the user accounts. For more information, see Manage User Accounts.

You can view, edit, and delete predefined roles and also any custom roles previously added. You can also manage the user accounts associated with a specific role.

Global administrators and users with the required role rights can modify both predefined and custom roles. Tenant administrators only have access to the roles associated with their tenant.

Add or Edit a User Role

You can add custom roles. Create the roles that each unique product operator requires to perform job responsibilities.

Custom roles work best within a system of custom groups. Custom groups let you precisely grant access to dashboards and product features while restricting access to sensitive data. The groups that you create to organize data can serve as “permission groups” when you set up user account permissions.

Follow these steps:

1. Hover over **Administration**, and click **User Settings: Roles**.
2. Click **New**, or select the role that you want to edit and click **Edit**.
3. Enter or edit the required information, and make selections in the provided fields:
   – **Name**

Maximum Characters: 45
- **Description**
- **Enable Role**
  Specify whether to make the role active. Enabling this setting gives users with this role the access granted by its role rights. A role can be disabled for security purposes. When a role is disabled, users who are assigned that role are no longer allowed to log in.

4. Select **Menu Set**, and click **Edit**.
   Move the desired menus from the **Available Menus** list to the **Selected Menus** list.
5. Order the menus in the **Selected Menus** list to determine their order on the **Dashboards** tab and click **OK**.
6. Select **NetOps Portal** , and click **Edit**.
7. Move the desired access rights from the **Available Rights** list to the **Selected Rights** list.
8. Order the role rights to determine their priority in cases where rights overlap and click **OK**.
9. Click **Save** or **Save and Add Another**.

Manage the Users Associated with a Role

Select a role and click **Users** to open the User List page, which is filtered to show only users who are assigned to the selected role. Then manage the users accounts associated with the selected role. Click **Roles** to return to the Manage Roles page. For more information, see Manage User Accounts.

Delete a Role

You can delete any custom role that you have created. The Administrator role cannot be deleted or disabled.

Before you delete a custom role, review the Users column to see whether any user accounts are using this role. Manage the users who are associated with the role to remove all associations with the role you want to delete.

Product Privilege

The user account role is used to grant or restrict user access, such as administration.

Individual data sources allocate product access differently. The 'product privilege' setting for data sources can be applied to create users with administrative capabilities. For example, a user who has no access to administration can have an Administrator product privilege to a specific instance of CA Network Flow Analysis (CA NFA). That user has full administrative privileges to that data source when following a drilldown path for a CA NFA managed item.

The following types of product privilege may be available in the data sources and synchronized to CA NetOps Portal:

- **Administrator**
  Performs all functions, including creating and editing SNMP profiles and other configuration.
- **Power User**
  Creates menus and dashboards, and edits and create roles.
- **User**
  Views menus and dashboards designated by an administrator or power user.
- **None**
  Has no access to a data source. This setting prevents the user from following a drilldown path from a view to the data source's user interface. By default, all users have this product privilege setting for all data sources.
  A user can be denied access to a particular data source while having access to others.

Administrators can customize a user’s access levels by selecting the appropriate role rights.

Coordinate the product privilege setting with the role rights settings. To follow a drilldown path to a data source, a user requires the appropriate role right and a product privilege for that data source.

The predefined administrator account, 'admin', has administrative privileges for any data sources that are registered. The predefined user account, 'user', has limited (user-level) privileges for registered data sources.

Data Source Product Privileges

Each registered data source has its own product privilege with unique privileges within that interface. Administrators can assign a product privilege to a data source. The data source product privilege applies when users follow a drilldown path from a data view to that particular data source. However, any privileges that are granted in this manner are specific to a data source instance. For example, if more than one CA Application Delivery Analysis (CA ADA) data source is registered, the product privileges for each management console are managed separately.

The default administrator account, admin, is locked to prevent changes to product privileges. This account is required to have Administrator privileges for all registered data sources. Selecting a group of accounts that includes the admin account prevents you from editing the product privileges for any of the selected accounts.

CA Application Delivery Analysis Product Privileges

The following list summarizes product privileges applicable to the CA ADA (formerly CA SuperAgent) management console:

A user must have product privileges on the CA ADA data source to log in to the management console. Product privileges also specify access to the Administration page:

- **User**
  Gives access to all pages of the management console, except the Administration page.
- **Administrator**
  Gives access to all pages of the management console, including the Administration page.
- **Power User**
  Gives user-level product privilege, and Show Me menu access to the SNMP Profiles, Network Devices, and Device Groups on the Administration page.

  NOTE

  If a user cannot log in to the management console user interface, verify that the user has been given a product privilege on the CA ADA data source.

CA Network Flow Analysis Product Privileges

A user must have product privileges for the CA Network Flow Analysis (NFA) data source to log in to the NFA console. Product privileges also determine whether a user can access the Administration page, and can perform certain functions:

- **Administrator**
  Gives access to the Administration page in the NFA console, and to all functions. Functions include creating and managing user accounts, roles, groups, SNMP profiles, and scheduling for reports.
- **Power User**
  Gives user-level access and any additional abilities that the Role setting grants. For CA NFA, the Power User privilege is equivalent to the Administrator privilege.
- **User**
  Gives access to Top Interfaces reports and Interface Utilization reports on the Enterprise Overview page.
  A User with the appropriate Permission Group settings also has access to the following reports:
  - Top Hosts and Top Protocols reports on the Enterprise Overview page, if the user also has access to All Groups
  - Interfaces page reports for the interfaces that are accessible to the user
  - Existing reports on the Custom Reporting, Flow Forensics, and Analysis pages
  - Menus that an administrator has assigned to the User role

The Role and Permission Group settings determine whether the user can also run existing reports, create reports, and manage reports. To create reports, a user must have access to All Groups.

- **None**
  Has no access to a data source. The user who has this product privilege cannot log in to the NFA console or drill down from a CA NetOps Portal view to the NFA console. By default, all users have this product privilege setting for all data sources.

  NOTE
  The same user account can have different privileges for different data sources.

CA UC Monitor Product Privileges

The following list summarizes the product privileges applicable to the CA UC Monitor management console:

- **Administrator**
  Gives access to all functions, including administrative tasks, such as creating and editing:
  - Locations
  - Media devices
  - Thresholds
  - Call Watch definitions
  - Incident responses
  - Roles
  - User accounts
- **User**
  Gives access to report pages, and the ability to perform basic functions that the administrator selects. The User permission does not give access to administrative functions.

Manage Product Access

Grant access to product features and data as you create each user account. Use the following method to verify and modify the role rights for a specific user.

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Select **Administration**, **User Settings**, and click **Users**.
   The Manage Users page opens.
3. Select the user account that you want to edit.

   NOTE

   : The rights and privileges that are assigned to the predefined administrator account, 'admin', cannot be modified. This user account must have administrator access to all registered data sources.

   The Create New User wizard opens.
4. Click **Product Privileges**.

   NOTE
   All registered data sources appear on the Product Privileges page.
5. Click the values that are shown in the Product Privileges column to enable drop-down lists.
6. Select one of the following product privileges from the drop-down lists:
   - **Administrator**
     Performs all functions, including creating and editing groups, menus, dashboards, roles, and user accounts.
   - **Power User**

Creates menus and dashboards, and edits and creates roles.
- **User**
  Views menus and dashboards that are designated by an administrator or power user.
- **None**
  Has no access to a data source. This setting prevents the user from following a drilldown path from a view to the data source's user interface. By default, all users have this product privilege setting for all data sources.

7. Click **Save**.
   The changes to product privileges are saved to the selected user account.

Manage User Accounts

You can see high-level settings for the user accounts on the Manage Users page. In a multi-tenant environment, the global administrator sees a list of user accounts that are unassociated with a tenant. Tenant administrators only see user accounts for their tenant.

Before you create any custom user accounts, only the two factory user accounts are available.

You can add custom user accounts in addition to the predefined administration and user accounts that come with NetOps Portal. You can view, edit, clone, delete, and proxy existing user accounts.

> **NOTE**
> You cannot delete the two predefined user accounts (**admin** and **user**).

Permission Groups and User Accounts

The predefined groups (or system groups) help you quickly organize performance data and allocate operator access to that data. However, a more secure and better managed system is based on custom groups that are assigned to users as permissions.

Permission groups comprise the scope of the managed items that each user can monitor. Administrators can create custom groups of managed items, such as applications, servers, networks, routers, and interfaces, to reflect each user's area of responsibility. When they are assigned to a user account as permissions, custom groups are called permission groups.

You can assign multiple permission groups to each user during user account creation. For example, assign the permission groups 'North American Core Routers' and 'North American Critical Applications' to the same user account.

> **NOTE**
> As a best practice, do not assign the 'Collections' group as part of a user's permission groups. This group should not be used for reporting.

We recommend speaking with a CA technical representative to plan a strategy for creating a grouping and role structure. The best configuration meets your current requirements and is flexible enough to accommodate changes to your system.

Predefined User Accounts

NetOps Portal provides two predefined ("factory") user accounts. These accounts are useful for performing initial setup. You can use them to allocate LDAP access with minimal role rights, or as templates for custom user accounts. But because they are common to all NetOps Portal installations, they are less secure.

> **IMPORTANT**
> The factory user accounts are not substitutes for custom user accounts. We recommend changing the default passwords immediately after installation for improved security.

The factory user accounts have the following parameters:

- **admin**

Grants all administrative privileges.
Role: Administrator
Special Role Rights: All (the "global administrator" or Default Tenant administrator)
Permission Groups: Can view data from all groups
Default password: admin

- **user**
  Specifies typical operator privileges, such as viewing data.
  Role: IT Operator
  Special Role Rights: None
  Permission Groups: Can view data from all groups
  Default password: user

User account status is "Enabled" or "Disabled". Disable an account to prevent a user from accessing the product.

User Account Parameters

User accounts have the following required associations:

- **Role**
  The *role* is a parameter assigned to a user account that controls user access to product features and dashboard pages. Based on user job functions, the role grants administrative access to product configuration using *role rights*. Roles let users access data and product features that they require to perform their duties and restrict access to features that they do not require.
  NetOps Portal provides multiple predefined roles, with different role rights. A user with the required role rights can create additional roles and assign them to user accounts.
- **Permission Groups**
  Permission groups comprise the scope of the managed items that each user can monitor. Administrators can create custom groups of managed items, such as applications, servers, networks, routers, and interfaces, to reflect each user's area of responsibility. When they are assigned to a user account as permissions, custom groups are called permission groups.
  By default, new user accounts have no group assignment. If you want new users to see managed items, you must assign one or more groups to their user accounts. The predefined 'admin' and 'user' accounts have access to all groups. For user accounts that you create, limit the groups users can see based on their responsibilities.
- **Product Privilege**
  The *product privilege* is a type of permission set associated with a user account. The product privilege grants user access to features in selected data sources and does not apply to NetOps Portal functionality.

  NOTE
  In previous versions of NetQoS NetOps Portal, the product privilege referred to administrative access to product configuration, such as the ability to create custom groups. The role rights assigned to the user account now determine access to these features in CA NetOps Portal.

Add, Clone, or Edit a User Account

Add a user account for each person who operates NetOps Portal. For security purposes, do not share user accounts.

To create new user accounts quickly, use the Clone feature. You use existing accounts, such as the predefined user account, "user", as templates for the new user accounts.

Administrators can also create user account templates that are based on job function. These templates can be cloned to create individual accounts more easily. For security reasons, we recommend disabling the 'Enable user account' setting for templates. Disabling this setting helps prevent unintentional access to NetOps Portal. Instead, enable NetOps Portal access as needed for the user accounts you create by cloning templates.

NOTE
Before you create a user account, confirm that the required roles and groups exist.

Modify a user account when its job responsibilities change, or when new permission groups or roles are created. Edit a user account to assign any new roles that you create.

We recommend checking the permissions that are associated with each user account periodically. Checking permissions helps to ensure that all items are being monitored. Each time a new data source is registered, new system groups are added to the Groups tree. Sometimes, no NetOps Portal operators monitor these new groups until you explicitly add them to user accounts.

Follow these steps:

1. Hover over **Administration**, and click **User Settings: Users**.
2. Click **New**, **Clone**, or select the account that you want to change, and then click **Edit**.

   NOTE
   The rights and privileges that are assigned to the predefined administrator account, 'admin', cannot be modified. This user account must have administrator access to all registered data sources. If you select a group of accounts that includes the 'admin' account, you cannot modify any of the selected accounts.
3. Enter or edit the required information, make selections in the provided fields, and advance the wizard:
   - **Name**
   - **Description**
   - **Preferred Language**
     Specify a language for the NetOps Portal user interface. NetOps Portal displays the selected language regardless of the language selected for the operating system or for the browser language.

     NOTE
     For a language to display appropriately, the relevant fonts must be installed on the NetOps Portal server and the client.
   - **Email Address**
   - **Password**
   - **Time Zone**
     Specify the time zone that is applied to all dashboards viewed while the user is logged in to NetOps Portal. Typically, the time zone matches the locale of the computer that the operator uses to access NetOps Portal.
     Default: UTC (Coordinated Universal Time)
   - **Role**
   - **Account Status**
4. Specify the access permissions settings, and advance the wizard:
   - Move the desired permissions groups or subgroups from the **Available** list to the **Selected** list.
     Map each user profile to a group that makes sense for their initial view.

     IMPORTANT
     As a best practice, do not assign the Collections group as part of a user's permission groups. Do not use this group for reporting.
   - **Enable My Custom Groups Functionality (Optional)**
     Allow the user to create custom groups to organize managed items for troubleshooting and analysis. These groups are only available to this user on the My Custom Groups page. They do not appear in the main Groups tree.
   - **Default Group**
     A default group is selected for the user automatically. When the user logs in, data from the default group appears in dashboards by default. The group selections on the Access Permissions dialog filter the Available Groups tree. This filtering prevents users from having administrative rights to a part of the tree from which they are prohibited.

     NOTE
     Do not set the default group to “All Groups.” Using "All Groups" as the default group can cause performance issues and result in slow dashboard performance overall.

5. Move the desired administer groups from the **Available Groups** list to the **Selected Groups** list for a user with the **Administer Groups** role right, and advance the wizard.
   Lock icons appear next to read-only groups, which cannot be administered.
   Adding administered groups for an Administrator is not required.
   A user with **Administer Groups** role right can create groups *under* the selected group or subgroups. They can then modify or delete only those administered groups. Users cannot modify or delete groups that another user owns. For more information, see Role Rights.
6. For each data source product, specify one of the following product privileges, and click **Save**:
   – **Administrator**
     Allow the user to perform all functions, including creating and editing groups, menus, dashboards, roles, and user accounts.
   – **Power User**
     Allow the user to create menus and dashboards and also edit and create roles.
   – **User**
     Allow the user to view menus and dashboards that are designated by an administrator or power user.
   – **None**
     Restrict the user so that it has no access to a data source. Prevent the user from following a drill-down path from a view in NetOps Portal to the data source user interface. By default, all users have this product privilege setting for all data sources.
     The same user account can have different privileges for different data sources.
   For more information, see Product Privilege and Data Source Product Privileges.

Proxy Users and Tenants

The proxy feature lets administrators see and interact with NetOps Portal as another user or tenant. When you proxy a user, the menus, dashboards, permission groups, and user settings are proxied. When you proxy a tenant, you can see the users, items, and settings of that tenant.

> **NOTE**
>
> Role rights and product privileges to other data sources are not proxied. The proxied user account only persists within NetOps Portal. If you follow a drilldown path to a data source, the user account defaults to the original user account settings.

The proxy feature is useful for the following tasks:

- Verify permission groups and role rights.
- Configure and test menus and dashboards for a user.
- Configure a tenant environment.

Proxy a Tenant

Hover over **Administration**, and click **Group Settings: Tenants.** Select the tenant, and click **Administer**.

Proxy a User

> **TIP**
>
> To proxy a user account from another tenant, first proxy that tenant.

Hover over **Administration**, and click **User Settings: Users**. Select the user account, and click **Proxy**.

To stop proxying, click the **X** next to the **Proxy User** or **Proxy Tenant** indicator.

Multi-tenancy

To create separate monitoring environments that you administer from a single user interface, add custom tenants. The multi-tenancy support lets you monitor discrete customer environments separately and securely. A tenant represents a customer environment that a managed service provider (MSP) administers. Each tenant environment is independent and effectively functions as a separate instance of DX NetOps Performance Management. Each instance can contain multiple users and roles that are not shared among tenants.

By default, all managed items and their data are associated with the Default Tenant.

The basic tenant definition contains a few parameters to identify the MSP customer. Each tenant is associated with one or more IP domains. All items in the associated IP domains are associated with that tenant. The global administrator or the tenant administrator sets up the monitoring environment for the tenant. The following configuration items are scoped to the tenant:

- SNMP profiles
- User accounts
- Roles
- Custom groups
- Custom dashboards
- Custom menus
- Discovery profiles
- Threshold profiles

Administrator Roles for Multi-tenancy

When multi-tenancy is deployed, DX NetOps Performance Management supports the Global Administrator and Tenant Administrator roles:

- **Global Administrator**
  The Default Tenant administrator, usually representing an MSP. Product settings and data are not shared among tenants, but the Default Tenant Administrator can access and modify all settings. This user must have the predefined "Administrator" role.
- **Tenant Administrator**
  A limited administrator who is associated with a single tenant. This operator cannot access shared infrastructure or configuration belonging to the host (usually, the MSP). Tenant user accounts can include one or more of these administrator accounts. When you create a tenant, the user interface prompts you to create a tenant administrator.

Multi-tenancy Deployment Considerations

Consider the following factors when you create tenants or IP domain definitions:

- The size, scope, and organization of your monitoring environment
- The CA data sources that you plan to install and register
- Data source support for the multi-tenancy features

All of these factors work together to determine your strategy. For example, some data sources do not detect IP domains that are created within tenants.

WARNING

Once data collection has started, changes IP domain or tenant definitions are difficult. Data sources collect and aggregate data that retains a database association with the original IP domain or tenant.

Domain Monitoring Considerations

The IP domains feature supports environments where multiple enterprise systems must be monitored separately. For example, a managed services provider wants to monitor the systems and networks of different customers separately. The MSP administrator creates a tenant in CA NetOps Portal for each customer enterprise. The data and the configuration for each tenant are hidden from all other tenant users.

However, in other situations, you can deploy multiple IP domains in CA NetOps Portal without multi-tenancy. In other words, some deployment models consist of *multiple IP domains within the Default Tenant*.

The IP domain lets you control data collection parameters. Use custom IP domains to determine which collection devices monitor the managed items in your infrastructure. Each collection device, such as a Data Collector or CA Unified Communications Monitor Collector, operates within a single IP domain.

The following list provides some examples of environments where you can deploy multiple IP domains within the Default Tenant:

- A deployment that includes a CA Application Delivery Analysis data source.
  CA Application Delivery Analysis monitors IP domains without a concept of tenants. The IP domains that you create within custom tenants are not detected. When the Data Aggregator or Network Flow Analysis monitors items in those domains, they appear as duplicates in CA Application Delivery Analysis. The duplicate data is not aggregated.
- A large deployment that requires load balancing.
  For example, your enterprise includes ten routers with many interfaces, IP SLA testing, and QoS policies in place. Such a deployment would have a polling load similar to an environment with hundreds of servers being monitored for CPU and memory statistics only.
  To monitor the busy routers, you can create an IP domain and can deploy a powerful system for the Data Collector within that domain. And you can monitor the servers in another IP domain, using a less powerful system for the Data Collector. By running discoveries in the appropriate IP domains, you can determine the devices that each Data Collector is polling.
- A method to minimize the potential network impact of bulk statistics collection.
  For example, you can deploy a Data Collector close to the devices that it is monitoring. Data Collectors can process a massive amount of bulk statistics and can reduce them to a much smaller set of monitored metrics, which are sent to the Data Aggregator. As a result, less data passes across the network between the two components.
- Isolation of potentially sensitive SNMP traffic to a specific area, such as a DMZ.
  For example, security policies do not let SNMP traffic travel across the router that limits an area of network. One option is to deploy a Data Collector behind the router. A path to return the processed metrics back to the Data Aggregator must be open.
  The metric data traveling between the components is not encrypted. However, it is packaged and compressed in a way that makes it less "sniffable." As a result, the data is more secure than raw SNMP flows. To accomplish this setup, create an IP domain for the DMZ and deploy a Data Collector within that IP domain.

Deployment Process

The global administrator who is associated with the default Tenant space performs the initial steps to create a multi-tenant environment.

We recommend the following process for setting up a multi-tenant deployment:

1. Collect data about MSP customer virtual and physical systems.
2. Make a list of IP domains and SNMP versions, communities, or passwords for each MSP customer.
3. Create tenants. The tenant definition consists of a few simple parameters to identify the associated customer.
   The tenant definition also includes tenant administrator and user accounts.
4. Set the scope to a tenant to administer tenant configuration while logged in as a global administrator.
5. Create at least one IP domain to represent customer networks.
6. Create at least one SNMP profile to enable SNMP polling of devices supporting customer infrastructure.

7. Exit tenant administration. Repeat the previous steps for each tenant.

If data sources are already registered and are collecting data, wait a few minutes. CA NetOps Portal creates system groups based on items that are discovered during monitoring. These groups are useful for creating custom groups that you can then allocate to users as permissions.

When system groups are available, take the following steps:

1. Set the scope to a tenant to administer tenant configuration, or log in as the tenant administrator.
2. Create any custom groups that are required to represent the customer networks and systems.
3. Edit the default tenant user account to add permission groups.
   Consider the likely role of this user, and the managed items that this user manages.
4. Create any other custom roles, user accounts, SNMP profiles, dashboards, and menus that are required for this customer.

Work with the IT staff of each customer to designate a user to act as the tenant administrator. The tenant administrator can complete the tenant configuration by creating custom groups and additional user accounts, if desired.

Data Source Support for Multi-tenancy

DX NetOps Performance Management offers full support for multi-tenant monitoring. Integrated environments that include the following data sources offer limited multi-tenancy support:

Network Flow Analysis

Supported Features

Full support for multi-tenancy.

Assign a tenant and IP domain to each Harvester and router. Tenant assignment determines the configuration items that are available (such as tenant SNMP profiles).

A few limitations are noted in Multi-tenancy and CA Network Flow Analysis.

CA Application Delivery Analysis

Supported Features

- IP Domains
- Custom Tenant configuration

Does not segregate data within the data source interface.

CA Application Delivery Analysis monitors IP domains without a concept of tenants. As a result, CA NetOps Portal receives all items from CA Application Delivery Analysis in the Default Tenant. However, CA Application Delivery Analysis does support IP domains. CA NetOps Portal can thus associate these items with tenants according to their IP domain. Be aware that some managed items are duplicated between the Default Tenant and custom tenants.

DX NetOps Spectrum

Supported Features

Full support for multi-tenancy. However, tenancy is only visible in DX NetOps Performance Management, not in OneClick.

OneClick receives IP domains from CA NetOps Portal. Models in IP domains are synchronized them with CA NetOps Portal (and thus, associated with custom tenants).

Tenants are not visible in CA Spectrum OneClick. However, tenants in CA NetOps Portal have associated CA Spectrum devices based on IP domain. The global administrator can also make these items available for monitoring by tenant users by placing them into the Global Tenant Items group.

CA Unified Communications Monitor

Supported Features

Full support for multi-tenancy.

Locations are automatically associated with IP domains by their subnets.

CA eHealth

Supported Features

No support for multi-tenancy.

All items from these data sources are associated with the Default Tenant and Default IP Domain. Add items from these data sources to Service Provider groups to grant tenant access to them.

CA Application Performance Management

Supported Features

No support for multi-tenancy.

All items from these data sources are associated with the Default Tenant and Default IP Domain. Add items from these data sources to Service Provider groups to grant tenant access to them.

When multi-tenancy is deployed, DX NetOps Performance Management supports the Global Administrator and Tenant Administrator roles:

- **Global Administrator** - The Default Tenant administrator, usually representing an MSP. Product settings and data are not shared among tenants, but the Default Tenant Administrator can access and modify all settings. This user must have the predefined "Administrator" role.
- **Tenant Administrator** - A limited administrator associated with a single tenant. This operator cannot access shared infrastructure or configuration belonging to the host (usually, the MSP). Tenant user accounts can include one or more of these administrator accounts.

When you create a tenant, the user interface prompts you to create a tenant administrator and a tenant user account. Operators who use these accounts can only perform monitoring or administrative tasks within this tenant. They cannot access the managed items and parameters associated with other tenants.

Configure a Tenant Environment

Configuration tasks in a multi-tenant environment are split between the global administrator and the tenant administrator. The global administrator creates the tenant and configures monitoring profiles. The tenant administrator configures discovery and reporting.

Gather Prerequisite Information

Work closely with the tenant customer to plan the tenant deployment. Collect basic information about the customer environment, such as IP domains and SNMP profiles. Knowledge of physical and virtual system topology is useful for creating a custom grouping structure to represent the customer environment.

Select a user to act as the tenant administrator. The tenant administrator can then complete the tenant configuration by creating custom groups, roles, users, SNMP profiles, menus, and dashboards.

Before you begin the tenant setup, gather the following information:

- List of IP domains for the tenant
  Each IP domain requires a dedicated Data Collector
- List of SNMP communities for the tenant networks
- The desired username of the tenant administrator
  For example, select a representative of the customer site that is monitored.
- A dedicated Data Collector or a multi-tenant Data Collector with available capacity
- Configured monitoring profiles
  Monitoring profiles are global. The global administrator creates the required monitoring profiles that are used across all tenants. For more information, see Configure Monitoring Profiles.

Set Up the Tenant

Global Administrator

Create the Tenant Definition

The global administrator creates the tenant definition and tenant administrator. The tenant administrator can only see data and configuration for a single tenant. Data from other tenants is not accessible to a tenant administrator.

Follow these steps:

1. Hover over **Administration**, and click **Group Settings: Tenants**.
2. Click **New**.
3. Specify the required information.
4. Create user accounts for the tenant administrator and default tenant user.
5. Click **Save**.
   The tenant and the tenant administrator are created. The tenant administrator can complete the following procedures. Alternatively, the global administrator can administer the tenant environment to complete configuration.

   TIP

   To administer a tenant as the global administrator, hover over **Administration: Custom Settings**, and click **Tenants**. Select the tenant, and click **Administer**.

Define IP Domains

Each tenant requires an associated IP domain.

Follow these steps:

1. Select **Administration**, **IP Domains**.
2. Click **New**.
3. Specify a name and description.
4. (Optional) To assign a primary and secondary DNS address for the domain in Network Flow Analysis, select **DNS Settings**, and specify the required values.

   NOTE

   Only Network Flow Analysis uses the DNS settings. DX NetOps Performance Management does not directly use the DNS settings.
5. Click **Save**.

Assign the IP Address to a Data Collector

For a tenant environment with a dedicated data collector, assign the tenant and the IP domain to the Data Collector. For a multi-tenant Data Collector environment, configure the association through REST. For more information, see Tenant-Agnostic Data Collectors.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Data Collectors**.
2. Select the Data Collector, and click **Assign**.
3. Select the IP domain and tenant, and click **Save**.
   The IP domain and tenant are bound to the Data Collector.

Discover Devices

Tenant Administrator

Discovery is the process that DX NetOps Performance Management uses to build an inventory of devices in your network.

For more information, see Discovery.

Configure SNMP Profiles

SNMP profiles provide authentication credentials to communicate with devices in your network.

Follow these steps:

1. Hover over **Administration**, and click **Configuration Settings: SNMP Profiles**.
2. Click **New**.
3. Complete the fields, and change any default settings. Some fields apply only to SNMPv3.
   For complete details, see SNMP Profiles.
4. Click **Save**.
   The SNMP profile is added to the system and used for discovery and polling.

Create Discovery Profiles

Discovery profiles specify which devices DX NetOps Performance Management discovers. Create granular discovery profiles for devices with different SNMP credentials or different rediscovery schedule. Granular discovery profiles reduce unnecessary SNMP requests.

For more information, see Discovery Profiles.

Follow these steps:

1. Hover over **Administration**, and click **Monitored Items Management: Discovery Profiles List**.
2. Click **New**.
3. Specify a name for the profile.
4. Specify the IP address, IP ranges, or hostnames to target for discovery.
5. (Optional) Open the **SNMP** tab, select **Use specific list of assigned SNMP profiles**, and select the SNMP profiles to include in discovery.
   Using a specific list of SNMP profiles reduces unnecessary SNMP requests.
6. (Optional) Open the Schedule tab, and define a schedule.
   During normal operation, discovery runs on a schedule basis to discover new devices in the target range.
7. Click **Save**.
   DX NetOps Performance Management uses the discovery profile to find devices in your network.

Run Discovery

To build your inventory, use the discovery profiles to run discovery.

Follow these steps:

1. Select the discovery profile.
2. Click **Run**. You can run discovery only if the State is Ready.
   DX NetOps Performance Management discovers the devices within the specified IP addresses and hostnames, and adds the devices to the system inventory.
   To view a list of the discovered devices, select the discovery profile, and click History.

Configure Monitoring Collections

Tenant Administrator

In a tenant environment, the tenant administrator defines monitoring by associating collections with monitoring profiles. Monitoring profiles control how often to poll devices and which information to collect. Assigned metric families determine which metrics the system collects. Collections are system groups that group devices for monitoring. Associating a collection with a monitoring profile causes DX NetOps Performance Management to monitor the devices according to the parameters in that profile. The global administrator defines monitoring profiles for all tenants.

For more information, see Configure Monitoring Profiles.

Configure a Collection

Consider the following best practices for organizing devices into collections for monitoring:

- Create custom collections that match the monitoring requirements in the environment.
  - Consider the different layers of the network, access, distribution, and core. Devices in different layers might require different levels of monitoring.
  - Consider which technologies and metric families are required. Metric families that would be applied to all devices, such as CPU and memory, apply to broad collections. Targeted monitoring, such as QoS and IPSLA, apply to limited collections.
- Create collections that enable the flexibility to break out monitoring.
  - Some devices are included in multiple collections so that specific metric families are polled at different rates.
  - Devices in different collections have different filtering criteria.
  - Different monitoring requirements depending on importance of device

Follow these steps:

1. Hover over **Administration**, and click **Group Settings: Groups**.
2. Select the **Collections** folder in the left pane.
3. Click **Add Group**.
4. Specify a name, and click **Save**.
   The collection is created. To add devices to the collection, add rules.
5. Click the **Rules** tab, and click **+ Add Rule**.
6. Specify a rule name, select devices for the item type, add conditions as required, and click **OK**.
7. Click **Save and Run Rules**.
   DX NetOps Performance Management adds the items to the collection.

Assign Monitoring Profiles to Collections

Follow these steps:

1. From the **Collections** page, select a collection, and click the **Monitoring Profiles** tab.

2. Click **Manage**.
3. Select monitoring profiles for the **Assigned Monitoring Profiles** list, and click **Save**.
   The monitoring behavior that is defined in the assigned monitoring profiles is applied to the device collection.

Reporting, dashboards, and threshold monitoring function as normal in a tenant environment. For more information, see Configure Reporting in a New Environment.

Manage Tenants

Tenants provide you with separate monitoring environments that you administer from a single user interface. Tenants are not required for all deployments. The multi-tenancy feature lets an MSP monitor discrete customer networks and systems from a single instance of DX NetOps Performance Management.

NOTE

To edit the SNMP profiles, IP domains, or other configuration for a tenant, see Administer Tenants.

The global administrator manages tenants. View and manage tenants from the Manage Tenants page, which lists all the tenants in the system. To access the page, hover over **Administration**, and click **Group Settings: Tenants**.

These procedures required the default Administrator role:

Create a Tenant

During tenant creation, you can also create a tenant administrator and a tenant user. Unlike the global administrator, the tenant administrator can only see data and configuration for a single tenant. Data from other MSP customers is not accessible to a tenant administrator.

Follow these steps:

1. On the Manage Tenants page, click **New**.
2. Supply the required information, and make selections in the fields provided:
   - **Name**
   - **Account ID**
     This ID identifies the tenant and often corresponds to the MSP account number.
   - **Description**
   - **Status**
     Select whether the tenant is enabled or disabled.
   - **Theme**
     The theme is applied to all user accounts that are associated with this tenant.
   - **Language**
3. Specify the credentials for the tenant administrator.
   This user has administrative privileges in the tenant.
4. Specify the credentials for the default tenant user.
   This user account can access tenant-specific dashboards, but cannot access any administrative functions.
5. Click **Save**.
   The new tenant definition is created. To configure monitoring in the tenant, Administer the tenant.

Clone a Tenant

To use status, theme, and language of an existing tenant as a template for a new tenant, select the existing tenant, and click **Clone**.

NOTE

Tenant-specific information, such as users, groups, and SNMP profiles, is not copied. Configure monitoring in a tenant clone as if the clone is a new tenant.

Edit a Tenant

To modify any of the parameters that are defined during tenant creation, select the tenant, and click Edit. To charge monitoring configuration in the tenant, administer the tenant.

Disable and Enable a Tenant

To stop active monitoring of the infrastructure of a tenant, edit the tenant, and change the status to Disabled.

After you disable the tenant, the following results occur after the next synchronization with the Data Aggregator:

- The Data Aggregator system stops all Data Collectors that are associated with the disabled tenant. Data Collectors have the **Not Collecting Data** status. For any new Data Collector installations for a disabled tenant, the status is **Not Collecting Data**.

  NOTE
  If you reenable the tenant, manually restart the Data Collectors.
- Polling is stopped for any devices and components that are being monitored for the tenant.
- Historical data on the devices and components for the tenant remains accessible.
- Discovery profiles that are associated with the tenant cannot be run. The discovery profiles have the **Tenant Disabled** state.
- If a discovery profile is invalidated while a discovery is running, the discovery is aborted.
- An audit event is generated on the Data Aggregator device for the disabled tenant.

When you enable a tenant, the following results occur after the next synchronization with the Data Aggregator:

- Discovery profiles that are associated with the enabled tenant are validated. The discovery profiles display their current state.
- An audit event is generated on the Data Aggregator device for the tenant.

To restart polling, restart the Data Collectors that are associated with the tenant. After the restart, the following results occur:

- Polling is restarted for any devices and components that are being monitored on for the tenant.
- Discovery profiles that are associated with the enabled tenant can be run. If the discovery profile is schedule, the system runs discovery at the next scheduled time.

Delete a Tenant

To remove a tenant and all associated data from the system, delete the tenant.

WARNING

Information in a deleted tenant is not recoverable. To stop monitoring in a tenant, disable the tenant.

When you delete a tenant, the following definitions are deleted and cannot be recovered:

- Data sources
- SNMP profiles
- IP domains
- Threshold profiles
- User accounts
- Roles
- Groups
- Custom dashboards
- Custom menus

After you delete the tenant, the following results occur after the next synchronization with the Data Aggregator:

- Polling on the deleted devices and device components is stopped.
- Historical data on the deleted devices and device components is no longer accessible.
- An audit event is generated on the Data Aggregator device for the deleted tenant.

> **NOTE**
> If you delete a tenant when an associated Data Collector is down, the Data collector immediately stops when it restarts. An error message is logged in the following file:*DC_installation_directory*/apache-karaf-<*vers*>/shutdown.log

Administer Tenants

After you add a tenant, set up the required monitoring parameters and user access. To set up a tenant environment, log in as a tenant administrator that is associated with that tenant. If you are a global administrator, you can use the Administer Tenant feature to access NetOps Portal from the perspective of the tenant.

When you set the tenant scope to a selected tenant, only the configuration items available to that tenant appear. You can then administer the tenant, creating the required IP domains, user accounts, and more. They will only be available to users with permission to see the items that belong to that tenant.

Tenant Administrator

As a global administrator or a tenant administrator, you can modify the monitoring parameters of a tenant. Custom definitions that you create while administering a tenant are specific to that tenant, and are not shared among tenants.

To modify the IP domain, SNMP profile, user, role, and group definitions for a tenant, the tenant administrator simply logs in. The global administrator (the administrator for the Default Tenant) must set the tenant scope to the selected tenant to gain access to these definitions.

> **NOTE**
> The global administrator can create tenant administrator user accounts for each tenant.

When the tenant scope has been set, the procedures for administering a tenant are identical to the procedures to perform in a single-tenant environment.

Follow these steps:

1. Log in as a tenant administrator associated with this tenant.
   You can also set the tenant scope to access tenant configuration while logged in as the global administrator.
   The Administering Tenant indicator appears to show that you are administering the selected tenant environment.
   You can now see and modify only definitions that are associated with this tenant.
2. Click the Admininstration tab, and select an item to modify:

- IP Domains
- SNMP Profiles
- Groups
- Menus
- Roles
- Users

3. Follow the procedures specific to the selected item.
4. Save your changes.
   The modifications are only visible to administrators and operators whose user accounts were created within this tenant environment.

Global Administrator

To set up the environment for a tenant that you have already created, use the Administer Tenant feature. For example, you can add custom IP domains, user accounts, or groups to the tenant. Set the scope to the tenant to access NetOps Portal from the perspective of the tenant.

Follow these steps:

1. Log in as an Administrator.
2. Select **Administration**, **Group Settings**, and click **Tenants**.
3. Select the tenant that you want to administer, and click **Administer**.
   You are only able to see the configuration that is associated with the selected tenant.
   You can now create the IP domains, SNMP profiles, roles, users, menus, and groups that are required to represent and monitor this tenant environment. Use the menus under the **Administration** tab to configure the tenant.
4. (Optional) Change the tenant scope to another tenant by clicking the [change] link.
   The Manage Tenants page appears, and you can select another tenant.

As a global administrator or a tenant administrator, you can modify the monitoring parameters of a tenant. Custom definitions that you create while administering a tenant are specific to that tenant, and are not shared among tenants.

To modify the IP domain, SNMP profile, user, role, and group definitions for a tenant, the tenant administrator simply logs in. The global administrator (the administrator for the Default Tenant) must set the tenant scope to the selected tenant to gain access to these definitions.

> **NOTE**
> The global administrator can create tenant administrator user accounts for each tenant.

When the tenant scope has been set, the procedures for administering a tenant are identical to the procedures to perform in a single-tenant environment.

Follow these steps:

1. Log in as a tenant administrator associated with this tenant.
   You can also set the tenant scope to access tenant configuration while logged in as the global administrator.
   The Administering Tenant indicator appears to show that you are administering the selected tenant environment.
   You can now see and modify only definitions that are associated with this tenant.
2. Click the Administration tab, and select an item to modify:
   - IP Domains
   - SNMP Profiles
   - Groups
   - Menus
   - Roles
   - Users
3. Follow the procedures specific to the selected item.

4. Save your changes.
   The modifications are only visible to administrators and operators whose user accounts were created within this tenant environment.

Automate Tenant Configuration with REST Web Services

As an MSP administrator, you use a third-party or proprietary tool to manage tenants. You want to automate the configuration of your tenant information for monitoring and reporting purposes. This scenario shows how REST web services can be used to configure tenant information. For automated tenant configuration, you would write an application or script that leverages the web services in this scenario.

To configure tenant information using REST web services, follow these steps:

> **NOTE**
> Perform steps 1-3 using NetOps Portal REST web services. Perform steps 4-6 using the DX NetOps Performance Management Data Aggregator REST web services.

This process requires making calls to two different web servers:

- The NetOps Portal web server is used to create tenants, IP domains, and SNMP profiles.
- The Data Aggregator web server is used to assign Data Collector to an IP domain, to create discovery profiles, and to review discovery results.

> **NOTE**
> Use either a REST client editor or an HTTP tool that sends requests and gets responses to perform these procedures manually. In this scenario, we simply refer to the REST client editor.

Considerations Before You Begin

Before you configure the web services, consider the following information:

- Identifiers from NetOps Portal REST web services and DX NetOps Performance Management Data Aggregator REST web services are not interchangeable.
- When you upgrade, the version of the web services you were using might no longer be compatible. Upon upgrade, review the Release Notes to see if the REST web services have changed. If the REST web services changed, update your application or script.

Create a Tenant

As an MSP administrator, you can create tenants with specific parameters. The basic tenant definition contains a few parameters to identify your customer and let other operators access managed items and configuration for the customer. An administrator account is a required component of the tenant definition so that the customer can perform some tenant setup.

Follow these steps:

1. Enter a URL for the NetOps Portal REST web services API in the REST client. Use the following format:

   ```
   http://pc_host:8181/pc/center/webservice/tenants/
   ```

2. Select POST for "HTTP" Method.
3. Provide a valid username and password for a user account that has administrator access to NetOps Portal.
4. Select 'application/xml' as the 'Body Content-type' in the Body settings.
5. Enter the following information within the "Body" text section:
   – **tenantName**

Provides a name for the tenant you are creating.

- **tenantDesc**
  Describes the tenant. The tenantDesc tag is required, but an actual description is optional.
- **accountIdentifier**
  (Optional) Identifies this tenant. This value usually corresponds to the MSP account number. If a value is supplied as input, it must be unique across all defined tenants.
  Default: null
- **status**
  (Optional) Defines the status of this tenant. Select one of the following values:
  - Activated: Enables tenant user accounts for use.
  - Disabled: Prevents any actions by user accounts that are associated with this tenant.

  Default: ACTIVATED
- **removable**
  (Optional) States whether the item can be deleted (removed from the database).
  Values: true or false.
  Default: true
- **theme**
  (Optional) Specifies the theme that controls the appearance of NetOps Portal pages for this tenant. All operators whose user account is associated with this tenant see this same theme. Two themes are available: CA-Blue and CA-Gray.
  Default: CA-Blue.
- **defaultCulture**
  (Optional) Specifies the language (locale) for this tenant. Supply a language identifier from the following list:
  - en_US (English, United States)
  - ja_JP (Japanese)
  - zh_CN (Simplified Chinese)
  - zh_TW (Traditional Chinese)
  - fr_FR (French, France)

  Default: en_US

For example:

```
<tenant>

  <tenantName>John Doe</tenantName>

  <tenantDesc>John Doe Corporation tenant</tenantDesc>

  <accountIdentifier>JD1234</accountIdentifier>

  <status>Enabled</status>

  <removable>false</removable>

  <theme>CA-Blue</theme>

  <defaultCulture>en-US</defaultCulture>

</tenant>
```

6. Execute the web service call.
   The tenant is created.

Create an IP Domain

A tenant definition must contain at least one IP domain that identifies the IP addresses of managed items in the tenant environment. Create an IP domain and add it to the tenant you created previously.

Follow these steps:

1. Enter a URL for the NetOps Portal REST web services API in the REST client. Use the following format:

   ```
   http://pc_host:8181/pc/center/webservice/domains/
   ```

2. Select POST for "HTTP" Method.
3. Provide a valid username and password for a user account that has administrator access to NetOps Portal.
4. Select 'application/xml' as the 'Body Content-type' in the Body settings.
5. Enter the following information within the "Body" text section:
   - **groupItemID**
     (Optional) Defines an internal (database) identifier for the group definition that is associated with a domain. You provide this number. To specify a valid groupItemID, make a web service call to the groups webservice:

     ```
     http://pc_host:8181/pc/center/webservice/groups
     ```

   - **itemDesc**
     Describes the IP domain. The itemDesc tag is required, but an actual description is optional.
   - **itemName**
     Defines a name for the IP domain.
   - **TenantID**
     Defines an internal (database) identifier for the tenant definition. The tenant ID was assigned when you created the tenant and the tenant information was synchronized with Data Aggregator. Determine what your tenant ID is by making a web service call to the tenant web service:

     ```
     http://pc_host:8181/pc/center/webservice/tenants/tenantName/tenant_name
     ```

   - **primaryDNSAddress**
     The IP address of the primary name server for this domain. This tag is required, but an actual IP address is optional.
   - **primaryDNSPort**
     The port number that the primary name server uses. This tag is required, but an actual port number is optional.
   - **secondaryDNSAddress**
     The IP address of the secondary name server for this domain. This tag is required, but an actual IP address is optional.
   - **secondaryDNSPort**
     The port number that the secondary name server uses. This tag is required, but an actual port number is optional.
   - **isDnsProxyEnabled**
     (Optional) Indicates whether the proxy address is enabled for this IP domain.
     Default: false
   - **dnsProxyAddress**
     (Optional) Indicates the IP address of the DNS proxy server.

Default: null

For example:

```
<domain>

  <groupItemID>7</groupItemID>

  <itemDesc>{Description }</itemDesc>

  <itemName>{IP Domain Item Name}</itemName>

  <TenantID>8</TenantID>

  <primaryDNSAddress>0.0.0.0</primaryDNSAddress>

  <primaryDNSPort>0.0.0.0</primaryDNSPort>

  <secondaryDNSAddress>0.0.0.0</secondaryDNSAddress>

  <secondaryDNSPort>0.0.0.0</secondaryDNSPort>

  <isDnsProxyEnabled>false</isDnsProxyEnabled>

</domain>
```

6. Execute the web service call.
   The IP domain is created.

Provide SNMP Credentials

To enable SNMP polling of devices, provide SNMP credentials in an SNMPv1/SNMPv2c or SNMPv3 profile.

During inventory discovery, Data Collector uses SNMP profiles to determine what credentials it uses when accessing a device. NetOps Portal maintains a ranked list of profiles. During inventory discovery, each profile is tried for device access. The profile with the highest rank that can access a device is used.

For this scenario, you create an SNMPv3 profile.

> **NOTE**
> Community strings and credentials are encrypted when they are stored in NetOps Portal and when they are sent to Data Aggregator and Data Collector. NetOps Portal REST web services use the HTTP protocol instead of the HTTPS protocol. Therefore, the community strings and passwords are sent over the Internet in clear text, and, can be compromised. We recommend that you invoke this method only on the NetOps Portal host.

Follow these steps:

1. Enter a URL for the NetOps Portal REST web services API in the REST client. Use the following format:

   ```
   http://pc_host:8181/pc/center/webservice/profiles/
   ```

2. Set the Content-type to application/xml.
3. Provide a valid username and password for a user account that has administrator access to NetOps Portal.
4. Enter the following information within the "Body" text section:

- **name**
  Defines a name for the SNMP profile.

  NOTE
  Profile names must be unique, cannot be duplicated across SNMP versions, and are not case-sensitive.
- **port**
  (Optional) Identifies the port that is used to make SNMP connections to devices associated with this profile.
  Default: 161
- **userName**
  (Optional) Identifies the user for the profile, whose secret keys were used potentially to authenticate and encrypt the SNMPv3 packets. The user name is a character string.
  Default: the encrypted value of the name
- **context**
  (Optional) Specifies a collection of management information that is accessible by an SNMP entity. The context name is necessary for providing end-to-end identification and for retrieving data from an SNMPv3 agent. The context name is an octet string.
  Default: an empty string

  NOTE

  The Data Aggregator does not use Context Name on the SNMPv3 profiles to communicate with the device.
- **version**
  Specifies the version of SNMP that the profile uses. Specify Version3 for this scenario.
  Default: Version1or2C
- **securityLevel**
  (Optional) Specifies the security level to use. Enter one of the following values:
  - `NoAuthNoPriv`
  - `AuthNoPriv`
  - `AuthAndPriv`

  Default: `NoAuthNoPriv`
- **authProtocol**
  (Optional) Specifies the authentication protocol to use when contacting devices associated with this profile. Enter one of the following algorithms for authenticating SNMPv3 packets:
  - None (Do not attempt authentication.)
  - MD5 (Message Digest 5)
  - SHA (Secure Hash Algorithm)

  Default: None
- **authPassword**
  Specifies the password for authentication using SNMPv3 and the selected authentication protocol. The password must contain a minimum of eight characters. This value is required for the MD5 and the SHA authentication protocol values.
- **privProtocol**
  (Optional) Specifies the encryption protocol to use for data flows sent to any devices or servers that are associated with this profile, as follows:
  - None (Does not encrypt communications. Use only with NoPriv option.)
  - DES
  - AES (128-bit encryption)
  - Triple DES

  Default: None

Note: The privacy protocol option is only enabled when authentication is enabled for this profile.

- **privPassword**
  Defines the password that is used when exchanging encryption keys. This value is required for DES, AES, and Triple DES privacy protocols.
- **rank**
  (Optional) Specifies the rank of the profile in the global list of SNMP profiles.
  Default: 0
- **enabled**
  (Optional) Indicates whether the information in this profile is used when not explicitly assigned to a device. Select true.
  Default: true
- **tenantID**
  The internal (database) identifier for the tenant definition.
  Default: The ID of the Default Tenant

  NOTE
  This number must be the same number that you chose when you created the IP domain.

Example: No authentication and no privacy

```
<SnmpProfile>

    <name>Tokyo</name>

    <port>161</port>

    <userName>myuser</userName>

    <context></context>

    <version>Version3</version>

    <securityLevel>NoAuthNoPriv</securityLevel>

    <authProtocol>None</authProtocol>

    <authPassword>None</authPassword>

    <privProtocol>None</privProtocol>

    <privPassword>None</privPassword>

    <rank>4</rank>

    <enabled>true</enabled>

    <tenantID>7</tenantID>

</SnmpProfile>
```

Example: Authentication and no privacy

```
<SnmpProfile>
    <name>Brasil</name>
    <port>161</port>
    <userName>myuser</userName>
    <context></context>
    <version>Version3</version>
    <securityLevel>AuthNoPriv</securityLevel>
    <authProtocol>MD5</authProtocol>
    <authPassword>test</authPassword>
    <privProtocol>None</privProtocol>
    <privPassword>None</privPassword>
    <rank>3</rank>
    <enabled>true</enabled>
    <tenantID>7</tenantID>
</SnmpProfile>
```

Example: Authentication and privacy

```
<SnmpProfile>
    <name>Boston</name>
    <port>161</port>
    <userName>myuser</userName>
    <context></context>
    <version>Version3</version>
    <securityLevel>AuthAndPriv</securityLevel>
    <authProtocol>MD5</authProtocol>
```

```
        <authPassword>test</authPassword>

        <privProtocol>TripleDES</privProtocol>

        <privPassword>test</privPassword>

        <rank>1</rank>

        <enabled>true</enabled>

        <tenantID>7</tenantID>

    </SnmpProfile>
```

5. POST the following URL to create the profile:

```
POST http://pc_hostname:8181/pc/center/webservice/profiles/saveProfile/{true|false}
```

   – **{true|false}**
   Specifies a Boolean value for the rankTiesAscendingByDate parameter. **True** indicates that the profile you are adding is the last in rank order (as determined by the creation date of the SNMP profile).

   The XML returns true when the operation succeeds.
   The SNMP profile is automatically synchronized with Data Aggregator and is available for inventory discovery to use it.
   SNMP credentials are provided.

Assign Data Collector to the Tenant

Each Data Collector installation is assigned to a tenant and IP domain. Assign a Data Collector installation to the tenant you created previously.

> **NOTE**
> This scenario assumes that Data Collector is installed already. This scenario also assumes that you did not already run a discovery against this Data Collector. Once a discovery has occurred on a Data Collector instance, the Data Collector instance cannot be assigned to another tenant.

Follow these steps:

1. Determine what your tenant ID number is by making a web service call to the Data Aggregator tenant web service:

   ```
   http://da_host:8581/rest/tenants
   ```

   Note the tenant ID of the tenant that you want to assign to Data Collector.
2. Determine what your IP domain ID is by making a web service call to the Data Aggregator IP domain web service:

   ```
   http://da_host:8581/rest/tenant/tenantID/ipdomains
   ```

   – **tenantID**
   The ID of the tenant that you want to assign to the Data Collector instance. You determined this number in the previous step.

   Note the IP domain ID of the IP domain that you want to assign to Data Collector.
3. Determine the Data Collector ID number by making a web service call to the Data Aggregator Data Collector web service:

```
http://da_host:8581/rest/dcms
```

Note the ID number of the Data Collector installation you want to assign your tenant and IP domain to.

4. Make a web service call to the Data Aggregator Generic Data Collector web service:

```
http://da_host:8581/genericWS/dcm/collectorID
```

   – ***collectorID***
     The ID of the Data Collector installation you want to assign to your tenant and IP domain. You determined this ID in the previous step.
5. Select PUT for the "HTTP" Method.
6. Enter the following information within the "Body" text section:

```
<DCM>

  <DCM>

    <IP_DOMAIN_ID>IPdomainID</IP_DOMAIN_ID>

  </DCM>

</DCM>
```

   – ***IPdomainID***
     The IP domain ID for the tenant you want to assign Data Collector to. You determined this ID in step 2.

   Data Collector is assigned to your tenant.

Create a Discovery Profile and Run a Discovery

Discovery profiles specify how discovery operates in your Data Aggregator environment. Within a discovery profile, specify the IP addresses, IP address ranges, or host names you want to discover devices for.

You create a discovery profile and run a discovery in one operation when using the REST web services. When discovery is run, devices are discovered based on the discovery profile you create.

Follow these steps:

1. Access the Data Aggregator web server.
2. Open a REST client editor and select 'application/xml' as the 'Body Content-type' in the Body settings.
3. Find and make a note of the default tenant ID using the following URL:

```
GET http://da_host:8581/rest/tenants
```

4. View the XSD schema XML (which defines the structure of the discovery profile) by going to the following URL:

```
http://da_host:8581/rest/discoveryprofiles/XSD/getlist.xsd
```

5. Include IP addresses and host names so that devices in your network are discovered. Do one or more of the following actions:

- Type individual IP addresses for which you want to discover devices in the IP Address List field.
- Type the host names for which you want to discover devices in the Host List field.

  NOTE
  These fields accept comma-delimited values. Single quotes, double quotes, backward slashes, forward slashes, and ampersands are not permitted.

6. Set the following required attributes:
   - **RunStatus**
     Specifies whether to run the discovery. For this scenario, set the attribute to START.

     NOTE
     To rerun discovery later, update (PUT) the run status to START.
   - **Name**
     Specifies a descriptive name for the discovery profile. This field cannot contain single quotes, double quotes, backward slashes, forward slashes, and ampersands.
   - **IPDomainID**
     An internal ID that is used to identify IP domains. The Data Aggregator generates this number. Determine what your IP domain ID is by making a web service call to the IP domain web service:

     ```
     http://da_host:8581/rest/tenant/tenantID/ipdomains
     ```

7. (Optional) Limit the discovery to specific SNMP profiles using the following attributes:
   - **SNMPProfileIDList**
     Specifies a ranked list of SNMP Profile ItemIDs for use during discovery. This list is used only if UseListOfSnmpProfiles equals true.
   - **UseListOfSnmpProfiles**
     A boolean indicating whether a specific list of SNMP profiles is used. If false, the global list is used.
8. (Optional) Change the priority in which you want the discovered device to be named, using the following attribute:
   - **DeviceNameRankingList**
     Specifies the priority in which you want discovered devices to be named.
9. (Optional) Set the IcmpDiscoveryEnabled attribute to true to enable ICMP discovery.

Example: Discovery profile XML that includes an optional list of specific SNMP profiles.

```
<?xml version="1.0" encoding="UTF-8"?>

<DiscoveryProfile version="1.0.0">

  <ActivationStatus>true</ActivationStatus>

  <SNMPProfileIDList>

    <SNMPProfileID>478</SNMPProfileID>

    <SNMPProfileID>2239</SNMPProfileID>

  </SNMPProfileIDList>

  <UseListOfSnmpProfiles>true</UseListOfSnmpProfiles>

  <IPRangesList>
```

```
      <IPRanges>10.0.64.202-10.0.64.206</IPRanges>
    </IPRangesList>
    <HostNamesList>
      <HostNames>ahost</HostNames>
    </HostNamesList>
    <IPListList>
      <IPList>10.10.10.10</IPList>
    </IPListList>
    <RunStatus>START</RunStatus>
    <Item version="1.0.0">
      <Name>BigRange_TestProfileViaAPI</Name>
    </Item>
    <IPDomainMember version="1.0.0">
      <IPDomainID>285</IPDomainID>
    </IPDomainMember>
    <DeviceNameRankingList>
      <DeviceNameRanking>{http://im.ca.com/inventory}
       ManageableDevice.SystemName</DeviceNameRanking>
      <DeviceNameRanking>{http://im.ca.com/inventory}
        Device.HostName</DeviceNameRanking>
      <DeviceNameRanking>{http://im.ca.com/inventory}
       Device.PrimaryIPAddress</DeviceNameRanking>
    </DeviceNameRankingList>
  <IcmpDiscoveryEnabled>true</IcmpDiscoveryEnabled>
  </DiscoveryProfile>
```

10. Save and run the new discovery profile by entering the following URL:

```
POST http://da_host:8581/rest/tenant/tenantID/discoveryprofiles
```

a. **tenantID**
The internal database identifier for the tenant definition. The tenant ID was assigned when you created the tenant and the tenant information was synchronized with Data Aggregator. Determine what your tenant ID is by making a web service call to the tenant web service:
`http://da_host:8581/rest/tenants`

The discovery profile is created and discovery runs.
All discovered devices are automatically added to the appropriate out-of-the-box device collection or another user-created device collection.

Review the Discovered Devices and Instances

After you create and run a discovery profile, verify your results. View the summary of the number of new pingable and manageable devices that were discovered. The summary also includes details about the discovered devices, including IP address, type, vendor association, SNMP profiles, and model type.

Follow these steps:

1. View a list of discovery profiles on the Data Aggregator web server using the following URL:

   ```
   GET http://da_host:8581/rest/discoveryprofiles
   ```

   A list of discovery profiles and their instance IDs is returned.
2. Find the discovery instance ID for the discovery profile that you created previously.
3. View the discovery instance details, using the following URL:

   ```
   GET http://da_host:8581/rest/discoveryinstances/instance_ID
   ```

   The instance XML returns information about new and existing devices and SNMP profiles that were tested.
   Example:

```
<?xml version="1.0" encoding="UTF-8"?>

<DiscoveryInstance version="1.0.0">

    <ID>236</ID>

   <IPSweepTotalSuccess>5</IPSweepTotalSuccess>

   <CompletionTime>Thu Apr 12 12:36:35 CDT 2012</CompletionTime>

  <ExistingFoundDevicesList>

      <ExistingFoundDevices>241</ExistingFoundDevices>

      <ExistingFoundDevices>239</ExistingFoundDevices>

      <ExistingFoundDevices>240</ExistingFoundDevices>
```

```
    <ExistingFoundDevices>238</ExistingFoundDevices>
</ExistingFoundDevicesList>
<IPSweepCompletionTime>Thu Apr 12 12:36:35 CDT 2012</IPSweepCompletionTime>
<ExistingFoundManageableDevicesList>
    <ExistingFoundManageableDevices>241</ExistingFoundManageableDevices>
    <ExistingFoundManageableDevices>239</ExistingFoundManageableDevices>
    <ExistingFoundManageableDevices>240</ExistingFoundManageableDevices>
    <ExistingFoundManageableDevices>238</ExistingFoundManageableDevices>
</ExistingFoundManageableDevicesList>
<StartTime>Thu Apr 12 12:36:31 CDT 2012</StartTime>
<NewlyCreatedDevicesList>
    <NewlyCreatedDevices>383</NewlyCreatedDevices>
 </NewlyCreatedDevicesList>
 <TestedCommProfilesList>
     <TestedCommProfiles>199</TestedCommProfiles>
      <TestedCommProfiles>198</TestedCommProfiles>
  </TestedCommProfilesList>
  <IPSweepStartTime>Thu Apr 12 12:36:31 CDT 2012</IPSweepStartTime>
  <ProgressPercentage>100</ProgressPercentage>
  <IPSweepTotal>7</IPSweepTotal>
  <ProfileID>235</ProfileID>
  <NewlyCreatedManageableDevicesList>
       <NewlyCreatedManageableDevices>383</NewlyCreatedManageableDevices>
   </NewlyCreatedManageableDevicesList>
   <PingResponseDeviceCount>5</PingResponseDeviceCount>
```

```
        <CompletionStatus>SUCCESS</CompletionStatus>

        <Item version="1.0.0">

            <CreateTime>Thu Apr 12 12:36:31 CDT 2012</CreateTime>

         </Item>

    </DiscoveryInstance>
```

4. (Optional) Use the following URL to review information about specific devices (new or existing):

   ```
   GET http://da_host:8581/rest/devices/device_ID
   ```

   – ***device_ID***
   Specifies the ID of the referenced datapoint, such as devices. Use the ID numbers that were returned when you viewed the discovery instance details.
5. (Optional) Review information about the SNMP profiles that were tested during the discovery, using the following URL:

   ```
   GET http://da_host:8581/rest/profiles/profile_ID
   ```

   – ***profile_ID***
   Specifies the ID of the SNMP profile. The <TestedCommProfilesList> section in the XML displays the SNMP profile IDs.

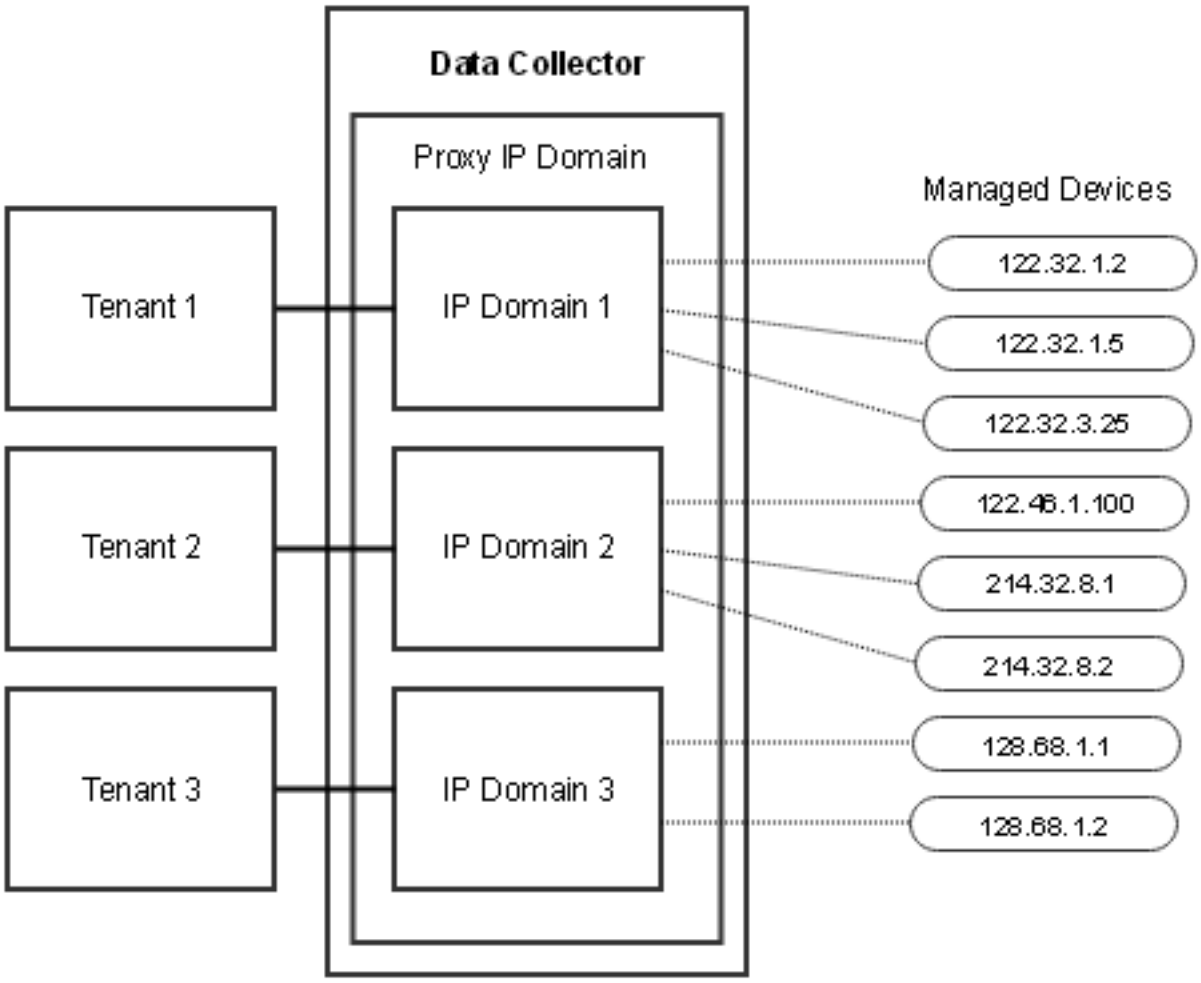
You have successfully used REST web services to configure tenant information. For automated tenant configuration, you would write an application or script that leverages the web services in this scenario.

Tenant-Agnostic Data Collectors

In a standard tenant deployment, each tenant has a dedicated Data Collector. For multiple tenants that reside in the same IP routing space, DX NetOps Performance Management can be configured to use fewer Data Collectors.

The following diagram illustrates the basic architecture of a tenant-agnostic Data Collector:

Figure 59: Multi-tenant Data Collector Architecture



- The Data Collector is associated with the proxy IP domain. This domain represents the IP domain of the managed environment, meaning that IP addresses must be unique across all tenants in the environment.

  TIP

  The IP proxy domain is the only new object to create this feature. This object must be created through REST.
- Multiple IP domains are associated with the Data Collector within the proxy IP domain.
- Each IP domain is associated with a single tenant.
- The Data Collector sends requests to the managed devices defined in each tenant.

Limitations

A tenant-agnostic Data Collector configuration has the following limitations:

- IP addresses in tenant IP domains cannot overlap. IP addresses must be unique across all tenants.

WARNING

The owner of the environment is responsible for ensuring IP address uniqueness. Without unique IP addresses, tenants can monitor and manage devices that belong to other tenants. To ensure IP address uniqueness, enforce limited IP ranges in discovery profiles.

- Devices cannot be migrated between tenants.
- Existing tenant deployments cannot be migrated to tenant-agnostic Data Collectors.
- Tenant-agnostic Data Collectors cannot host DX NetOps Mediation Manager (CAMM) or DX NetOps Virtual Network Assurance (CA VNA). For each tenant, a separate Data Collector is required for CAMM and CA VNA.

Configure the Data Collector Though REST

To configure a tenant-agnostic Data Collector, use REST to create the required items and associations. This process uses NetOps Portal and Data Aggregator REST.

WARNING

If you script these steps, account for synchronization time between steps. Synchronization can take up to 5 minutes.

Get Item IDs

Several item IDs are required to configure the Data Collector for multiple tenants. Get the item IDs before you begin configuration. Use the GET method with your preferred REST client for the following item IDs:

- Data Collector IDhttp://*da_host*:8581/rest/dcms
- Pseudo Tenant ID

```
http:// da_host :8581/rest/pseudotenants
```

NOTE

The pseudo tenant proxy (Pseudo Tenant Proxy) is predefined. The pseudo tenant works with the proxy IP domain to support multiple tenants and IP domains on a single Data Collector.

Configure the Data Collector

Configure the Data Collector to handle multiple tenants. Complete this procedure for each tenant-agnostic Data Collector.

For the bold IDs, use the IDs from the previous step.

Follow these steps:

1. Create a proxy IP domain:
   - **Method:** POST
   - **Endpoint:** `http://da_host:8581/rest/tenant/ {pseudo_Tenant_ID} /proxyipdomains/`
   - **Body:**

```
<ProxyIPDomain version="0.0.0">
    <IPDomain version="0.0.0">
        <Name>Proxy IP Domain</Name>
        <Description>Description for Proxy IP Domain</Description>
        <DNSProxyEnabled>false</DNSProxyEnabled>
        <DNS1Address>0.0.0.0</DNS1Address>
        <DNS2Address>0.0.0.0</DNS2Address>
        <DNS1Port>0</DNS1Port>
        <DNS2Port>0</DNS2Port>
```

```
        </IPDomain>
    </ProxyIPDomain>
```

2. Get and note the proxy IP domain ID:
   - **Method:** GET
   - **Endpoint:** *http://da_host:8581/rest/proxyipdomains*
3. Associate the proxy IP domain with the Data Collector:
   - **Method:** PUT
   - **Endpoint:** `http://da_host:8581/genericWS/dcm/` ***{DataCollectorID}***
   - **Body:**

```
<DCM>
    <IP_DOMAIN_ID> {proxyDomainId} </IP_DOMAIN_ID>
</DCM>
```

Add Tenants to the Proxy IP Domain

Create tenants and assign those tenants to the Data Collector. Complete this procedure once for each tenant.

For more information about the tenant and IP domain XML, see Automate Tenant Configuration with REST Web Services.

> **TIP**
>
> You can create the required tenants and the IP domains in those tenants, through the NetOps Portal UI. For more information see Manage Tenants and IP Domains. If you create these items in the UI, start this procedure from step 4.

Follow these steps:

1. Create the tenant:
   - **Method:** POST
   - **Endpoint:** `http://pc_host:8181/pc/center/webservice/tenants/`
   - **Body:**

```
<tenant>
  <tenantName>Tenant name</tenantName>
  <tenantDesc>Tenant description</tenantDesc>
  <accountIdentifier>AccountNumber</accountIdentifier>
  <status>Enabled</status>
  <removable>false</removable>
  <theme>CA-Blue</theme>
  <defaultCulture>en-US</defaultCulture>
</tenant>
```

2. Get and note the tenant ID:
   - **Method:** GET
   - **Endpoint:** `http://pc_host:8181/pc/center/webservice/tenants/tenantName/tenant_name`
3. Create the tenant IP domain:
   - **Method:** POST
   - **Endpoint:** `http://pc_host:8181/pc/center/webservice/domains/`
   - **Body:**

```
<domain>
```

```
  <itemDesc>IP domain description</itemDesc>
  <itemName>IP domain name</itemName>
  <TenantID> {tenantID} </TenantID>
  <primaryDNSAddress>0.0.0.0</primaryDNSAddress>
  <primaryDNSPort>0.0.0.0</primaryDNSPort>
  <secondaryDNSAddress>0.0.0.0</secondaryDNSAddress>
  <secondaryDNSPort>0.0.0.0</secondaryDNSPort>
  <isDnsProxyEnabled>false</isDnsProxyEnabled>
</domain>
```

4. Get the tenant IP domain ID:
   - **Method:** GET
   - **Endpoint:** `http://da_host:8581/rest/ipdomains`
5. Associate the proxy IP domain with the tenant IP domain:
   - **Method:** PUT
   - **Endpoint:** `http://da_host:8581/rest/ipdomains/{tenantIPDomainID}`
   - **Body:**

```
<IPDomain version="0.0.0">
    <ProxyIPDomain> {proxyIpDomainID} </ProxyIPDomain>
</IPDomain>
```

Configure the Tenant

Use the standard methods to configure monitoring in the tenant space.

Multi-tenancy and CA Application Delivery Analysis

CA Application Delivery Analysis (CA ADA) does not offer a native multi-tenancy feature. However, it does support IP domains.

CA ADA also supports data segregation per user account, so tenant users only see the data within their associated tenant.

CA ADA can observe duplicate IP traffic, which occurs in a managed service provider (MSP) environment. The provider can host an application on a single server for multiple customers whose environments contain overlapping client IP addresses.

You enable CA ADA to identify separate IP traffic during data collection setup. As you verify and modify data collection parameters, assign the same IP domain to the appropriate:

- Monitor feeds
- Client networks
- Servers or server subnets

With the same IP domain assignments for these feeds, CA ADA reports on the application traffic between a client and a server by domain.

Since applications are domain-independent, you are not required to define the same application twice to report on application performance across domains. However, to set different thresholds for application performance, performance OLAs, and availability OLAs, create an application for each IP domain.

If you do not need to separate duplicate IP traffic, you can use the DNS settings in the Default Domain to query DNS and resolve the hostname of a CA ADA server. Otherwise, CA ADA uses the monitor feed that is assigned to the server to resolve the hostname.

View a List of Domains in CA Application Delivery Analysis

You can view a list of domain definitions and current domain associations in the Administration section of the CA ADA management console.

NOTE

Any items that are not assigned to a specific domain in a data source are included in the Default Domains group. In the data source, they appear to be associated with the Default Domain.

Follow these steps:

1. Click the Administration tab in the management console.
2. Click Data Monitoring, Domains in the Show Me menu.
   The Domains page opens.
3. (Optional) View the DNS settings for a domain by clicking the magnifying glass symbol in the View column.
   The Domain Properties page opens.
4. Verify the properties.
5. Click OK when you have finished.
   The Domains page appears.

Assign a Domain to a Monitor Feed

You can instruct each Standard Monitor to associate the items that it monitors with a custom domain as part of CA ADA collection device setup.

NOTE

Any managed items that are not associated with a custom IP domain by a data source are associated with the Default Domain. This assignment is transparent to users who are not deploying custom IP domains.

Follow these steps:

1. Click the Administration tab in the management console.
2. Click Data Monitoring, Monitoring Devices in the Show Me menu.
   The CA ADA Monitors list page opens.
3. Click Edit to edit a multifunction monitoring device, such as a Standard or Multi-Port Monitor.
   The Monitor Properties page opens.
4. Scroll down to the Monitor Feeds list.
5. Click to edit a monitor feed.
6. Select a custom IP domain.
7. Click Update.
   All items detected by this monitor feed are automatically associated with the selected IP domain.

Assign a Domain to a Client Network

After you add a client network, you cannot change its IP domain association. If you need to change the assigned IP domain, you must delete the network, and then add it to the correct domain.

NOTE

Any managed items that are not associated with a custom IP domain by a data source are associated with the Default Domain. This assignment is transparent to users who are not deploying custom IP domains.

Follow these steps:

1. Click the Administration tab in the management console.
2. Click Data Monitoring, Networks in the Show Me menu.
   The Networks List page opens.
3. Select the IP domain from the list.
4. Click Add Network.
5. Enter the required information to add the network.
6. Click OK.

Assign a Domain to a Server or Server Subnet

After you add a server or server subnet, you cannot change its IP domain. If you add a server or server subnet to the wrong IP domain, you must delete it, and then add it to the correct domain.

> **NOTE**
>
> Any managed items that are not associated with a custom IP domain by a data source are associated with the Default Domain. This assignment is transparent to users who are not deploying custom IP domains.

Follow these steps:

1. Click the Administration tab in the management console.
2. Click Data Monitoring, Servers in the Show Me menu.
   The Server Subnet List and Server List page opens.
3. Select the IP domain from the list.
4. Supply the information to add the Server or Server Subnet.
5. Click OK.

Other Deployment Considerations

CA ADA supports the multi-tenancy features in CA NetOps Portal. However, take care when selecting user account product privileges. The product privilege to a data source enables a user to drill down from a view back to the source of the data.

Assuming that you have carefully segregated data from different customer environments into separate tenants, you probably want to prevent users from returning to the CA ADA interface. In that interface, tenant separation is not applied, and all data is available for viewing in reports. Product privileges are set in the Add or Edit User Account wizard.

> **WARNING**
> Assign the 'User' product privilege to any user who does not require access to all data in the CA ADA data source.

Multi-tenancy and CA Network Flow Analysis

The Network Flow Analysis (NFA) data source does not offer a native multi-tenancy feature. However, the harvesters and routers can associate monitored items with the appropriate tenant by means of the IP domain.

Interfaces and CVIs inherit their initial tenant-domain setting from the parent router and harvester. The setting is inherited when the parent harvester is added, and the router and interfaces first become active. If the harvester is not associated with a custom domain, the routers and interfaces are assigned to the Default Domain as they become active.

You can edit the settings for interfaces and CVIs to associate them with any tenant and domain at any time. The setting does not have to match the parent router or harvester.

Changing this setting can affect which operators have access to the interface's data. The setting does not affect which SNMP profiles are used for polling. The router tenant determines the set of SNMP profiles for polling.

Follow these steps:

1. Open the Active Interfaces page:
   a. Select Administration from the NFA console menu.
      The Administration page opens.
   b. Select Interfaces: Physical & Virtual from the Administration menu.
      The Active Interfaces page opens.
2. Select the check box next to one or more interfaces that you want to associate with a tenant and domain.
   – To search for parent routers, interfaces, or CVIs, enter all or part of a router IP address, a router or interface name, or an interface description in the Search field, and then click Search. Expand the router details.
   – To navigate to an interface or CVI manually, go to the page that contains the parent router and click the arrow next to the router name. The router details appear, showing the interfaces and CVIs.
3. Click **Edit**.
   The editing dialog opens. The Domain selection list is included in the dialog only if multiple domains exist.
4. Select a tenant/domain option from the Domain list.
5. Click **Save**.
   The dialog closes. The changes are shown on the Active Interfaces page.

   NOTE
   You can also change the tenant-domain setting for harvesters and routers.

Interface Domain Changes

When an administrator allocates the interfaces from a single router to multiple MSP customer domains, interfaces are often switched to different IP domains. Network Flow Analysis detects interface domain changes. These changes are not applied to data being sent to Data Aggregator, however, because Data Aggregator only identifies interfaces at the device level.

As a result, when interfaces are switched to a different domain after monitoring and data collection have begun, the global administrator sees two different interface items for each affected interface. The two interfaces continue to be monitored in separate IP domains, and their data is not aggregated. In this situation, individual tenant users do not see any problem. Device-level statistics for the routers or switches that contain these interfaces are not affected. Only the global administrator sees two interfaces to represent a single monitored interface.

Multi-tenancy and CA Unified Communications Monitor

CA Unified Communications Monitor (CA UCM) supports the multi-tenancy features of CA NetOps Portal (CAPC). You perform all tenant and IP domain configuration in CAPC. The collector then associates monitored items with the appropriate tenant by means of the IP domain.

In the CA UCM management console, you can instruct collectors to associate the items that they discover with custom domains in CAPC. The act of creating a single custom domain in CAPC enables domain associations for Locations, voice gateways, and call servers in any registered data sources.

Items appear with domain designations as soon as they are discovered from call traffic. Items discovered previously do not receive retroactive associations.

Locations are automatically associated with IP domains by the subnets that they contain. To preserve the flow of data collection and the appropriate association of data with IP domains, take care when moving Locations to new IP domains. Follow the procedure provided in the CA UCM Online Help to change IP domain assignments.

NOTE

: Any managed items that are not associated with a custom IP domain by a data source are associated with the Default Domain. This assignment is transparent to users who are not deploying custom IP domains.

Instruct collectors to associate items with custom IP domains.

Follow these steps:

1. Click Administration, Data Collection, Collectors.
2. Edit each collector to select its domain for the IP Domain parameter.
3. Reload the collectors to send them the domain information.
   Domains are populated with managed items after the next product synchronization.

Multi-tenancy and CA Spectrum

When you register the DX NetOps Spectrum data source, database synchronization occurs. DX NetOps Spectrum retrieves a list of IP domains. All IP domain definitions are sent over, regardless of their association with individual tenants. OneClick displays these NetOps Portal IP Domain models in the same area as DX NetOps Spectrum Global Collections in the OneClick Navigation panel. The IP Domain models have the same names as the IP domain definitions:

- Use these IP domains to determine which models are synchronized with DX NetOps Performance Management. To include a device model in DX NetOps Performance Management monitoring and make it available in NetOps Portal dashboards, add it to an IP domain in OneClick.
- Add only device models that should be synchronized with NetOps Portal. When the device models are synchronized, they are associated with the corresponding IP domain in NetOps Portal. The NetOps Portal IP domain may belong to the Default Tenant, or to any custom tenant. Do not add interface models. Device interfaces are automatically added to the IP domain with which their device is associated.
- DX NetOps Spectrum devices can be members of only a single IPDomain model type. If you attempt to add a model to multiple IP domains, you see an error message.

Performance Center Administration

To maximize the value of reporting and to make DX NetOps Performance Management fit the needs of your business, customize NetOps Portal.

To customize NetOps Portal, do any of the following tasks:

- To let users send reports by email, either manually or on a schedule, configure an email server. For more information, see Set the Email Server.
- To change the appearance of exported reports, apply a new theme to a NetOps Portal tenant. For more information, see Customize a Theme.
- To change the display settings, such as view suppression and item name display names and aliases, customize the display settings. For more information, see Customize Your User Settings.
- To let the NetOps Portal daemons run effectively, modify the maximum memory usage. For more information, see Modify Maximum Memory Usage for Each Performance Center Service.
- To avoid losing valuable data, back up the NetOps Portal database before you upgrade to a new release. Also create a backup archive of the database on a weekly basis. For more information, see Back Up Performance Center.

Back Up Performance Center

Back up NetOps Portal before an upgrade. To avoid losing valuable data, back up and archive NetOps Portal regularly.

Back Up the NetOps Portal Database

Create a backup archive of the current database anytime that you plan to reinstall or upgrade the software. We recommend that you create a backup archive on a weekly basis.

Follow these steps:

1. Log in to the NetOps Portal host as 'root', or use the 'sudo' account that you configured for the installation.
2. Estimate the size of the backup:

   ```
   du –hs MySql/data
   ```

3. Stop all the NetOps Portal services, using the following commands:

   ```
   service caperfcenter_console stop

   service caperfcenter_devicemanager stop

   service caperfcenter_eventmanager stop

   service caperfcenter_sso stop
   ```

4. Change to a directory where you want to save the database archive:

   ```
   cd /$backupDir
   ```

   Use any secure location with sufficient space for the backup directory.
5. Create a MySQL dump of the database using the following command:

   NOTE

   If you leave out the optional password syntax from the following command, you are prompted for the password.

   ```
   /opt/CA/MySql/bin/mysqldump --routines -u root -ppassword  netqosportal > $backupDir/
   netqosportal.sql
   ```

   NOTE
   During the installation, you are prompted to 'Select a Location for the MySQL Data Directory'. The default location is /opt/CA/MySql/data.
6. Create a MySQL dump of Event Manager data:

   ```
   /opt/CA/MySql/bin/mysqldump -u root -ppassword em > $backupDir/em.sql
   ```

7. Compress these backup files to save space using the following commands:

   ```
   tar czvf netqosportal.tgz netqosportal.sql

   tar czvf em.tgz em.sql
   ```

8. Remove the uncompressed MySQL dump files using the following commands:

```
rm netqosportal.sql

rm em.sql
```

9. Start the NetOps Portal services on the new system as follows:
   a. Start the SSO service:

```
service caperfcenter_sso start
```

   b. Wait one minute, then start the event manager and device manager:

```
service caperfcenter_eventmanager start

service caperfcenter_devicemanager start
```

   c. Wait one minute, then start the console service:

```
service caperfcenter_console start
```

Back Up Single Sign-On Configuration Files

If you configure single sign-on, backup the configuration settings. Use rsync or another preferred method, such as a script, to back these files up automatically.

Back up the following files:

- `/opt/CA/PerformanceCenter/sso/start.ini`
- `/opt/CA/PerformanceCenter/PC/start.ini`

Back up the following directories:

- `/opt/CA/PerformanceCenter/sso/webapps/sso/configuration`
- `/opt/CA/PerformanceCenter/sso/etc`
- `/opt/CA/PerformanceCenter/sso/conf`
- `/opt/CA/PerformanceCenter/PC/etc`
- `/opt/CA/PerformanceCenter/PC/conf`

If you have enabled SSL, back up the following files:

- `/opt/CA/PerformanceCenter/sso/start.d/ssl.ini`
- `/opt/CA/PerformanceCenter/PC/start.d/ssl.ini`

Back Up Custom Settings

Custom OpenAPI applications reside on the NetOps Portal host. If your deployment includes custom OpenAPI applications, back up the application folder:

- `/opt/CA/PerformanceCenter/PC/webapps/pc/apps`

If you use custom logos for your themes, back up the following files:

- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Blue/images/customLogo
- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images/customLogo

Back Up Reports

Full PDF reports are temporarily saved for download.

Back up the following directory:

- /opt/CA/PerformanceCenter/DM/repository

Back Up Script Notification Actions

If you have script notification actions, back up the following directory:

- /opt/CA/PerformanceCenter/NotificationScripts

Customize a Theme

DX NetOps Performance Management supports user interface themes. These themes primarily describe the colors that are used to draw the user interface and when generating PDF files. Several themes are shipped with the product (CA-Blue, CA-Gray, CA-White). You can define more site-specific themes, which provide different color schemes.

WARNING

Custom themes require reconfiguration every time a new version of DX NetOps Performance Management is installed. Carefully consider whether a new theme is necessary. Only experienced administrators should customize themes.

NOTE

If you only want to apply a unique logo, simply manage your theme settings and apply a new logo.

Create a New Theme

The theme directories that are shipped with the product are CA-Blue, CA-Gray, and CA-White. To define more site-specific themes, duplicate one of the existing theme directories using an appropriate naming convention. Then deploy the theme in NetOps Portal.

NOTE

Define the custom theme directory name as "XXXXXXX-Theme" where XXXXXXX is some identifier that the user can define. For example, "CA-Blue-Modified-Theme". The name should exclude any spaces or special characters.

If the theme directory name is appended with "-Theme," it is available for deployment and it is preserved during an upgrade. Custom theme directories are not preserved after an uninstall. Custom themes require reconfiguration every time a new version of DX NetOps Performance Management is installed.

NOTE

You can use the following procedure to change the user interface coloring, icon coloring, or the PDF font and coloring.

Follow these steps:

1. Go to the following location:
   /PC InstallDirectory/PerformanceCenter/PC/webapps/pc/css
2. Package one of the existing standard theme directories. For example, zip up the CA-Blue theme.

3. Copy the ZIP file to your local computer, unzip it, and name it appropriately.

   NOTE

   Define the custom theme directory name as "XXXXXXX-Theme" where XXXXXXX is some identifier that the user can define. For example, "CA-Blue-Modified-Theme". The name should exclude any spaces or special characters.
4. Do any of the following tasks:
   - To change the user interface coloring, go to the `/ThemeDirectory/includes` directory and edit the `capc_theme.css` file. When you are done editing `capc_theme.css` , copy and replace `capc_theme.css` to `capc_theme-min.css` .
     Example:
     To change the background color, locate the comment "page background color" and replace the color #f7f7f7 with "pink". After you save the file, users using your theme have a pink page background color instead of a pale gray one.
   - To change the icon coloring, go to the `/ThemeDirectory /images` directory and edit the relevant files in a graphics editor.
     Example:
     To change all the gray icons to be white icons, edit the `IconsSecondary.png` file.
   - To change the PDF font and font coloring, go to the `/ThemeDirectory /xsl/pdf` directory and edit the `defaultPageContent.xml` file.
5. Package the customized theme directory and name it appropriately.
6. From the NetOps Portal UI, manage your theme settings, and deploy the new theme.

Manage Your Theme Settings

To change the logo that appears in PDF report headers or apply a different existing theme, edit your theme settings. By default, all themes use the CA Technologies corporate logo. As a global administrator, you apply a theme to a specific tenant. If you do not deploy multi-tenancy, the theme applies to the default tenant. For more information, see Manage Tenants.

Apply a Logo

You can upload and apply a unique logo to the PDF output.

Follow these steps:

1. Log in as a user with the Administrator role.
2. Hover over **Administration**, and click **Group Settings: Themes**.
   The Theme Settings page opens.
3. To upload a unique logo, click **Browse** and select the image file for your logo.
4. To apply the logo the logo to a theme, select the theme from the **Apply to theme** drop-down list.
   If you do not deploy multi-tenancy, select **All Themes**.
5. Click **Upload Image**.
6. Edit the tenant to select the theme that you modified.

   NOTE

   To restore the default theme settings, click **Reset Images**.

Deploy a Theme

After you create a theme, you must deploy the theme to use use it.

NOTE
Theme deployment occasionally hangs when you use the Chrome browser. If this known limitation occurs, deploy the theme using Firefox or Internet Explorer as your browser.

Follow these steps:

1. Log in as a user with the Administrator role.
2. Hover over **Administration**, and click **Group Settings: Themes**.
   The Theme Settings page opens.
3. In the Deploy a Theme section, click **Browse**, and select the new theme.

   NOTE

   The maximum filesize is 100 MB. The file must have a ZIP file extension. One top-level theme directory should exist in the ZIP file. The name of the theme directory must end with "-Theme".
4. To replace an existing theme, select **Replace existing themes**.
5. Click **Add**.

Manage Authentication Requirements

By default, user passwords must meet the following requirements:

- Be different from the username
- Minimum length of 8 characters
- Maximum length of 30 characters
- Contain at least 3 of the following types of characters:
  - Special characters
  - Uppercase letters (A-Z)
  - Lowercase letters (a-z)
  - Numbers (0-9)

For more information, see Customize Your User Settings.

By default, non-LDAP passwords expire after 105 days. When passwords expire, access to REST and the OpenAPI is blocked. The next time users log in, they must change their passwords.

You can enable a setting that disables users after multiple failed login attempts within a timeframe. By default, 6 failed login attempts within 3 minutes disable the user. In addition to disabling the user, you can also block the IP address of the user for a specified amount of time. This functionality is *not* an intrusion detection system.

Configure Authentication Settings

If desired, you can change authentication requirements using the Single Sign-On Configuration/Performance Center Tool.

Follow these steps:

1. Log in to the Performance Center host.
2. Navigate to the Performance Center directory:
   ```
   cd PC_Install_Directory/PerformanceCenter
   ```
3. Launch the SSO Configuration utility:
   ```
   ./SsoConfig
   ```
4. Select CA Performance Center.
5. Select and run option 8: Performance Center Local Password Authentication.

6. Complete the following prompts:
   - **1. Enforce password requirements**
     Specify whether to enforce the password requirements.
     Default: Enabled
   - **2. Allow REST to create users with usernames and passwords that match**
     Specify whether to allow the REST web services to create users with usernames and passwords that match. If disabled, users are created with randomized passwords.
     Default: Enabled
   - **3. Minimum password length**
     Specify the minimum password length.
     Default: 8
   - **4. Password lifespan**
     Specify when passwords expire. To disable password expiration, specify 0. If disabled, passwords never expire.
     Default: 105 days
   - **5. Disable password expiration for a specific user**
     Specify the user to disable password expiration for. The password for the specified user never expires.
   - **6. Enable password expiration for a specific user**
     Specify the user to enable password expiration for. The password lifespan is applied.
   - **7. Expire password for a specific user**
     Specify the user to expire the password for. The specified user must change their password the next time they log in.
   - **8. Expire the password for all users**
     Confirm whether to expire the passwords for all users. If yes, all users must change their passwords the next time they log in.
   - **9. Failed login attempts before blocking**
     Specify the number of failed login attempts before blocking the user.
     Default: 6
   - **10. Timeframe for failed login attempts**
     Specify the timeframe that the failed login attempts must occur before blocking the user.
     Default: 3 minutes
   - **11. Disable user after failed login attempts**
     Specify whether multiple failed login attempts within a timeframe disable the user.
     Default: Disabled
   - **12. Number of minutes to block IP address after failed login attempts**Specify the number of minutes to block an IP address after multiple failed login attempts within a timeframe.
     Default: 0
7. Enter q to close the Single Sign-On Configuration Tool.
   The Single Sign-On Configuration Tool closes.

Enable a Disabled User

If a user is disabled after multiple failed login attempts, you can enable them using the Single Sign-On Configuration/ Performance Center Tool.

You can also manage user account status in the Performance Center administration UI. For more information, see Manage User Accounts.

Follow these steps:

1. Log in to the Performance Center host.
2. Navigate to the Performance Center directory:
   ```
   cd PC_Install_Directory/PerformanceCenter
   ```

3. Launch the SSO Configuration utility:
   ```
   ./SsoConfig
   ```
4. Select CA Performance Center.
5. Select and run option 9: Enable or Disable a user account.
6. Complete the prompts.
7. Enter q to close the Single Sign-On Configuration Tool.
   The Single Sign-On Configuration Tool closes.

Migrate Performance Center

If you upgrade the Linux OS release, you can use the following procedure to migrate NetOps Portal to a new host with a new IP address and hostname.

> **NOTE**
>
> You must upgrade the existing system to the product version you are migrating to before migrating. This migration procedure copies over NetOps Portal and does not require you to install NetOps Portal on the new host.

Prepare for the Migration

Follow these steps:

1. Verify that the new host meets the system requirements. For more information, see Review Installation Requirements and Considerations and the DX NetOps Performance Management Sizing Tool
2. Prepare the new host. For more information, see Prepare to Install CA Performance Management.
3. If you installed NetOps Portal on the original system as *sudo user,* add the command alias on the new system:
   a. Locate the following file on the NetOps Portal host:
      ```
      /etc/sudoers
      ```
   b. Add a command alias with the following permissions to the file:

- /tmp/CAPerfCenterSetup.bin
- /etc/init.d/caperfcenter_console **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_devicemanager **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_eventmanager **(for RHEL 6.x)**
- /etc/init.d/caperfcenter_sso **(for RHEL 6.x)**
- /etc/init.d/mysql
- /opt/CA/PerformanceCenter/PC/bin/caperfcenter_console **(for RHEL 7.x, SLES, or OL)**
- /opt/CA/PerformanceCenter/DM/bin/caperfcenter_devicemanager **(for RHEL 7.x, SLES, or OL)**
- /opt/CA/PerformanceCenter/EM/bin/caperfcenter_eventmanager **(for RHEL 7.x, SLES, or OL)**
- /opt/CA/PerformanceCenter/sso/bin/caperfcenter_sso **(for RHEL 7.x, SLES, or OL)**
- /opt/CA/PerformanceCenter/Tools/bin/npcshell.sh
- /opt/CA/PerformanceCenter/SsoConfig
- /opt/CA/PerformanceCenter/Uninstall_MySql
- /opt/CA/PerformanceCenter/Uninstall_PerformanceCenter
- /opt/CA/PerformanceCenter/Uninstall_SSO
- /sbin/service
- /opt/CA/MySql/bin/mysql
- /opt/CA/MySql/bin/mysqldump
- /opt/CA/PerformanceCenter/sso
- /opt/CA/PerformanceCenter/PC
- /opt/CA/PerformanceCenter/PC/webapps/pc/apps
- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Blue/images
- /opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images
- /usr/bin/vim
- /opt/CA/jre/bin/keytool
- /opt/CA/PerformanceCenter/DM/repository
- /opt/CA/PerformanceCenter/NotificationScripts

Separate the permissions with commas and place all permissions on a single line.

Example:

```
Cmnd_Alias CAPERFCENTER = /tmp/CAPerfCenterSetup.bin,/opt/CA/
PerformanceCenter/PC/bin/caperfcenter_console,/opt/CA/PerformanceCenter/
DM/bin/caperfcenter_devicemanager,/opt/CA/PerformanceCenter/EM/bin/
caperfcenter_eventmanager,/opt/CA/PerformanceCenter/sso/bin/caperfcenter_sso,/
etc/init.d/mysql,/opt/CA/PerformanceCenter/Tools/bin/npcshell.sh,/opt/CA/
PerformanceCenter/SsoConfig,/opt/CA/PerformanceCenter/Uninstall_MySql,/opt/
CA/PerformanceCenter/Uninstall_PerformanceCenter,/opt/CA/PerformanceCenter/
Uninstall_SSO,/sbin/service,/opt/CA/MySql/bin/mysql,/opt/CA/MySql/bin/
mysqldump,/opt/CA/PerformanceCenter/sso,/opt/CA/PerformanceCenter/PC,/opt/CA/
PerformanceCenter/PC/webapps/pc/apps,/opt/CA/PerformanceCenter/PC/webapps/pc/css/
CA-Blue/images,/opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images,/usr/
bin/vim, /opt/CA/jre/bin/keytool, /opt/CA/PerformanceCenter/DM/repository, /opt/
CA/PerformanceCenter/NotificationScripts
caadmin ALL = CAPERFCENTER
```

4. Verify that the new host has network access from the original host.

Copy the Files from the Existing System

Follow these steps:

1. Log in to the original NetOps Portal host.
2. Stop the NetOps Portal services on the original system:
   ```
   service caperfcenter_console stop
   service caperfcenter_devicemanager stop
   service caperfcenter_eventmanager stop
   service caperfcenter_sso stop
   ```
3. Create a dump of the MySQL `netqosportal` database from the original system:
   ```
   /opt/CA/MySql/bin/mysqldump --routines netqosportal -unetqos -ppassword > $backupDir/netqosportal.sql
   ```
4. Create a dump of MySQL Event Manager data from the original system:
   ```
   /opt/CA/MySql/bin/mysqldump em -unetqos -ppassword > $backupDir/em.sql
   ```
5. Copy the database backups:
   ```
   scp $backupDir/netqosportal.sql <new_PC_host>:/tmp/netqosportal.sql
   scp $backupDir/em.sql <new_PC_host>:/tmp/em.sql
   ```
6. Stop the mysql service on the original system:
   ```
   service mysql stop
   ```
7. Package the files in the installation directory:
   ```
   cd /opt
   tar czf PC.tgz ./CA
   ```

   NOTE

   The following path is the default installation directory: `/opt/CA`
8. Copy the files to the new NetOps Portal host:
   ```
   scp /opt/PC.tgz <new_PC_host>:/opt
   ```
9. Copy the registry file that stores the installation and version information:
   ```
   scp /var/.com.zerog.registry.xml <new_PC_host>:/var
   ```
10. If you are migrating to a RHEL 6.x system, copy the NetOps Portal service startup scripts:
    ```
    scp /etc/init.d/caperfcenter_console <new_PC_host>:/etc/init.d/caperfcenter_console
    scp /etc/init.d/caperfcenter_devicemanager <new_PC_host>:/etc/init.d/
    caperfcenter_devicemanager
    scp /etc/init.d/caperfcenter_eventmanager <new_PC_host>:/etc/init.d/
    caperfcenter_eventmanager
    scp /etc/init.d/caperfcenter_sso <new_PC_host>:/etc/init.d/caperfcenter_sso
    ```
11. Copy the MySQL startup script:
    ```
    scp /etc/init.d/mysql <new_PC_host>:/etc/init.d/mysql
    ```
12. Copy the MySQL configuration file:
    ```
    scp /etc/my.cnf <new_PC_host>:/etc/
    ```

Configure the New System

NOTE
If SSL is configured on the source system, reconfigure it on the new system after setup.

Follow these steps:

1. Log in to the new NetOps Portal host.

2. Change the directory:
   ```
   cd /opt
   ```
3. Extract PC.tgz file:
   ```
   tar -xvf PC.tgz
   ```
4. Verify that the paths in
   ```
   /etc/profile
    point /opt/CA
   ```
   to the root where NetOps Portal is installed. Verify the following PATHs:
   ```
   PATH="${PATH}:/opt/CA/jre/bin"
   export PATH
   PATH="${PATH}:/opt/CA/MySql/bin"
   export PATH
   PATH="${PATH}:/opt/CA/PerformanceCenter/Tools/bin"
   export PATH
   ```
5. Do one of the following steps:
   - If you are migrating to a RHEL 6.x system, add the following services to add runlevel information for the NetOps Portal system services:
     ```
     chkconfig --add mysql
     chkconfig --add caperfcenter_console
     chkconfig --add caperfcenter_devicemanager
     chkconfig --add caperfcenter_eventmanager
     chkconfig --add caperfcenter_sso
     ```
   - If you are migrating to a RHEL 7.x, SLES, or OL system, add the following services to add runlevel information for the NetOps Portal system services:
     ```
     chkconfig --add mysql
     /opt/CA/PerformanceCenter/PC/bin/caperfcenter_console install
     /opt/CA/PerformanceCenter/DM/bin/caperfcenter_devicemanager install
     /opt/CA/PerformanceCenter/EM/bin/caperfcenter_eventmanager install
     /opt/CA/PerformanceCenter/sso/bin/caperfcenter_sso install
     ```
6. Configure MySQL in the `/etc/group` and `/etc/passwd` files:
   a. Add the following command to /etc/group:
      ```
      mysql:x:27:
      ```
   b. Add the following command to `/etc/passwd` file:
      ```
      mysql:x:27:27:MySQL Server:/var/lib/mysql:/bin/bash
      ```
   c. To ensure that the edits take effect, log out from the new NetOps Portal host, and log in again.
   d. Start the mysql service on the new system:
      ```
      service mysql start
      ```
7. Restore the databases:
   ```
   cd /opt/CA/MySql/bin
   mysql netqosportal -unetqos -ppassword -e 'source /tmp/netqosportal.sql'
   mysql em -unetqos -ppassword -e 'source /tmp/em.sql'
   ```
8. Start the NetOps Portal services on the new system as follows:
   a. Start the SSO service:
      ```
      service caperfcenter_sso start
      ```
   b. Wait one minute, then start the Event Manager and Device Manager:

```
service caperfcenter_eventmanager start
service caperfcenter_devicemanager start
```

c. Wait one minute, then start the console service:

```
service caperfcenter_console start
```

Update the Event Manager Data Source

If the new NetOps Portal hostname is different from the original NetOps Portal host, update the Event Manager data source. You must run a full Event Manager data source sync after you update the host name in the NetOps Portal UI.

Follow these steps:

1. Log in to the NetOps Portal UI as the Administrator user. Use the new host name:
   `http://new_PC_host:8181`

   NOTE

   If you cannot log in, run the following commands to check for database errors:

   ```
   mysqlcheck mysql
   mysqlcheck em
   mysqlcheck netqosportal
   ```

   If you see missing functions or corrupt table issues, see the following procedure for repairing the database.
2. Hover over **Administration**, and click **Data Sources: Data Sources**.
3. Select the Event Manager data source, and click **Edit**.
4. Edit the Host Name and Display Name fields:

   NOTE

   If SSL is configured, specify HTTPS for the communication protocol.
5. To validate communication, click **Test**.
6. Click **Save**.
7. Select the Event Manager data source, and click **Resync**.
8. Select **Perform a Full Resynchronization**, and click **Resync**.
   NetOps Portal resynchronizes with the Event Manager data source.
9. After the Event Manager has completed a full resynchronization, re-register the Event Manager with the data sources:
   a. Run the following command to log in to MySQL:

      ```
      /opt/CA/MySql/bin/mysql em -unetqos -ppassword
      ```

   b. Run the following command:

      ```
      UPDATE em.data_sources SET LastEvent = 0, ConsumerID = 0;
      ```

   The new Event Manager IP address is pushed to the Data Aggregator.

Repair the Database

If you cannot log in to to the NetOps Portal UI, check for database errors. If there are errors, stop the NetOps Portal services. Repair the database with the appropriate command. Then restart the NetOps Portal services.

Follow this procedure:

1. Stop the NetOps Portal services:

   ```
   service caperfcenter_console stop
   service caperfcenter_devicemanager stop
   service caperfcenter_eventmanager stop
   ```

```
service caperfcenter_sso stop
```

2. Repair the database with the appropriate command:

```
mysqlcheck -r mysql
mysqlcheck -r em
mysqlcheck -r netqosportal
```

3. Start the NetOps Portal services on the new system as follows:
   a. Start the SSO service:

```
service caperfcenter_sso start
```

   b. Wait one minute, then start the event manager and Device Manager:

```
service caperfcenter_eventmanager start
service caperfcenter_devicemanager start
```

   c. Wait one minute, then start the console service:

```
service caperfcenter_console start
```

Configure the Data Source Connector for a Report

If you have the *Unified Dashboards and Reporting for Infrastructure Management* solution set up, and the new NetOps Portal hostname has changed, reconfigure the data source connector for the reports.

Follow these steps:

1. Ensure that the CA Business Intelligence data source is installed.
2. Open the CA Business Intelligence JasperReports login page in a browser. Log in to the CA Business Intelligence JasperReports Server as a user with an Administration role for the **Public** organization.
3. Select **View**, **Repository**.
4. In the Folders panel on left, expand **Public**, **ca**, **Performance Management**, **datasources**.
5. Select the NetOps Portal data source and click **Edit**.
6. Update the data source parameters and click **Save**:
   - **Schema**
     Specify HTTP or HTTPS.
   - **Host**
     Specify the NetOps Portal host name. Do not specify the Data Aggregator host name.
   - **Port**
     Specify the NetOps Portal port (default: 8181).
   - **NetOps Portal GUID**
     The NetOps Portal GUID (unique) is used when the password for the CA Business Intelligence web user is not available. This information passes to the Data Aggregator to ensure that the request is going to the correct NetOps Portal instance. A web service call on NetOps Portal retrieves this information.
     GUID Endpoint URL: `http://hostname:8181/pc/center/webservice/datasources/performanceCenterGUID`
7. Click **Save** to apply the changes.

Verify the Migration

You must run Resync All to update the IP addresses for the NetOps Portal `netqosportal` tables.

Follow these steps:

1. Log in to the NetOps Portal UI as the Administrator user. Use the new host name:
   `http://new_PC_host:8181`
2. Hover over **Administration**, and click **Data Sources: Data Sources**.

3. Click **Resync All**.
   NetOps Portal synchronizes with all registered data sources and updates the required contact information.
4. To verify that the NetOps Portal host name is correct on the Data Aggregator, use the following REST call:
   `http://<DA_host>:8581/rest/dataaggregator`
   The value for `NpcHostName` is the IP address of the new NetOps Portal host.

Configure Authentication

NetOps Portal supports external authentication schemes, such as LDAP, SAML 2.0, SSL.

- For LDAP, no additional configuration is required with a NetOps Portal migration.
- For SAML 2.0, reconfigure SAML 2.0 on the new system. For more information, see Set Up SAML 2.0 Support.
- For SSL, set up new SSL certificates with the new hostname and alias. For more information, see Set Up SSL Certificates for Performance Center.

NOTE

If you have overridden the NPC hostname that Data Aggregator contacts, update Web Service Host in SSO Config. For more information, see Update Performance Center Website Settings.

Modify Maximum Memory Usage for Each Performance Center Service

Modify the maximum memory usage for the NetOps Portal daemons to let the daemons run effectively. Configure memory allocation during or after the installation.

Follow these steps:

1. On the server where you installed NetOps Portal, run the following command:
   ```
   more /proc/meminfo
   ```
   The total memory usage of the server is displayed.
2. Make a note of the total memory.
3. Modify the maximum memory for a daemon as follows:
   a. Edit the following file:
      `/Installation Directory/PerformanceCenter/Service Subdirectory/conf/wrapper.conf`

      NOTE

      The Service subdirectory is one of the following options:

      - PC (Console daemon)
      - DM (Device Manager daemon)
      - EM (Event Manager daemon)

   b. Search for the parameter 'wrapper.java.maxmemory'.
   c. Change the current value. For example, in a small deployment, set it to '3072' (the units are MB).
   d. Save the file.
4. Stop and restart each daemon by entering the following commands:
   ```
   service service name stop
   service service name start
   ```

   NOTE

   The service name is one of the following options:

- caperfcenter_console
- caperfcenter_devicemanager
- caperfcenter_eventmanager

The maximum amount of memory is configured for a deployment of your scalability requirements.

Restore Performance Center

Restore an existing backup of NetOps Portal.

Restore the Database After a Reinstallation

Restore the NetOps Portal database from a backup archive after you reinstall the software. Restoring the database from a backup preserves data continuity and enables most historical reporting after a failure occurs.

Database restoration is required only if a failure occurs. Take the cleanup steps that are described in Clean Up After a Failed Installation before you attempt the installation again. Then, take the steps in this procedure.

NOTE

For upgrade failure situations, follow the steps in Recover from an Upgrade Failure.

Follow these steps:

1. Log in to the server as 'root', or use the 'sudo' account that you configured for the installation.
2. Stop all the NetOps Portal services using the following commands:

```
service caperfcenter_eventmanager stop

service caperfcenter_devicemanager stop

service caperfcenter_sso stop

service caperfcenter_console stop
```

3. Change to the directory where you saved the backup archive:

```
cd backup_Directory
```

4. Uncompress the database backup archives for NetOps Portal and Event Manager by executing the following commands:

```
tar zxvf netqosportal.tgz

tar zxvf em.tgz
```

5. Import the uncompressed NetOps Portal backup file:

```
mysql netqosportal -u root -ppassword -e 'source $backupDir/netqosportal.sql'
```

6. Import the uncompressed Event Manager backup file:

```
mysql em -u root -ppassword -e 'source $backupDir/em.sql'
```

7. Start the NetOps Portal services on the new system as follows:
   a. Start the SSO service:

      ```
      service caperfcenter_sso start
      ```

   b. Wait one minute, then start the event manager and device manager:

      ```
      service caperfcenter_eventmanager start
      ```

      ```
      service caperfcenter_devicemanager start
      ```

   c. Wait one minute, then start the console service:

      ```
      service caperfcenter_console start
      ```

8. Delete the uncompressed archive files to save space:

   ```
   rm netqosportal.sql
   ```

   ```
   rm em.sql
   ```

9. Log in to NetOps Portal as an administrator.
10. Verify that your configuration data appears in the Admin pages.

Recover from an Upgrade Failure

Follow these steps to restore the NetOps Portal database and verify the database schema version. If the schema version matches the current product version, try the upgrade again. If not, see *Recover from an Upgrade Failure with an Error* for the steps to update the schema version.

> **NOTE**
> Database restoration is required after an upgrade only if a failure occurs. Take the cleanup steps that are described in *Clean Up After a Failed Installation* before you attempt the upgrade again. Then, take the steps in this procedure.

Follow these steps:

1. Log in to the server as 'root', or use the 'sudo' account that you configured for the installation.
2. Stop all the NetOps Portal services, using the following commands:

   ```
   service caperfcenter_eventmanager stop
   ```

   ```
   service caperfcenter_devicemanager stop
   ```

   ```
   service caperfcenter_sso stop
   ```

   ```
   service caperfcenter_console stop
   ```

3. Change to the directory where you saved the backup archive:

   ```
   cd backup_Directory
   ```

4. Uncompress the database backup archives for NetOps Portal and Event Manager by executing the following commands:

   ```
   tar zxvf netqosportal.tgz

   tar zxvf em.tgz
   ```

5. Import the uncompressed NetOps Portal backup file:

   NOTE

   If you leave out the optional password syntax from the following command, you are prompted for the password.

   ```
   mysql netqosportal -u root -ppassword -e 'source $backupDir/netqosportal.sql'
   ```

6. Import the uncompressed Event Manager backup file:

   ```
   mysql em -u root -ppassword -e 'source $backupDir/em.sql'
   ```

7. Change to the following installation directory:

   ```
   cd /opt/CA/PerformanceCenter/Tools/bin
   ```

8. Run the following command to verify the database version:

   ```
   mysql -P3306 -D netqosportal -u root -ppassword

   mysql> select InstallDate, version, dbschemaversion from revision_info order by
    InstallDate asc;
   ```

   The output lists installation dates and versions of the software and database schema.
   If the database version does not match the current product version, follow the steps in *Recover from an Upgrade Failure with an Error*.

Recover from an Upgrade Failure with an Error

If an error occurs during an upgrade of the NetOps Portal software, restore the database and update the schema. See *Recover from an Upgrade Failure* for the steps to restore the database and verify the database schema version. If the schema version does not match the current product version, update the schema version.

Follow these steps:

1. Upgrade the database schema. From the Tools/bin directory, run the npcshell database utility to upgrade the schema to the current version:

   ```
   ./npcshell.sh upgradedb
   ```

2. Run the following commands to import database translation files:

   ```
   /opt/CA/jre/bin/java -jar /opt/CA/PerformanceCenter/SQL/seedlu/bin/seedlu.jar -
   resfile "/opt/CA/PerformanceCenter/SQL/messages_en_US.properties" -ctrlfile "/opt/
   CA/PerformanceCenter/SQL/control.sdlctrl" -connection "jdbc:mysql://localhost:3306/
   netqosportal?useUnicode=true&characterEncoding=UTF-8" -user netqos -pwd password -
   lang en-US
   /opt/CA/jre/bin/java -jar /opt/CA/PerformanceCenter/SQL/seedlu/bin/seedlu.jar -
   resfile "/opt/CA/PerformanceCenter/SQL/messages_zh_CN.properties" -ctrlfile "/opt/
   CA/PerformanceCenter/SQL/control.sdlctrl" -connection "jdbc:mysql://localhost:3306/
   netqosportal?useUnicode=true&characterEncoding=UTF-8" -user netqos -pwd password -
   lang zh-CN
   /opt/CA/jre/bin/java -jar /opt/CA/PerformanceCenter/SQL/seedlu/bin/seedlu.jar -
   resfile "/opt/CA/PerformanceCenter/SQL/messages_zh_TW.properties" -ctrlfile "/opt/
   CA/PerformanceCenter/SQL/control.sdlctrl" -connection "jdbc:mysql://localhost:3306/
   netqosportal?useUnicode=true&characterEncoding=UTF-8" -user netqos -pwd password -
   lang zh-TW
   /opt/CA/jre/bin/java -jar /opt/CA/PerformanceCenter/SQL/seedlu/bin/seedlu.jar -
   resfile "/opt/CA/PerformanceCenter/SQL/messages_fr_FR.properties" -ctrlfile "/opt/
   CA/PerformanceCenter/SQL/control.sdlctrl" -connection "jdbc:mysql://localhost:3306/
   netqosportal?useUnicode=true&characterEncoding=UTF-8" -user netqos -pwd password -
   lang fr-FR
   /opt/CA/jre/bin/java -jar /opt/CA/PerformanceCenter/SQL/seedlu/bin/seedlu.jar -
   resfile "/opt/CA/PerformanceCenter/SQL/messages_ja_JP.properties" -ctrlfile "/opt/
   CA/PerformanceCenter/SQL/control.sdlctrl" -connection "jdbc:mysql://localhost:3306/
   netqosportal?useUnicode=true&characterEncoding=UTF-8" -user netqos -pwd password -
   lang ja-JP
   ```

   NOTE

   Replace the '*password*' variable with the password.

3. Update the information that NetOps Portal uses to display administration pages and views. Run the following commands:
   - **CA Infrastructure Management Administration Pages:**

     ```
     ./npcshell.sh dbmigrate -package com.ca.im.plugin.pc -path ../../SQL/plugins/pc/
     ```

   - **Event-Related Views:**

     ```
     ./npcshell.sh dbmigrate -package com.ca.im.plugin.em -path ../../SQL/plugins/
     eventmanager/
     ```

- **Data Aggregator Administration Pages and Views:**

```
./npcshell.sh dbmigrate -package com.ca.im.plugin.da -path ../../SQL/plugins/
polaris/
```

4. Run the following command again to verify the database version after you have upgraded it:

```
mysql -P3306 -D netqosportal -u root -ppassword

mysql> select InstallDate, version, dbschemaversion from revision_info order by
 InstallDate asc;
```

5. Start all the NetOps Portal services:

```
service caperfcenter_eventmanager start

service caperfcenter_devicemanager start

service caperfcenter_sso start

service caperfcenter_console start
```

6. Delete the uncompressed archive files to save space:
```
rm netqosportal.sql
rm em.sql
```
7. Log in to NetOps Portal as an administrator.
8. Verify that your configuration data appears in Admin pages.

Restore Single Sign-On Settings

If your NetOps Portal deployment uses single sign-on, restore the configuration settings.

Restore the following files:

- `/opt/CA/CA/PerformanceCenter/sso/start.ini`
- `/opt/CA/CA/PerformanceCenter/PC/start.ini`

Restore the follow directories:

- `/opt/CA/CA/PerformanceCenter/sso/webapps/sso/configuration`
- `/opt/CA/CA/PerformanceCenter/sso/etc`
- `/opt/CA/CA/PerformanceCenter/sso/conf`
- `/opt/CA/CA/PerformanceCenter/PC/etc`
- `/opt/CA/CA/PerformanceCenter/PC/conf`

If you have enabled SSL, restore the following files:

- `/opt/CA/CA/PerformanceCenter/sso/start.d/ssl.ini`
- `/opt/CA/CA/PerformanceCenter/PC/start.d/ssl.ini`

Restore Custom Settings

If your deployment includes custom OpenAPI applications, restore the application folder:

- `/opt/CA/PerformanceCenter/PC/webapps/pc/apps`

If you use custom logos for your themes, restore the following files:

- `/opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Blue/images/customLogo`
- `/opt/CA/PerformanceCenter/PC/webapps/pc/css/CA-Gray/images/customLogo`

Restore Reports

Full PDF reports are temporarily saved for download.

Restore the following directory:

- `/opt/CA/PerformanceCenter/DM/repository`

Restore Script Notification Actions

If you have script notification actions, restore the following directory:

- `/opt/CA/PerformanceCenter/NotificationScripts`

Update the Data Aggregator and Event Manager Data Sources

If the new NetOps Portal hostname is different from the original NetOps Portal host, update the the Data Aggregator and Event Manager data sources.

NetOps Portal Disaster Recovery Script

Location: `/opt/CA/PerformanceCenter/Tools/bin/update_pc_da_database_references.sh`

On the NetOps Portal host in the recovery system, update the bold sections of the script to match your system:

```
...

#####################################################################

# UPDATE THE FOLLOWING PC/DA VARIABLES TO REFLECT NEW ENVIRONMENT

#####################################################################

NEW_PC_IP_ADDRESS="<Recovery/New PC IP Address>"

NEW_PC_HOSTNAME="<Recovery/New PC Hostname>"

NEW_PC_EVENT_PRODUCER_PORT=8181

NEW_PC_EVENT_PRODUCER_PROTOCOL="http" # change to "https" if using SSL
```

```
NEW_DA_IP_ADDRESS="<Recovery/New DA IP Address>"

NEW_DA_HOSTNAME="<Recovery/New DA Hostname>"

NEW_DA_PORT_NUMBER=8581

...
```

Start NetOps Portal

Follow these steps:

1. Restore the NetOps Portal backups.
2. Run the NetOps Portal disaster recovery script:

   ```
   /opt/CA/PerformanceCenter/Tools/bin/your_update_pc_da_database_references.sh
   ```

3. Start the SSO service:

   ```
   service caperfcenter_sso start
   ```

4. Wait one minute, then start the event manager and device manager:

   ```
   service caperfcenter_eventmanager start

   service caperfcenter_devicemanager start
   ```

5. Wait one minute, then start the console service:

   ```
   service caperfcenter_console start
   ```

Resynchronize the Event Manager Database

The recommended backup and restore procedures include an instruction to back up the Event Manager database.

If you neglect this step, problems can occur when the Event Manager tries to synchronize with NetOps Portal. The synchronization can fail because NetOps Portal has outdated Event Manager information. The newly installed Event Manager has the new information.

If this problem occurs, resynchronize these two databases.

> **WARNING**
> Since this procedure does not include a step to restore the Event Manager database, notifications are not preserved, and must be recreated. Otherwise, the Event Manager runs normally.

Follow these steps:

1. Log in as a user with the Administrator role.

2. Navigate to the Manage Data Sources page.
   The current list of registered data sources appears on the Manage Data Sources.
3. Select the data source that you want to remove (unregister).
4. Click Remove, and then click Yes to confirm the deletion.
   The data source is removed from the list.
5. Remove all properties that are related to NetOps Portal from the em.general database table using the following command:

```
DELETE from em.general where Attribute LIKE 'NPC.%';
```

6. Restart Event Manager using the following command:

```
service caperfcenter_eventmanager restart
```

7. Return to the Manage Data Sources page.
8. Register the Event Manager data source.

Set the Email Server

To let users send reports by email, configure an email server. NetOps Portal sends reports on a schedule or as needed. Select a server that the NetOps Portal server has network access to.

Follow these steps:

1. Log in as a user with administrative role rights.
2. Select **Administration**, **Configuration Settings**, and click **Email Server**.
   The Email Server Settings page opens.
3. Select the **Enable Email** check box.
   The page refreshes to highlight the required field.
4. Complete the following fields as necessary:
   - **SMTP Server Address**
     Is the IP address or hostname of the server to use to send reports by email.
   - **SMTP Server Port**
     Is the port on the email server that is used to send messages.
     Default: Port 25.
   - **Email Reply Address**
     Is the email address from which NetOps Portal sends reports. An administrator monitors this address for responses to email messages sent by the product.
5. (3.7.6 and lower only) Enable SSL encryption. This parameter is required if you want to use a secure connection to send email from NetOps Portal.

   NOTE

   To enable this feature, you must enable NetOps Portal to use SSL. For more information, see Enable Performance Center to use SSL.

   This parameter is unsupported for 3.7.7 and higher. For 3.7.7 and higher, if email server supports STARTTLS, Performance Center automatically tries to send all emails securely.

6. (Optional) Take the following steps to enable SMTP authentication:
   a. Select **Enable Authentication**.
   b. Type the username for SMTP authentication in the Username field.
   c. Type the authentication password in the Password field.
   d. Type the authentication password again in the Confirm Password field.

      NOTE
      SMTP authentication is disabled by default.
7. Click **Save**.
   The email server is set.

Import the Email Server Certificate

Import the email server certificate so that the email server is a trusted connection.

Follow these steps:

1. Import the email server certificate into the java trusted certificate keystore using the following steps:
   ```
   keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
   -storepass cacertspassword -alias alias_name -file filename.cer
   ```
   - ***cacertspassword***
     Specify the password for the Certificate Authority keystore.

     NOTE
     The default password for the Certificate Authority keystore is **changeit**.
   - ***alias_name***
     Specify an alias that can be used to refer to the keystore entry that is created for the email server certificate.
   - ***filename*.cer**
     Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
     Example: /tmp/capcCert.cer
2. Import the root and intermediate certificates into the java trusted certificate keystore for each certificate:
   ```
   keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
   -storepass cacertspassword -alias alias_name -file filename.cer
   ```
   - ***cacertspassword***
     Specify the password for the Certificate Authority keystore.

     NOTE
     The default password for the Certificate Authority keystore is **changeit**.
   - ***alias_name***
     Specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
   - ***filename*.cer**
     Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
     Example: /tmp/capcCert.cer
3. Confirm that you trust the certificate.
4. Verify that your imported keystore is available:
   ```
   keytool -list -keystore InstallDirectory/jre/lib/security/cacerts
   ```

Update Performance Center Website Settings

The Single Sign-On Configuration Tool lets you change the default settings for the NetOps Portal website and web service. For example, you can specify a different host or port number for the NetOps Portal web service. These settings instruct the Single Sign-On application how to connect to NetOps Portal.

Follow these steps:

1. Log in to the NetOps Portal host as root or with the 'sudo' command.
2. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:
   InstallDirectory/PerformanceCenter

   NOTE
   /opt/CA is the default installation directory.

   You are prompted to select an option. The available options correspond to CA applications running on the local server.
3. Use the following commands as needed while you are selecting settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
4. Enter 1 to configure NetOps Portal.
   You are prompted to select a configuration option.
5. Enter 3 for NetOps Portal.
   You are prompted to specify the priority.
   The Priority parameter only applies to NetOps Portal.
6. Enter one of the following options:
   - **1. Remote Value**These settings are propagated to all other CA products and data sources that are registered to this instance of NetOps Portal. This includes the Event Manager in NetOps Portal, which embeds the URL of NetOps Portal. NetOps Portal uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this NetOps Portal instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of NetOps Portal. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.

   NOTE
   Configure the scheme or port using Remote Value to include the correct CAPC URL in threshold event email messages.
7. Enter one or more of the following properties. When prompted, enter u to update the value and supply a new value:
   - **1. Web Service Scheme**
     Specifies the URL scheme for Device Manager service.
   - **2. Web Service Host**
     Specifies the URL host for the Device Manager service.

     NOTE
     OpenAPI SSO Authentication must be able to access NetOps Portal console and SSO ports. If these ports are blocked for the listed hostname or IP address, use a specified hostname or IP address with access to console and SSO ports.
   - **3. Web Service Port**
     Specifies the URL port for the Device Manager service.
   - **4. Web Service Inventory**

Specifies the URL path for the Device Manager inventory web service (version 1).

- **5. Web Service Data Source Admin**
  Specifies the URL path for the Device Manager data source web service.
- **6. Web Site Scheme**
  Specifies the URL scheme for all access to the NetOps Portal website. If you have set up HTTPS, use https.
- **7. Web Site Host**
  Specifies the URL host for all access to the NetOps Portal website.

  NOTE
  To use a specified hostname in emails instead of the IP address for the NetOps Portal host, set the Remote Value to that hostname.
- **8. Web Site Port**
  Specifies the URL port for all access to the NetOps Portal website.
- **9. Web Site Path**
  Specifies the URL path for all access to the NetOps Portal website.
- **10. SMTP Enabled**
  Specifies whether the Simple Mail Transfer Protocol (SMTP) is enabled to allow NetOps Portal operators to email reports and event notifications.
  Default: Disabled

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **11. SMTP Server Address**
  Is the IP address of the SMTP server.
  Default: Disabled

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **12. SMTP Ports:**
  Specifies the port to use for SMTP requests.
  Default: Port 25.

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **13. SMTP SSL**
  Specifies whether to use SSL encryption when sending email from NetOps Portal or other CA data source products. Verify that SSL has been properly set up on your system before you enable this option.
  Default: Disabled

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **14. Email Reply Address**
  Specifies the return address to use for email messages that are generated by NetOps Portal. Enter u to update the value, and supply an email address. Use the format username@mydomain.com.

NOTE

We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.

- **15. Email Format**
  Specifies the format to use for email messages that are sent by NetOps Portal. Enter u to update the value, and supply either HTML or text.

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **16. SMTP Username**
  Specifies a username to use when the email server challenges an SMTP request. Supply a username, or supply an empty string to disable client-side authentication.

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **17. SMTP Password**
  Specifies a username to use when the email server challenges an SMTP request. Supply any valid password. The SMTP Username parameter is required.

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **18. Web Service Inventory (Version 2) (Local Override)**
  Specifies the URL path for the Device Manager inventory web service (version 2).
- **19. SMTP Authentication (Local Override)**
  Specifies whether to use authentication when sending email from CA products.

  NOTE

  We recommend you update SMTP settings on the Email Server Settings page. For more information, see Set the Email Server.
- **20. Allow NetOps Portal in a frame (Local Override)**
  Determines whether NetOps Portal is allowed to display within a frame in a web page.
  Default: Enabled

8. Enter b when you have finished changing the default settings.
   You return to the previous set of options.
9. Enter b again to go back to the first set of options.
10. Enter q to quit.
    The Single Sign-On Configuration Tool closes. NetOps Portal directs all users to the Single Sign-On website using the new values that you supplied.

Data Aggregator Administration

The following articles relate to administration tasks for data aggregators and data collectors:

Authenticate and Encrypt ActiveMQ Communication

By default, the communication between the Data Aggregator and Data Collector is unencrypted and unauthenticated. To secure communications, secure the communication between the ActiveMQ brokers on these servers.

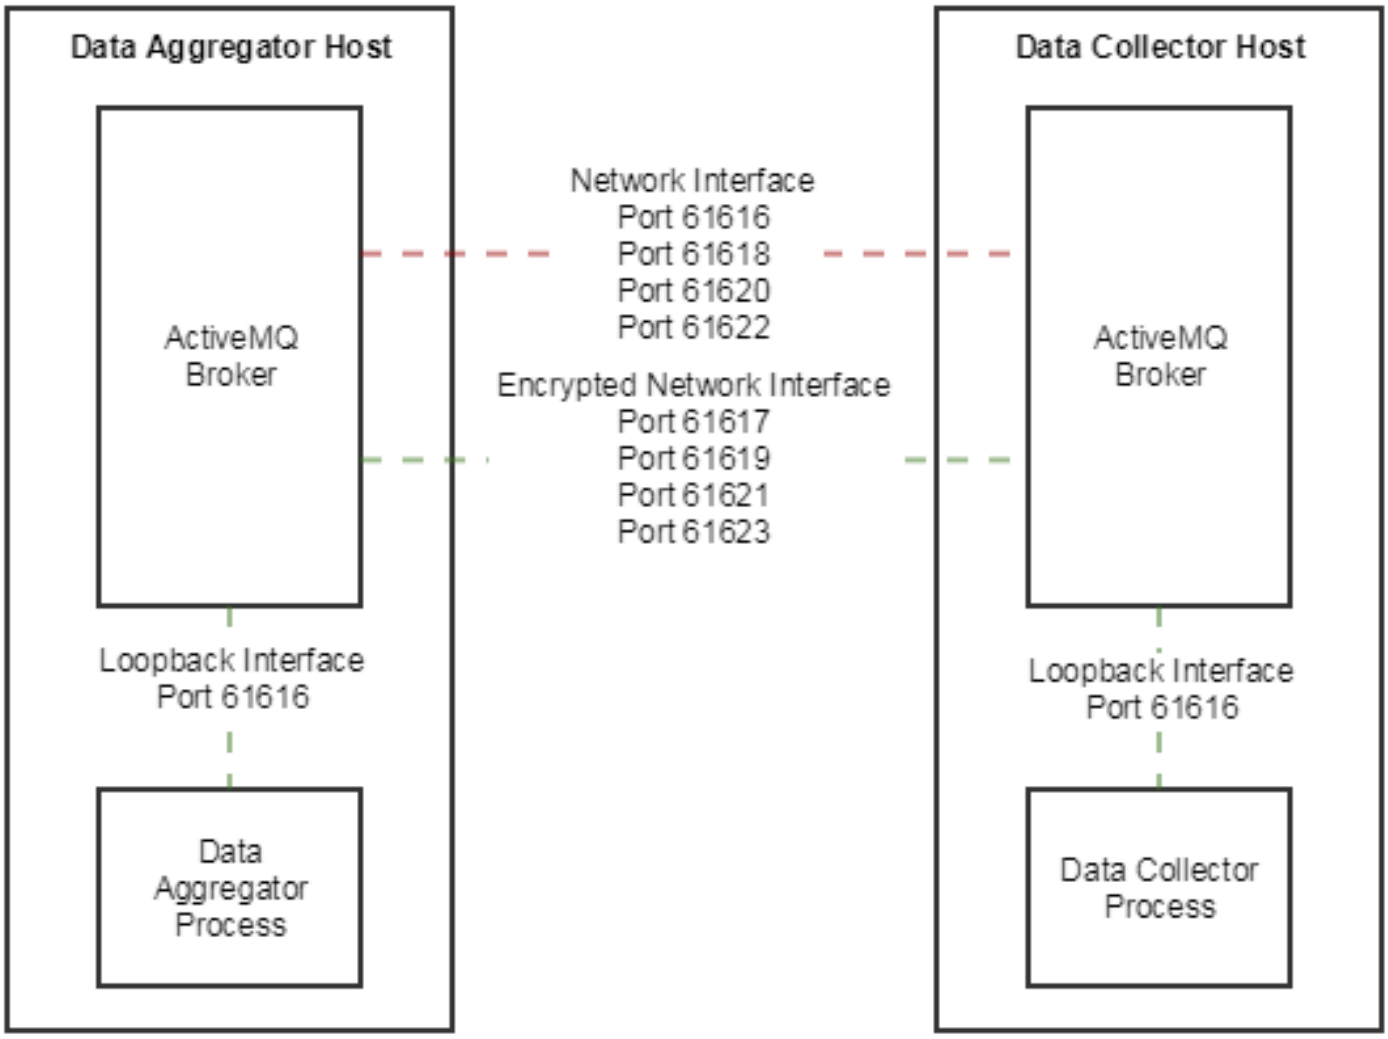
The following ports enable ActiveMQ communication between the Data Aggregator and the Data Collectors:

- **TCP 61616**
  Enables only ActiveMQ traffic
- **TCP 61618**
  Enables poll response delivery traffic
- **TCP 61620**
  Enables distributed IREP traffic
- **TCP 61622**
  Enables large data transfers
  This port also enables the simplified upgrade for Data Collectors. For more information, see Upgrade the Data Collectors.

The Data Aggregator does not communicate directly with the Data Collector. Each host server has an ActiveMQ broker. The Data Aggregator and Data Collector each communicate to the local broker over the loopback interface on port 61616. In the default configuration, the ActiveMQ brokers communicate on the same port over a network interface.

The following diagram shows the communication between the services, brokers, and hosts:

Figure 60: Diagram that shows the communication architecture between the Data Aggregator and Data Collectors.



To secure the communication between the brokers, use TLS and communicate on a different port. This procedure uses 61617, 61619, 61621, and 61623. Leave ports 61616, 61618, 616120, and 61622 unencrypted and restrict communication on these ports to the loopback interface.

NOTE

Throughout the documentation 8182, 8382, 61617, 61619, 61621, and 61623 appear as suggested port numbers for secured communications. In the instances where these ports appear, you are free to use any value you want as long as no other processes are using it.

Communication between the ActiveMQ broker and the Data Aggregator or Data Collector java process is not encrypted or authenticated. Because this traffic occurs only on the loopback interface, this communication is not vulnerable to sniffing.

WARNING

If DX NetOps Performance Management was installed to be run as a sudo user, run these commands as that sudo user.

To secure communications between the Data Aggregator and Data Collectors, complete the following procedures:

TIP

Save a backup copy of the activemq.xml file from the Data Aggregator and each Data Collector. To revert the authentication configuration, replace the updated XML files with the backups.

NOTE

A restart of the Data Aggregator and Data collectors, is not required during this process. The configuration changes take effect after restarting the ActiveMQ brokers. Restart the brokers after the configuration changes are complete.

WARNING

When you configure the Data Aggregator broker for TLS, configure all the Data Collector brokers for TLS too. Set up the configuration on each host, shut down all brokers. Then, restart the brokers, starting with the Data Aggregator.

Open Ports on Firewalls

On all relevant firewalls between the Data Aggregator host and Data Collector hosts, open port 61617 for TLS communications.

Generate Keys and Establish Trust

To establish a trusted connection, generate private/public key pairs for the Data Aggregator and each Data Collector and set up trust stores. Each Data Collector must trust itself and the Data Aggregator. The Data Aggregator must trust itself and all the Data Collectors.

Each system needs two private keys: one for the ActiveMQ broker, and one for the client, which is the Data Aggregator or Data Collector process. On each system, you replace two **.ks** files and one **.ts** files. Each file has a nonsecure password that is stored in clear text in activemq.xml. Because of the passwords, and the general sensitivity of encryption keys, the files activemq.xml ***.ts *.ks** require 400 permission. The user that runs the ActiveMQ broker must own these files.

The local local security policy dictates how to generate the key pairs. After you generate the keys, copy the public keys to the other hosts. All the Data Collectors need the Data Aggregator key, and the Data Aggregator needs all the Data Collector keys.

Example

This example procedure uses the JDK keytool. The following command generates a self-signed key using the JDK keytool:

```
keytool -genkey -alias KEY_ALIAS -keyalg RSA -keystore broker.ks
```

- **KEY_ALIAS** is a string that identifies the key.

The keytool is interactive and requires a series of inputs. The following example shows the interaction for the keytool:

NOTE
For the first and last name prompt, you must enter the host name of the system where you are creating the certification.

```
[root@hostname-dc conf]# keytool -genkey -alias dc1 -keyalg RSA -keystore broker.ks
Enter keystore password: 123456
Re-enter new password: 123456
What is your first and last name?
  [Unknown]:  Host_Name
What is the name of your organizational unit?
  [Unknown]:  Team1
What is the name of your organization?
```

```
  [Unknown]:  CGPM
What is the name of your City or Locality?
  [Unknown]:  Framingham
What is the name of your State or Province?
  [Unknown]:  MA
What is the two-letter country code for this unit?
  [Unknown]:  US
Is CN=Host_Name, OU=Team1, O=CGPM, L=Framingham, ST=MA, C=US correct?
  [no]:  yes
Enter key password for <dc1>
        (RETURN if same as keystore password):
```

Generate Keys and Establish Trust on the Data Collectors

Complete this procedure on each Data Collector host. Each keytool command is interactive and requests a password for each **.ks** and **.ts** file.

DC_ALIAS is a user defined unique identifier for each Data Collector host and can be any string as long as it is unique for each Data Collector.

Follow these steps:

1. Change directories:
   `cd /opt/IMDataCollector/broker/apache-activemq-version/conf`
2. Remove existing security files:
   `rm -f *.ks *.ts *.cert`
3. Generate the broker keystore and private key:
   `keytool -genkey -alias DC_ALIAS -keyalg RSA -keystore broker.ks`
4. Export the broker key for the Data Collector:
   `keytool -export -alias DC_ALIAS -keystore broker.ks -file DC_ALIAS.cert`
5. Import the client key for the Data Collector:
   `keytool -import -alias DC_ALIAS -keystore client.ts -file DC_ALIAS.cert`
6. Copy the Data Collector key to the Data Aggregator for import when you establish trust on the Data Aggregator:
   `scp DC_ALIAS.cert root@$DA_HOST:/tmp/DC_ALIAS.cert`

Generate Keys and Establish Trust on the Data Aggregator

Follow these steps:

1. Change directories:
   `cd /opt/IMDataAggregator/broker/apache-activemq-version/conf`
2. Remove existing security files:
   `rm -f *.ks *.ts *.cert`
3. Generate the broker keystore and private key:
   `keytool -genkey -alias DA_ALIAS -keyalg RSA -keystore broker.ks`
4. Export the broker key for the Data Aggregator:
   `keytool -export -alias DA_ALIAS -keystore broker.ks -file DA_ALIAS.cert`
5. Import the client key for the Data Aggregator:
   `keytool -import -alias DA_ALIAS -keystore client.ts -file DA_ALIAS.cert`
6. Import the client keys for *each* Data Collector:
   `keytool -import -alias DC_ALIAS -keystore client.ts -file /tmp/DC_ALIAS.cert`

   Repeat the keytool import command for each Data Collector with each DC_ALIAS.

7. Remove CERT files from the /tmp directory:
   ```
   rm /tmp/*.cert
   ```
8. Copy the broker key for the Data Aggregator to the /tmp directory:
   ```
   cp DA_ALIAS.cert /tmp
   ```
9. Grant the appropriate permissions to the security files:
   ```
   chmod 400 *.ks *.ts *.cert
   ```

Establish Trust from the Data Collectors to the Data Aggregator

Complete this procedure on *each* Data Collector host.

Follow these steps:

1. Change directories:
   ```
   cd /opt/IMDataCollector/broker/apache-activemq-version/conf
   ```
2. Copy the Data Aggregator key to the Data Collector host:
   ```
   scp root@$DA_HOST:/tmp/DA_ALIAS.cert .
   ```
3. Import the Data Aggregator key to the Data Collector keystore:
   ```
   keytool -import -alias DA_ALIAS -keystore client.ts -file DA_ALIAS.cert
   ```
4. Grant the appropriate permissions to the security files:
   ```
   chmod 400 *.ks *.ts *.cert
   ```

Configure ActiveMQ on the Data Aggregator

On the Data Aggregator, enable TLS with client authentication, and restrict OpenWire to localhost only.

Follow these steps:

1. On the Data Aggregator host, edit the following file:
   /opt/IMDataAggregator/broker/apache-activemq-version/conf/activemq.xml
2. Add the following XML section before <transportConnectors> parameter:
   ```
   <sslContext>
      <sslContext
         keyStore="broker.ks" keyStorePassword="123456"
         trustStore="client.ts" trustStorePassword="123456"/>
   </sslContext>
   ```
3. Restrict the existing OpenWire transport connector to the local host only:
   ```
   <transportConnector name="openwire" uri="tcp://127.0.0.1:61616"/>
   ```
4. Change the permissions for the file:
   ```
   chmod 400 activemq.xml
   ```

Configure ActiveMQ on the Data Collectors

On the Data Collectors, enable TLS, update the URL for the Data Aggregator, and restrict OpenWire to localhost only.

Complete the procedure on *each* Data Collector host.

Follow these steps:

1. On the Data Aggregator host, edit the following file:
   `/opt/IMDataCollector/broker/apache-activemq-version/conf/activemq.xml`
2. Add the following XML section before <transportConnectors> parameter:

```
<sslContext>
   <sslContext
      keyStore="broker.ks" keyStorePassword="123456"
      trustStore="client.ts" trustStorePassword="123456"/>
</sslContext>
```

3. Restrict the existing OpenWire transport connector to the local host only:
   ```
   <transportConnector name="openwire" uri="tcp://127.0.0.1:61616?
   maximumConnections=100&amp;wireFormat.maxFrameSize=104857600"/>
   ```
4. For all `<networkConnector>` entries, change `tcp://dahostname` to `ssl://dahostname` and update the ports.
   Example:
   The following example is a `<networkConnector>` entry that you might see:
   ```
   <networkConnector name="da_manager" uri="static:(tcp://dahostname:61616)"
    duplex="true" suppressDuplicateTopicSubscriptions="false">
   ```
   Replace `tcp` with `ssl` as shown in the following example:
   ```
   <networkConnector name="da_manager" uri="static:(ssl://dahostname:61617)"
    duplex="true" suppressDuplicateTopicSubscriptions="false">
   ```
5. Change the permissions for the file:
   ```
   chmod 400 activemq.xml
   ```

   NOTE

   The user running the ActiveMQ service must own this file.

Restart ActiveMQ Brokers

The ActiveMQ brokers reread the configuration when the broker restarts. Restart all the brokers simultaneously. Do not restart the Data Aggregator or Data Collector processes.

During the shutdown, the Data Collectors cache incoming traffic. To minimize data loss, perform the shutdowns and restarts in this order:

1. Shut down the ActiveMQ broker on each Data Collector:
   ```
   service activemq stop
   ```
2. Shut down the ActiveMQ broker on the Data Aggregator:
   ```
   service activemq stop
   ```
3. Start the ActiveMQ broker on the Data Aggregator:
   ```
   service activemq start
   ```
   If you do not, the Data Aggregator starts the broker automatically.
4. The Data Collectors automatically restart the ActiveMQ brokers. Use the following command to restart the brokers manually:
   ```
   service activemq start
   ```

Block Port 61616

On all relevant firewalls, restrict the communication on port 61616 to the loopback interface.

Verify Communication and Polling

After you secure communications, confirm that the system is polling.

Follow these steps:

1. Log in to NetOps Portal.
2. Select **Administration**, **Data Collector List**.
3. Verify that the status for each Data Collector is **Collecting Data**.
4. Wait 5 minutes, then click the **Refresh** button.
5. Verify that the status for each Data Collector is still **Collecting Data**.
6. (Optional) For further validation, look at a device on each Data Collector, and confirm that polled data is being loaded.

If any Data Collector does not have the **Collecting Data** status, use the following options to troubleshoot the Data Collector:

- On the Data Collector host, verify the ActiveMQ status:
  ```
  service activemq status
  ```
- Check for errors in Data Collector **Karaf** log: `/opt/IMDatacollector/apache-karaf-<vers>/karaf.log`
- Check for errors in Data Collector **ActiveMQ** log: `/opt/IMDataCollector/broker/apache-activemq-version/data/activemq.log`
- Check the permissions on activemq.conf and the **.ks** and **.ts** files. These files must be readable by the user that is attempting to run them.
- Verify the contents of the **.ks** and **.ts** files:
  ```
  keytool -list -keystore client.ts
  ```

Automate Device Inventory Synchronization

You want to automate the maintenance of the Data Aggregator device inventory through automated synchronization with a CMDB source. You use a configuration management database to maintain an inventory of all devices within your environment. This information is kept in one place, where it is then provisioned out to various monitoring tools. You want to build an automated means of keeping Data Aggregator device inventory in synchronization with your CMDB. To do so, configure NetOps Portal and Data Aggregator before you write your integration script.

To manually execute web service calls, use either a REST client editor or an HHTP tool that sends requests and gets responses to perform these procedures. In this scenario, we simply refer to the REST client editor.

> **NOTE**
> For automated inventory control, you would write an application or script that leverages the web services described in this documentation.

This process requires making calls to two different web servers:

- The NetOps Portal web server is used to create SNMP profiles.
- The Data Aggregator web server is used to create discovery profiles and review discovery results.

To discover devices and monitor components in your network using REST web services, follow these steps:

> **NOTE**
> Perform step 1 using NetOps Portal REST web services. Perform steps 2-3 using the Data Aggregator REST web services.

Provide SNMP Profile Credentials

SNMP profiles are definitions that contain the information necessary to enable secure queries of device MIBs using SNMP. These definitions provide SNMP parameters from NetOps Portal to the Data Aggregator data source, as needed, while ensuring data security.

For this scenario, you will create an SMPv3 profile.

NOTE
The methods that return SNMP profile definitions do not include community strings, user names, or passwords. The save method takes a community string, user name, or passwords that are not encrypted. We recommend that you only invoke this method on the computer where NetOps Portal is installed.

Follow these steps:

1. Access the NetOps Portal web server.
2. Open a REST client that is configured to access the NetOps Portal server. Log in using administrator credentials.

   NOTE
   For information about configuring your REST client, see the REST client documentation.
3. Set the Content-type to application/xml. Enter the Body text and modify the attributes as needed:
   - **Profile Name**
     Defines a name for the SNMP profile.

     NOTE
     Profile names must be unique, cannot be duplicated across SNMP versions, and are not case-sensitive.
   - **SNMP Version**
     Specifies the version of SNMP that the profile uses. Enter SNMPv3 for this scenario.
   - **Port**
     Identifies the port that is used to make SNMP connections to devices associated with this profile.
     Default: 161
   - **User Name**
     Identifies the user for the profile, whose secret keys were used potentially to authenticate and encrypt the SNMPv3 packets. The User Name is a character string.
   - **Context Name**
     Specifies a collection of management information that is accessible by an SNMP entity. The Context Name is necessary for providing end-to-end identification and for retrieving data from an SNMPv3 agent. The Context Name is an octet string.

     NOTE

     The Data Aggregator does not use Context Name on the SNMPv3 profiles to communicate with the device.
   - **Security Level**
     Specifies the security level to use. Enter one of the following values:
     - NoAuthNoPriv
     - AuthNoPriv
     - AuthAndPriv
   - **Authentication Protocol**
     Specifies the authentication protocol to use when contacting devices associated with this profile. Enter one of the following algorithms for authenticating SNMPv3 packets:
     - None (Do not attempt authentication.)
     - MD5 (Message Digest 5)
     - SHA (Secure Hash Algorithm)
   - **Authentication Password**
     Specifies the password for authentication using SNMPv3 and the selected authentication protocol. The password must contain a minimum of eight characters.
   - **Verify Authentication Password**
     Confirms the authentication password.
   - **Privacy Protocol**
     (Optional) Specifies the encryption protocol to use for data flows sent to any devices or servers that are associated with this profile, as follows:

- None (Does not encrypt communications. Use only with NoPriv option.)
- DES
- AES (128-bit encryption)
- Triple DES

Note: The privacy protocol option is only enabled when authentication is enabled for this profile.

– **Privacy Password**
(SNMPv3 only) Defines the password that is used when exchanging encryption keys.
– **Verify Privacy Password**
(SNMPv3 only) Confirms the password that is used when exchanging encryption keys.
– **Rank**
Specifies the rank of the profile in the global list of SNMP profiles.
– **Enabled**
For NetOps Portal, this indicates whether the information in this profile is used when not explicitly assigned to a device. For Data Aggregator, this value must be set to **true**.
– **TenantID**
Specifies the tenant ID. The default tenant ID is 8. Enterprise customers must enter the default tenant ID.

Example: No authentication and no privacy

```
<SnmpProfile>
    <name>Tokyo</name>
    <port>161</port>
    <userName>myuser</userName>
    <context></context>
    <version>Version3</version>
    <securityLevel>NoAuthNoPriv</securityLevel>
    <authProtocol>None</authProtocol>
    <authPassword>None</authPassword>
    <privProtocol>None</privProtocol>
    <privPassword>None</privPassword>
    <rank>4</rank>
    <enabled>true</enabled>
    <tenantID>8</tenantID>
</SnmpProfile>
```

Example: Authentication and no privacy

```
<SnmpProfile>
    <name>Brasil</name>
    <port>161</port>
    <userName>myuser</userName>
    <context></context>
    <version>Version3</version>
    <securityLevel>AuthNoPriv</securityLevel>
    <authProtocol>MD5</authProtocol>
    <authPassword>test</authPassword>
    <privProtocol>None</privProtocol>
    <privPassword>None</privPassword>
    <rank>3</rank>
    <enabled>true</enabled>
```

```
    <tenantID>8</tenantID>
</SnmpProfile>
```

Example: Authentication and privacy

```
<SnmpProfile>
    <name>Boston</name>
    <port>161</port>
    <userName>myuser</userName>
    <context></context>
    <version>Version3</version>
    <securityLevel>AuthAndPriv</securityLevel>
    <authProtocol>MD5</authProtocol>
    <authPassword>test</authPassword>
    <privProtocol>TripleDES</privProtocol>
    <privPassword>test</privPassword>
    <rank>1</rank>
    <enabled>true</enabled>
    <tenantID>8</tenantID>
</SnmpProfile>
```

4. POST the following URL to create the profile:

```
POST http://pc_hostname:8181/pc/center/webservice/profiles/saveProfile/{true|false}
```

   – ***pc_hostname***
     Specifies the NetOps Portal host name. (8181 is the required port.)
   – **{true|false}**
     Specifies a Boolean value for the rankTiesAscendingByDate parameter. **True** indicates that the profile you are adding will be the last in rank order (as determined by the creation date of the SNMP profile).

   The XML returns true when the operation succeeds.
   The SNMP profile is automatically synchronized with Data Aggregator and is available for inventory discovery to use it.

Create a Discovery Profile and Run a Discovery

Discovery profiles specify how discovery operates in your Data Aggregator environment. Within a discovery profile, you can specify the IP addresses, IP address ranges, and host names you want to discover devices for.

> **NOTE**
> This scenario is for an enterprise environment and discovers devices using the SNMP protocol. However, MSPs may also want to limit discovery to specific SNMP profiles. A full list of attributes is available by accessing the URL: http://*da_hostname port*/rest/discoveryprofiles/documentation.

You create a discovery profile and run a discovery in one operation when using the REST web services. When discovery is run, devices are discovered based on the discovery profile you create.

Follow these steps:

1. Access the Data Aggregator web server.
2. Open a REST client editor and set the Content-type to application/xml.
3. Find and make a note of the default tenant ID using the following URL:

```
GET http://da_hostname:port/rest/tenants
```

- ***da_hostname*:*port***
  Specifies the Data Aggregator host name and the port number.
  Default port: 8581

4. Enter the Body text for the discovery profile in a REST client and modify the attributes as needed.

   NOTE
   You can view the XSD schema which defines the structure of the discovery profile XML by going to the URL:

   `http://da_hostname:port/rest/discoveryprofiles/XSD/getlist.xsd`

5. Include IP addresses and host names so that the end-user switches in your network are discovered. Do one or more of the following actions:
   - Type individual IP addresses for which you want to discover devices in the IP Address List field.
   - Type the host names for which you want to discover devices in the Host List field.

   NOTE
   These fields accept comma-delimited values. Single quotes, double quotes, backward slashes, forward slashes, and ampersands are not permitted.

6. Set the following attributes:
   - **Name**
     Specifies a descriptive name for the discovery profile. This field cannot contain single quotes, double quotes, backward slashes, forward slashes, and ampersands.
   - **RunStatus**
     Specifies whether to run the discovery. For this scenario, set the attribute to START.

     NOTE
     To rerun discovery later, update (PUT) the run status to START.

   Example:

```
<?xml version="1.0" encoding="UTF-8"?>
<DiscoveryProfile version="1.0.0">
  <ActivationStatus>true</ActivationStatus>
  <IPRangesList>
    <IPRanges>10.0.64.202-10.0.64.206</IPRanges>
  </IPRangesList>
  <HostNamesList>
    <HostNames>ahost</HostNames>
  </HostNamesList>
  <IPListList>
    <IPList>10.10.10.10</IPList>
  </IPListList>
  <RunStatus>READY</RunStatus>
  <Item version="1.0.0">
    <Name>BigRange_TestProfileViaAPI</Name>
  </Item>
  <IPDomainMember version="1.0.0">
    <IPDomainID>285</IPDomainID>
  </IPDomainMember>
</DiscoveryProfile>
```

7. Save and run the new discovery profile by entering the following URL:

```
POST http://da_hostname:port/rest/tenant/default_tenant_ID/discoveryprofiles
```

– **tenant/*default_tenant_ID***
Specifies the ID number for the default tenant workspace. Enterprise customers typically only use the default tenant workspace. For the POST operation, you *must* enter the default tenant ID when there are no other tenants.

The discovery profile is created and discovery runs.
All discovered devices are automatically added to the appropriate out-of-the-box device collection or another user-created device collection.

8. Verify the discovery profile displays in the discovery profiles list. Note the ID of the new discovery profile because it is used to review the discovery results.
```
GET http://da_hostname:port/rest/discoveryprofiles
```

Review the Discovered Devices and Instances

Verify that your initial discovery was successful by reviewing the discovered devices and instances.

Follow these steps:

1. To view a list of discovery profiles, access the Data Aggregator web server. Type the following URL:
```
GET http://da_hostname:port/rest/discoveryprofiles
```

– ***da_hostname*:*port***
Specifies the Data Aggregator host name and the port number.
Default port: 8581

A list of discovery profiles and their instance IDs is returned.

2. Find the discovery instance ID for the discovery profile that you created:

NOTE
Example:

```
<DiscoveryInstanceIDList relatesURL="relatesto/instances"
            rootURL="discoveryinstances">
                <ID>236</ID>
 </DiscoveryInstanceIDList>
```

3. View the discovery instance details using the following URL:
```
GET http://da_hostname:port/rest/discoveryinstances/instance_ID
```

The instance XML returns information about new and existing devices and SNMP profiles that were tested.
Example:

```
<?xml version="1.0" encoding="UTF-8"?>
<DiscoveryInstance version="1.0.0">
    <ID>236</ID>
    <IPSweepTotalSuccess>5</IPSweepTotalSuccess>
    <CompletionTime>Thu Apr 12 12:36:35 CDT 2012</CompletionTime>
    <ExistingFoundDevicesList>
        <ExistingFoundDevices>241</ExistingFoundDevices>
        <ExistingFoundDevices>239</ExistingFoundDevices>
        <ExistingFoundDevices>240</ExistingFoundDevices>
        <ExistingFoundDevices>238</ExistingFoundDevices>
```

```
        </ExistingFoundDevicesList>
        <IPSweepCompletionTime>Thu Apr 12 12:36:35 CDT 2012</IPSweepCompletionTime>
        <ExistingFoundManageableDevicesList>
            <ExistingFoundManageableDevices>241</ExistingFoundManageableDevices>
            <ExistingFoundManageableDevices>239</ExistingFoundManageableDevices>
            <ExistingFoundManageableDevices>240</ExistingFoundManageableDevices>
            <ExistingFoundManageableDevices>238</ExistingFoundManageableDevices>
        </ExistingFoundManageableDevicesList>
        <StartTime>Thu Apr 12 12:36:31 CDT 2012</StartTime>
        <NewlyCreatedDevicesList>
            <NewlyCreatedDevices>383</NewlyCreatedDevices>
        </NewlyCreatedDevicesList>
        <TestedCommProfilesList>
            <TestedCommProfiles>199</TestedCommProfiles>
            <TestedCommProfiles>198</TestedCommProfiles>
        </TestedCommProfilesList>
        <IPSweepStartTime>Thu Apr 12 12:36:31 CDT 2012</IPSweepStartTime>
        <ProgressPercentage>100</ProgressPercentage>
        <IPSweepTotal>7</IPSweepTotal>
        <ProfileID>235</ProfileID>
        <NewlyCreatedManageableDevicesList>
            <NewlyCreatedManageableDevices>383</NewlyCreatedManageableDevices>
        </NewlyCreatedManageableDevicesList>
        <PingResponseDeviceCount>5</PingResponseDeviceCount>
        <CompletionStatus>SUCCESS</CompletionStatus>
        <Item version="1.0.0">
            <CreateTime>Thu Apr 12 12:36:31 CDT 2012</CreateTime>
        </Item>
    </DiscoveryInstance>
```

4. (Optional) Review information about specific devices (new or existing) using the following URL:
   `GET http://da_hostname:port/rest/devices/device_ID`

   – ***endpoint_ID***
   Specifies the ID of the referenced endpoint, such as devices. Use the IDs you found in the previously.
5. (Optional) Review information about the SNMP profiles that were tested during discovery using the following URL:
   `GET http://da_hostname:port/rest/profiles/profile_ID`

All discovered devices and instances appear.

Back Up the Data Aggregator

To avoid losing your settings and custom certifications due to an unexpected failure, back up the data aggregator. Back up the data aggregator and the data repository during specific events, such as before an upgrade.

You do not need to stop the data repository, the data collector, or the data aggregator services when you back up the data aggregator. Backups are stored in the location that you specify, which can be on the data aggregator system or on a different backup host system.

Prerequisite: You have root or sudo privileges.

Follow these steps:

1. From a command prompt, create a backup a backup directory in a secure location on the same or different backup host system:
   `mkdir DA_Backup`
   – ***DA_Backup***
   Specifies the directory path and name of the backup directory.
2. Create subdirectories within DA_Backup using all the following commands:
   ```
   mkdir DA_Backup/deploy_backup
   mkdir DA_Backup/cert_backup
   mkdir DA_Backup/MIBDepot_backup
   mkdir DA_Backup/CustomDeviceType_backup
   mkdir DA_Backup/etc
   mkdir DA_Backup/data
   ```
3. Run the following commands to back up the files on the DA:
   – This command backs up the deploy directory:
   `cp -r DA_install_directory/apache-karaf-version/deploy/* DA_Backup/deploy_backup`
   - ***DA_install_directory***
   Specifies the Data Aggregator install directory.
   Default: `/opt/IMDataAggregator`
   – This command backs up your certifications:
   IMPORTANT
   Do not back up the `local-jms-broker.xml` file and the README files from that directory.
   `cp -r DA_install_directory/data/certifications DA_Backup/cert_backup`
   In a fault tolerant environment, a shared directory (example: `/DASharedRepo`) is defined to help limit data loss. Therefore, in a fault tolerant environment the files would be located in the following directory:
   `cp -r DASharedRepo/certifications DA_Backup/cert_backup`
   For more information, see Fault Tolerance.
   – This command backs up all the custom MIBs in the MIBDepot directory:
   `cp -r DA_install_directory/apache-karaf-version/MIBDepot/ DA_Backup/MIBDepot_backup`
   NOTE
   If there are no customizations, this directory might be empty.
   – This command backs up all the custom device subtype xml files:
   `cp DA_install_directory/data/custom/devicetypes/DeviceTypes.xml DA_Backup/CustomDeviceType_backup/`
   In a fault tolerant environment, the files would be located in the following directory:
   `DASharedRepo/custom/devicetypes/DeviceTypes.xml`
   – This command backs up the etc directory files:
   `cp -r DA_install_directory/apache-karaf-version/etc DA_Backup/`
   – This command backs up the data/log directory:
   `cp -r DA_install_directory/apache-karaf-version/data/log DA_Backup/data/`

NOTE
By default, a `caVerticaUtility.sh` script is located in the `/opt/CA/IMDataRepository*/` directory. The script is a support tool available for exporting the iRep data from an existing system and importing it into a different schema.You can then query the iRep data to determine how the original system was configured.

Choose Another Host in a Cluster When Selected Host Fails

If the database host that is specified during Data Aggregator installation fails at runtime, Data Aggregator shuts down automatically. If you installed Data Repository in a cluster, point database connections to another host in the cluster before you restart Data Aggregator.

If more than one host in the Data Repository cluster fails, Data Repository and Data Aggregator shuts down automatically. The Data Repository cluster is only capable of losing one host.

If a single host in the cluster that is *not* specified during the Data Aggregator installation disconnects from the network (for example, because a firewall was put in place, or the Ethernet cable was removed), Data Aggregator shuts down. Data Aggregator restarts automatically if you set up the automatic recovery of the Data Aggregator process during the Data Aggregator installation. Once the host that is offline becomes available, return that host to the cluster. Select the “Restart Vertica on Host” option on the main menu of the admintools utility and follow the prompts.

If a single host in the cluster that is *not* specified during the Data Aggregator installation is stopped through the “Kill Vertica Process on Host” option on the Advanced Menu of the admintools utility, Data Aggregator continues to function. Once the host that is offline becomes available, return that host to the cluster. Select the “Restart Vertica on Host” option on the main menu of the admintools utility and follow the prompts.

Follow these steps:

1. Open the *DA_install_directory*`/apache-karaf-<`*vers*`>/etc/dbconnection.cfg` file on the Data Aggregator host.
2. Modify the following line in the dbconnection.cfg file. Modify the line to reference a hostname or IP address of one of the Data Repository cluster hosts that is still up and running:

   ```
   dbUrl=jdbc:vertica://database server hostname:database server port/databasename?
   use35CopyFormat=true&BinaryDataTransfer=false
   ```

   – ***database server hostname*:*database server port***
   Indicates the hostname or IP address of Data Repository and the Data Repository port number that you entered during the Data Aggregator installation.
   Default port number: 5433

   Example:
   If host2 is up and running in the cluster and you choose database connections to point to host2, your updated dbUrl entry could look like the following line:

   ```
   dbUrl=jdbc:vertica://host2:5433/mydatabasename?
   use35CopyFormat=true&BinaryDataTransfer=false
   ```

3. Save the dbconnection.cfg file.
4. Do one of the following steps:
   – Start the Data Aggregator service:

     ```
     service dadaemon start
     ```

NOTE

For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.

– (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:

- **RHEL 6.x:**

```
service dadaemon activate
```

- **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon activate
```

5. To help ensure that Data Aggregator is not still running, type the following command:

```
Ps  - ef | grep java | grep  - v grep
```

Data Aggregator processes are not returned when Data Aggregator is not running.
Database connections point to the specified host in the cluster going forward.

Configure Data Collector When the Data Aggregator IP Address Changes

If the IP address of the Data Aggregator host changes, update the Data Collectors to point to the new IP. If the Data Collector uses the hostname to communicate with the Data Aggregator, restart the Data Collector. If the Data Collector uses the IP address to communicate with the Data Aggregator, complete the following procedure:

Follow these steps:

1. Log in to the Data Collector host.
2. Stop the Data Collector service:

```
service dcmd stop
```

3. Locate and edit the IP address in the following file:
`/opt/IMDataCollector/apache-karaf-<vers>/etc/com.ca.im.dm.core.collector.cfg`

NOTE

is the default installation directory.

4. Edit the following line:

```
...

collector-manager-da-hostname=
DA_host_IP
```

```
...
```

Save the file.

5. Locate and edit the following file:
   `/opt/IMDataCollector/broker/apache-activemq-<vers>/conf/activemq.xml`
6. Edit the IP address in the following lines:

```
...

<networkConnector name="da_manager" uri="static:(tcp://
DA_host_IP
:61616)" duplex="true" suppressDuplicateTopicSubscriptions="false"/>

<networkConnector name="da_manager-PRQ" uri="static:(tcp://
DA_host_IP
:61618)" duplex="true" suppressDuplicateTopicSubscriptions="false"/>

<networkConnector name="da_manager-IREP" uri="static:(tcp://
DA_host_IP
:61620)" duplex="true" suppressDuplicateTopicSubscriptions="false"/>

<networkConnector name="da_manager-blob" uri="static:(tcp://
DA_host_IP
:61622)" duplex="true" suppressDuplicateTopicSubscriptions="false"/>

...
```

In a fault tolerant tolerant environment, the content of the activemq.xml has the following format:

```
...

<networkConnector name="da_manager" uri="static:(failover:(tcp://
DA1_host_IP
:61616,tcp://
DA2_host_IP
:61616)?maxReconnectAttempts=3)" duplex="true"
 suppressDuplicateTopicSubscriptions="false"/>

<networkConnector name="da_manager-PRQ" uri="static:(failover:(tcp://
DA1_host_IP
:61618,tcp://
DA2_host_IP
:61618)?maxReconnectAttempts=3)" duplex="true"
 suppressDuplicateTopicSubscriptions="false"/>
```

```
<networkConnector name="da_manager-IREP" uri="static:(failover:(tcp://
DA1_host_IP
:61620,tcp://
DA2_host_IP
:61620)?maxReconnectAttempts=3)" duplex="true"
 suppressDuplicateTopicSubscriptions="false"/>

<networkConnector name="da_manager-blob" uri="static:(failover:(tcp://
DA1_host_IP
:61622,tcp://
DA2_host_IP
:61622)?maxReconnectAttempts=3)" duplex="true"
 suppressDuplicateTopicSubscriptions="false"/>

...
```

7. Start the Data Collector:

```
service dcmd start
```

8. Verify that the correct address appears in the Data Collector List.
   a. Open NetOps Portal as an administrator.
   b. Select Admin, Data Sources, and click a Data Aggregator data source.
   c. Click Data Collectors from the System Status menu.
      The IP address of each Data Collector appears under the 'Address' column. The status of each Data Collector is "Collecting Data".

Data Aggregator Configuration Changes During Network Disconnects to a Data Collector Host

Occasionally, the connection between a Data Aggregator host and a Data Collector host breaks, such as, when a network disconnect occurs. If the Data Aggregator and Data Collector processes are running during a disconnect, you can make configuration changes to the Data Aggregator installation. In this case, polling continues on the Data Collector host according to the configuration that existed before the network disconnect. Once the connection between the Data Aggregator and the Data Collector hosts reestablishes, Data Collector downloads the new configuration and adjusts polling accordingly.

For example, you make one of the following configuration changes:

- Change the expression an SNMP vendor certification uses to calculate a value on a metric family.
- Change the metric family to poll a new operational metric.

When the connection between the Data Aggregator and the Data Collector hosts is broken, the changes cannot take effect. After reconnection, Data Collector begins polling the new SNMP MIB objects used in the new expression or in calculating the new operational metric.

Manage Data Collector Installations

Select an IP domain and a tenant for each Data Collector installation. Each Data Collector instance that does discovery requests can be associated with only one IP domain.

IP domains are logical groupings that identify data from different devices and networks. IP addresses with associated interfaces or applications that belong to separate customer networks are monitored separately. When combined with appropriate permissions, IP domains are monitored from a single console, but users view data only for the domains that they monitor.

A tenant represents a customer environment that a managed service provider administers. Each tenant environment is independent and effectively functions as a separate instance of NetOps Portal. Each instance can contain multiple users and roles that are not shared among tenants.

The Default Tenant represents the tenant space for the managed service provider within the managed infrastructure. Assign the Default Tenant if you are not deploying multi-tenancy. In a single-tenant environment, the Default Tenant is the space used for monitoring the entire infrastructure.

Follow these steps:

1. Open CA NetOps Portal as an administrator.
2. Select **Administration**, **Data Sources**, and click a Data Aggregator data source.
3. Select a Data Collector instance from the list.
4. Verify that Data Collector is available for assignment. The Polled Items column lists the number of polled devices and components that are assigned to this Data Collector instance.

   WARNING
   If the number of polled devices and components is greater than one, you cannot change the tenant or IP domain assignment for the Data Collector instance.
5. Click **Assign**.
   The Assign Data Collector dialog opens.
6. Select the tenant that you want to assign to this Data Collector instance from the drop-down list.
   All monitored devices and components that this Data Collector instance discovers are automatically associated with this tenant.
   Select 'Default Tenant' if you want to use the default tenant.
7. Select the IP domain that you want to associate with this Data Collector instance.
   All managed devices and components that this Data Collector instance discovers are automatically associated with this IP domain.
8. Click **Save**.
   The tenant and IP domain are assigned to the Data Collector installation.

Migrate the Data Aggregator

To migrate the Data Aggregator, install the Data Aggregator on a new host with a new IP address and hostname and copy over your files. The following situations might require migration:

- You are moving to new hosts for a major OS upgrade (for example, RHEL 6.9 to RHEL 7.3).
- The current database hardware no longer meets sizing requirements.
- You are moving from virtual machines to physical hardware for the database.

NOTE

You must upgrade the existing system to the product version you are migrating to before migrating.

Install the Data Aggregator on the New Host

Prepare the host and install the Data Aggregator on the new host. During installation, use the details for the Data Repository for the new Data Aggregator host.

You can find the Data Repository details on the current Data Aggregator host in the following location:

- *DA_Install_Directory*/apache-karaf-<*version*>/etc/dbconnection.cfg

For more information, see Prepare to Install the Data Aggregator and Install the Data Aggregator.

WARNING

If the Data Repository was migrated, follow the Data Aggregator installation instructions in the console, and answer NO when prompted to drop the schema and the installation continues. If you answer YES, you lose your migrated data.

Migrate the Data Aggregator to the New Host

Create a backup and copy it over to the new host.

NOTE

To avoid corrupting the Vertica database, ensure the old Data Aggregator host is not pointing to the new Data Repository host.

Follow these steps:

1. Back up the Data Aggregator. For more information, see Back Up Data Aggregator.
2. Package the files:
   ```
   tar czf DA.tgz backup_dir
   ```
3. Copy the backup directory from the old Data Aggregator host to the new Data Aggregator host.
   ```
   scp -r backup_dir/DA.tgz DA_user@backuphost:/tmp
   ```
   - ***DA_user***
     User who owns the DA process (root or sudo user)

     NOTE

     If /tmp is not a preferred location, specify another directory location.
4. Restore the Data Aggregator. For more information, see Restore Data Aggregator.
5. Do one of the following steps:
   - Stop the Data Aggregator service:
     ```
     service dadaemon stop
     ```

     NOTE

     For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.
   - (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**
       ```
       service dadaemon maintenance
       ```
     - **RHEL 7.x, SLES, or OL:**
       ```
       DA_Install_Directory/scripts/dadaemon maintenance
       ```
6. Do one of the following steps:
   - Start the Data Aggregator service:
     ```
     service dadaemon start
     ```

- (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
  - **RHEL 6.x:**

    ```
    service dadaemon activate
    ```

  - **RHEL 7.x, SLES, or OL:**

    ```
    DA_Install_Directory/scripts/dadaemon activate
    ```

Update the Data Repository Configuration

On the Data Aggregator host, ensure the `dbconnection.cfg` file points to the correct Data Repository hosts.

Follow these steps:

1. Open the *DA_installation_directory*`/apache-karaf-<`*version*`>/etc/dbconnection.cfg` file on the Data Aggregator host.
2. Modify the following line in the `dbconnection.cfg` file. Modify the line to reference the hostname or IP address of each Data Repository host:

   `dbHostNames=`*dbNode1Hostname*`,`*dbNode2Hostname*`,`*dbNode3Hostname*

3. Save the `dbconnection.cfg` file.
4. Do one of the following steps:
   - Restart the Data Aggregator service:

     ```
     service dadaemon start
     ```

   - (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
     - **RHEL 6.x:**

       ```
       service dadaemon activate
       ```

     - **RHEL 7.x, SLES, or OL:**

       ```
       DA_Install_Directory/scripts/dadaemon activate
       ```

Update Data Collector Configurations

Update the Data Collectors to point to the new Data Aggregator host. On each Data Collector host, edit the Data Aggregator host information in following files:

NOTE

If you are upgrading or migrating the Data Collectors, do this procedure after the upgrade or migration.

- `/opt/IMDataCollector/apache-karaf-<`*version*`>/etc/com.ca.im.dm.core.collector.cfg`
- `/opt/IMDataCollector/broker/apache-activemq-<`*version*`>/conf/activemq.xml`

Run the following commands to restart the Data Collector Karaf and Data Collector ActiveMQ services:

```
 service activemq stop
service activemq start
service dcmd stop
service dcmd start
```

For more information, see Configure Data Collector When the Data Aggregator IP Address Changes.

Update the Data Aggregator Data Source in NetOps Portal

Update the Data Aggregator Data Source in NetOps Portal to point to the new Data Aggregator host. For more information, see Configure a Data Source.

Follow these steps:

1. Go to **Administration**, and click **Data Sources**.
2. Click **Edit** and specify the IP address or hostname of the new Data Aggregator host.
3. Configure the Data Aggregator settings:

   NOTE

   If SSL is configured, specify HTTPS for the communication protocol.

   – **Synchronize component items that are not currently present on the monitored device**
   When the Data Aggregator finds a device component that is no longer present in the environment, that status of the component is set to **Not Present**. By default, the Data Aggregator does not synchronize these items because data can no longer be collected for the item. Historical data that has not reached the data retention limit is still available for these items.

   WARNING

   If the properties of an active component match the identifying properties of the not present component, the components are indistinguishable. Data from the old component might contribute to group based dashboards instead of data from the active component. Enable this feature only under the following circumstances:

   - You want to report on historical data for items that are no longer present in the environment.
   - You can ensure that the not present item does not conflict with an actively monitored item.
   - You can identify the not present items so that you can exclude the items from groups.

   – **Discover devices from other data sources**
   This option specifies whether synchronization includes devices that are reported by other data sources. Automatic synchronization includes only devices that are discovered after you select this option. To discover previously discovered devices, perform a full synchronization of the Data Aggregator.
   DX NetOps Performance Management creates a discovery profile that includes the IP addresses of the devices. This discovery profile attempts discovery once per day.
4. Click **Save**.
   If the Data Aggregator data source is enabled, data appears in NetOps Portal after the next synchronization.

Modify Maximum Memory Usage for Data Aggregator and Data Collector Components

For the Data Aggregator and the Data Collectors, the default maximum memory is 80% of the total system memory. AMQ uses 20% of total memory on both components. Both components reserve 2 GB of memory for the operating system. If you add more memory to the system, modify the maximum values to match the changes.

Follow these steps:

1. Open a console and type the following command:
   ```
   more /proc/meminfo
   ```
   The total memory usage is displayed.
2. Make a note of this total memory.

3. Modify the maximum memory for Data Aggregator by performing the following steps:
   a. Access the following file:
      DA_installation_directory/apache-karaf-<*vers*>/bin/setenv

   b. Modify the following line:
      IM_MAX_MEM=*numberUnit*

      - **numberUnit**
        Specifies the maximum amount of memory. *number* is a positive integer. *Unit* is “G” for GB or “M” for MB. Reserve 2 GB for operating system operations and reserve 20 percent for AMQ. Use the following formula to determine the value:
        total memory * 80% - 2 GB

      Example:
      ```
      33554432 KB * 80% - 2G = 24 GB
      IM_MAX_MEM=24G
      ```

   c. Save the file.
   d. Do one of the following steps:
      - Start the Data Aggregator service:
        ```
        service dadaemon start
        ```

        NOTE

        For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.
      - (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
        - **RHEL 6.x:**
          ```
          service dadaemon activate
          ```

        - **RHEL 7.x, SLES, or OL:**
          DA_Install_Directory/scripts/dadaemon activate

   e. In order for the memory setting change to persist during a Data Aggregator upgrade, modify the /etc/DA.cfg file, replacing the updated value for the property "da.memory".
      Example:
      ```
      da.memory=24G
      ```

4. Modify the maximum memory for all Data Collector hosts by performing the following steps:
   a. Access the following file:
      DC_installation_directory/apache-karaf-<*vers*>/bin/setenv

   b. Modify the following line:
      IM_MAX_MEM=*numberUnit*

      - **numberUnit**
        Specifies the maximum amount of memory. *number* is a positive integer. *Unit* is “G” for GB or “M” for MB. Reserve 2 GB for operating system operations and reserve 20 percent for AMQ. Use the following formula to determine the value:

total memory * 80% - 2 GB

c. Save the file.
d. Restart Data Collector hosts using the following commands:

```
service dcmd stop
service dcmd start
```

e. In order for the memory setting change to persist during a Data Collector upgrade, modify the /opt/DCM.cfg, replacing the updated value for the property "IM_MAX_MEM".

The maximum amount of memory is configured.

Example

The following example configures the maximum memory usage for Data Aggregator where the total memory is 48 GB:

1. Open a console and type the following command:

```
more /proc/meminfo
```

The following result appears:

```
MemTotal: 50331648KB
```

2. Calculate the maximum memory:
   Equation: total memory * 80% - 2 GB = maximum memory
   Solution: 50331648 KB * 80% - 2 GB≅ 38 GB
3. Access the following file:

```
DA_installation_directory/apache-karaf-<vers>/bin/setenv
```

4. Modify the following line:

```
IM_MAX_MEM=38G
```

5. Save the file.
6. Restart Data Aggregator.
7. Modify the da.memory value in the /etc/DA.cfg file:

```
da.memory=38G
```

The maximum amount of memory is modified.

Modify the External ActiveMQ Memory Limit

The Data Aggregator installer calculates the memory that is needed on your system to accommodate the ApacheMQ process. However, you can manually modify the memory limit settings to fine-tune ActiveMQ on your Data Aggregator system. For example, you can modify the settings under the following circumstances:

- When the system memory has changed.
- When the number of Data Collector systems have changed.
- To optimize the memory settings.
- When you have determined that ActiveMQs performance is degraded, by monitoring either the JConsole or the DX NetOps Performance Management custom chart with ActiveMQ metrics.

Follow these steps:

1. Calculate the amount of memory for the Data Aggregator ActiveMQ based on the following settings:
   – **Maximum java heap size**

This value is set to 20% system memory by default. The minimum value is 512M.
- **Initial minimum java heap size**
  This value should be 50% of maximum java heap size.
- **Memory limit for all messages**
  This value should be 50% of the maximum java heap size.
- **Memory limit per queue**
  This value should be calculated based on how many Data Collector installations you have.
  Example: The memory per queue
  (system memory for all messages)/5/(Data Collector count)

2. Calculate the amount of memory for the Data Collector ActiveMQ based on the following settings:
   - **Maximum java heap size (-Xmx)**This value is equal to 1GB, which is the recommended minimum.
   - **Initial java heap size (-Xms)**This value is equal to 50% of the maximum java heap size. By default, the value is equal to 512M.
   - **Default Disk Cache Size**This value is equal to 50% of the maximum Data Collector memory. By default, this value is equal to 45 minutes, or 500K, of data when you use a 5-minute poll rate.
   - **Default Drop Rate**This value is equal to 10% of the default disk cache size. The checker captures the amount of data in the cache every 30 seconds, and drops 10% of the data when the maximum cache size is reached.
3. Log in to the Data Aggregator host as the root user or the sudo user.
4. Stop the ActiveMQ broker:
   ```
   service activemq stop
   ```
5. Modify the java heap size for ActiveMQ:
   a. Access the following file:
      DA_installation_directory/scripts/activemq
   b. Modify the following line:
      ```
      ACTIVEMQ_OPTS_MEMORY=" -Xms788M -Xmx2575M -Xmn394M -server -XX:SurvivorRatio=6 -
      XX:+UseConcMarkSweepGC -XX:+UseParNewGC ...
      ```
      Change - **Xms** to be the Initial minimum java heap size.
      Change - **Xmx** to be the Maximum java heap size.
   c. Save the changes.
6. Modify the ActiveMQ memory limit for the producer flow control:
   a. Access the following file:
      DA_installation_directory/broker/apache-activemq-*vers*/conf/activemq.xml
   b. Locate the following line and change the value to Memory limit for all messages:
      ```
      <memoryUsage limit="value"/>
      ```
   c. Locate the following line, change the value to Memory limit per queue:
      ```
      <policyEntry queue=">" producerFlowControl="true" memoryLimit="value"/
      ```
   d. Save the changes.
7. In order for the memory setting change to persist during a Data Aggregator upgrade, modify the /etc/DA.cfg file, replacing the updated value for the property "da.activemq.memory".
   Example:
   ```
   da.activemq.memory=value
   ```
8. Start the ActiveMQ broker:
   ```
   service activemq start
   ```

ActiveMQ starts and uses the new memory settings.

Configure the Data Aggregator Cleanup

For 20.2.3 and higher, a cleanup runs daily by default to remove deleted items from the Data Aggregator. You can configure whether the cleanup runs. You can also disable the cleanup for attribute instance tables or relationships.

To configure when the cleanup occurs, see Schedule Data Purges.

Follow these steps:

1. Go to the following location:
   DA_install_directory/apache-karaf-2.4.3/etc
2. Create the following file in this location:
   com.ca.im.dm.core.database.dao.impl.DeletedItemCleanupDAO.cfg
3. Specify the following parameters and save the file:
   Example:
   ```
   cleanupEnabled=true
   attributeCleanupEnabled=true
   relationshipCleanupEnabled=true
   ```

Monitor System Health

System Health dashboards monitor system utilization and identify performance trends and degradation. In each of the suggested views, observe the value trend to detect abnormal changes.

To view the System Health dashboards, you need the View System Health Dashboards role right and the System Health - Data Aggregator group that is assigned to you. By default, only the Administrator has the View System Health Dashboards role right.

Use the following derived rollup metrics to identify changes:

- **Average**
  The average value across the resolution window
- **Maximum** The maximum value within the resolution window. Use this metric to visualize high peaks.
- **95th Percentile**
  95 percent of the samples within the resolution window have a lower value. Use this metric to smooth out spikes.

The following System Health dashboards are available:

Data Aggregator / Data Collector Health Dashboard

Data Aggregator Event Processing Dashboard

The Data Aggregator Event Processing dashboard monitors the health of event processing.

This dashboard has built-in thresholds, which can help you to identify issues with event processing. The following values indicate that the system is in good health:

- **Event Queue** - Less than two. An Event Queue Size of greater than two indicates that the system is behind, or that the system is at risk.
- **Poll Cycle Percent** - The Threshold Evaluation engine continues to run if the Poll Cycle Percent is less than 50%. When you use a 1-minute poll rate, the evaluation has to complete in less than 30 seconds. When you use a 5-minute poll rate, the evaluation has to complete in less than 150 seconds.
- **Events Created and Cleared** - The sum of Created and Cleared Events during a 5-minute interval is less than 900.
- **Event Evaluations** - Less than 150,000 during a 5-minute interval.

Event processing deteriorates if any of the following conditions occur:

- The Data Aggregator event processing is slow to process rules.
- You create and clear more than the recommended number of events.
- Event processing is backing up.

Data Aggregator General Processing Dashboard

The Data Aggregator General Processing dashboard monitors all Data Aggregator activities. To customize the views to fit the needs of your environment, specify thresholds on this dashboard. The following values or conditions indicate that the system is in good health:

- **Rate Data Loading Times**
  Less than 30 seconds
- **Roll-Up Calculation Times**
  Spikes in the Roll-Up Calculation Times after 00:30 UTC
  Daily and weekly processing causes these normal spikes.
- **Baseline Calculation Times**Spikes in the Baseline Calculation Times after 00:30 UTC
  Daily and weekly processing causes these normal spikes.
- **Data Repository Maintenance Times**Normal trend changes
  The maintenance times vary based on the size of the schema.
- **Reporting ETL Processing Times**
  Execution time does not exceed 15 minutes.
  Consistent processing time unless a significant number of new devices have been discovered.
- **Reporting ETL Count of Loaded Rows**The count is consistent with the number of items that the system is monitoring.
  This count tracks the number of dimension items, both device and component items, loaded into the reporting table.

Data Aggregator Polling Dashboard

The Data Aggregator Polling dashboard is used to determine the polling load on the Data Aggregator and the Data Collectors.

The following values help you to monitor the system health:

- **Polled Item Count** - To determine the threshold for the polled item count, use the DX NetOps Performance Management Sizing Tool.
- **Calculated Metrics per Second** - This value is equal to the value that you identified when setting up your environment, unless there is a change in the metric families or items in your environment.

Consider the following when using this dashboard:

- If the Data Aggregator is polling too many items, redistribute polled items to other Data Collectors.
- Observe the polling statistics to monitor the polling health, and to see whether the Data Aggregator is polling devices too quickly.
- The Stopped Polls by Device view helps you to identify problematic devices, which cause excessive polling, such as when the device is unavailable.

  TIP

  If you have multiple Data Collectors, hover over the graph for accurate information for each Data Collector.

Data Aggregator Queries Dashboard

The Data Aggregator Queries dashboard monitors the quantity and timing of RIB and OpenAPI queries. The RIB queries and OpenAPI queries views specify the number of corresponding queries for a specific time period. The following value indicates that the system is in good health:

RIB Query Processing TImes - Less that 120 seconds.

Update the Data Collector

You can migrate the Data Collector without having to rediscover network devices and components or lose historical data. For example, if you are a tool administrator, your server administrator can instruct you to relocate Data Collector to another host. Data Collector is polling 500,000 devices and components, and you do not want to lose data or perform rediscovery.

The Data Collector component can be moved even if you have device packs installed.

Note the following considerations:

- The amount of data loss is equal to the amount of time that has elapsed from the time the old Data Collector component is shut down to the time when the new Data Collector component has been deployed.
- If the old Data Collector component happens to start accidentally, the SNMP data is polled twice. A warning appears in the Data Aggregator karaf log:

  ```
  WARN  | Session Task-810 | 2013-01-02 13:52:09,062 | DCHeartBeatLog |
  ore.collector.interfaces |
        | HeartBeat message not received.  Expected: 93, Received: 255
  ```

  To fix this problem, stop or uninstall the old Data Collector component.

To move Data Collector to another system, follow this process:

NOTE

Backup and restore is not required for the Data Collector. For installations that use CA Mediation Manager, migrate the device packs before you install the Data Collector on the new host.

Determine the Unique Identifier for Data Collector

Determine the unique identifier for Data Collector before moving this component to another host.

Retrieve the Data Collector ID using *one* of the following methods:

- Log in to NetOps Portal as a user with the Administrator role, and do the following steps:
  a. Select **Administration**, and select a Data Aggregator data source from the menu.
     The Data Aggregator Admin UI opens.
  b. Select **System Status**, **Data Collectors** from the menu.

c. Find the Data Collector component that you want to move and notate its ID.
The format of the Data Collector component ID is HOSTNAME:UUID.

- Open a web browser and issue the following web service call:

```
http://DA_hostname:port/rest/dcms
```

DA_hostname:port
Specifies the Data Aggregator host name and the port number.
Default port: 8581
Find the <DataCollectionMgrInfo> section whose HostName and IPAddress match the one you want to move. Note the value for <DcmID>.

Stop Data Collector

Stop the Data Collector services on the current host before moving Data Collector to another host.

Follow these steps:

1. If you have installed device packs for this Data Collector, take the following steps. If no device packs are installed, proceed to Step 2.
   a. Log in to NetOps Portal as a user with the Administrator role.
   b. Select **Administration**, and then select a Data Aggregator data source from the menu.
   The Data Aggregator Admin UI opens.
   c. Select **EMS Integration Profiles** from the **Monitoring Configuration** menu.
   d. Right-click on a profile that is associated with this Data Collector host, and select **Stop**. Do this step for every EMS profile that is related to this Data Collector host.
   e. Archive CA Mediation Manager artifacts by running this command:

```
tar -zcvf filename /opt/IMDataCollector/apache-karaf-{n.n.n}/MediationCenter
```

   - ***filename***
     Specifies the name of the archive file, which is moved to the new Data Collector host.
2. Log on to the Data Collector host and run the following command:

```
service dcmd stop
```

3. Verify that Data Collector has stopped:
   a. Log in to NetOps Portal as a user with the Administrator role.
   b. Select **Administration**, and select a Data Aggregator data source from the menu.
   c. Select **System Status**, **Data Collectors** from the menu.
   d. Verify that the Data Collector status is "Not Connected".

Reinstall the Data Collector on a Clean Host

After you stop the Data Collector services on the original host, reinstall the Data Collector on a clean host. Use the same `DCM_ID` . Doing so allows the Data Collector to retrieve the original Data Collector configuration from the Data Aggregator when the new Data Collector process starts.

Verify that DX NetOps Mediation Manager and DX NetOps Virtual Network Assurance point to the correct Data Collectors:

- For DX NetOps Mediation Manager, see the CAMM documentation.
- For DX NetOps Virtual Network Assurance, see the CA VNA documentation.

Follow these steps:

1. (DX NetOps Mediation Manager only) Migrate your device packs. On the old Data Collector host, run the *$CAMM_HOME*/tools/migratePMtoCAMM script with the - t flag.
   This step assumes that you are running the script on a Data Collector server where a Local Controller is installed. You must also have the CA Mediation Manager Console running on another server. For more information, see the CAMM documentation.
2. (DX NetOps Virtual Network Assurance only) For DX NetOps Virtual Network Assurance, see the CA VNA documentation.
3. Log in to the new host system and open a command shell session.
4. Set an environment variable with the ID of the data collector by running this command:
   ```
   export DCM_ID=data collector id
   ```
   – ***data collector id*** The DcmID that we obtained as the unique identifier for the Data Collector in the previous section.
5. Install Data Collector from the same session by running the **install.bin** binary. For more information, see Install the Data Collectors.
6. Install the CA Mediation Manager LC on the same server.
7. If you have previously installed device packs for this Data Collector, perform these additional steps:
   a. Copy the zip files that you created previously with the migration script to local directories on this host.
   b. Use the CA Mediation Manager web console to deploy these device packs and start them.
      You do not need to redeploy the certification packs to the Data Aggregator host.
8. (Optional) After several polling cycles, verify that data is being collected on the new host.Uninstall the old Data Collector, and delete any associated EMS profiles.

Rebalance the Load on Data Collector

As a Data Collector instance monitors more devices, the capacity can be exceeded and the Data Collector can become overloaded. You can transfer the workload from one overloaded Data Collector instance to other Data Collector instances. You can rebalance the load on Data Collector in two ways:

- Select the Data Collector instances that you want to rebalance and click **Rebalance**. The product automatically rebalances the load among the selected Data Collector instances.

  NOTE

  When the load on the Data Collectors is rebalanced, DX NetOps Mediation Manager and DX NetOps Virtual Network Assurance devices are not rebalanced. Only SNMP devices are rebalanced.
- Move selected devices from one Data Collector instance to another.

  WARNING
  Do not rebalance or move many items during peak hours. These operations might negatively affect end-user performance.

Follow these steps:

1. Open CA NetOps Portal as an administrator.
2. Select **Administration**, **Data Sources**, and click a Data Aggregator data source.
3. Click **Data Collectors** from the **System Status** menu.
   You can see the number of devices and components that each Data Collector installation is polling. You can also see the total number of devices that are assigned to each Data Collector instance, including devices that are not currently polled.

Automatically Rebalance the Load on Data Collector

1. Select the Data Collector instances that you want to rebalance and click **Rebalance**.

   NOTE
   Be sure to select Data Collector instances within the same IP domain. Only Data Collector instances within the same IP domain can rebalance devices between one another.
2. A confirmation dialog displays the current device and polled item count for each selected Data Collector and the proposed resulting device and polled item counts.

   NOTE
   Devices can only be moved to Data Collector instances that can contact them.
3. Click **Yes**.

   NOTE
   Rebalancing polled items restarts the baseline average calculations for all rebalanced polled items.

Move Selected Devices to a Specific Data Collector Instance

1. Select the Data Collector instance that you want to move selected devices from.
2. In the Devices table, select the devices that you want to move to another Data Collector instance and then click Move Devices.
3. The Move Devices to Selected Data Collector dialog opens.
4. Select the Data Collector instance that you want to move your selected devices to from the drop-down list.

   NOTE
   Devices can only be moved to Data Collector instances that can contact them. Only Data Collector instances that are within the same IP domain are included for selection.
5. Click Yes.

   NOTE
   Moving devices restarts the baseline average calculations for the moved devices.

Restore Data Aggregator

You can restore the Data Aggregator files that you backed up. If Data Repository remains intact, you can restore only the Data Aggregator component.

Data Aggregator can remain running while you restore the backup. The files that are backed up can be dropped in the desired directories while Data Aggregator is running.

Backup and restore into the same product version.

NOTE
You must have root or sudo privileges to perform this task.

Follow these steps:

1. Open a command prompt.
2. (Optional) In the situations where the Data Aggregator karaf service is not running, uninstall the existing Data Aggregator and reinstall it.
3. Run all of the following commands:

```
cp -r DA_Backup/deploy_backup/* DA_install_directory/apache-karaf-version/deploy/
cp -r DA_Backup/cert_backup/* DA_install_directory/data/
cp -r DA_Backup/MIBDepot_backup/* DA_install_directory/apache-karaf-version/
MIBDepot/
```

```
cp DA_Backup/CustomDeviceType_backup/DeviceTypes.xml DA_install_directory/data/
custom/devicetypes/
cp -r DA_Backup/etc DA_install_directory/apache-karaf-version/
cp -r DA_Backup/data/log DA_install_directory/apache-karaf-version/data/
```

If prompted, overwrite the existing file.

- ***DA_Backup***
  Specifies the directory path and name of the backup directory.
- ***DA_install_directory***
  Specifies the Data Aggregator install directory.
  Default: /opt/IMDataAggregator

In a fault tolerant environment, a shared directory (example: `/DASharedRepo`) is defined to help limit data loss. Therefore, in a fault tolerant environment the `certifications` and `devicetype` files would be located in the following directories:

```
DASharedRepo/certifications
DASharedRepo/custom/devicetypes/DeviceTypes.xml
```

For more information, see Fault Tolerance.

4. Wait for a few minutes for Data Aggregator to synchronize automatically with CA NetOps Portal. When the connections between the Data Aggregator and the Data Collector hosts are established, the Data Collector hosts resume polling.
   Data Aggregator is restored.

   NOTE
   If you must restore Data Collector to a previous state, you can uninstall and reinstall Data Collector.

View the Health of the System

The System Status page provides the following health statuses:

- **Data Source Synchronization**
  View the overall health status of your data sources. To view details for each data source, click the expand arrow to the right.
- **Data Aggregator**
  View the overall health status of your Data Aggregators. To view details for each Data Aggregator, click the expand arrow to the right.
- **Data Collector**
  View the overall health status of your Data Collectors. To view details for each Data Collector, click the expand arrow to the right. The Data Collector List shows the tenant and IP domain to which each Data Collector installation is assigned, and the Data Collector status and version. You can also see the total number of devices and components that each Data Collector installation is polling, and that are assigned to the Data Collector instance, including devices that are not currently polled. The administrator can see a list of Data Collector installations for all tenants. Tenant administrators can see only the Data Collector installations that are assigned to their tenant.
- **VNA Gateway**
  View the overall health status of your VNA Gateway. To view details for the VNA Gateway, click the expand arrow to the right.
- **Scheduled Report Repository**
  View the overall health status of your Scheduled Report Repository. To view details, click the expand arrow to the right.
- **Report Generation Services**

View the overall health status of your Report Generation Services. To view details for reports on All Pages and reports for the First Page, click the expand arrow to the right. The following operational statuses apply to the Report Generation Services:
  - **Low Load**
    0-1 reports are waiting to run.
  - **Medium Load**
    2-5 reports are waiting to run.
  - **High Load**
    6 or more reports are waiting to run.

  You can also see the percentage of that last 12 hours that each operation status occurred.
- **Alarm Status Service**
  View the overall health status of your Alarm Status Service. To view the details for the Alarms Status Service, click the expand arrow to the right.
- **Usage Data**
  View your overall usage data. To view details, click the the expand arrow to the right.
- **Network Flow Analysis**
  View the overall health status of your Network Flow Analysis components. To view the details the Network Flow Analysis components, click the expand arrow to the right.

Follow these steps:

1. Log in as an Administrator.
2. Hover over **Administration**, and click **Data Sources: System Status**.
3. To view details, click the expand arrow to the right of the overall health status.

View Data Aggregator Details

You can view the total number of manageable and pingable devices that Data Aggregator monitors for all tenants. Individual device totals for each tenant are also displayed in a table. Tenant administrators can only view the total number of manageable and pingable devices that Data Aggregator monitors for their tenant.

You can also view the version and the build number of Data Aggregator.

Follow these steps:

1. Log in as an Administrator.
2. Select **Administration**, **Data Sources**, and click a Data Aggregator data source.
3. Click **Data Aggregator** from the System Status menu.
   The **Data Aggregator List** page opens.

Data Repository Administration

The Data Repository uses Vertica database software. The Data Repository does not support any customization.

- *Do not* deploy custom projections or modify database parameters.
- The Data Repository *does not support* a Vertica k-safety value greater than 1.
- The Data Repository *does not support* the use of Management Console, which is an Vertica management tool. This product can modify the Vertica database configuration.

The following topics provide information about configuring the Data Repository:

Configure Data Retention Rates

The default data retention rates for the Data Repository help to conserve disk space and improve reporting, and can be customized. Polled data is generated each poll cycle for all devices, and this data represents the most granular data available in the product. This raw, polled data is set to roll up at hourly, daily, and weekly aggregation levels.

Because higher-level aggregated data requires less disk space, you can keep this data for a longer period than polled data.

You can change how long the Data Repository retains the polled data, hourly rollup data, daily rollup data, and weekly rollup data. For example, you can change the polled data retention value to 30 days to conserve disk space. Find the balance that best suits your needs and environment.

By default, data is retained in Data Repository for the following number of days:

- Polled data: 45 days
- Hourly rollup data: 90 days
- Daily rollup data: 365 days
- Weekly rollup data: 730 days

The minimum number of days that Data Repository can retain data for is as follows:

- Polled data: 2 days
- Hourly rollup data: 8 days

  NOTE

  When the hourly retention rate is less than 32 days, the calendar heat chart views show daily data (only one sample per day). The charts appear sparse as a result.
- Daily rollup data: 31 days
- Weekly rollup data: 366 days

Follow these steps:

1. Enter the following information in a web browser:
   `http://hostname:port/rest/globalretentiondefinition`
   - ***hostname*:*port***
     Use this parameter to specify the Data Aggregator host name and the port number.
     Default port: 8581
2. Take note of the ID that is assigned to the globalretentiondefinition.
3. Look for the following elements:
   - `GtdRollupDataRetentionPeriod`
   - `DailyRollupDataRetentionPeriod`
   - `PolledDataRetentionPeriod`
   - `HourlyRollupDataRetentionPeriod`

   This information helps you determine which types of data you want to modify the retention period for.
4. Look for the elements that has the HistoricConfigurationDataRetentionPeriod parameter. This information helps you specify the number of days to keep item repository attribute values.
5. Open a REST client editor or HTTP tool that sends requests and gets responses and set the Content-type to application/xml.
6. Enter the following criteria:
   - URL: `http://hostname:port/rest/globalretentiondefinition/ID`
     - **ID**

A unique identification number that is assigned to the globalretentiondefinition parameter

- HTTP method = PUT
- Enter the retention periods that you want to change in the Body tab of the HTTP Request pane.
  For example:

```
<GlobalRetentionDefinition version="1.0.0">

<PolledDataRetentionPeriod>4</PolledDataRetentionPeriod>

</GlobalRetentionDefinition>
```

WARNING
Verify that there is no white space at the beginning of each of these lines, otherwise the PUT fails.

In this example, the polled data retention period has been changed to four days.

Results are returned in the Body tab of the HTTP Response pane.
For example:

```
<GlobalRetentionDefinitionList>

  <GlobalRetentionDefinition version="1.0.0">

    <ID>4</ID>

    <GtdRollupDataRetentionPeriod>730</GtdRollupDataRetentionPeriod>

    <HistoricConfigurationDataRetentionPeriod>7</
HistoricConfigurationDataRetentionPeriod>

    <DailyRollupDataRetentionPeriod>365</DailyRollupDataRetentionPeriod>

    <PolledDataRetentionPeriod>4</PolledDataRetentionPeriod>

    <HourlyRollupDataRetentionPeriod>90</HourlyRollupDataRetentionPeriod>

    <Item version="1.0.0">

      <CreateTime>Thu Dec 08 16:03:05 CST 2011</CreateTime>

      <Name>Global Retention Definition</Name>

    </Item>

  </GlobalRetentionDefinition>

</GlobalRetentionDefinitionList>
```

In this example, the polled data retention period has been changed to four days. The default retention periods for weekly rollup data, daily rollup data, and hourly rollup data remain.

Back Up the Data Repository

To protect your data, back up the Data Repository.

> **WARNING**
>
> The following procedure is the supported method for backing up the Data Repository. Taking a virtual machine snapshot is *not* a supported method for backing up the Data Repository.

The first backup is a full backup of all historical data. Subsequent backups are incremental and include all database activity that occurred since the snapshot at the start of the previous backup.

About Data Repository Backups

- The Data Repository and Data Aggregator continue to run during a Data Repository backup.
- Backup processing can be resource-intensive, but is prioritized below other processing. To let backups to proceed more quickly, and to minimize the impact to other processing, perform backups during non-peak hours.
- You can back up Data Repository to a remote host, or you can back it up to the same host. If you back up to the same host, save the backup to a different disk than the one that is used by the catalog and data directories.
- Perform full backups weekly. Perform incremental backups daily.
- Full backups occur only when the backup location is a new directory. The snapshotName can be the same as previous backups.
- The incremental snapshots store new files and hard links to unchanged files from the previous backup. Restoring to any incremental snapshot depends on the integrity of the files that are linked to in previous snapshots.
- For information about the size of the backup files, see the DX NetOps Performance Management Sizing Tool.

To ensure data integrity, back up each node of the data repository to a dedicated backup host. To prepare for the backup, perform the following procedure for each Data Repository node.

Before you begin, verify the following information about the Data Repository host and the remote backup host:

- Neither host is connected to LDAP.
- Neither host is connected to Network Information Service (NIS) and have the same Vertica Linux database administrator user.
- Port 50000 is open on any firewalls so that the Data Repository host can access the custom rsync/ssh port 50000 on the backup host.

> **NOTE**
>
> If you do not have a backup host, you can back up the Data Repository locally. For more information, see Configure the Data Repository Host for a Local Backup.

Follow these steps:

1. Log in to the backup host as the root user.
2. Create the Vertica Linux database administrator user on the remote backup host:
   ```
   useradd db_admin -s /bin/bash
   ```
   db_admin is the same Vertica Linux database administrator user that exists on the Data Repository hosts.
3. Set the Vertica Linux database administrator user password:
   ```
   passwd db_admin
   ```
4. Create the Vertica directories on the remote backup host:
   ```
   mkdir /opt/vertica/bin
   mkdir /opt/vertica/oss
   ```
5. Change the owner of the Vertica directories:
   ```
   chown -R db_admin /opt/vertica
   ```

6. Log out from the remote backup host.
7. Set up passwordless ssh on the Data Repository host for the remote backup host:
   a. Log in to the Data Repository host as the Vertica Linux database administrator user.
   b. Generate the keys for passwordless ssh:
      ```
      ssh-keygen -N "" -t rsa -f ~/.ssh/id_rsa
      cp ~/.ssh/id_rsa.pub ~/.ssh/authorized_keys2
      chmod 644 ~/.ssh/authorized_keys2
      ```
   c. Copy the Vertica Linux database administrator user public key into the list of authorized keys on the remote backup host:
      ```
      ssh-copy-id -i dradmin@backuphost
      ```
   d. Log in to the remote backup host as the Vertica Linux database administrator user.
   e. Copy the Vertica rsync and python tools from the Data Repository host to the remote backup host:
      ```
      scp dradmin@drhost:/opt/vertica/bin/rsync /opt/vertica/bin
      scp -r dradmin@drhost:/opt/vertica/oss/python /opt/vertica/oss
      ```
8. Verify that the remote backup host has the following directories:
   – /opt/vertica/bin/rsync
   – /opt/vertica/oss/python
9. Create the backup directory:
   ```
   mkdir backup_directory
   ```
   backup_directory specifies the directory where you want to save the backup files. Select a backup directory that is on a disk partition with a large amount of free space. If these directories are not writable by the database administrator user, give this user access to these directories.
   The remote host is ready for the backup configuration file to be created and for the backup directory to be initialized.

Configure the Data Repository Backup

To back up the Data Repository and configure automatic backups, create a configuration file for the backup. Vertica performs a full backup during the first backup into a new backup directory. All subsequent backups to the same directory are incremental backup, even if the snapshot name changes.

The node where you perform this procedure initiates the backup.

To configure the vbr utility, Vertica automatically installs sample configuration files at the following location:

`/opt/vertica/share/vbr/example_configs .`

For more information, see the Vertica documentation.

Follow these steps:

1. Log in to the Data Repository host as the database administrator user.
2. Create a password file:
   Example: `/opt/vertica/config/password.txt`

   NOTE

   You can choose a different location for the password file.

   ```
   [Passwords]
   ; Specified password for db admin account
   dbPassword = DBpassword
   ; Specifies password for rsync user account – if different than DB admin
   ; serviceAccessPass = rsyncpwd
   ```

```
; Specifies password for the dest_dbuser Vertica account. Used only for restoring to
 alternate cluster.
; dest_dbPassword = DestinationPwd
```

3. Go to the sample configuration files:
   `/opt/vertica/share/vbr/example_configs`
   The database administrator user requires write privileges for the directory.
4. Copy, edit, and deploy a configuration file for backup. See the following examples from Vertica.
   Example 1: `backup_restore_full_local.ini`
   Back up the Data Repository to a local area on the same machine. The backup can be a mount from an external shared drive or a local disk. You cannot use the same disk as `data/catalog`.

```
[Mapping]
; node_name = backup_host:backup_dir
; [] indicates backup to localhost
v_drdata_node0001 = []:/backups
v_drdata_node0002 = []:/backups
v_drdata_node0003 = []:/backups

[Misc]
; Backups with the same snapshotName form a time sequence limited by
 restorePointLimit.
; SnapshotName is used for naming archives in the backup directory, and for
 monitoring and troubleshooting.
; Valid values: a-z A-Z 0-9 - _
snapshotName = backup_snapshot

[Misc]
; The temp directory location on all database hosts.
; The directory must be readable and writeable by the dbadmin, and must implement
 POSIX style fcntl lockf locking.
; tempDir = /tmp/vbr

; Specifies the number of historical backups to retain in addition to the most recent
 backup.
; 1 current + n historical backups
restorePointLimit = 7

; Full path to the password configuration file
; Store this file in directory readable only by the dbadmin.
passwordFile = /opt/vertica/config/password.txt

; When enabled, Vertica confirms that the specified backup locations contain
; sufficient free space and inodes to allow a successful backup. If a backup
```

```
; location has insufficient resources, Vertica displays an error message explaining
 the shortage and
; cancels the backup. If Vertica cannot determine the amount of available space
; or number of inodes in the backupDir, it displays a warning and continues
; with the backup.
; enableFreeSpaceCheck = True

; When performing a backup, replication, or copycluster, specifies the maximum
; acceptable difference, in seconds, between the current epoch and the backup epoch.
; If the time between the current epoch and the backup epoch exceeds the value
; specified in this parameter, Vertica displays an error message.
; SnapshotEpochLagFailureThreshold = 3600
```

Example 2: `backup_restore_full_external.ini` Back up the Data Repository to a different machine. Replace the IP addresses with the IP address of the backup host(s).

```
[Mapping]
; node_name = backup_host:backup_dir
; In this "parallel backup" configuration, each node backs up to a distinct external
 host.
; To backup all database nodes to a single external host, use that single hostname/IP
 address in each entry below.
v_drdata_node0001 = 1.1.1.1:/backups
v_drdata_node0002 = 2.2.2.2:/backups
v_drdata_node0003 = 3.3.3.3:/
backups
[Misc]
; Backups with the same snapshotName form a time sequence limited by

; tempDir = /tmp/
vbr
; Specifies the number of historical backups to retain in addition to the most recent
 backup.
; 1 current + n historical backups
restorePointLimit =
 7
; Full path to the password configuration file
; Store this file in directory readable only by the dbadmin
; (no default)
```

```
passwordFile = /opt/vertica/config/
password.txt
; When enabled, Vertica confirms that the specified backup locations contain
; sufficient free space and inodes to allow a successful backup. If a backup
; location has insufficient resources, Vertica displays an error message explaining
 the shortage and
; cancels the backup. If Vertica cannot determine the amount of available space
; or number of inodes in the backupDir, it displays a warning and continues
; with the backup.
; enableFreeSpaceCheck =
 True
; When performing a backup, replication, or copycluster, specifies the maximum
; acceptable difference, in seconds, between the current epoch and the backup epoch.
; If the time between the current epoch and the backup epoch exceeds the value
; specified in this parameter, Vertica displays an error message.
; SnapshotEpochLagFailureThreshold = 3600
```

5. (First Time Only) Initialize the backup directory before the first time you run the backup.

   ```
   /opt/vertica/bin/vbr.py --task init --config-
   file configuration_directory_path_filename
   ```

   – ***configuration_directory_path_filename*** indicates the directory path and filename of the configuration file that you will reference when you restore. This file is located where you ran the backup utility.

   Once initialized, multiple configuration files can use the directory if the files share the same backup directory location.
6. Back up Data Repository:

   ```
   /opt/vertica/bin/vbr.py --task backup --config-
   file configuration_directory_path_filename
   ```

   For example:

   ```
   /opt/vertica/bin/vbr.py --task backup --config-file /home/vertica/vert-db-
   production.ini
   ```
7. If you are prompted about the authenticity of the host, answer yes.
   The Data Repository starts the backup. This process can take a long time, especially for a full backup.
8. (Optional) If you do not want to retain the Data Repository password in clear text for future manual backups.

   WARNING
   The configuration file that is generated contains a clear text password. Automated backups require the password. This procedure prevents automated backups from this configuration file.

   a. Verify that the following line exists under the [Database] section:

      ```
      dbPromptForPassword = True
      ```

   b. Remove the following line from the [Database] section:

      ```
      dbPassword = password
      ```

Set Up an Automatic Backup

To ensure regular backups of the Data Repository, create a cron job to schedule automatic backups. The first backup is a full backup and the following backups are incremental. Run a full backup weekly or biweekly. Vertica performs a full backup only when you use a new backup directory.

TIP

Run a full backup weekly. If disk space is limited, retain only two to three weeks of data. Delete the oldest backup file at the beginning of each week. Use the vbr utility remove task to delete old backups. Vertica does not support removing backups through the file system.

Follow these Steps:

1. Create a wrapper shell script that contains the following line:
   ```
   /opt/vertica/bin/vbr.py --task backup --config-
   file configuration_directory_path_filename
   ```
   configuration_directory_path_filename indicates the directory path and filename of the configuration file that you will reference when you restore.
2. Save the contents to a new file named backup_script.sh in a location of your choice.
   For example:
   ```
   /home/vertica/backup_script.sh
   ```
3. Change permissions for running the script:

   WARNING

   `chmod 777` makes the file readable, writable, and executable by everyone. If you want only the script owner to run the file, use `chmod 700` . If you want only the root user to run the file, use `chmod 755` .

   ```
   chmod 777 location_backup_script.sh/backup_script.sh
   ```
   For example:
   ```
   chmod 777 /home/vertica/backup_script.sh
   ```
4. As the database administrator user, open the crontab to define a cron job:
   ```
   crontab -e
   ```
5. Add a cron job that runs the backup script.

   TIP

   Create a cron job to run the script daily at an off-peak time.

   For example:
   ```
   00 02 * * *   /home/vertica/backup_script.sh >/tmp/backup.log  2>&1
   ```
   This example cron job runs the backup script every day at 2:00 AM.
   The cron job runs a daily incremental backup.
6. Add a script to copy the configuration file, and change the snapshot name in the configuration file. Also use a new backup directory in the configuration file to cause Vertica to perform a full backup.

   WARNING

   Do not delete the previous configuration file. The original configuration file is required to remove a backup or restore from an older series of backups.
7. (Optional) Remove older backup sequences as required with the vbr utility with the remove task using the configuration that was used to create it.
   ```
   /opt/vertica/bin/vbr.py --task remove --archive=[<date>_<time>|"all"] --config-
   file configuration_directory_path_filename
   ```
   The remove command is destructive and removes the data and free space on the disk. The archive must be specified to remove a single restore point, a comma separated list, or "all". To display the list of backups, run `--task listbackup` .

VBR Utility Reference

The Vertica vbr utility lets you back up and restore either the full database, or one or more schema and table objects of interest. You can also copy a cluster and list backups you created previously.

For a full reference for the vbr utility, see the Vertica Documentation.

Configure the Data Repository Host for a Local Backup

If you do not have a dedicated backup host, you can back up the Data Repository locally. For best data integrity, we recommend a dedicated backup host.

For more information about Data Repository backups, see Back Up the Data Repository.

Follow these steps:

1. Log in to the Data Repository host as the database administrator user.
   In a cluster installation, you can log in to any host in the cluster.
2. Verify that the database administrator user is set up with a passwordless ssh key. In a cluster installation, ensure that passwordless ssh keys are set up for *each* host that is participating in the cluster.

   ```
   ssh hostname ls
   ```

   hostname is the name of the host where Data Repository is installed.
   If the passwordless ssh key is set up, you are *not* prompted for a password. If youare prompted for a password, set up passwordless ssh:
   a. Press Ctrl+C.
   b. Set up the Linux user account for the database administrator user with a passwordless ssh key:

      ```
      ssh-keygen -N "" -t rsa -f ~/.ssh/id_rsa

      cp ~/.ssh/id_rsa.pub ~/.ssh/authorized_keys2

      chmod 644 ~/.ssh/authorized_keys2
      ```

   c. Copy the SSH credentials to the other hosts in the cluster:

      ```
      ssh-copy-id -i dradmin@other-hostname-in-the-cluster
      ```

   d. Confirm that you are *not* prompted for a password:

      ```
      ssh hostname ls
      ```

3. Create a backup directory for each host in the cluster:

   ```
   mkdir backup_directory
   ```

   backup_directory specifies the directory where you want to save the backup files. Select a backup directory that is on a disk partition with a large amount of free space. If these directories are not writable by the database administrator user, give this user access to these directories.

The Data Repository Host is ready for the backup to run.

Restore Data Repository

You can restore Data Repository from an existing backup. To restore Data Repository, ensure that the database administrator user is part of the sudoers file.

WARNING

Do not restore a backup of an older release into a newer environment. The data from the older version might not be fully compatible with schema changes.

Usually, you restore Data Repository to the same computer where you backed it up from. However, you *can* restore Data Repository to a different computer. The computer that you restore to must be configured in the same way that the computer you backed up Data Repository from is. In a cluster environment, each computer you restore to must be configured in the same way that each computer you backed up each Data Repository node from is.

The following configurations must be the same:

- the IP address
- the hostname
- the catalog and data directories
- the catalog and data directory permissions
- the Vertica Linux database administrator user credentials
- the database administrator user account credentials
- the database user account credentials

Follow these steps:

1. Stop all Data Collector hosts that are associated with Data Aggregator by logging in to the computers where Data Collector is installed as the root user or a sudo user with access to a limited set of commands. Open a command prompt and type the following command:

   ```
   service dcmd stop
   ```

   NOTE

   For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.

   Data Collector hosts stop.
2. Stop Data Aggregator by logging in to the computer where Data Aggregator is installed as the root user or a sudo user with access to a limited set of commands. Do one of the following steps:
   – Stop the Data Aggregator service:

     ```
     service dadaemon stop
     ```

   – (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**

       ```
       service dadaemon maintenance
       ```

     - **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon maintenance
```

Data Aggregator stops.

3. Log in to the database server you use for Data Repository as the database administrator user, *not* as the root user.
4. Type the following command:

```
/opt/vertica/bin/adminTools
```

The Administration Tools dialog opens.

5. Select (4) Stop Database.
6. Press the Space bar next to the database name, select OK, and press Enter.
   You are prompted for the database password.
7. Enter the database password and press Enter.
   Data Repository stops.

   NOTE
   If Data Repository does not stop, select (2) Stop Vertica on Host from the (7) Advanced Tools Menu.
8. Select Exit and press Enter.
9. To prepare to restore the Data Repository backup, log in as the Linux user account for the database administrator user to the database server you use for Data Repository.
   When you set up automatic backups of Data Repository, you configured the configuration file with a restore point of seven. Data Repository can be restored to the most recent backup or to any of the previous seven incremental backups.
10. Do one of the following steps:
    a. To restore Data Repository to the most recent backup, type the following command:

```
/opt/vertica/bin/vbr.py --task restore --config-
file configuration_directory_path_filename
```

- ***configuration_directory_path_filename***
  Indicates the filename and directory path of the configuration file you created when you ran the backup configuration procedure. This file is located where you ran the backup utility (/opt/vertica/bin/vbr.py).

For example:

```
/opt/vertica/bin/vbr.py --task restore --config-file /home/vertica/vert-db-
production.ini
```

NOTE
In a cluster installation, you can run the restore task from any of the hosts that are participating in the cluster.

TIP

For a list of available restore points, run the following command:

```
/opt/vertica/bin/vbr.py --task listbackup --config-
file configuration_directory_path_filename
```

    b. To restore Data Repository to any of the previous seven incremental backups, type the following command:

```
/opt/vertica/bin/vbr.py --task restore --config-
file configuration__directory_path_filename  --archive archive_name
```

- **configuration_directory_path_filename**
  Indicates the filename and directory path of the specific configuration file you want to restore a specific archive from. You created this configuration file when you ran the backup configuration procedure. This file is located where you ran the backup utility (/opt/vertica/bin/vbr.py).
- **archive_name**
  Indicates the name of the specific restore point that you want to restore to. Change to the backup directory that the configuration file for the restore point indicates. All of the restore points that are available are listed. Determine the archive name for the restore point that you want to restore to.

For example:

```
/opt/vertica/bin/vbr.py --task restore --config-file myconfig.ini  --
archive 20131020_170018
```

NOTE
In a cluster installation, you can run the restore task from any of the hosts that are participating in the cluster.

TIP

For a list of available restore points, run the following command:

```
/opt/vertica/bin/vbr.py --task listbackup --config-
file configuration_directory_path_filename
```

11. Restart Data Repository by logging in to the computer where Data Repository is installed as the database administrator user, *not* as the root user. Open a command prompt and do the following steps:
    a. Type the following command:

    ```
    /opt/vertica/bin/adminTools
    ```

    The Administration Tools dialog opens.
    b. Select (3) Start Database.
    c. Press the Space bar next to the database name, select OK, and press Enter.
    You are prompted for the database password.
    d. Enter the database password and press Enter.
    Data Repository starts.
    e. Select Exit and press Enter.
12. Restart the Data Aggregator. Log in to the Data Aggregator host as the root user or a sudo user, and start the dadaemon service. Do one of the following steps:
    – Start the Data Aggregator service:

    ```
    service dadaemon start
    ```

    – (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
      - **RHEL 6.x:**

      ```
      service dadaemon maintenance
      ```

- **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon maintenance
```

Data Aggregator starts.

13. Restart the Data Collectors. Log in to each Data Collector host as the root user or a sudo user, and start the dcmd service:

    Data Collector hosts start.

Add a Node to the Data Repository Cluster

To increase system performance or replace a node, add a node to the Data Repository cluster.

> **NOTE**
>
> This process applies to expanding a node that was set up with a hostname. If a node was set up using localhost, the nodes table in Vertica has node_address or node_ip set to 127.0.0.1. To expand a node that was set up using localhost, contact CA Support.

For more details about this process, see the Vertica documentation.

Complete the Prerequisites

Before you add the new node to the Data Repository cluster, complete the prerequisites:

- Stop the Data Aggregator:

```
service dadaemon stop
```

  > **NOTE**
  > Keep the Data Aggregator stopped until you complete the entire process.

- Prepare the new host for the Data Repository installation. For more information see, Prepare to Install the Data Repository.
- Back up the Data Repository. For more information, see Back Up the Data Repository.

Prepare the New Host

Before you add the host to the cluster, configure and validate the drinstall.properties file.

Follow these steps:

1. Copy the installDR.bin file to /tmp on the new host.
2. On the new host, extract the installation files from the BIN file:

```
./installDR.bin
```

3. Configure the drinstall.properties file.

   > **WARNING**
   >
   > The parameters must match the properties file from the original cluster. We recommend that you copy the drinstall.properties from an active node, and modify only the necessary parameters.

   – DbAdminLinuxUser=*The Linux user that is created to serve as the Vertica database administrato*r
   Default: dradmin
   – DbAdminLinuxUserHome=*The Vertica Linux database administrator user home directory*
   Default: /export/dradmin

NOTE
This directory is created if the Vertical installer creates the user. Be sure that the directory leading up to the home account already exists on the system. For example, if you are using /export/dradmin, verify that /export exists.

- DbDataDir=*The location of the data directory*
  Default: /data
- DbCatalogDir=*The location of the catalog directory*
  Default: /catalog
- DbHostNames=*The names of the new hosts*
- DbName=*The database name*
  Default: drdata

  NOTE

  This parameter is case-sensitive.
- DbPwd=*The database password*
  Default: dbpass

  NOTE
  The database password that you define here is used during the installation of Data Aggregator.

4. Run the validation script:
   ```
   ./dr_validate.sh -p drinstall.properties
   ```

   The validation script might ask you to reboot.

Add a Host to the Cluster

After you have prepared the new host, add the host to the cluster.

WARNING

Use the same configuration for the new cluster as for the source cluster. For example, the vertica version, node count, database name, administrator, user, catalog directory, and data directory must be the same as the original Data Repository.

Follow these steps:

1. Log in to one of the existing Data Repository hosts.
2. To add the host to the cluster, do one of the following tasks:
   - If you have root access, enter the following command and specify the italic values:
     ```
     /opt/vertica/sbin/update_vertica --add-hosts hostname -u DbAdminLinuxUser
     -l DbAdminLinuxUserHome -L location/resources/vlicense.dat --rpm location/
     resources/vertica-release.rpm -T -S default
     ```

     - **hostname**
       Specify the name of the new host to add to the cluster.
     - **DbAdminLinuxUser**
       The database administrator user name for the cluster as specified in the properties file
     - **DbAdminLinuxUserHome**
       The database administrator user home directory
     - **Location** The location where you extracted installDR.bin file
     - **vertica-release.rpm**

The current RPM file that exists in the extracted installation directory

– If you do not have root access, run the command as the sudo user.

```
export SUDO_USER=root
/opt/vertica/sbin/update_vertica --add-hosts hostname -u DbAdminLinuxUser
-l DbAdminLinuxUserHome -L location/resources/vlicense.dat --rpm location/
resources/vertica-release.rpm -T -S default
```

The script installs Vertica on the new host and incorporates the host into the cluster.

NOTE

If the database administrator user does not already exist, the installation script creates the user. The script prompts you to assign a new password. If the database administrator user exists, but passwordless SSH is not set up, the script prompts for the password to set up.

3. Ensure the Vertica database administrator can write to the data and catalog directories. Run the following commands:

```
chown DbAdminLinuxUser.verticadba DbDataDir DbCatalogDir
chmod 755 DbDataDir DbCatalogDir
```

NOTE

If expanding from one node, segment the database after expansion is complete. For more information, see Segment Database Tables.

Add a Node to the Database

After you add the host to the cluster, add the node to the database. If you are adding multiple nodes to the cluster, prepare all nodes before you add any nodes to the database.

Follow these steps:

1. Log in to any host in the cluster as the Data Repository administrator.
2. Open the Administration Tools:

```
/opt/vertica/bin/adminTools
```

3. Select **Advanced Menu**, and press Enter.
4. Select **Cluster Management**, and press Enter.
5. Select **Add Host(s)**, and press Enter.
6. Select the database, and press Enter.
   The console displays a list of unused hosts.
7. Select the new host, and press Enter.
8. Confirm the selection, and follow the instructions in the console.
   The Data Repository adds the node to the cluster. This process can take a long time.

Create the Buddy Projection

Before you can make an expanded cluster k-safety of 1, you must create the buddy projection for the `migration_status table`.

1. Log into vsql as the `dradmin` user.
2. Run the following command:

```
select export_objects('/tmp/migration_status.sql', 'SCHEMA.migration_status');
```

– ***SCHEMA***
  Specify the schema, for example, `dauser` .

3. Edit the following file:
   `/tmp/migration_status.sql`
4. Remove the `CREATE TABLE` definition and everything above it.
5. Edit the `CREATE PROJECTION` as follows:
   a. Change the name from `migration_status_super` to `migration_status_super_b1`
   b. After `ALL NODES` and before the semi-colon (;) add `OFFSET 1`
   c. Before the `SELECT MARK_DESIGN_SAFE` line, add `SELECT START_REFRESH();`
   d. Change `MARK_DESIGN_KSAFE(0)` to `MARK_DESIGN_KSAFE(1)`
6. Save the `migration_status.sql` file.
7. Run the following command:
   `vsql -U dradmin -w dradminPassword -f /tmp/migration_status.sql`

   A prompt should confirm that the refresh background process has begun.

Update the Data Repository Configuration

On the Data Aggregator host, ensure the `dbconnection.cfg` file points to the correct Data Repository hosts.

Follow these steps:

1. Open the *DA_installation_directory*`/apache-karaf-<`*version*`>/etc/dbconnection.cfg` file on the Data Aggregator host.
2. Modify the following line in the `dbconnection.cfg` file. Modify the line to reference the hostname or IP address of each Data Repository host:
   `dbHostNames=`*dbNode1Hostname*`,`*dbNode2Hostname*`,`*dbNode3Hostname*
3. Save the `dbconnection.cfg` file.
4. Do one of the following steps:
   – Start the Data Aggregator service:
   `service dadaemon start`

   NOTE

   For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.
   – (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
   - **RHEL 6.x:**
     `service dadaemon activate`
   - **RHEL 7.x, SLES, or OL:**
     DA_Install_Directory`/scripts/dadaemon activate`

Migrate the Data Repository

To migrate the Data Repository, install Vertica on the new cluster and migrate the data. The following situations might require migration:

- You are moving to new hosts for a major OS upgrade (for example, RHEL 6.9 to RHEL 7.3).
- The current database hardware no longer meets sizing requirements.
- You are moving from virtual machines to physical hardware for the database.

NOTE

You must upgrade the existing system to the product version you are migrating to before migrating.

For more information about copying the database to another cluster, see the Vertica documentation.

NOTE

Depending on the amount of data, migrating the Data Repository can take a significant amount of time.

TIP

To minimize downtime, perform incremental backups after your initial backup.

Prepare to Install the Destination Data Repository

Before you install Vertica on the new cluster, prepare the environment for the installation. For more information about preparing the destination cluster, see Prepare to Install the Data Repository.

The target cluster must have the following things:

- The same number of nodes the source cluster
- A database with the same name as the source database

  NOTE

  The target database can be empty.
- The same node names as the source cluster

  NOTE

  The nodes names that are listed in the NODES system tables on both clusters must match. To change node names post install on the new system to match the existing one, contact Support.
- Be accessible from the source cluster
- The same database administrator account and all nodes must allow a database administrator of the source cluster to log in through SSH without a password

  NOTE

  Passwordless access within the cluster is not the same as passwordless access between clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.
- Adequate disk space for the `vbr --task copycluster` command to complete.

Install Vertica on the New Cluster

The installation process is the same as a normal Data Repository installation, for more information, see Install the Data Repository.

WARNING

Use the same configuration for the new cluster as for the source cluster. For example, the vertica version, node count, database name, administrator, user, catalog directory, and data directory must be the same as the original Data Repository.

Migrate the Cluster

After you install the database on the new cluster, migrate the existing data. The migration uses the copy cluster command, which simultaneously backs up the existing database and restores the data to the new cluster. The copy cluster is configured and started and run on the source system to point to the new system. You can run copy cluster on a single node on the source system and it copies over to all nodes on the new system. Copy cluster copies all data in the Data

Repository from before you run the command. Because DX NetOps Performance Management continues to collect data during the migration, the process requires multiple runs of the copy cluster command.

Create a Configuration File for Copy Cluster

Before you can configure the target cluster, you need to know the exact names that `admintools` supplied to all nodes in the source database.

To see the node names, run a query similar to following example:

```
 VMart=> select node_name from nodes;
node_name
------------------
v_vmart_node0001
v_vmart_node0002
v_vmart_node0003
(3 rows)
```

The copy cluster command requires a configuration file that includes the necessary information. You can create the file in any desired location on the source system and give it any name with a `.ini` extension. In the configuration file, specify the host names of nodes in the target cluster as the backup hosts. Specify the nodes in a `[Mapping]` section as shown in the following example. Specify the full node name, not the short name (for example, `v_vmart_node0001` , not `node0001`).

Example:

The following example configuration file is set up to copy a database on a three node cluster (`v_vmart_node0001` , `v_vmart_node0002` , and `v_vmart_node0003`) to another cluster consisting of nodes: test-host01, test-host02, and test-host03:

> **NOTE**
>
> The dbName parameter is case-sensitive.

```
 [Misc]
snapshotName = CopyVmart
restorePointLimit = 5
 objectRestoreMode = createOrReplace
tempDir = /tmp/vbr
retryCount = 5
retryDelay = 1

[Database]
dbName = vmart
dbUser = dradmin
dbPassword =  password
dbPromptForPassword = False

[Transmission]
encrypt = False
checksum = False
port_rsync = 50000
```

```
[Mapping]
; backupDir is not used for cluster copy
v_vmart_node0001= test-host01
v_vmart_node0002= test-host02
v_vmart_node0003= test-host03
```

NOTE

Ensure the `/tmp/vbr` directory has read and write permissions.

Stop the Target Database

Before you start the migration, shut down the database on the target cluster.

Follow these steps:

1. Log in to the target database cluster as the database admin user.
2. Open Vertica admin Tools:
   ```
   /opt/vertica/bin/adminTools
   ```
3. Select (4) Stop Database. Wait for the shutdown to complete before you run copy cluster.

Copy Historical Data

After you install the database on the new cluster, copy the data from the existing database. The copy cluster command copies all information from before you initiate the command. New data continues to come in while the command is running, but the command does not copy this data. The target cluster must be stopped before you invoke copy cluster.

Follow these steps:

1. Log in to the source cluster with the database administrator account.
2. Ensure passwordless SSH is enabled for the database administrator account. In a cluster installation, ensure that passwordless ssh keys are set up for *each* host that is participating in the cluster.
   ```
   ssh hostname ls
   ```
   hostname is the name of the host where Data Repository is installed.
   If the passwordless ssh key is set up, you are *not* prompted for a password. If youare prompted for a password, set up passwordless ssh:
   a. Press Ctrl+C.
   b. Set up the Linux user account for the database administrator user with a passwordless ssh key:
      ```
      ssh-keygen -N "" -t rsa -f ~/.ssh/id_rsa
      cp ~/.ssh/id_rsa.pub ~/.ssh/authorized_keys2
      chmod 644 ~/.ssh/authorized_keys2
      ```
   c. Copy the SSH credentials to the other hosts in the cluster:
      ```
      ssh-copy-id -i dradmin@other-hostname-in-the-cluster
      ```
   d. Confirm that you are *not* prompted for a password:
      ```
      ssh hostname ls
      ```
3. Run the copy cluster command:

```
vbr.py --task copycluster --config-file CopyClusterConfigurationFile.ini
```

The command copies the historical data for the database and displays the following message:

```
 > vbr.py --config-file CopyVmart.ini --task copycluster
Preparing...
Copying...
 1871652633 out of 1871652633, 100%
 All child processes terminated successfully.
 copycluster done!
```

NOTE

If the `copycluster` command fails, ensure passwordless SSH is enabled for the database administrator account.

Verify the Copy of the Historical Data

After the copy cluster process completes, ensure the integrity of your data.

Follow these steps:

1. Log in to the target database cluster as the database admin user.
2. Open Vertica adminTools:
   ```
   /opt/vertica/bin/adminTools
   ```
3. Start the database.
4. From any node in the cluster, open open the Vertica SQL prompt:
   ```
   /opt/vertica/bin/vsql -U dauser
   ```
5. Run the following queries to verify the timestamp of these key database tables:
   ```
    SELECT to_timestamp(max(tstamp)) from dauser.reach_rate;
   SELECT to_timestamp(max(tstamp)) from dauser.ifstats_rate;
   ```

   The date and time must correspond to the time when you started the copy.
6. Open adminTools, and stop the database.

Stop the Data Aggregator

To maintain integrity of your data, stop the Data Aggregator before the final copy of the Data Repository. Polling continues on Data Collector if it is running and polling when Data Aggregator is stopped. Data Collector queues polled data for future delivery to Data Aggregator.

Follow these steps:

1. Log in to the Data Aggregator host as the root user or a sudo user.

   NOTE
   If you installed Data Aggregator as the sudo user, you set up a sudo command alias for the service dadaemon command. Use the sudo commands.
2. Use firewall rules to block traffic from all the Data Collectors. Run the following command for each Data Collector:
   ```
   iptables -A INPUT -s DC_IP -j DROP
   ```

DC_IP specifies the IP of the Data Collector.

3. Do one of the following steps:
   – Stop the Data Aggregator service:
     ```
     service dadaemon stop
     ```

     NOTE

     For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.
   – (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**
       ```
       service dadaemon maintenance
       ```
     - **RHEL 7.x, SLES, or OL:**
       ```
       DA_Install_Directory/scripts/dadaemon maintenance
       ```

   The Data Aggregator stops.

Copy Recent Data

After you stop the Data Aggregator, run the copy cluster command again to copy recent data. The Data Repository copies only new data that arrive after the initial copy.

Follow these steps:

1. Log in to the source cluster with the database administrator account.
2. Run the copy cluster command:
   ```
   vbr.py --task copycluster --config-file CopyConfigurationFile.ini
   ```

   The command copies the recent data.

Verify the Copy of the Recent Data

To ensure the integrity of your data, verify the data.

Follow these steps:

1. Log in to the target database cluster as the database admin user.
2. Open Vertica admin Tools:
   ```
   /opt/vertica/bin/adminTools
   ```
3. Start the database.
4. From any node in the cluster, open the Vertica SQL prompt:
   ```
   /opt/vertica/bin/vsql -U dauser
   ```
5. Run the following queries to verify the timestamp of these key database tables:
   ```
   SELECT to_timestamp(max(tstamp)) from dauser.reach_rate;
   SELECT to_timestamp(max(tstamp)) from dauser.ifstats_rate;
   ```

   The date and time must correspond to the time when you started the copy.

Update the Database Connection Information

If you are not migrating the Data Aggregator, to enable communication between the Data Aggregator and the new Data Repository cluster, update the database connection information.

Follow these steps:

1. Log in to the Data Aggregator host.
2. Open the following file:
   ```
   vi /opt/IMDataAggregator/apache-karaf-version/etc/dbconnection.cfg
   ```
3. Update the following parameter with the hostnames of the new Data Repository cluster:
   ```
   dbHostNames=hostname1,hostname2,hostname3
   ```

Restart Data Aggregator

After the migration is complete, restart the Data Aggregator.

Follow these steps:

1. Log in to the Data Aggregator host as the root user or a sudo user.

   NOTE
   If you installed Data Aggregator as the sudo user, you set up a sudo command alias for the service dadaemon command. Use the sudo commands.
2. Do one of the following steps:
   - Start the Data Aggregator service:
     ```
     service dadaemon start
     ```
   - (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
     - **RHEL 6.x:**
       ```
       service dadaemon activate
       ```
     - **RHEL 7.x, SLES, or OL:**
       ```
       DA_Install_Directory/scripts/dadaemon activate
       ```

   Data Aggregator starts and synchronizes with CA NetOps Portal and the Data Repository. When the iptables entries are removed, any queued, polled data on the Data Collectors is sent to the Data Aggregator. The oldest data is discarded if the queued data exceeds a disk space limit that is configured on the Data Collector system. As a result, there is a gap in the polled reporting data.
3. Monitor the Data Aggregator restart process:
   a. Log in to the Data Aggregator host and navigate to the following directory:
      ```
      /opt/IMDataAggregator/performance-spool
      ```
   b. Wait for few minutes after starting the Data Aggregator service. Verify that no DTO files exist with a size greater than zero.
   c. Enable traffic from the SNMP Data Collector with largest number of polled items:
      ```
      iptables -D INPUT -s DC_IP -j DROP
      ```

      Data Aggregator starts schema validation and processing of cached and new polled data from this Data Collector.

d. After the Data Aggregator system utilization decreases, enable traffic from the remaining SNMP Data Collectors.
e. After the Data Aggregator system utilization decreases, enable traffic from the CAMM Data Collectors.

Verify the Migration

After the Data Aggregator startup is complete, log in to NetOps Portal, and verify the following indicators:

- The system status is good and the Data Aggregator data source is available.
- Verify the Last Polled on data and time.
- Navigate to the Data Collector List and verify that all Data Collectors are up and collecting data.
- Open the Infrastructure Overview dashboard, and verify that data is available for the following time ranges:
  - Last hour
  - Last 7 days

Data Repository Heartbeat Monitor Process

The heartbeat monitor process checks whether Data Repository is running every 10 seconds. If the heartbeat process fails to confirm that the database is running after 5 minutes, Data Aggregator shuts down. An audit message is logged in the *DA_installation_directory*/apache-karaf-<*vers*>/shutdown.log file.

In a cluster environment, all nodes in the cluster are continuously checked for availability every 10 seconds. If a node cannot be contacted within 5 minutes, DX NetOps Performance Management generates and logs an event. An audit message is logged in the *DA_installation_directory*/apache-karaf-<*vers*>/shutdown.log file.

If the Data Repository node that failed is the primary node, Data Aggregator automatically switches to the next available node. DX NetOps Performance Management generates and logs an event.

> **WARNING**
> Certain administrative functions that are occurring during a high availability failover are interrupted and then fail. One poll cycle is lost. These functions will not resume after Data Repository connects to another node in the cluster environment. Administrative functions that you perform after Data Repository connects to another node in the cluster environment work as designed.

If more than one Data Repository node fails, the Data Aggregator shuts down.

Data Aggregator shuts down automatically if it fails to connect to Data Repository on start-up.

Data Repository Audit Process

The license agreement states that the total data stored in Data Repository cannot exceed 64 TB. The audit process audits the database daily at 3:00 AM to calculate the total space that Data Aggregator data occupies.

To view the most recent result of an audit, access the following URL in your browser:
`http://da_host:8581/rest/datarepositorymaintenance/audit`

This URL returns XML. The "Current Size" tag displays the current size of Data Repository in bytes.

> **WARNING**
> Review the audit results periodically. If you see a value greater than 64 TB, you are not in compliance with the license agreement. Contact CA Technical Support for further instructions.

Run Data Repository Diagnostic Utilities

Vertica provides a set of utilities that test the performance of your hardware for the Data Repository. To verify that the environment is ideal for the database, run these tests before you upgrade the Data Repository.

NOTE

If you have already installed the Data Repository, you can perform these tests at any time to verify performance. The utilities are available on each node in `/opt/vertica/bin` .

If the tests do not meet the recommendations, fix the issues before you continue the upgrade.

vcpuperf

This utility measures the CPU processing speed of the host and compares the speed against benchmarks for common server CPUs. The utility measures how long the server requires to complete the test, and determines whether CPU throttling is enabled.

Follow these steps:

1. Execute the following command on *each* Data Repository node:

```
./vcpuperf > /tmp/vcpuperf.out
```

2. Verify that the performance meets the following requirements:
   - The CPU time is consistent with the benchmark values in the output.
   - The low load time and high load time are within 10 microseconds. If the difference is grater than 50 microseconds, CPU throttling might be enabled on your system. Disable CPU throttling.

Example:

The following example shows the return from this utility:

```
$ /opt/vertica/bin/vcpuperf

Compiled with: 4.1.2 20080704 (Red Hat 4.1.2-52)

Expected time on Core 2, 2.53GHz: ~9.5s

Expected time on Nehalem, 2.67GHz: ~9.0s

Expected time on Xeon 5670, 2.93GHz: ~8.0s

This machine's time:

CPU Time: 7.740000s

Real Time:7.740000s
```

```
Some machines automatically throttle the CPU to save power.

This test can be done in <100 microseconds (60-70 on Xeon 5670, 2.93GHz).

Low load times much larger than 100-200us or much larger than the corresponding high
 load time

indicate low-load throttling, which can adversely affect small query / concurrent
 performance.

This machine's high load time: 67 microseconds.

This machine's low load time: 64 microseconds.
```

This test was performed on a system with 2.67-GHz processors, so the real time is acceptable. The difference between the high load time and low load time is within the expected tolerance.

For more information about this utility, see the Vertica documentation.

vioperf

This utility tests the performance of the disk input and output (I/O). The utility performs a series of reads and writes.

> **NOTE**
>
> To measure the read/write speeds when using the same SAN/NAS for the disk or VM disk, you must run vioperf on all nodes of the cluster at the same time for the data or catalog directory.

Follow these steps:

1. Execute the following commands on *each* Data Repository node:

   ```
   ./vioperf /data > /tmp/vioperf.out --duration=60sec
   ```

   /data is the full path of the data directory.

   ```
   ./vioperf /catalog > /tmp/vioperf.out --duration=60sec
   ```

   /catalog is the full path of the catalog directory.
2. Verify the Write and Read counter values at least 40 MB/s per core.
   The recommended I/O is 40 MB/s per physical core on each node. For example, the recommended I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 480 MB/s.

   > **WARNING**
   >
   > If the **thread count** column shows a value of 1, the utility cannot determine the number of cores. Add the following arguement to the command to run the utility:

`--thread-count=`*`CORES`*

Cores defines the number of cores in the system as a fixed integer.

Example:

The following example shows the return from this utility for the data directory:

```
The minimum required I/O is 20 MB/s read and write per physical processor core on each
 node, in full duplex i.e. reading and writing at this rate simultaneously, concurrently
 on all nodes of the cluster. The recommended I/O is 40 MB/s per physical core on each
 node. For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs
 is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/drdata"

test      | directory                                    | counter name        |
 counter value       | counter value (10 sec avg)      | counter value/core  | counter
 value/core (10 sec avg) | thread count  | %CPU  | %IO Wait  | elapsed time (s)|
 remaining time (s)

-------------------------------------------------------------------------------------------------

Write     | /drdata                                      | MB/s
  | 873                | 873                            | 54.5625            |
 54.5625                         | 16            | 29    | 40        | 10              |

 0
```

This server has 16 cores. The Read and Write counter values indicate the I/O is greater than 40 MB/s per core.

For more information about this utility, see the Vertica documentation.

vnetperf

This utility tests the network performance of the Data Repository hosts. The utility measures network latency and the throughput for the TCP and UDP protocols.

> **WARNING**
>
> This utility causes a high network load and affects database performance. Do not run this utility while the database is running.

Follow these steps:

1. Log in as a user that has passwordless ssh between the nodes.
2. Execute the following command on *one* of the Data Repository nodes:

   ```
   ./vnetperf --hosts DAhost,DRhost1,DRhost2,DRhost3 > /tmp/vnetperf.out
   ```

   Specify the hostname or IP address of the Data Aggregator host and each Data Repository host.
3. Verify that the network performance meets the following requirements:

- Round-trip time (RTT) latency of 200 microseconds or less
- Clock skew under 1 second
- Throughput of 800 MB/s or more
  The utility runs a series of throttled tests. Verify the throughput for the highest speed test.

For more information about this utility, see the Vertica documentation.

Segment Database Tables

If you received a table segmentation warning during the Data Aggregator upgrade, segment the database tables on the Data Repository. Table segmentation is a one-time task that is required for systems where the original installation was a release earlier than 2.3.3. Segmenting the tables reduces the amount of disk space that is required for the database. Segmenting the tables also improves general query performance.

TIP

If you are unsure whether your database requires segmentation, download the script and attempt to identify tables that require segmentation. If segmentation is already complete or not required, the script does not return any tables.

You can segment the database tables when the Data Aggregator and the Data Collectors are up or down.

WARNING

Segmentation is a resource-intensive process. We *strongly* recommend that you segment the database tables when the Data Aggregator and the Data Collectors are down.

Segmentation can take several hours to segment large tables in the database. During tests, migration of tables larger than 100 GB took over 10 hours. The segmentation time is not uniform to table size. Time depends on many factors including row count, column count, compression of the data, and system specifications.

No active monitoring of your infrastructure environment occurs when the Data Aggregator and Data Collectors are down.

If you segment the database tables while the Data Aggregator is up, the following restrictions apply:

- Do not perform any Data Aggregator administrative functions:
  - Modifying monitoring profiles
  - Associating collections to monitoring profiles
  - Increasing poll rates
  - Running new discoveries
- Minimize the report load.

Use the following process to segment the database tables:

Identify Tables That Require Segmentation

Before you start table segmentation, identify the tables that require segmentation.

Follow these steps:

1. Download the segment.py script from CA Support:
   - https://https://support.broadcom.com/enterprise-software
   - https://casupport.broadcom.com/phpdocs/7/8568/segment.py
   This procedure assumes that the segment.py script is in the home directory of the Vertica Linux database administrator user.
2. Log in to any host in the Data Repository cluster as the Vertica Linux database administrator user.
3. Run the script:

```
./segment.py --task tables --pass database_admin_user_password  [--
name database_name] [--port database_port]
```

- **database_admin_user_password**
  The Vertica Linux database administrator user password
- **database_name**
  The name of the database
  Defulat: drdata

  NOTE

  This parameter is case-sensitive.
- **database_port**
  The Vertica port
  Default: 5433

For example:

```
./segment.py --task tables --pass password --name mydatabase
```

Any currently unsegmented table projections, which are sorted from largest to smallest, are returned. If any tables require segmentation, continue this process.

Back up the Data Repository

Before you segment the tables, back up the Data Repository.

WARNING

After segmentation, the disk space for the backup increases by the amount of data in the new segmented table projections. Verify that the backup system has enough disk space available after segmentation is completed and before backups run.

The data for the old unsegmented table projections is removed from the backup data one day after the time of the restorePointLimit. To remove this data immediately, change the snapshot name in the backup configuration file, and do a full backup. You can then archive the older backup, and delete the backup from the backup disk. Use the presegmentation backup only if you cannot use the backup that was created after segmentation completed. If you use the presegmentation backup, the tables will require segmentation again.

For information, see Back Up the Data Repository.

Segment Tables with No Data

Tables with no date are segmented quickly and segmentation does not negatively affect performance. You can segment these tables without stopping the Data Aggregator.

Follow these steps:

1. Log in to any host in the Data Repository cluster as the Vertica Linux database administrator user.
2. Run the script:

```
./segment.py --task segment --zerotables --pass database_admin_user_password [--
name database_name] [--port database_port]
```

- **database_admin_user_password**
  The Vertica Linux database administrator user password
- **database_name**
  The name of the database

Default: drdata

NOTE

This parameter is case-sensitive.

– **database_port**
The Vertica port
Default: 5433

The script segments the database tables with no data.

Determine the Table Segmentation Time

To determine whether to segment the tables while the Data Aggregator is up or down, calculate the necessary time for segmentation.

Follow these steps:

1. Get a list of the tables that require segmentation:
```
./segment.py --task tables --pass database_admin_user_password [--
name database_name] [--port database_port]
```

NOTE

The `database_name` parameter is case-sensitive.

The list sorts the tables from largest to smallest.
2. Disable scheduled Data Repository backups until segmentation is complete. Backups can interfere with the segmentation process.
3. Select a table from step 1 that is about 5 GB in size, and segment that table:
```
./segment.py --task segment --table rate_table_name --
pass database_admin_user_password [--name database_name] [--port database_port]
```

NOTE

The `database_name` parameter is case-sensitive.

NOTE
You can run this command when Data Aggregator is running, but we recommend that you run the command during a 2-3 hour maintenance window.
4. Reenable the scheduled Data Repository backups.
5. Use the segmentation time for the 5-GB table to determine how long segmentation might take to segment all of the tables that are less than 100 GB.

NOTE
The actual time segmentation time for the database tables can vary based on the type and compression of the data in the tables. The values that are calculated here are rough estimates. When planning a scheduled maintenance window, add an extra hour of time for every 10 GB to 15 GB of database tables. For large databases, you might not be able to schedule a single maintenance window that is long enough to segment the entire database. In this case, you can segment the database tables over multiple maintenance windows.

Segment the Remaining Database Tables

Segment the remaining tables.

WARNING
When segmenting the tables in the database, if Data Aggregator is running, at least 40 percent of the available disk space must remain free for query processing and other database activities. When the Data Aggregator is not running, the total disk utilization during segmentation must not exceed 90 percent of available disk space. Tables that would cause the disk utilization to exceed these limits during segmentation are not segmented.

Follow these steps:

1. As the Vertica Linux database administrator user, log in to one of the computers in the cluster where Data Repository is installed.
2. During the table projection segmentation validation in the previous procedure, if more than ten zero-length table projections were seen during this verification, type the following command to segment them:
   ```
   ./segment.py --task segment --pass database_admin_user_password --zerotables [--name database_name] [--port database_port]
   ```
   - **database_admin_user_password**
     The Vertica Linux database administrator user password
   - **database_name**
     The name of the database
     Default: drdata

     NOTE

     This parameter is case-sensitive.
   - **database_port**
     The Vertica port
     Default: 5433

   For example:
   ```
   ./segment.py --task segment --pass password --zerotables --name mydatabase --port 1122
   ```
3. If there are table projections that are greater than 100 GB in size, type the following command to create a script to segment the table projections that are *less than* 100 GB first:
   ```
   ./segment.py --task script --pass database_admin_user_password --lt100G [--name database_name] [--port database_port]
   ```
   - **database_admin_user_password**
     The Vertica Linux database administrator user password
   - **database_name**
     The name of the database
     Default: drdata

     NOTE

     This parameter is case-sensitive.
   - **database_port**
     The Vertica port
     Default: 5433

   For example:
   ```
   ./segment.py --task script --pass password --lt100G --name mydatabase --port 1122
   ```
4. Disable scheduled backups until segmentation is complete. Backups can interfere with the segmentation process.
5. To execute the segment-script.sh script, type the following command:

```
nohup ./segment-script.sh
```

The script segments all unsegmented table projections that are less than 100 GB and sorts them from smallest to largest. The output is sent to nohup.out. If the shell is closed accidentally, the script continues to run.
Depending on your maintenance window size and the combined size of all of the tables under 100 GB, determine which tables can be segmented in the maintenance window. Modify the generated script by removing the tables that do not fit inside the maintenance window. Run the generated segment-script.sh during the maintenance window. If all of the tables under 100 GB could not be segmented in the maintenance window, regenerate the script, and run the segment-script.sh during the next maintenance window until all of the tables have been segmented.

WARNING

When you run the script, any tables that cause disk utilization to exceed 90 percent displays an error message. These tables are not segmented. To segment these tables, more available disk space is needed. You are prompted for each table that can cause disk utilization to exceed 60 percent. We strongly recommend that Data Aggregator be brought down before segmenting these tables.

This script can take several hours to execute. Do not interrupt the script execution once it begins to avoid corruption of the database.

6. Reenable scheduled backups only if more segmentation is needed and will be done in a future maintenance window.
7. Generate a script, segment-script.sh, that segments remaining table projections that are over 100 GB:

```
./segment.py --task script --pass database_admin_user_password [--name
database_name] [--port database_port]
```

   - **database_admin_user_password**
     The Vertica Linux database administrator user password
   - **database_name**
     The name of the database
     Default: drdata

     NOTE

     This parameter is case-sensitive.
   - **database_port**
     The Vertica port
     Default: 5433

   For example:

```
./segment.py --task script --pass password --name mydatabase --port 1122
```

   WARNING
   When the script is generated, any tables that might cause disk utilization to exceed 60 percent and 90 percent are indicated.
8. Disable scheduled backups, if they are not already disabled.
9. To execute the segment-script.sh script, type the following command:

```
nohup ./segment-script.sh
```

   The script segments all unsegmented tables and sorts them from smallest to largest.
10. Verify that all tables are now segmented:

```
./segment.py --task tables --pass database_admin_user_password [--
name database_name] [--port database_port]
```

NOTE

The `database_name` parameter is case-sensitive.

The following message appears:

```
No tables found with unsegmented projections.
```

11. Reenable scheduled backups.
12. If you segmented the database tables when Data Aggregator and Data Collector were down, start these components.

Move the Data Repository Data Directory

If necessary, you can move the Data Repository data directory from an existing location to another location on the same Vertica cluster.

This process involves the following steps:

1. Create the new location.
2. Move the data.
3. Drop the old location.

For more information, see the Vertica documentation.

You might need to move the Data Repository data directory for the following reasons:

- You want to add new storage to an existing server.
- You want to move the database from an old mount point to a new mount point because of an updated server build template.

The following process causes some downtime for DX NetOps Performance Management while the move occurs.

The following factors impact the total amount of downtime:

- Size of the database
- Storage input and output speed

The following process covers only moving the Data Repository data directory. For information about moving the Data Repository database from one server to another, see Disaster Recovery.

Example:

- You are moving the data directory for a three-node cluster:
  - node0001
  - node0002
  - node0003
- The current data directory is: `/spare/dbdata/data`
- The new data directory is: `/opt/application/CA/drdata`
- The Vertica database name is `drdata` .
- The `dbadmin` user for Veritca is `dradmin` .
- The following end goals apply to this scenario:

```
 /spare/dbdata/data/drdata/v_drdata_node0001_data >> /opt/application/CA/drdata/
drdata/v_drdata_node0001_data
 /spare/dbdata/data/drdata/v_drdata_node0002_data >> /opt/application/CA/drdata/
drdata/v_drdata_node0002_data
```

```
 /spare/dbdata/data/drdata/v_drdata_node0003_data >> /opt/application/CA/drdata/
drdata/v_drdata_node0003_data
```

Follow these steps:

1. On each node, create the new data directory:
   ```
   mkdir -p /new_data_directory/dbname/v_dbname_node000x_data
   ```
   - ***new_data_directory***
     Specify the new data directory.
   - ***dbname***
     Specify the name of the database.
   - ***x***
     Specify the existing node number.
2. Grant permissions to the new data directory:
   ```
   chown -R dradmin:verticadba /new_data_directory/dbname
   ```
3. For each parent in the path to /*new_data_directory*/dbname, grant permissions:
   ```
   chown dradmin:verticadba /parent
   ```
4. As `dradmin` , create the new storage location for each node in Vertica:
   ```
   create location '/new_data_directory/dbname/v_dbname_node000x_data' NODE
   'v_dbname_node000x' USAGE 'DATA,TEMP' LABEL 'TO_DATA_TEMP';
   ```
   - ***TO_DATA_TEMP***
     Specify a label for the new storage location. This label is required when you set the object policy.
5. Confirm the new storage locations:
   ```
    select * from storage_locations;
   ```
6. Set the object policy:
   ```
   select set_object_storage_policy('schema_name', 'TO_DATA_TEMP', true );
   ```
   - ***schema_name***
     Specify the name for the schema.
     Example: `dauser`
     To view a lists of the available schemas, run the following command:
     ```
     dradmin=> \dn
     ```
   - ***TO_DATA_TEMP***
     Specify the same label used when you created the new storage location.
7. Trigger the object to move:
   ```
   select enforce_object_storage_policy('schema_name');
   ```
8. Confirm that the policy is applied:
   ```
   select * from storage_policies;
   ```
9. Retire the old storage locations for each node:

```
select retire_location('/existing_data_directory/dbname/v_dbname_node000x_data',
'v_dbname_node000x', true);
```

- ***existing_data_directory***
  Specify the existing data location.

10. Confirm that the old storage locations are retired:
```
select is_retired, location_path from storage_locations;
```

11. Drop the old storage location for each node:
```
select drop_location('/existing_data_directory/dbname/v_dbname_node000x_data',
'v_dbname_node000x');
```

12. Clear the storage policy:
```
select clear_object_storage_policy( 'schema_name' );
```

13. Remove the label from the new storage location for each node:
```
select alter_location_label('/new_data_directory/dbname/v_dbname_node000x_data',
'v_dbname_node000x', '');
```

Flow Administration

You can configure flow monitoring from Network Flow Analysis in the NetOps Portal user interface. Configure the overall Application settings and the Watchdog settings. Watchdog Services let you monitor Network Flow Analysis components. The Watchdog Services poll each server in your Network Flow Analysis configuration once every two hours to determine the status of all components. You can establish thresholds, an email address for receiving messages, and other settings for the Watchdog Services to ensure that you are notified of issues with the components as soon as possible. You can also view, add, delete, and edit details about the Harvesters that supply flows to DX NetOps.

> **NOTE**
> Any Application settings or Watchdog settings left blank default to the values fetched from Network Flow Analysis.

You can also enable and disable network flow processing for your Network Flow Analysis interfaces. You can also delete interfaces. For more information, see Manage Network Flow Processing.

Configure Application Settings

You can configure a wide range of settings on the **Application Settings** pane.

Follow these steps:

1. Hover over **Administration**, and click **Data Sources: the Network Flow Analysis datasource**.
   The page for the data source opens.
2. Select **Application Settings** from the menu on the left side of the page.
   The **Application Settings** pane opens.
3. (*Optional*) Change any of the following settings as needed, then click **Save**.
   - **Interface Data Absence Limit**
     Specifies how long the program waits for an update before it flags an interface as missing.
     Default: 4 Hours
   - **TCP Rebase Port**

Specifies the target port for TCP traffic that is redirected by an application mapping rule. TCP traffic that you do not want to go to a target port goes to the TCP Rebase Port instead. Other settings that affect application mapping behavior are **UDP Rebase Port**, **ToS Mask**, and **Preserve ToS Map Proto**.
Default: 9000

- **ToS Mask**
  Specifies the number of bits that application mapping rules use for matching ToS values. The default value of 255 sets the program to look for matches throughout all ToS values. Other settings that affect application mapping behavior are **TCP Rebase Port**, **UDP Rebase Port**, and **Preserve ToS Map Proto**.
  Default: 255
- **UDP Rebase Port**
  Specifies the target port for UDP traffic that is redirected by an application mapping rule. UDP traffic that you do not want to go to a target port goes to the UDP Rebase Port instead. Other settings that affect application mapping behavior are **TCP Rebase Port**, **ToS Mask**, and **Preserve ToS Map Proto**.
  Default: 8000
- **Auto-Enable Interfaces**
  Specifies whether newly discovered interfaces are enabled automatically (True) or are disabled (False). If you want to control which interfaces are reported and consume licenses, set the value to False. This setting affects the **Enabled** status for new interfaces. Interfaces that have already been discovered are not affected by changes to this setting.
  Default: True
- **Default Time Zone**
  Specifies the time zone used for custom reports and analysis.
  Default: GMT
- **DNS Domains**
  Removes the specified suffixes from host names in NFA console views and reports. If you include `.my_company.com` , for example, this suffix is not shown in the host names that appear in any views or reports. To specify multiple entries, separate the entries with commas and without intervening spaces.
  Default: <no default>
- **Show Trendline Zeroes**
  Specifies whether trendlines drop to zero when there are gaps in data.
  Default: False
- **From Address**
  Specifies the email address of the Administrator, which is used as the **From** value when reports are emailed. If this setting is not configured properly, users cannot send scheduled or on-the-fly reports. These functions also require a properly configured **SMTP Server** value.
  Default: <no default>
- **SMTP Server**
  Specifies the IP address of the SMTP mail server that is used for emailing reports. If this setting is not configured properly, users cannot send scheduled or on-the-fly reports. These functions also require a properly configured **From Address** value.
  Default: <no default>
- **Licensed Devices**
  Records the total number of licenses that you purchased. This value is used to calculate the percentage of licenses in use. The **License Utilization** percentage is accurate only if the **Licensed Devices** value is accurate.
  Default: 50
- **Preserve ToS Map Proto**
  Specifies whether protocol traffic for ToS-based application-mapped data is combined (N) or is shown as separate data streams that are labeled with the original protocol designators (Y).
  For example, suppose the value is Y and you map TCP, UDP, and some other IP protocol traffic to one port. To continue the example, suppose you drill in to a link in the **Enterprise Overview** view in the NFA console for a host that has the mapped data. In this case, the **Stacked Protocol Trend** and **Protocol Trend** views show and label the protocol traffic separately, whether the protocol traffic is for TCP, UDP, or some other IP protocol.

- **Stacked Protocol Trend** and **Protocol Trend** views show protocol traffic that meets the following conditions: (1) The traffic passes the minimum threshold and (2) The protocol volume is high enough to place it in the Top N group.

If the **Preserve ToS Map Proto** value is N and the **Stacked Protocol Trend** views show related protocol traffic, all of the protocols for the mapped traffic are combined in a single traffic stream that has a TCP label.
Other settings that affect application mapping are **TCP Rebase Port**, **UDP Rebase Port**, and **ToS Mask**.
Default: Y

– **Pump Broadcast/Multicast**
Specifies whether interface views and reports include (True) or hide (False) broadcast/multicast traffic.
Default: True

– **Reporter IP**
Specifies the IP address of the NFA console.
Default:
- Stand-alone deployment: Loopback IP address of the stand-alone server
- Distributed 2-tier deployment: Loopback IP address of the NFA console

– **Report Service Polling Delay**
Specifies the number of seconds between checks to see if reports have finished running.
Default: 15

– **Router Domains**
Removes the specified suffixes from the flow router names. To specify multiple entries, separate the entries with commas and without intervening spaces.
Default: <no default>

– **Show Aggregations**
Specifies whether to include interface aggregations in the **Enterprise Overview**. If the value is True, interface aggregations are included in the views. To be included in the **Enterprise Overview**, the aggregations must have enough traffic to pass the minimum thresholds and to rank in the Top N group.
Default: False

– **Show Device Name**
Specifies whether the interface name format starts with the device name (True) or omits it (False).
Default: True

– **Display Notes Field**
Displays (True) or hides (False) the **Notes** icon for interfaces. If the **Notes** icon is visible, you can click it to add, edit, or view additional information about an interface.
Default: False

– **Trap Destination**
IP address or DNS name of the target server for sending the traps that are shown as events in the NetOps Portal. Traps can be displayed as events only when this setting is configured correctly. Set the **Trap Destination** value to match the IP address of one of the NFA console or stand-alone server that is registered as a data source for NetOps Portal
Default: IP address of the NFA console (distributed deployment) or stand-alone server (stand-alone deployment)

– **Traps Use Unique Domains**
Specifies whether all traps on a single domain system use the single domain.
Default: False

Edit Watchdog Service Settings

Edit the Watchdog settings to change configuration values such as thresholds, trap settings, polling settings, notification address, and community strings.

Follow these steps:

1. Display the **Watchdog Settings** pane:
   a. Hover over **Administration**, and click **Data Sources: the Network Flow Analysis datasource**.
      The page for the data source opens.
   b. Select **Watchdog Settings** from the menu on the left side of the page.
      The **Watchdog Settings** pane opens and displays the current settings.
2. Edit the **Watchdog Service** settings:
   - **Memory Threshold**
     Threshold for memory utilization. You are notified by email when the memory threshold on a server is exceeded, provided that the address and string are set.
     Default: 80 percent memory utilization
   - **SNMP Retries**
     Number of times the program attempts to poll an SNMP device. A high number of SNMP Retries can affect performance, depending on your network configuration.
     Default: 2
   - **Community String**
     SNMP string that the Watchdog Services use to verify the identity of components in a distributed deployment. The community string is used for gathering information from Harvesters. Use the same community name throughout the Network Flow Analysis deployment:
     - **Watchdog Settings** pane
     - SNMP service on each Windows server
     - `snmpd.conf` file on each Linux server

     Default: public
   - **Disk Threshold**
     Threshold for disk utilization. If the disk threshold on a server is exceeded, you are notified by email and an SNMP trap notification is generated, provided that the address and string are set.
     Default: 80 percent disk utilization
   - **SNMP Timeout**
     Number of seconds before an SNMP poll times out.
     Default: 5
   - **CPU Threshold**
     Threshold for CPU utilization. You are notified by email when the CPU threshold on a server is exceeded on any server and an SNMP trap notification is generated, provided that the address and string are set.
     Default: 80 percent CPU utilization
   - **Email Address**
     Destination email address to use for email notifications when thresholds are exceeded. To notify multiple recipients, separate the addresses with commas. The **Email Address** setting has no default value.
     Default: (none)
   - **Trap Community String**
     SNMP string to use for sending traps to a third-party trap receiver. Use one of the community names that the trap receiver is configured to accept.
     Default: public
   - **System Check Interval**
     Number of minutes between Watchdog system checks.
     Default: 60
   - **Trap Destination**
     IP address of the server that receives SNMP traps from the Watchdog Services. The traps are generated when thresholds for DX NetOps component performance are violated.
     Default: (none)
3. Click **Save** when you finish editing the settings.

Add a Harvester

Make sure the Harvesters you add have not been deleted from the **Harvester** pane previously. To add a Harvester instance successfully in DX NetOps after deleting it, the Harvester installation server must be re-imaged and the Harvester software must be re-installed.

Follow these steps:

1. Display the **Harvester** pane:
   a. Hover over **Administration**, and click **Data Sources: the Network Flow Analysis datasource**.
      The page for the data source opens.
   b. Select **Harvester** from the menu on the left side of the page.
      The **Harvester** pane opens and displays the current settings.
2. Click **Add**.
   The **Add Harvester** dialog opens.
3. Enter the following information:
   – **IP Address**
     Address of the Harvester server.
   – **Description**
     Identifying text about the Harvester, which appears in the **Harvester** page table.
   – **Domain**
     Parent tenant and domain combination for the Harvester and for any routers and interfaces that begin to supply data to the Harvester.
     Changing this setting affects the tenant-domain association for new routers that begin exporting flow data and any new interfaces that begin generating flow.
     In a multi-tenant environment, the Harvester tenant affects which SNMP profiles are available for routers to poll interfaces.
     The domain affects which operators and reports have access to the data from routers and interfaces.
     This option is visible only in an environment that contains multiple domains.
4. Click **Save**.
   The new Harvester is added and appears in the Harvester list.
   The usual process is to add one or more Harvesters, then configure the router interfaces to export flow to the Harvesters. If you configure the routers to export flow to the Harvesters first, the DX NetOps console immediately begins to collect data from the new Harvester. In this case, the domain for the routers is set at the time you add the parent Harvester.

   NOTE
   To validate the IP Address, the system checks the reachability of the Harvester on the IP. This process can take up to a minute when the IP is not a valid Harvester IP.

Edit the Details for Harvesters on the Harvester Page

You can edit the IP address, description, and tenant-domain setting.

NOTE
You can edit the IP address with Network Flow Analysis 10.0.4 and higher only.

Follow these steps:

1. Click **Edit** on the Harvester row that you want to edit.
   The **Edit Harvester** dialog opens.
2. Change any of the following settings:
   – **IP Address** (Network Flow Analysis 10.0.4 and higher only)
     Address of the Harvester server.
   – **Description**

(*Optional*) Additional information to help identify the Harvester

- **Domain**
  The tenant-domain association of the Harvester in a multi-domain deployment.
  Changing this setting affects the tenant-domain for any new routers that begin exporting flow data. Existing routers and interfaces retain their previous tenant-domain associations.
  The domain affects which operators and reports have access to the data from routers and interfaces.
  Default: Default Tenant\Default Domain

3. Click **Save**.
   Your changes are saved immediately and appear in the **Harvester** table.

   NOTE
   To validate the IP Address, the system checks the reachability of the Harvester on the IP. This process can take up to a minute when the IP is not a valid Harvester IP.

Delete a Harvester

Once you delete a Harvester, you cannot recover any of the data that the Harvester collected previously.

Follow these steps:

1. Click **Delete** in the row for the Harvester that you want to delete.
   A confirmation message opens.
2. Click **Yes** to confirm that you want to delete the Harvester.
   The Harvester is deleted and is not listed in the **Harvester** table. The NFA console no longer collects data from the routers that are associated with the deleted Harvester. The data that was collected from those routers previously is not available in reports.

Bulk Data Export

As a systems administrator or architect, you want to export polled rate data from Data Aggregator as a continuous CSV export to your own reporting tool for analysis and custom reporting purposes.

IMPORTANT
The bulk data export feature is unsupported in environments with fault tolerant Data Aggregators.

TIP

To export specific data, or to run a one-time export, the OpenAPI is a more flexible. For more information, see OpenAPI.

Data Aggregator provides data export capabilities that are done at the frequency of polling rate. When you start data export, all poll responses are written to CSV files. You can configure inclusive lists for metric families so that you only export the data you need.

The CSV files contain rate data and internal names, which are mapped to readable display names. If exported metric families include suppressed metrics, the CSV shows a null value for those metrics.

The size of CSV output files that are generated can come close to or can exceed the following limits:

Environment	Limit per hour (uncompressed)
Large scale	50 GB
Medium scale	25 GB
Small scale	5 GB

TIP

To avoid exhausting the available disk space, regularly process the output CSV files. For example, copy the files to another system and remove the files from the Data Aggregator host.

For performance reasons, create a separate disk partition on the Data Aggregator system. Select this partition for the output of the CSV rate data.

To export data, follow this process:

Configure the Export File Output Options

Configure the output file options using the **streamexport.csvoutwriter.cfg** file. This configuration file is copied to the directory during the Data Aggregator installation.

Example of the path:

```
/opt/IMDataAggregator/apache-karaf-2.4.3/etc
```

Follow these steps:

1. Change the directory to /opt/IMDataAggregator/apache-karaf-2.4.3/etc.
2. Edit the **streamexport.csvoutwriter.cfg** file as needed:
   - **output.filenameExtension**
     Specifies the extension or suffix of the CSV files.
   - **output.csvFileDelimiter**
     Specifies the column delimiter that is used in the output CSV file. For example, if the bundle is started and this parameter is changed, a new file is written immediately using this new column delimiter.
   - **output.filenameLocationPath**
     Specifies the file path and the prefix of the output file name. (The output file also consists of the date and time.)

     WARNING
     This file path must be on a different partition than the Data Aggregator installation. If DX NetOps Performance Management was installed with a sudo user, change the ownership of the directory to enable access to the sudo user.

     The syntax of the complete file name is:

     ```
     output.filenameLocationPath=<DC_host>_yyyy-MM-dd-
     Thh-mm-sec-ms.output.filenameextension
     ```

     Example:
     The file is written on April 2, 2013 at 8:42:04 a.m. and 123 ms. The Data Collector hostname is server.abc.com, and the following parameters are configured:

     ```
     output.filenameLocationPath=/opt/export_data/mydata
     output.filenameExtension=.csv
     ```

     The file name is:

     ```
     mydata_server.abc.com_2013-04-02T08-42-04-123.csv
     ```

     You can configure files with an absolute name, such as /myOutputDir/mydata. If the parent folders in the absolute path do not exist, the folders are created.
   - **output.filesize**
     Specifies the file size in bytes using a valid integer greater than 0. If the file size is exceeded, a new output file gets written.
     If the value is -1, this parameter is ignored and *all* the data is written into a single file (infinite).
   - **output.duration**
     Specifies the number of minutes using a valid integer greater than 1. If a file is older than *x* minutes, then a new file is written.

If the value is 1, then this parameter is ignored. If the value is -1, then *all* the data is written into a single file (infinite).

The output.filesize and output.duration parameters affect each other. If the output.filesize is exceeded *or* the file is older than output.duration, then a new file is written.

Example: streamexport.csvoutwriter.cfg

```
output.filesize=100000000
output.filenameLocationPath=/opt/data_export/ratedata_
feature.enabled=on
output.duration=60
output.csvFileDelimiter=,
output.filenameExtension=.csv
```

3. Save your changes.

Configure an Inclusive List of Metric Families

You can specify the metric families whose data you do want to export by configuring an inclusive list (whitelist). Data is collected only for the listed metric families. This configuration is optional.

Two files pertain to scoping by metric family:

- **streamexport.allMetricFamilies.out**
  This file is auto-generated at the start-up of the Data Aggregator system. The file includes all the available metric families.
  This file is periodically updated to include new metric families that are added to the system.
  Location: $KARAF_HOME/etc folder
  This file has the following format:

  ```
  metricFamilyInternalName=metricFamilyDisplayNameinEnglish
  ```

  Example:

  ```
  #Metric Family Name List for Customer Reference
  #Mon Jun 17 11:18:50 EDT 2013
  normalizedmemoryinfo=Memory
  normalizedavailabilityinfo=Availability
  normalizedcpuinfo=CPU
  normalizedportinfo=Interface
  ```

- **streamexport.metricFamilyWhiteList.cfg**
  Specifies all the metric families to export.
  Location: $KARAF_HOME/etc folder
  This file has the following format:

  ```
  whitelist.number=metricFamilyInternalName
  ```

  Example:

  ```
  #This is the whitelist file for the metric families.
  #Mon Jun 10 17:25:46 EDT 2013
  feature.enabled=on
  whitelist.1 = NormalizedMemoryInfo
  whitelist.2 = NormalizedPortInfo
  ```

Follow these steps:

1. On the local Data Aggregator system, open **streamexport.allMetricFamilies.out** using a text editor.
2. On the local Data Aggregator system, also open **streamexport.metricFamilyWhiteList.cfg** using a text editor.

3. Copy one or more metric family internal names from the **streamexport.allMetricFamilies.out** file. Paste the copied text into the **streamexport.metricFamilyWhiteList.cfg** file.
   Example:
   ```
   whitelist.1=<paste here>
   whitelist.2=<paste here next metric family name>
   Set feature.enabled=on
   ```
4. Save your changes to the **streamexport.metricFamilyWhiteList.cfg** file.

Export Extra Columns for Components

To include more information about component items, configure the export to include the ifAlias and ifDescr columns.

> **WARNING**
>
> If you configure this option after you start the data export, the output file might contain mixed data. Lines that are exported before you add the columns do not include the extra columns. Lines that are exported after the change include the columns. To avoid a mixed file, stop the Data Aggregator before you change the configuration.

Follow these steps:

1. Edit the following file:
   ```
   etc/streamexport.exportInfoResolver.cfg
   ```
2. Set the following parameter:
   ```
   enableInterfaceOutput=true
   ```
3. Save the changes.
   The Data Aggregator adds the ifAlias and ifDescr columns to the output file. This change occurs immediately.

Start the Rate Data Export Feature

Start the Data Aggregator Rate Data Export Service (export feature) using Data Aggregator REST web services. You can use any REST client tool or an HTTP tool that can send requests and can get responses. For this scenario, we use a REST client.

Follow these steps:

1. Set up a REST client with a connection to the Data Aggregator server.
2. Set the REST Content-type to application/xml.
3. Enter the following URL:
   ```
   GET http://da_host:8581/rest/dataexport/
   ```
4. Take note of the id of the data export profile you want to modify. By default, there is only one profile.
5. Enter text in the Body tab of the HTTP Request pane. At a minimum, set Enabled to true. For example:
   ```
   <DataExportInfo version="1.0.0">
               <Enabled>true</Enabled>
   </DataExportInfo>
   ```
6. Review other options that can be set at the following URL:
   ```
   http://da_host:8581/rest/dataexport/xsd/get.xsd
   ```
7. Save and start the rate data export feature by entering the following URL:
   ```
   PUT http://da_host:8581/rest/dataexport/id
   ```
   – ***id***
   Specifies the ID of the Data Export service.
   The following URL retrieves the ID of the Data Export service:
   ```
   GET http://da_host:8581/rest/dataexport
   ```

8. To verify that your changes took effect, enter the following URL:
   `GET http://da_host:8581/rest/dataexport/id`

   The data export starts automatically and temporary export files are created.
   When the export file is ready, the exporter automatically renames it to the previously configured file extension, such as .csv.
   You do not need to restart the services for a newly written file.
   After the data is exported, copy the data to your other system using the method required by that other system.

Stop the Bulk Data Export

To stop the data rate export at any time, set the Enabled attribute to **false**.
Example:

```
<DataExportInfo version="1.0.0">
 <Enabled>false</Enabled>
</DataExportInfo>
```

View Health Monitoring Information

A built-in mechanism monitors the health of the Data Aggregator and the Data Collector devices. Self-monitoring monitoring profiles determine the statistics that are discovered and polled for these devices. The discovered statistics are collected automatically.

> **WARNING**
> We recommend that you do not change or stop this self-monitoring.

As an administrator, you want to monitor your Data Aggregator and Data Collector items so that you can manage their performances proactively and you can perform capacity planning.

In this scenario, you will view the monitoring profiles that are associated with Data Aggregator and Data Collector self-monitoring. You will also view the components that are being monitored on the Data Aggregator device. This information helps you to understand how the health of these items is managed.

You will also create dynamic trend views, where you can view changes that are occurring on Data Aggregator over time. This information is useful when you are troubleshooting performance issues and performing capacity planning.

To view health monitoring information, follow these steps:

View Metric Families That Are Associated with Self-Monitoring

You can view the metric families that are related to the self-monitoring of Data Aggregator and Data Collector. You can also view the metrics within these metric families, which are used for polling the devices. This information helps you to gain an understanding of what types of data is collected and at what rates the data is collected. You can then understand how the health of these devices is managed. You will see this information in the view that you will create later in this scenario.

Follow these steps:

1. Log in to CA NetOps Portal as an administrator.
2. Select **Administration**, and click a Data Aggregator data source.
   The Data Aggregator Admin pages open.
3. Click **Monitoring Profiles** from the Monitoring Configuration menu.
4. Select each "DA Health (<Rate>)" monitoring profile individually and view the corresponding metric families on the Metric Families tab.

NOTE
To view a description for each metric family, hover over it.

5. Make a note of the metric families you see on the Metric Families tab.
6. Click **Metric Families** from the **Monitoring Configuration** menu.
7. Find and select each metric family individually and view the specific metrics that are collected on the Metrics tab.

View Monitored Components on Data Aggregator

You can view which components are being monitored on Data Aggregator. You can also view the polling status on the components. For example, for capacity planning purposes, you can see all of the Data Collector instances that are being monitored on the Data Aggregator instance.

NOTE
Only Data Collector instances for the tenant you are administering will be displayed. In an enterprise environment, you will likely only use the default tenant workspace and therefore will see all of the Data Collector instances.

Follow these steps:

1. Click **Monitored Devices** from the Monitored Inventory menu for a Data Aggregator data source.
2. Expand the "All Data Aggregators" folder and select the Data Aggregator device.
   The Polled Metric Families tab shows the metric families that are associated with the Data Aggregator device.
   The Components table for a given metric family shows the polling status on the discovered components.

NOTE
When new components are discovered on the self-monitoring metric family, the components are monitored automatically. Performing an "Update Metric Family" operation on a self-monitoring metric family will result in no change in the state of monitoring.

Create a Group

As an administrator, you can create a custom group to organize managed devices in CA NetOps Portal. In this scenario, you create a group for the Data Aggregator device. The Data Aggregator device will be the context for the view you will create in a later step.

Follow these steps:

1. Log in to CA NetOps Portal as a user with the Administrator role.
2. Select **Administration**, **Group Settings**, and click **Groups**.
   The Manage Groups dialog opens.
3. To find a location for the new group, expand nodes in the Groups tree. Create the group under the All Groups node in the Groups tree, or within an existing custom or site group. You cannot add groups to system groups, which appear "locked" in the Groups tree.

NOTE
We recommend that you create this group under a node where only you have access rights.

4. Right-click the node, and select **Add Group**.
   The Add Group window opens. The New tab is selected by default.
5. Type the words "Data Aggregators" for the name of the group and optionally provide a description.
6. Select **Custom** from the Group Type list.
7. Click **Save**.
   The new group appears in the Groups tree.
8. Select the "Data Aggregators" group that you created.
9. Click the Items tab in the right pane.
10. Click **Add Item** Type.

The Add Items dialog opens.
The list of items refreshes to show items of the selected type that are available to add to the group. The available items depend on the item type, the data sources that are registered, and the items discovered.

NOTE
To see more pages of items, click the links below the list. Or use the Search field to search for an item in the list.

11. Select the DataAggregator@*ip_address* item and click Add Items.
    – ***ip_address***
    Indicates the IP address of the Data Aggregator device.
12. Click **Close**.
    The Add Items dialog closes. The Items tab shows the DataAggregator@*ip_address* device that you added. Synchronization with Data Aggregator can take up to 5 minutes to begin.

Create a Dashboard and View Relevant Information

Custom dashboards are useful for displaying data from a particular item or group of items. (*Item* can be a device, component, or interface.) In this scenario, you want to display self-monitoring data on the Data Aggregator item. In particular, you want to look at the Polled Item Count metric, the SNMP Poll Failure Count metric, and the SNMP Request Count metric. By looking at this information, you can view any changes that are occurring over time. Use this information when troubleshooting performance issues and when you are performing capacity planning.

Follow these steps:

1. Click the Dashboards tab.
   The Available Dashboards page opens. Each view on the page corresponds to a menu.
2. Click **Add Dashboard** next to the menu where you want the new dashboard to appear.
   The Add Dashboard page opens.
3. Complete the following fields:
   a. Type "Data Aggregator Health' in the Menu Item and Dashboard Title fields.
   b. (Optional) Select a layout template for the dashboard.
   Each layout treats the page as a table with rows and columns for views. The layout buttons indicate the number of views in each column and row on the page.

   NOTE
   Select your layout before you add the Dynamic Trend View. If you change the layout after you add a view, the views will be removed.
4. Expand **Dynamic Views** in the left pane. Select and drag the Dynamic Trend View to the page layout, and drop the view where you want it to appear.
5. To create two more Dynamic Trend Views, select the view and click the **Copy** button twice.
6. Add the **Polled Item Count** metric to the first view. Add the **SNMP Poll Failure Count** metric to the second view. Add the **SNMP Request Count** metric to the third view. To add the metrics to the view, do the following steps:
   a. Select the Dynamic Trend View and click the **Edit** button.
   b. If it is not already selected, select **Device** from the **Context Type** drop-down box.
   c. For the title, type "Polled Item Count" for the first view, "SNMP Poll Failure Count" for the second view, and "SNMP Request Count" for the third view.
   d. Keep the default, **Multitrend**, as the View Type.
   e. Select the "DA Data Collector Polling Statistics" metric family for each view.

   NOTE
   It can take a few minutes for the available metric families to synchronize with CA NetOps Portal. If the self-monitor metric families are not immediately available, wait a few minutes and then try again.

f. Select the **Polled Item Count - Average** metric value for the first dynamic trend view. Select the **SNMP Poll Failure Count - Total** metric value for the second view. Select the **SNMP Request Count - Total** metric value for the third view.
g. Select the **Add Groups** radio button and then click the **Add/Remove Groups** button. Select the "Data Aggregators" group you created previously from the list of available groups and move it to the list of selected groups. Click OK.
h. Click **Save**.

Your report is generated automatically.

7. View any changes that are occurring over time.
   For example:
   – Polled item count increases when you were *not* expecting it to - Did you unintentionally start monitoring more items?
   – Polled item count remains the same, but you see spikes in the SNMP Request Count occasionally - Do you have change detection turned on in one of your monitoring profiles or perhaps scheduled discoveries?
   – Polled item count remains the same, but you see changes in the SNMP Poll Failure Count - Perhaps there has been a network outage.
   – Polled item count increases and the SNMP Poll Failure Count increases - Perhaps Data Collector is overloaded and cannot respond to all of the requests.

Restart Performance Management Component Services

To restart DX NetOps Performance Management, restart the component services on the host servers.

See the following pages for the procedures to restart the component services:

Restart the Data Aggregator

Restart the Data Aggregator service when required, such as when you upgrade the operating system on the Data Aggregator host. Stop Data Aggregator, complete the required actions, and restart Data Aggregator.

During a planned shutdown, the Data Aggregator continues processing for 5 minutes before the service stops:

- Data that has been received continues processing and is sent to the Data Repository. Data that is not processed is saved, and loaded when the Data Aggregator restarts.
- Incomplete rollup processing resumes when the Data Aggregator restarts.

Data Collectors queue poll data when the Data Aggregator is stopped. Data loading of queued data, threshold event processing, and rollup processing resume when Data Aggregator restarts. If queued data exceeds the disk space limit on the Data Collector, the oldest data is discarded.

If the Data Aggregator stops ungracefully, polled data and threshold event processing information might be lost.

Fault Tolerant Data Aggregators

If you are applying a patch to Data Aggregators in a fault tolerant environment, do the following restart steps in the following order:

1. Put the inactive Data Aggregator(B) into maintenance mode.
2. Apply the patch to the inactive Data Aggregator(B).
3. Activate the inactive Data Aggregator(B).
   This Data Aggregator(B) becomes available for failover.
4. Put the active Data Aggregator(A) into maintenance mode.

WARNING

This step causes failover. The previously inactive Data Aggregator(B) becomes the active Data Aggregator.

5. Apply the patch to the now inactive Data Aggregator(A).
6. Activate the now inactive Data Aggregator(A).
   This Data Aggregator(A) becomes available for failover. The other Data Aggregator(B) is the active Data Aggregator.

Stop the Data Aggregator

Shut down the Data Aggregator in preparation for any required tasks (for example, applying a security patch). In an environment with fault tolerant Data Aggregators, put the inactive Data Aggregator and then the active Data Aggregator into maintenance mode.

Follow these steps:

1. Log in to the Data Aggregator host as the root user or the sudo user.

   NOTE
   If you installed Data Aggregator as the sudo user, you set up a sudo command alias for the service dadaemon command. Use the sudo commands.
2. Do one of the following steps:
   – Stop the Data Aggregator service:
   `service dadaemon stop`

   NOTE

   For RHEL 7.x, `service` invokes `systemctl` . You can use `systemctl` instead.
   – (Fault tolerant environment) If the local Data Aggregator is running, run one the following commands to shut it down and prevent it from restarting until maintenance is complete:
   - **RHEL 6.x:**
     `service dadaemon maintenance`
   - **RHEL 7.x**, **SLES, or OL:**
     DA_Install_Directory`/scripts/dadaemon maintenance`

   The Data Aggregator completes processing and the service stops.

Start the Data Aggregator

After you complete any required tasks (for example, applying a security patch), restart the Data Aggregator. In an environment with fault tolerant Data Aggregators, activate each Data Aggregator.

Follow these steps:

1. Do one of the following steps:
   – Start the Data Aggregator service:
   `service dadaemon start`
   – (Fault tolerant environment) Run one the following commands to enable the fault tolerant Data Aggregator so that it can start when necessary:
   - **RHEL 6.x:**
     `service dadaemon activate`
   - **RHEL 7.x**, **SLES, or OL**:
     DA_Install_Directory`/scripts/dadaemon activate`

   Data Aggregator starts and synchronizes with CA NetOps Portal automatically. If the Data Repository is unavailable, the Data Aggregator shuts down. The Data Collectors send any queued data to the Data Aggregator.

Restart the Data Collector

Restart the Data Collector service when required, such as for the following reasons:

- The host loses power.
- You change the location of the host.
- You install an operating system patch.

When a Data Collector is stopped, polling stops. Discovery cannot run during this time. When Data Collector is restarted, scheduled polling and discovery resumes.

Follow these steps:

1. Log in to the Data Collector host as the root user or the sudo user.

   NOTE
   If you installed Data Collector as the sudo user, you set up a sudo command alias for the service dcmd command. Use the sudo commands.
2. Use one of the following commands to stop the Data Collector service:
   –
   ```
   service dcmd stop
   ```
   –
   ```
   sudo service dcmd stop
   ```
   The Data Collector stops.
3. Complete any required tasks.
4. Use one of the following commands to start the Data Collector service:
   –
   ```
   service dcmd start
   ```
   –
   ```
   sudo service dcmd start
   ```
   The Data Collector restarts and resynchronizes automatically. If the Data Aggregator is not available, the Data Collector shuts down. If the ActiveMQ Broker is unavailable, the Data Collector restarts that service.

Restart the Data Repository

Restart the data repository when required, such as for the following reasons:

- The data repository host loses power or locks up.
- The data repository host is relocated.
- You install an operating system patch.

NOTE
This procedure includes a restart of the data aggregator.
For more information, see Restart the Data Aggregator.

WARNING

If you try to restart one data repository node before another restarted node has completely rejoined the cluster, the whole cluster can go down. The cluster does not come back up until you manually start it.

Stop the Data Aggregator

Before you shut down the data repository, stop the data aggregator. In an environment with fault-tolerant data aggregators, put the inactive data aggregator and then the active data aggregator into maintenance mode.

Follow these steps:

1. Log in to the data aggregator host as the root user or a sudo user.
2. Do one of the following steps:
   – Stop the Data Aggregator service by issuing the following command:
   `service dadaemon stop`

   NOTE
   For RHEL 7.x, `service` invokes `systemctl` . You can use `systemctl` instead.
   – (Fault-tolerant environment) Issue one of the following commands to shut down the inactive data aggregator and prevent it from restarting. Then run the command on the active data aggregator:
   - **RHEL 6.x:**
     `service dadaemon maintenance`
   - **RHEL 7.x, SLES, OL:**
     DA_Install_Directory`/scripts/dadaemon maintenance`

Shut Down the Data Repository

Shut down the data repository in preparation for any required tasks (for example, applying a security patch).

WARNING

If you try to restart a data repository node before another restarted node has completely rejoined the cluster, the whole cluster can go down. The cluster does not come back up until you manually start it.

Stop the Database

Follow these steps:

1. Log in to the data repository host as the database administrator user.
2. Open Vertica adminTools by issuing the following command:
   `/opt/vertica/bin/adminTools`
3. Select **(4) Stop Database**.
4. Select the database, select **OK**, and then press **Enter** on your keyboard.
5. Provide the database password, and then press **Enter** on your keyboard.
   The data repository stops.

   TIP

   If the data repository does not stop, select **(2) Stop Vertica on Host** from **(7) Advanced Tools Menu**.
6. Select **(E) Exit**, and press **Enter** on your keyboard.

Stop Vertica on One Node in a Cluster

Follow these steps:

1. With the Vertica adminTools open, select **(7) Advanced Tools Menu**.
2. Select **(2) Stop Vertica on Host**.
3. Select the node to stop, and then press **Enter** on your keyboard.
4. Provide the database password, and then press **Enter** on your keyboard.
   The data repository on the node stops.

5. Select **(M) Main Menu**, and then press **Enter** on your keyboard.
6. Select **(E) Exit**, and then press **Enter** on your keyboard.

Start the Data Repository

After you complete required tasks, such as applying a security patch, restart the data repository.

WARNING

To avoid the cluster from going down and having to manually restart it, ensure that other restarted nodes have completely rejoined the cluster before restarting a data repository node.

Start the Database

Follow these steps:

1. With the Vertica adminTools open, select **(3) Start Database**.
2. Select the database, select **OK**, and then press **Enter** on your keyboard.
   You are prompted for the database password.
3. Provide the database password, and then press **Enter** on your keyboard.
   The Data Repository starts.

   TIP

   If Vertica fails to start normally, try running the following command:

   ```
   /opt/vertica/bin/admintools -t restart_node -d dbname --hosts host_ip_address --force
   ```
4. Select **(E) Exit** and press Enter.

Start a Node that is Down in a Cluster

Follow these steps:

1. With the Vertica adminTools open, select **(5) Restart Vertica on Host**.
2. Select the database, select **OK**. and then press **Enter** on your keyboard.
3. Select the node to start, and then press **Enter** on your keyboard.
4. Provide the database password, and then press **Enter** on your keyboard.
   The Data Repository on the node starts.
5. Select **(E) Exit**, and then press **Enter** on your keyboard.

Start the Data Aggregator

After you start the data repository, start the data aggregator. In an environment with fault-tolerant data aggregators, activate each data aggregator.

Follow these steps:

1. Do one of the following steps:
   – Start the Data Aggregator service:
   ```
   service dadaemon start
   ```
   – (Fault-tolerant environment) Run one the following commands to enable the fault-tolerant data aggregator so that it can start when necessary:
   - **RHEL 6.x:**
   ```
   service dadaemon activate
   ```
   - **RHEL 7.x, SLES, OL:**

```
DA_Install_Directory/scripts/dadaemon activate
```

The data aggregator starts and the system resumes normal operations.

Restart the ActiveMQ Broker

If a problem is detected, the Data Aggregator or Data Collector restarts the ActiveMQ broker automatically. If the restart is unsuccessful, restart the ActiveMQ broker manually. By default, the Data Aggregator and Data Collector determine the availability of the ActiveMQ broker every 30 seconds.

Follow these steps:

1. Open the ActiveMQ, which is located in the following location:

   ```
   da_install_dir/broker/apache-activemq-version/bin
   ```

   - ***da_install_dir*** specifies the location of the Data Aggregator or Data Collector installation directory.
   - **apache-activemq-*version*** specifies the version of Apache ActiveMQ.
     Example: apache-activemq-5.5.1b
2. Stop ActiveMQ:

   ```
   service activemq stop
   ```

3. Start ActiveMQ:

   ```
   service activemq start
   ```

Restart Performance Center

You can stop and restart NetOps Portal, such as when you are backing up your database. To restart NetOps Portal successfully, stop and restart all relevant services in the correct order.

Stop NetOps Portal

Run the following commands in the order in which they appear to stop NetOps Portal:

```
service caperfcenter_console stop

service caperfcenter_devicemanager stop

service caperfcenter_eventmanager stop

service caperfcenter_sso stop
```

(Optional) Restart the MySQL Database

Usually, you do not need to restart MySQL database. If you are experiencing issues with NetOps Portal, you can restart the MySQL database.

WARNING

Before you stop the MySQL database, verify that all NetOps Portal services are stopped.

Run the following commands to stop and restart MySQL:

```
service mysql stop

service mysql start
```

Start NetOps Portal

To start NetOps Portal, restart the component services.

Follow these steps:

1. Start the SSO service:

   ```
   service caperfcenter_sso start
   ```

2. Wait one minute, then start the event manager and device manager:

   ```
   service caperfcenter_eventmanager start

   service caperfcenter_devicemanager start
   ```

3. Wait one minute, then start the console service:

   ```
   service caperfcenter_console start
   ```

Verify Status of NetOps Portal Services

Run the following commands to verify the status of NetOps Portal services after you start NetOps Portal:

```
service caperfcenter_sso status

service caperfcenter_eventmanager status

service caperfcenter_devicemanager status

service caperfcenter_console status
```

The following sample message indicates that the NetOps Portal console is running:

```
Performance Center Console is running: PID:12993, Wrapper:STARTED, Java:STARTED
```

Disaster Recovery

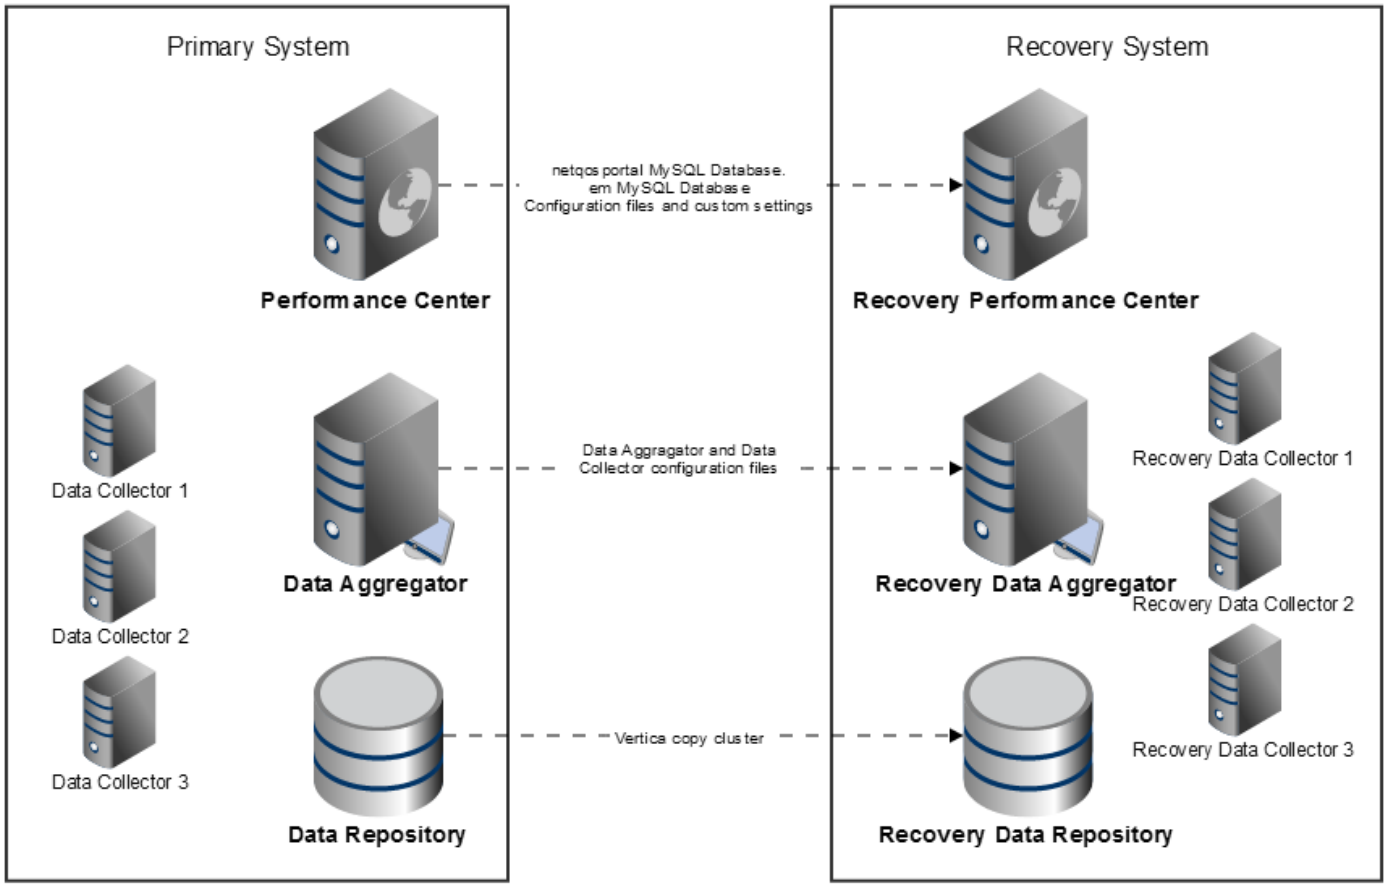
If a large-scale disaster occurs, the disaster recovery plan for DX NetOps Performance Management enables a switchover to a recovery system. The disaster recovery plan involves provisioning a secondary system as a recovery environment and regularly transferring data from the primary system. This scenario is not a temporary measure. The recovery system completely replaces the primary system.

> **NOTE**
> To reverse this process and return monitoring to the original site, go through the same process with the recovery and primary hosts switched. If new hardware is deployed due to the disaster, start by reinstalling the DX NetOps Performance Management components on the new hardware. If the original hardware is available and no upgrades have occurred on the active recovery system, start by configuring incremental data transfer.

The following video introduces how DX NetOps Performance Management establishes a detailed disaster recovery procedure meant to re-establish normal operations in the event of a major disruption such as a hurricane or fire:

The following diagram shows the primary and recovery systems, and the files that are copied regularly:

Figure 61: Disaster Recover Architecture



Install Components for the Recovery System

The recovery system is a secondary system that contains all the components for DX NetOps Performance Management. Under normal operations, the recovery system is offline. The recovery system has the same requirements as the primary system. For more information, see Review Installation Requirements and Considerations.

IMPORTANT
If you upgrade you primary system, upgrade the components in the recovery system. Each recovery component must be running the same version of the product as the primary system.

truetop

Install the Data Repository

Before you install Vertica on the recovery cluster, prepare the environment for the installation. For more information about how to prepare the recovery cluster, see Prepare to Install the Data Repository.

Ensure that the recovery system has the same settings as the primary cluster for the following settings:

- Database version
- Node names

  TIP
  To get the node name, run the following command on each node:
  ```
  /opt/vertica/bin/admintools -t list_allnodes
  ```
  This command also returns the installed Vertica version and the database name.
- Database name
- Database administrator
- Database user
- Catalog directory

  TIP
  To get the catalog directory configuration, run the following command on each node:
  ```
  /opt/vertica/bin/admintools -t list_db -d <database name>
  ```
- Data directory

The recovery cluster has the following requirements:

- Accessible from the primary cluster
- The same number of nodes as the primary cluster
- Passwordless SSH access to and from the recovery cluster for the Database Administrator account (default: dradmin) from the primary cluster.
  Provide passwordless SSH access for the Database Administrator account (default: dradmin) from each host in the primary cluster to each host in the recovery cluster. Then, provide passwordless SSH access for the dradmin account from each host in the recovery cluster back to each host in the primary cluster.

  TIP
  To configure passwordless SSH, run the following command from each host in the primary cluster to each node in the recovery cluster. Then run the command from each node in the recovery cluster to each node in the primary cluster:
  ```
  ssh-copy-id -i dradmin@target_host
  ```
- For each node pair, run the following command:
  ```
  ssh dradmin@<paired-node> '/opt/vertica/bin/admintools -t list_allnodes
  ```
  If you are prompted for a password, the ssh setup for the Database Administrator account (default: dradmin) is incomplete. Copy cluster will fail.
- Port 50000 must be open between all the Data Repository nodes and disaster recovery hosts.

The installation process is the same as a normal Data Repository installation, for more information, see Install the Data Repository.

WARNING

Use the same configuration for the new cluster as for the source cluster. For example, the vertica version, node count, database name, administrator, user, catalog directory, and data directory must be the same as the original Data Repository.

Install the Data Aggregator

Prepare the host and install the data aggregator for the recovery system.

During installation, use the details for the Data Repository for the recovery system.

For more information, see Prepare to Install the Data Aggregator and Install the Data Aggregator.

Install the Data Collectors

For each data collector in the primary system, install a data collector in the recovery system. The DCM ID identifies the data collector to the system.

TIP
This scenario assumes that the data collectors are centrally located with the other components. Some deployments use remote data collectors, which are deployed close to the monitored infrastructure in other data centers or geographical locations. To continue using a remote data collector if a disaster occurs, update it to communicate to the recovery data aggregator. For more information, see Configure Data Collector When the Data Aggregator IP Address Changes.

Use the following process:

1. Prepare the hosts for the recovery system data collectors. For more information, see Prepare to Install the Data Collectors.
2. Record the DCM ID values for each data collector in the primary system:
   a. Go to the following URL:
      `https://primary_da_host:8581/rest/dcms`
   b. For each data collector, note the value in the **<DcmID>** tag.
      The following XML shows an example:

```
<DataCollectionMgrInfoList>
   <DataCollectionMgrInfo version="1.0.0">
      <ID>4077</ID>
       <DcmID>primary-dc:69658898-a48c-44a6-9cba-963bb9c09684</DcmID>
      <Enabled>true</Enabled>
      <IPAddress>10.237.1.67</IPAddress>
      <RelatedDeviceItem>4078</RelatedDeviceItem>
...
```

3. For *each* recovery data collector, export the DCM ID for the corresponding primary data collector, and install the component in the recovery system:
   a. On the data collector host for the recovery system, export the DCM ID for the primary system data collector:
      `export DCM_ID=DATA_COLLECTOR_DCM_ID`

      Example:
      `export DCM_ID=primary-dc:69658898-a48c-44a6-9cba-963bb9c09684`

b. From the same session, install the data collector.
During installation, specify the details for the data aggregator for the recovery system.
For more information, see Install the Data Collectors.

4. To verify the installation, look at the DCM ID on the recovery data collector:
   a. Open the following file:
   `/opt/IMDataCollector/broker/apache-activemq-version/conf/activemq.xml`
   b. Find the broker name property and verify the DCM ID.
   The following example shows the section of the activemq.xml file that includes the broker name:

```
...    <broker
         xmlns="http://activemq.apache.org/schema/core"
         brokerName="dc_broker_69658898-a48c-44a6-9cba-963bb9c09684 "
         dataDirectory="${activemq.data}"
         useShutdownHook="false"
         useJmx="true">
 ...
```

   If the broker name does not match the expected DCM_ID UUID from the originating system, update the file with the correct DCM_ID UUID from the DCM_ID of the originating data collector.
5. Stop the data collector services:

```
service dcmd stop
```

NOTE

For RHEL 7.x or OL, `service` invokes `systemctl` . You can use `systemctl` instead.

```
service activemq stop
```

6. Stop the data aggregator services:
   a. Log in to the data aggregator host for the recovery system.
   b. Do one of the following steps:
   - Stop the data aggregator and ActiveMQ services:

```
service dadaemon stop

service activemq stop
```

   - (Fault tolerant environment) If the local data aggregator is running, run one of the following commands to shut it down and prevent it from restarting until maintenance is complete:
     - **RHEL 6.x:**

```
service dadaemon maintenance
```

     - **RHEL 7.x, SLES, or OL:**

```
DA_Install_Directory/scripts/dadaemon maintenance
```

Install NetOps Portal

Prepare the host and install NetOps Portal for the recovery system.

Do not configure LDAP integration or HTTPS on the recovery system. The settings are inherited from the primary system.

For more information, see Prepare to Install Performance Center and Install Performance Center.

Configure Incremental Data Transfer

Copy data provides the recovery system everything that is required to continue operation when the primary system is down. Devise a plan with a regular interval that occurs often enough to duplicate the required data. Use the same frequency for all components and start the transfer from each component simultaneously. We recommend a daily transfer of all components.

TIP
The data aggregator and NetOps Portal components require regular file copies between the primary system and the recovery system. You can use any file copy and schedule method as required in your system. In our lab environment, we configured SSH between the primary and recovery system, and used crontab to invoke the SCP command from the recovery system.

Example:

The following crontab example is configured on the secondary data aggregator host to copy a backup directory from the primary data aggregator. The copy occurs daily at 12:30 AM:

```
30 0 * * * scp -r root@primary_DA:/tmp/backup /tmp/backup
```

top

Data Repository

For the Data Repository, use copy cluster to duplicate the primary database to the recovery database. Copy cluster is an incremental backup that copies all updates to the database. Because this data transfer is the longest transfer, the backup frequency to the recovery system is limited by the runtime of the copy cluster command. Run the command multiple times before you schedule a regular transfer to verify the runtime. Ensure that the backup frequency is at lease twice the runtime of the copy cluster.

NOTE
For existing large databases, the copy cluster command takes as long as a full backup to complete. To minimize the performance impact to the system, restore a backup of the primary system to the recovery system, then configure and run copy cluster.

TIP
For a large database, an incremental copy cluster command for one day takes about one hour. We recommend you run an incremental copy cluster at least daily.

Follow these steps:

1. Create a configuration file for copy cluster on a host in the primary Data Repository cluster in the following directory: `/home/dradmin`
2. Use the example as a model to create the configuration file.
   Example: The following example configuration file is set up to copy a database on a three node cluster (v_drdata_node0001, v_drdata_node0002, and v_drdata_node0003) to another cluster consisting of nodes (recovery-host01, recovery-host02, and recovery-host03):

   NOTE
   The dbName parameter is case-sensitive.

```
[Misc]
snapshotName = Copydrdata
```

```
restorePointLimit = 5
tempDir = /tmp/vbr
retryCount = 5
retryDelay = 1

[Database]
dbName = drdata
dbUser = dradmin
dbPassword =  password
dbPromptForPassword = False

[Transmission]
encrypt = False
checksum = False
port_rsync = 50000

[Mapping]
; backupDir is not used for cluster copy
 v_drdata_node0001= recovery-host01:/data
 v_drdata_node0002= recovery-host02:/data
 v_drdata_node0003= recovery-host03:/data
```

3. Stop the database in the recovery system:
   a. Log in to the recovery database cluster as the database admin user.
   b. Open Vertica admin Tools:
      ```
      /opt/vertica/bin/adminTools
      ```
   c. Select (4) Stop Database. Wait for the shutdown to complete before you run copy cluster.
4. Copy historical data:
   a. Log in to the primary cluster as the database administrator account.
   b. Run the copy cluster command:
      ```
      vbr.py --task copycluster --config-file
      home/dradmin/CopyClusterConfigurationFile.ini
      ```

      The command copies the historical data for the database and displays the following message:
      ```
      > vbr.py --config-file home/dradmin/CopyClusterConfigurationFile.ini --task
      copycluster
      Preparing...
      Copying...
      1871652633 out of 1871652633, 100%
      All child processes terminated successfully.
      copycluster done!
      ```
5. Create a cron job to schedule copy cluster from the primary system on a regular interval. The following command initiates the transfer:
   ```
   vbr.py --task copycluster --config-file
   home/dradmin/CopyClusterConfigurationFile.ini
   ```

Data Aggregator

For the data aggregator, schedule a regular copy of the following files from the primary system to the recovery system:

- *DA_install_directory*/apache-karaf-*version*/deploy/*.xml

  NOTE
  Do not copy the following file from this directory: `local-jms-broker.xml` This directory might not initially contain other files.
- *DA_install_directory*/apache-karaf-*version*/etc/org.ops4j.pax.web.cfg
- *DA_install_directory*/data/custom/devicetypes/DeviceTypes.xml
  In a fault tolerant environment, a shared directory (example: `/DASharedRepo`) is defined to help limit data loss. Therefore, in a fault tolerant environment the file would be located in the following directory:
  DASharedRepo/custom/devicetypes/DeviceTypes.xml

  For more information, see Fault Tolerance.

Data Collectors

The data collectors do not require a regular backup. All relevant information is stored on the data aggregator and Data Repository.

NOTE
If the primary data collectors include custom memory settings, configure the recovery data collectors as required.

NetOps Portal

For NetOps Portal, create a database dump of the netqosportal and em databases, and back up custom settings. For more information, see Back Up and Restore the CA Performance Management Database.

Prepare the Disaster Recovery Scripts

The disaster recovery scripts replace hostname and IP address references to match the components in the recovery system.

For each script, create a copy, and provide the relevant information for your system.

Data Repository Disaster Recovery Script

Location: `/opt/CA/IMDataRepository_vertica`*Version*`/update_da_dc_database_references.sh`

On the Data Repository host in the recovery system, update the bold sections of the script to match your system:

```
############################################################
# UPDATE DAUSER/DAPASS BELOW TO REFLECT THE NON-ADMIN
# VERTICA USERNAME/PASSWORD FOR THIS SYSTEM
############################################################
DAUSER=dauser
DAPASS=dapass

#####################################################################
# UPDATE TO REFLECT THE NEW/RECOVERY DATA AGGREGATOR'S IP ADDRESS BELOW
```

```
#####################################################################
RECOVERY_DA_IP_ADDRESS="<Recovery/New IP Address for the Data Aggregator>"

#####################################################################
# UPDATE TO REFLECT THE NEW/RECOVERY DATA AGGREGATOR'S HOSTNAME BELOW
#####################################################################
SOURCE_DA_HOSTNAME="<Source/Original Hostname for the Data Aggregator>"
RECOVERY_DA_HOSTNAME="<Recovery/New Hostname for the Data Aggregator>"

#############################################################################################################
#
# UPDATE THE FOLLOWING ARRAYS TO REFLECT THE SOURCE DATA
# COLLECTOR HOSTNAMES, NEW RECOVERY HOSTNAMES, AND NEW RECOVERY
# IP ADDRESSES RESPECTIVELY.
#
# IMPORTANT: THE ORDER OF THE ENTRIES BELOW IS CRITICAL FOR
# MAPPING PURPOSES.  IN ADDITION, PLEASE NOTE THAT IF MULTIPLE VALUES
# ARE REQUIRED, PLEASE SEPARATE VALUES WITH A SINGLE SPACE.
#
#############################################################################################################
declare -a SOURCE_DC_HOSTNAMES=(<Source/Original DC Hostname 1> <Source/Original DC
Hostname 2>)
declare -a RECOVERY_DC_HOSTNAMES=(<New/Recovery DC Hostname 1> <New/Recovery DC
Hostname 2>)
declare -a RECOVERY_DC_IP_ADDRESSES=("<New/Recovery DC Hostname 1 IP Address>" "<New/
Recovery DC Hostname 2 IP Address>")
```

IMPORTANT
Ensure that the order of the data collectors for the source system and the recovery system is the same. The script uses the order of the list to map the primary system components to the recovery system.

NetOps Portal Disaster Recovery Script

Location: `/opt/CA/PerformanceCenter/Tools/bin/update_pc_da_database_references.sh`

On the NetOps Portal host in the recovery system, update the bold sections of the script to match your system:

```
...
#####################################################################
# UPDATE THE FOLLOWING PC/DA VARIABLES TO REFLECT NEW ENVIRONMENT
#####################################################################
NEW_PC_IP_ADDRESS="<Recovery/New PC IP Address>"
NEW_PC_HOSTNAME="<Recovery/New PC Hostname>"
NEW_PC_EVENT_PRODUCER_PORT=8181
NEW_PC_EVENT_PRODUCER_PROTOCOL="http" # change to "https" if using SSL
```

```
NEW_DA_IP_ADDRESS="<Recovery/New DA IP Address>"
NEW_DA_HOSTNAME="<Recovery/New DA Hostname>"
NEW_DA_PORT_NUMBER=8581
...
```

Activate the Recovery System

If a large-scale disaster occurs, and the primary system is unavailable, start the recovery system.

TIP
Startup time for the recovery system takes the same time that is required to start the data aggregator.

Start the Data Repository

Follow these steps:

1. Log in to the recovery database cluster as the database admin user.
2. Open Vertica admin Tools:
   `/opt/vertica/bin/adminTools`
3. Select (3) Start Database.
4. Press the Space bar next to the database name, select OK, and then **Enter**.
   You are prompted for the database password.
5. Enter the database password, and then press **Enter**.
   Data Repository starts.
6. Select **Exit**, and then **Enter**.
7. Run the Data Repository disaster recovery script:
   `/opt/CA/IMDataRepository_vertica/`*`your_update_da_dc_database_references.sh`*

Start the Data Aggregator

Do one of the following steps:

- Start the ActiveMQ and data aggregator services:
  ```
  service activemq start

  service dadaemon start
  ```
- (Fault tolerant environment) Run one of the following commands to enable the fault tolerant data aggregator so that it can start when necessary:
  - **RHEL 6.x:**
    ```
    service dadaemon activate
    ```
  - **RHEL 7.x, SLES, or OL:**
    `DA_Install_Directory``/scripts/dadaemon activate`

The data aggregator starts. If the Data Repository is unavailable, the data aggregator shuts down.

Start NetOps Portal

Follow these steps:

1. Restore the NetOps Portal backups. For more information, see Restore Performance Center.
2. Run the NetOps Portal disaster recovery script:
   `/opt/CA/PerformanceCenter/Tools/bin/your_update_pc_da_database_references.sh`
3. Start the SSO service:
   `service caperfcenter_sso start`
4. Wait one minute, then start the event manager and device manager:
   `service caperfcenter_eventmanager start`
   `service caperfcenter_devicemanager start`
5. Wait one minute, then start the console service:
   `service caperfcenter_console start`

Start the Data Collectors

Run the following command to start the data collector service:

```
service dcmd start
```

The data collector restarts. If the data aggregator is unavailable, the data collector shuts down.

> **TIP**
> For remote data collectors, update them to connect to the recovery data aggregator. For more information, see Configure Data Collector When the Data Aggregator IP Address Changes.

(Optional) Test the Recovery System

You can optionally test the recovery system manually.

Follow these steps:

1. Pause the incremental data transfer.
2. Start the Data Repository:
   a. Log in to the recovery database cluster as the database admin user.
   b. Open Vertica admin Tools:
      `/opt/vertica/bin/adminTools`
   c. Select (3) Start Database.
   d. Press the Space bar next to the database name, select OK, and press **Enter**.
      You are prompted for the database password.
   e. Enter the database password and press **Enter**.
      Data Repository starts.
   f. Select Exit, and press **Enter**.
   g. Run the Data Repository disaster recovery script:
      `/opt/CA/IMDataRepository_vertica/your_update_da_dc_database_references.sh`

3. Start the data aggregator:
   a. Do one of the following steps:
      - Start the ActiveMQ and data aggregator services:
        ```
        service activemq start

        service dadaemon start
        ```
      - (Fault tolerant environment) Run one of the following commands to enable the fault tolerant data aggregator so that it can start when necessary:
        - **RHEL 6.x:**
          ```
          service dadaemon activate
          ```
        - **RHEL 7.x, SLES, or OL:**
          ```
          DA_Install_Directory/scripts/dadaemon activate
          ```

   The data aggregator starts. If the Data Repository is unavailable, the data aggregator shuts down.
4. Start NetOps Portal:
   a. Restore the NetOps Portal backups. For more information, see Restore Performance Center.
   b. Run the NetOps Portal disaster recovery script:
      ```
      /opt/CA/PerformanceCenter/Tools/bin/your_update_pc_da_database_references.sh
      ```
   c. Start the SSO service:
      ```
      service caperfcenter_sso start
      ```
   d. Wait one minute, then start the event manager and device manager:
      ```
      service caperfcenter_eventmanager start
      service caperfcenter_devicemanager start
      ```
   e. Wait one minute, then start the console service:
      ```
      service caperfcenter_console start
      ```
5. Log in to the recovery NetOps Portal component and run reports against the recovery Data Repository and data aggregator.
6. Verify the data is available.
7. (Optional) If you have a set of recovery data collectors that you can double-poll for testing, start one or more data collectors. Verify polling occurs and the data is stored in the database.

   NOTE
   To prevent the recovery system from issuing duplicate notifications and reports during testing, disable them beforehand.

   a. Run the following command to start the data collector service:
      ```
      service dcmd start
      ```

   The data collector restarts. If the data aggregator is unavailable, the data collector shuts down.

   TIP
   For remote data collectors, update them to connect to the recovery data aggregator. For more information, see Configure Data Collector When the Data Aggregator IP Address Changes.

8. Shut down each component.
   After the next incremental data transfer, the database is in sync with the primary systems again. To fail over or test again, repeat these steps.

Fault Tolerance

Fault tolerance enables DX NetOps Performance Management to continue operating properly when a hardware failure or network issue occurs. In an environment where fault tolerance is configured, a secondary inactive data aggregator automatically becomes active. The newly-active data aggregator takes over to organize and feed data to NetOps Portal and to the data repository. The newly-active data aggregator retains state information from the previously-active data aggregator. The data aggregator host the network issue or hardware failure is available for failover when it becomes available.
For more information about how to view the health of your data aggregators, see View the Health of the System.

NOTE
If failover occurs, but the ActiveMQ process is still running, you can manually stop ActiveMQ by issuing the following command:

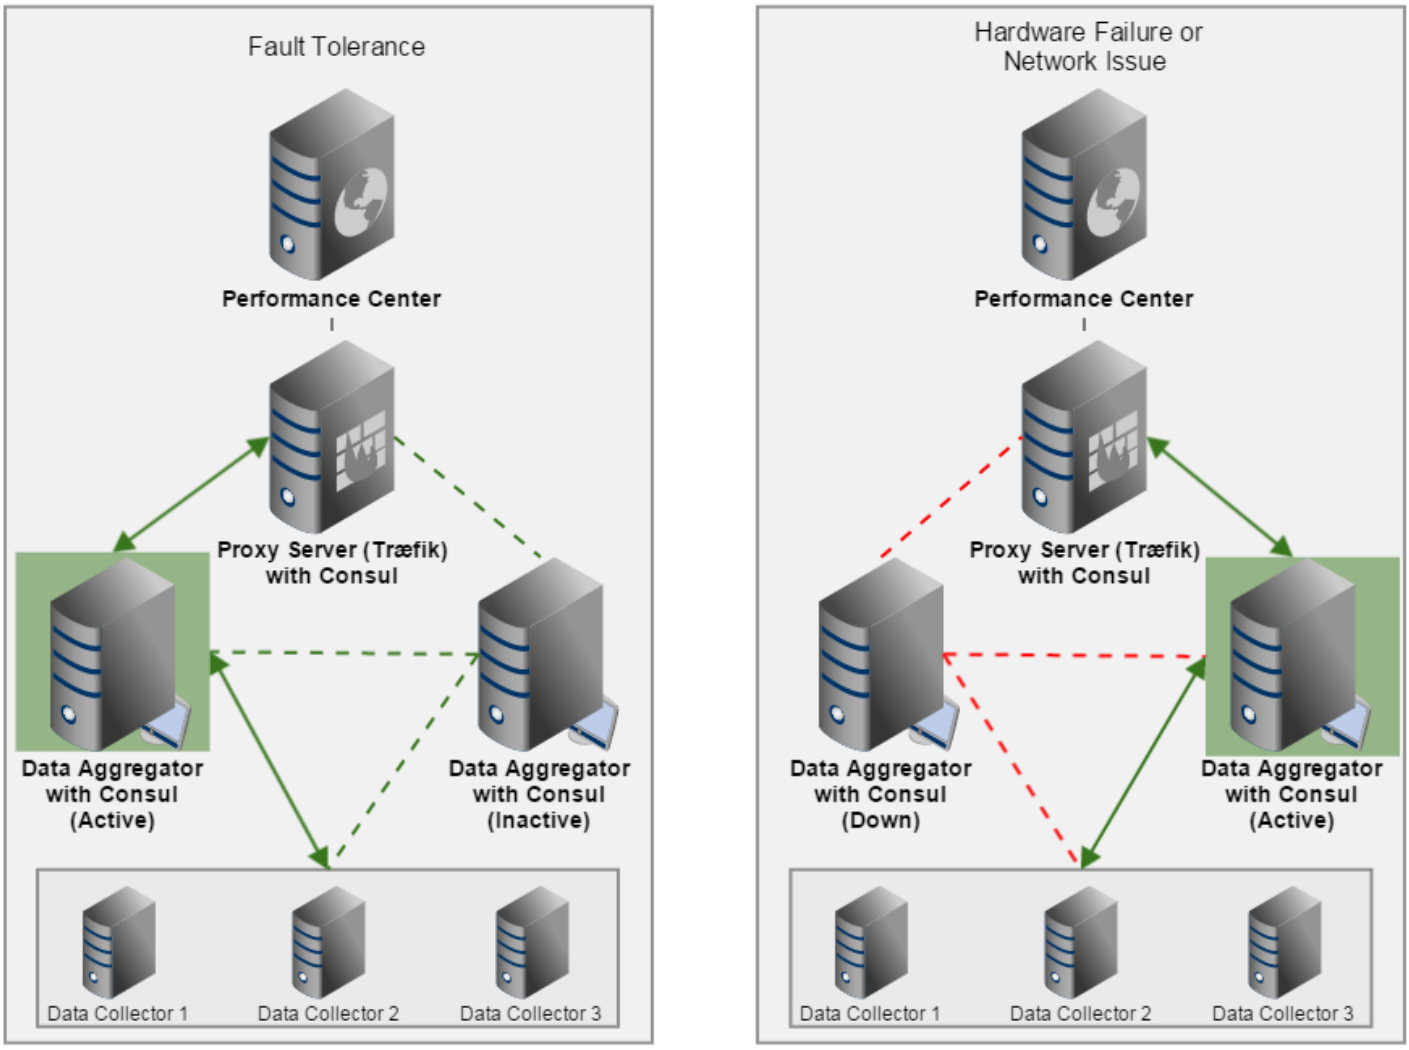
```
service activemq stop
```

Fault-Tolerant Architecture

The following diagram shows the system architecture of a fault-tolerant environment:

NOTE
Træfik is a modern HTTP reverse proxy and load balancer that you can use to deploy microservices with ease. Consul is a tool that you can use to manage services in the DX NetOps Performance Management deployment.

Figure 62: High Availability



Hardware Requirements

The following extra hardware is required for a fault-tolerant environment:

- An additional data aggregator server
- A proxy server. The proxy server works as the third node of the service management cluster for fault tolerance.
- Ensure that you have a new shared data directory (for example, `/DASharedRepo`) and that the same user ID is shared between data aggregator hosts. Data from whichever data aggregator is active is stored in this directory. For more information about the sizing requirements, see the DX NetOps Performance Management Sizing Tool.

> **NOTE**
> If you are using Network File System (NFS), DX NetOps Performance Management supports only NFSv4 and higher because of the ActiveMQ Kaha locking requirements.

> **WARNING**
> To avoid data loss and to prevent data from loading, the shared data directory must be accessible and up at all times.

Data Loss Comparison

In a fault-tolerant environment, some data loss might still occur when a hardware failure or network issue occurs. However, the amount of data loss is less than in an environment without fault tolerance configured. The following table compares the data loss from a hardware failure or network outage:

	Hardware Failure		Network Outage	
Is fault tolerance configured?	**No**	**Yes**	**No**	**Yes**
What happens to rollups?	Pending rollups are lost and never recovered.	The other available data aggregator consumes the pending rollups when it becomes active.	Pending backups are consumed when the network is restored.	The other available data aggregator consumes the pending rollups when it becomes active.
What is lost in memory?	For 10K polls in memory at scale, loss should not exceed 1 poll cycle. Max loss would be 10K items per metric family.	For 10K polls in memory at scale, loss should not exceed 1 poll cycle. Max loss would be 10K items per metric family.	For 10K polls in memory at scale, loss should not exceed 1 poll cycle. Max loss would be 10K items per metric family.	For 10K polls in memory at scale, loss should not exceed 1 poll cycle. Max loss would be 10K items per metric family.
What happens to data transfer object (DTO) files?	If the hardware failure is the disk, all files are lost. Otherwise, whole DTO files are consumed when the hardware is restarted after repair. Incomplete files are discarded.	Whole DTO files are processed and partially written DTO files are discarded. A DTO file is 1 metric family over 1 poll cycle.	Whole DTO files are processed and partially written DTO files are discarded. The data aggregator attempts to shut down gracefully and close any DTO file in flight.	Whole DTO files are processed and partially written DTO files are discarded. A DTO file is 1 metric family over 1 poll cycle.
What happens with the ActiveMQ Broker?	For 600-MB cache in memory and an average message size of 1.3K, approximately 470K messages could be lost.	For 600-MB cache in memory and an average message size of 1.3K, approximately 470K messages could be lost.	For 600-MB cache in memory and an average message size of 1.3K, approximately 470K messages could be lost.	For 600-MB cache in memory and an average message size of 1.3K, approximately 470K messages could be lost.
What happens with thresholding?	Data loss does not exceed 1 poll cycle.	Data loss does not exceed 1 poll cycle.	Data loss does not exceed 1 poll cycle.	Data loss does not exceed 1 poll cycle.

Configure the Failover Settings

During failover, the inactive data aggregator has 45 minutes to start by default. If the data aggregator does not start within 45 minutes, the fault-tolerant environment tries to start the other data aggregator host. This process repeats for each host every 45 minutes until one of the hosts start.

We recommend that you observe how much time passes between when you issue the command to start the data aggregator REST service and when the service is available. Adjust the `startwait` parameter as appropriate before configuring fault tolerance.

> **WARNING**
>
> Ensure that you configure enough time. Do not set the configurable start time to less than 45 minutes. A start time that is too low can result in data loss or system malfunction.

If it always takes longer than 20 to 30 minutes to start a data aggregator, the hardware might be under resourced. If the hardware is under resourced, DX NetOps Performance Management stops functioning.
For more information about the sizing requirements, see the DX NetOps Performance Management Sizing Tool.

A configurable failover wait time is set to 5 minutes by default. Failover only happens when the active data aggregator is unresponsive to the fault tolerance heartbeat for longer than the configure time (default: 5 minutes). If you have limited

network availability with periodical network outages or system thrashing that may last several minutes, you can increase the failover wait time.

WARNING
To avoid data corruption or data loss, do not set the configurable failover wait time to less than 5 minutes.

Follow these steps:

1. Edit the `config.json` file in the *`Data_Aggregator_Install_Directory`*`/consul-ext/conf/` directory.
2. Edit the `startime` and `failwait` parameters (**s** second, **m** minute, **h** hour).
3. Save your changes.

Configure a Fault-Tolerant Environment

When you first install or upgrade the DX NetOps Performance Management components to the 3.5 release or higher, you are prompted to configure a fault-tolerant environment. After the initial installation or upgrade to a fault-tolerant environment, the responses to the fault-tolerant environment prompts are saved and the prompts do not appear during future upgrades of the fault-tolerant environment. A fault-tolerant environment requires a new shared directory (example: `/DASharedRepo`) to help limit data loss. The shared drive stores customized metric families, DTO files, and the ActiveMQ Kaha database. When a hardware failure or network issue occurs, the newly-active data aggregator accesses the shared drive. The data aggregator picks up where the now inactive data aggregator left off. The user ID that the shared drive is created with must be synced to both of the data aggregators. Then both data aggregators have read and write permissions to that directory.

Follow these steps:

1. Follow the installation or upgrade procedure for the data repository:
   - Install the Data Repository
   - Upgrade the Data Repository
2. Ensure that you have a new shared data directory (example: `/DASharedRepo`) and that the same user ID is shared between data aggregator hosts. Data from the active data aggregator is stored in this directory.

   NOTE
   If you are using NFS, only NFSv4 and higher is supported because of the ActiveMQ Kaha locking requirements.

   WARNING
   The shared data directory must be accessible at all times. If the shared data directory is down and is inaccessible, no data is loaded and data loss occurs.
3. Install the proxy server.
   For more information, see Install or Uninstall the Proxy Server.
4. Follow the installation or upgrade procedure for the active data aggregator:
   - Install the Data Aggregator
   - Upgrade the Data Aggregator

   As you proceed through the data aggregator install or upgrade, you are prompted about configuring fault tolerance. In a fault-tolerant environment, the database user credentials for both data aggregators must match.
5. Complete the following prompts:

   WARNING
   The entries to the following prompts must match for both data aggregators.

   - **Configure Data Aggregator For Fault Tolerance**
     Specify 2 to configure fault tolerance.
     Default: 1

NOTE
The default is for a non-fault tolerant environment.

- **Data Aggregator Proxy Host**
  Specify the host name/IP address of the proxy server.

  NOTE
  You can specify only an IPv4 address.
- **Consul HTTP port:**
  Specify the port for communication with Consul.
  Default: 8500
- **Choose host IP address for Consul**

  NOTE
  This prompt appears only when multiple public IP addresses are configured.

  Specify the bind address that the Consul agents use to communicate with each other. The Consul agents include the proxy host and the data aggregators in the cluster. If prompted for an address, specify an address that the other two hosts in the Consul cluster can reach.

6. Install the secondary inactive data aggregator.
   One of the two available data aggregators becomes the active data aggregator. The other data aggregator is available for failover.
7. Follow the installation or upgrade procedure for each data collector:
   - Install the Data Collectors
   - Upgrade the Data Collectors

   As you proceed through the data collector install or upgrade, you are prompted for a failover location for fault tolerance. The Data Collector installer prompts for the inactive data aggregator host if fault tolerance is configured.
8. Follow the installation or upgrade procedure for NetOps Portal:
   - Install Performance Center
   - Upgrade Performance Center

   As you proceed through the NetOps Portal upgrade, you are prompted about fault tolerance. Follow the prompts to migrate the data aggregator data source from the original data aggregator to the proxy host.

Verify Communication Ports

Open the following ports to allow communications to function properly in a fault-tolerant environment:

- **TCP 8300**
  In a fault-tolerant environment, enables communication between the proxy server and the data aggregators.
- **TCP/UDP 8301**
  In a fault-tolerant environment, enables LAN communication between the proxy server and the data aggregators.
- **TCP 8500**
  In a fault-tolerant environment, enables communication between the proxy server and the data aggregators to the HTTP API.

Verify the Fault-Tolerant Environment Configuration

After you install each data aggregator and add it as a data source, the **System Status** page provides the overall health status of the data aggregators.
For more information about how to view this page, see View the Health of the System.

Next Steps

After setting up your environment, enable the fault-tolerant data aggregators to use HTTPS.

For more information, see Enable Fault Tolerant Data Aggregators to use HTTPS.

Install or Uninstall the Proxy Server

The proxy server sends traffic from NetOps Portal to the active data aggregator. The proxy server works as the third node of the service management cluster for fault tolerance. The service management cluster includes the proxy server, the active data aggregator, and the inactive data aggregator.
For more information about fault tolerance, see Fault Tolerance.

In this article:

(Optional) Configure the Sudo User Account for the Proxy Server

If you do not have root access to install and run the proxy server, configure the sudo user account.

Follow these steps:

1. Locate the `/etc/sudoers` file on the proxy server host.
2. Add a command alias with the following permissions to the file:
   ```
   Cmnd_Alias CA_DAPROXY = /tmp/installDAProxy.bin,/sbin/service daproxy *,/sbin/service
    consul *,/opt/CA/daproxy/Uninstall/Uninstall
    ## Allows the daproxy user to manage the proxy server
     dasudouser_name ALL = CA_DAPROXY
   ```
   This command alias details the commands that the sudo user must be able to run.

The sudo user account for the proxy server is configured.

Install the Proxy Server

Before you install and configure the fault-tolerant data aggregators, install the proxy server.

Follow these steps:

1. Log in to the proxy server host as the root or sudo user.
2. Copy the `installDAProxy.bin` file to the `/tmp` directory.
3. Change to the `/tmp` directory:
   ```
   cd /tmp
   ```
4. Change permissions for the installation file:
   ```
   chmod a+x installDAProxy.bin
   ```
5. Run the console installation using one of the following options:
   - If you have root access to the proxy sever, run the installation by issuing the following command:
     ```
     ./installDAProxy.bin -i console
     ```
   - If you have configured the sudo user account for the proxy server, run the installation by issuing the following command:
     ```
     sudo ./installDAProxy.bin -i console
     ```
6. Follow the instructions in the console.
7. When prompted, specify the following parameters for the proxy server:
   - **Install Set**
     Specify 1 for an installation set including both the proxy server and Consul.
   - **Install Folder**
     Specify where to install the proxy server.

Default: `/opt/CA/daproxy`

- **First DA Host**
  Specify the hostname of the first active Data Aggregator.
- **Second DA Host**
  Specify the hostname of the second inactive Data Aggregator.
- **DA HTTP API Port**
  Specify the port for communication with the Data Aggregator HTTP API.
  Default: 8581
- **Consul Port**
  Specify the port for communication with Consul.
  Default: 8500
- **Choose host IP address for Consul**

  NOTE
  This prompt appears only when multiple public IP addresses are configured.

  Specify the bind address that the Consul agents use to communicate with each other. The Consul agents include the proxy host and both Data Aggregators in the cluster. If prompted for an address, specify an address that the other two hosts in the Consul cluster can reach.

The proxy server is installed.

Uninstall the Proxy Server

If necessary, you can uninstall the proxy server.

Follow these steps:

1. Log in to the proxy server host as the root or sudo user.
2. Issue the following command:
   Proxy_Install_Directory`/daproxy/Uninstall/Uninstall`

The proxy server is uninstalled.

Single Sign-On

Single Sign-On is the authentication scheme for NetOps Portal and all supported data sources. Once they are authenticated to NetOps Portal, users can navigate the console and registered data sources without signing in again.

Enabling the navigation of multiple product interfaces ensures a seamless drilldown experience for operators analyzing performance and status data. For example, if a user logs in to NetOps Portal and follows a drilldown path to the data source interface, that user does not log in again.

NetOps Portal uses a distributed architecture. The Single Sign-On website is automatically installed on every server where a supported data source or NetOps Portal is installed. The distributed architecture lets users log in to data source products by logging in to the servers where these products are running.

Authentication and Security

Single Sign-On provides authentication services to NetOps Portal and supported data sources. It also supports external authentication schemes, such as LDAP and SAML 2.0. This support lets you integrate NetOps Portal and other CA data source products into the same authentication scheme, enterprise-wide.

When a user is required to enter a username and password, the Single Sign-On security auditing feature logs information about who is logging in, and at what time of day. On Linux servers, the log is saved in the following location:

```
[InstallationDirectory]/PerformanceCenter/sso/logs
```

Authentication Methods

The Single Sign-On login page supports user authentication in CA NetOps Portal and in the data source products. Single Sign-On supports the following authentication methods:

- Product authentication, which is based on user accounts
- LDAP
- Security Assertion Markup Language (SAML) 2.0

The CA NetOps Portal administrator can modify settings for an individual instance of Single Sign-On. For example, you can set up LDAP authentication in Single Sign-On. You can also configure optional encryption with Secure Sockets Layer (SSL) or change the default virtual directory.

> **NOTE**
> As a result of the distributed architecture, any updates to the Single Sign-On website affect only those data source products that are running on the same server.

Single Sign-On Configuration Tool

The Single Sign-On Configuration Tool is a command-line application. The application lets administrators adjust the settings for the Single Sign-On website and the associated CA data source products.

> **NOTE**
> The 'Remote Value' option in the Configuration Tool propagates the settings to each registered data source. Use the 'Local Override' option to override the propagated settings on the local server.

The Single Sign-On Configuration Tool was designed to run on Linux systems. However, you can also deploy it on the Windows servers where data sources are installed. If you launch the Configuration Tool from a Windows server, log in as an Administrator on that server.

Use the Single Sign-On Configuration Tool to perform the following tasks:

- Configure data source products to use LDAP authentication.
  All the LDAP settings for each product are updated using this tool. You can also test the current LDAP configuration to verify settings.
- Configure data source products to use SAML 2.0 authentication.
  In addition to using the Configuration Tool, the administrator must also take some steps on the Identity Provider to set up SAML 2.0 authentication.
- Update the Single Sign-On virtual directory that each product references.
  If you added an encryption scheme or you changed the Single Sign-On virtual directory, use this tool to synchronize the data source products. For example, data sources on the modified server need instructions on where to redirect users who do not successfully authenticate.
- Enable communications among servers running CA software products using HTTPS.
  This change affects the Single Sign-On URL scheme and port. The Single Sign-On Configuration Tool lets administrators easily update these values in all the necessary data source products.
- Enable FIPS-compliant encryption and hashing algorithms (where applicable).
  The Single Sign-On configuration tool configures the DX NetOps Performance Management to use FIPS-compliant encryption and hashing algorithms. For more information, see FIPS-Compliant Encryption.

  > **WARNING**
  >
  > DX NetOps Performance Management is not fully FIPS-compliant. This feature is for FIPS-compliant encryption only and does not meet full FIPS compliance.

Data Source Support

CA Single Sign-On supports the following data sources:

- Data Aggregator
- CA Network Flow Analysis
- CA Application Delivery Analysis
- CA UC Monitor

The Single Sign-On Configuration Tool was designed to run on Linux systems. However, you can also deploy it on the Windows servers where data sources are installed. If you launch the Configuration Tool from a Windows server, log in as an Administrator on that server.

You can also run the Configuration Tool on Linux and send configuration instructions to data sources running on Windows by using the Remote Value option.

The Configuration Tool is installed in the following directory location on Linux:

```
[InstallationDirectory]/CA/PerformanceCenter
```

On Windows servers where the data sources are installed, the Configuration Tool is installed in the following directory:

```
[InstallationDirectory]\Portal\SSO\bin\SsoConfig.exe
```

Set Up LDAP Authentication

Single Sign-On provides Lightweight Directory Access Protocol (LDAP) integration, which lets users authenticate to an LDAP server in your environment. Once authenticated, they are mapped to a predefined or a custom user account that the administrator specifies.

The Single Sign-On Configuration Tool lets you precisely specify how the Single Sign-On server connects to the LDAP server. You can also map individual NetOps Portal users to the user accounts that support their workflow while protecting sensitive data.

> **NOTE**
>
> : Changes made in the Single Sign-On Configuration Tool only affect newly created LDAP users. They do not apply to existing LDAP users registered within NetOps Portal.

The LDAP parameters available in the Single Sign-On Configuration Tool let you integrate DX NetOps Performance Management and all registered data sources into an existing authentication scheme. For example, the LDAP server can authorize groups of users who are mapped to a single custom user account in NetOps Portal. The actual account names and LDAP groups can be extensively customized. Search scope parameters let you determine how the directory search is conducted. And you can select the user account properties that are considered when validating users.

Enable LDAP Authentication with No Authentication Mechanism

Use the Single Sign-On Configuration Tool to instruct registered data sources to use the same LDAP scheme to authenticate users. The Single Sign-On Configuration Tool lets you supply parameters that enable the CA server to connect securely to the LDAP server. Using the Configuration Tool, you can also associate users in the LDAP catalog with either predefined or custom user accounts in CA NetOps Portal.

The steps to take to enable LDAP authentication are slightly different if you are using an authentication mechanism such as GSSAPI. Without an authentication mechanism, you must use a service account to bind to the LDAP server. This account requires read and search access to the LDAP server. You must supply the full DN (distinguished name) of the connection user, and you must also enable the User Bind parameter.

Single Sign-On binds to the LDAP server using the credentials that you supply for the Connection User and Connection Password parameters. Then Single Sign-On performs a directory search that is based on the string that you supply for the Search String parameter. The search results include the DN of the user. Single Sign-On performs a second bind to the LDAP server using this DN and password.

> **WARNING**
> In cases where no authentication mechanism is used, we strongly recommend establishing an SSL connection to the LDAP server. Otherwise, the passwords are transmitted to the LDAP server in cleartext.

Follow these steps:

1. Log in to the server where CA NetOps Portal or a CA data source product is installed.
   Log in as root or with the 'sudo' command.
2. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:
   `InstallationDirectory/CA/PerformanceCenter`
   You are prompted to select an option. The available options correspond to CA applications running on the local server.
3. Use the following commands as needed while you are selecting settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
4. Enter 1 to configure CA NetOps Portal.
   You are prompted to select an option.
5. Enter 1 for LDAP Authentication.
   You are prompted to specify the priority.
   The Priority parameter only applies to CA NetOps Portal.
6. Enter one of the following options:
   - **1. Remote Value**
     These settings are propagated to all other CA products and data sources that are registered to this instance of CA NetOps Portal. This includes the Event Manager in CA NetOps Portal, which embeds the URL of CA NetOps Portal. CA NetOps Portal uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this CA NetOps Portal instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of CA NetOps Portal. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.

   > **NOTE**
   >
   > Configure the scheme or port using Remove Value to include the correct CAPC URL in threshold event email messages.
7. Enter one or more of the following properties. When prompted, enter u to update the value and supply a new value:
   - **1. Connection User**
     Defines the user ID (in this case, the user ID of the service account) that the login server uses to connect to the LDAP server. This LDAP username is used to bind to the server.

     > **WARNING**
     > A service account with read and search access to the LDAP server is required for this parameter if you are not using an authentication mechanism, such as GSSAPI.
   - **2. Connection Password**
     Defines the password for the login server to use to connect to the LDAP server.
     Example: If the login server uses a fixed account, enter text like the following example:

```
SomePassword
```

- **3. Search Domain**
  Identifies the LDAP server and port to which CA Single Sign-On connects. Also identifies the location in the directory tree where the search looks for users when verifying user account credentials. If you do not also supply a port number after the server in the string, Port 389 is used.
  Use the following format for the search domain:

  ```
  LDAP://ldap_server:port/path_to_search
  ```

  NOTE
  The search path is *required*.
- **4. Search String**
  Specifies the criteria that are used to locate the correct record for the user. Works with the Search Scope parameter. If only a subset of LDAP users is allowed to log in, the search string can be used to search the record for multiple properties. The value for this parameter can include any valid LDAP search criterion.
  Example:

  ```
  (saMAccountName={0})
  ```
- **5. Search Scope**
  Specifies the criteria that are used to locate the correct record for the user. Used with the Search String parameter. Determines the scope of the search that the LDAP server performs for the user account. Type one of the following values:
  - **onelevel**
    Includes the current directory in the search. Matches objects in the current directory and prevents unexpected matches deeper in the directory.
  - **subtree**
    Includes all subdirectories in the search. Recommended for most installations.
  - **base**
    Limits the search to the base object.
- **6. User Bind**
  Specifies whether to do an additional authentication step (bind) using the distinguished name (DN) and password of the user to validate the supplied credentials.

  WARNING
  This parameter must be set to Enabled if you entered a service account in Steps 1 and 2.

  Default: Disabled.
- **7. Encryption**
  Specifies the authentication mechanism to use when binding a second time to the LDAP server.
  Default: Simple.
  Accepted Values: Simple, GSSAPI, DIGEST-MD5.
- **8. Account User**
  Specifies the CA NetOps Portal default account to which to map validated LDAP users who lack a group membership. Works with the Account Password parameter. If a valid user does not match any group definitions, the user is logged in with the default user ID specified for this parameter.
  To allow all users to log in with their own username, enter:
  - {saMAccountName}
  - {saMAccountName} or {CN}

  NOTE
  The Account User parameter corresponds to a field from the directory entry for this user. Typically, the value matches your search filter.
- **9. Account User Default Clone**
  Specifies a user account to clone if validated LDAP users are members of a group that is not specified for the Group parameter.

Example: Enter 'user' if you want such users to have minimal privileges.

NOTE

An existing user account is required.

- **10. Group**
  Lets you determine the default account handling for selected user accounts or groups of accounts.
  Example: To enable all members of a group to log in using an administrator account, enter:
  ```
  <LDAPGroups><Group searchTag="memberOf" searchString="CN=SEC_All Employees,CN=Users,DC=company,DC=local"
   user="{saMAccountName}" passwd="" userClone="admin"/></LDAPGroups>
  ```
- **11. Timeout**
  Specifies the amount of time that CA NetOps Portal waits while making authorization checks to the LDAP server. When the authorization check times out, users who try to log in are denied access. To view the errors, open the SSOService.log file. The default timeout is 10000.

8. Verify that the LDAP Status is set to Enabled. If the LDAP status is set to Disabled, then authentication uses the internal NetOps Portal user database.
9. Enter q to quit.
   The Configuration Tool closes.

Example Configuration

1. Connection User: CN=********,OU=Role-Based,OU=North America,DC=ca,DC=com [the full DN of the service account]
2. Connection Password: ******* [the password of the service account]
3. Search Domain: LDAP://******.ca.com/DC=ca,DC=com
4. Search String: (sAMAccountName={0})
5. Search Scope: Subtree
6. User Bind: Enabled
7. Encryption: false
8. Account User: {sAMAccountName}
9. Account User Default Clone: user
10. Group: 'All Employees'
11. Krb5ConfigFile: krb5.conf

Encrypt the Connection to the LDAP Server Using GSSAPI

CA Single Sign-On supports encrypted connections using DIGEST-MD5 or GSSAPI. When you use an encrypted connection to the directory server, you do not have to use a service account to bind to the LDAP server (the UserBind parameter that you set in the Single Sign-On Configuration Tool).

To use GSSAPI for encryption, you must change some settings in a configuration file.

Follow these steps:

1. Log in to the server where CA NetOps Portal or a CA data source product is installed.

   NOTE

   If the settings for GSSAPI LDAP are pushed to a data source, configure the **krb** file on the data source system.

   Log in as root or with the 'sudo' command.
2. Change to the following directory:
   ```
   Installation Dir/webapps/sso/Configuration/
   ```
3. Open the krb5.conf file in that directory for editing.

4. Set the following required parameters:

```
[libdefaults]
        default_realm = CA.COM
[realms]
        CA.COM  = {
                kdc = EXAMPLE.CA.COM
                default_domain = CA.COM
}

[domain_realm]
       .CA.COM = CA.COM
}
```

   where:
   - **[libdefaults]**
     Contains default values for the Kerberos V5 library.
   - **default_realm**
     Maps subdomains and domain names to Kerberos realm names. Lets programs determine the realm for a host, based on its fully qualified domain name. In this example, the default realm is CA.COM.
   - **realms**
     Contains information about Kerberos realm names, which describe the location of Kerberos servers and include other realm-specific information.
   - **kdc**
     Is the Kerberos key distribution center to support authentication services. For example, EXAMPLE.CA.COM.
   - **default_domain**
     Is the default IP domain. For example, CA.COM.

     NOTE
     Your Active Directory or LDAP Administrator can probably provide you with a krb5.conf file or help you to create one.
5. Save your changes.
6. Now follow the steps in Enable LDAP Authentication Using an Encryption Mechanism to configure LDAP authentication with CA Single Sign-On.

Enable LDAP Authentication Using an Encryption Mechanism

Use the Single Sign-On Configuration Tool to instruct registered data sources to use the same LDAP scheme to authenticate users. The Single Sign-On Configuration Tool lets you supply parameters that enable the CA server to connect securely to the LDAP server. When you use Digest-MD5 or GSSAPI to encrypt the connection to the LDAP server, a single bind operation -- as the user you specify -- occurs.

Using the Configuration Tool, you can also associate users in the LDAP catalog with either predefined or custom user accounts in CA NetOps Portal.

Follow these steps:

1. Log in to the server where NetOps Portal or a CA data source product is installed.
   Log in as root or with the 'sudo' command.
2. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:

```
InstallationDirectory/CA/PerformanceCenter
```

   You are prompted to select an option. The available options correspond to CA applications running on the local server.
3. Use the following commands as needed while you are selecting settings:

- q (quit)
- b (go back to the previous menu)
- u (update)
- r (reset)

4. Enter 1 to configure CA NetOps Portal.
   You are prompted to select an option.
5. Enter 1 for LDAP Authentication.
   You are prompted to specify the priority.
   The Priority parameter only applies to CA NetOps Portal.
6. Enter one of the following options:
   - **1. Remote Value**
     These settings are propagated to all other CA products and data sources that are registered to this instance of CA NetOps Portal. This includes the Event Manager in CA NetOps Portal, which embeds the URL of CA NetOps Portal. CA NetOps Portal uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this CA NetOps Portal instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of CA NetOps Portal. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.

   NOTE

   Configure the scheme or port using Remove Value to include the correct CAPC URL in threshold event email messages.
7. Enter one or more of the following properties. When prompted, enter u to update the value and supply a new value:
   - **1. Connection User**
     Defines the user ID that the login server uses to connect to the LDAP server. This LDAP user name is used to bind to the server. A service account is not typically required for a connection that uses an authentication mechanism, such as GSSAPI.
     Example: If the login server uses a fixed account, enter text with the following syntax:
     ```
     CN=The User,cn=Users,dc=domain,dc=com
     ```
     Or you can enter the following value because the connection is using an authentication mechanism:
     ```
     {0}
     ```
     Complex configurations need the user principal name to identify the user. Supply '{0}' and use their email address as the domain name. For example:
     ```
     {0}@domain.com
     ```
     The LDAP server typically does not require a full DN for an encrypted connection.

     NOTE
     For security reasons, do not make the connection user a static account. The LDAP authentication only checks the password when binding to the server. If you use a static account, any user that exists in the LDAP tree is able to log in with any password.
   - **2. Connection Password**
     Defines the password for the login server to use to connect to the LDAP server.
     Example: If the login server uses a fixed account, enter text like the following example:
     ```
     SomePassword
     ```
     Or you can enter the following value because the connection is using an authentication mechanism:
     ```
     {1}
     ```
   - **3. Search Domain**

Identifies the LDAP server and port to which CA Single Sign-On connects. Also identifies the location in the directory tree where the search looks for users when verifying user account credentials. If you do not also supply a port number after the server in the string, Port 389 is used.
Use the following format for the search domain:

```
LDAP://ldap_server:port/path_to_search
```

NOTE
The search path is *required*.

- **4. Search String**
  Specifies the criteria that are used to locate the correct user in the directory. Works with the Search Scope parameter. If only a subset of LDAP users is allowed to log in, the search string can be used to search a record for multiple properties. The value for this parameter can include any valid LDAP search criterion.
  Example:

```
(saMAccountName={0})
```

- **5. Search Scope**
  Specifies the criteria that are used to locate the correct record for the user. Used with the Search String parameter. Determines the scope of the search that the LDAP server performs for the user account. Type one of the following values:
  - **onelevel**
    Includes the current directory in the search. Matches objects in the current directory and prevents unexpected matches deeper in the directory.
  - **subtree**
    Includes all subdirectories in the search. Recommended for most installations.
  - **base**
    Limits the search to the base object.
- **6. User Bind**
  Specifies whether to do an additional authentication step (bind) using the distinguished name (DN) and password of the user to validate the supplied credentials.
  Default: Disabled. This value is acceptable with an encrypted connection.
- **7. Encryption**
  Specifies the authentication mechanism to use when binding again to the LDAP server.
  In this case (that is, using an authentication mechanism), enter 'GSSAPI' or 'DIGEST-MD5', based on the mechanisms of your LDAP server.
  Default: Simple.
  Accepted Values: Simple, GSSAPI, DIGEST-MD5.
- **8. Account User**
  Specifies the CA NetOps Portal default account to which to map validated LDAP users who lack a group membership. Works with the Account Password parameter. If a valid user does not match any group definitions, the user is logged in with the default user ID specified for this parameter.
  To allow all users to log in with their own username, enter:
  - {saMAccountName}
  - {saMAccountName} or {CN}

  NOTE
  The Account User parameter corresponds to a field from the directory entry for this user. Typically, the value matches your search filter.
- **9. Account User Default Clone**
  Specifies a user account to clone if validated LDAP users are members of a group that is not specified for the Groups parameter.
  Example: Enter 'user' if you want such users to have minimal privileges.

NOTE

An existing user account is required.

- **10. Group**
  Lets you determine the default account handling for selected user accounts or groups of accounts.
  Example: To enable all members of a group to log in using an administrator account, enter:
  ```
  <LDAPGroups><Group searchTag="memberOf" searchString="CN=SEC_All Employees,CN=Users,DC=company,DC=local"
   user="{saMAccountName}" passwd="" userClone="admin"/></LDAPGroups>
  ```
- **11. Krb5ConfigFile**
  Configure the **krb** file location.

NOTE

If another data source, such as Network Flow Analysis or CA Application Delivery Analysis, is getting the LDAP settings, configure the **krb** file location on the data source. Use a local override with the Single Sign-On Configuration Tool on the data source system.

8. Verify that the LDAP Status is set to Enabled. If the LDAP status is set to Disabled, then authentication uses the internal NetOps Portal user database.
9. Enter q to quit.
   The Configuration Tool closes.

Example Configuration

SSO Configuration/CA NetOps Portal/LDAP Authentication/Remote Value:

1. Connection User: {0}
2. Connection Password: {1}
3. Search Domain: LDAP://******.ca.com/DC=ca,DC=com
4. Search String: (sAMAccountName={0})
5. Search Scope: Subtree
6. User Bind: Disabled
7. Encryption: DIGEST-MD5
8. Account User: {sAMAccountName}
9. Account User Default Clone: user
10. Group: 'All Employees'
11. Krb5ConfigFile: /opt/CA/PerformanceCenter/sso/webapps/sso/configuration/krb5.conf

Enable LDAPS Authentication

Use the Single Sign-On Configuration Tool to instruct registered data sources to use LDAP over SSL (LDAPS) for secure user authentication. By default, LDAP traffic is transmitted unsecured. Enable LDAPS by installing a certificate from a certification authority (CA). With CA Single Sign-On, you must import your certificate into the Java trusted keystore.

The Single Sign-On Configuration Tool lets you supply parameters that enable the CA server to connect securely to the LDAP server. Using the Configuration Tool, you can also associate users in the LDAP catalog with either predefined or custom user accounts in CA NetOps Portal.

Follow these steps:

1. Log in to the server where CA NetOps Portal or a CA data source product is installed.
   Log in as root or with the 'sudo' command.
2. Follow the instructions in the topic titled Import the LDAP Certificate to obtain your certificate and import it into the Java keystore.
3. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:

```
InstallationDirectory/CA/PerformanceCenter
```

You are prompted to select an option. The available options correspond to CA applications running on the local server.

4. Use the following commands as needed while you are selecting settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
5. Enter 1 to configure CA NetOps Portal.
   You are prompted to select an option.
6. Enter 1 for LDAP Authentication.
   You are prompted to specify the priority.
   The Priority parameter only applies to CA NetOps Portal.
7. Enter one of the following options:
   - **1. Remote Value**These settings are propagated to all other CA products and data sources that are registered to this instance of CA NetOps Portal. This includes the Event Manager in CA NetOps Portal, which embeds the URL of CA NetOps Portal. CA NetOps Portal uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this CA NetOps Portal instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of CA NetOps Portal. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.

   NOTE

   Configure the scheme or port using Remove Value to include the correct CAPC URL in threshold event email messages.
8. Enter one or more of the following properties. When prompted, enter u to update the value and supply a new value:
   - **1. Connection User**
     Defines the user ID that the login server uses to connect to the LDAP server. This LDAP user name is used to bind to the server. A service account is not typically required for a connection that uses an authentication mechanism, such as GSSAPI.
     Example: If the login server uses a fixed account, enter text with the following syntax:

     ```
     CN=The User,cn=Users,dc=domain,dc=com
     ```

     Or you can enter the following value because the connection is using an authentication mechanism:

     ```
     {0}
     ```

     Complex configurations need the user principal name to identify the user. Supply '{0}' and use their email address as the domain name. For example:

     ```
     {0}@domain.com
     ```

     The LDAP server typically does not require a full DN for an encrypted connection.

     NOTE
     For security reasons, do not make the connection user a static account. The LDAP authentication only checks the password when binding to the server. If you use a static account, any user that exists in the LDAP tree is able to log in with any password.
   - **2. Connection Password**
     Defines the password for the login server to use to connect to the LDAP server.
     Example: If the login server uses a fixed account, enter text like the following example:

     ```
     SomePassword
     ```

     Or you can enter the following value because the connection is using an authentication mechanism:

```
{1}
```

- **3. Search Domain**
  Identifies the LDAP server and port to which CA Single Sign-On connects. Also identifies the location in the directory tree where the search looks for users when verifying user account credentials. If you do not also supply a port number after the server in the string, Port 389 is used.
  Use the following format for the search domain:

  ```
  LDAPS://ldap_server:port/path_to_search
  ```

  NOTE
  The search path is *required*.

  To establish an SSL connection to the LDAP server, use 636 or another SSL connection port for your LDAP server:

  ```
  LDAPS://LDAP Server:636/OU=Users,OU=North America,DC=ca,DC=com
  ```

- **4. Search String**
  Specifies the criteria that are used to locate the correct user in the directory. Works with the Search Scope parameter. If only a subset of LDAP users is allowed to log in, the search string can be used to search a record for multiple properties. The value for this parameter can include any valid LDAP search criterion.
  Example:

  ```
  (saMAccountName={0})
  ```

- **5. Search Scope**
  Specifies the criteria that are used to locate the correct record for the user. Used with the Search String parameter. Determines the scope of the search that the LDAP server performs for the user account. Type one of the following values:
  - **onelevel**
    Includes the current directory in the search. Matches objects in the current directory and prevents unexpected matches deeper in the directory.
  - **subtree**
    Includes all subdirectories in the search. Recommended for most installations.
  - **base**
    Limits the search to the base object.
- **6. User Bind**
  Specifies whether to do an additional authentication step (bind) using the distinguished name (DN) and password of the user to validate the supplied credentials.
  Default: Disabled. This value is acceptable with an encrypted connection.
- **7. Encryption**
  (Optional) Specifies the authentication mechanism to use when binding again to the LDAP server.
  The default (Simple authentication) is acceptable with LDAPS.
- **8. Account User**
  Specifies the CA NetOps Portal default account to which to map validated LDAP users who lack a group membership. Works with the Account Password parameter. If a valid user does not match any group definitions, the user is logged in with the default user ID specified for this parameter.
  To allow all users to log in with their own username, enter:
  - {saMAccountName}
  - {saMAccountName} or {CN}

  NOTE
  The Account User parameter corresponds to a field from the directory entry for this user. Typically, the value matches your search filter.
- **9. Account User Default Clone**
  Specifies a user account to clone if validated LDAP users are members of a group that is not specified for the Groups parameter.
  Example: Enter 'user' if you want such users to have minimal privileges.

NOTE

: An existing user account is required.

- **10. Group**Lets you determine the default account handling for selected user accounts or groups of accounts.
  Example: To enable all members of a group to log in using an administrator account, enter:
  ```
  <LDAPGroups><Group searchTag="memberOf" searchString="CN=SEC_All Employees,CN=Users,DC=company,DC=local"
   user="{saMAccountName}" passwd="" userClone="admin"/></LDAPGroups>
  ```

9. Enter q to quit.
   The Configuration Tool closes.
10. Restart all NetOps Portal services:
    ```
    service caperfcenter_console restart
    service caperfcenter_devicemanager restart
    service caperfcenter_eventmanager restart
    service caperfcenter_sso restart
    ```

Example Configuration

1. SSO Configuration/CA NetOps Portal/LDAP Authentication/Remote Value
2. Connection User: {0}
3. Connection Password: {1}
4. Search Domain: LDAPS://******.ca.com:636/OU=Users,OU=North America,DC=ca,DC=com
5. Search String: (sAMAccountName={0})
6. Search Scope: Subtree
7. User Bind: Disabled
8. Encryption: Simple
9. Account User: {sAMAccountName}
10. Account User Default Clone: user
11. Group: 'All Employees'
12. Krb5ConfigFile: krb5.conf

Import the LDAP Certificate

To run with LDAPS, import an LDAP certificate into the Java keystore.

To generate an SSL certificate, use the keytool command. Import a certificate from a Certificate Authority and install it in the keystore.

Follow these steps:

1. Obtain the certificate from the LDAP server administrator.
2. Determine whether the root Certificate Authority certificate is part of the default java trusted authorities:
   ```
   keytool -list -v -keystore InstallDirectory/jre/lib/security/cacerts -
   storepass cacertspassword
   ```

   - ***cacertspassword***
     Specify the password for the Certificate Authority keystore.

     NOTE
     The default password for the Certificate Authority keystore is **changeit**.
3. Import the LDAP, intermediate, or root certificates into the java trusted certificate keystore using the following steps for each certificate:

```
keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts -
storepass cacertspassword -alias alias_name -file filename.cer
```

- ***cacertspassword***
  Specify the password for the Certificate Authority keystore.

  NOTE
  The default password for the Certificate Authority keystore is **changeit**.
- ***alias_name***
  Specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
- ***filename* .cer**
  Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
  Example: /tmp/capcCert.cer

4. Create a backup of the cacerts file.
5. (Optional) Change the password of the java trusted certificates keystore:
   ```
   keytool -storepasswd -keystore installDirectory/
   jre/lib/security/cacerts
   ```
6. Verify that your imported certificate is available:
   ```
   keytool -list -keystore installDirectory/jre/
   lib/security/cacert
   ```

Validate LDAP Settings

The Single Sign-On Configuration Tool lets you test the LDAP settings that you have supplied. You can verify that LDAP authentication is set up correctly. An LDAP test script prompts you to specify a username and password combination to test, using the current settings for LDAP authentication. If you have not already used the Configuration Tool to change LDAP authentication settings, the defaults are used.

Follow these steps:

1. Log in to the server where CA NetOps Portal or a supported data source product is installed.
   Log in as root or with the 'sudo' command.
2. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:
   ```
   InstallationDirectory/CA/PerformanceCenter
   ```
   You are prompted to select an option. The available options correspond to CA applications running on the local server.
3. Use the following commands as needed while you are selecting settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
4. Enter 1 to configure CA NetOps Portal.
   You are prompted to select an option.
5. Enter 5 for the Test LDAP option.
   The prompt asks you to enter a username.
6. Enter a username and a password that you know can authenticate using LDAP.
   Single Sign-On attempts to use the parameters you supplied when you set up LDAP authentication to connect to the LDAP server and validate the user account. If the test succeeds, numerous steps are logged.
   A message reports whether the authentication succeeded or failed.
7. Enter q to quit.

Set Up SAML 2.0 Support

The Security Assertion Markup Language (SAML) is a security protocol that is based on XML. SAML allows the exchange of security assertions about a subject, such as a person or a computer, that is requesting access to a secure domain. Assertions include whether the subject can access certain resources, and whether an external data source, such as a policy store, is used.

A typical use of SAML-based authentication is in a federated environment, such as cloud-based services that require an extra layer of security in the corporate network. But any SAML implementation involves at least three component roles:

- **Relying Party**
  Uses identity information that is stored on another server to let authorized users gain access to a system. Also referred to as the 'service provider.' CA NetOps Portal has this role when Single Sign-On is configured to use SAML for authentication.
- **Asserting Party**
  Stores identity or security information and provides it when requested for authentication purposes. The SAML term for this component is the *Identity Provider* or *IdP*. The CA SiteMinder server has this role, for example.
- **Subject**
  Is the user (or computer) associated with the identity information that is stored by the IdP.

SAML 2.0 Support in Single Sign-On

CA Single Sign-On supports authentication with Security Assertion Markup Language (SAML) 2.0. A Single Sign-On service can accept and decode SAML 2.0 tokens and can present them to authentication agents that conform to the SAML standard.

Single Sign-On support for SAML 2.0 includes support for single logout. With this support, a user who is logged in to multiple user interfaces can log out of all of them simultaneously. For example, a user who logs in to CA NetOps Portal and later drills down into flow data in CA Network Flow Analysis can log out of one interface and be logged out of the other interface automatically.

Single Sign-On uses a standards-based SAML 2.0 library. As a result, it potentially supports many more products that rely on the SAML 2.0 standards. However, the following CA products are the only Identity Providers that we have tested with CA Single Sign-On:

- CA SiteMinder Federation Manager
- CA Arcot A-OK™ On-Demand

In a SAML environment, you can select from multiple authentication methods. CA NetOps Portal users can log in using the typical ('Product') authentication method in Single Sign-On, or they can use a SAML token. The Product method is enabled by default for all active user accounts. Users access the CA NetOps Portal user interface using the standard URL for CA Single Sign-On.

To let users authenticate using SAML 2.0, the administrator must change some Single Sign-On settings using the Configuration Tool. The administrator must also enable External Authentication for all user accounts, and for all registered data sources that support SAML 2.0.

Not all CA data source products support SAML 2.0. If you configure SAML 2.0 for external authentication in Single Sign-On and register a data source that lacks SAML support, CA NetOps Portal users must reauthenticate when they drill down into that data source.

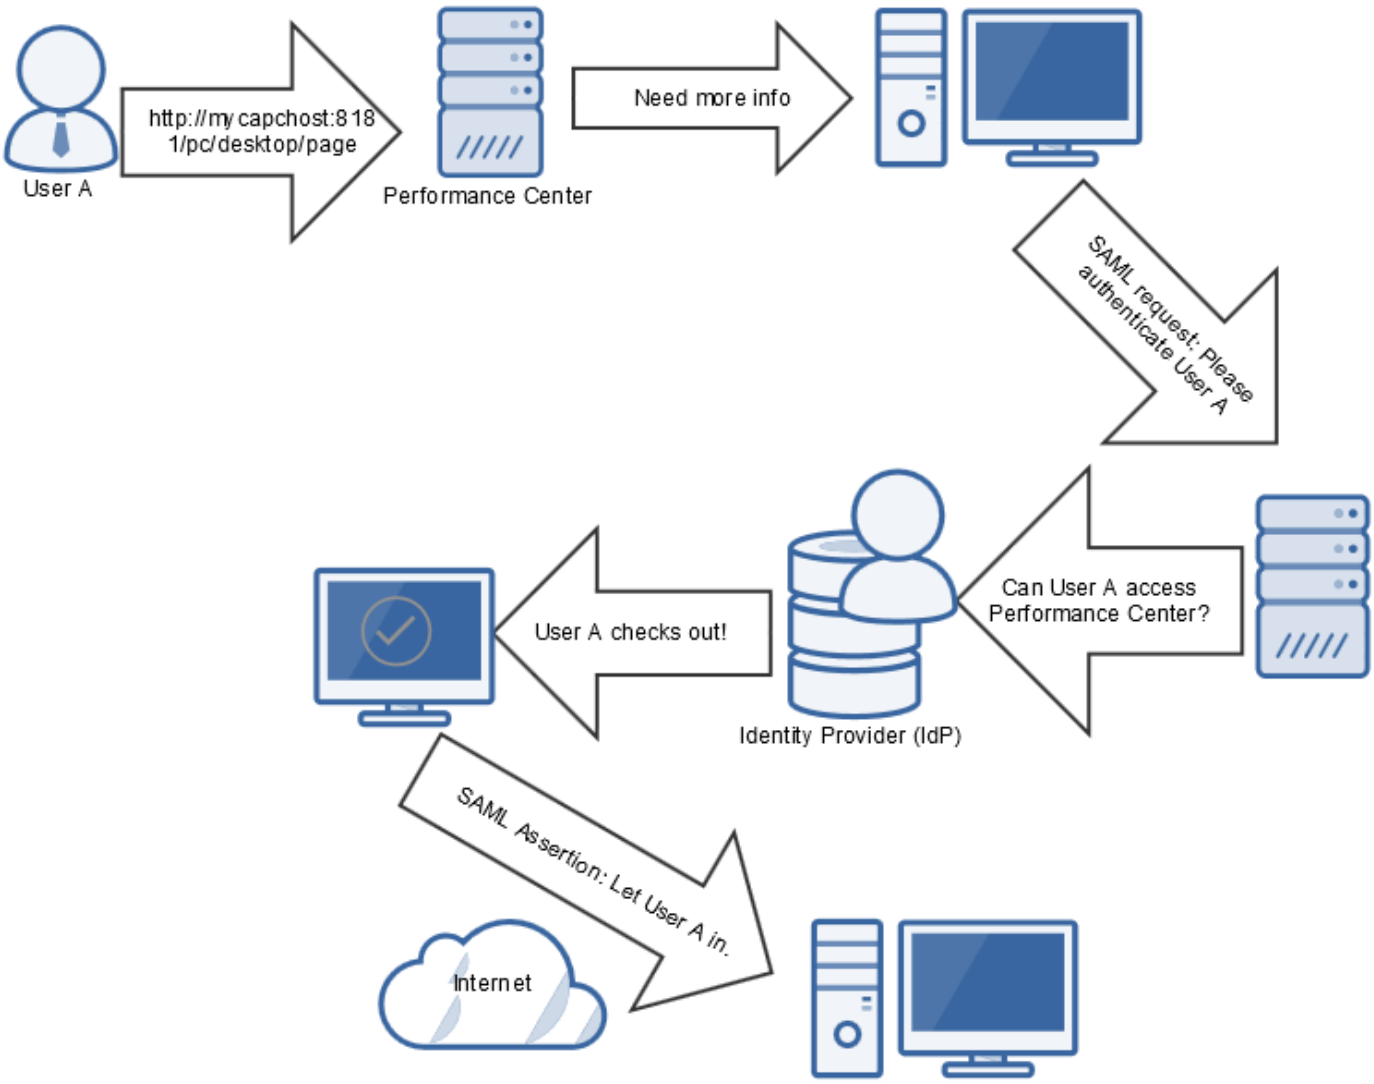
About Single Sign-On Support for SAML 2.0

The NetOps Portal authentication process that uses Single Sign-On differs from authentication that takes advantage of SAML 2.0 support. With SAML 2.0 authentication, users do not see the CA NetOps Portal Login page. They are instead

redirected to an interface that the IdP provides. For all other supported authentication methods, Single Sign-On provides the login page.

The following diagram illustrates the SAML 2.0 authentication process with Single Sign-On, CA NetOps Portal, and an IdP that supports the SAML 2.0 standard, such as CA SiteMinder:

Figure 63: SSO



The following generic process describes how CA NetOps Portal supports SAML 2.0 authentication. Implementation-specific options, such as digitally signed certificates and transport binding, have been omitted:

1. A user attempts to access CA NetOps Portal, by navigating to http://mycapchost:8181/pc/desktop/page, for example.
2. CA NetOps Portal responds with a SAML request for authentication from the Identity Provider (IdP).
3. The browser processes the request and contacts the authentication software running on the IdP server.
4. The IdP determines whether the user has an existing logon security context -- whether the user is already logged on.
5. If the user is not logged on, the IdP authenticates the user with an implementation-specific method.
   For example, the IdP might interact with the browser to challenge the user to provide credentials. This stage of the authentication is irrelevant to CA Single Sign-On.

6. The IdP builds and sends a SAML assertion representing the user's logon security context to the browser.
   The assertion includes a required attribute, subjectNameId, and an optional attribute, ClonedUser.
   The value of subjectNameId corresponds to the authorized user.
   You can include the name of the cloned user account in the assertion. This attribute defines the user account to which authorized SAML users are mapped.
7. The browser sends the SAML assertion to CA NetOps Portal.
8. CA NetOps Portal obtains the assertion and processes it.
9. If the assertion is valid, CA NetOps Portal establishes a session for the user. The browser redirects to the target page, the Home dashboard page for the user.

How to Set Up SAML Authentication

To enable SAML 2.0 authentication in Single Sign-On, the administrator performs the following procedures:

1. Following the guidelines specific to the Identity Provider (IdP), create a metadata file that establishes the agreement between the IdP and Single Sign-On.
   For more information, see Prepare the IdP Agreement.
2. (Optional) Create a properties file to enable digital signatures and encryption for communications between the IdP and servers running CA software.
   For more information, see Preparing the Security Properties File.
3. Use the Single Sign-On Configuration Tool to set parameters for SAML Authentication.
   For more information, see Configure SAML 2.0 Support in Single Sign-On.
4. Set parameters on the IdP server. For example, add all data source product websites that support SAML to the list of trusted sites.
   For more information, see Configure the IdP.
5. Update user accounts in CA NetOps Portal Administration to add an instruction to use external authentication.
   For more information, see Complete SAML 2.0 Setup.

Prepare the IdP Agreement

A metadata file in XML format is required to establish the agreement between the IdP and the Service Provider. In this case, CA NetOps Portal and all registered data sources that support SAML 2.0 require this agreement. The metadata file describes the IdP and contains information about the profiles it supports. This file also contains data about the services that it requires from the Service Provider.

Single Sign-On can import this file to set up the relationship with the IdP.

Some types of IdP, such as CA SiteMinder, provide utilities to help you create these files and export them. Or they create the agreement automatically, based on the parameters you set.

Consult the documentation for your IdP to perform this task.

Preparing the Security Properties File

To use encryption and digital certificates for communications between NetOps Portal and the IdP, a properties file is required. In this file, you specify the certificate to use for signing and encryption and other parameters to enable the encryption.

The SAML properties file is saved in the Single Sign-On configuration directory:

```
/opt/CA/PerformanceCenter/sso/webapps/sso/configuration
```

For example, a file like this is required:

```
/opt/CA/PerformanceCenter/sso/webapps/sso/configuration/
```

```
saml.properties
```

The properties file must include the following parameters:

- Directory location and filename of the signing certificate. For more information, see Set Up SAML Certificates.
- Verification certificate alias and password to access the certificate.
- Hostname of the CA NetOps Portal server.
- Directory location and filename of the agreement that you exported from the IdP.

Here is an example of the syntax:

```
# Location of the certificate used for signing SAML documents
saml.sp.certificate.location=/opt/CA/saml2configuration/[Certificate filename]
saml.sp.certificate.password=[password]
saml.sp.certificate.alias=[alias]

saml.sp.metadata.hostname=[Full Hostname of <npc> server]
saml.sp.metadata.entityId=[Name of the <npc> server without IP domain]
saml.sp.metadata.organizationName=[Name of your organization]
saml.sp.metadata.contactPerson=[First and last name of administrator]
saml.sp.metadata.email=[Email address of contact person]

# Location of the metadata file for the Login Site
saml.idp.metadata.file=/opt/CA/saml2configuration/[Filename].xml
```

Whenever you modify the saml.properties file, export the metadata file (which establishes the agreement with the IdP) again. For more information, see Configure SAML 2.0 Support in Single Sign-On. You must also restart Single Sign-On.

Set Up SAML Certificates

To configure the single sign-on website to use SAML over SSL, obtain and install a private key and an associated public certificate. SAML can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed. The procedures are typically specific to an organization and the policies of its security team. However, these procedures provide some guidance.

Select the appropriate procedure for your situation:

> **NOTE**
> For more information about the keytool command, see the Java documentation on the Oracle website.

Generate and Import a Certificate

To generate an SAML certificate, use the keytool command. Generate a self-signed certificate and install it in the keystore.

Follow these steps:

1. Change the directory:
   ```
   textcd InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration
   ```

   > **NOTE**
   > /opt/CA is the default installation directory.
2. If a keystore file exists, rename the existing keystore file to create a backup of it:
   ```
   textmv InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration/
   keystore InstallDirectory/PerformanceCenter/PerformanceCenter/sso/webapps/sso/
   configuration/keystore.bak
   ```

WARNING
Move the old keystore. If you do not, an error appears in later steps: "Keystore was tampered with, or password was incorrect."

3. Generate a private key and a public, self-signed certificate:
   `keytool -genkeypair -keystore keystore_file.ks -storepass password -keyalg RSA -keysize 2048 -keypass password -alias alias_name`

   Note your entries for the following variables:
   – ***keystore_file.*** **ks**
   Specify the name of the keystore file to create
   – ***password***
   Specify the password for the keystore and self-signed certificate. Specify a secure password.
   – ***alias_name***
   Specify an alias that can be used to refer to the keystore entry that is created for the self-signed certificate.

   NOTE
   N ote: When you are prompted for your first and last name, provide the fully qualified hostname of the server.
4. Proceed through the security prompt questions and confirm your responses.
   Your self-signed SAML certificate is generated and installed in the keystore.
5. Configure the `saml.properties` with the keystore location and filename, keystore password, and alias. For more informarion, see Preparing the Security Properties File.

Convert a Self-Signed Certificate to a Certification Authority SAML Certificate

A self-signed certificate is signed by the same entity whose identity it certifies rather than a Certification Authority. Therefore, a self-signed certificate is not trusted. The following procedure explains how to convert the self-signed certificate to a certificate that a trusted Certification Authority has signed.

Follow these steps:

1. Change the directory:
   `cd InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration`

   NOTE
   /opt/CA is the default installation directory.
2. Export a certificate signature request:
   `keytool -certreq -keystore keystore_file.ks -storepass password -alias alias_name -keypass password -file RequestFileName.csr`

   – ***keystore_file.ks***
   Specify the same keystore file name previously created.
   – ***password***
   Specify the same password when creating the self-signed certificate.
   – ***alias_name***
   Specify the same alias when creating the self-signed certificate.
   – ***RequestFileName*****.csr**
   Specify the path and file name of the exported signature request.
3. Send the resulting file (***RequestFileName*** .csr) to a qualified signing authority with any other requested information.

The Certificate Authority sends you a signed certificate (***SignedCert*** .cer). They might also provide a root Certificate Authority certificate (***RootCA*** .cer) to authenticate the signed certificate.

4. (Optional) Determine whether the root Certificate Authority certificate is part of the default java trusted authorities:

   ```
   keytool -list -v -keystore InstallDirectory/jre/lib/security/cacerts -
   storepass password
   ```

   – ***password***
   Specify the same password when creating the self-signed certificate.

   NOTE
   The default password for the Certificate Authority keystore is **changeit**.
5. (Optional) Search the output for the Certificate Authority that signed your certificate. If the Certificate Authority is not listed, add it to the list of trusted authorities:

   ```
   keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts -
   storepass cacertspassword -alias alias_name -file RootCA.cer
   ```

   – ***cacertspassword*** Specify the password for the Certificate Authority keystore.
   – ***alias_name***
   Specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
   – ***RootCA*** **.cer**
   Specify the filename of the root certificate.

   NOTE
   Import the root certificate and any intermediate certificates between the certificate authority root certificate and the certificates authorities signed certificate.
6. Import the signed certificate:

   ```
   keytool -importcert -trustcacerts -keystore keystore_file.ks -storepass password -
   alias alias_name -keypass password -file SignedCert.cer
   ```

   – ***password***
   Specify the same password when creating the self-signed certificate.
   – ***alias_name***
   Specify the same alias when creating the self-signed certificate.
   – ***SignedCert*****.cer**
   Specify the certificate file from the Certificate Authority.
7. Confirm that you trust the certificate.
8. Validate the contents of the keystore:

   ```
   keytool -list -keystore InstallDirectory/PerformanceCenter/sso/webapps/sso/
   configuration/keystore_file.ks
   ```

   The single certificate that you imported appears in the list.
   The Certificate Authority SAML certificate replaces your self-signed certificate in the keystore.
9. Update the certificate in the IdP with the same certificate that you just imported.

Import a Key and an Existing Certificate

You can use a private key and public certificate (a self-signed or a Certificate Authority certificate) from a different source. For example, your security team provides an SAML certificate that is customized for your organization. To use this SAML certificate, import the private key and the signed certificate.

Follow these steps:

1. Change the directory:
   ```
   cd InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration
   ```

   NOTE
   /opt/CA is the default installation directory.
2. If a keystore file exists, rename the existing keystore file to create a backup of it:
   ```
   textmv InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration/
   keystore InstallDirectory/PerformanceCenter/sso/webapps/sso/configuration/
   keystore.bak
   ```

   WARNING
   Move the old keystore. If you do not, an error appears in later steps: "Keystore was tampered with, or password was incorrect."
3. Create a PKCS#12 keystore from the private key and certificate:
   ```
   openssl pkcs12 -export -in certificate.pem -inkey privatekey.pem -name alias_name -
   out keystore.pkcs12
   ```

   - ***certificate*.pem**
     Specify the certificate that is provided to you.
   - ***privatekey*.pem**
     Specify the private key that is provided to you.
   - **alias_name**
     Specify an alias that can be used to refer to the keystore entry that is created for the certificate
   - ***keystore*.pkcs12**
     Specify the keystore to create to store the keys provided.

     NOTE
     This command works on Linux only.
4. Import the key and certificate into the CA NetOps Portal keystore:
   ```
   keytool -importkeystore -destkeystore keystore_file.ks -deststorepass password
   -srckeystore keystore.pkcs12 -srcstoretype pkcs12 -srcalias src_alias_name -
   destalias dest_alias_name -destkeypass password
   ```

   - ***keystore_file.* ks** Specify the name of the keystore file to create.
   - ***password*** Specify the password for the keystore and imported certificate. Specify a secure password.
   - ***keystore.* pkcs12** Specify the PKCS#12 keystore previously created.
   - ***src_alias_name*** Specify the alias_name when importing the private key and certificate.
   - ***dest_alias_name*** Specify an alias that can be used to refer to the keystore entry that is created for the imported certificate.

   Your existing SAML certificate is imported into the keystore.
5. Determine whether the certificate includes a chain terminating at a certificate in the keystore. If the certificate is missing, import it into the Java keystore.
   ```
   keytool -printcert -file filename
   ```

   - ***filename*** specifies the name of the certificate.
6. Update the certificate in the IdP with the same certificate that you just imported.

Configure SAML 2.0 Support in Single Sign-On

The administrator uses the Single Sign-On Configuration Tool to set parameters for SAML authentication. Take these steps on all servers with a data source that has users who authenticate using SAML 2.0.

> **NOTE**
>
> : Multiple authentication schemes can be in use simultaneously. For example, users of a CA Network Flow Analysis data source can use LDAP to log in, while users of DX NetOps Performance Management are using SAML 2.0.

Follow these steps:

1. Log in to the server where CA NetOps Portal or a CA data source product is installed.
   Log in as root or with the 'sudo' command.
2. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:
   `InstallationDirectory/CA/PerformanceCenter`
   You are prompted to select an option. The available options correspond to CA applications running on the local server.
3. Use the following commands as needed while you are selecting settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
4. Enter the value that corresponds to the data source that you want to configure. For example, enter 1 to configure CA NetOps Portal.
   You are prompted to select an option.
5. Enter 2 for SAML Authentication.
   You are prompted to specify the priority.
   The Priority parameter only applies to CA NetOps Portal.
6. Enter one of the following options:
   - **1. Remote Value**These settings are propagated to all other CA products and data sources that are registered to this instance of CA NetOps Portal. This includes the Event Manager in CA NetOps Portal, which embeds the URL of CA NetOps Portal. CA NetOps Portal uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this CA NetOps Portal instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of CA NetOps Portal. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.
   To supply values for the SAML2 properties, enter u to update the value and then enter a new value.

   > **NOTE**
   >
   > Configure the scheme or port using Remove Value to include the correct CAPC URL in threshold event email messages.
7. Enter 1 to select the 'Enable SAML2 Authentication' parameter.
   You are prompted to select an option.
8. Enter u to change the value, and enter 1 to enable SAML 2.0 authentication.
9. Enter 2 to set the 'Clone Default User Accounts' parameter.
   - **2. Clone Default User Accounts**
     Defines the user account to which authorized SAML users are mapped. The role and product privileges that are associated with the user account you specify are applied to all users who successfully authenticate.
     Default: Blank.
     Example: Enter 'user' if you want all users to log in with user-level privileges.

NOTE

An existing user account is required.

The user accounts configured on the IdP are sent to CA NetOps Portal when the agreement is established. They appear in the User List on the Manage Users Admin page, where they can be edited.

10. Enter 3 to enable security parameters.
    - **3. SAML2 Signature and Encryption Enabled**Enables security and encryption for communications between CA NetOps Portal and the IdP.**Default**: Disabled
11. You are prompted to choose an option.
12. Enter u to change the value, and enter 1 to enable it.

    NOTE
    This setting must match the setting on the IdP.
13. Enter 4 to enable automatic reauthentication.
    - **4. SAML2 Auto-Reauthentication**Specifies whether the system keeps the IdP session for the user active. Enable this parameter to allow DX NetOps Performance Management to perform a passive reauthentication ('auto-reauthentication').
      The next parameter lets you set the duration of the timeout period.**Default**: Disabled.
14. Enter u to change the value, and enter 1 to enable it.
15. Enter 5 to set the reauthentication timeout period.
    - **5. Auto-Reauthentication Time Period**Specifies the period of time before a passive reauthentication is performed. If the 'SAML2 Auto-Reauthentication' parameter is disabled, this parameter is ignored.
      Default: None.
16. Enter u to change the value, and enter a new value.
17. Enter b twice to go back to the initial prompt.
18. Enter 6 to export the metadata file that establishes the agreement with the IdP.The metadata file supplies the identity provider with the parameters to use when authenticating users.
19. You are asked to supply a directory path and filename.
20. Enter the filename. For example, enter the following:

    ```
    /tmp/CAPCMetadata.xml
    ```

    The file is generated automatically, based on the settings you selected in the Configuration Tool.
21. You see a printout of the XML if the export operation succeeds. If the operation fails, you see an error message.
22. Enter q to quit.The Configuration Tool closes.

Configure the IdP

To use SAML 2.0 for user authentication in NetOps Portal, set the appropriate parameters on the identity provider (IdP). Any IdP that supports the SAML 2.0 standard should work, but CA has tested only CA SiteMinder.

You can manually configure the IdP, or you can import the IdP agreement from the Single Sign-on server.

Manually Configure the IdP

Follow these steps:

1. Enable the SAML2 authentication mode on the IdP.
2. Provide a URL for the assertion consumer service, which is running on the servers where Single Sign-On is installed. For example:

   ```
   http://MyServerName:8381/sso/saml2/UserAssertionService
   ```

where 8381 is the port that Single Sign-On uses.

3. Set the binding method to 'HTTP-Redirect'.

   NOTE
   HTTP Redirect is the only binding method that Single Sign-On supports.

4. Provide URLs for the single logout service.
   The logout service and the response location are both required. These services are running on the server where Single Sign-On is installed.
   Use the following examples:

   ```
   http://MyServerName:8381/sso/saml2/LogoutService
   http://MyServerName:8381/sso/saml2/LogoutServiceResponse
   ```

5. Add all data source product websites that support SAML 2.0 to the list of trusted sites.
   This step can involve adding these websites to a list of federation partnership entities.
6. (*Optional*) Verify digital signature and encryption settings. You must also configure these settings in Single Sign-On.

Import the IdP Agreement File

Follow these steps:

1. Import the IdP agreement file from its location on the Single Sign-On server.
   You exported this file after you completed other setup steps using the Single Sign-On Configuration Tool. For more information, see Configure SAML Support in Single Sign-On.
2. Add all data source product websites that support SAML 2.0 to the list of trusted sites.
   This step can involve adding these websites to a list of federation partnership entities.
3. (*Optional*) Verify digital signature and encryption settings. You must also configure these settings in Single Sign-On.

Troubleshooting

Problem:

You see the following error message after configuring SAML:

```
RelayState is either null or a blank string. RelayState must be set for SSO to work correctly.
Invalid syntax, RelayState=<value>
RelayState does not have parameter SsoRedirectUrl, RelayState=<value>
```

Reason:

Some IdPs do not return the RelayState= value that CA NetOps Portal sends to the IdP during authentication verification.

Solution:

Manually configure RelayState for your IdP. Use the following syntax:

```
SsoProductCode=pc&SsoRedirectUrl=http://<capc>:8181/pc/desktop/page
```

NOTE
For secure communications, replace http: with https:, and replace the port number.

Complete SAML 2.0 Setup

To enable SAML 2.0 authentication, edit user accounts to use External Authentication. New user accounts in CA NetOps Portal are set to use NetOps Portal Authentication by default. The administrator must update the accounts of all operators who authenticate using SAML 2.0.

During SAML2.0 configuration, you specify an existing CA NetOps Portal user account to be 'cloned' in the IdP. Any users who are already defined on the IdP receive the same level of product privilege as the user account you designate. These

accounts are also propagated to CA NetOps Portal, where they appear as new users in the User List. In many cases, you must edit these accounts to make sure that these users can access only the data they require to do their jobs.

Follow these steps:

1. Log in to CA NetOps Portal as a user with administrative privileges.
2. Select **Administration**, **User Settings**, and click **Users**.
   The Manage Users page opens.
3. Select a user account to edit.
4. Click **Edit**.
   The Edit User wizard opens.
5. Select **External** as the Authentication Type.
6. Use the wizard to make any other desired changes to the user account.
7. Click **Save**.
   The changes to the user account are saved.

Set Up HTTPS

By default, Single Sign-On uses HTTP for communications between the browser and DX NetOps Performance Management. TLS (Transport Layer Security) and its predecessor, SSL (Secure Sockets Layer), are widely supported encryption protocols that secure data transmissions over the Internet. TLS and SSL can be used with HTTP to form HTTPS (HTTP-Secure). This guide uses *SSL* as a blanket term to mean "TLS and SSL."

> **NOTE**
>
> Older HTTPS ciphers and protocols (TLS v1.0, v1.1 and SSL v3) are no longer supported by default. TLS v1.2 is the only cipher suite offered by default.

You can enhance the security in your monitoring system by configuring Single Sign-On to use HTTPS instead of HTTP.

Configuring CA Single Sign-On to use HTTPS is optional. Before you can configure the Single Sign-On website to use HTTPS, you must obtain a server certificate. The team that creates and enforces security policies for your organization can probably assist you with these steps.

Enhance the security in your monitoring system by configuring Single Sign-On to use HTTPS instead of HTTP. To enable HTTPS for CA Single Sign-On, first enable SSL for NetOps Portal:

1. Install the certificates that validate the identity of the server.
2. Change the database to ensure that NetOps Portal properly redirects to the correct port and scheme for Single Sign-On, and the reverse.
3. Change the services for both NetOps Portal and Single Sign-On to reflect the new ports and schemes.

Two ports are important for these steps: the NetOps Portal port (which defaults to 8181) and the Single Sign-On port (which defaults to 8381). Port 8181 is the NetOps Portal connection port. If users require authentication, the server redirects them to Single Sign-On on port 8381, where they see the Login page. Once a user has successfully logged in, the server redirects that user back to the original URL at port 8181.

Therefore, you cannot use the same port in each configuration step. Otherwise, a conflict occurs between NetOps Portal and Single Sign-On.

You can enable HTTPS using the SSL configuration tool, or you can configure SSL manually.

To enable HTTPS for NetOps Portal and Single Sign-On with the SSL configuration tool, see Enable Performance Center to use SSL.

To enable HTTPS for NetOps Portal and Single Sign-On manually, complete the following steps:

1. Set Up SSL Certificates for Performance Center.
2. Configure the Port and Website for HTTPS.

3. Configure Performance Center to Use HTTPS.
4. Update Single Sign-On Configuration and Restart the Services.

To enable HTTPS for the Data Aggregator, complete the following steps:

1. Configure the Data Aggregator to Use HTTPS
2. Configure the Data Aggregator and Performance Center for HTTPS

Enable Performance Center to use SSL

You can enable HTTPS using the SSL configuration tool. Before you enable HTTPS using the SSL configuration tool, Set Up SSL Certificates for Performance Center. To configure SSL manually, see Enable Performance Center to use SSL Manually.

In addition to setting up SSL, you can secure the single sign-on to prevent possible redirection to other sites. For more information, see Limit Single Sign-On Redirection.

The SSL configuration tool also allows you to check for any configuration issues or revert to the default settings.

NOTE
The private and signed certificate should be in PEM format.

Configure SSL

Use the SSL configuration tool to configure NetOps Portal to use SSL.

To configure signed certificates, see Set Up SSL Certificates for Performance Center.

Follow these steps:

1. Launch the SSL configuration tool by running the '`./SslConfig`' command in the following directory:
   `PC_Install_Directory``/PerformanceCenter`

   NOTE
   `/opt/CA`
   is the default installation directory.
2. Complete the following prompts:
   - **Preferred Language**
     Specify a language for the configuration tool.
   - **Options**
     To configure NetOps Portal to use SSL, specify 2. Confirm your selection.
   - **Single Sign-On Port**
     Specify the port for Single Sign-On (for example: 8382).
   - **NetOps Portal Port**
     Specify the port for NetOps Portal (for example: 8381).
   - **Existing Certificate**
     Specify whether an SSL certificate exists.
     If you are generating a new certificate, specify No and complete the certificate prompts.
   - **Host Name**
     Specify the full host name for your NetOps Portal server.
   - **Password**
     Specify a newly created password for importing the certificate into the jetty keystore:

PC_Install_Directory/PerformanceCenter/jetty/etc/keystore

- **Obfuscate**
  Specify whether to obscure the password in the jetty configuration files.
- **Trust Store Password**
  Specify the password to the JRE trust store:
  PC_Install_Directory/jre/lib/security/cacerts
  Default: changeit

  NOTE

  In the rare event that you encounter issues with the SSL configuration tool, a debug log is available in the *InstallDirectory*/PerformanceCenter directory.

Check for Configuration Issues

You can also use the SSL configuration tool to check your SSL configuration for any potential issues. Common issues include certificate errors.

Follow these steps:

1. Launch the SSL configuration tool by running the '**.**/SslConfig' command in the following directory:
   PC_Install_Directory/PerformanceCenter

   NOTE

   /opt/CA is the default installation directory.
2. Complete the following prompts:
   - **Preferred Language**
     Specify a language for the configuration tool.
   - **Options**
     To check your configuration for any potential issues, specify 1. Confirm your selection.
3. Review output.

Revert to the Default Settings

If necessary, use the SSL configuration tool to revert to the default settings.

Follow these steps:

1. Launch the SSL configuration tool by running the '**.**/SslConfig' command in the following directory:
   PC_Install_Directory/PerformanceCenter

   NOTE

   /opt/CA is the default installation directory.
2. Complete the following prompts:
   - **Preferred Language**
     Specify a language for the configuration tool.
   - **Options**
     To revert to the default settings, specify 3. Confirm your selection.

Enable Performance Center to use SSL Manually

You can enable HTTPS using the SSL configuration tool, or you can configure SSL manually. To enable HTTPS using the SSL configuration tool, see Enable Performance Center to use SSL.

To configure the single sign-on website to use HTTPS, obtain and install a private key and an associated public certificate. SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed. The procedures are typically specific to an organization and the policies of its security team.

To set up HTTPS, use the Single Sign-On Configuration Tool to update the default website scheme and port to match the encryption settings. By default, Single Sign-On uses Port 8381.

To configure NetOps Portal to use HTTPS, edit the configuration files with the website and port settings. Replace the HTTP connector with an HTTPS connector.

Edit startup files to support SSL encryption in Single Sign-On and restart all NetOps Portal and single sign-on services to update the settings. In addition to setting up SSL, you can secure the single sign-on to prevent possible redirection to other sites.

In summary, to enable HTTPS for CA NetOps Portal and Single Sign-On manually, complete the following steps:

1. Set Up SSL Certificates for Performance Center.
2. Configure the Port and Website for HTTPS.
3. Configure Performance Center to Use HTTPS.
4. Update Single Sign-On Configuration and Restart the Services.

Set Up SSL Certificates for Performance Center

To configure the single sign-on website to use HTTPS, obtain and install a private key and an associated public certificate. SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed. The procedures are typically specific to an organization and the policies of its security team. However, these procedures provide some guidance.

Select the appropriate procedure for your situation:

> **NOTE**
> For more information about the keytool command, see the Java documentation on the Oracle website.

Generate and Import a Certificate

To generate an SSL certificate, use the keytool command. Generate a self-signed certificate and install it in the keystore.

Follow these steps:

1. Change the directory:
   ```
   cd InstallDirectory/PerformanceCenter/jetty/etc
   ```

   > **NOTE**
   > /opt/CA is the default installation directory.
2. If a jetty keystore file exists, rename the existing jetty keystore file to create a backup of it:
   ```
   mv InstallDirectory/PerformanceCenter/jetty/etc/keystore InstallDirectory/
   PerformanceCenter/jetty/etc/keystore.bak
   ```

WARNING
Move the old keystore. If you do not, an error appears in later steps: "Keystore was tampered with, or password was incorrect."

3. Generate a private key and a public, self-signed certificate:

```
keytool -genkeypair -ext SAN=dns:fully_qualified_hostname -keystore keystore_file.ks
-storepass password -keyalg RSA -keysize 2048 -keypass password -alias alias_name
```

Note your entries for the following variables:

- ***fully_qualified_hostname*** Specify the fully qualified host name of the server. Enter the same value when you are prompted for your first and last name.
- ***keystore_file.*** **ks**
  Specify the name of the keystore file to create.
- ***password***
  Specify the password for the keystore and self-signed certificate. Specify a secure password.
- ***alias_name***
  Specify an alias that can be used to refer to the keystore entry that is created for the self-signed certificate.

  NOTE
  N ote: When you are prompted for your first and last name, provide the fully qualified hostname of the server.

4. Proceed through the security prompt questions and confirm your responses.
5. Export the self-signed certificate from the keystore:

```
keytool -exportcert -keystore keystore_file.ks -storepass password -alias alias_name
-file filename.cer
```

- ***keystore_file*** **.ks** Specify the same keystore file name previously created.
- ***password***
  Specify the same password when creating the self-signed certificate.
- ***alias_name***
  Specify the same alias when creating the self-signed certificate.
- ***filename*****.cer**
  Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
  Example: /tmp/capcCert.cer

  NOTE
  We recommend backing up any certificates that could be rewritten before continuing.

6. Import the self-signed certificate into the java trusted certificate keystore:

```
keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
-storepass cacertspassword -alias alias_name -file filename.cer
```

- ***cacertspassword***
  Specify the password for the Certificate Authority keystore.

  NOTE
  The default password for the Certificate Authority keystore is **changeit**.
- ***alias_name***
  Specify the same alias when creating the self-signed certificate.
- ***filename*** **.cer**

Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
Example: /tmp/capcCert.cer

7. Confirm that you trust the certificate.
8. Back up the certificate file:
   `cp filename.cer filename.cer.bak`
9. (Optional) For more security, change the password of the java trusted certificates keystore:
   `keytool -storepasswd -keystore InstallDirectory/jre/lib/security/cacerts`

   You are prompted to provide the existing keystore password and a new keystore password.
10. Verify that your imported keystore is available:
    `keytool -list -keystore InstallDirectory/jre/lib/security/cacerts`

WARNING
To enable the web services, the self-signed certificate must be in the Certificate Authority keystore. Otherwise, you see an error in the log that reports that PKIX did not find a certificate.

Your self-signed SSL certificate is generated and installed in the keystore.

Convert a Self-Signed Certificate to a Certification Authority SSL Certificate

A self-signed certificate causes a browser warning to appear when you open NetOps Portal. The warning does not appear if you use a certificate that a trusted Certification Authority has signed. The following procedure explains how to convert the self-signed certificate to a certificate that a trusted Certification Authority has signed.

Follow these steps:

1. Change the directory:
   `cd InstallDirectory/PerformanceCenter/jetty/etc`

   NOTE
   /opt/CA is the default installation directory.
2. Export a certificate signature request:
   `keytool -certreq -keystore keystore_file.ks -storepass password -ext SAN=dns:[FQHN] -alias alias_name -keypass password -file RequestFileName.csr`

   - ***keystore_file***
     Specify the same keystore file name previously created.
   - ***password***
     Specify the same password when creating the self-signed certificate.
   - ***alias_name***
     Specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
   - ***RequestFileName*.csr**
     Specify the path and file name of the exported signature request.
3. Send the resulting file (***RequestFileName*** .csr) to a qualified signing authority with any other requested information. The Certificate Authority sends you a signed certificate (***SignedCert*** .cer). They might also provide a root Certificate Authority certificate (***RootCA*** .cer) to authenticate the signed certificate.
4. Determine whether the root Certificate Authority certificate is part of the default java trusted authorities:

```
keytool -list -v -keystore InstallDirectory/jre/lib/security/cacerts -
storepass cacertspassword
```

- ***cacertspassword***
  Specify the password for the Certificate Authority keystore.

  NOTE
  The default password for the Certificate Authority keystore is **changeit**.

5. Import the intermediate or root certificates into the java trusted certificate keystore using the following steps for each certificate:

```
keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
-storepass cacertspassword -alias alias_name -file filename.cer
```

- ***cacertspassword***
  Specify the password for the Certificate Authority keystore.

  NOTE
  The default password for the Certificate Authority keystore is **changeit**.
- ***alias_name***
  Specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
- ***filename* .cer**
  Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
  Example: /tmp/capcCert.cer

6. Import the signed certificate into the jetty keystore:

```
keytool -importcert -trustcacerts -keystore keystore -storepass password -
alias alias_name -keypass password -file SignedCert.cer
```

- ***password***
  Specify the same password when creating the self-signed certificate.
- ***alias_name***
  Specify the same alias when creating the self-signed certificate.
- ***SignedCert*.cer**
  Specify the certificate file from the Certificate Authority.

7. Confirm that you trust the certificate.
8. Validate the contents of the jetty keystore:

```
keytool -list -keystore InstallDirectory/PerformanceCenter/jetty/etc/keystore
```

   The single certificate that you imported appears in the list.
   The Certificate Authority SSL certificate replaces your self-signed certificate in the keystore.
9. Import the signed certificate into the java trusted certificate keystore:

```
keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
-storepass cacertspassword -alias alias_name -file filename.cer
```

- ***cacertspassword***
  Specify the password for the Certificate Authority keystore.

  NOTE
  The default password for the Certificate Authority keystore is **changeit**.
- ***alias_name***

Specify the same alias when creating the self-signed certificate.

- ***filename* .cer**
  Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
  Example: /tmp/capcCert.cer

10. Confirm that you trust the certificate.
11. Verify that your imported keystore is available:
    `keytool -list -keystore InstallDirectory/jre/lib/security/cacerts`

Import a Key and an Existing Certificate

You can use a private key and public certificate (a self-signed or a Certificate Authority certificate) from a different source. For example, your security team provides an SSL certificate that is customized for your organization. To use this SSL certificate, import the private key and the signed certificate.

Follow these steps:

1. Change the directory:
   `cd InstallDirectory/PerformanceCenter/jetty/etc`

   NOTE
   /opt/CA is the default installation directory.
2. If a jetty keystore file exists, rename the existing jetty keystore file to create a backup of it:
   `textmv InstallDirectory/PerformanceCenter/jetty/etc/keystore InstallDirectory/PerformanceCenter/jetty/etc/keystore.bak`

   WARNING
   Move the old keystore. If you do not, an error appears in later steps: "Keystore was tampered with, or password was incorrect."
3. Create a PKCS#12 keystore from the private key and certificate:
   `openssl pkcs12 -export -in certificate.pem -inkey privatekey.pem -name alias_name -out keystore.pkcs12`

   - ***certificate*.pem**
     Specify the certificate that is provided to you.
   - ***privatekey*.pem**
     Specify the private key that is provided to you.
   - **alias_name**
     Specify an alias that can be used to refer to the keystore entry that is created for the certificate
   - ***keystore*.pkcs12**
     Specify the keystore to create to store the keys provided.

     NOTE
     This command works on Linux only.
4. Import the key and certificate into the CA NetOps Portal keystore:
   `keytool -importkeystore -destkeystore keystore_file.ks -deststorepass password -srckeystore keystore.pkcs12 -srcstoretype pkcs12 -srcalias src_alias_name -destalias dest_alias_name -destkeypass password`

- ***keystore_file.*** **ks** Specify the name of the keystore file to create.
- ***password*** Specify the password for the keystore and imported certificate. Specify a secure password.
- ***keystore.*** **pkcs12** Specify the PKCS#12 keystore previously created.
- ***src_alias_name*** Specify the alias_name when importing the private key and certificate.
- ***dest_alias_name*** Specify an alias that can be used to refer to the keystore entry that is created for the imported certificate.

Your existing SSL certificate is imported into the keystore.

5. Determine whether the certificate includes a chain terminating at a certificate in the keystore. If the certificate is missing, import it into the Java keystore.

   ```
   keytool -printcert -file filename
   ```

   - ***filename*** specifies the name of the certificate.
6. Import the signed certificate, and intermediate or root certificates into the java trusted certificate keystore using the following steps for each certificate:

   ```
   keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
   -storepass cacertspassword -alias alias_name -file filename.cer
   ```

   - ***cacertspassword***
     Specify the password for the Certificate Authority keystore.

     NOTE
     The default password for the Certificate Authority keystore is **changeit**.
   - ***alias_name***
     Specify the same alias when importing the signed certificate into the NetOps Portal keystore. Or, specify an alias that can be used to refer to the keystore entry that is created for the root or intermediate certificate.
   - ***filename*** **.cer**
     Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
     Example: /tmp/capcCert.cer
7. Confirm that you trust the certificate.
8. Verify that your imported keystore is available:

   ```
   keytool -list -keystore InstallDirectory/jre/lib/security/cacerts
   ```

Configure the Port and Website for HTTPS

To set up HTTPS, use the Single Sign-On Configuration Tool to update the default website scheme and port to match the encryption settings. By default, Single Sign-On uses Port 8381.

Perform the tasks in this procedure on every server where a data source is installed.

Follow these steps:

1. Launch the Single Sign-On Configuration Tool by running the './SsoConfig' command in the following directory:

   ```
   InstallDirectory/PerformanceCenter
   ```

   NOTE
   /opt/CA is the default installation directory.

   You are prompted to select an option.

2. Use the following commands as needed while you are changing settings:
   - q (quit)
   - b (go back to the previous menu)
   - u (update)
   - r (reset)
3. Enter 1 to select CA NetOps Portal (CAPC).
4. Enter 4 to configure Single Sign-On.
   You are prompted to specify the priority.
5. Enter one of the following options:
   - **1. Remote Value**
     These settings are propagated to all other CA products and data sources that are registered to this instance of CAPC. This includes the Event Manager in CAPC, which embeds the URL of CAPC. CAPC uses Remote Value settings only if a corresponding Local Override value is not present.
   - **2. Local Override**
     Overrides a setting on this CAPC instance, which does not propagate to other CA products and data sources (including Event Manager) registered to this instance of CAPC. Local Override takes precedence over both the Remote Value and default settings.

   You are prompted to select a property to configure.

   NOTE

   Configure the scheme or port using Remove Value to include the correct CAPC URL in threshold event email messages.
6. Enter 12 for the Scheme property.
7. Enter 'u' to update the value.
8. Supply 'https' for the value.
9. Enter 13 for the Port property.
10. Update the value to '8382'.
11. Enter 'b' twice to go back to the SSO Configuration/CA NetOps Portal menu.
12. Enter '3' to configure the NetOps Portal.
    You are prompted to specify the priority.
13. Enter either '1' for Remote Value or '2' for Local Override.
14. Enter '6' to select Web Site Scheme.
15. Update the value to 'https'.
16. Enter '8' to select Web Site Port.
17. Update the value to '8182'.
18. Enter q to quit.

Configure Performance Center to Use HTTPS

To configure NetOps Portal to use HTTPS, edit the configuration files with the website and port settings and replace the HTTP connector with an HTTPS connector.

NOTE
By default, TLS v1.2 is the only cipher suite offered. Older HTTPS ciphers and protocols, such as TLS v1.0, v1.1, and SSL v3, are not supported.

Follow these steps:

1. Change to the following directory:
   `cd /InstallDirectory/PerformanceCenter/PC`

NOTE
`/opt/CA` is the default installation directory.

2. Edit the `start.ini` file and apply the following changes:
   – Find the following lines and update them, as follows:
   Original Text
   ```
   # To enable ssl, modify this line to use module https
   # Module: http
   --module=http
   ```
   New Text
   ```
   # To enable ssl, modify this line to use module https
   # Module: https
   --module=https
   ```
   Original Text
   ```
   # To enable ssl, uncomment this line module
   # Module: ssl
   #--module=ssl
   #etc/ssl-lucky13.xml
   ```
   New Text
   ```
   # To Enable ssl, uncomment this line module
   # Module: ssl
   --module=ssl
   etc/ssl-lucky13.xml
   ```
   – If NetOps Portal is not installed in the default installation directory location, update the directory path.
3. Add the port and password information to the `PC/start.d/ssl.ini` file:
   ```
   # SSL
   # define the port to use for secure redirection
   jetty.ssl.port=8182
   jetty.https.port=8182
   jetty.httpConfig.securePort=8182
   # Set up a keystore and truststore
   jetty.sslContext.keyStoreType=JKS
   jetty.sslContext.keyStorePath=etc/keystore_file.ks
   jetty.sslContext.trustStorePath=etc/keystore_file.ks
   # Set up passwords
   jetty.sslContext.keyStorePassword=password
   jetty.sslContext.keyManagerPassword=password
   jetty.sslContext.trustStorePassword=password
   ```
4. Specify the following values from the SSL certificate setup:
   – ***keystore_file*.ks**
   Specify the name of the keystore file that is used to store the certificate.

   NOTE
   The keystore file must be in the `etc` directory.
   – ***password***
   Specify the password for the keystore that is selected when creating the certificate.

NOTE
By default, the password values for the `jetty.sslContext.keyStorePassword`, `jetty.sslContext.keyManagerPassword`, and `jetty.sslContext.trustStorePassword` parameters are stored in plain text. However, you can obfuscate them.
For more information, see Obfuscate Jetty Passwords.

5. Change to the following directory:
   `cd /InstallationDirectory/CA/PerformanceCenter/sso/webapps/sso/configuration`
6. Edit the `CAPerformanceCenter.xml` file.
7. Replace the `Scheme` and `Port` values with settings that are appropriate for SSL:

```
<?xml version="1.0" encoding="utf-8" ?>
<Configuration>
     <SingleSignOnEnabled>True</SingleSignOnEnabled>
     <SingleSignOnProductCode>pc</SingleSignOnProductCode>
     <SignInPageProductDefaultUrl>
          <Scheme>https</Scheme>
          <Port>8182</Port>
          <PathAndQuery>/pc/desktop/page</PathAndQuery>
     </SignInPageProductDefaultUrl>
     <SingleSignOnWebServiceUrl>
          <Scheme>https</Scheme>
          <Port>8182</Port>
          <PathAndQuery>/pc/center/webservice/sso</PathAndQuery>
     </SingleSignOnWebServiceUrl>
</Configuration>
```

8. Edit the `CADataAggregator.xml` file.
9. Replace the `Scheme` and `Port` values for `SingleSignOnWebServiceUrl` with settings that are appropriate for SSL. Do not change values for **SignInPageProductDefaultUrl**:

```
<?xml version="1.0" encoding="utf-8" ?>
<Configuration>
  <SingleSignOnEnabled>True</SingleSignOnEnabled>
  <SingleSignOnProductCode>da</SingleSignOnProductCode>
  <RemoteWebSite>True</RemoteWebSite>
  <SignInPageProductDefaultUrl>
    <Scheme>http</Scheme>
    <Port>8581</Port>
    <PathAndQuery>/</PathAndQuery>
  </SignInPageProductDefaultUrl>
  <SingleSignOnWebServiceUrl>
    <Scheme>https</Scheme>
    <Port>8182</Port>
    <PathAndQuery>/pc/center/webservice/sso</PathAndQuery>
  </SingleSignOnWebServiceUrl>
</Configuration>
```

Update Single Sign-On Configuration and Restart the Services

Edit startup files to support SSL encryption in Single Sign-On and restart all NetOps Portal and Single Sign-On services to update the settings. In addition to setting up SSL, you can secure the single sign-on to prevent possible redirection to other sites. For more information, seeLimit Single Sign-On Redirection.

Follow these steps:

1. Change to the following directory:
   `cd InstallDirectory/PerformanceCenter/sso`

   NOTE
   `/opt/CA` is the default installation directory.
2. Edit the `start.ini` file and apply the following changes:
   – Find the following lines and update them, as follows:
   Original Text
   ```
   # To enable ssl, modify this line to use module https
   # Module: http
   --module=http
   ```
   New Text
   ```
   # To enable ssl, modify this line to use module https
   # Module: https
   --module=https
   ```
   Original Text
   ```
   # To enable ssl, uncomment this line module
   # Module: ssl
   #--module=ssl
   #etc/ssl-lucky13.xml
   ```
   New Text
   ```
   # To Enable ssl, uncomment this line module
   # Module: ssl
   --module=ssl
   etc/ssl-lucky13.xml
   ```
   – If NetOps Portal is not installed in the default location, update the directory path.
3. Add the port and password information to the `sso/start.d/ssl.ini` file:
   ```
   # SSL
   # define the port to use for secure redirection
   jetty.ssl.port=8382
   jetty.https.port=8382
   jetty.httpConfig.securePort=8382
   # Set up a keystore and truststore
   jetty.sslContext.keyStoreType=JKS
   jetty.sslContext.keyStorePath=etc/keystore_file.ks
   jetty.sslContext.trustStorePath=etc/keystore_file.ks
   # Set up passwords
   jetty.sslContext.keyStorePassword=password
   jetty.sslContext.keyManagerPassword=password
   jetty.sslContext.trustStorePassword=password
   ```

   Specify the following values from the SSL certificate setup:
   – ***keystore_file*.ks**

Specify the name of the keystore file used to store the certificate.

– ***password***
Specify the password for the keystore selected when creating the certificate.

4. (Optional) To disable all protocols except TLSv1.2, modify the following file:
`PC_install_directory/PerformanceCenter/jetty/etc/jetty-ssl-context.xml`
Add the following code to the end of the file before `</Configure>` :

```
<Set name="IncludeProtocols">
     <Array type="java.lang.String">
          <Item>TLSv1.2</Item>
     </Array>
</Set>
```

5. Stop the console, device manager, and SSO services by entering the following commands:
```
service caperfcenter_console stop
service caperfcenter_devicemanager stop
service caperfcenter_sso stop
```
6. Restart the services by entering the following commands:
   a. Start the SSO service:
   ```
   service caperfcenter_sso start
   ```
   b. Wait one minute, then start the device manager:
   ```
   service caperfcenter_devicemanager start
   ```
   c. Wait one minute, then start the console service:
   ```
   service caperfcenter_console start
   ```

Enable the Data Aggregator to use SSL

In an environment with a single Data Aggregator, you can enable HTTPS using the Data Aggregator SSL configuration tool. To configure HTTPS manually, see Enable the Data Aggregator to use SSL Manually.

You can also enable HTTPS for the Data Aggregator in a fault tolerant environment with multiple Data Aggregators. For more information, see Enable Fault Tolerant Data Aggregators to Use SSL.

> **NOTE**
> The private and signed certificate should be in PEM format. 3.7.4 and higher supports the PKCS12 file format in addition to the PEM file format.

Configure HTTPS

Use the Data Aggregator SSL configuration tool to configure the Data Aggregator to use HTTPS.

Follow these steps:

1. Launch the SSL configuration tool by running the `./sslConfig.sh` command in the following directory:
`DA_Install_Directory/scripts`

   > **NOTE**
   > `/opt/IMDataAggregator` is the default installation directory.

2. Select `Enable HTTPS FIPS`.
3. Complete the following prompts:

- **Existing Signed Certificate**
  Specify whether an SSL certificate and private key exist.
  If you have an existing certificate and private key, specify Yes and the location and filename of the certificate and key.
  If you are generating a new certificate, specify No and complete the certificate prompts.
- **HTTPS Port**
  Specify the port for secure communication.
  Default: 8582

Import the Data Aggregator Certificate into the NetOps Portal TrustStore

Use the NetOps Portal SSL configuration tool to import the Data Aggregator certificate into the NetOps Portal trustStore.

Follow these steps:

1. Copy the Data Aggregator certificate to the NetOps Portal host.
2. Launch the SSL configuration tool by running the `./SslConfig` command in the following directory:
   PC_Install_Directory`/PerformanceCenter`

   NOTE
   `/opt/CA` is the default installation directory.
3. Complete the following prompts:
   - **Preferred Language**
     Specify a language for the configuration tool.
   - **Options**
     To import the Data Aggregator certificate, specify 4. Confirm your selection.
4. Specify the location and filename of the certificate.
5. Specify the password for the NetOps Portal trustStore.

Revert to the Default Settings

If necessary, use the Data Aggregator SSL configuration tool to revert to the default settings.

Follow these steps:

1. Launch the SSL configuration tool by running the `./sslConfig.sh` command in the following directory:
   DA_Install_Directory`/scripts`

   NOTE
   `/opt/IMDataAggregator`
   is the default installation directory.
2. Select `Disable HTTPS FIPS`.

Enable the Data Aggregator to use SSL Manually

In an environment with a single Data Aggregator, you can enable HTTPS for the Data Aggregator manually. SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed. To set up HTTPS, update the default port and cipher suites.

You can also enable HTTPS for the Data Aggregator in a fault tolerant environment with multiple Data Aggregators. For more information, see Enable Fault Tolerant Data Aggregators to Use SSL.

After you configure the Data Aggregator to use HTTPS, configure the Data Aggregator and NetOps Portal to communicate with HTTPS. After you configure NetOps Portal to use HTTPS, import the Data Aggregator root and intermediate certificates into the NetOps Portal JRE trustStore. Then export the NetOps Portal certificate to the Data

Aggregator. Import the NetOps Portal certificate into the Data Aggregator trustStore. From the NetOps Portal UI, edit the data source scheme and port for the Data Aggregator.

To enable HTTPS for the Data Aggregator, complete the following steps:

1. Configure the Data Aggregator to Use HTTPS
2. Configure the Data Aggregator and Performance Center for HTTPS

Revert the Data Aggregator Back to Use HTTP

If necessary, you can revert the Data Aggregator back to use HTTP.

Follow these steps:

1. Remove the keyStore file from the following location:
   `$DA_install_directory/apache-karaf-version/etc/keystore`
2. Remove the trustStore file from the following location:
   `$DA_install_directory/apache-karaf-version/etc/truststore`
3. Revert the following file:
   `$DA_install_directory/apache-karaf-version/etc/org.ops4j.pax.web.cfg`
4. Revert the following file:
   `$DA_install_directory/apache-karaf-version/etc/jetty.xml`
5. Revert the following file:
   `$DA_install_directory/apache-karaf-version/etc/system.properties`
6. Restart the Data Aggregator service:

```
service dadaemon stop
service dadaemon start
```

Configure the Data Aggregator to Use HTTPS

In an environment with a single Data Aggregator, you can enable HTTPS for the Data Aggregator manually. You cannot enable HTTPS for the Data Aggregator in a fault tolerant environment. SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed. To set up HTTPS, update the default port and cipher suites.

If necessary, you can revert the Data Aggregator back to use HTTP. For more information, see Enable the Data Aggregator to Use HTTPS.

Set Up SSL Certificates for the Data Aggregator

Generate a self-signed certificate or request a certificate from a trusted Certificate Authority.

> **NOTE**
>
> Provide all alternative Data Aggregator host names. If you generate an SSL certificate with the OpenSSL utility, add the alternative host names. Add each host name as a Subject Alternative Name (SAN) in the v3 certificate extension.

To generate an SSL certificate, use the keytool command. Generate a self-signed certificate and install it in the keystore.

Follow these steps:

1. Change the directory:
   `cd DA_install_directory/apache-karaf-version/etc`

2. If a keystore file exists, rename the existing keystore file to create a backup of it:
   ```
   mv DA_install_directory/apache-karaf-version/etc/keystore DA_install_directory/
   apache-karaf-version/etc/keystore.bak
   ```

   WARNING
   Move the old keystore. If you do not, an error appears in later steps: "Keystore was tampered with, or password was incorrect."
3. Generate a private key and a public, self-signed certificate:
   ```
   keytool -genkeypair -ext SAN=dns:fully_qualified_hostname -keystore keystore -
   storepass password -keyalg RSA -keysize 2048 -keypass password -alias alias_name
   ```

   Note your entries for the following variables:
   - ***fully_qualified_hostname***
     Specify the fully qualified host name of the server. Enter the same value when you are prompted for your first and last name.
   - ***keystore***
     Specify the name of the keystore file to create.
   - ***password***
     Specify the password for the keystore and self-signed certificate. Specify a secure password.
   - ***alias_name***
     Specify an alias that can be used to refer to the keystore entry that is created for the self-signed certificate.

     NOTE
     When you are prompted for your first and last name, provide the fully qualified hostname of the server.
4. Proceed through the security prompt questions and confirm your responses.
5. Export the self-signed certificate from the keystore:
   ```
   keytool -exportcert -keystore keystore -storepass password -alias alias_name -
   file filename.cer
   ```

   - ***keystore***
     Specify the same keystore file name previously created.
   - ***password***
     Specify the same password when creating the self-signed certificate.
   - ***alias_name***
     Specify the same alias when creating the self-signed certificate.
   - ***filename*.cer**
     Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
     Example: /tmp/DA_Cert.cer

     NOTE
     We recommend backing up any certificates that could be rewritten before continuing.
6. Import the self-signed certificate into the java trusted certificate keystore:
   ```
   keytool -importcert -keystore InstallDirectory/jre/lib/security/cacerts
   -storepass cacertspassword -alias alias_name -file filename.cer
   ```

   - ***cacertspassword***
     Specify the password for the Certificate Authority keystore.

NOTE
The default password for the Certificate Authority keystore is **changeit**.

- ***alias_name***
  Specify the same alias when creating the self-signed certificate.
- ***filename*.cer**
  Specify the file to which the certificate is exported. We recommend using a full pathname that does not place the file in the current directory.
  Example: /tmp/DA_Cert.cer

7. Confirm that you trust the certificate.
8. Back up the certificate file:
   `cp filename.cer filename.cer.bak`
9. (Optional) For more security, change the password of the java trusted certificates keystore:
   `keytool -storepasswd -keystore InstallDirectory/jre/lib/security/cacerts`

   You are prompted to provide the existing keystore password and a new keystore password.
10. Verify that your imported keystore is available:
    `keytool -list -keystore InstallDirectory/jre/lib/security/cacerts`

    WARNING
    To enable the web services, the self-signed certificate must be in the Certificate Authority keystore. Otherwise, you see an error in the log that reports that PKIX did not find a certificate.

    Your self-signed SSL certificate is generated and installed in the keystore.

Import a Certificate

SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed.

Follow these steps:

1. Import the public certificate for the Data Aggregator host to create a keystore:
   `keytool -import -file DA_public_cert -alias alias_name -keystore $DA_install_directory/apache-karaf-version/etc/keystore`

   - ***DA_public_cert***
     Specify the public certificate for the Data Aggregator host.
   - ***alias_name***
     Specify the alias that is used to refer to the certificate.
   - ***DA_install_directory***
     Specify the Data Aggregator installation directory.
   - ***version***
     Specify the version.
2. Specify the keystore password when prompted.
3. (Optional) If a Certificate Authority provided a root certificate, import the root certificate:
   `keytool -import -file root_cert -alias alias_name -keystore $DA_install_directory/apache-karaf-version/etc/keystore`

   - ***root_cert***
     Specify the root certificate for generating the public certificate.

4. (Optional) If a Certificate Authority provided intermediate certificates, import each intermediate certificate:
   `keytool -import -file intermed_cert -alias alias_name -keystore $DA_install_directory/apache-karaf-version/etc/keystore`

   – ***intermed_cert***
   Specify the intermediate certificate for generating the public certificate.

Configure the Data Aggregator Port and Cipher Suites

To set up HTTPS, update the default port and cipher suites.

Follow these steps:

1. Back up the following file:
   DA_install_directory/apache-karaf-*version*/etc/org.ops4j.pax.web.cfg
2. Replace the file contents with the following lines:
   ```
   org.osgi.service.http.enabled=false
   org.osgi.service.http.port.secure=8582
   org.osgi.service.http.secure.enabled=true
   org.ops4j.pax.web.config.file=${karaf.home}/etc/jetty.xml
   ```
3. Back up the following file:
   DA_install_directory/apache-karaf-*version*/etc/jetty.xml
4. Add the following XML within the <Configure> tag:

```
<Call name="addConnector">
   <Arg>
      <New class="org.eclipse.jetty.server.ssl.SslSelectChannelConnector">
         <Arg>
            <New class="org.eclipse.jetty.http.ssl.SslContextFactory">
               <Set name="keyStore"><Property name="jetty.home" default="." />/etc/keystore</Set>
               <Set name="keyStorePassword">changeit</Set>
               <Set name="keyManagerPassword">changeit</Set>
               <Set name="trustStore"><Property name="jetty.home" default="." />/etc/keystore</Set>
               <Set name="trustStorePassword">changeit</Set>
               <Set name="excludeProtocols">
                  <Array type="java.lang.String">
                     <Item>TLSv1</Item>
                     <Item>SSLv3</Item>
                     <Item>SSLv2</Item>
                     <Item>SSLv2Hello</Item>
                  </Array>
               </Set>
               <Set name="includeCipherSuites">
                  <Array type="String">
                     <Item>TLS_DH_RSA_WITH_AES_128_CBC_SHA</Item>
                     <Item>TLS_DH_RSA_WITH_AES_128_CBC_SHA256</Item>
                     <Item>TLS_DH_RSA_WITH_AES_128_GCM_SHA256</Item>
                     <Item>TLS_DH_RSA_WITH_AES_256_CBC_SHA</Item>
                     <Item>TLS_DH_RSA_WITH_AES_256_CBC_SHA256</Item>
                     <Item>TLS_DH_RSA_WITH_AES_256_GCM_SHA384</Item>
                     <Item>TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA</Item>
                     <Item>TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256</Item>
```

```
                        <Item>TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_ECDH_ECDSA_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_ECDH_RSA_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_PSK_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_PSK_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_PSK_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_PSK_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_PSK_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_PSK_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_256_CBC_SHA384</Item>
                        <Item>TLS_RSA_PSK_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_RSA_WITH_AES_128_CBC_SHA</Item>
                        <Item>TLS_RSA_WITH_AES_128_CBC_SHA256</Item>
                        <Item>TLS_RSA_WITH_AES_128_GCM_SHA256</Item>
                        <Item>TLS_RSA_WITH_AES_256_CBC_SHA</Item>
                        <Item>TLS_RSA_WITH_AES_256_CBC_SHA256</Item>
                        <Item>TLS_RSA_WITH_AES_256_GCM_SHA384</Item>
                        <Item>TLS_AES_128_CCM_8_SHA256</Item>
                        <Item>TLS_AES_128_CCM_SHA256</Item>
                        <Item>TLS_AES_128_GCM_SHA256</Item>
                        <Item>TLS_AES_256_GCM_SHA384</Item>
                    </Array>
                </Set>
            </New>
        </Arg>
        <Set name="port">8582</Set>
        <Set name="maxIdleTime">30000</Set>
      </New>
    </Arg>
</Call>
```

NOTE

The following line specifies the secure port for the Data Aggregator configured to use HTTPS:

```
<Set name="port">8582</Set>
```

5. Edit the `keyStorePassword`, `keyManagerPassword`, and `trustStorePassword` attributes.

NOTE

The `keyManagerPassword` should be the same as the `keyStorePassword`.

6. Back up the following file:
   DA_install_directory/apache-karaf-*version*/etc/system.properties
7. Add the following lines at the end of the file:

```
javax.net.ssl.keyStore=${karaf.home}/etc/keystore
javax.net.ssl.keyStorePassword=changeit
javax.net.ssl.trustStore=${karaf.home}/etc/truststore
javax.net.ssl.trustStorePassword=changeit
```

8. Edit the keystorePassword and the trustStore password.
9. Restart the Data Aggregator service:

```
service dadaemon stop
service dadaemon start
```

Configure the Data Aggregator and Performance Center for HTTPS

After you configure the Data Aggregator to use HTTPS, configure the Data Aggregator and NetOps Portal to communicate with HTTPS.

Configure NetOps Portal Communication

After you configure NetOps Portal to use HTTPS, import the Data Aggregator root and intermediate certificates into the NetOps Portal JRE trustStore. Then export the NetOps Portal certificate to the Data Aggregator.

Follow these steps:

1. Copy the root certificate and the intermediate certificates from the Data Aggregator host to the NetOps Portal host.
2. Import the root certificate to the NetOps Portal JRE trustStore:

```
keytool -import -file root_cert -alias alias_name -keystore $PC_install_directory/
jre/lib/security/cacerts
```

   – ***PC_install_directory***
   Specify the NetOps Portal installation directory.
3. Import each intermediate certificate to the NetOps Portal JRE trustStore:

```
keytool -import -file intermed_cert -alias alias_name -keystore
 $PC_install_directory/jre/lib/security/cacerts
```

4. Restart the NetOps Portal services:

```
service caperfcenter_sso stop
```

```
service caperfcenter_console stop

service caperfcenter_sso start

service caperfcenter_console start
```

5. Export the NetOps Portal certificate:

```
keytool -export -keystore $PC_install_directory/jre/lib/security/cacerts -
alias alias_name -file PC_filename.cer
```

– ***PC_filename.cer***
Specify the filename of the NetOps Portal certificate.

Configure Data Aggregator Communication

Import the self-signed, or root and intermediate certificates that are used to generate the NetOps Portal public certificate into the Data Aggregator trustStore.

Follow these steps:

1. Copy the NetOps Portal certificate from the NetOps Portal host to the Data Aggregator host.
2. Import the NetOps Portal certificate into the Data Aggregator trustStore:

```
keytool -import -file PC_filename.cer -alias alias_name -keystore
 $DA_install_directory/apache-karaf-version/etc/truststore
```

3. Restart the Data Aggregator service:

```
service dadaemon stop

service dadaemon start
```

Edit the Data Aggregator Data Source

From the NetOps Portal UI, edit the data source scheme and port for the Data Aggregator.

Follow these steps:

1. Hover over **Administration**, and click **Data Sources: Data Sources**.
2. Select the Data Aggregator data source, and click **Edit**.
3. Specify 8582 as the secure port for the Data Aggregator.
4. Change the communication protocol to **https**.
5. Click **Save**.

Enable Fault Tolerant Data Aggregators to Use HTTPS

You can enable HTTPS for a data aggregator in a fault-tolerant environment with multiple data aggregators. For more information, see Fault Tolerance.

In an environment with a single data aggregator, you can enable HTTPS for the data aggregator. For more information, see Enable the Data Aggregator to use SSL and Enable the Data Aggregator to use SSL Manually.

SSL can be used with either a self-signed certificate or a certificate that a trusted Certificate Authority has signed.

Follow these steps:

- Configure the Traefik Connection as HTTPS from Performance Center to Proxy Server.
- Configure Consul as HTTPS.
- Configure the Traefik Connection as HTTPS from Proxy Server to Data Aggregator.

Configure the Traefik Connection as HTTPS from Performance Center to Proxy Server

You can enable HTTPS for the data aggregator in a fault tolerant environment with multiple data aggregators. For more information, see Enable Fault Tolerant Data Aggregators to Use HTTPS.

Configure the NetOps Portal to proxy server connection as HTTPS.

Configure the Proxy Server

Manage the keystore file, certificates, and configure the proxy server.

Follow these steps:

1. If a keystore file already exists, back it up:
   Example:
   ```
   cp /opt/CA/daproxy/conf/cacerts /opt/CA/daproxy/conf/cacerts.bak
   ```
2. Generate a private key and a public, self-signed certificate:
   ```
   keytool -genkeypair -ext SAN=dns:fully_qualified_hostname,dns:hostname -keystore keystore -
   storepass store_password -keyalg RSA -keysize 2048 -keypass key_password -alias alias_name
   ```
   NOTE
   Specify the proxy host name both with and without the domain within the `SAN=` argument.
   a. Note your entries for the following variables:
      - **fully_qualified_hostname**
        Specify the fully qualified host name of the server. Enter the same value when you are prompted for your first and last name.
      - **hostname**
        Specify the host name of the server without the domain.
      - **keystore**
        Specify the name of the keystore file to create.
      - **store_password**
        Specify the password for the keystore. Specify a secure password.
      - **key_password**
        Specify the password for the private key. Specify a secure password.
      - **alias_name**
        Specify an alias for the keystore entry created for the self-signed certificate.
        Example: `daproxy`

      Example:
      ```
      keytool -genkeypair -ext SAN=dns:myDaproxyHost.my.domain.net,dns:myDaproxyHost -keystore /opt/CA/
      daproxy/conf/cacerts -storepass changeit -keyalg RSA -keysize 2048 -keypass changeit -alias daproxykey
      ```
   b. Proceed through the security prompt questions and confirm your responses.
      Output:
      ```
      What is your first and last name?
      ```

```
   [Unknown]:  myDaproxyHost.my.domain.net
What is the name of your organizational unit?
   [Unknown]:  MyOrgUnit
What is the name of your organization?
   [Unknown]:  MyOrg
What is the name of your City or Locality?
   [Unknown]:  MyCity
What is the name of your State or Province?
   [Unknown]:  MyStateFullName
What is the two-letter country code for this unit?
   [Unknown]:  US
Is CN=myDaproxyHost.my.domain.net, OU=MyOrgUnit, O=MyOrg, L=MyCity, ST=MyStateFullName, C=US correct?
   [no]:  yes

Warning:
The JKS keystore uses a proprietary format. It is recommended to migrate to PKCS12 which is an
 industry standard format using "keytool -importkeystore -srckeystore /opt/CA/daproxy/conf/cacerts -
destkeystore /opt/CA/daproxy/conf/cacerts -deststoretype pkcs12".
```

3. Verify that the key generated:
   Example:
   ```
   keytool -list -keystore /opt/CA/daproxy/conf/cacerts -storepass changeit |grep daproxy
   ```
   Output:
   ```
   daproxykey, Jun 24, 2020, PrivateKeyEntry,
   ```
4. Export the self-signed certificate from the keystore:
   ```
   keytool -exportcert -keystore keystore -storepass store_password -alias alias_name -file /tmp/filename.cer
   ```
   - **keystore**
     Specify the name of the keystore file that you created previously.
   - **store_password**
     Specify the password for the keystore that you created previously.
   - **alias_name**
     Specify the alias for the keystore entry created previously for the self-signed certificate.
   - **filename.cer**
     Specify the file to which the certificate is exported.

     TIP
     We recommend that you specify a full path that places the file outside the current directory. Before you continue, we recommend that you back up any certificates that might get rewritten.

   Example:
   ```
   keytool -exportcert -keystore /opt/CA/daproxy/conf/cacerts -storepass changeit -alias daproxykey -file /
   tmp/daproxyss.cer
   ```
   Output:
   ```
   Certificate stored in file </tmp/daproxyss.cer>

   Warning:
   The JKS keystore uses a proprietary format. It is recommended to migrate to PKCS12 which is an industry
    standard format using
   "keytool -importkeystore -srckeystore /opt/CA/daproxy/conf/cacerts -destkeystore /opt/CA/daproxy/conf/
   cacerts -deststoretype pkcs12".

   ls -alrt /tmp
          -rw-r--r--.  1 root   root         945 Jun 24 13:56 daproxyss.cer
   ```

5. Extract the private certificate and key as .pem files:
   a. Convert the keystore to pkcs12:

      NOTE
      (Optional) If you have converted the keystore to pkcs12 before, remove or rename the pks12 copy of the keystore:

      ```
      rm -f /opt/CA/daproxy/conf/cacerts.p12
      ```

      ```
      keytool -importkeystore -srckeystore source_keystore -srcstorepass source_store_password
       -srckeypass source_key_password -srcalias source_alias -destalias destination_alias -
      destkeystore destination_keystore -deststoretype PKCS12 -deststorepass destination_store_password -
      destkeypass destination_key_password
      ```

   b. Note your entries for the following variables:
      - **source_keystore**
        Specify the name of the keystore file that you created previously.
      - **source_store_password**
        Specify the password for the keystore that you created previously.
      - **source_key_password**
        Specify the password for the private key that you created previously.
      - **source_alias**
        Specify the alias for the keystore entry created previously for the self-signed certificate.
        Example: `daproxy`
      - **destination_alias**
        Specify an alias for the resulting keystore entry created for the self-signed certificate.
        Example: `daproxy`
      - **destinaion_keystore**
        Specify the name of the resulting keystore file to create.

        TIP
        Specify a full path. Before continuing, back up any destination files that might get rewritten.
      - **destination_store_password**
        Specify the password for the resulting keystore. Specify a secure password.
      - **destination_key_password**
        Specify the password for the resulting private key. Specify a secure password.

      Example:

      ```
      keytool -importkeystore -srckeystore /opt/CA/daproxy/conf/cacerts -srcstorepass changeit -srckeypass
       changeit -srcalias daproxykey -destalias daproxykeyp12 -destkeystore /opt/CA/daproxy/conf/cacerts.p12
       -deststoretype PKCS12 -deststorepass changeit -destkeypass changeit
      ```

      Output:

      ```
      Importing keystore /opt/CA/daproxy/conf/cacerts to /opt/CA/daproxy/conf/cacerts.p12...
      ```

   c. Extract the key to a file:

      NOTE
      (Optional) If you have extracted the key to a file before, remove or rename the file:

      ```
      rm -f /tmp/daproxyss_key.pem
      ```

      Example:

      ```
      openssl pkcs12 -in /opt/CA/daproxy/conf/cacerts.p12 -nodes -nocerts -out /tmp/daproxyss_key.pem
      ```

      Output:

      ```
      Enter Import Password: <enter password value you passed in "-deststorepass" above>
      MAC verified OK
      ```

   d. Write the certificate as a .pem file:

      NOTE
      (Optional) If you have written the certificate as a .pem file before, remove or rename the file:

```
rm -f /tmp/daproxyss.pem
```

Example:

```
openssl x509 -inform der -in /tmp/daproxyss.cer -out /tmp/daproxyss.pem
```

e. Verify the list of files produced:

Example:

```
ls -alrt /tmp/daproxyss*
```

Output:

```
-rw-r--r--. 1 root root  961 Jul 23 11:06 /tmp/daproxyss.cer
-rw-r--r--. 1 root root 1853 Jul 23 11:09 /tmp/daproxyss_key.pem
-rw-r--r--. 1 root root 1359 Jul 23 11:09 /tmp/daproxyss.pem
```

6. (Optional) Request a CA-signed certificate for the proxy server host using the self-signed certificate produced here. Copy and use your CA-signed certificate file(s), including any intermediate and root certificates, in the following steps.
7. Copy the proxy server certificate files for the DAProxy/Traefik service and NetOps Portal:

Example:

```
// copy to daproxy config folder for use by traefik on DAProxy...
cp /tmp/daproxyss.cer /opt/CA/daproxy/conf/daproxyss.cer
cp /tmp/daproxyss.pem /opt/CA/daproxy/conf/daproxyss.pem
cp /tmp/daproxyss_key.pem /opt/CA/daproxy/conf/daproxyss_key.pem

// move the certificate file(s) to a temp folder on PC...
cp /opt/CA/daproxy/conf/daproxyss.cer <myPcHost>/tmp/daproxyss.cer
```

8. Configure the proxy server based on your NetOps Portal version:

20.2.3 and Lower:

a. Back up the following file:

Proxy_Server_Install_Directory/bin/conf/daproxy.cfg

Example:

```
cp /opt/CA/daproxy/conf/daproxy.cfg /opt/CA/daproxy/conf/daproxy.cfg.bak
```

b. Edit the `daproxy.cfg` file and set the following parameters:

Example:

```
vi /opt/CA/daproxy/conf/daproxy.cfg

[entryPoints]
   [entryPoints.da]
         address = ":8582"
         [entryPoints.da.tls]
            minVersion = "VersionTLS11"
            cipherSuites = [
                "TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256",
                "TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256",
                "TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384",
                "TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256",
                "TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256",
                "TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384",
                "TLS_RSA_WITH_AES_128_CBC_SHA256",
                "TLS_RSA_WITH_AES_128_GCM_SHA256",
                "TLS_RSA_WITH_AES_256_GCM_SHA384",
                "TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA",
                "TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA",
                "TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA",
                "TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA",
                "TLS_RSA_WITH_AES_128_CBC_SHA",
```

```
            "TLS_RSA_WITH_AES_256_CBC_SHA"
        ]
        [[entryPoints.da.tls.certificates]]
            certFile = "<da_proxy_server_cert>"
            keyFile = "<da_proxy_server_key>"
```

Example:

The following example shows the `tls.certificates` settings:

```
[[entryPoints.da.tls.certificates]]
    certFile = "/opt/CA/daproxy/conf/daproxyss.pem"
    keyFile = "/opt/CA/daproxy/conf/daproxyss_key.pem"
```

NOTE

Until you configure the fault-tolerant data aggregators for HTTPS, the backend definition in the `daproxy.cfg` file remains `http` .

Example:

```
[backends]
   [backends.da]
        [backends.da.healthcheck]
         path = "/"
         interval = "10s"
        [backends.da.servers.server1]
         url = "http://<da1_hostname>:8581"
        [backends.da.servers.server2]
         url = "http://<da2_hostname>:8581"
```

20.2.4 and Higher:

a. Back up the following file:

Proxy_Server_Install_Directory/bin/conf/daproxy.toml

Example:

```
cp /opt/CA/daproxy/conf/daproxy.toml /opt/CA/daproxy/conf/daproxy.toml.bak
```

b. Edit the `daproxy.toml` file and set the following parameters:

Example:

```
vi /opt/CA/daproxy/conf/daproxy.toml
```

a. Update the `entryPoints` section to set the port to reach the proxy server, usually 8582:

Before Example:

```
[entryPoints]
# Web entry point for traefik on daproxy host
   [entryPoints.web]
        # For HTTPS, change to '8582'.
           address = ":8581"
```

After Example:

```
[entryPoints]
# Web entry point for traefik on daproxy host
   [entryPoints.web]
        # For HTTPS, change to '8582'.
           address = ":8582"
```

b. Update the rule in `http.routers.DARouter` to include the domain name:

Before Example:

```
[http.routers]
     # Define which incoming requests are routed to which service
     [http.routers.DARouter]
          entryPoints = ["web"]
```

```
          # This rule routes all requests to DAService
          # For HTTPS, the hostname here will need to include domain name
          #  if your daproxy host certificate uses fully qualified hostname,
          #  for example:
          #    Host(`yourhost.yourdomain.net`}
          #    ...or to support urls with and without domain...
          Host(`yourhost.yourdomain.net`,`yourhost`}
          #  The hostname used in Performance Center's Data Source
          #   configuration should include domain if your certificate does.
          rule = "Host(`DaproxyHost`) && PathPrefix(`/`)"
          service = "DAService"
```

After Example:

```
[http.routers]
     # Define which incoming requests are routed to which service
     [http.routers.DARouter]
          entryPoints = ["web"]
          # This rule routes all requests to DAService
          # For HTTPS, the hostname here will need to include domain name
          #  if your daproxy host certificate uses fully qualified hostname,
          #  for example:
          #    Host(`yourhost.yourdomain.net`}
          #    ...or to support urls with and without domain...
          Host(`yourhost.yourdomain.net`,`yourhost`}
          #  The hostname used in Performance Center's Data Source
          #   configuration should include domain if your certificate does.
          rule = "Host(`myDaproxyHost.my.domain.net`) && PathPrefix(`/`)"
          service = "DAService"
```

c. Uncomment the following sections:

```
# For HTTPS, uncomment these.
#  [http.routers.DARouter.tls]
#    options = "DAOptions"

# For HTTPS, uncomment these.
#[tls.options]
#  [tls.options.DAOptions]
#    minVersion = "VersionTLS12"
#    cipherSuites = [
#                     "TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256",
#                     "TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256",
#                     "TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384",
#                     "TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256",
#                     "TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256",
#                     "TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384",
#                     "TLS_RSA_WITH_AES_128_CBC_SHA256",
#                     "TLS_RSA_WITH_AES_128_GCM_SHA256",
#                     "TLS_RSA_WITH_AES_256_GCM_SHA384",
#                     "TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA",
#                     "TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA",
#                     "TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA",
#                     "TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA",
#                     "TLS_RSA_WITH_AES_128_CBC_SHA",
#                     "TLS_RSA_WITH_AES_256_CBC_SHA"
```

```
#                ]

# For HTTPS, uncomment these and set path and filenames to
# your daproxy host's cert & key files.
#[[tls.certificates]]
#    certFile = "/opt/CA/daproxy/conf/daproxy_cert.pem"
#    keyFile = "/opt/CA/daproxy/conf/daproxy_key.pem"
#[tls.stores]
#  [tls.stores.default]
#    [tls.stores.default.defaultCertificate]
#      certFile = "/opt/CA/daproxy/conf/daproxy_cert.pem"
#      keyFile = "/opt/CA/daproxy/conf/daproxy_key.pem
```

Example:
The following example shows the `tls.certificates` settings:

```
[[tls.certificates]]
     certFile = "/opt/CA/daproxy/conf/daproxyss.pem"
     keyFile = "/opt/CA/daproxy/conf/daproxyss_key.pem"
[tls.stores]
     [tls.stores.default]
       [tls.stores.default.defaultCertificate]
        certFile = "/opt/CA/daproxy/conf/daproxyss.pem"
        keyFile = "/opt/CA/daproxy/conf/daproxyss_key.pem"
```

NOTE
Until you configure the fault-tolerant data aggregators for HTTPS, the `http.services` section remains the same.
Example:

```
[[http.services.DAService.loadBalancer.servers]]
     # For HTTPS, change to 'https' and '8582'.
     url = "http://myDaHost1:8581"
[http.services.DAService.loadBalancer.servers]]
     # For HTTPS, change to 'https' and '8582'.
     url = "http://myDaHost2:8581"
```

9. Restart the Proxy services:
   ```
   service daproxy stop
   service daproxy start
   ```
10. Test the HTTPS connection to the proxy server:
    `https://<daproxy_hostname>:8582/`

Configure NetOps Portal

Use the NetOps Portal SSL configuration tool to import the proxy server certificate into the NetOps Portal trustStore.

Follow these steps:

1. Copy the proxy server certificate to the NetOps Portal host:
   Example:
   ```
   cp /tmp/daproxyss.cer /opt/CA/daproxyss.cer
   ```
   NOTE
   If you imported a data aggregator or proxy server certificate to the NetOps Portal keystore before, find and remove the existing certificate:
   1. Find the existing certificate in NetOps Portal keystore:
      – **da-cert**

The alias that `SslConfig` uses when importing a data aggregator certificate to NetOps Portal.

Example:

```
keytool -list -keystore /opt/CA/jre/lib/security/cacerts -storepass changeit |grep -i da-cert
```

Output:

```
da-cert, Jul 23, 2020, trustedCertEntry,
```

2. If found, remove the certificate:
   Example:

```
keytool -delete -keystore /opt/CA/jre/lib/security/cacerts -alias da-cert -storepass changeit
```

2. Launch the SSL configuration tool by running the `./SslConfig` command in the following directory:

```
PC_Install_Directory/PerformanceCenter
./SslConfig
```

NOTE
`/opt/CA` is the default installation directory.

Example:

```
cd /opt/CA/PerformanceCenter
./SslConfig
```

NOTE
Launching the SSL configuration tool restarts the `caperfcenter_console` and `caperfcenter_devicemanager` services.

3. Complete the following prompts:
   - **Preferred Language**
     Specify a language for the configuration tool.
   - **Options**
     To import the data aggregator certificate, specify 4. Confirm your selection.
4. Specify the location and filename of the certificate.
   Example: `/opt/CA/daproxyss.cer`
5. Specify the password for the NetOps Portal trustStore.
   Default: `changeit`
6. (Optional) If you used a CA-signed certificate, import any included intermediate and root certificates to the to the NetOps Portal keystore:
   Example:

```
keytool -import -file /tmp/intermed_cert.pem -alias daproxyintermediate -keystore /opt/CA/conf/cacerts -
storepass changeit
```

7. Open NetOps Portal, hover over **Administation: Data Sources**, and then click **Data Sources**.
8. Edit the data aggregator data source:
   - Specify HTTPS.
   - Specify 8582 for the port.
   - Specify the fully qualified domain name for the host (for example, `myDaProxyHost.my.domain.net`).
9. Click **Test** to validate, and then click **Save**.

Troubleshooting

Symptom:

NetOps Portal cannot connect to the proxy server and the following error appears:

```
Caused by: javax.net.ssl.SSLHandshakeException: java.security.cert.CertificateException: No subject
 alternative DNS name matching <myDaproxyHost> found.
```

Solution:

Verify whether you specified the proxy server host name with and without the domain when you generated the key.

Example:

```
keytool -genkeypair -ext SAN=dns:myDaproxyHost.my.domain.net,dns:myDaproxyHost -keystore /opt/CA/daproxy/conf/
cacerts -storepass changeit -keyalg RSA -keysize 2048 -keypass changeit -alias daproxykey.
```

Configure Consul as HTTPS

You can enable HTTPS for the data aggregator in a fault-tolerant environment with multiple data aggregators. For more information, see Enable Fault Tolerant Data Aggregators to Use HTTPS.

Configure Consul on the proxy server to the data aggregators as HTTPs.

Generate the Consul Certificates

On the proxy server, run the following commands to generate the Consul certifications for all Consul hosts.

Follow these steps:

> **NOTE**
> The following steps generate files in the current working directory.

1. Go to the following location:
   ```
   cd Proxy_Install_Directory/daproxy/conf
   ```
   – **Proxy_Install_Directory**
   Specify the installation directory of the proxy server.
   Default:`opt/CA`

   Example:
   ```
   cd /opt/CA/daproxy/conf
   ```
2. Generate the Consul agent certificates:
   ```
   Proxy_Install_Directory/daproxy/bin/consul tls ca create -domain=my.domain.net
   ```
   – **my.domain.net**
   Specify the domain of your host.

   Example:
   ```
   /opt/CA/daproxy/bin/consul tls ca create -domain=my.domain.net
   ```
   Output:
   ```
   ==> Saved my.domain.net-agent-ca.pem
   ==> Saved my.domain.net-agent-ca-key.pem
   ```
3. Generate the Consul server certificates for the Proxy host:
   ```
   Proxy_Install_Directory/daproxy/bin/consul tls cert create -server --additional-dnsname=proxy_host --
   additional-dnsname=fully_qualified_proxy_host -dc=capm -domain=my.domain.net
   ```
   – **proxy_host**
   Specify the host name of the proxy server.
   – **fully_qualified_proxy_host**
   Specify the fully qualified host name of the proxy server.
   – **my.domain.net**
   Specify the domain of your host.

   Example:
   ```
   /opt/CA/daproxy/bin/consul tls cert create -server --additional-dnsname=myDaproxyHost --additional-
   dnsname=myDaproxyHost.my.domain.net -dc=capm -domain=my.domain.net
   ```
   Output:
   ```
   ==> WARNING: Server Certificates grants authority to become a
           server and access all state in the cluster including root keys
   ```

```
        and all ACL tokens. Do not distribute them to production hosts
        that are not server nodes. Store them as securely as CA keys.
==> Using my.domain.net-agent-ca.pem and my.domain.net-agent-ca-key.pem
==> Saved capm-server-my.domain.net-0.pem
==> Saved capm-server-my.domain.net-0-key.pem
```

4. Generate the Consul server certificates for the first data aggregator host:

   Proxy_Install_Directory/daproxy/bin/consul tls cert create -server --additional-dnsname=*DA1_host* --additional-dnsname=*fully_qualified_DA1_host* -dc=capm -domain=*my.domain.net*

   – **DA1_host**
   Specify the host name of the first data aggregator.
   – **fully_qualified_DA1_host**
   Specify the fully qualified host name of the first data aggregator.
   – **my.domain.net**
   Specify the domain of your host.

   Example:

   ```
   /opt/CA/daproxy/bin/consul tls cert create -server --additional-dnsname=myDa1Host --additional-dnsname=myDa1Host.my.domain.net -dc=capm -domain=my.domain.net
   ```

   Output:

   ```
   ==> WARNING: Server Certificates grants authority to become a
           server and access all state in the cluster including root keys
           and all ACL tokens. Do not distribute them to production hosts
           that are not server nodes. Store them as securely as CA keys.
   ==> Using my.domain.net-agent-ca.pem and my.domain.net-agent-ca-key.pem
   ==> Saved capm-server-my.domain.net-1.pem
   ==> Saved capm-server-my.domain.net-1-key.pem
   ```

5. Generate the Consul server certificates for the second data aggregator host:

   Proxy_Install_Directory/daproxy/bin/consul tls cert create -server --additional-dnsname=*DA2_host* --additional-dnsname=*fully_qualified_DA2_host* -dc=capm -domain=*my.domain.net*

   – **DA2_host**
   Specify the host name of the second data aggregator.
   – **fully_qualified_DA2_host**
   Specify the fully qualified host name of the second data aggregator.
   – **my.domain.net**
   Specify the domain of your host.

   Example:

   ```
   /opt/CA/daproxy/bin/consul tls cert create -server --additional-dnsname=myDa2Host --additional-dnsname=myDa2Host.my.domain.net -dc=capm -domain=my.domain.net
   ```

   Output:

   ```
   ==> WARNING: Server Certificates grants authority to become a
           server and access all state in the cluster including root keys
           and all ACL tokens. Do not distribute them to production hosts
           that are not server nodes. Store them as securely as CA keys.
   ==> Using my.domain.net-agent-ca.pem and my.domain.net-agent-ca-key.pem
   ==> Saved capm-server-my.domain.net-2.pem
   ==> Saved capm-server-my.domain.net-2-key.pem
   ```

Copy the Consul Certificate Files

Copy the Consul certificate files from the proxy server to the data aggregators.

Follow these steps:

1. Run the following command to get the shared folder name:

   NOTE
   You can use the home folder of your fault tolerant environment to store certificate files for transfer between the Data Aggregators and the proxy server. The home folder is defined in the `DA.cfg` file on the Data Aggregator as shown in following output example.

   ```
   cat /etc/DA.cfg |grep -i da.data.home=
   ```

   Output:

   ```
   da.data.home=/myDaDataHome
   ```

2. Copy the files from the proxy server to the shared folder:
   Example:

   ```
   cp /opt/CA/daproxy/conf/my.domain.net-agent-ca.pem /myDaDataHome/my.domain.net-agent-ca.pem
   cp /opt/CA/daproxy/conf/capm-server-my.domain.net-1.pem /myDaDataHome/capm-server-my.domain.net-1.pem
   cp /opt/CA/daproxy/conf/capm-server-my.domain.net-1-key.pem /myDaDataHome/capm-server-my.domain.net-1-key.pem
   cp /opt/CA/daproxy/conf/capm-server-my.domain.net-2.pem /myDaDataHome/capm-server-my.domain.net-2.pem
   cp /opt/CA/daproxy/conf/capm-server-my.domain.net-2-key.pem /myDaDataHome/capm-server-my.domain.net-2-key.pem
   ```

3. On the first data aggregator, copy the agent certificate of the proxy server, and the server certificate of this data aggregator from the shared folder:
   Example:

   ```
   cp /myDaDataHome/my.domain.net-agent-ca.pem /opt/IMDataAggregator/consul/conf/my.domain.net-agent-ca.pem
   cp /myDaDataHome/capm-server-my.domain.net-1.pem /opt/IMDataAggregator/consul/conf/capm-server-my.domain.net-1.pem
   cp /myDaDataHome/capm-server-my.domain.net-1-key.pem /opt/IMDataAggregator/consul/conf/capm-server-my.domain.net-1-key.pem
   ```

4. On the second data aggregator, copy the agent certificate of the proxy server, and the server certificate of this data aggregator from the shared folder:
   Example:

   ```
   cp /myDaDataHome/my.domain.net-agent-ca.pem /opt/IMDataAggregator/consul/conf/my.domain.net-agent-ca.pem
   cp /myDaDataHome/capm-server-my.domain.net-2.pem /opt/IMDataAggregator/consul/conf/capm-server-my.domain.net-2.pem
   cp /myDaDataHome/capm-server-my.domain.net-2-key.pem /opt/IMDataAggregator/consul/conf/capm-server-my.domain.net-2-key.pem
   ```

Configure Consul

Configure Consul on the proxy server and each data aggregator.

Follow these steps:

NOTE
Perform the following steps on the proxy server and each of the data aggregators.

1. Back up the following file:
   Proxy server:

   ```
   cp Proxy_install_directory/daproxy/conf/config.json Proxy_install_directory/daproxy/conf/config.json.orig
   ```

   Example:

   ```
   cp /opt/CA/daproxy/conf/config.json /opt/CA/daproxy/conf/config.json.orig
   ```

   Data aggregator:

   ```
   cp DA_install_directory/consul/conf/config.json DA_install_directory/consul/conf/config.json.orig
   ```

   Example:

```
cp /opt/IMDataAggregator/consul/conf/config.json /opt/IMDataAggregator/consul/conf/config.json.orig
```

2. Edit the `config.json` file to replace `"ports": {"http":8500}'` with the following parameters:
   Example:

```
"bind_addr": "x.x.x.x",
"ports": {
"http": -1,
"https": 8443
},
"verify_incoming": false,
"verify_outgoing": true,
"verify_server_hostname": true,
"ca_file": "/opt/CA/daproxy/conf/my.domain.net-agent-ca.pem",
"cert_file": "/opt/CA/daproxy/conf/capm-server-my.domain.net-0.pem",
"key_file": "/opt/CA/daproxy/conf/capm-server-my.domain.net-0-key.pem",
"auto_encrypt": {
"allow_tls": true
},
"tls_min_version": "tls11",
"tls_cipher_suites":
 "TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256,TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA38
```

   - **bind_addr**
     Specifies the IP address of this host, which is reachable from the data aggregator and proxy server hosts.
   - **ca_file**
     Specifies the Consul agent certificate file generated on the proxy server. Use the same file on all Consul hosts.
   - **cert_file**
     Specifies the Consul server certificate generated on the proxy server specifically for this host.
   - **key_file**
     Specifies the Consul server key generated on the proxy server specifically for this host.
3. Append the domain of the current host to the Consul service startup arguments:
   Example:

```
vi /etc/systemd/system/consul.service
          ExecStart=<existing args> -domain my.domain.net
systemctl daemon-reload
```

   - **my.domain.net**
     Specifies the domain of this host.
4. (Optional) To enable Consul logging, append logging arguments to the Consul service using the install path of the current host:
   Example:

```
vi /etc/systemd/system/consul.service
          ExecStart=<existing args> -log-file=/opt/IMDataAggregator/consul/log/ -log-rotate-duration=24h -
log-rotate-max-files=7
systemctl daemon-reload
```

Configure the Data Aggregators

The following steps apply only to the data aggregators, and not to the proxy server.

Follow these steps:

> **NOTE**
> Perform the following steps for each data aggregator.

1. Back up the following file:

`/etc/DA.cfg`

Example:

```
cp /etc/DA.cfg /etc/DA.cfg.orig
```

2. Edit the `DA.cfg` file, and set the following parameters:

```
da.consul.port=8443
da.consul.secure=true
```

3. Back up the following file:

```
DA_install_directory/consul-ext/bin/start-consul-ext.sh
```

NOTE
`/opt/IMDataAggregator` is the default installation directory.

Example:

```
cp /opt/IMDataAggregator/consul-ext/bin/start-consul-ext.sh /opt/IMDataAggregator/consul-ext/bin/start-consul-ext.sh.orig
```

4. Edit the `start-consul-ext.sh` file and set the following parameters:

```
CONSUL_PORT=8443
CONSUL_SECURE=true
```

5. Import the agent certificate of the proxy server into the data aggregator's Java keystore.

Example:

```
/opt/IMDataAggregator/jre/bin/keytool -import -file /opt/IMDataAggregator/consul/conf/my.domain.net-agent-ca.pem -alias daproxyagent -keystore /opt/IMDataAggregator/jre/lib/security/cacerts -storepass changeit
```

Restart Consul

Restart the Consul services on the proxy server and data aggregators.

Follow these steps:

1. Stop the Consul service on the proxy server:

```
service consul stop
```

2. Stop the Consul service on the data aggregators:

```
service consul stop
service consul-ext stop
```

3. Start the Consul service on the proxy server:

```
service consul start
```

4. Start the Consul service on the data aggregators:

NOTE
Start the service on the active data aggregator first.

```
service consul start
service consul-ext start
```

5. Verify that Consul is responding to HTTPS requests on port 8443.
The following URL should show Consul cluster members:

```
https://myDaproxyHost.my.domain.net:8443/v1/agent/members?segment=_all
```

Import the Consul Certificate

Import the Consul server certificate from the proxy server to the NetOps Portal server.

Follow these steps:

1. Copy the Consul server certificate file, `capm-server-my.domain.net-0.pem` from the proxy server to NetOps Portal:

Example:

```
cp capm-server-my.domain.net-0.pem /tmp/capm-server-my.domain.net-0.pem
```

2. Import the certificate into NetOps Portal:
   Example:
   ```
   keytool -import -file /tmp/capm-server-my.domain.net-0.pem -alias consulserverlvndaproxy -keystore /opt/CA/conf/cacerts -storepass changeit
   ```
3. Restart the NetOps Portal console service:
   ```
   service caperfcenter_console.service stop
   service caperfcenter_console.service start
   ```

Configure the Traefik Connection as HTTPS from Proxy Server to Data Aggregator

You can enable HTTPS for the data aggregator in a fault tolerant environment with multiple data aggregators.

For more information, Enable Fault Tolerant Data Aggregators to Use HTTPS.

Configure Traefik on the proxy server to the data aggregators as HTTPS.

> **IMPORTANT**
> The following configuration steps apply to 20.2.4 and higher. For more information, see Upgrade Fault Tolerant Data Aggregators.

Configure the Data Aggregators

Enable HTTPS on each data aggregator.

Follow these steps:

1. Run the following command:
   ```
   cd DA_install_directory/scripts
   ./sslConfig.sh
   ```
   > **NOTE**
   > `/opt/IMDataAggregator` is the default installation directory.

   Example:
   ```
   cd /opt/IMDataAggregator/scripts
   ./sslConfig.sh
   ```
   > **NOTE**
   > When prompted for the "common name for the certificate," use the fully qualified host name of your data aggregator (for example, "`myDaHost.my.domain.net` ").

   Output:
   ```
   ----------------------------------------
   Data Aggregator HTTPS FIPS Configurator
   ----------------------------------------

   Please choose an option:
   1 - Enable HTTPS FIPS
   2 - Disable HTTPS FIPS
   q - Quit

   ------------------------------------------
   HTTPS FIPS status                : DISABLED
   HTTP Connection status [port 8581] : SUCCESS
   ------------------------------------------

   Your choice: [Default=1]: 1
   ```

```
Would you like to proceed with enabling HTTPS FIPS on the Data Aggregator? [y/n, Default=n]: y
Do you have an existing signed certificate and key? [y/n, Default=n]: n
CA temporary files will be located in the /root/cadafips directory.

Getting Private key
Create PKCS12 keystore with the server certificate
Transform the keystore into JKS format
Importing keystore server.pkcs12 to keystore.jks...
Entry for alias 1 successfully imported.
Import command completed:  1 entries successfully imported, 0 entries failed or cancelled

Warning:
The JKS keystore uses a proprietary format. It is recommended to migrate to PKCS12 which is an industry
 standard format using "keytool -importkeystore -srckeystore keystore.jks -destkeystore keystore.jks -
deststoretype pkcs12".
Create truststore with server certificate
Certificate was added to keystore
Saving the original keystore to /opt/IMDataAggregator//apache-karaf-2.4.3/etc/keystore.bak
Saving the original truststore to /opt/IMDataAggregator//apache-karaf-2.4.3/etc/truststore.bak
Copy keystore and truststore to /opt/IMDataAggregator//apache-karaf-2.4.3/etc directory
Modify org.ops4j.pax.web.cfg
Modify jetty.xml
Modify system.properties.
Stopping DA daemon. This may take a while. Please be patient.
Redirecting to /bin/systemctl stop dadaemon.service

------------------------------------------------------------------
SSL is now enabled.
DataAggregator should be available in HTTPS at https://<da_hostname>:8582
------------------------------------------------------------------
Press enter to back to menu.
```

2. Verify that your key generated:
   Example:

   NOTE
   The following example uses "alias 1" because the `sslConfig.sh` script creates the key using that alias.

```
keytool -list -keystore /opt/IMDataAggregator/apache-karaf-2.4.3/etc/keystore -storepass changeit -alias 1
```

Output:

```
1, Sep 17, 2020, PrivateKeyEntry,
Certificate fingerprint (SHA1): 81:47:DE:CF:BC:15:DA:FB:57:1B:2A:01:C9:17:E7:F8:6E:AE:EE:EA

Warning:
The JKS keystore uses a proprietary format. It is recommended to migrate to PKCS12 which is an industry
 standard format using "keytool -importkeystore -srckeystore /opt/IMDataAggregator/apache-karaf-2.4.3/etc/
keystore -destkeystore /opt/IMDataAggregator/apache-karaf-2.4.3/etc/keystore -deststoretype pkcs12".
```

3. Copy the certificate files from the data aggregator for the DAProxy/Traefik service to use later:

   NOTE
   (Optional) Request a CA-signed certificate for this data aggregator using the self-signed certificate produced here. Copy and use your CA-signed certificate file(s), including any intermediate and root certificates, in the following steps.

   Example:

   NOTE
   In the following example, `server.cert` is the self-signed certificate that the `sslConfig.sh` script created. Change file names containing "da1" to "da2" for subsequent data aggregators.

   ```
   cp /root/cadafips/server.crt <myDAProxyHost>/tmp/da1_cert.pem
   ```

   Optional:

   NOTE
   If you requested a CA-signed certificate, include any provided intermediate and root cert files here.

   ```
   cp /tmp/IntermediateCA.crt <myDAProxyHost>/tmp/IntermediateCA.crt
   ```

4. Import the data aggregator certificate to the Java keystore for use by the consul-ext service.
   In the following example, `server.cert` is the self-signed certificate that the `sslConfig.sh` script created:

   ```
   /opt/IMDataAggregator/jre/bin/keytool -import -file /root/cadafips/server.crt -alias dacert -keystore /
   opt/IMDataAggregator/jre/lib/security/cacerts -storepass changeit
   ```

5. (Optional) If you used a CA-signed certificate for this DA, import any included intermediate and root certificates to the java keystore.

   Example:

   ```
   /opt/IMDataAggregator/jre/bin/keytool -import -file /tmp/IntermediateCA.crt -alias daintermediate -
   keystore /opt/IMDataAggregator/jre/lib/security/cacerts -storepass changeit
   ```

6. Back up the `checkDAStatus.groovy` file.

   Example:

   ```
   cp /opt/IMDataAggregator/consul-ext/scripts/checkDAStatus.groovy /opt/IMDataAggregator/consul-ext/scripts/
   checkDAStatus.groovy.orig
   ```

7. Edit the `checkDAStatus.groovy` file to use the fully qualified host name.

   NOTE
   This assumes you specified the fully qualified host name when generating the certificates for this data aggregator host.

   Example:

   ```
   vi /opt/IMDataAggregator/consul-ext/scripts/checkDAStatus.groovy
   ```

   Change this:

   ```
   hostname = InetAddress.getLocalHost().getHostName()
   ```

   To this:

   ```
   hostname = InetAddress.getLocalHost().getCanonicalHostName()
   ```

Configure the Proxy Server

Update the proxy server configuration.

Follow these steps:

1. Copy the data aggregator certificates to the trusted root certificate folder:
   Example:
   ```
   cp /tmp/da1_cert.pem /etc/pki/ca-trust/source/anchors/da1_cert.pem
   cp /tmp/da2_cert.pem /etc/pki/ca-trust/source/anchors/da2_cert.pem
   ```
   Optional:
   NOTE
   If you requested a CA-signed certificate, include any provided intermediate and root cert files here.
   ```
   cp /tmp/IntermediateCA.crt /etc/pki/ca-trust/source/anchors/IntermediateCA.crt
   ```
2. To update the trusted root certificates, run the following command:
   ```
   update-ca-trust extract
   ```
3. Update the proxy server configuration:
   NOTE
   The following steps configure the connection from the proxy server to the data aggregators only. Do not modify the other "HTTPS" sections of the `daproxy.toml` file at this time.
   Example:
   ```
   cd /opt/CA/daproxy/conf
   vi daproxy.toml
   ```
4. Update the "url" values to use "https", the host names that include the domain, and the port values for your data aggregators:
   Example:
   ```
   [http.services]
       [http.services.DAService.loadBalancer]
           [http.services.DAService.loadBalancer.healthcheck]
            path = "/"
            interval = "10s"
           [[http.services.DAService.loadBalancer.servers]]
             # Change to https and 8582 when configuring HTTPS
             url = "https://myDaHost1.my.domain.net:8582"
           [[http.services.DAService.loadBalancer.servers]]
             # Change to https and 8582 when configuring HTTPS
             url = "https://myDaHost2.my.domain.net:8582"
   ```
5. Restart the DAProxy service:
   ```
   service daproxy stop
   service daproxy start
   ```
6. Do one of the following steps to verify your connection:
   - If you have not configured NetOps Portal to the proxy server connection as HTTPS, access the following URL:
     Example:
     ```
     https://myDAProxyHost:8581
     ```
   - If you have configured NetOps Portal to the proxy server connection as HTTPS, access the following URL:
     Example:
     ```
     https://myDAProxyHost.my.domain.net:8582
     ```
   - Open NetOps Portal, hover over **Administation: Data Sources**, click **Data Sources**, **Data Aggregator**, and **Test**.

Enable Single Sign-On Spoofing Protection

For enhanced security, enable Single Sign-On URL spoofing protection. When this protection is enabled, users can log in using only authorized URLs. The Log In button is disabled for all other URLs. Otherwise, users get only a warning regarding suspicious URLs.

The list of available authorized URLs is populated based on successful log in attempts before protection is enabled.

Follow these steps:

1. Hover over **Administration**, and click **Configuration Settings: Single Sign-On Settings**.
2. Select **Enable SSO URL Protection**.
3. Select Authorized URLs.
4. Click **Save**.

Obfuscate Jetty Passwords

The password values for the `jetty.sslContext.keyStorePassword` , `jetty.sslContext.keyManagerPassword` , and `jetty.sslContext.trustStorePassword` parameters are stored in plain text by default in the `PC/start.d/ssl.ini` file and the `sso/start.d/ssl.ini` file. However, you can obfuscate them.

Follow these steps:

1. Run the following command to generate a secured version of the password:

```
$ cd /opt/CA/PerformanceCenter/jetty

$ java -cp lib/jetty-util-
version
.jar org.eclipse.jetty.util.security.Password
password
```

– ***version*** The installed version of jetty

Example output:

```
$ java -cp lib/jetty-util-9.4.7.v20170914.jar
 org.eclipse.jetty.util.security.Password password_to_encrypt

2018-03-16 17:37:01.212:INFO::main: Logging initialized @148ms to
 org.eclipse.jetty.util.log.StdErrLog

password_to_encrypt

OBF:1y7v1ugg1zsp1yf41w9f1wu81vnw1rpg1tv31z0f1tvz1rp61vn61wu61w8b1yf21zt11uha1y83

MD5:403956d7e303ee5f1c3714041a74e0fa
```

2. Open the `PC/start.d/ssl.ini` file.
3. Replace the plain text password with the entire obfuscated value including "`OBF` ":

```
# SSL
# define the port to use for secure redirection
```

```
jetty.ssl.port=8182
jetty.https.port=8182
jetty.httpConfig.securePort=8182
# Set up a keystore and truststore
jetty.sslContext.keyStoreType=JKS
jetty.sslContext.keyStorePath=etc/keystore_file.ks
jetty.sslContext.trustStorePath=etc/keystore_file.ks
# Set up passwords
jetty.sslContext.keyStorePassword=
password
jetty.sslContext.keyManagerPassword=
password
jetty.sslContext.trustStorePassword=
password
```

Example:

```
# SSL
# define the port to use for secure redirection
jetty.ssl.port=8182
jetty.https.port=8182
jetty.httpConfig.securePort=8182
# Set up a keystore and truststore
jetty.sslContext.keyStoreType=JKS
jetty.sslContext.keyStorePath=etc/keystore_file.ks
jetty.sslContext.trustStorePath=etc/keystore_file.ks
# Set up passwords

jetty.sslContext.keyStorePassword=OBF:1y7v1ugg1zsp1yf41w9f1wu81vnw1rpg1tv31z0f1tvz1rp61vn61wu
jetty.sslContext.keyManagerPassword=OBF:1y7v1ugg1zsp1yf41w9f1wu81vnw1rpg1tv31z0f1tvz1rp61vn61
jetty.sslContext.trustStorePassword=OBF:1y7v1ugg1zsp1yf41w9f1wu81vnw1rpg1tv31z0f1tvz1rp61vn61
```

Update Single Sign-On Website Settings

You can change the default settings for Single Sign-On using the Single Sign-On Configuration Tool. For example, you can change the virtual directory for the Single Sign-On website.

You can change other settings that affect Single Sign-On behavior when users attempt to log in. Some parameters also affect user interface (UI) behavior, such as the timeout period that logs the user out automatically in response to inactivity.

> **WARNING**
> Updates to the Single Sign-On website only affect CA data source products that are running on the same server because of the distributed architecture of the software.

Follow these steps:

1. Log in to the server where NetOps Portal or a CA data source product is installed.

Log in as root or with the `sudo` command.

2. Launch the Single Sign-On Configuration Tool by running the `./SsoConfig` command in the following directory:
   InstallDirectory`/PerformanceCenter`

   NOTE
   `/opt/CA` is the default installation directory.

   You are prompted to select an option. The available options correspond to CA applications running on the local server.
   Use the following commands as needed while you are selecting settings:
   - `q` (quit)
   - `b` (go back to the previous menu)
   - `u` (update)
   - `r` (reset)
3. Enter **1** to configure NetOps Portal.
4. Enter **4** for Single Sign-On.
   You are prompted to specify the priority.
   The `Priority` parameter only applies to NetOps Portal.
5. Enter one of the following options:
   - **1. Remote Value**
     These settings are propagated to all other CA applications and data sources that are registered to this instance of NetOps Portal. This includes the Event Manager in NetOps Portal, which embeds the URL of NetOps Portal. NetOps Portal uses `Remote Value` settings only if a corresponding `Local Override` value is not present.
   - **2. Local Override**
     Overrides a setting on this NetOps Portal instance, which does not propagate to other CA applications and data sources (including Event Manager) registered to this instance of NetOps Portal. `Local Override` takes precedence over both the `Remote Value` and default settings.

   You are prompted to select a property to configure.

   NOTE
   Configure the scheme or port using `Remote Value` to include the correct Performance Center URL in threshold event email messages.
6. Enter one or more of the following properties. When prompted, enter `u` to update the value and supply a new value:
   - **1. Anonymous User Enabled**
     Specifies whether the Sign-In page appears when users attempt to log in to a data source product interface. A value for the `Anonymous User ID` parameter is required if this parameter is enabled. Users do not see the Sign-In page when they attempt to log in. They are logged in as the user associated with the `Anonymous User ID` parameter.
     The `Localhost User Enabled` parameter takes precedence when the following conditions are met:
     - The user is logging in from the Single Sign-On server.
     - The `Localhost User Enabled` and `Anonymous User Enabled` parameters are enabled.

     Default: Disabled

     NOTE
     The Anonymous User login takes precedence over Windows Authentication.
   - **2. Anonymous User ID**
     Specifies the username that is used to authenticate the user automatically, bypassing the Sign-In page. This parameter is used only if the `Anonymous User Enabled` parameter is enabled. Select one of the following values:
     - **1 -** The username for the default administrator account (admin).
     - **2 -** The username for the default user account (user).
     - Another username that exists in the NetOps Portal database.
   - **3. Localhost User Sign-In Page Enabled**

Specifies whether the Sign-In page appears when users log in from the server where Single Sign-On is installed. If this parameter is enabled, the Sign-In page appears, even if users log in from the server where Single Sign-On is installed.
If this parameter is disabled, the following rules apply:

- The `Localhost User Enabled` parameter must be enabled.
- The value for the `Localhost User ID` parameter must contain a valid product username. This value is used to log in the user to the UI, bypassing the Sign-In page.

Default: Disabled

– **4. Localhost User Enabled**
Specifies whether users are automatically signed in--bypassing the Sign-In page--when they are logging in from the server where Single Sign-On is installed. A value for the `Localhost User ID` parameter is required if this parameter is enabled.

- If the `Localhost User Sign-In Page Enabled` parameter is enabled, this parameter is used in cases where users click **Sign In** without entering a username or password. Users are then logged in to the application as the user associated with the `Localhost User ID` parameter.
- If users do supply a username and password, those credentials are used for authentication.
- If this parameter is enabled but the `Localhost User Sign-In Page Enabled` parameter is disabled, users bypass the Sign-In page. Users are instead logged in to the UI using the value of the `Localhost User ID` parameter.
- If users log in from the server where Single Sign-On is installed and the `Localhost User Enabled` and `Anonymous User Enabled` parameters are enabled, the `Localhost User Enabled` parameter takes precedence.

Default: Disabled

– **5. Localhost User ID**
Specifies the user ID that is used to authenticate users automatically--bypassing the Sign-In page--when they log in to the server where Single Sign-On is installed. This parameter is used only if the `Localhost User Enabled` parameter is enabled. Enter one of the following values:
1 - The username for the default administrator account (admin).
2 - The username for the default user account (user).

– **6. Cookie Timeout Minutes**
Specifies the number of minutes that pass before a Single Sign-On cookie expires. Each time a user performs an action in a data source product interface, the cookie timeout resets. If the timeout expires, the user is logged out and must reauthenticate.
Default: 20 minutes

– **7. Encryption Decryption Key**
Specifies the key that is used to encrypt and decrypt a Single Sign-On cookie.

– **8. Encryption Algorithm**
Specifies the encryption algorithm that is used to encrypt and decrypt a Single Sign-On cookie. Enter **DES** or **AES** as the value.

> **WARNING**
> For FIPS-compliant encryption, use AES encryption. DX NetOps Performance Management is not fully FIPS-compliant. This feature is for FIPS-compliant encryption only and does not meet full FIPS compliance. CA Application Delivery Analysis, Network Flow Analysis, and CA Unified Communications Monitor do not support AES encryption.
> For more information, see FIPS-Compliant Encryption.

– **9. Failed Sleep Seconds**
Specifies the number of seconds Single Sign-On waits after a failed sign-in attempt.

– **10. Remember Me Enabled**
Specifies whether the **Remember Me** check box is displayed on the Sign-In page. When the **Remember Me** check box is selected, Single Sign-On uses the value for `Remember Me Timeout Days` to determine when the Single

Sign-On token expires. If the `Remember Me Enabled` parameter is disabled, a user is automatically logged out when the Single Sign-On token expires after `Cookie Timeout Minutes` . When using SAML, if the `Remember Me Enabled` parameter is enabled, the Single Sign-On token uses the value for `Remember Me Timeout Days` to set its expiration. If the `Remember Me Enabled` parameter is disabled, the Single Sign-On token uses `Cookie Timeout Minutes` to set its expiration.
Default: Enabled

- **11. Remember Me Timeout Days**
  Specifies the number of days that pass before a user who selected the **Remember Me** check box on the Sign-In page must re-authenticate. This parameter is only used if the `Remember Me Enabled` parameter is enabled. A value of **0** indicates that the **Remember Me** setting does not expire; the user must click the **Sign Out** link in a data source product interface.
- **12. Scheme**
  Specifies the URL scheme that data source products can use to access the Single Sign-On application. If you are using SSL, enter **https:** as the value.
- **13. Port**
  Specifies the URL port that data source products can use to access the Single Sign-On application.
- **14. Virtual Directory**
  Specifies the name of the virtual directory for Single Sign-On.

  NOTE
  The virtual directory is required to use an encryption scheme for communications among CA servers.

  Default: SingleSignOn

  NOTE
  Changing the value for any of the previous parameters does not replace the default value, but the new value now takes precedence. The new value is actually a Local Override.
- **15. Allow Single Sign-On in a frame (Local Override)**
  Determines whether Single Sign-On can display within a frame in a web page.
  Default: Disabled

  NOTE
  With single sign-on in frames set to disabled, the browser view is functional only for pages that are also on the server where Single Sign-On is installed.

7. Enter **b** after you have finished changing the default settings.
   You return to the previous set of options.
8. Enter **b** again to go back to the first set of options.
9. Enter **q** to close the Single Sign-On Configuration Tool.
   The Single Sign-On Configuration Tool closes.
   NetOps Portal directs all unauthenticated users to the Single Sign-On website using the new values that you supplied.

Add Custom HTTP Headers

For enhanced security, in 3.7.9 and higher only, you can add custom HTTP headers with the SSO configuration tool.

Follow these steps:

1. Launch the SSO configuration tool by running the '`./SSOConfig`' command in the following directory:
   PC_Install_Directory`/PerformanceCenter`

   NOTE
   `/opt/CA`
   is the default installation directory.
2. Specify `1` for **CA Performance Center**.

3. Specify `3` for **Performance Center**.
4. Specify `2` for **Local Override**.
5. Specify `21` for **Custom HTTP Headers**.
6. Specify `u` to update the setting.
7. Specify the following code:

```
X-XSS-Protection:1; mode=block|X-Content-Type-Options:nosniff|Strict-Transport-Security:max-age=31536000;
 includeSubDomains
```

   NOTE
   A vertical bar(|) separates the headers. The headers contain the header name and value separated by a colon(:).
8. Specify `q` to exit the SSO configuration tool.
   Responses now include your custom headers and these settings remain after upgrade.

Logs

To investigate issues, review any log messages that occurred around the time of the issue. Each DX NetOps Performance Management component includes separate log files:

Support often requests log files or changes the log configuration. CARE collects the log files.

Data Aggregator Logs

The Data Aggregator supports standard log4j configuration and logging levels. Use the following file to configure the logs:
`/opt/IMDataAggregator/apache-karaf-2.4.3/etc/org.ops4j.pax.logging.cfg`

Data Aggregator logs are available in the following directory:
`/opt/IMDataAggregator/apache-karaf-2.4.3/data/log`

The following logs provide potentially useful information.

- `Exception.log`
  This log includes exceptions and warnings. When the system is operating normally, this log contains no messages. Exceptions in this log require attention from CA Support.
  If an exception is repeated, recurring entries in the log do not include the stack trace. A recurrence count indicates how many times the exception has occurred.
- `karaf.log`
  This log is a catch all for Data Aggregator information.
- `LongRunningAndFailedQueries.log`
  This log lists errors and information messages related to database queries.
  – Long running queries are requests that take longer than 60 seconds to complete.
  – Queries time out and fail after 110 seconds.
- `PollSummary.log`
  This log shows poll responses that the data aggregator receives from the Data Collectors. Use this log to verify that Data Aggregator is receiving poll responses.

By default, the Data Aggregator supports 1-10 backups with a max files size of 100 MB.

Undocumented logs in the log directory are for internal use only.

Performance Center Logs

NetOps Portal log filenames include the relevant date and time. New log files are generated automatically each day. Older log files are removed automatically after 14 days to avoid consuming excessive disk space.

Access the most recent log file to find errors that are associated with the database or data source synchronization. You can start by opening the Events dashboard from the Dashboards tab and sorting by Status. If you want to look at the related log file, note the event type and failure date and time. In the log directory, open the log file with the corresponding date in the filename.

The following logs are stored in subfolders that correspond to a service (or daemon). Find the following log files in the following path:
`CA/PerformanceCenter/servicename/logs`

Replace the ***servicename*** parameter with one of the following service names:

- **DM**
  The Device Manager
  - **DMService.log**
    Output from the Device Manager, primarily related to synchronization.
  - **wrapper.log**
    caperfcenter_devicemanager process logging.
- **EM**
  The Event Manager
  - **EMService.log**
    Output from the Event Manager; includes details of events and alarms.
  - **wrapper.log**
    caperfcenter_eventmanager process logging.
- **PC**
  The main console program
  - **PCService.log**
    NetOps Portal-related logging; comprises user interface and view components.
  - **wrapper.log**
    caperfcenter_console process logging.
- **SSO**
  The Single Sign-On authentication software
  - **SSOService.log**
    Single Sign-On logging, including HTTPS (Secure Sockets Layer) information where HTTPS has been configured.
  - **wrapper.log**
    caperfcenter_sso process logging.

  For problems with the Single Sign-On Configuration Tool, view the following application log:
  `/opt/CA/PerformanceCenter/sso/logs/application.log`

The MySQL error log is stored by default in the following path:

`/opt/CA/MySql/data`

- **MySQL**
  - ***hostname*.err**
    The hostname is the name of the system. This file contains errors related to MySQL.

SSO Audit Log

To support security auditing, Single Sign-On logs details about user login activity to a file. Each time a user attempts to log in to the NetOps Portal login page, SSO logs an entry in the audit log. If SSO redirects the user to a SAML2 server to log

in or re-authenticate, SSO only logs successful logins. Check the log to verify user activity. The log contains one line per login.

The following details are written to the log per login request:

- Time and date stamp when the user logged in
- Product code (for example, pc for NetOps Portal)
- Username
- Whether the Remember Me option was selected
- Single Sign-On version
- The remote host IP address

Follow these steps:

1. Log in to the server where a CA data source product is installed.
2. Open a command prompt, and cd to the following directory:
   `[InstallationDirectory]/PerformanceCenter/sso/logs`

   NOTE
   The audit log is saved in the following location on Windows servers:

   `[InstallationDirectory]\Portal\SSO\logs.`
3. Enter dir to see the contents of the directory.
   The filename of the log file is SingleSignOnAuditLogyyyy-mm-dd.log.
4. Enter the name of the audit file you want to view.
   The file opens in the local text editor application.

FIPS-Compliant Encryption

By default, when DX NetOps Performance Management synchronizes the Simple Network Management Protocol (SNMP) Profiles to Federal Information Processing Standards (FIPS)-compatible data sources, it encrypts the following parameters using a FIPS-compliant algorithm:

SNMPv1/v2c:

- Community Name

SNMPv3:

- User Name
- Authentication Password
- Privacy Password

FIPS-compatible data sources include the data aggregator, the Event Manager, and DX NetOps Spectrum. For other data sources, DX NetOps Performance Management synchronizes these parameters using a non-FIPS-compliant algorithm. For more information, see SNMP Profiles.

You can also configure DX NetOps Performance Management to use FIPS-compliant encryption and hashing algorithms (where applicable) for user passwords and Single Sign-On. By default, FIPS-compliant encryption is not enabled.

IMPORTANT
DX NetOps Performance Management is not fully FIPS-compliant. This feature is for FIPS-compliant encryption only and does not meet full FIPS compliance.

Enable FIPS-Compliant Encryption

If you enable FIPS-compliant encryption and you upgrade NetOps Portal before the data aggregator as recommended, temporary FIPS compatibility synchronization errors occur. This temporary condition is resolved when you upgrade the data aggregator.

> **WARNING**
> To avoid disabling the data aggregator data source, do not enable FIPS when a product upgrade is in progress and different versions of NetOps Portal and the data aggregator might be in place.

After you enable FIPS-compliant encryption, you cannot register or use data sources which do not support FIPS. Registered data sources that do not support FIPS are disabled when you enable this feature.

> **WARNING**
> Enabling FIPS-compliant encryption is not reversible. The only way to roll back the configuration is to restore the **netqosportal** and **em** database for NetOps Portal.
> For more information, see Restore Performance Center.

> **TIP**
> Enable FIPS-compliant encryption during non-business hours. Any active user sessions are invalidated when FIPS is enabled. Users need to log back in. The logs might also temporarily show encryption errors when these user sessions are invalidated.

Follow these steps:

1. Back up the **netqosportal** NetOps Portal database.
   For more information, see Back Up Performance Center.
2. Log in to the NetOps Portal host.
3. Navigate to the NetOps Portal directory by issuing the following command:
   ```
   cd /opt/CA/PerformanceCenter
   ```
4. Launch the SSO Configuration utility by issuing the following command:
   ```
   ./SsoConfig
   ```
5. Select CA NetOps Portal.
6. Select and run **option 7: Enable FIPS**.
7. Follow the prompts in the console.

The utility configures DX NetOps Performance Management to use FIPS-compliant encryption and hashing algorithms.

Next Steps

After you enable FIPS-compliant encryption, verify that the system is working. Store the most recent NetOps Portal backup in a secure location in case you have to roll back the configuration. Remove previous NetOps Portal backups or store the backups in a secure location. Passwords in backups from before you enable FIPS-compliant encryption do not use FIPS-compliant encryption.

Integrating

DX NetOps Performance Management integrates with other CA Technologies monitoring software. Each integration enriches the available data and provides more information about your infrastructure.

Many integrations, such as CA Application Delivery Analysis and Network Flow Analysis, use the data source model. The integrated product collects data and sends it to NetOps Portal for visualization. NetOps Portal controls administrative functions. For more information, see Manage Data Sources.

Other integrations, such as DX NetOps Virtual Network Assurance and DX NetOps Mediation Manager, connect to a Data Collector, and inject the data into the Data Aggregator data source. With these integrations, data appears to be native to the DX NetOps Performance Management environment.

Table 1: Performance Monitoring Integrations

Product Integrations with DX NetOps Performance Management	Integration Business Value
DX NetOps Virtual Network Assurance	DX NetOps Virtual Network Assurance enables existing infrastructure management solutions to monitor software-defined networking (SDN) and network functions virtualization (NFV). For more information, see Modern Network Monitoring.
CA Application Delivery Analysis	CA Application Delivery Analysis provides end-to-end performance monitoring through dashboards and views that show historically normal performance for users and metrics that cross acceptable performance thresholds. For more information, see Application Delivery Analysis Views.
Network Flow Analysis	Network Flow Analysis gives you an enterprise-wide view into the composition of traffic on every link and helps you detect threatening traffic patterns in the making. For more information, see Register and Configure Network Flow Analysis.
CA Unified Communications Monitor	CA Unified Communications Monitor passively monitors the performance of your unified communications systems to maintain and report on the quality of audio and video calls. For more information, see UC Monitor Views in NetOps Portal.
CA Application Performance Management	The NetOps Portal, Data Aggregator, and Data Collector components are supported for instrumentation with CA Application Performance Management (APM). APM receives performance metrics about the component services and hosts. For more information, see Monitor Server Performance with DX Application Performance Management.
DX NetOps Mediation Manager	DX NetOps Mediation Manager monitors the performance for non-SNMP based devices, such as mobile wireless, fiber-optic switch, radio access, and 3G or 4G voice data. DX NetOps Mediation Manager supports a wide range of protocols to access data, for example, SOAP, SSH, XML, SQL, JMS, SFTP, and HTTP. DX NetOps Mediation Manager is portable across all platforms. For more information, see Generate MM Device Packs.
DX NetOps Spectrum	DX NetOps Spectrum is a services and infrastructure management system that monitors the state of managed elements including the following: • Devices • Applications • Host systems • Connections For more information, see Integrate DX Spectrum for Fault Management.

Product Integrations with DX NetOps Performance Management	Integration Business Value
CA Business Intelligence	The CA Business Intelligence integration with DX NetOps Performance Management offers access to CA Business Intelligence reports and dashboards through NetOps Portal. For more information, see Integrate CA Business Intelligence.

Application Delivery Analysis Views

CA Application Delivery Analysis provides end-to-end performance monitoring through dashboards and views that show historically normal performance for users and metrics that cross acceptable performance thresholds. CA Application Delivery Analysis gathers troubleshooting information, and helps you to determine the origin of an application, network, or server performance problem. A CA Application Delivery Analysis user with the Administrator product privilege can configure the product to automatically initiate notifications or investigative actions for performance anomalies.

The CA Application Delivery Analysis views available in NetOps Portal are different from the views available in CA Application Delivery Analysis. Each view has a column titled Data Source when multiple data sources are available. Also, each view offers a context that filters the results. For example, CA Application Delivery Analysis views can be configured with a server context, which allows you to report on a particular server.

Metrics

When registered as a data source, CA Application Delivery Analysis views report on the following metrics:

Active Sessions

Measures the number of active TCP sessions reported by a monitor feed that match an application/server/network combination on the management console.

Byte Loss Percentage

Measures the ratio of retransmitted data to total data, percentage of data lost on the monitored network, and loss rate in bytes per second.

Completed Sessions

Measures the number of sessions completed during a 5-minute monitoring period.

Connection Setup Time

Measures the amount of time that it takes to establish a TCP session between the client and server before data transfer can begin.

Data Transfer Time

A Combined metric that measures the time that it takes to transmit a complete application response from the first response (the end of the Server Response Time) to the last packet sent in that request. Data Transfer Time excludes the initial server response time and includes NRTT if there is no more data to send than fits in the TCP window. The response

time can be impacted by the design of the application or the performance of the server or network. The CA Application Delivery Analysis management console does not open an incident when the Data Transfer Time threshold is crossed.

Effective Network Round Trip Time

Is a Network metric that consists of Network Round Trip Time plus Retransmission Delay. Note that Retransmission Delay is not the delay due to any retransmissions; it is the average amount of retransmission delay per round trip. It is important to note that the management console adds two averages, and combines two metrics. The CA Application Delivery Analysis management console opens a Network incident when the incident threshold for this metric is crossed.

Estimated Client Transaction TIme

Provides an approximation of Total Transaction Time in the absence of a Client segment. This metric is the summation of the Server segment Transaction Time and the WAN segment Network Round Trip Time. This is not an “engineering” level metric, but it can provide an indicator of the order of magnitude of response time for a given location or time of day. This metric is only available with a CA ADA 9.3 data source.

Expired Sessions

Measures the number of TCP sessions where the CA ADA Monitor service did not see the TCP session tear down (FIN or RST packet). Sessions which are inactive for a period of time are cleared out of memory and marked as Expired. The management console classifies a session as Expired if it does not observe any packets in a 15-minute period. Too many expired sessions left open can cause servers to become unresponsive.

From Server Bytes

Measures the number of bytes that a server sent to a client.

From Server Packets

Measures the number of packets that a server sent to a client.

Network Connection Time (NCT or NSCT)

Is a Network metric that measures the amount of time between the Syn-Ack sent by the server and the Ack received back from the client. When a network is uncongested, it is a measurement of network latency that represents the minimum latency due to distance and serialization, and is the best possible round trip time for your network architecture. Sudden spikes in this value are commonly attributed to congestion, while a plateau (which goes up and stays up) typically indicates a path change. The CA Application Delivery Analysis management console opens a Network incident when the incident threshold for this metric is crossed.

Network Round Trip Time

A Network metric that measures the time that a packet takes to travel across the network in both directions between the server and clients on a network, excluding loss. Application, server, and client processing time are excluded. The CA Application Delivery Analysis management console opens a Network incident when the incident threshold for this metric is crossed.

Observations

The observation count measures the number of times during a 5-minute monitoring interval that a monitoring device calculated a performance metric for a particular application/server/network combination. Within a TCP transaction there can be different numbers of observations of different metrics. For example, there may be more observation counts for Network Round Trip Time than Server Response Time. Other metrics are links, and always have the same number of observations. For example, each TCP transaction has one Server Response Time observation and one Data Transfer

Time observation. To rate a metric as Normal, Minor (yellow), or Major (orange), the metric must have a minimum number of observations.

Open Sessions

Measures the number of sessions still open at the end of the data collection period. Open sessions might become Expired or Completed during subsequent reporting intervals.

Packet Loss Percentage

A Network metric that measures the ratio of retransmitted data to total data within the network. This is measured from the vantage point of the monitoring device, which is next to the server. The monitoring device can identify packets retransmitted by the server because of data losses in the server-to-client direction along the network path. When data loss occurs in the client-to-server direction (in the network path before reaching the server, for example), the monitoring device cannot observe such packet loss, and that delay is not included in the Packet Loss Percentage. On the Engineering page of the CA Application Delivery Analysis management console, Packet Loss Percentage is part of the QoS report. The CA Application Delivery Analysis management console opens a Network incident when the incident threshold for this metric is crossed.

Rate from Server in Bytes

Measures the rate of data from the server in bytes.

Rate from Server in Packets

Measures the rate of data from the server in packets.

Rate to Server in Bytes

Measures the rate of data to the server in bytes.

Rate to Server in Packets

Measures the rate of data to the server in packets.

Refused Session Percentage

A Server metric that measures the percentage of connection requests that the server explicitly rejected during the reporting interval. This metric is part of the Unfulfilled TCP/IP Session Requests report in the CA Application Delivery Analysis management console. The CA Application Delivery Analysis management console opens a Server incident when the incident threshold for this metric is crossed.

Refused Sessions

Measures the number of connection requests that were explicitly rejected by the server during the three-way handshake.

Retransmission Delay

A Network metric that measures the elapsed time between sending the original packet and sending the last duplicate packet. The management console reports Retransmission Delay as an average across observations, and not just for the retransmitted packets. For example, if one packet in a set of 10 requires 300 ms of retransmission time, the Retransmission Delay is reported as 30 ms (300 ms/10 packets). The CA Application Delivery Analysis management console opens a Network incident when the incident threshold for this metric is crossed.

Retransmitted Bytes

Measures the amount of bandwidth used by retransmitted data.

Retransmitted Packets

Measures the increased load on the network infrastructure due to retransmitted packets.

Server Connection Time (SCT)

A Server metric that measures the amount of time that a server takes to acknowledge the initial client connection request by sending a Syn-Ack in response to the client's SYN packet. The CA Application Delivery Analysis management console opens a Server incident when the incident threshold for this metric is crossed.

Server Response Time

A Server metric that measures the time that it takes for a server to send an initial response to a client request or the initial server "think time." Increases in the Server Response Time generally indicate a lack of server resources such as CPU, memory, disk, or I/O, a poorly written application, or a poorly-performing tier in a multi-tier application. The CA Application Delivery Analysis management console opens a Server incident when the incident threshold for this metric is crossed.

Session Duration

Measures the duration of each TCP session.

To Server Bytes

Measures the number of bytes that a client sent to a server.

To Server Packets

Measures the number of packets that a client sent to a server.

Total Bytes

Measures the total bytes transmitted in and out.

Total Packets

Measures the total packets transmitted in and out.

Total Sessions

Indicates the total number of sessions that Completed or Expired in the sampling period. The sum of completed sessions and expired sessions is equal to the number of total sessions. It does not include Open, Unresponsive, or Refused sessions.

Transaction Time

A Combined metric that measures the amount of time elapsed from when the client sends the request to when it receives the last packet in the response. Transaction Time is the sum of Server Response Time, Network Round Trip Time, Retransmission Delay, and Data Transfer Time. The CA Application Delivery Analysis management console does not open an incident when the Transaction Time threshold is crossed.

Unresponsive Session Percentage

A Server metric that measures the percentage of sessions where a connection request was sent, but the server never responded. Part of the Unfulfilled TCP/IP Session Requests view. The CA Application Delivery Analysis management console opens a Server incident when the incident threshold for this metric is crossed.

Unresponsive Sessions

Indicates the number of sessions where a connection request was sent, but the server never responded.

User Count

Indicates the number of unique clients observed during the sample period.

User Throughput

Indicates the number of bytes transmitted divided by the time required to transmit the information.

ADA Dashboards

DX NetOps Performance Management offers CA Application Delivery Analysis (ADA) dashboards. ADA views are also included in NetOps Portal dashboards. The following CA ADA dashboards are available:

- Application Performance Dashboard
- Network Overview Dashboard (CA ADA)
- Network Performance Dashboard (CA ADA)
- Performance Events Dashboard
- Server Overview Dashboard (CA ADA)
- Server Performance Dashboard (CA ADA)

Application Performance Dashboard

The Application Performance Dashboard provides the following application performance and incident views:

Incident Count by Application (CA ADA)

The Incident Count by Application view lists the applications that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching Network and Server incidents to trouble tickets.

By default, the incident count includes Open and Closed incidents where the performance threshold for a Server metric or Network metric was exceeded during more than one 5-minute reporting interval.

> **NOTE**
>
> This view does **not** include Combined Metrics (Data Transfer Time and Transaction Time) because CA Application Delivery Analysis (CA ADA) opens a Network or Server incident when the threshold for a Combined metric is exceeded.

Click an application to view its incidents in the CA ADA management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**

Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.

- **Included**
  Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
  - Closes the existing incidents
  - Opens new incidents, if performance degrades

- **Metric Type**
  Filter the incident count by Server metric, Network metric, or Combined metric.
  - **Minimum Elapsed Time (Minutes)**
    Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
  - **Minimum Severity**
    From least severe to most severe, include:
    - **Minor:** Includes all incident severities in the Incident count. This is the default.
    - **Major:** Includes incidents that have a Major or Unavailable severity.
    - **Unavailable:** Includes Unavailable incidents.
  - **Incident State**
    For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

    Choose one of the following options:
    - Open
    - Closed
    - Open and Closed. This is the default.
  - **Context Settings**
    Displays the view filter. A context type of:
    - **Summary**
      Filters the view based on the selected group.
    - **Server**
      Filters the view based on the selected server.
  - **Apply Changes**
    Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Application (CA ADA)

The Performance by Server view provides information about application performance. This view displays performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**

Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.

- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**
  Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Map by Application (CA ADA)

The Performance Map by Application view provides a Top N view into the worst performing applications based on a particular metric. Configure this view to measure application performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Network view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**

Choose a metric to filter the list of networks.

- **Context Settings**
  Display the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Network Overview Dashboard (CA ADA)

Use the Network Overview Dashboard to determine the network device status. This dashboard gives you a broad view of network performance, and helps you to track discards and errors associated with networking infrastructure.

By default, the Network Overview Dashboard contains the following views. Note that some views require a CA Application Delivery Analysis data source:

- Incident Count By Network
- Performance Scorecard
- Top CPU Utilization Routers/Switches Gauge/Table
- Top Enterprise Hosts by Volume
- Top Enterprise Protocols by Volume
- Top Interface Errors - Discards
- Top Interface Utilization - In - Trend/Table
- Top Interface Utilization - Out - Trend/Table
- Top Memory Utilization Routers/Switches - Gauge/Table

Network Performance Dashboard (CA ADA)

The Network Performance dashboard provides network performance and incident views, and views of interface and router health and status. This dashboard emphasizes interface utilization, and includes lists of devices for easy drilldown into device performance and availability data.

By default, the Network Performance dashboard contains the following views. Note that some views require a CA Application Delivery Analysis data source:

- Groups and Sites
- Incident Count By Network
- Incident List by Network
- Performance Maps
- Top Interface Errors - Discards
- Top Interface Utilization - In - Trend/Table
- Top Interface Utilization - Out - Trend/Table
- Top Performance by Network
- Top Performance Map by Network

Performance Events Dashboard

The Performance Events dashboard provides performance and incident views of network, server, and applications.

By default, the Performance Events dashboard contains the following views:

- Incident Count by Application
- Incident Count By Network
- Incident Count by Server
- Incident List by Network
- Incident List by Server
- Performance by Application
- Performance by Network
- Performance by Server

Server Overview Dashboard (CA ADA)

The Server Overview Dashboard shows an overview of server and application performance. The views on this dashboard help you to track memory and CPU utilization levels on critical servers.

The following topics are covered in this section:

- Performance Scorecard
- Top CPU Utilization
- Top Disk Storage
- Top Disk Utilization
- Top Least Available Servers
- Top Least Reachable Servers
- Top Memory Utilization

Server Performance Dashboard (CA ADA)

The Server Performance dashboard provides server performance and incident views, and health- and status-related data from servers and groups of servers.

- Groups and Sites
- Incident Count by Server
- Performance by Server
- Performance Map by Server
- Servers (Universal List)

ADA Views

The following CA Application Delivery Analysis (ADA) views are available in NetOps Portal:

- Engineering Trend
- Incident Counts
- Incident Lists
- Performance Maps
- Performance Scorecard (ADA View)
- Performance Views

Engineering Trend

The Engineering Trend view provides an engineering chart for a particular Server metric, Network metric or Combined metric.

If baseline data is applicable, the grey line indicates the number of observations. Not every metric supports baseline or observation data.

> **NOTE**
> This view does not support data from multiple data sources. If you registered multiple instances of CA ADA, edit the view to filter by one data source. You may also change the dashboard group context by clicking the Group link. Using either method, you can select one data source in the Groups tree to serve as the view context.

Configure this view to measure application performance using any of the available CA ADA metrics. If you receive an incident notification, or notice degraded performance, use this view to quickly drill to the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

Edit the filter criteria for the view to display performance information for a different metric:

- **Metric Type**
  Choose a CA ADA metric to filter the list of applications.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Count by Application

The Incident Count by Application view lists the applications that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching Network and Server incidents to trouble tickets.

By default, the incident count includes Open and Closed incidents where the performance threshold for a Server metric or Network metric was exceeded during more than one 5-minute reporting interval.

> **NOTE**
>
> This view does **not** include Combined Metrics (Data Transfer Time and Transaction Time) because CA Application Delivery Analysis (CA ADA) opens a Network or Server incident when the threshold for a Combined metric is exceeded.

Click an application to view its incidents in the CA ADA management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**

Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
  - Closes the existing incidents
  - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by Server metric, Network metric, or Combined metric.
  - **Minimum Elapsed Time (Minutes)**
    Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
  - **Minimum Severity**
    From least severe to most severe, include:
    - **Minor:** Includes all incident severities in the Incident count. This is the default.
    - **Major:** Includes incidents that have a Major or Unavailable severity.
    - **Unavailable:** Includes Unavailable incidents.
  - **Incident State**
    For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

    Choose one of the following options:
    - Open
    - Closed
    - Open and Closed. This is the default.
  - **Context Settings**
    Displays the view filter. A context type of:
    - **Summary**
      Filters the view based on the selected group.
    - **Server**
      Filters the view based on the selected server.
  - **Apply Changes**Select the scope of your changes from the **Apply Changes** drop-down.

Incident Count By Network

The Incident Count by Network view lists the networks that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching network incidents to trouble tickets. By default, the incident count includes open and closed incidents where the performance threshold for a Network metric was exceeded during more than one 5-minute reporting interval.

Click a network to view its incidents in the CA Application Delivery Analysis (CA ADA) management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**

Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.

- **Included**
  Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
  - Closes the existing incidents
  - Opens new incidents, if performance degrades

- **Metric Type**
  Filter the incident count by the Network metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

  NOTE

  Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Count by Server

The Incident Count by Server view lists the servers that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching server incidents to trouble tickets. By default, the incident count includes open and closed incidents where the performance threshold for a Server metric was exceeded during more than one 5-minute reporting interval.

Click a server to view its incidents in the CA Application Delivery Analysis (CA ADA) management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:

  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA Application Delivery Analysis:
    - • Closes the existing incidents
      - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by the Server metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Counts

The Incident Count views show the networks, servers, and applications with the most incidents. The following Incident Count views are available:

Incident Count by Network

The Incident Count by Network view lists the networks that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching network incidents to trouble tickets. By default, the incident count

includes open and closed incidents where the performance threshold for a Network metric was exceeded during more than one 5-minute reporting interval.

Click a network to view its incidents in the CA Application Delivery Analysis (CA ADA) management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
    - Closes the existing incidents
    - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by the Network metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Count by Server

The Incident Count by Server view lists the servers that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching server incidents to trouble tickets. By default, the incident count includes

open and closed incidents where the performance threshold for a Server metric was exceeded during more than one 5-minute reporting interval.

Click a server to view its incidents in the CA Application Delivery Analysis (CA ADA) management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA Application Delivery Analysis:
    - • Closes the existing incidents
      - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by the Server metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Count by Application

The Incident Count by Application view lists the applications that are impacted with the most incidents. Use this view to help you start troubleshooting reported issues by matching Network and Server incidents to trouble tickets.

By default, the incident count includes Open and Closed incidents where the performance threshold for a Server metric or Network metric was exceeded during more than one 5-minute reporting interval.

NOTE

This view does **not** include Combined Metrics (Data Transfer Time and Transaction Time) because CA Application Delivery Analysis (CA ADA) opens a Network or Server incident when the threshold for a Combined metric is exceeded.

Click an application to view its incidents in the CA ADA management console.

You may also edit the view to change the filter criteria for the view. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
    - Closes the existing incidents
    - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by Server metric, Network metric, or Combined metric.
  - **Minimum Elapsed Time (Minutes)**
    Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
  - **Minimum Severity**
    From least severe to most severe, include:
    - **Minor:** Includes all incident severities in the Incident count. This is the default.
    - **Major:** Includes incidents that have a Major or Unavailable severity.
    - **Unavailable:** Includes Unavailable incidents.
  - **Incident State**
    For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

    Choose one of the following options:
    - Open
    - Closed
    - Open and Closed. This is the default.
  - **Context Settings**
    Displays the view filter. A context type of:
    - **Summary**
      Filters the view based on the selected group.
    - **Server**
      Filters the view based on the selected server.
  - **Apply Changes**

Select the scope of your changes from the **Apply Changes** drop-down.

Incident List by Network

The Incident List by Network view displays a summary of Network incidents. Use this view to drill into details on an incident in the CA Application Delivery Analysis (CA ADA) management console. By default, the incident list includes Open and Closed incidents where the performance threshold for a Network metric was exceeded during more than one 5-minute reporting interval.

Click an incident to view its details in the CA ADA management console.

You may also edit the view to change the filter criteria for the list of incidents. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
    - Closes the existing incidents
    - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by the Network metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

  NOTE

  Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**

Filters the view based on the selected server.

- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident List by Server

The Incident List by Server view shows a summary of Server incidents, and lets you drill into details on an incident in the CA Application Delivery Analysis (CA ADA) management console. By default, the incident list includes Open and Closed incidents where the performance threshold for a Server metric was exceeded during more than one 5-minute reporting interval.

Click an incident to view its details in the CA ADA management console.

You may also edit the view to change the filter criteria for the list of incidents. Filter criteria include:

- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Metric Type**
  Filter the list of incidents by Server metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

  NOTE

  Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident Lists

The Incident List views show summaries of network and server incidents. The following Incident List views are available:

Incident List by Network

The Incident List by Network view displays a summary of Network incidents. Use this view to drill into details on an incident in the CA Application Delivery Analysis (CA ADA) management console. By default, the incident list includes Open and Closed incidents where the performance threshold for a Network metric was exceeded during more than one 5-minute reporting interval.

Click an incident to view its details in the CA ADA management console.

You may also edit the view to change the filter criteria for the list of incidents. Filter criteria include:

- **Scheduled Maintenance**
  Choose whether to include incidents that are opened or closed during a scheduled maintenance period:
  - **Excluded**
    Choose this option to exclude incidents that are opened or closed during a server's scheduled maintenance period. This is the default.
  - **Included**
    Choose this option to include incidents that are opened or closed during a server's maintenance period. This option increases the number of open and closed incidents because when a scheduled maintenance period begins, CA ADA:
    - Closes the existing incidents
    - Opens new incidents, if performance degrades
- **Metric Type**
  Filter the incident count by the Network metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

  NOTE

  Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Incident List by Server

The Incident List by Network view displays a summary of Server incidents. Use this view to drill into details on an incident in the CA Application Delivery Analysis (CA ADA) management console. By default, the incident list includes Open and Closed incidents where the performance threshold for a Server metric was exceeded during more than one 5-minute reporting interval.

Click an incident to view its details in the CA ADA management console.

You may also edit the view to change the filter criteria for the list of incidents. Filter criteria include:

- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Metric Type**
  Filter the list of incidents by Server metric.
- **Minimum Elapsed Time (Minutes)**
  Choose a time period to specify a threshold for the total duration required to include an incident in the Incident Count. To include all incidents with the specified Minimum Severity, choose a Duration of Any. The default is 10 minutes.
- **Minimum Severity**
  From least severe to most severe, include:
  - **Minor:** Includes all incident severities in the Incident count. This is the default.
  - **Major:** Includes incidents that have a Major or Unavailable severity.
  - **Unavailable:** Includes Unavailable incidents.
- **Incident State**
  For the metrics that you have selected, specify whether to filter open or closed incidents in the Incident Count. By default, open and closed incidents are included based on the specified Minimum Severity and Duration.

    NOTE

    Closed incidents help you to identify incident trends that can lead to problem resolution. By default, CA ADA retains incidents for 3 months.

  Choose one of the following options:
  - Open
  - Closed
  - Open and Closed. This is the default.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Application

The Performance by Application view shows application performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**

Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.

- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**
  Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Network

The Performance by Network view shows network performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal user acknowledged an incident. When this happens, the CA NetOps Portal (CAPC) marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**

Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.

- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**
  Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also edit the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics that you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Server

The Performance by Server view provides server performance data for the last 24 hours. If the time period for the report is longer than 24 hours, the view displays performance data only for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**

Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Map by Server

The Performance Map by Server view provides a Top N view into the worst performing servers based on a particular metric. Configure this view to measure server performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Server view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected server.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing servers at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of servers.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Maps

A performance map provides a Top N view into the worst performing networks, servers, or applications based on a particular metric.

If you receive an incident notification, or notice degraded performance in a Performance view, use this view to drill into the Components reports on the Engineering report of the CA Application Delivery Analysis (CA ADA) management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

Top Performance Map by Network

The Top Performance Map by Network view provides a Top N view into the worst performing networks based on a particular metric. Configure this view to measure application performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Network view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of networks.
- **Context Settings**
  Display the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Map by Server

The Performance Map by Server view provides a Top N view into the worst performing servers based on a particular metric. Configure this view to measure server performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Server view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected server.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing servers at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of servers.
- **Context Settings**
  Displays the view filter. A context type of:

  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Map by Application

The Performance Map by Application view provides a Top N view into the worst performing applications based on a particular metric. Configure this view to measure application performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Network view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of networks.
- **Context Settings**
  Display the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Scorecard

The Performance Scorecard view provides a high-level view into the worst-performing applications by summarizing the percentage of time that an application is operating at different levels of performance, such as Normal, Minor, or Major.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate that a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**

Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.

- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also edit the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance Views

Performance views show the performance data for servers, networks, and applications from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If there are enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis classifies the metric.

Contents

Performance by Network

The Performance by Network view provides information about network performance. This view displays performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal user acknowledged an incident. When this happens, the CA NetOps Portal (CAPC) marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**

Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.

- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**
  Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also edit the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics that you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Server

The Performance by Server view provides information about server performance. This view displays performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**

Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.

- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**
  Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Performance by Application

The Performance by Server view provides information about application performance. This view displays performance data from the last 24 hours. If the time period for the report is longer than 24 hours, the view only displays performance data for the most recent 24 hours.

If you have enough observations, and if a threshold is available for each combination of application, server, network, and 5-minute period, CA Application Delivery Analysis (CA ADA) classifies the metric using one of these ratings:

- **Acknowledged**
  Displays a severity state (diagonal stripes) to indicate a CA ADA or CA NetOps Portal (CAPC) user acknowledged an incident. When this happens, CAPC marks data that the incident covers as Acknowledged. CA ADA automatically marks future data covered by an acknowledged incident as Acknowledged.
- **No Data**
  Displays a severity state (blank) to indicate that no data is available.
- **Unrated**
  Displays a severity state (gray) to indicate that either there is insufficient past data (two full business days of data are needed) to establish a threshold, or there were not enough observations to exceed the minimum observations threshold.
- **Normal**
  Displays a severity state (green) to indicate that the metric value is between zero and the Minor threshold.
- **Minor**
  Displays a severity state (yellow) to indicate that the metric value exceeds the Minor threshold as defined in the CA ADA management console.
- **Major**
  Displays a severity state (orange) to indicate that the metric value exceeds the Major threshold as defined in the CA ADA management console.
- **Unavailable**

Displays a severity state (red) to indicate that the application on a server is not running (unavailable). This rating appears when you click All Server Metrics in Settings. This rating is only applicable to a user-defined application where the CA ADA administrator has assigned servers to the application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing items at the top of the graph.

You may also the filter criteria for the view. By default, all data is included. Filter criteria include:

- **Metric Type**
  Select the Server metrics, Network metrics or Combined metrics you want to use to filter the list of networks.
- **Context Settings**
  Displays the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Top Performance by Network

The Top Performance Map by Network view provides a Top N view into the worst performing networks based on a particular metric. Configure this view to measure application performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Network view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of networks.
- **Context Settings**
  Display the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Top Performance Map by Network

The Top Performance Map by Network view provides a Top N view into the worst performing networks based on a particular metric. Configure this view to measure application performance using any of the available CA Application Delivery Analysis (CA ADA) metrics. If you receive an incident notification, or notice degraded performance in the Performance By Network view, use this view to drill into the Components reports on the Engineering report of the CA ADA management console. Use the Components reports to begin troubleshooting the metric details for the selected application.

To isolate the component and metric contributing to a performance problem, click one of the worst-performing networks at the top of the graph.

You may also edit the filter criteria for the view to display performance information for a different metric. Filter criteria include:

- **Metric Type**
  Choose a metric to filter the list of networks.
- **Context Settings**
  Display the view filter. A context type of:
  - **Summary**
    Filters the view based on the selected group.
  - **Server**
    Filters the view based on the selected server.
- **Apply Changes**
  Select the scope of your changes from the **Apply Changes** drop-down.

Register and Configure Network Flow Analysis

This use case describes how an administrator can register CA Network Flow Analysis (CA NFA) as a data source for an instance of CA NetOps Portal (CAPC) or CA NetQoS NetOps Portal (CA NPC), and perform initial configuration tasks. As soon as you register CA Network Flow Analysis as a data source, you can perform some key administrative tasks, such as setting up SNMP profiles, user accounts, user permissions, and groups. You perform these tasks in the Console for CAPC or CA NPC. The settings that you specify are synchronized down to CA NFA.

You must have the Administrator role in both product interfaces to perform the steps that are outlined in the accompanying procedures.

Change the Domain of Interfaces and CVIs in NFA

Interfaces and CVIs inherit their initial tenant-domain setting from the parent router and Harvester. The setting is inherited when the parent Harvester is added and the router and interfaces first become active. If the Harvester is not associated with a custom domain, the routers and interfaces are assigned to the Default Domain as they become active.

You can edit the settings for interfaces and CVIs to associate them with any tenant and domain at any time. The setting does not have to match the parent router or Harvester.

Changing this setting can affect which operators have access to the interface's data. The setting does not affect which SNMP profiles are used for polling. The router tenant determines the set of SNMP profiles for polling.

Follow these steps:

1. Open the Active Interfaces page.
   a. Select **Administration** from the NFA console menu.
      The Administration page opens.
   b. Select Interfaces: **Physical & Virtual** from the Administration menu.
      The Active Interfaces page opens.
2. Select check boxes next to one or more interfaces that you want to associate with a tenant and domain.
   - To search for parent routers, interfaces, or CVIs, type all or part of a router IP address, a router or interface name, or an interface description in the Search field, and then click **Search**. Expand the router details.
   - To navigate to an interface or CVI manually, go to the page that contains the parent router, and click the arrow next to the router name. The router details expand to show the interfaces and CVIs.
3. Click **Edit**.
   The editing dialog opens. The Domain selection list is included in the dialog only if multiple domains exist.
4. Select a tenant / domain option from the Domain list.

5. Click **Save**.
   The dialog closes. The changes are shown on the Active Interfaces page.

   NOTE
   You can also change the tenant-domain setting for harvesters and routers.

Configure Network Flow Analysis in Performance Center

As an IT engineer or tools administrator, you can start monitoring network traffic composition and utilization statistics by deploying Network Flow Analysis (NFA).

This use case walks you through the steps to configure NFA as a data source for NetOps Portal (CAPC) or CA NetQoS NetOps Portal (CA NPC). This use case also describes how to configure CA NFA to receive flow data, and to configure the following elements, which are administered in CAPC or CA NPC:

- SNMP profiles
- IP domains
- User accounts, permissions, and roles
- Groups

Before you perform these procedures, install NFA and CAPC or CA NPC in your environment. You must have administrative role rights for both products to perform the tasks that are described here.

Configure Flow Collection

Configure the routers in CA Network Flow Analysis (CA NFA) to verify that they are sending data to the Harvesters.

CA NFA can begin to collect flows as soon as you complete the following tasks:

Add One or More Harvesters

Add one or more Harvesters to enable data to be processed and displayed.

Prerequisite:

Recommended: If you have not already done so, register CA Network Flow Analysis (CA NFA), and set up the domains before you add any Harvesters.

Follow these steps:

1. Open the NFA console, logged in with Administrator rights. For example, enter the following address in a browser:
   http://<ipaddress>/ra/
   User name: *admin*
   Password: *admin*
2. Open the Harvester page:
   a. Select Administration from the NFA console menu.
      The Administration page opens.
   b. Select System: Harvester from the Administration page menu.
      The Harvester page opens and displays the current list of Harvesters.
3. Click Add.
   The Add Harvester dialog opens.
4. Enter the following information:
   – **IP Address**
     Address of the Harvester server.
   – **Description**

Identifying text about the Harvester, which appears in the Harvester page table.

– **Domain**
Parent tenant and domain combination for the Harvester and for any routers and interfaces that begin to supply data to the Harvester.
Changing this setting affects the tenant-domain association for new routers that begin exporting flow data and any new interfaces that begin generating flow.
In a multi-tenant environment, the Harvester tenant affects which SNMP profiles are available for routers to poll interfaces.
The domain affects which operators and reports have access to the data from routers and interfaces.

NOTE
This option is visible only in an environment that contains multiple domains.

5. Click Save.
The new Harvester is added and appears in the Harvester list, provided that the IP address passes the connection test. If the test connection to the web service fails, an error message opens.
The usual process is to add one or more Harvesters, then configure the router interfaces to export flow to the Harvesters. If you configure the routers to export flow to the Harvesters first, the NFA console immediately begins to collect data from the new Harvester. In this case, the domain for the routers is set at the time you add the parent Harvester.

NOTE
Make sure that the Harvesters that you add have not been deleted from the Harvester page previously. To add a Harvester instance successfully in CA NFA 2.4 after deleting it, the Harvester installation server must be re-imaged and the Harvester software must be re-installed.

Verify the Harvester Domain

Verify that each Harvester is associated with the appropriate domain before you set up routers to export flow data. If you have not already done so, set up any needed custom tenants and domains before you proceed.

NOTE
The tenant feature is applicable only to deployments that include CA NetOps Portal. If your deployment uses CA NetQoS NetOps Portal, the tenant setting is always Default Tenant.

Follow these steps:

1. Open the Harvester page:
   a. Select Administration from the NFA console menu.
   The Administration page opens.
   b. Select System: Harvester from the Administration page menu.
   The current list of Harvesters appears.
2. Click Edit next to the Harvester that you want to edit.
The Edit Harvester dialog opens.
3. (Optional) Change the Domain setting (tenant-domain combination) as needed.
Default: Default Tenant \ Default Domain.
You can also change the IP Address and Description.

NOTE
If no custom IP domains have been created, the Harvester table includes only the IP Address and Description columns.

4. Click Save when your changes are complete.
Your changes are saved immediately.

Set Up the Routers

Enable NetFlow on each CA Network Flow Analysis router by completing the steps in this topic. You can configure routers to export any of the following flow protocols:

- NetFlow v5, v7, v9, and Sampled NetFlow
- sFlow version 5
- IPFIX, J-Flow, cFlow, and NetStream flow that complies with the standards for NetFlow v5, v7, or v9

Configure flow from each source to be exported to a single Harvester. If flow from one source is exported to multiple Harvesters, a number of problems result. If this occurs, contact CA Support for help.

NetFlow provides a broad view of your network packet streams by creating flow records for all packets. The data from these flow records represents all packets. Sampled NetFlow/IPFIX and sFlow take samples from your packet streams, producing fewer flow records and lessening the impact to a collector. The lower your sampling rate, the less precise the data is likely to be.

In order for data from non-sampled flows to appear in reports of 15-minute (historical) data, the following minimum fields are required:

- One of the following: 1 - IN_BYTES, 85 - IN_PERMANENT_BYTES, 231 - FW_INITIATOR_OCTETS, or 232 - FW_RESPONDER_OCTETS
- 4 - PROTOCOL
- 7 - L4_SRC_PORT
- 8 - IPV4_SRC_ADDR
- 10 - INPUT_SNMP
- 11 - L4_DST_PORT
- 12 - IPV4_DST_ADDR
- 14 - OUTPUT_SNMP

Complete these tasks:

1. Back up the current router configuration.
2. Configure NetFlow export for each interface individually:
   a. Set the flow export version.
   b. Set the flow source IP address. Cisco recommends that you configure a loopback source interface. The IP addresses of non-loopbacked interfaces can change.
   c. Set the flow destination IP address and set the destination port to 9995. If you are using a custom value for the harvester listening port, use that value as the destination port. The port values must match or the Harvester does not receive flow data.
   d. Set the flow expiration timeout to 1 minute.
3. Enable flow for each interface.
   – NetFlow v5 or v5-compatible flow:
     - Monitoring multiple interfaces on a router: Use either all ingress or all egress. Use the same option for all of the interfaces. Ingress and egress values may vary slightly due to routers dropping packets and changing ToS values as traffic travels between interfaces.
     - Monitoring a single known interface on a router: Use ingress and egress. This option results in fewer total flows from the router to the Harvester and puts less load on the network and the Harvester.
   – NetFlow v9 or v9-compatible flow:
     The Harvester identifies and deduplicates multiple flows on a single router, so you can use ingress and egress on multiple interfaces. You may find it most efficient to use this option for two or three interfaces. You have the option to enable ingress and egress across all interfaces, but this configuration may put an unnecessary burden on the Harvester.
4. Configure SNMP index persistence on each router that supports this feature.

Add DSAs (Three-Tier Deployment)

We recommend that you add at least one DSA within 30 minutes of starting flow collection. Until you add a DSA to your three-tier deployment, 15-minute data is not available for reports. Reports that show a time range of more than 2 hours do not show any data.

NOTE

Do not add a DSA instance instead of editing the IP address of a retired DSA. In this case, routers continue to send data to the retired DSA--and that data is not available in reports. If you have to delete a DSA, contact CA Support for assistance.

Add a DSA

Follow these steps:

1. Open the NFA console, logged in with Administrator rights.
2. Display the DSA page in the NFA console user interface:
   a. Select Administration from the NFA console menu.
      The Administration page opens.
   b. Select System: DSA from the Administration menu.
      The DSA page opens and shows a list of the current DSAs.
3. Click Add.
   The Add DSA dialog opens.
4. Enter the IP address for the DSA server.
5. Click Test Connection.
   A connection test is performed to determine whether the NFA console server can contact the DSA server and can verify that MySQL is installed. If the test succeeds, a "Test success" message opens.
6. Respond to the test results:
   a. If the Test success message opens, click OK to close it.
   b. If an error message opens, close the error message and respond as described in Troubleshoot DSA Addition.
7. Once the test completes successfully, click Save in the Add DSA dialog.
   The connection test is performed, followed by a test to locate DSA settings on the target server.
8. Note the test results:
   – If no error message opens, the tests have succeeded. The following events result:
     • The dialog closes and the DSA is added to the DSA list.
     • The Harvesters begin to include the new DSA in the destinations for new enabled interfaces that report 15-minute data.
     • The NFA console pushes settings down to the new DSA.
     • The DSA is configured to retrieve 15-minute data files from the NFA console.
     • Data from the DSA begins to be available for reports in approximately 30 minutes.
   – If an error message opens, close the error message and respond as described in Troubleshoot DSA Addition.

NOTE

- If a DSA does not begin to collect the 15-minute data within 30 minutes after flow collection begins, problems can result. The processed data accumulates on the NFA console server and processing slows. If the problem continues, the NFA console stops collecting the 15-minute data and unprocessed data accumulates on the Harvesters. If Watchdog traps are configured, the Watchdog sends out alerts that the Harvester or Reaper

is falling behind. If the problem is left unchecked, the CA Network Flow Analysis services on the Harvesters may stop running.
- Each DSA is enabled to collect data for a maximum of 5,000 enabled interfaces that have reported data.
- For information about the data types, storage lifespan, minimum thresholds, and report types for the 15-minute data that is stored on DSA servers, see the topic 15-Minute Data in the *CA Network Flow Analysis Administrator Guide.*

Test Connection Errors

Use the following tips for troubleshooting error messages that may open when you click Test Connection in the Add DSA dialog

- "An invalid server IP address was entered":
  You entered an IP address in an invalid format. Make sure that you enter the IP address correctly.
- "System.Web.Services.Protocols.SoapException...'":
  Verify that the NetQoS MySql service is running on the NFA console server. If the service is not running, start it.
- "Unable to connect to any of the specified MySQL hosts":
  Start the NetQoS MySql service on the DSA server. Verify that the NetQoS MySql service is running on the DSA server. If the service is not running, start it.
- "Unknown database 'nqrptr'":
  The DSA database nqrptr was not found on the target server. Verify that the DSA software installation was successful.

Save Errors

Use the following tips for troubleshooting error messages that may open when you click Save in the Add DSA dialog

- "An existing record is already in use":
  Enter the IP address of a DSA that is not already in the DSA list.
- "Connection must be valid and open'":
  Verify that the NetQoS MySql service is running on the DSA server. If the service is not running, start it.
- "System.Web.Services.Protocols.SoapException...'":
  Verify that the target server is running and can be reached by the NFA console server. Verify that the NetQoS MySql service is running on the NFA console server. If the service is not running, start it.
- "Table 'nqrptr.settings' doesn't exist"
  The DSA settings table was not found. The DSA software was not installed successfully on the target server.
  - Verify that you entered the correct IP address for the DSA--not the IP address for a Harvester or for the NFA console.
  - Verify that the DSA software installation was successful.

Configure Traps

Trap configuration is complete when you have finished the following tasks:

- Create the traps that you need, as described in the *CA Network Flow Analysis Administrator Guide "*Create Traps" topic.
- Enable traps to be displayed as events in the NetOps Portal Console:
  a. Open the Application Settings page in the NFA console.
  b. Set the Trap Destination value to match the IP address of one of the following servers:
     - (CA PC) NFA console or stand-alone server that is registered as a data source
     - (NPC) Event Manager server
- (Optional) Enable Watchdog trap notifications to be sent to your trap receiver: Open the Watchdog Settings page in the NFA console. Configure values for the Trap Destination, Email Address, and other Watchdog settings.
- (Optional) Verify that the events are displayed on the NetOps Portal Console--on the Events page (CA PC) or the Event List page (NPC). If the events are not shown as expected, verify that the following conditions are met:

- The logs show that events have been generated and have been forwarded to the Event Manager.
- The Event Manager host name is resolvable by the DNS server for CA Network Flow Analysis.
- The Trap Destination value on the Application Settings page in the NFA console matches the IP address of one of the following servers:
  - (CA PC) NFA console or stand-alone server that is registered as a data source
  - (NPC) Event Manager server
- (NPC Only): The Event Manager is installed.

Set Up User Accounts

One predefined user account, admin, is included with the installation of CA Network Flow Analysis. The admin account has full administrative privileges.

The administrator must create a user account for each person who will use the product--administrators and operators. Custom user accounts enhance security and take advantage of the narrowly defined role rights that determine access to product features and data.

Custom user accounts are best deployed in a well-planned system that includes custom groups. Custom groups are assigned as permissions to let product operators view only the data, menus, and dashboards that they need to perform their daily tasks.

View a List of User Accounts in NFA

The Manage Users page lets you see high-level settings for user accounts. In a multi-tenant environment, the global administrator sees a list of user accounts that are not explicitly associated with a tenant. Tenant administrators only see user accounts for their tenant.

Before you create any custom user accounts, only the two factory user accounts are available.

Follow these steps:

1. Log in as a user with the required administrative role rights.
2. Select **Administration**, **User Settings**, and click **Users**.
   The current list of user accounts appears.

   NOTE
   Tenant administrators only see the items that are associated with their tenant.

   The table includes the following information about each user account:
   - **Name**
     Login name for the user account.
   - **Role**
     Role assigned to the user account.
   - **CAPC Privilege**
     Identifies the level of access to registered data sources.
   - **Permission**
     Lists the permission groups that are assigned to this account. Permission groups are shown as nested locations within the Groups tree. If this user is able to create custom groups that are not visible to other users, "My Custom Groups" are indicated.
     Default: '/All Groups'.
   - **Status**
     Indicates whether the user account is enabled or disabled.

Add User Accounts

Add a user account for each person who will operate the products. For security purposes, operators should not share user accounts.

> **NOTE**
> If you register CA Network Flow Analysis as a data source for CA NetQoS NetOps Portal, the steps are slightly different.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the required administrative role rights.
2. Confirm that the required roles and groups exist.
3. Select **Administration**, **User Settings**, **Users**.
   The current list of user accounts is displayed.
4. Click **New**.
   The Create New User wizard (CA PC) or Add User page (NPC) opens.
5. Enter the appropriate information for the account parameters.
6. Add permission groups to the user account, described in Assign Product Privileges.
7. Click **Save**.
   The new user appears in the list of user accounts.

Add Role Rights for Users

If the predefined user roles do not fit your requirements, you can add custom user roles. Ideally, you create the roles that each unique product operator needs to be able to perform his or her job responsibilities.

Custom roles work best within a system of custom groups. Custom groups let you precisely grant access to dashboards and product features while restricting access to sensitive data. The same groups that you create to organize data can serve as “permission groups” when you set up user account permissions.

A new role has no rights until you add them. The following graphic shows the Add Role dialog in the CA NetOps Portal Console with a role that is beginning to be defined.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the required administrative role rights.
2. Navigate to the Manage Roles or Roles List page.
   The page displays the current list of roles.
3. Click New.
   The Add Role dialog opens.
4. Supply the required information and make selections in the fields provided.
5. Specify the menus that will be visible to users with the new role:
   a. Select Menu Set (CA PC) or select a menu or product from the list at the bottom of the dialog (NPC).
   b. Click Edit.
      The Edit Menu Set dialog opens. Menus in the 'Available Menus' list can be added to the role.
   c. Click an item on the left that you want to add to the role, then click the right arrow.
      Use Shift + Click or Ctrl + Click to select multiple items.
      Each selected item moves to the Selected Menus list.
   d. (Optional) Use the Up and Down arrows to move items around in the list. The order of menus in the list determines their order on the Dashboards tab.
   e. Click OK.
      You return to the Add Role page.

6. Set the NetOps Portal rights for the role:
   a. Select NetOps Portal (CA PC) or NetQoS NetOps Portal (NPC).
   b. Click Edit.
      A dialog opens, which you use to select NetOps Portal access rights.
   c. Click an item on the left that you want to add to the role, then click the right arrow.
      The access right moves to the Selected Rights list.
   d. (Optional) Use the Up and Down arrows to move items around in the list. The order of role rights determines their priority in cases where rights overlap.
   e. Click OK.
      You return to the Add Role page.
7. Set the CA Network Flow Analysis rights for the role:
   a. Select the name of the registered CA Network Flow Analysis instance.
   b. Click Edit.
      A dialog opens, which you use to select access rights for CA Network Flow Analysis in the same way you selected access rights for NetOps Portal.
   c. When the access rights are set up correctly, click OK.
      The new role is created and appears in the Role List.
8. Repeat the previous step to set the rights for any additional data source that you want to include.
9. Click Save on the Add Role page.
   You return to the Manage Roles page (CA PC) or Roles List page (NPC).

NOTE

When you finish creating a role, assign it to a user account as a separate step. Roles are inoperative until they are assigned to user accounts. Only users with the 'Administer Users' and 'Administer Roles' role rights can assign roles to user accounts.

Assign Permission Groups to User Accounts

Individual operators require data access permissions to monitor data in the products. Access permissions are based on groups. You can assign access permissions according to your plan for custom groups. Your goal as the administrator is to make sure that all operators see only the data they require to do their job.

For example, suppose you create custom groups and assign them as permissions to IT staff. When staff members log in to NetOps Portal, they can view data from the systems that are assigned to them.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with administrative privileges.
2. Click **Administration**, **User Settings: Users**. The Manage Users page opens.
3. Select a user account that you want to change, and click Edit.
   The Edit User wizard or dialog opens.
4. Display the permission groups:
   – (CAPC) Click the **Access Permissions** button.
   – (NPC) Locate the **Permission Groups** pane in the middle of the page.

   The group settings are displayed.
5. Add permission groups to the user account
   – Expand the groups in the **Available Groups** tree on the left so that subgroups are shown.
   – Select a group or subgroup.
   – Click the right arrow or **Add** button to add the group.
   – Repeat as necessary.

The selected permission groups appear in the Selected Groups pane.

6. Select the default group for the user--the data that appears by default in the dashboards for the user:
   – (CAPC) Right-click the target group and select **Make Default**.
   – (NPC) Select the target group and click **Make Default**.
7. Click **Save**.
   The changes are saved to the user account, and you return to the Manage Users page.
   When the user logs in, data from the default group appears in dashboards by default.

Assign Product Privileges

Each registered data source has its own product privilege setting, which grants unique privileges within that product interface. Administrators give users product privileges for each data source. For example, the product privilege determines whether a user can log in to CA Network Flow Analysis or drill down from a NetOps Portal view to details in the NFA console. Privileges are specific to the data source instance.

The default administrator account, admin, is locked to prevent changes to product privileges. This account must have Administrator privileges for all registered data sources. If you select a group of accounts that includes the admin account, you cannot edit the product privileges for any of the selected accounts.

CA Network Flow Analysis Product Privileges

A user must have product privileges for the CA Network Flow Analysis data source to log in to the NFA console. Product privileges also determine whether a user can access the Administration page, and can perform certain functions:

- **Administrator**
  Gives access to the Administration page in the NFA console and to all functions. Functions include creating and managing user accounts, roles, groups, SNMP profiles, and scheduling for reports.
- **Power User**
  Gives user-level access and any additional abilities that the Role setting grants. For CA Network Flow Analysis, the Power User privilege is equivalent to the Administrator privilege.
- **User**
  Gives access to Top Interfaces reports and Interface Utilization reports on the Enterprise Overview page.
  A User with the appropriate Permission Group settings also has access to the following reports:
  – Top Hosts and Top Protocols reports on the Enterprise Overview page, if the user also has access to All Groups
  – Interfaces page reports for the interfaces that are accessible to the user
  – Existing reports on the Custom Reporting, Flow Forensics, and Analysis pages
  – Menus that an administrator has assigned to the User role
  The Role and Permission Group settings determine whether the User also can run existing reports, create reports, and manage reports. To create reports, a User must have access to All Groups.
- **None**
  Has no access to a data source. The user who has this product privilege cannot log in to the NFA console or drill down from a NetOps Portal view to the NFA console. By default, all users have this product privilege setting for all data sources.

  NOTE
  The same user account can have different privileges for different data sources.

Set Up Groups

We recommend that you create custom groups to help manage items in the NetOps Portal Console. Custom groups are required to let operators see performance data from the routers they manage.

Properly configured, groups can prevent operators from viewing particular types of data for security reasons. The administrator can selectively grant users access to data in their area of responsibility, such as a physical location or subnet.

Before you start creating groups, plan a strategy and a structure. Consider the types of access permissions that operators require to perform their monitoring duties. If necessary, you can discuss your organizational and monitoring goals with a CA technical representative.

Create groups under the All Groups node in the Groups tree, or within an existing custom or site group. You cannot add groups to system groups, which appear "locked" in the Groups tree.

You can add a maximum of 2000 child groups to a parent group.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the required administrative role rights.
2. Navigate to the Manage Groups page.
   The page displays current groups in a tree structure.
3. Expand nodes in the Groups tree to find a location for the new group.
4. Right-click the node, and select Add Group (CA PC) or Add New Group (NPC).
   The Add Group window opens with the New tab selected by default.
5. Supply values for the following parameters:
   - **Group Name**
     Specifies a name for the group. Do not use the following special characters in group names: /&\,%.
   - **Description**
     (Optional) Helps you identify the group.
6. Confirm the setting for the following parameter:
   - **Include the children of managed items**
     Adds the children of managed items automatically when the items are added to this group. If this option is disabled and you add a router, the router interfaces are not included. As a result, the data from those interfaces is not visible in drilldown views.
     Default: Selected (CA PC) or Not Selected (NPC).
     Icon
     Note: Clear this option for a custom group that contains routers or the group will not be usable in in the NFA console.
7. Select Custom or Site from the Group Type list.
   If you selected Site as the type, specify values for the additional parameters that appear, including Location.
8. Click Save.
   The new group appears in the Groups tree.
   The group contains no items until you add them. You have two options for adding items to a custom group:
   - Manually populate the group by adding items in the Manage Groups interface.
   - Create rules to manage group membership.

Results of Unregistering

On rare occasions, you may want to unregister CA Network Flow Analysis. For example, you would unregister a CA Network Flow Analysis instance before registering it with a different NetOps Portal instance. Unregister only if it is really necessary.

If you unregister CA Network Flow Analysis, the following rules apply:

- Users: Users without product privileges to CA Network Flow Analysis in NetOps Portal are deleted from the CA Network Flow Analysis database. Existing User IDs remain unchanged. You cannot add new users or edit user account settings while unregistered.
- Roles: Roles are not deleted. Users continue to have their previous roles. Existing Role IDs remain unchanged. You cannot change the roles or permissions for existing users while unregistered.
- Groups:
  - Groups that do not exist in CA Network Flow Analysis are deleted. You cannot add or change groups while unregistered.
  - Nested groups that are associated with an interface are displayed as interface groups in the NFA console.
  - Groups that are not associated with an interface are displayed as permissions.
- Single Sign-On and LDAP: Single Sign-On and LDAP values remain unchanged.

NOTE
For a more detailed description of the results of unregistering during an upgrade of CA Network Flow Analysis, see the CA Network Flow Analysis documentation.

Register Network Flow Analysis

Register the product in the NetOps Portal Console--on the Manage Data Sources page (CA PC) or the Data Source List page (NPC).

NOTE
For information about the number of data sources that you can use, see the *Release Notes* for your NetOps Portal version.

Follow these steps:

1. Verify that no one else is running a session of Network Flow Analysis. If multiple users write to the database simultaneously, problems can result.
2. Log in to the NetOps Portal Console as a user who has the Administrator role.
3. Click Admin, Data Sources.
   The current list of registered data sources are shown on the Manage Data Sources page (CA PC) or the Data Source List page (NPC).
4. Click Add (CA PC) or New (NPC).
   The Add Data Source dialog opens.
5. Select the type of data source you want to add from the Source Type list.

   NOTE
   All CA products that can be registered as data sources are shown in the Source Type list. The list is not filtered to hide products that are installed already.
6. Enter the Host Name of the data source.
   The hostname is the IP address or DNS hostname of the server that hosts the database for the data source. For a distributed deployment of the product, enter the hostname of the NFA console or stand-alone server.
7. Enter the port to use for contacting CA Network Flow Analysis.
   For more information about the port setting, see the *CA Single Sign-On User Guide*.
8. Select the protocol to use for contacting the data source. Select **https** if your network uses SSL for communications. Verify that you have configured the system correctly before you select the **https** option.

   NOTE
   For more information about using SSL for communication between the product and NetOps Portal, see the *CA Single Sign-On User Guide.*
9. (Optional) Enter a Display Name for the CA Network Flow Analysis data source.

If you do not enter a name, a default name is created by combining the data source type and hostname. For example, you can use a default name like NetworkFlowAnalysis@xxx.x.x.xx or you can use a name like NetworkFlowAnalysis_NewYork.

10. Confirm whether the web console address is the same as the Host Name. If it is not, take the following steps:
    - Clear the 'Same as Data Source' check box.
    - Provide the web console hostname, port, and protocol.
11. Click Save.
    The updated list shows the data sources that are registered.

Test Data Source Connections (Register and Configure NFA Use Case)

In most cases, the status indicates that data source registration has completed successfully. If the status indicates an error, use the test feature on the Manage Data Sources page.

Click the Test button to run a test that confirms the proper registration and connection of a new data source. The test checks for version compatibility, and verifies that the data source is not registered with a different instance of the CA NetOps Portal software.

If the test fails, verify that the server name or IP address is accurate for the source type. For more information, see Data Source Test Fails.

Verify IP Domains

The IP domains feature helps to address potential IP address conflicts. Domain identifiers indicate that two managed items that otherwise appear as duplicate IP addresses are actually two different managed items.

IP domains also let a global administrator in NetOps Portal control which managed items are visible to and accessible by a particular administrator or user.

Information about custom IP domains is sent down to the data sources during synchronization. Domains are available for use during configuration. You can use the NFA console Administration functions to add interfaces, custom virtual interfaces (CVIs), routers, and Harvesters to the custom domains that you create.

During the initial setup, verify that the existing IP domains are adequate to monitor your environment. To see the domains, complete one of the following actions in the NetOps Portal Console:

- (CA PC) Select **Administration**, **IP Domains**, and review the domains on the Manage IP Domains page.
- (NPC) Select **Administration**, **Groups**, and expand the All Groups tree on the Manage Groups page.

View the IP Domains List

IP domains are required for monitoring multiple environments with overlapping IP addresses. Set up all the domains that you need before you begin to export flow data.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the required administrative role rights.
2. Display the current domains:
   - (CA PC) Select **Administration**, **Configuration Settings: IP Domains**.
     The Manage IP Domains page opens and displays the current domains.
   - (NPC) Select **Administration**, **NetQoS Settings: Groups**, and expand the All Groups tree on the Manage Groups page.
     The current domains are shown under **All Domains**. To display the parameters for a domain in CA NetQoS NetOps Portal, select the domain and click the **Properties** tab.

If you have not created any custom IP domains, only the Default Domain appears in the list. This predefined domain has a 'null' setting for all parameters.

Any custom domains that you have created include values for the following parameters:

- **Name**
  Identifies the domain.
- **Description**
  (Optional) Describes this domain namespace, such as naming the enterprise that owns it.
- **Primary DNS Address**
  Is the IP address of the primary name server for this domain.
- **Primary DNS Port**
  Is the port number that the primary name server uses.
- **Secondary DNS Address**
  Is the IP address of the secondary name server for this domain. Can be the same as the primary address.
- **Secondary DNS Port**
  Is the port number that the secondary name server uses.

Add Custom IP Domains

Administrators can set the domain assignment for Harvesters, routers, interfaces, and custom virtual interfaces (CVIs). We recommend that you set up any custom tenants and domains that you need before you add the Harvesters.

Having the appropriate IP domains set up helps to achieve the following goals:

- Assign the correct tenant-domain when you add Harvesters so that their routers and interfaces inherit the correct associations. The routers have the appropriate SNMP profiles available to poll their interfaces.
- Make specific content accessible only to the operators who monitor the content.
- Enable Administrators to create domain-specific ToS labels, protocol groups, and Autonomous System (AS) names in CA Network Flow Analysis.
- Avoid IP address conflicts.
  For example, suppose that a router with a single IP address has interfaces that belong to different enterprises. The domain identifiers clarify that the interfaces are different managed items, even though they have the same IP address.

The Default Domain is created automatically. The Default Domain includes any items that are not assigned to a custom domain.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the required administrative role rights.
2. Display the current domains by completing one of the following actions:
   – (CA PC) Select **Configuration Settings: IP Domains**.
     The Manage IP Domains page opens and displays the current domains.
   – (NPC) Select **Administration**, **NetQoS Settings: Groups**, then expand the **All Groups** tree on the **Manage Groups** page.
     The current domains are shown under All Domains.

   If you have not created any custom IP domains, only the Default Domain appears in the list.
3. Create a domain:
   – (CA PC) Click **New**.
     The IP Domains Administration dialog opens.
   – (NPC) Right-click **All Domains** and select **Add New Domain**.
     The Add Domain dialog opens.
4. Specify the appropriate parameters in the provided fields.

The Device Name Alias (CAPC only) field indicates the alias to use for a managed device. A device alias is a user-configured name that is applied to the associated managed item in NetOps Portal. Click **Browse** to navigate to and import a CSV file of aliases. The CSV file contains a list of IP address-to-device alias mappings.
Aliases that are associated with the primary IP address of a device take precedence over aliases that are associated with any secondary IP addresses. Look for the primary IP address in the Address column of the Inventory Devices list. We recommend using the primary IP address of the device in the CSV file.
For example:

```
172.24.36.107,Austin Router
```

Browse to select the file and click Open.
If you include aliases for devices that you are managing, it can take up to 5 minutes to begin synchronizing these aliases with NetOps Portal.

> **NOTE**
> To remove an alias, import a CSV file that includes the IP address for the device and a blank alias column. To change an alias, modify the alias entry in the CSV file and reimport the file.

5. **Interface Description Override**
   (CA PC only) Indicates the alternate description to use for an interface. Interface descriptions appear in CA NetOps Portal already, but you can provide an alternate description. Click Browse to navigate to and import a CSV or TXT file of alternate descriptions. The file contains a comma-separated list of values that include the device IP address, interface name, interface description, and alternate interface description (alias) mappings.
   For example:

```
172.24.36.107,ethernet_7,vmxnet3 Ethernet Adapter,Connection to Dallas
```

> **NOTE**
> Use the primary IP address of the associated device in the CSV or TXT file. Secondary IP addresses are not supported. Look for the primary IP address in the Address column of the Inventory Devices list.

   Browse to select the file and click Open.
   If you include alternate descriptions for interfaces you are managing already, it can take up to 5 minutes to begin synchronizing these descriptions with CA NetOps Portal.

> **NOTE**
> You can use the same alternate interface descriptions for more than one interface. To remove an alternate description, import a CSV or TXT file that includes the IP address for the device, the interface name, the interface description, and a blank alias column. When you remove an alternate description, the original interface description reappears in NetOps Portal views.

> **WARNING**
> If you use a spreadsheet program to remove all the alternate descriptions from a CSV file, include a column heading for the interface description override column in the imported file. If you do not include this column heading, the original interface descriptions do not reappear in NetOps Portal views.

   To change a description, modify the alias entry in the CSV or TXT file and re-import the file.
   - **DNS Settings check box**
     (CA PC only) If selected, displays the Primary DNS/Port and Secondary DNS/Port options.
   - **Primary DNS Address**
     Is the IP address of the primary name server for this domain.
   - **Primary DNS Port**
     Is the port number that the primary name server uses.
   - **Secondary DNS Address**
     Is the IP address of the secondary name server for this domain. Can be the same as the primary address.
   - **Secondary DNS Port**
     Is the port number that the secondary name server uses.
   - **Enable DNS Proxy Address**

(NPC only) Indicates whether the proxy address is enabled for this IP domain.
- **DNS Proxy Address**
  (NPC only) Is the IP address of the DNS proxy server.
  This setting is required only if your network is located behind a DNS proxy server.

6. Click **Save**.The new IP domain appears on the page.
7. Repeat the steps as required to add more IP domains.

Verify SNMP Profiles for NFA

CA Network Flow Analysis sends secure SNMP information to NetOps Portal at registration. This information is transformed into SNMP profiles that contain the information necessary to enable secure queries of device MIBs using SNMP. Profile information is updated at each synchronization.

During initial product setup, verify that the available SNMP profiles are adequate to monitor your environment. The available SNMP profiles are listed on the Manage SNMP Profiles page (CAPC) or SNMP Profile List page (NPC).

View SNMP Profiles

You can view a list of SNMP profiles that are defined. The list includes high-level information about the contents of each profile.

If no tenant definitions have been created, the SNMP profiles are shared among all registered data sources. The global administrator sees a list of SNMP profiles that are not explicitly associated with a tenant. Tenant administrators see only the items that are associated with their tenant.

Follow these steps:

1. Log in as a user with the Administrator role.
2. Select **Administration**, **Configuration Settings**, and click **SNMP Profiles**.
   The Manage SNMP Profiles page opens, and the current list of SNMP profiles appears.

Add SNMP Profiles

Administrators can create SNMP profiles in the NetOps Portal Console.

Follow these steps:

1. Log in to the NetOps Portal Console as a user with the Administrator role.
2. Display the list of SNMP profiles:
   - CAPC: Select **Administration**, **Configuration Settings: SNMP Profiles**.
   - NPC: Select **Administration**, **NetQoS Settings: SNMP Profiles**.

   The page displays the current list of SNMP profiles.
3. Click **New**.
   The Add SNMP Profile dialog opens.
4. Complete the fields and change the default settings as needed.
5. Click **Save**.
   You return to the list of SNMP profiles. The new profile appears in the list.
   NetOps Portal performs a global synchronization to send the profile information to CA Network Flow Analysis.

Verify That Data Is Received

To verify that data is received, complete the following tasks:

Verify That the Interfaces Are Enabled

Once you configure CA Network Flow Analysis to receive flow data, verify that the expected interfaces are monitored.

Follow these steps:

1. Open the NFA console, logged in with Administrator rights.
2. Open the Available Interfaces page:
