If you determine you want to model new devices directly in the World topology, you can use one of these options:

- The Create Model by IP option
- The Create Model by Type option

Modeling Manually in the TopOrg Topology View

You can manually model your network in the TopOrg topology when you want to group infrastructure models by organizational units or by services. For example, you can create a TopOrg topology view that depicts devices that are essential for supporting a network service, such as email. You can also depict services by department or by individual responsibility.

> **NOTE**
> When you populate a TopOrg topology view, copy the modeled elements from a Universe topology view and paste them into a TopOrg topology view. Or you can use the Create Model by IP or the Create Model by Type option to manually model devices in a TopOrg topology view. However, we do not recommend this alternative because the Universe topology views represent the connectivity views of your network.

How to Model Services in the TopOrg Topology

Within the **TopOrg** topology, you can create multiple levels of containers. These multiple container levels represent organizations or individuals responsible for tracking the performance of mission critical services in your IT infrastructure.

When modeling multiple organizational containers in the **TopOrg** topology, consider following this process:

1. **Create layers of ownership or responsibility:** Using the Model by Type dialog, depict one or more containers that represent a department, individual, customer, or enterprise that is:
   - Supported by a network service, or
   - Responsible for tracking the performance of a network service.
2. **Populate Service_Owns container with supporting devices:** Populate the Service_Owns container with the modeled devices supporting the network service. You can populate these containers by copying and pasting modeled devices from the Universe topology to the **TopOrg** topology. You can also populate these containers by defining new devices using the Create Model by IP Address dialog.

Define Service-Related Organizational Views

You can create organizational and **Service_Owns** containers as well as populate a service_owns type container with modeled devices.

Follow these steps:

1. In the Explorer tab of the OneClick Navigation panel, click the TopOrg topology node.
   The TopOrg topology view displays in the Topology tab of the Contents panel.
2. Click
   
   (Creates a new model by type) in the Topology tab toolbar.
   The Select Model Type dialog opens.
3. Click the Containers tab, select a container type that best describes the organization you are depicting, and click OK.
   The Create Model of Type dialog opens.
4. Specify a name that best describes the organization that is responsible for tracking the performance of the network services or that these services supports.
5. (Optional) Specify a security string in the Security String field when you want to secure this view from certain users.
6. Click OK.
   The named container icon appears in the top-level view of the TopOrg topology. The named folder representing the container appears in the Navigation panel under the TopOrg topology node.
7. Repeat Steps 2 through 6 for each organizational or Service_Owns container you want to depict in the TopOrg topology.

Populate Service_Owns or Org_Owns Containers

Populate the Service_Owns container with the modeled devices supporting the network service. You can populate these containers by copying and pasting modeled devices from the Universe topology to the **TopOrg** topology. You can also define new devices using the Create Model by IP Address dialog.

Follow these steps:

1. Go to the Universe topology.
2. Copy the modeled devices that you want to display in a **TopOrg** topology view.
3. Go to the **TopOrg** topology view.
4. Navigate to a Service_Owns container view.
5. Paste the modeled devices.

> **NOTE**
> To model new devices in the **TopOrg** topology, you can use either the Create Model by IP option or Create Model by Type option.

Using and Deleting Favorites

Using Favorites

The Favorites folder contains modeled elements that the user has tagged for easy reference.

In the Navigation panel Explorer tab, you can add any OneClick element below the landscape level to your Favorites folder by right-clicking the element and choosing Add To, Favorites. You can also add Global Collections to your favorites by right-clicking your Favorites folder and choosing Add Collections.

To remove an element from the Favorites folder, right-click the element within the Favorites folder and choose Remove.

> **WARNING**
> If you right-click the element within the Favorites folder and you choose Delete, the element is removed from the Favorites folder. Plus, some models could also be deleted permanently from the system.

You can create subfolders by right-clicking Favorites (or a subfolder within Favorites) and choosing New Folder. Use the right-click menu to cut, copy, paste, rename, and delete subfolders.

Deleting from Favorites

Consider the following behaviors when deleting elements from the Favorites folder:

- When deleting containers from the Favorites folder, container models are permanently deleted from the system. Any models within the container are sent to the Lost and Found.
- When deleting a global collection from the Favorites folder, the global collection is permanently deleted from the system. Any models within the global collection are removed from favorites but are not deleted from the system.
- When deleting a model from the Favorites folder, the model is permanently deleted from the system. The model is *not* sent to the Lost and Found.

Lost and Found Model Information Subview

The Lost and Found Model Information subview lets you clear unattached models that are stored in the Lost and Found repository. The unattached models are models that have been cut but not pasted, models that Discovery could not resolve, and so on.

To access the Lost and Found Model Information view, select **LostFound** in the Navigation panel and select the Information tab in the Component Detail panel.

The Lost and Found model information view includes the following options:

- **Automatic Model Destruction**
  Specifies whether models in the Lost and Found are destroyed at specified times.
- **Next Model Destruction Date and Time**
  Specifies the next scheduled date and time at which models in Lost and Found are destroyed when Automatic Model Destruction has been enabled. The value of the Model Destruction Interval determines this value.
- **Model Destruction Interval**
  The interval (in seconds) at which models in Lost and Found are destroyed when Automatic Model Destruction has been enabled.
  Default: 24 hours

Device and Interface Threshold Settings

DX NetOps Spectrum includes several device and interface alarms configured with three variables to define the alarm and reset conditions:

- **Threshold Setting**
  Specifies the threshold setting above which an alarm condition can exist.
- **Reset Level**
  Specifies the reset level below which an existing threshold alarm condition is automatically cleared. DX NetOps Spectrum does not generate subsequent alarms for the parameter until the value falls below the reset level.
- **Allowed Threshold Violation Duration**
  Specifies how long the parameter can be greater than the threshold setting, in seconds, before DX NetOps Spectrum generates an alarm.

You can configure device thresholds so that an alarm is generated if a given threshold is exceeded for a certain duration.

> **NOTE**
> To configure device and interface threshold alarm settings, the Device Threshold attribute on the SpectroSERVER must be enabled. You can turn off individual device or interface thresholds by setting the threshold and reset level variables equal to zero.

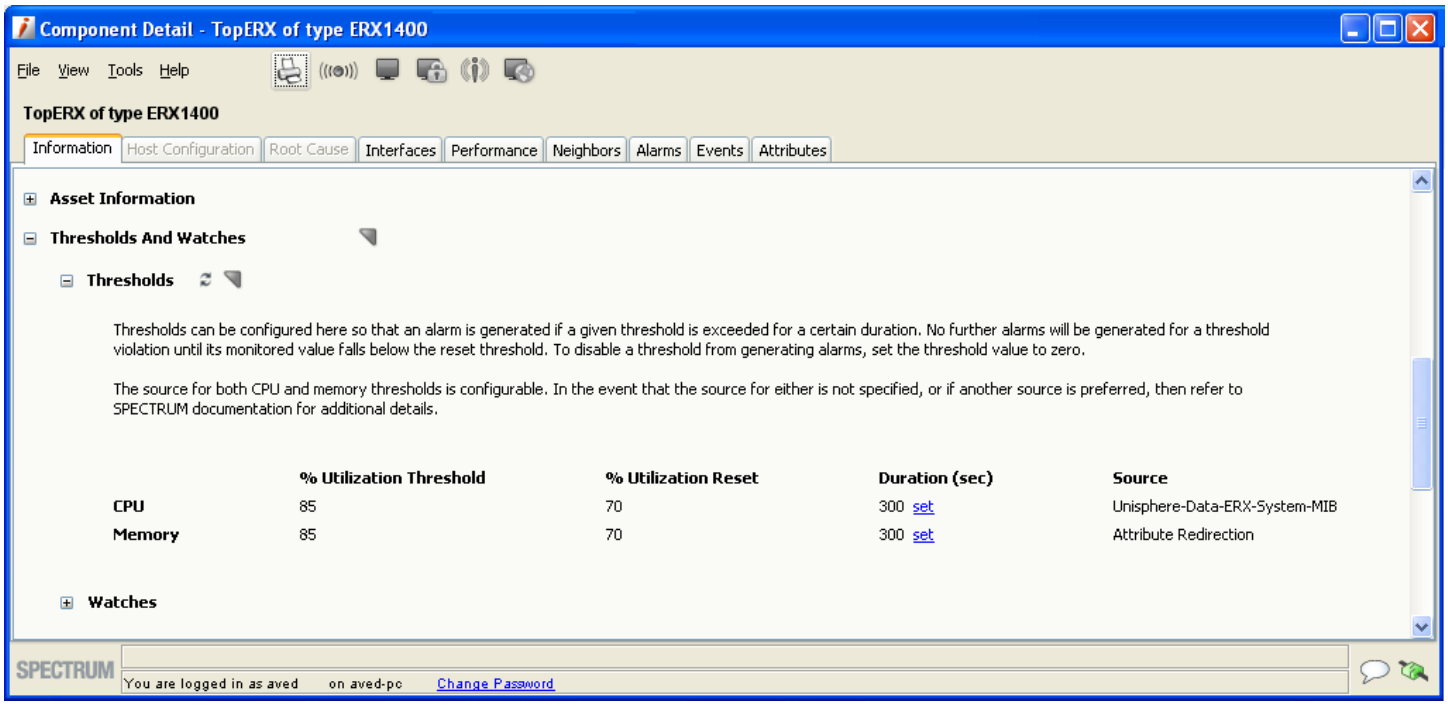
Device Threshold Settings

You can configure device thresholds so that an alarm is generated if a value is exceeded for a certain duration. No further alarms are generated for a threshold violation until its monitored value falls below the reset threshold. To disable a threshold from generating alarms, set the threshold value to zero.

The device threshold settings available are ‘% CPU Utilization’ and ‘% Memory Utilization’. You can access these OneClick settings in the following ways:

- The Thresholds and Watches subview in the Information tab for the selected device.
- The Attribute Editor, Thresholds, Device Thresholds grouping.
  When using the Attribute Editor to set the Device Threshold attributes, the Allowed Threshold Violation Duration attribute is not available, and the default value of 300 seconds (five minutes) is used.

You can view the source that is used to calculate the CPU and memory utilization for a device in the Thresholds and Watches, Thresholds subview in the Information tab of the Component Detail panel.



Example % CPU Utilization Default Settings

This example illustrates how the default % CPU Utilization Threshold settings work together to trigger an alarm. The example is illustrated in the following graphic. The default settings for this alarm setting are as follows:

- % CPU Utilization Threshold = 85%
- % CPU Utilization Reset = 70%
- Allow Threshold Violation Duration = 300 seconds

Using the default settings, when the device's % CPU Utilization parameter exceeds the threshold setting of 85% at time Y, DX NetOps Spectrum begins the 300 second Allowed Threshold Duration timer.

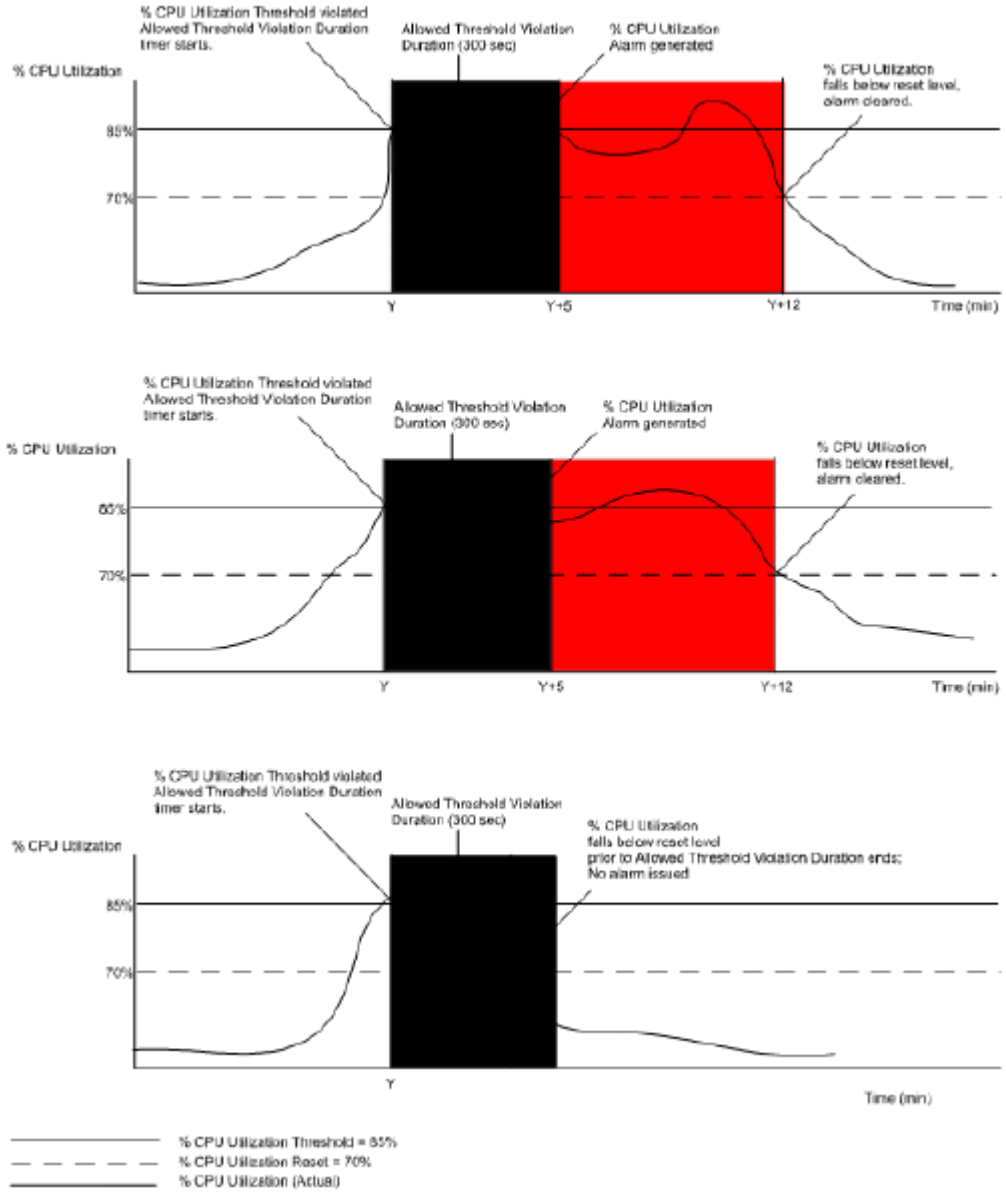
The % CPU Utilization does not fall below the reset value of 70% for the duration of the timer.

At time = Y+5 minutes, DX NetOps Spectrum triggers a % CPU Utilization alarm for the device.

DX NetOps Spectrum will not generate another % CPU Utilization alarm until this alarm is cleared manually or automatically.

At time = Y+12 minutes, the device's % CPU Utilization falls below the reset value of 70%. DX NetOps Spectrum clears the % CPU Utilization alarm for the device.

Illustration: % CPU Utilization Default Settings



Interface Threshold Settings

The following interface thresholds parameters are available:

- **% Utilization Threshold**
  Defines the level of port capacity used that triggers an alarm condition for a port.
- **Packet Rate Threshold (packets/sec)**
  Defines the number of packets per second that triggers an alarm condition for a port.
- **% Error Rate Threshold**
  Defines the error rate on a port that triggers an alarm condition.
- **% Discarded Threshold**
  Defines the percentage of discarded packets on a port that triggers an alarm condition.

Each of these attributes has a reset value and Allowed Threshold Violation Duration timer attribute setting. You can access these OneClick settings in the following ways:

The Thresholds and Watches subview in the Information tab for the selected device interface.

- The Attribute Editor, Thresholds, Interface Thresholds grouping.

NOTE
See Threshold Attributes for information about accessing Device Threshold settings using the Attribute Editor.

Update Device Interface and Connection Information

DX NetOps Spectrum can perform automatic discovery and mapping of a device's interfaces and connections based on the following events and conditions:

- A change in the number of configured interfaces on a device.
- When a device sends a LINK up trap.
- When DX NetOps Spectrum reconfigures a modeled device.

OneClick administrators can also manually update this information about a modeled device. See Using OneClick for information about viewing a device's interface, sub-interface, and connection information.

Automatic Updates of Device Interface and Connection Information

You can use the following attributes to configure DX NetOps Spectrum to automatically update interface and connection information about a device.

- Automatically Reconfigure Interfaces
- Discover Connections After Link-Up Events
- Create Subinterfaces
- Discovery After Reconfigure
- Topologically Locate Model

Automatically Reconfigure Interfaces

When this attribute is set to Yes, DX NetOps Spectrum monitors the device for a change in the number of configured interfaces. If it detects a change, DX NetOps Spectrum automatically updates the device model to reflect the interface changes. The updated interface information appears in the Interfaces view for the device.

Discover Connections After Link-Up Events

DX NetOps Spectrum automatically discovers and maps a model's connections one poll interval after it receives a Link Up trap from a device when the Discover Connections After Link-Up Events attribute is set to Yes. This delay lets the device fully reconfigure its related SNMP tables before DX NetOps Spectrum reads them. The Poll Interval setting for the device appears in the Information view, SPECTRUM Modeling Information subview.

Special Considerations for Flapping Interfaces

A "flapping" interface is one that is constantly coming up and going back down, usually because of a problem on the device. When Device Discovery After Link-Up Events is set to 'Yes,' DX NetOps Spectrum excludes LinkUp traps from flapping interfaces. As a result, the stream of LinkUp traps from a flapping interface does not interfere with a LinkUp trap for another interface on the same device. The connection discovery action can run as expected.

When DX NetOps Spectrum detects a flapping interface, a minor alarm is generated on the related device. After a default interval of 10 minutes without receiving a trap from that interface, the alarm clears. The default settings that are used to

identify and track flapping interfaces are configured using Event Rules associated with Events 0x220002, 0x220006. The default settings are as follows:

- An Event Sequence Rule on Event 0x220002, which generates Event 0x220006 if a LinkUp trap is received and is followed by a LinkDown trap from the same interface within 60 seconds.
- An Event Rate Window Rule on Event 0x220006, which generates Event 0x220007 if 15 0x220006 events are generated within 5 minutes (300 seconds). Event 0x220007 generates a Minor alarm on the device.
- An Event Pair Rule on Event 0x220006 which generates Event 0x220008 if Event 0x220006 is not followed by Event 0x220007 within 10 minutes (600 seconds). Event 0x220008 clears the minor alarm generated by Event 0x220007.

The default values generate an alarm after 15 LinkUp/Down trap pairs are received. Also by default, the alarm is cleared 10 minutes after the last LinkUp/Down Trap pair is received. You can modify these settings by defining flapping interface event thresholds. The applicable rules are specified in the *<$SPECROOT>*/SS/CsVendor/IETF/EventDisp file.

> **NOTE**
> For information about manually editing the files, for information about DX NetOps Spectrum events and event rules, and for information about changing the event rules associated with events 0x220002 and 0x220006, see the Event Configuration .

Create Sub-Interfaces Attribute

When this attribute is set to Yes, and the modeled device supports RFC 1573, DX NetOps Spectrum models the sub-interfaces for the device. DX NetOps Spectrum differentiates between physical and logical interfaces. It creates sub-interfaces using the logical interface information that it gathered from the device. A sub-interface appears in the Interfaces tab for a device, nested beneath the logical interface where it is configured.

Discovery After Reconfigure

When this attribute is set to Yes, DX NetOps Spectrum rediscovers device connections each time that the device model is reconfigured. Both an interface reconfiguration and a manual device reconfiguration trigger a rediscovery when this attribute is enabled.

Topologically Relocate Model

When this attribute is set to Yes, DX NetOps Spectrum determines whether a device model must be moved to a different topology during a Discovery. DX NetOps Spectrum moves the device if necessary, based on updated connection mapping.

Manually Updating Interface and Connection Information

You can manually initiate an interface reconfiguration and connection discovery using the following options in the Tools, Reconfiguration menu and the Reconfiguration subview on the Information tab:

- Reconfigure Model
- Discover Connections
- Rediscover SNMP MIBs
- Rename Interface Models
- Reevaluate Model Name
- Reevaluate NCM Device Family

About Reconfiguring Models

When you activate a Reconfigure Model action, DX NetOps Spectrum finds the interfaces on the device and updates the device interface modeling.

NOTE
Reconfigure Model actions do *not* change the model type. To change the model type, either run the NewMM.pl script or delete and remodel the device by IP address. For more information about running NewMM.pl, see Install DX NetOps Spectrum .

The following parameters are reevaluated during a Reconfigure Model action:

- **Device Type**
  Verifies the current Device Type attribute value.
- **Model Name**
  Checks the Model Naming Order setting on the VNM, and determines whether the device model requires a change.
- **Application Discovery**
  Performs a Reconfigure SNMP MIBs action.
- **Interface Discovery**
  Determines which interfaces exist on a device, and updates the device modeling as needed.
- **Normalized Source**
  Verifies the attribute to use for gathering device CPU and memory usage information.
- **Serial Number**
  Verifies the device serial number, if available, and updates the device model if necessary.
- **802.3ad Trunk Memberships**
  Checks to see if the device interfaces are members of a 802.3ad trunk.
- **NCM Device Family**
  Checks the Device Family value that Network Configuration Manager uses to groups devices by vendor.

Reconfigure a Model

You can reconfigure a model to update device interface information. When you activate a Reconfigure Model action, DX NetOps Spectrum finds the interfaces on the device and updates the device interface modeling.

Follow these steps:

1. Locate the model.
2. Right-click the model and select Reconfiguration, Reconfigure Model.
   The Reconfigure Model dialog opens, showing the progress of the requested action.
3. Click OK.
   The Reconfigure Model dialog closes. The model is reconfigured.

Discover Connections

Starting from this release, you can run Discover Connections on multiple devices. When you run the Discover Connections command, DX NetOps Spectrum performs a Discovery on the selected devices. Discovery data lets DX NetOps Spectrum update and remap the device model connection information. You can also use this functionality to discover connections in a network container.

NOTE

If the discovery is already running on a device, the remaining devices are added to the Discovery queue. A pop-up message appears with the following message:"Another discovery process is currently in progress. Only one discovery process at a time is allowed per <Landscape Name> landscape, queuing request for background processing."

To know how to view the queue, refer View Queue.

Follow these steps:

1. Locate the container for which you want to discover connections in the Explorer tab.
2. Right-click the container, and select Reconfiguration, Discover Connections.

The Discover Connections dialog shows the progress of the requested action. If connections are successfully discovered, this dialog indicates success.

3. Click OK.
   The Discover Connections dialog closes. The connections among the devices in the selected LAN container now appear as pipes in the Topology view.

Discover Connections Queue

The Discover Connections Queue feature allows you to initiate multiple discover connectivity tasks (for example, discover connections after reconfiguration) by adding them to a queue. You do not have to wait for a discovery task to complete to initiate a new one. When the previous task completes, the discovery tasks that are added to the Discover Connections Queue start automatically. You can review the status of a discovery task in the Events tab.

If a mapping process is in progress and you initiate a new Discover Connection action, the following message appears:

“Another discovery process is in progress. Only one discovery process at a time is allowed per landscape, so it is queued.”

NOTE

If you trigger the Discover Connections action through REST API, you get the message as 'SUCCESS' when the action is queued.

Also, if the “Discovery After Reconfigure” or the “Discover Connection After Link-up Events” option is set to 'Yes' then the Discover Connectivity action triggers are queued to Discover Connections Queue.

Once the task that is already running completes, a new task in the queue starts. When you select a model, the discovery status messages for that model appear in the Events tab.

View Discover Connections Queue

To view the queue, run the following CLI command on the TopologyWrkSpc model. The queue entries are written to the $SPECROOT/SS/ADiscDebug file.

NOTE

To enalbe the ADiscDebug file, go to VNM -> AutoDiscovery Control -> Debug Options -> Debug AutoDiscovery then set the value to 'ON'.

./update action=0x10601 mh=themodelhandleofthe"TopologyWrkSpc"model

Example: > ./update action=0x10601 mh=0x10003aupdate action: successfulResponse has 0 attributes:

In the ADiscDebug file, the following message appears: 'Dumping the pending rediscovery models'

Clear Discover Connections Queue

To clear the discover connection queue, run the following CLI command on the TopologyWrkSpc model:

./update action=0x10602 mh=themodelhandleofthe"TopologyWrkSpc"model

Example: > ./update action=0x10602 mh=0x10003aupdate action: successfulResponse has 0 attributes:

In the ADiscDebug file, the following message appears:
'Clearing the pending rediscovery queue'

Rediscover SNMP MIBs

When a device model is created, DX NetOps Spectrum automatically creates models for each of the major and minor applications the device supports. Click Reconfigure SNMP MIBs to retrieve application support information from the device. The application models for the device are updated with any changes.

Rename Interface Models

Use this function to update a device's interface model names after changing the device's Interface Name Primary Suffix attribute or the Interface Name Secondary Suffix attribute. Using this command forces DX NetOps Spectrum to rename the interface models using the current values of both the primary and secondary suffixes for the interface model. Some of the suffix options include ifName, ifAlias, ifDescr, and ifIndex.

Entity Table Interface Stacking

When modeling interfaces, DX NetOps Spectrum uses the information contained within the MIB II ifStackTable to determine their logical stacking. For example, in the case of a frame relay interface with DLCI sub-interfaces, DX NetOps Spectrum attempts to stack the interfaces using information in the ifStackTable.

If you set the use_if_entity_stacking (0x12a83) attribute to TRUE on a device model in the Attributes tab, DX NetOps Spectrum attempts to use information from RFC2737 (Entity MIB) to determine interface stacking if the ifStackTable method fails. If an interface does not support ifStackTable, but the interface *does* support the Entity MIB, DX NetOps Spectrum will attempt to stack the interface model using information in the entPhysicalTable.

Note: This is done on a case-by-case basis as some vendors do not implement the RFC2737 indexing scheme correctly, which can cause interfaces to be incorrectly stacked.

Reevaluate Model Name

Determines whether to change the device's model name based on the VNM Model Naming Order setting for the VNM managing the device. See SpectroSERVER Control Subview for information about the VNM Model Naming Order setting.

Reevaluate NCM Device Family

Automatically places a device in the proper device family after a firmware upgrade. For example, if you have a Cisco device that appears in the CatOS family and you then upgrade this device with new firmware and it changes to CiscoIOS, the device does not switch its family automatically. Instead, you can update it using the Reconfigure menu.

Access Interface and Connection Update Controls

You can access to the interface and connection update controls described in this section as shown in the following table:

Attribute	Tools, Reconfiguration Menu	Reconfiguration	Attribute Editor
Automatically Reconfigure Interfaces		X	X
Discovery Connections After Link Up Events		X	X
Discovery After Reconfigure		X	X
Create Sub-Interfaces		X	
Topologically Relocate Model		X	X
Reconfigure Model	X	X	
Discover Connections	X	X	
Rediscover SNMP MIBs	X	X	
Rename Interface Models	X	X	
Reevaluate Model Name	X	X	
Reevaluate NCM Device Family	X		

Tools, Reconfiguration Menu

The Tools, Reconfiguration menu provides quick access to reconfiguration actions you can perform on a selected device model. You can also access this menu by right-clicking the device you want to reconfigure.

Reconfiguration Subview and Advanced Subview

The Reconfiguration subview provides access to attributes that control when DX NetOps Spectrum updates a device's interface, connection, and topology information. You can also manually reconfigure a device and discover a device's connections from this subview.

The Advanced section of the Reconfiguration subview provides access to individual model reconfiguration functions that occur as part of the Reconfigure Model function. In some cases, you may want to perform these actions separately instead of performing an overall Reconfigure Model action.

Attribute Editor

Use the Attribute Editor to access some of the interface and connection update parameters for many models or modeled devices.

The Discover Connections Queue feature in the latest release of DX NetOps Spectrum allows you to initiate multiple discovery tasks by adding them to a queue. You do not to wait till a discovery task to complete to initiate a new one. The discovery tasks added to the Discover Connections Queue are started automatically if the previous task is complete. You can review the status of a discovery task in the Events tab.

Redundant Connections

If a modeled device is configured with a pool of IP addresses available to it for use in communicating on the network, DX NetOps Spectrum can use these IP addresses to create redundant connectivity with that device. If the redundancy feature is enabled on a device and DX NetOps Spectrum cannot reach the device using the designated primary address, DX NetOps Spectrum attempts to re-establish contact using the list of available IP addresses.

Redundancy Preferred Addresses List

A device that supports the DX NetOps Spectrum redundancy feature has a Redundancy Preferred Addresses list containing the device's interface IP addresses that is created when the router is originally modeled. DX NetOps Spectrum uses this list in determining redundant connectivity to the device. Devices have a primary address that is determined when the device is modeled. The DX NetOps Spectrum modeling process includes loopback functionality. If the VNM is configured to use the loopback feature, the first valid loopback address detected for the device is used as device model's primary address.

Removal of Shared IP Addresses from Preferred List

DX NetOps Spectrum automatically removes the IP addresses that it detects as "shared" from a Redundancy Preferred Addresses list for a device model. DX NetOps Spectrum places these shared addresses in the Redundancy Excluded Addresses list. Such shared IP addresses are not used when DX NetOps Spectrum attempts to restore communication with a lost device that was using redundant IP addresses.

> **NOTE**
> If you manually add a shared IP address to the Redundancy Preferred Addresses list, DX NetOps Spectrum automatically moves it back to the Redundancy Excluded Addresses list. You cannot see this list until you close and reopen the current view.

Device Primary Address

By default, the primary address for a device is the IP address assigned to the device for network communications. You can change the primary address in OneClick if the network address for the device changes. If DX NetOps Spectrum cannot contact the device using its primary address, it attempts to contact the device using the first IP address in the Redundancy Preferred Addresses List.

You can change a device's primary address and the IP addresses listed in the Redundancy Preferred Addresses list using the IP Redundancy subview.

IP Redundancy Subview

The IP Redundancy subview displays the attributes and settings DX NetOps Spectrum uses to create and monitor redundant communication paths to the device. Access the IP Redundancy subview by selecting a device in either the Navigation panel, the List tab, or the Topology tab, and then selecting the Information tab in the Component Detail panel. The IP Redundancy subview appears in the Information tab.

Enable Redundancy

When this attribute is set to Yes, DX NetOps Spectrum uses the addresses in a modeled device's Redundancy Preferred Addresses list, if it exists, to contact a device when the primary address is not available.

Generate Redundancy Alarms

When this attribute is set to Yes, DX NetOps Spectrum generates an alarm when a device cannot be contacted using its primary address.

Select Preferred Redundant Addresses

The Redundancy Preferred Addresses list displays IP addresses that a device can use for communicating on the network. You can manually add or remove IP addresses to or from the Redundancy Preferred Addresses list for a device.

Follow these steps:

1. Select the device with a redundant IP address.
2. Click the Information tab and expand the IP Redundancy subview.
3. Click Configure next to Primary Address.
   The Preferred Addresses dialog opens.
4. Click Add below the Redundancy Preferred Addresses list.
5. Enter the IP address that you want to add to the list in the Add IP Address dialog, and click OK.
   The IP address now appears in the Redundancy Preferred Addresses list.
6. Click OK.
   The changes to the device's Redundancy Preferred Addresses list are applied.

Exclude Redundant Addresses

The Redundancy Excluded Addresses list displays IP addresses that a device cannot use for communicating on the network. You can manually add or remove IP addresses to or from a device's Redundancy Excluded Addresses list.

Follow these steps:

1. Select the device for which you want to add an excluded IP address.
2. Click the Information tab and expand the IP Redundancy subview.
3. Click Configure next to Primary Address.
   The Preferred Addresses dialog opens.
4. Click Add below the Redundancy Excluded Addresses list.

5. Enter the IP address that you want to add to the excluded list Add dialog and click OK.
   The IP address now appears in the Redundancy Excluded Addresses list.

   NOTE
   You can also select an address in the Preferred list and move it to the Excluded list by clicking the single right arrow located between the two lists. Similarly, you can move an address from the Excluded list to the Preferred list by selecting the address in the Excluded list and clicking the single left arrow located between the two lists.

About Shared IPs in Device Communication

Since any of your shared IP addresses will already have been added to the Redundancy Excluded Addresses list, the DX NetOps Spectrum redundancy intelligence will never attempt to communicate with a device using a shared IP. DX NetOps Spectrum will also never assign a shared IP address to the PrimaryAddress attribute.

Also, if you try to write a new value to a device model's NetworkAddress or PrimaryAddress attribute, if it is a shared IP address, the new value is not written and a warning dialog opens.

Interface Reconfigurations

Device models can potentially reconfigure interfaces at every poll cycle. This reconfiguration increases CPU usage and generates SNMP traffic due to interface table changes or interface stack table changes.

To disable interface reconfiguring, do the following:

- Set the Use_If_Table_Last_Change (0x11f7f) attribute to FALSE to disable interface reconfiguring for an interface table.
- Set the Use_If_Stack_Last_Change (0x130bc) attribute to FALSE to disable interface reconfiguring for an interface stack table.

You can configure a device model to trigger an alarm if it is continually reconfiguring interfaces. By default, a device model triggers a minor alarm if any one of the following sequences occurs in a 31-minute timeframe:

- Six interface reconfigurations for an interface table
- Six interface reconfigurations for an interface stack table
- Both sequences.

Primary IP Address Modification

The primary IP address is the address DX NetOps Spectrum uses to communicate with a modeled device. You can change a modeled device's primary IP address. There are three ways to change a device's primary IP address:

- Change a device's primary IP address in the device's preferred address list.
- Change a device's primary IP address to an interface's primary IP address.
- Change a device's primary IP address to an interface's secondary IP address.

Change the Primary IP Address for a Device in the Preferred Address List

You can change the primary IP address for a modeled device. If you know the IP address that you want to use to contact the device, you can change the address in the preferred address list for that device.

Follow these steps:

1. In the Explorer tab, select the device whose primary IP address you want to change.
2. Click the Information tab and expand the IP Redundancy subview.
3. Click Configure next to Primary Address.

The Preferred Addresses dialog opens. The current primary address for the device appears in the Primary Address field.

4. Select an IP address from the Redundancy Preferred Addresses list on the left side of the dialog, and click Primary.
   The IP address you selected appears in the Primary Address field. The IP address that had originally been the primary address now appears in the Redundancy Preferred Addresses list.
5. Click OK.
   The change to the device's primary address is applied and the Preferred Addresses dialog is closed.

Change the Device IP Address to an Interface Address

You can change the primary IP address of a modeled device to an interface address. In some situations, you do not know the IP address to contact a device, but you do know the device interface that you want to use. You can change the primary IP address for that device by selecting an interface primary IP address.

> **NOTE**
> For more information about interfaces, see the *Operator section*.

Follow these steps:

1. In the Explorer tab, select the device whose primary IP address you want to change.
2. Click the Interfaces tab in the Component Detail panel.
   Interface information for the selected device opens in table format.
3. Right-click the interface you want to use to contact the device, click Configure Primary Address for Device, and then click Use Interface IP As Primary Address to set the interface's primary IP address as the device's primary IP address.
   A confirmation dialog opens.
4. Click Yes.
   The change to the device's primary address is applied.

> **NOTE**
> You cannot select an interface that does not have a primary IP address configured for it (for example, if the IP Address column in the interfaces table is blank). If you try to select the interface, an error message appears.

Change the Primary IP Address for a Device to use an Interface Secondary IP Address

You can change the primary IP address of a modeled device. In some cases, you do not know the IP address that you want to use to contact a device, but you do know the particular interface. You can change the primary IP address for a device by selecting an interface and then selecting one of the interface secondary IP addresses.

> **NOTE**
> For more information about interfaces, see the *Operator section*.

Follow these steps:

1. In the Explorer tab, select the device whose primary IP address you want to change.
2. Click the Interfaces tab in the Component Detail panel.
   Interface information for the selected device opens in table format.
3. Right-click the interface that you want to use to contact the device.
4. Click Configure Primary Address for Device.
5. Click Use Secondary IP to set one of the interface secondary IP addresses as the primary IP address for the device.
   The Interface IP Mask Table opens.
6. Select an IP address to use from the list of secondary IP addresses and click Use as Primary Address for Device.
   A confirmation dialog opens.
7. Click Yes.
   The change to the device's primary address is applied.

NOTE
You cannot select an interface that does not have any IP addresses configured for it (for example, if the Secondary IPs and IP Address columns in the interfaces table are blank). If you try to select the interface, an error message appears.

IPv6 Information

You can view IPv6 information for devices that support RFC2465 and RFC2452 MIBs in the Information tab of the Component Detail panel. The following tables provide specific information:

- IPv6 Interface Configuration Table
- IPv6 Routing Table
- IPv6 Address Table

Editing and Enhancing Topology Views

This section contains the following topics:

- Topology Edit Mode
- Set Topology View Edit Mode Preferences
- Modifying Topology Views

Topology Edit Mode

Topology Edit mode refers to the condition you place a topology view in when you want to edit its appearance. When you place a view into Edit mode, you automatically prevent other users from editing that view. Once in Edit mode you can use its drawing tools to draw rectangles, ellipses, lines, or text boxes. After you create these items in a view, you can later apply styles or colors to them.

The following image shows an example of the Edit mode toolbar that appears when you enter Edit mode:

Access Edit Mode

If your user account has the required privileges, you can access Edit mode to modify the current topology view.

Follow these steps:

1. Click the Topology tab in the Contents panel.
   The Topology view and the Topology toolbar open.
2. Click
   
   (Edit) in the Topology tab toolbar.

The Edit mode toolbar opens. The topology view is locked to prevent other users from editing this view.

3. Modify the topology view.
4. Click Save.
   Your changes are saved, and you exit Edit mode.

Edit Mode Toolbar

The following table describes the editing tools that you can access and use from the Edit mode toolbar.

Tool	Description
	**Move Tool:** Moves modeled elements in a view.
	**Rectangle Tool:** Draws rectangles. Click and hold the rectangle button to access additional tools.
	**Ellipse Tool:** Draws ellipses. Click and hold the Ellipse Tool button to access additional tools.
	**Line Tool:** Draws lines.
	**Text Box:** Creates a text box used to enter text.
	**Font Properties:** Opens the Select Font dialog for the selected text annotation. Choose a font family, style, and size from the respective columns in the Select Font dialog. You can also choose the text foreground and background color and whether to show the text background.
	**Shape Color:** Opens the Select Shape Color dialog for the selected annotation. Select a shape color in the Select Color dialog.
	**Line Weight:** Sets the line weight for lines, ellipses, and rectangles.
	**Line Pattern:** Sets the style for lines, ellipses, and rectangles.
	**Group:** Group selected modeled elements in a view.
	**Ungroup:** Ungroup selected modeled elements in a view.
	**Background Editor:** Changes topology background characteristics (edit mode grid, grid spacing and color, background color, image, and size).
Arrangement	**Arrangement drop-down list:** Contains the following options for arranging the elements in the topology: Radial, Tree, or Manual.

Set Topology View Edit Mode Preferences

You can set preferences to specify how you want Edit mode to behave.

To set topology view Edit mode preferences

1. Click View, Preferences.
   The Set Preferences dialog opens.
2. Expand the Topology Tab folder in the Name column.
3. Click any of the following options to make changes:
   – **Annotation Font**
   Specifies the default font settings for topology annotation text. You can modify font, style, size, and background and foreground colors.
   – **Grid Properties**
   Specifies the following settings for the grid that can appear in the Topology tab in Edit mode:
   • **Show grid:** Set the size of the grid squares using the value displayed using the Show grid option. Decreasing the value decreases the size of the grid squares, while increasing the value increases the size of the grid squares.
   • **Snap to grid:** Enables snap-to-grid while the topology view is in Edit mode, making it easier to align modeled device icons in the topology view.
   – **Initial Zoom**
   Specifies the zoom behavior for topology views when they are first shown.
   – **Show Pipe Label**
   Specifies whether you want to show pipe labels in the topology view.
4. Click OK.
   Your changes are saved and the Set Preferences dialog closes.

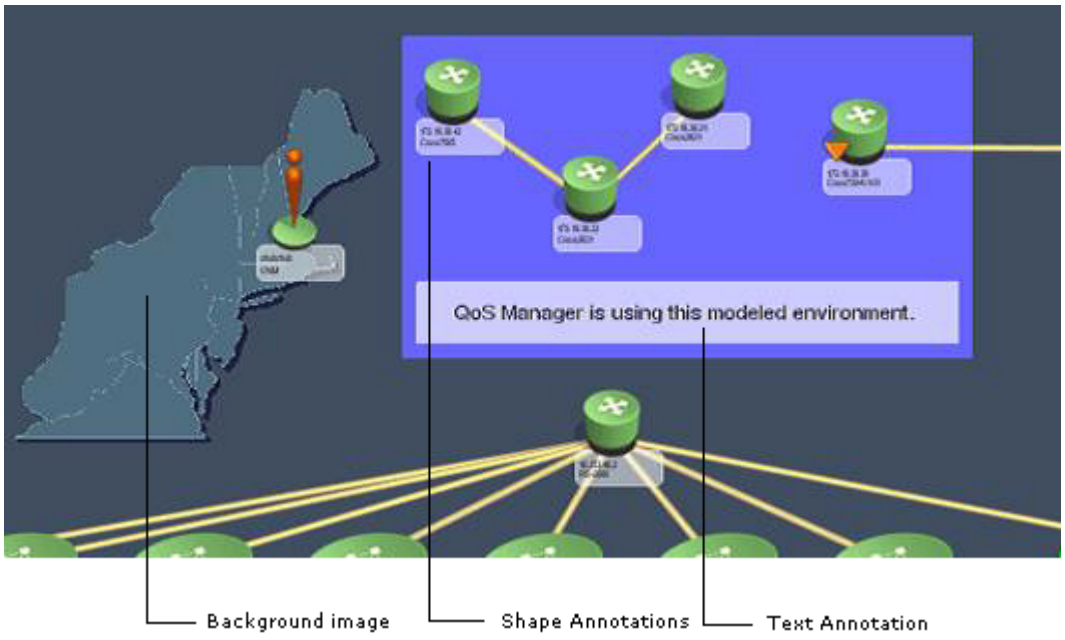
   NOTE
   You can also set these preferences in the Background Editor dialog.

Modifying Topology Views

You can modify the appearance of any topology view by using the Edit feature in the view. Some of the enhancements you can make include the following:

- Change the background characteristics of a view.
- Add lines, rectangles, or ellipses to a view.
- Change the placement of modeled elements in a view.
- Change font characteristics in a view.

The following image shows an example of an enhanced topology view:



Multi-User Considerations

Be aware that OneClick topology view enhancements are shared across all users. Also, when you edit a view using the Edit mode button in a Topology tab toolbar, DX NetOps Spectrum automatically prevents all other users from editing that view until you have finished.

Resize Model Icons

You can resize model icons displayed in a topology view.

Follow these steps:

1. Switch to Edit mode, as described in Access Edit Mode.
2. Select the model icon that you want to resize in a topology view.
   A green box appears around the icon.
3. Click one of the corners of the green box, and drag the icon to resize it.
   The icon size changes proportionally.
4. Deselect the icon when it reaches the desired size.
5. Click Save.
   The model icon is resized, and you exit Edit mode.

Add Shapes, Lines, or Text to a View

You can add rectangles, ellipses, lines, or text in a topology view.

Add a rectangle or ellipse to a topology view in Edit mode.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, select the desired style for the shape from the menu by clicking the Rectangle Tool or the Ellipse

   Tool 

The pointer changes from an arrow to a crosshair when hovering over the background area of the topology view.
3. In the desired location, click and drag the pointer starting at the upper left corner of the shape and ending at the lower right-hand corner of the shape.
4. Release the mouse button.
The shape you created now appears in the view, behind any existing models or pipes.

Add a line to a view in Edit mode.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, click the line tool  .
The pointer changes from an arrow to a crosshair.
3. In the topology view, click and drag the pointer to draw the line.
4. Release the mouse button.
The line appears in the view, behind any existing models or pipes.

Add text to a view.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, click the text box  .
The pointer changes from an arrow to a crosshair pointer.
3. Click in the location where you want the text box to begin.
A text box appears.
4. Type the text in the text box.
5. Click outside the text box to exit.
The text boundaries of the text box disappear. The text is placed in the background of the topology view.

Change Shapes, Lines, and Text Characteristics

You can apply different font properties to text, colors to shapes, or line weights to lines.

> **NOTE**
> We recommend setting properties for shapes, lines, or text before adding (or drawing) these elements in a view as a best practice.

You can change text font properties in a topology view.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, click the text you want to change and click Font Properties  .
The Select Font dialog opens.
3. Select the desired font family, style, size, foreground color, and background color.
The preview pane shows the font properties that you selected.
4. Click OK.
The font properties are applied to the selected text.

You can apply color to shapes or lines in a topology view.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. Click the shape or line that you want to edit.
3. in the Edit mode toolbar, click Shape Color  .

   The Select Color dialog opens.
4. Modify the color settings by clicking each of the tabs in the Select Color dialog:
   - **Swatches**
     Specifies the color of the shape or line. Select a color from the palette. A preview of the selected color appears at the bottom of the dialog. If you selected and previewed multiple colors, the colors you have chosen appear in the Recent color grid for re-selection.
   - **HSB**
     Specifies the Hue, Saturation, and Brightness settings associated with standard color selected from the Swatches tab and shown in the preview at the bottom of the dialog. Use the slider to increase or decrease the settings associated with Red, Green, and Blue colors. Or, you can individually change the color settings associated with the Hue (H), Saturation (S), and Brightness (B).

     NOTE
     When you change the color settings in the HSB tab, the color settings in the RGB tab are updated respectively.
   - **RGB**
     Specifies customization settings for a standard color chosen on the Swatches tab. Use the sliders to customize the standard color by adding more or less red, green, or blue.
5. Click OK.
   The color settings are applied to the shape or line you selected.

You can also apply line weight and patterns to components of a topology view.

Follow these steps:

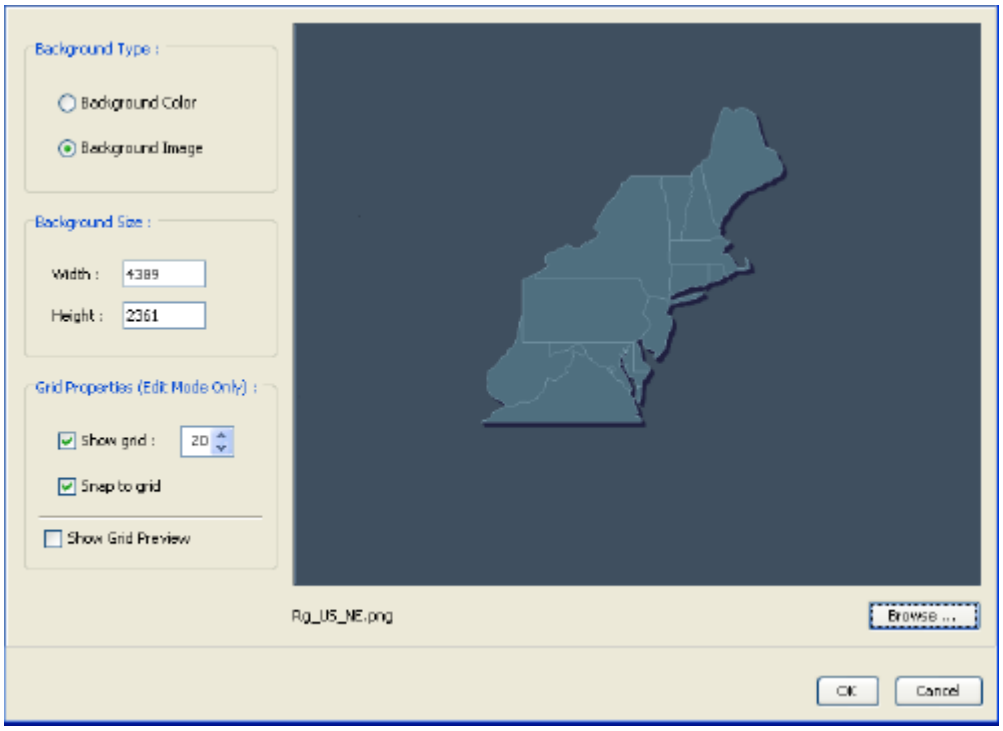
1. Switch to Edit mode as described in Access Edit Mode.
2. Select the line that you want to edit.
3. In the Edit mode toolbar, click Line Weight or Line Pattern  .

   A menu appears.
4. Click the desired line weight or line pattern.
   The selected line weight or pattern is applied to the line.

Background Editor

Use the Background Editor dialog to modify the appearance of a topology view's background. You can modify a topology view's background color, add a background image, or change the size of the background. For example, you might want to change the background size of the topology view to create additional room for modeling network entities.

The following image shows the Background Editor dialog:



Modify the Topology Background

You can use the Background Editor to modify a topology background. You can change the background color, add a background image, or change the size of the background. For example, change the background size of the topology view to create additional room for modeling network entities.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, click the Background icon 
   The Background Editor dialog opens.
3. Specify whether to change the color or image in the Background Type section.
4. Click Browse to preview colors or images.
   The 'Select Topology Background Image' or 'Select Topology Background Color' dialog opens.
5. Select the desired image or color and click OK.
   A preview of the selected item appears in the Background Editor dialog.
6. Click OK to apply the changes to the background.
   The background view refreshes to reflect the changes.

You can use a similar procedure to change the background size.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. In the Edit mode toolbar, click the Background icon 
   The Background Editor dialog opens.

3. Specify pixel values in the Width and Height fields.
4. Click OK.
   The background view refreshes to reflect the changes.

Group Items in a View

You can group items in any OneClick topology view. Grouping items within a view lets you edit, move, copy, paste, or delete items as one group. One of the most common group operations you may perform within a topology view is to group text (annotations) with modeled devices.

To group items in a view

1. Switch to Edit mode as described in Access Edit Mode.
2. Press and hold down the Shift key, and select the items you want to represent as a group.
3. In the Edit mode toolbar, click the Group
   icon 
   The selected items in the view are represented as a single group.

Ungroup Items in a View

Ungroup a set of grouped items within a view when you want to edit the items, or when you want to move individual items.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. Click one of the grouped items to select the entire group.
3. Click the Ungroup
   icon 
   The items are ungrouped. You can now select individual items.

Send Items to the Back

You can send items to the back of a view so that other items within that view appear to be in front.

Follow these steps:

1. Switch to Edit mode, as described in Access Edit Mode.
2. Right-click an item, and select Send to Back.
   The item moves to the back of the view relative to other items in the view.

Bring Items to the Front

You can bring items to the front of a view relative to other items within that view.

Follow these steps:

1. Switch to Edit mode as described in Access Edit Mode.
2. Right-click the item you want to move and select Bring to Front.
   The item moves to the front of the view relative to other items in the view.

Model Attributes

Model attributes can be used to set values on models, set values directly on devices, turn DX NetOps Spectrum features on or off, configure DX NetOps Spectrum features, set default values in the DX NetOps Spectrum modeling catalog, and

so on. You can modify an attribute which is associated with a device's MIB object, thus changing the device's value for that object without having to use the device's local management. For example, you can modify a device's contact details. You can modify the Maintenance or Hibernation mode attribute to control those features.

> **WARNING**
> Use caution when changing default settings for models; this can affect the overall performance of DX NetOps Spectrum. Additionally, attribute value changes you make to the selected models will affect the same values for similar models created in the future, and for any existing model if that model's type is using the default value.

You can review and modify model attributes as follows in OneClick:

- **Information tab:** Use the Information tab in the Component Detail panel to view and modify certain common attributes for a single model. See Attributes in the Information Tab for more information about viewing and setting attribute values for a single model from the Information tab.
- **Attributes tab:** Use the Attributes tab in the Component Detail panel to access every possible attribute for a selected model. You can also create custom views of attributes and modify each one as needed, depending on your access rights. See Attributes Tab for more information about viewing and setting attribute values for a single model using the Attributes tab.
- **Attribute Editor:** Use the Attribute Editor to modify non-list attributes for a model or subset of models as well as to modify default attribute values in the DX NetOps Spectrum modeling catalog. If you change any attribute values and apply them to the DX NetOps Spectrum modeling catalog, each device model that is subsequently created based on that model type will use the new attribute value. See OneClick Attribute Editor for information about using the Attribute Editor. You must have administrative read/write privileges for those models you want to configure with the Attribute Editor.

Attributes in the Information Tab

You can view and set attribute values for individual models using the Information tab. Subviews in the Information tab display grouped categories of information available for the model. The subviews available in the Information tab depend on the selected model.

The attribute values that appear in the Information tab for the selected model are a result of a combination of the following processes:

- Automated discovery and modeling
- Manual modeling
- Using the Attribute Editor
- Direct entry using OneClick
- Default DX NetOps Spectrum values

You can set some attribute values that appear in the subviews of the Information tab. Specific attributes that you can set depend on the model selected, privileges applied to model or model types, and other factors. You can change the values of attributes for which 'set' appears next to the attribute value.

VNM Attributes in the Information Tab

In OneClick, you can view and set various attributes for each Virtual Network Machine (VNM), or SpectroSERVER, in your DX NetOps Spectrum installation. The attributes available in the VNM Information view depend on the add-on applications that are installed as part of your DX NetOps Spectrum environment. The VNM attributes are grouped into subviews for specific applications and functionality. Most of the attributes have descriptive tooltips.

General Information Subview

The General Information subview provides information about the VNM such as its network or IP address, condition, contact status, and when it was last polled successfully. With administrator privileges, you can set the VNM rollup alarm attributes. See Rollup Alarm Settings for more information. It also contains the following option:

- **Percent Models Activated**
  The percentage of models in the SpectroSERVER database that have been activated. The VNM icon will not change from its initial (blue) state until this value reaches 100%. This is useful to determine how close the SpectroSERVER is to becoming fully active after a restart. This value is also displayed in the message area of the DX NetOps Spectrum Control Panel.

DX NetOps Spectrum Modeling Information Subview

The DX NetOps Spectrum Modeling Information subview provides information about attributes such as SNMP community string, landscape, device type, and model type name.

Online Database Backup Subview

Use the settings available in this subview to configure online backups of the DX NetOps Spectrum database.

- **Automatic Backups**
  Specifies whether the DX NetOps Spectrum database is automatically backed up.
  Default: Disabled.
- **Backup Interval**
  Specifies how often, in hours and minutes, the DX NetOps Spectrum database is automatically backed up.
- **New Backup Date & Time**
  Specifies the date and time of the next database backup.
- **Backup Compression**
  Specifies whether to compress the backup file using the default compression mode.
  Default: Enabled.
- **Prefix for Backup File Name**
  Specifies the prefix used in the database backup file name. File names are appended with the date the backup occurred.
- **Backup Directory**
  Specifies the directory on the server where the backup files are written to. You must know the full path to the directory, as this is not a browse function.
- **Minimum Required Disk Space (MB)**
  Specifies the amount of free disk space that must exist on the server for a backup to start.

  NOTE
  You can initiate an online backup immediately by clicking Begin Backup Now.

SpectroSERVER Control Subview

The SpectroSERVER Control subview lets you configure various aspects of each of your local landscapes through various attributes and settings. It also contains the following views:

- Alarm Information Subview
- Event Log Information Subview
- Statistics Log Information Subview
- Thread Log Information Subview

The attributes and settings available in the SpectroSERVER Control subview include the following:

- **Device Thresholds**

Set the Device Thresholds attribute to Enabled to activate the threshold functionality on devices supporting threshold. Each threshold values setting must also be set to a non-zero value for the threshold to be active.
Default: Enabled

- **Auto Connects**
  Specifies whether DX NetOps Spectrum attempts to resolve the port connections when a pipe is created between two device models. This functionality will use the options that are enabled in the AutoDiscovery Control subview to resolve the port connections. Disabling Auto Connects can improve DX NetOps Spectrum performance if your modeled network contains management modules that support non-standard MIBs.
  Default: Enabled
- **Copy Users When Copying Group**
  If the Copy Users when Copying Group attribute is set to Yes, whenever you copy a group or a user in a group from one landscape to another, the group and all users in the group are copied as well.
  Default: Enabled
- **Log When Device Cannot Be Contacted**
  Specifies whether to continue logging attribute values (such as contact status) for models that have lost primary management contact with the devices they represent. In most cases, this is undesirable since it results in extra traffic to a part of the network where there may already be a problem. Hence, this option is disabled by default, and logging is automatically suspended for a device when contact is lost.
- **VLAN Configuration**
  Specifies whether Virtual Local Area Networks (VLANs) are modeled for networks on this VNM.
  Default: Disabled
- **Server Polling**
  Stops SpectroSERVER from polling the devices it is managing on the network. When SpectroSERVER polling is stopped, the VNM icon displays a gray condition status but no alarm will be generated. To restart SpectroSERVER polling of models, click Start.
- **Minimum Disk Space (kBytes)**
  Specifies the minimum amount of free disk space in kilobytes that must exist on the partition that the SpectroSERVER starts from for the SpectroSERVER to start. When the available space is less than this amount, a shutdown message is generated and the SpectroSERVER shuts down.
  Default: 2000
- **Use Fully Qualified Host Name**
  Specifies whether the domain name is included with the host name when the Name Service selection is placed first in the Model Naming Order list. For example, if you select Yes here, the model's icon would be created with a fully qualified name such as myhost.ca.com. If you select No here, the model's icon would be created without a fully qualified name such as myhost. This only applies when you use the device name returned from the operating system.
  Default: Yes
- **Model Naming Order**
  Specifies the order of the list of sources used by DX NetOps Spectrum to create model names for new models. If the first source at the top of the list is not available for a device, DX NetOps Spectrum attempts to use the next source in the list. The default order is as follows, with the top source being the first in priority:
  – SysName
  – IP Address
  – Name Service

  After changing the model naming order, click 'Reevaluate All Model Names' to have DX NetOps Spectrum run through all the models in the database and rename each one using the new model naming order.
  The following additional scenarios will trigger the device model name to be reevaluated using the current model name selection. It will not reevaluate based on a new model name selection:
  – If the IP address of the device changes and the model naming is based on IP Address or Name Service
  – If the Reconfiguration, Reevaluate Model Name(s) action is manually applied
  – If the Reconfiguration, Reconfigure Model action is manually applied

NOTE
If you do not want a specific device model name to be changed, set the value of the model's LOCK_MODEL_NAME (0x12a52) attribute to TRUE. This attribute locks the model name value so that it will not be changed.

- **Use Loopback**
  If Use Loopback is set to Yes, the SpectroSERVER will use the loopback interface as a primary agent address.
  Default: No
- **Loopback if Description**
  Enter a string in this field to identify a preferred loopback interface for DX NetOps Spectrum to use when modeling the device. DX NetOps Spectrum compares the string entered with the if_descr entries in the device IFTABLE for loopback interfaces only. If a match is found, DX NetOps Spectrum uses that loopback interface when it models the device. If there is no match, or no value is specified, DX NetOps Spectrum chooses the loopback interface on the device with the lowest if_index value.
- **Update Event Configuration**
  Updates the SpectroSERVER with current alert and event mappings.

Alarm Information Subview

The Alarm Information subview provides the number of each type of generated alarm.

- **Active Alarms**
  Displays currently outstanding alarms by severity.
- **Total Active Alarms**
  Displays the sum of the outstanding alarms.
- **Total Alarms**
  Displays the break-down of the different types of alarms generated since the last server restart.

  NOTE
  Blue alarms that are caused by the creation of location or organization models are never cleared.
- **Total Alarms Generated**
  Displays the total number of alarms generated since the last server restart.

Event Log Information Subview

The Event Log Information subview provides information related to the event logs. This subview contains the following settings:

- **Events Generated**
  Indicates the total number of events generated since the last server restart.
- **Locally Stored Events**
  Indicates the number of event records currently held in the database. This field will read "0" unless the Archive Manager is shut down. This will serve as backup storage area for database records until the Archive Manager is restarted.
- **Events Purged**
  Indicates the number of event records written to the archive since the last server restart.
- **Max Log Size**
  Indicates the maximum number of event records held in the database. When this number is reached, records will be deleted.

Statistics Log Information Subview

The Statistics Log Information subview provides information related to the statistics logs. This subview contains the following settings:

- **Records Generated**
  Indicates the total number of statistic records generated since the last server restart.
- **Locally Stored Records**
  Indicates the number of statistic records currently held in the database. This field will read "0" unless the Archive Manager is shut down. This will serve as a backup storage area for database records until the Archive Manager is restarted.
- **Records Purged**
  Indicates the number of statistic records written to the archive since the last server restart.
- **Max Log Size**
  Indicates the maximum number of statistic records held in the database. When this number is reached records will be deleted.

Thread Information Subview

The Thread Information subview provides information about the configuration and usage of threads. Comparing the In Use and Available columns for polling, logging, notification, and timer threads can help in determining if SpectroSERVER is running out of thread resources.

Trap Management Subview

- **Unmanaged Trap Handling**
  Specifies whether DX NetOps Spectrum processes “unmanaged” traps. Unmanaged traps are traps that come from devices which were not modeled in DX NetOps Spectrum. By default, the SpectroSERVER creates event records for any “unmanaged” traps it receives As long as this setting is enabled, SpectroSERVER processes these unmanaged traps just as it processes traps from modeled devices; that is, until a trap “storm” occurs (as defined by the Trap Storm Rate and Trap Storm Length attributes).
  The processing of unmanaged traps not only lets the network administrator know about unmodeled devices that may need to be modeled, but also allows monitoring of overall trap traffic. And it provides troubleshooting capabilities when traps are not mapped correctly. However, unmanaged trap handling can place a significant performance burden on the event logging and the Archive Manager. Depending on your priorities, you can use this setting to disable unmanaged trap handling entirely, or you can leave it enabled but limit it through the trap storm rate and length settings. Remember though that these settings also govern trap processing for modeled devices as well.

  > **NOTE**
  > Currently, only VNM models and EventAdmin models (created by users of the Southbound Gateway Toolkit) offer views that let you adjust these settings. For most device models, however, you can use the Attributes tab to create a custom view where you can adjust the default trap storm rate and length settings for that model. For more information about trap storm detection, see How Trap Storm Detection Works.

  Default: Enabled
- **Enable Trap Director**
  Lets you enable Trap Director when you want a given SpectroSERVER to forward incoming traps to models on remote landscapes in a distributed SpectroSERVER environment.
  Default: Disabled
- **Remote Forwarding Cache Age Out (minutes)**
  Lets you configure the Remote Forwarding Cache age out time (in **minutes)**
  Default: 180 minutes

How Trap Storm Detection Works

The SpectroSERVER can block the processing of traps that are coming from managed and unmanaged devices when a threshold is reached. Excessive traps that are coming at a high rate can take down your SpectroSERVER and Archive Manager. You can enable the trap storm detection at your SpectroSERVER or at the level of a modeled

device. When devices that are modeled in DX NetOps Spectrum send more than 20 traps per second, you must adjust traps_per_sec_storm_threshold so that trap storm detection does not limit the ability to receive traps.

You can enable trap storm detection at any level by configuring the following two attributes. These attributes are available under the Attributes in the Component detail pane for the selected VNM model or for a selected device model:

- **traps_per_sec_storm_threshold**
  Defines the rate at which traps are received per second from a managed or unmanaged device. When this rate is sustained for the amount of time that is specified by the TrapStormLength, the SpectroSERVER stops the processing of traps from that unmanaged or managed device.
  Default: 20 traps per second
- **TrapStormLength**
  Defines the time in seconds for which the traps_per_sec_storm_threshold value is sustained. SpectroSERVER considers it a trap storm and disables the processing of traps from that unmanaged or managed device.
  Default: 5 seconds

When traps received from any device reach the configured thresholds, the SpectroSERVER identifies this rate as a trap storm. The SpectroSERVER stops handling traps from that device and traps from other devices are not blocked. SpectroSERVER trap storm detection logic is based on each IP address of an unmanaged or a managed device (trap source) that sends traps to SpectroSERVER. As a result, you can configure each device to send traps to the SpectroSERVER at the appropriate rate.

> **NOTE**
> SpectroSERVER does not stop the processing of unmanaged traps when the overall trap storm rate from all the unmanaged devices exceeds the single trap storm threshold rate of an unmanaged device. As a result, you can configure each unmanaged device to send traps to the SpectroSERVER at the appropriate rate.

AutoDiscovery Control Subview

The attributes available in the AutoDiscovery Control subview affect actions that occur during Discovery and Modeling sessions. If you have a DSS environment, you must make any changes in these settings to all your SpectroSERVERs.

These parameters are applied when you are using the Discover LANs functionality available in a device model's Redundancy and Model Reconfiguration Options view, the Discover Connections functionality available from the right-click menu for a container model (LAN, Network, and so on), or the Auto Connects functionality used to resolve port connections when you manually draw a connection between two models. These parameters are also applied when you use the Discover Connections functionality with the Model by IP or New Model commands.

> **NOTE**
> Each of these parameters is also available when you are selecting modeling options for Discovery. Parameters set in the AutoDiscovery modeling options override the default values for that AutoDiscovery.

Modeling and Protocol Options Subview

The modeling and protocol attributes affect how DX NetOps Spectrum discovers and models elements on a network using the following functionality:

- Discovering and modeling LAN functionality available when reconfiguring a device model.
- Discovering connections functionality for a container model (LAN, Network, and others).
- Auto Connects functionality used to resolve port connections when you manually create a connection between two models.
- Discover Connections functionality when creating a new model.
- **Create WA_Link Models**
  Creates a WA_Link model between the interfaces of two routers linked by a wide area connection. This occurs during layer 3 mapping. If this option is not selected, the two linked interfaces are directly connected without the WA_Link model. See Wide Area Link Monitoring for information about Wide Area Link models and how they are used.

Default: Yes

- **Create LANs (IP subnets)**
  Specifies whether DX NetOps Spectrum uses a LAN container to represent an IP Subnet. Discovery creates the LAN container during the Layer 3 mapping process for any router interface that routes to a local LAN.
- **Create Physical Addresses**
  When this option is enabled, a physical address model is created for any MAC address that is not associated with any modeled device but was heard by a switch. The layer 2 mapper attempts to find a connection for each address found. If a connection is found, a Fanout is created and the physical address is associated to it through Connects_To. If no connection is found the model is placed in Lost and Found. This option is not recommended.
- **Create 802.3 Fanout**
  If this parameter is set to Yes and if DX NetOps Spectrum cannot make an accurate connection among three or more interfaces, a Fanout model named “802.3_Segment” will be created and these interfaces will be connected to the Fanout model. If this parameter is set to No, a Fanout model will not be created for the interfaces that have unclear connection information, and therefore these interfaces will not be mapped. However, if there is a data relay device’s interface among these interfaces, and all other interfaces are for end node devices, a Fanout model with name “Rpt_Segment” will be created.

Note: If you have 50 or more connections to a single Fanout model, consider changing this model to a Shared Media Link. The Shared Media Links must be modeled manually. These models can provide more control over fault management behavior when multiple connections are monitored. Unlike a Fanout model, Shared Media Links provide configurable thresholds for handling downstream connections that report problems. For example, a Fanout model reports a problem only when *all* downstream connections are down. However, a Shared Media Link can report the problem sooner, as when 60 percent of the downstream connections are down.

- **IP Address Tables**
  Discovery disables Layer 3 mapping and maps only the Layer 2 connections, when this option is disabled. In addition, when this option is disabled, Discovery automatically disables the IP Route Tables option, the Create WA_Link Models option, and the Create LANs (IP subnets) option.
  Default: Yes
- **IP Route Tables**
  Specifies whether DX NetOps Spectrum will use the IP Address Table to map routers. This option is set to No by default because these tables can be very large and very time-consuming for DX NetOps Spectrum to read. When this option is enabled, DX NetOps Spectrum will not be able to map unnumbered IP interfaces (0.0.0.0).
- **Source Address Tables**
  If this is set to Yes, DX NetOps Spectrum will use the device’s Source Address table when discovering connectivity information about this device.
- **Spanning Tree Tables**
  If this is set to Yes, DX NetOps Spectrum will use the device’s Spanning Tree table when discovering connectivity information about this device.
- **Discovery Protocol Tables**
  Set the Discovery Protocol Tables attribute to Yes to allow DX NetOps Spectrum to map device connectivity using discovery protocol MIB information. Currently, the following discovery protocols are supported:
  – Nortel Discovery Protocol
  – Cisco Discovery Protocol
  – Extreme Discovery Protocol
  – Cabletron Discovery Protocol
  – Alcatel Discovery Protocol
  – Foundry Discovery Protocol
  – Link Layer Discovery Protocol
- **Traffic Resolution**

If the Traffic Resolution parameter is set to Yes, DX NetOps Spectrum will use network traffic data (ifInOctet and ifOutOctet statistics) to determine connections between interfaces, and in many cases eliminate the need for a Fanout model.

- **ARP Tables**
  When enabled, DX NetOps Spectrum uses the ARP table to determine pingable MAC addresses for the connectivity mapping.
- **ATM Protocols**
  If the ATM Protocols parameter is set to Yes, the ATM Discovery runs against all ATM switches in the SpectroSERVER database.
  Default: No
- **SNMP Community Strings**
  Create, order, and delete community strings and profiles for SNMP v1, v2c, and v3, which are used, in order, when DX NetOps Spectrum attempts to access and model devices that were discovered using SNMP and for which no device community string was provided.
- **SNMP Ports**
  The SNMP Ports section lets you create, order, and delete the list of ports to use when accessing and modeling devices. To add port numbers to this list, click Add under the SNMP Ports field, enter the port number and click OK.
- **IP Exclusion List**
  A list of IP addresses or IP address ranges that will be ignored and which will not be modeled when devices are discovered.

Trap Based Continuous Discovery Subview

Use the Trap Based Continuous Discovery subview to configure DX NetOps Spectrum to automatically create a device model when it receives an SNMP or syslog trap from a device not already modeled. When the SpectroSERVER receives an unmanaged trap, it asserts an event on the VNM model indicating that an unmanaged trap was received.

All models created using Trap Based Continuous Discovery are placed in the New Device Container. DX NetOps Spectrum places new models created by a scheduled continuous discovery or by an unmanaged trap into this container.

- **Unmanaged Trap Discovery**
  Set the Unmanaged Trap Discovery attribute to Yes to discover and model the source of an unmanaged trap using the IP address sent with the trap. This includes both SNMP and syslog traps from devices as well as Agent Log file matching traps. See SpectroSERVER Control Subview for information about how to enable unmanaged trap handling on the VNM.
- **New Devices In Maintenance**
  Set the New Devices In Maintenance attribute to Yes to have new device models created based on an unmanaged trap put into maintenance mode when they are discovered.
- **Create Pingables**
  Set the Create Pingables attribute to Yes to have DX NetOps Spectrum model devices that cannot be modeled using SNMP as type ‘Pingable,’ if the devices respond to a ping (ICMP) echo request.
- **Discover Connections**
  If the Discover Connections attribute is set to Yes, DX NetOps Spectrum attempts to discover and model the connections for devices discovered by Trap-based Continuous Discovery.

Debug Options Subview

The Debug Options subview lets you turn on the AutoDiscovery debugging functionality using the following settings:

- **Debug AutoDiscovery**
  Set the Debug AutoDiscovery attribute to ‘On’ to have DX NetOps Spectrum create a debug output file containing data on the status of the device modeling and mapping process for each Discovery session. These files are available at *<$SPECROOT>/SS/ADiscDebug_<timestamp>*. The Debug AutoDiscovery option is useful when the discovery

modeling or mapping process is hanging or when there are connectivity mapping issues. In these cases, the output file indicates where and on which devices any difficulties were encountered.

NOTE
In addition, you can debug a particular device's connectivity mapping process. To do this, set the Debug AutoDiscovery option to On.

When Discovery's modeling process is running, DX NetOps Spectrum prints out all connection information. This information includes the data collected from bridge tables, Proprietary Discovery Protocols, Spanning Tree tables, potential connections, errors encountered, and any additional, pertinent information related to the mapped devices.

- **Abort Discovery**
  The Abort Discovery button lets you stop and cancel a currently running AutoDiscovery.

Fault Isolation Subview

The Fault Isolation subview lets you configure various aspects of the DX NetOps Spectrum fault isolation functionality. For more information about this view, see Fault Isolation Settings.

Live Pipes Subview

Live Pipes functionality lets you enable port status monitoring for individual links and view link status. In DX NetOps Spectrum, a *link* is a connection between two devices that DX NetOps Spectrum has resolved to the port level. For more information about Live Pipes and network fault management, see Live Pipes and Fault Management.

The Live Pipes attribute must be set to 'Enabled' on the VNM to enable Live Pipes functionality on the VNM.

If you have administrator privileges, you can set other attributes in this view: Alarm Linked Ports, Suppress Linked Port Alarms, and Port Always Down Alarm Suppression.

Live Pipes and Global Collections in DSS Environments

In a DSS environment, the Live Pipes attribute must be set to the same value on all VNMs so that the Live Pipes functionality provides accurate link connection information in Global Collections. If Live Pipes is set to different values on VNMs in a DSS setup, the Live Pipes information in Global Collections will be unpredictable.

Alarm Management Subview

The Alarm Management subview lets you control some aspects of alarm management.

The AlarmMgmt model, which governs the Alarm Management subview, is a SpectroSERVER application. The AlarmMgmt model inherits the security string of the VNM model only if you have not independently changed the security string of the AlarmMgmt model.

For example, the security strings for the VNM and AlarmMgmt models are initially empty. You change the AlarmMgmt model security string to "Jack" and later, you change the security string for the VNM model to "Jill." The AlarmMgmt mode security string is not changed to "Jill."

AlarmMgmt model attributes are not distributed. Bring up the Alarm Management subview for each SpectroSERVER whose alarm management attribute values you want to change. Changing an attribute on one SpectroSERVER does not apply to any other SpectroSERVER.

WARNING
Displaying Initial and Suppressed alarms is not recommended in OneClick. These alarms can generate a significant volume of network traffic. DX NetOps Spectrum generates initial and suppressed alarms if the Disable Initial Alarms and Disable Suppressed Alarms settings for the Virtual Network Machine (VNM) managing your network are set to Yes.

The Alarm Management subview contains the following attribute settings:

- **Generate Alarm Events**
  Enables the generation of alarm change events; DX NetOps Spectrum creates events (viewable in the Events tab) for alarm changes based on alarm creation, updating, and clearing events.

  NOTE
  If the Generate Alarm Events option is disabled, you do not see Alarm History in the Alarms view.

  Default: Yes
- **Add Events to Alarms**
  Controls whether alarm change events are added to each alarm. If disabled, alarm change events are not displayed under the Events tab of the Alarm view.
  Default: No
- **Age Out Residual Alarms Only**
  Specifies whether only residual old alarms are cleared. Residual alarms are alarms that existed before SpectroSERVER restart and have not been reverified. If enabled, DX NetOps Spectrum clears only residual alarms that are based on the Alarm Age Out timer setting.
  Default: Yes
- **Alarm Age-Out Time (hours)**
  Defines how long an alarm can exist in DX NetOps Spectrum. Once an alarm has existed for the number of hours that you specify by this attribute, it is a candidate for automatic removal. To disable this functionality, set this attribute to zero (0).
  Every hour, DX NetOps Spectrum checks the status of all alarms in the landscape and uses this option to determine whether alarms are cleared. Therefore, an alarm is not removed at the precise moment when its existence time has exceeded the time-out. An alarm can be, at most, an hour “overdue.”
  You cannot age out non-user clearable alarms. The system functionality that generates such alarms, clears them. Maintenance Mode, Device Has Stopped Responding, and Management Agent Lost are the non-user clearable alarms.

  NOTE
  An aged out alarm which is cleared displays the "System.Alarm_AgeOut" value in its corresponding "Cleared By" column under "Cleared Alarms History" tab. The corresponding cleared event also displays this value in its "Cleared By" column under Events tab.
- **Disable Initial Alarms**
  Specifies whether to generate an alarm when the condition of a model changes to Initial. Because these changes in the condition of a model can cause a flood of alarms, disabling this option can improve system performance.
  Default: Yes

  NOTE
  If Initial, Suppressed, or the Maintenance alarms are disabled and later enabled, these alarms are not displayed in the Alarm view for existing models. Only the alarms that are generated after this option is enabled appear in the view.
- **Disable Suppressed Alarms**
  Specifies whether to generate an alarm when the condition of a model changes to Suppressed. Because these changes in the condition of a model can cause a flood of alarms, disabling this option can improve system performance.
  Default: Yes
- **Disable Maintenance Alarms**
  Specifies whether to generate an alarm when the condition of a model changes to Maintenance. Because these changes in the condition of a model can cause a flood of alarms, disabling this option can improve system performance.

  NOTE
  For more information about putting devices in Maintenance mode, see the Using OneClick section.

Default: No

- **Auto UnAcknowledge On New Occurrence**
  Specifies whether to unacknowledge the new occurrence of an alarm.
  Default: No

BGP Manager Subview

The BGP Manager subview lets you globally configure BGP peer session monitoring.

The BGP Manager subview contains the following attribute settings:

- **BGP Peer Session Monitoring**
  Monitors the status of the peer session on the BGP port at the polling interval of the port model's Polling_Interval Attribute value if this setting is enabled and the live pipe on the BGP peer session port is turned on. If you disable this option, an event of type 0x220018 is generated on the BGP downed port models to clear the BGP alarm.
  Default: Disabled
- **BGP Peer Session Discovery Interval (minutes)**
  Indicates the interval for BGP peer session Discovery. If BGP Peer Session Monitoring is enabled, BGP Peer Session Discovery initially runs on each BGP device at SpectroSERVER startup and when a new BGP device is modeled. After, BGP Peer Session Discovery runs according to the interval you set.
  Default: 24 hours

Network Configuration Manager Subview

The Network Configuration Manager subview provides information about Network Configuration Manager.

This subview contains the following setting:

- **Export Directory**
  Specifies the local directory to which you want to export configuration text files. If you want to export configuration text files to a network share, you must specify the UNC path to the directory. For example, \\Shared_Server\Export \ExportFiles.

TFTP Configuration Subview

The TFTP Configuration subview provides information about the Trivial FIle Transfer Protocol (TFTP). TFTP transfers configuration files.

This subview contains the following settings:

- **Default TFTP Directory**
  Specifies the TFTP server path.
- **TFTP Transfer Timeout (sec)**
  Specifies the maximum time (in seconds) for a data transfer to complete.
  Default: 50 seconds, which means the data must be completely transferred within 50 seconds.

  NOTE
  For more information about the TFTP server, see the Network Configuration Managersection.

FTP Configuration Subview

The FTP Configuration subview provides information about the File Transfer Protocol (FTP).

This subview contains the following settings:

- **FTP Username**

Specifies the FTP server username.

- **FTP Password**
  Specifies the FTP server password.
- **Default FTP Directory**
  Specifies the FTP server path.

> **NOTE**
> For more information about the FTP server, see the Network Configuration Manager section.

Thresholds And Watches Subview

You can create, configure, and administer watches in OneClick. View and configure watches from a table in the Thresholds And Watches subview.

> **NOTE**
> You can access the Thresholds and Watches subview from the Information tab for a model.

The Watches table displays information for each watch defined on that model. The Watch Status column displays the watch condition with color codes as follows:

- **Gray**
  Indicates that the watch is inactive. The watch is not currently running because it has not been activated.
- **Blue**
  Indicates the initial state of the watch. The watch is activated but has yet to run for the first time.
- **Green**
  Indicates that the watch is active and running without any violation.
- **Yellow**
  Indicates that the watch threshold is violated.
- **Red**
  Indicates that the watch failed to evaluate. The text explains the reason.

The toolbar buttons let you do the following:

- Activate
- Deactivate
- Create
- Edit
- Copy
- Delete
- Display watch information
- Print watch information
- Export the Watches table

Host Security Information Subview

When a client application connects to a SpectroSERVER, DX NetOps Spectrum reads the .hostrc file to obtain a list of valid hosts. If a host name from the .hostrc file does not resolve to a network address, you will receive a “Permission Denied” error message. In addition, an event and an alarm (Event00010e01, Prob00010e01) will be generated on the VNM indicating that there are unresolved host names.

To help you find the cause of this problem, the Host Security Information subview displays a list of resolved and unresolved host names.

Modeling Gateway Subview

You can view information about recent imports in a table in the Modeling Gateway subview.

The Modeling Gateway table displays information about recent imports. The number of import files listed is controlled by the Max Records field. The default value for the Max Records field is 30.

> **NOTE**
> For more information about the Modeling Gateway table, see the Modeling Gateway Toolkitsection.

IP Services Subview

The IP Service subview provides information about VPN Manager and VPLS Manager. Further options are available depending upon the products you have installed.

Logical Connection Import Subview

The Logical Connection Import subview lets you create logical connections between virtual link models by importing a comma-delimited, ASCII file (text file or XML file) that defines the connections. You can define connections that include two ATM models or an ATM model and a Frame Relay model. Click the Import button to import a file.

> **NOTE**
> For more information about logical connections between virtual link models, see the ATM Circuit Manager section.

Shared IP Detection and Alarming

The following settings control when DX NetOps Spectrum generates alarms for shared IP addresses.

- **Shared IP Alarming**
  Specifies whether shared IP alarming is enabled.
  Default: Disabled

  > **NOTE**
  > Shared IP alarms will be cleared when you set the Shared IP Alarming attribute to Disabled.
- **Currently Shared IP Addresses**
  Specifies which IP addresses are currently considered “shared” in DX NetOps Spectrum.

  > **NOTE**
  > The IP addresses in the loopback subnet are displayed as shared addresses in the ‘Currently Shared IP Addresses’ list, however, no alarms will be triggered based on these addresses to help prevent multiple unnecessary alarms for a known and desired configuration.
- **Allowed Shared IP Addresses**
  Specifies which IP addresses can be shared in DX NetOps Spectrum. Click Add or Remove to modify this list as needed.

  > **NOTE**
  > You can modify a device model's NETWORK_ADDRESS (0x12d7f) attribute and PrimaryAddress (0x12d80) attribute if the device model's IP address is included in the Allowed Shared IP Addresses list on the VNM model.

Shared IP Alarms and Events

When DX NetOps Spectrum detects that two or more devices share one or more IP addresses, and you have configured DX NetOps Spectrum to generate alarms in this case, you will see an orange alarm on all device models that share the IP address or addresses. The event generated on each device will contain a list of all device models involved as well as a list of all shared IPs. The event will look similar to the following:

```
Device {X} of type {Y} has the following shared IP addresses:
<list of shared IPs and devices>
```

Since the detection of shared IP addresses is dependent on DX NetOps Spectrum device models, each time a new device model is created or destroyed, a new event containing updated data may need to be generated on the devices that have shared IPs.

No Unique IP Alarms and Events

If a device is found to contain no unique IP addresses, then a red alarm is asserted on it to notify you of this condition because no reliable communication or management may be made with that device. The event will look similar to the following:

```
Device {X} of type {Y} has no globally unique IP addresses.  Each of the following addresses is shared with
 another device:
<list of shared IPs and devices>
```

Network Address Is Shared

If you manually create a device using a shared IP address as the Network_Address you receive an event such as the following:

```
Device {X} of type {Y} has its Network Address set to an IP that is currently shared by multiple devices.  No
 reliable communication or management may be made with this device.  The shared IP {shared IP} is shared by
 the following other devices:
<list of other devices>
```

Troubleshooting Tip:

In case you cannot update network_address on switch model due to "The update to attribute Network_Address was disallowed" error, see the KB article.

Configuring Allowed/Non-Alarming Shared IP Addresses

You can configure DX NetOps Spectrum with a list of IP addresses, IP address ranges, or subnets for which sharing between multiple devices is allowed. Populate the Allowed Shared IP Addresses list with the addresses to share. The IP addresses on this list do not generate alarms.

You can use OneClick to add or remove IP addresses, IP address ranges, or subnets from this list. Shared alarms are cleared when you add an IP address to the list. Adding an IP address causes the associated device to have no more shared IP addresses that generate alarms.

Mtype Based IfType Filtering Subview

From 10.3, you can filter interfaces of a device model which you do not want to model and monitor in DX NetOps Spectrum. In OneClick, The 'Mtype Based IfType Filtering Subview' allows you to filter interfaces of a device model.

You can access the 'Mtype Based IfType Filtering Subview' in the Information tab for a selected VNM model in the OneClick.

Mtype Iftype Map

The Mtype Iftype Map settings allow you to map the device model of the interfaces, which you want to filter and do not want to model.

- **Mtype Value**Specify the model type (MType) of the device model.For example: Rtr_Cisco Mtype value is 0x21000c
- **IfType Value**
  Specify the interfaces type (Iftype) values, which you do not want to model. The values must be comma (,) separated for multiple Iftype values.
  For example: The Iftype values for Ethernet interface (6) and Prop Virtual Interface (53) values are mentioned as 6,53 (refer to the screenshot)

  NOTE
  If these settings are done after the discovery of a device model, you must reconfigure the models to apply these settings.

CreateWALinkForPropVirtualInterface Attribute

The following attribute has been added to the VNM model type:

```
CreateWALinkForPropVirtualInterface
```

Type: Boolean

Default: False

Attribute ID: 0x1321b

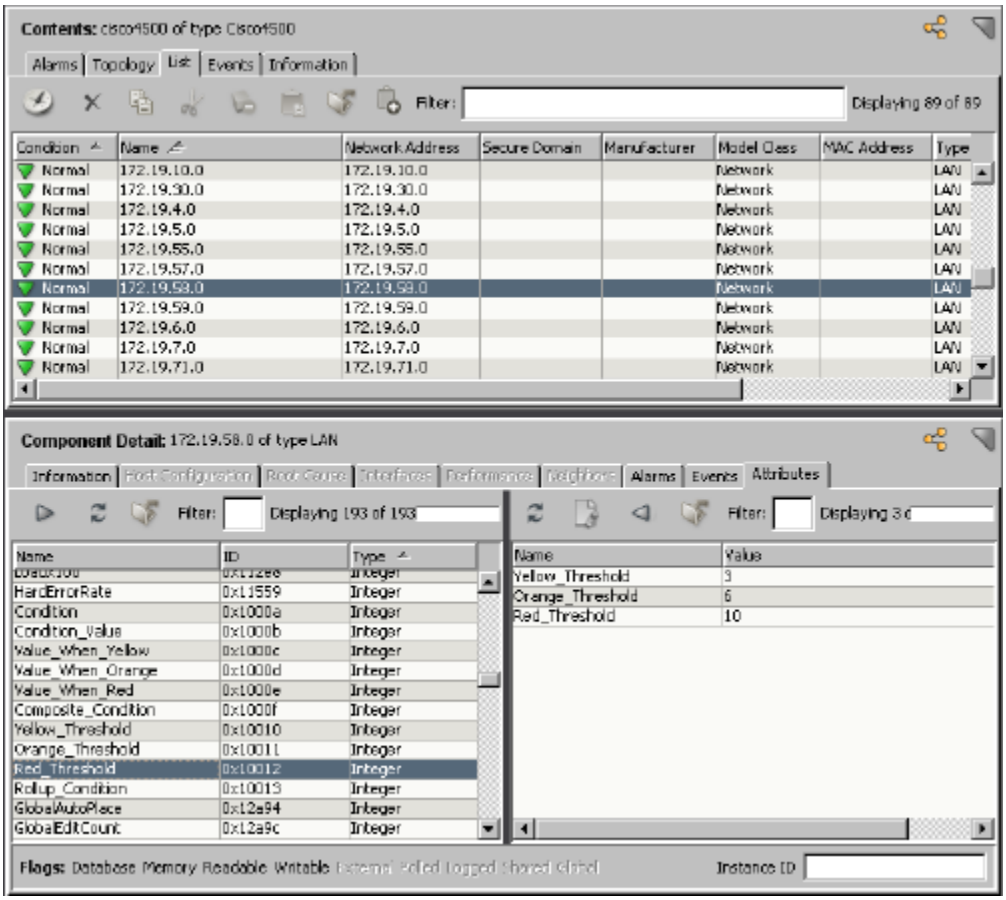
You do not have a separate view for this attribute. Therefore, to view this attribute, navigate to the Component Details window of the VNM model type and click the Attributes tab.

You can set the attribute value to True to create a WA_Link connection between proprietary virtual interfaces. Previously discovered devices and connections are not affected by changing the value of this attribute. To view the changes, run the discovery again.

Attributes Tab

The Attributes tab in the Component Detail panel provides access to all of a selected model's attributes. From the Attributes tab you can select one or more attributes related to the specific model or model type and review details, poll values, export values, and edit each attribute as needed, depending on your access rights. You can also use the Attributes tab to cycle through models, quickly checking the same attribute for each one, to review attribute flags by scanning the Flags information located at the bottom of the Attributes view, or to review values for list attributes individually or all at once, depending on your preference.

The following graphic shows an example of the Attributes tab. The attributes being shown in the Attributes tab belong to the model selected in the List tab:



Access Attributes from the Attributes Tab

You can access attributes from the Attributes tab and personalize your view of them as required.

Follow these steps:

1. Select the model whose attributes you want to view or edit.
2. Click the Attributes tab in the Component Detail panel.
   A list of attributes appears in the left half of a split panel.
3. (Optional) Enter text in the Filter field at the top of the list to filter it.
4. Double-click each attribute that you want to display in a view.
   Each attribute that you double-click appears in the right-side of the panel along with its value.
5. (Optional) Click a column header to sort the attributes as needed.
6. (Optional) Select an attribute in the right-side of the panel and click the left arrow button at the top of the panel to move the selected attribute back to the left-side of the panel when you no longer want to review it.

Edit Attributes in the Attributes Tab

You can edit attributes for a single model from the Attributes tab.

Follow these steps:

1. Select the model whose attributes you want to modify.
2. Click the Attributes tab in the Component Detail panel.
   The model's available attributes appear in the left side of the panel.

3. Double-click each attribute that you want to edit.
   Each selected attribute and its value appear in the right side of the panel.
4. Double-click an attribute in the right side of the panel.
   If the selected attribute can be modified, the Edit dialog opens.
5. Clear the 'No Change' check box in the Edit dialog to enable editing.
6. Modify the attribute as needed, and click OK.
   The Attribute Edit Results dialog opens, indicating whether the attribute edit was successful.

   NOTE
   Click Undo in the Attribute Edit Results dialog to revert to the original attribute settings.
7. Click Close.
   The attributes have been edited and the Attribute Edit Results dialog closes.
8. (Optional) Click Export to send the selected attributes and their values to a CSV file, a text file, or web page.

Edit Multiple Attributes at Once in the Attributes Tab

You can edit multiple attributes simultaneously in the Attributes tab.

Follow these steps:

1. Select the model whose attribute values you want to modify.
2. Click the Attributes tab in the Component Detail panel.
   The available attributes for this model appear in the left side of the panel.
3. Double-click each attribute that you want to edit.
   Each selected attribute and its value appear in the right side of the panel.
4. Click the Edit button in the toolbar of the right panel.
   The Edit dialog lists the attribute values that are available for editing from your selected list.
5. Clear the 'No Change' check box in the Edit dialog for each attribute, modify each attribute as required, and click OK.
   The Attribute Edit Results dialog opens, indicating whether each edit operation was successful.

   NOTE
   Click Undo in the Attribute Edit Results dialog to revert to the original attribute settings.
6. Click Close.
   The attributes have been modified. The Attribute Edit Results dialog closes.
7. (Optional) Click Export to send the selected attributes and their values to a CSV file, a text file, or web page.

Examine the Same Attribute on Multiple Models

From the Attributes tab, while you are in either the List tab or the Topology tab, you can select an attribute or multiple attributes and quickly view the attribute value on a number of models.

Use the List tab to examine the values of the same attributes for multiple models.

Follow these steps:

1. Select the first model for which you want to modify attribute values from the List tab in the Contents panel.
2. Click the Attributes tab in the Component Detail panel.
   The model's available attributes appear in the left side of the panel.
3. Double-click each attribute whose values you want to review.
   Each selected attribute and its value appear in the right-side of the panel.
4. Press the down or up arrow on your keyboard to review the same attributes for a different model.
   The Attributes view refreshes to display the values for the same attributes on the selected model.

   NOTE
   If you move to a different container, these attributes remain selected. The attributes stay in the Attributes tab until you exit OneClick.

View List Attribute Values

You can use the Attributes tab to review the values of a model's list attributes.

To view the value for a particular instance of a list attribute

1. Select the model for which you want to view attribute values.
2. Click the Attributes tab in the Component Detail panel.
   The model's available attributes appear in the left side of the panel.
3. Double-click the list attribute for which you want to review values.
   The list attribute and the value of the first instance in the list appear in the right-side of the panel.
4. Do *one* of the following to review the list attribute's values:
   – In the Instance ID field at the bottom of the Attributes tab, type the OID of the particular value you want to view, and press Enter.

     NOTE
     The Instance ID applies to the list attributes in the right-side panel. If you place a new list attribute in the right-side panel, the value displayed in the Value column corresponds to the OID specified in the Instance ID field.

   – Click the table link in the Value column to open a dialog which displays the instances and values for the list attribute.

     NOTE
     You can perform a number of actions from this table including the following: refresh values, print values, and export values.

Update Attribute Values

The values of selected attributes are not dynamically updated. They reflect the value returned as of the SpectroSERVER poll prior to their selection.

To update attribute values, click Refresh in the toolbar in the right panel of the Attributes tab.

The values of all the attributes you originally selected from the left panel refresh to display any new values.

OneClick Attribute Editor

The Attribute Editor is an advanced DX NetOps Spectrum utility used to configure management 'policies' that govern how DX NetOps Spectrum manages network devices and their components. It is best suited for performing bulk attribute changes on multiple devices models.

You can change attribute values for one or more selected models in a view. The Attribute Editor dialog groups attributes into categories. You can edit the default settings provided within these categories, or you can define additional attributes to edit within the User Defined category.

Open Attribute Editor

You can open the Attribute Editor in OneClick by right-clicking any model and selecting Tools, Utilities, Attribute Editor.

You can also launch the Attribute Editor from anywhere in OneClick where you can select a model, including the List tab, the Explorer tab, Interfaces tab in Component Details panel, the Locater Results tab, or from the Tools menu.

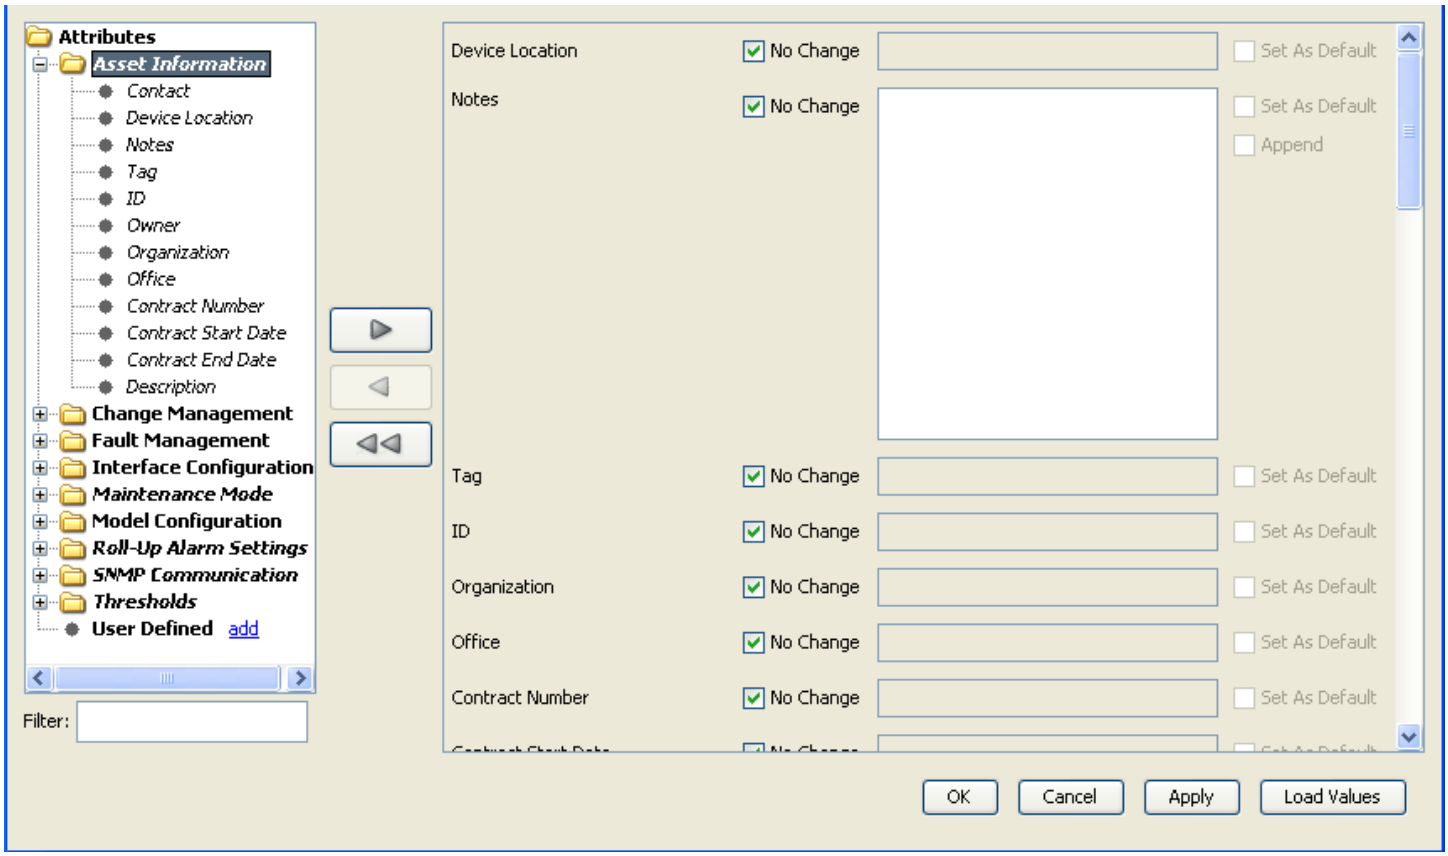
Open Attribute Editor with Device Context

You can open the Attribute Editor within the context of selected models. Select a model or multiple models in the List tab, the Explorer tab, or the Interfaces tab. Then right-click and select Utilities, Attribute Editor. The Attribute Editor opens with the context of the selected models.

Any changes that you make apply to the selected models. If you select Set as Default, the changes are applied to the DX NetOps Spectrum modeling catalog for the selected models.

Attribute Editor Dialog

The Attribute Editor includes a right and left panel. The left panel groups attributes in a tree display. The right panel provides an editing area to view current attribute values and make changes.



Task-Oriented Attribute Groupings

The left panel of the Attribute Editor provides attributes grouped by tasks you perform on devices and by categories of attribute types. The SNMP Communications folder groups attributes related to tuning SNMP communications between the SpectroSERVER and a device.

Filter Attribute Categories

You can type text in the Filter text box to locate attributes in the attribute categories in the Attribute Editor left panel. When you type text in the Filter text box, attribute categories that do not contain an attribute that matches the filter appear as bullets, becoming inaccessible. All attribute categories that contain an attribute that matches the filter appear as folders that you can expand and you can select the subcategories within to move into the right panel for editing.

For example, if you want to find attributes related to alarms, type **alarm** in the Filter text box.

Attribute Edit Panel

To edit attribute values, select the attribute category from the left panel, then click the right facing arrow to place the attributes in the Editor panel. An attribute that has been placed in the Editor panel appears in *italics* in the left panel.

Note: Tooltips are available for some attributes when they appear in the right panel for editing.

The Attribute Editor provides the following options:

- **No Change:** The No Change setting appears to the left of most attribute input fields. When No Change is selected, the input value, if any, is not written when you click Apply or OK. When you make changes to the attribute value by selecting a value or by clicking in the input field, No Change is automatically cleared. Clear No Change or click in the input field to makes the attribute value editable.
- **Set as Default:** This option appears to the right of most attribute input fields in the Editor panel. If you select Set as Default, the value is written to the model types in the DX NetOps Spectrum modeling catalog when you click Apply or OK. All future models that use these model types inherit the new value.

  WARNING
  The changes are made to the modeling catalog. As a result, existing models that use the current default value(s), and any new models that are created in the future inherit these new values. The type of device that they represent is irrelevant. Changing the default value affects existing models that you did not explicitly select, but these changes might not take effect until after a server restart. Existing models that use different value(s) are not changed.

  A model is an instance of a model type. The model type has default values for every attribute. When the model is created, every attribute that is not explicitly set inherits the default that is set on the model type.
  Once you create an instance of that model type, the new model can have its own values for every attribute. By default, it does not have a value for the ifModelNameOption. When you edit the model to change the ifModelNameOption, the model has its own value for that attribute and no longer uses the default that is set in the model type. From that point on, the new model only uses its own value and does not use the default setting of the model type.
  You can also edit the model and enable the option that sets this new value as the default. The new default then affects all of the following:
  – This new model.
  – The model type (which now has a new default for that attribute).
  – All existing models of that model type that lack their own default value. They now use the new default because they still point to the model type value.
  – All new models of that model type. These models also use that model type default value.

  However, models of that model type that existed before the attribute change and had their own value set for this attribute are not changed. They still use their own custom setting.
  For example, assume that you use the Attribute Editor to change Model A to use ifAlias (11f7e). You then change Model B to use ifAlias and enable the Set As Default option. All models that use that model type will then use ifAlias. If you then change Model B and the default value to use ifDesc (1134b), all models *except for* Model A will use that new value. Model A does not use it because it already has its own value for that attribute, set to ifAlias. Models C, D, and E also had their own values set when you changed Model B and designated ifAlias as the default. Therefore, Models C, D, and E are similarly unchanged.
- **Load Attribute Values:** You view the current value for a set of selected attributes when you have launched the Attribute Editor in the context of a specific model. After populating the edit panel, click Load Attribute Values to view the current values for the attributes. If the selected models do not use or have a value for an attribute, no value displays when you click Load Attribute Values.

If you have launched Attribute Editor in the context of multiple model types, they can have different values for the same attribute. If this occurs, the Select Model dialog opens when you click Load Attribute Values. Select the model for which to load attribute values, and click OK.

When you click Apply or OK in the Attribute Editor, DX NetOps Spectrum attempts to write the new attribute values and displays the Attribute Edit Results dialog.

Attribute Edit Results Dialog

The results of attribute value changes appear in the Attribute Edit Results dialog. Each item in the table represents the result of a single attribute written to a model. The Result column indicates whether the write operation succeeded or failed. The Old Value and New Value columns show the original value and the last written value. If the write operation failed or the previous value could not be obtained, the corresponding field will display N/A. If the write operation failed, for example, if the device did not respond, you can select the item in the table and click Retry.

Click the Undo button to undo the selected successful attribute value change in results list if necessary.

User-Defined Attributes

In the Attribute Editor dialog, you can create a list of attributes that display when you expand the User Defined category. After you create this list, you can access the user-defined attributes. You can at any time remove the user defined attributes.

Create User-Defined Attributes

Each OneClick user can create a unique set of user-defined attributes. You can select user-defined attributes using the Attribute Selector dialog.

Follow these steps:

1. In the left panel of the Attribute Editor dialog, next to the User Defined folder, click Add.
   The Attribute Selector dialog opens.
2. If you have more than one model type selected, select the model type whose attributes you want to edit from the left pane of the Attribute Selector dialog.
   The attributes for the selected model type appear in the right pane of the Attribute Selector dialog.
3. Select the attribute to edit from the list, and click OK.

   NOTE
   Use the Filter text box to quickly locate an attribute or model type in the list.

   The attribute that you selected appears in the User Defined category in the Attribute Editor dialog. You can only add attribute at a time to the User Defined category.
4. Repeat this process to select additional user-defined attributes.

   NOTE
   Remove user-defined attributes by clicking the remove link next to the attribute that you want to remove.

Change Attributes in Conjunction with Search

You can use the Attribute Editor feature in conjunction with the Search feature in the Locater tab (Locater Search). By using the Locater Search feature with the Attribute Editor feature you can locate all models meeting certain criteria and attempt to change the attribute values on those matching models.

The following example combines ‘creating and running a new search’ with ‘changing attributes through the Attribute Editor.’ It walks you through adding user-defined attributes and writing changes to the component (that is, SpectroSERVER, devices, interfaces) meeting the search criteria.

NOTE
For more information about using the Search feature in the Locater tab, see the Using OneClick section.

Example Define a Search to Create an Attribute for Editing

This example demonstrates how to create and run a search to locate the GlobalConfig model on the SpectroSERVER. It then shows how to use the Attribute Editor to add the HibernationCommSuccessTries attribute to the User Defined category so that you can update the value as needed.

NOTE
The value for HibernationCommSuccessTries determines the number of successful attempts the SpectroSERVER must make to devices in hibernation mode before the devices can resume normal management communication. By default, the value of this attribute is 3.

To define a search to create a user-defined attribute for edit

1. In the OneClick Locater tab, to create a new search,
   click 
   The Create Search dialog opens.
2. Select 'Model Type Name (0x10000)' from the Attribute drop-down list.
3. Select 'Equal To' from the Comparison Type drop-down list.
4. Type **GlobalConfig** in the Attribute Value field.
5. Click Save As, type a name for the search (for example, 'Hibernation attempts'), and click OK.
6. Click OK in the Create Search dialog.
7. Select the search you just created ('Hibernation attempts') in the Locater tab.
8. To launch the selected search,
   click 
   The Select Landscape to Search dialog opens.
9. Select the landscapes to search and click OK.
   The search results appear in the Results tab.
10. Right-click the GlobalConfig entry and select Utilities, Attribute Editor.
    The Attribute Editor dialog opens.
11. Click the add link in the left panel of the Attribute Editor dialog, next to the User Defined folder.
    The Attribute Selector dialog opens.
12. Click the folder named Other in the left panel of the Attribute Selector dialog.
13. In the Filter text box (below the left panel) type **GlobalConfig** and select the GlobalConfig entry under the 'Other' folder.
14. In the Filter text box under the right panel of the Attribute Selector dialog, type **HibernationCommSuccessTries**.
    The HibernationCommSuccessTries attribute appears in the Attribute for GlobalConfig list in right panel.
15. Double-click the HibernationCommSuccessTries entry in the list to add it to the User Defined category.
16. In the Attribute Editor dialog, edit the user-defined attribute value by selecting it in the left panel and clicking the right arrow button to move its associated attribute fields to the editing panel.
17. In the right panel, edit the attribute values as desired then click Apply to write the changes to the component.
    The Attribute Edit Results dialog opens listing the results of the changes made.

Edit Attributes for Specific Devices or for Model Types

This section provides examples for changing an attribute value for a specific model type, or for a specific set of devices.

Example 1: Edit Interface_Polling_Interval for Cisco Devices Supporting IPsec

Cisco IPSec tunnel interface management is available in DX NetOps Spectrum for Cisco devices that support the IPSec related MIBs. Once modeled, the tunnel models are updated every hour. If your environment requires less or more frequent updates to the tunnel models, use the Attribute Editor to change the polling interval.

The attribute Interface_Polling_Interval defines how frequently DX NetOps Spectrum monitors the MIB associated with the tunnel interface models so that the modeling is up to date. To disable this monitoring, set the Interface_Polling_Interval attribute to 0. To change the frequency at which DX NetOps Spectrum monitors these MIBs, change the value for the attribute to the desired number of seconds between polling cycles.

Edit the Interface_Polling_Interval attribute for Cisco devices.

Follow these steps:

1. Locate the Cisco routers on your network by creating a new Global Collection of Cisco routers that have the Interface_Polling_Interval set to 3600 seconds.
2. Select the Cisco routers whoseInterface_Polling_Int erval value you want to edit from the Global Collection.
3. Right-click and select Utilities, Attribute Editor.
4. Add the Interface_Polling_Interval to the User Defined attributes list, as described in Create User-Defined Attributes.
5. Move the Interface_Polling_Interval attribute into the right panel for editing.
6. Enter the value in seconds of the polling interval.
7. Click OK.
   The Attribute Edit Results dialog displays the results for each device whose attribute value you attempted to change.
8. If the change failed on any of the selected devices, select them and click Retry.
9. Close the Attribute Edit Results dialog, and click OK to close the Attribute Editor.

Example 2: Edit the DeviceTypeDiscEnable Attribute for Specific Devices

The DeviceTypeDiscEnable attribute is used to allow or prevent changes to the device type name value for device models and model types. You can modify the value for this attribute.

To edit DeviceTypeDiscEnable for specific models, you first must add the DeviceTypeDiscEnable attribute to the User Defined category. Once you have done that you can begin to select the devices on which you want to prevent device type name customizations, as described in the following procedure.

Edit DeviceTypeDiscEnable for specific device models.

Follow these steps:

1. Add the DeviceTypeDiscEnable attribute to the User Defined category using the procedure described in using the procedure described in Create User-Defined Attributes.
2. Select the Locater tab in the Navigation panel.
3. Expand the Devices folder and double-click By Model Name.
   The Search dialog opens.
4. Enter the name of the device type model on which you want to prevent device type name customizations; select all applicable landscapes as necessary and click OK.
   The devices using the device type model specified appear in the Lists tab.
5. Select the specific devices on which you want to prevent customizations.
6. Right-click and select Utilities, Attribute Editor to launch the Attribute Editor.
7. Expand the User Defined folder, select DeviceTypeDiscEnable, and click the right arrow to place the attribute in the right-side editing panel.
8. Set the attribute value to No and click Apply.
9. Verify that ‘Set as Default’ is not selected.
   The Attribute Edit Results dialog opens and displays the results of the edit, either successful or unsuccessful. If successful, the DeviceTypeDiscEnable attribute is now set to false, or no, on the devices you selected in Step 5.

Example 3: Edit DeviceTypeDiscEnable for a Model Type

You can set an attribute value and apply it to the model type in the DX NetOps Spectrum modeling catalog and to all device models. Also, all device models created in the future using the model type will use the attribute value that you set in this manner.

Edit DeviceTypeDiscEnable for a model type.

Follow these steps:

1. Add the DeviceTypeDiscEnable attribute to the User Defined category using the procedure described in Create User-Defined Attributes.
2. Create a search using the Locater tab in the Explorer that finds some or all the device models that use the new custom model type.
3. Select one of the device models using the new custom model type in the search results list, right-click it and select Utilities, Attribute Editor.
   The Attribute Editor opens with the context of the select device.
4. In the Attribute Editor, select the DeviceTypeDiscEnable attribute in the User Defined category and move it to the Attribute Editing panel by clicking the right arrow.
5. Set the attribute value to No.
6. Select Set as Default to apply this change to the DX NetOps Spectrum catalog for the model type used by the device model selected in Step 3.
7. Click Apply.
   A warning message appears.
8. Click Yes.
   This action sets the attribute value for all the device models using the model type, and applies it to the model type in the DX NetOps Spectrum modeling catalog and to all device models. All future device models created using this model type will have the DeviceTypeDiscEnable attribute set to No, and the Device Type Attribute cannot be overwritten.

Model Type Reevaluation

In cases where devices have been replaced on your network, IP addresses may be assigned to new devices without your knowledge. Therefore, device models periodically verify that they are modeled using the correct model type. If the model type no longer matches the device identify, an alarm is generated on the model.

By default, this reevaluation of model types occurs every 24 hours. You can change this setting for all models.

Edit the Model Type Reevaluation Interval

You can modify the interval for model type reevaluation. The MTypeVerifyInterval attribute on the VNM model determines the reevaluation interval, which is every 24 hours by default. Set this value to 0 to disable model type reevaluation.

Follow these steps:

1. Select the VNM model and click the Attributes tab in the Component Detail panel.
   The available attributes for the VNM model appear on the left side of the panel.
2. Locate the MTypeVerifyInterval attribute by typing it in the Filter field.
   The MTypeVerifyInterval attribute appears on the left side of the panel.
3. Double-click the MTypeVerifyInterval attribute.
   The MTypeVerifyInterval attribute and its value appear on the right side of the panel.
4. Double-click the MTypeVerifyInterval attribute on the right side of the panel.
   The Edit dialog opens.
5. Clear the ‘No Change’ check box in the Edit dialog and type **0** in the field.
   The attribute value is changed to 0.
   The Attribute Edit Results dialog indicates whether the modification succeeded.
6. Click Close.
   The Attribute Edit Results dialog closes; model type reevaluation has been disabled for all models.

Change Management Attributes

This group of attributes lets DX NetOps Spectrum maintain up-to-date configuration information about modeled devices. The following attributes in this grouping let DX NetOps Spectrum interrogate a device and gather information about its interfaces and connections after a specific event occurs:

- Automatically Reconfigure Interfaces
- Discovery After Reconfigure
- Discover Connections after Link Up Events
- Topologically Relocate Model

See Update Device Interface and Connection Information for more information about these attributes, and about configuring DX NetOps Spectrum to maintain updated device configurations.

The following attributes in this grouping configure DX NetOps Spectrum to have redundant ways of contacting devices:

- Enable Redundancy
- Generate Redundancy Alarms

DX NetOps Spectrum will use multiple IP addresses in a cascading manner to contact devices if a device fails to respond to queries made on its primary address. The devices must have multiple IP addresses configured in their IP tables.

Interface Configuration Attributes

Interface Configuration Attributes

You set the value for a set of model type interface configuration attributes in the Interface Configuration grouping. Some of the attributes available include the following:

- **Admin Status**
  This attribute sets the administrative status for an interface.
- **Create Sub-Interfaces**
  Set this attribute to Yes, and if a device supports RFC1573, DX NetOps Spectrum will model the device's sub-interfaces.
- **Interface Name Primary Suffix**
  DX NetOps Spectrum uses the value of this required attribute to name interfaces for the model or models for the Rename Interface Models action. Choose from a set of available suffixes in the drop-down list when editing this attribute.
- **Interface Name Secondary Suffix**
  DX NetOps Spectrum uses the value of this optional secondary attribute to name interfaces for the model or models for the Rename Interface Models action. It is prefixed by an underscore (_) and follows the value of the primary suffix. This secondary attribute is optional.

Stale Interfaces

DX NetOps Spectrum handles interface definitions that are temporarily removed from their corresponding MIB tables using its Stale Interface functionality. These types of situations can include:

- A module is temporarily removed from a device
- A configured tunnel temporarily goes down on a device

In these situations, it is advantageous for DX NetOps Spectrum to retain the interface modeling information rather than immediately destroying them. This prevents useful model-specific attributes and resolved connections from being lost.

DX NetOps Spectrum determines that an interface model is stale when no corresponding entry exists in the MIB where the interface is defined. Once the stale interface 'ages out' DX NetOps Spectrum removes it from the model. The age out period for an interface is defined by the Stale Interface Age Out attribute (in minutes) on the device model.

An event is generated when DX NetOps Spectrum determines an interface is stale. If the stale interface has resolved connections, a minor alarm is generated on the interface model. If DX NetOps Spectrum determines that the interface is no longer stale before the age out period expires, and prior to a reconfiguration which causes the interface model to be destroyed, an event is generated and any stale interface alarm is cleared.

- **Enable Stale Interface Alarms**
  Set this attribute to Yes to enable DX NetOps Spectrum to generate a minor alarm on an interface model when the interface becomes stale and it has resolved connections. Set this attribute to No if you do not want this condition to generate an alarm.
- **Stale Interface Age Out (min)**
  This attribute specifies the amount of time in minutes that DX NetOps Spectrum waits for the stale interface to 'age out' before removing the model. To disable the stale interface functionality, set this attribute to 0.
  Default: 120

Maintenance Mode Attributes

You can set values for the Maintenance and Hibernation mode attributes in the Attribute Editor's Maintenance Mode folder. You can also set these attribute values and create and apply maintenance mode schedules in the model's Information tab.

> **NOTE**
> For more information about Maintenance and Hibernation modes and managing maintenance mode schedules, see the Using OneClick section.

Rollup Alarm Attributes

Access the DX NetOps Spectrum attributes used to manage rollup alarm settings (conditions) and threshold levels in the Attribute Editor's Roll-Up Alarm Settings folder. You can also view and set these attributes in the Information tab under the General Information subview. You can adjust these attributes for containers modeled on your network and for the DX NetOps Spectrum container model library. The following section lists the attributes, describes how they are used, and defines their default values.

Note: Change threshold levels carefully; you may see an increase in generated alarms if threshold levels are set lower, or a decrease in generated alarms if levels are set higher.

- **Value When Yellow**
  The point value of a Yellow alarm condition existing in a child towards the roll up alarm threshold value for the parent container.
  Default: 1
- **Value When Orange**
  The point weight of an Orange alarm condition existing in a child towards the roll up alarm threshold value for the parent container.
  Default: 3
- **Value When Red**
  The point weight of a Red alarm condition existing in a child towards the roll up alarm threshold value for the parent container.
  Default: 7
- **Yellow Threshold**
  The minimum points needed to trigger a Yellow roll up alarm for a container.

Default: 3

- **Orange Threshold**
  The minimum points needed to trigger an Orange roll up alarm for a container.
  Default: 6
- **Red Threshold**
  The minimum points needed to trigger a Red roll up alarm for a container.
  Default: 10

Model Status and Alarm Conditions

OneClick uses rollup alarm thresholds and model alarm thresholds to determine the status for modeled entities. OneClick displays two types of status for modeled entities, Condition and Rollup Condition. The following section lists the details about what these conditions describe, and what OneClick applies them to.

- **Condition**
  Applies to all models. Reflects the current contact or alarm status of the model itself.
- **Rollup Condition**
  Applies to container models, such as networks, LANs, and WANs. Reflects the composite status of all the other models in the container, which are sometimes referred to as their children.

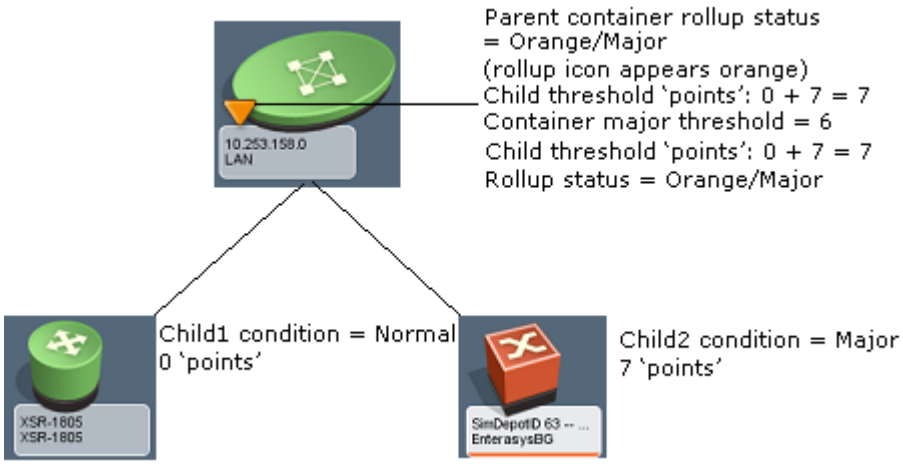
If a modeled device or interface exists in a container, its condition rolls up to the parent container and is reflected in the container's rollup condition. The model status types listed previously rely on threshold values to determine when and how to use the associated color indicators. The rollup condition is displayed using an inverted triangle that appears adjacent to a container icon in the container's Information tab.

Rollup Condition Thresholds

A container model has attributes that define values for alarm conditions that may exist on the children of the container. A container model also has attributes that define when its rollup alarm conditions are triggered. The combined value of all the alarm conditions for a container's children is used to determine the rollup alarm condition for the container.

The following illustration shows a container that has a rollup condition of orange, or major, based on the alarm conditions of its two children. The rollup alarm setting for the container uses the default values listed previously.

- One child has a green or normal condition; this contributes zero points toward the container's rollup condition.
- The other child has a red or critical condition that contributes seven points toward the container's rollup condition (Value When Red = 7).
- The total value of the alarm conditions on the container's children is 7.
- The rollup thresholds for the container use the default values for the Rollup alarm settings listed in this article. The Orange Threshold value = 6, so the container's rollup appears as Orange, indicating a major alarm condition.



NOTE
Configure the Rollup Alarm settings and Fault Management settings of the container model according to your requirement. Otherwise, child alarms do not roll up the container model in the Explorer view.

SNMP Communication Attributes

You can tune overall SNMP communications by changing the values of the attributes in the Attribute Editor's SNMP Communication folder. The following attributes define how DX NetOps Spectrum communicates with a device:

- **SNMP Community String**
  Lets the SpectroSERVER communicate with devices on your network.
- **DCM Timeout (ms)**
  The number of milliseconds the polling agent will wait for a response from the device before timing out.
- **DCM Retry Count**
  Specifies the number of times the SpectroSERVER retries to establish device communication after the DCM timeout value expires.
- **Polling Interval (sec)**
  The number of seconds between polls DX NetOps Spectrum makes to devices.

  NOTE
  Increasing this number results in less SNMP-related traffic on your network and a smaller load on the SpectroSERVER. Decreasing this number for mission critical devices and interfaces lets you see updated information about these devices in OneClick more often. This can improve your ability to see potential issues on the network before they affect network performance. A decreased Polling Interval will result in more SNMP network traffic generated by DX NetOps Spectrum.
- **Poll To Log Ratio**
  The number of polls per log. If it is set to 3, then data is logged every third poll.

Threshold Attributes

The Thresholds grouping contains the DX NetOps Spectrum device and interface threshold settings.

NOTE
For more information about interface threshold parameters, see the Using OneClick section.

Calculating CPU and Memory Utilization

The MIB objects that are read to calculate the source of the CPU and memory utilization can be customized for an individual device model or set as the default for a given model type. This is only necessary if DX NetOps Spectrum is unable to identify a source for CPU and memory utilization, or if you prefer to use a different source.

Do one of the following to customize CPU and memory utilization:

- Modify the order and the types of sources to be tested.
- Modify the source attributes used by the attribute redirection type.

Attribute redirection is the process of using well-known attributes as a pointer, or redirectors, to proprietary attributes. For example, the well-known attribute NRM_CPUUtilAttr (0x12e2d) on the AirespaceSw model type holds the attribute ID of the Airespace proprietary CPU attribute, agentCurrentCPUUtilization (0x4b605ae).

With attribute redirection, it is possible for generic code to reference unique attributes for each device model or model type. Additionally, attribute redirection lets you change the source attributes without having to restart the SpectroSERVER. By default, for most model types, attribute redirection is the first source type that is tested. Therefore, in most circumstances, you only have to modify the attributes that attribute redirection is using.

NOTE
Only certain attribute types can be used for attribute redirection.

Before you make changes to the normalized CPU and memory intelligence, understand how DX NetOps Spectrum calculates CPU and memory utilization.

DX NetOps Spectrum does the following to calculate CPU and memory utilization:

1. DX NetOps Spectrum identifies the source that is used to calculate the CPU and memory utilization. DX NetOps Spectrum identifies the source any time the device is reconfigured.
   A list of the possible sources is provided in a new preference attribute. Each source is tested in order. If a valid source is found, the source intelligence, the attributes that are used, and the attribute's model type are stored for reuse during the utilization calculation. This helps ensure that the source does not change until the source is reconfigured. If the list of sources is empty, or a valid, functioning source is not identified, the source type is set to “None” and no further reads are made to the device.
   In general, the sources are tested in the following order:
   – Attribute redirection
   – CA proprietary intelligence
   – Standard intelligence (RFC 2790 and Net-SNMP)
2. DX NetOps Spectrum performs the actual calculation of the utilization using the correct source, attribute IDs, and model type handles that were identified. The running attribute IDs list and the running model handle list are passed into the calculation method each time, to help ensure that the same attributes are read.

Normalized CPU Utilization Calculation Requirements

You can calculate the normalized CPU utilization for any device using attribute redirection as the source for the utilization, however, the device must meet the following requirements:

- The device must have a single MIB object which has a data type of either integer, 64-bit integer, text string, float, or real. The MIB object must be a scalar object or a list object.
- If the MIB object has a data type of text string, the values of the MIB object are valid if the text string represents a valid number. For example, 9.4, 43, and 1200, are considered valid text strings. A text string that contains numbers with extra text is not valid. For example, 43% is considered invalid.
- If the MIB object is a list object, each instance in the list must report a valid CPU value (no filtering of lists is provided). The reported value must be an instantaneous usage (or an aggregate of a short time period).
- The MIB object must report the utilization of all CPUs in the device in units of 0-100 percent.

  NOTE
  DX NetOps Spectrum does not attempt to adjust invalid results. For example, if an attribute returns 110 percent utilization, DX NetOps Spectrum reports the 110 percent utilization. Verify that the values that are reported in the attribute always yield the correct utilization, once calculated. If negative values are returned, thresholds can indicate a violation, even though a threshold was not exceeded.

Normalized Memory Utilization Calculation Requirements

You can calculate the normalized memory utilization for any device, using attribute redirection as the source for the utilization, however, the device must meet the following requirements.

The device must have one of the following:

- A single MIB object which is of the data type integer, 64-bit integer, text string, float, or real, and is either a list or a scalar. In addition, this object must report the utilization of all memory for the device in units of 0-100 percent.

  NOTE
  DX NetOps Spectrum does not attempt to adjust invalid results. For example, if an attribute returns 110 percent utilization, DX NetOps Spectrum reports the 110 percent utilization. Verify that the values that are reported in the attribute always yield the correct utilization, once calculated. If negative values are returned, thresholds can indicate a violation, even though a threshold was not exceeded.

- If the MIB object has a data type of text string, the values of the MIB object are valid if the text string represents a valid number. For example, 9.4, 43, and 1200, are considered valid text strings. A text string that contains numbers with extra text is not valid. For example, 9.4 MB, 43 MB, and 1,200 are considered invalid.
- Two or more MIB objects which are all either scalars or lists. Additionally, two of the objects must report either the total amount of free memory, used memory, or total memory. The units in which each MIB object reports its respective value *must* be the same.

  NOTE
  DX NetOps Spectrum does not attempt to verify that the units in which each MIB object reports its respective value are the same.

The values reported by the MIB objects must be instantaneous (or an aggregate of a short time period).

Normalized CPU Utilization Attributes

DX NetOps Spectrum uses the following attributes to calculate the normalized CPU utilization for a device:

- **NRM_CPUIntelPref**
  Lists possible sources to test when identifying normalized CPU utilization. These sources are tested in the order in which they appear in this attribute.
- **NRM_DeviceCPUUtilization**
  Reports the device's CPU utilization. The normalized CPU utilization calculation is triggered based on what this attribute reports.
- **NRM_DeviceCPUUtilizationNames**

Contains the names of each instance of the CPU utilization value. By default, the instance is displayed as:

```
CPU: <instance>
```

– ***<instance>***
Is the instance ID of each CPU utilization value.

NOTE
If the NRM_CPUUtilNameAttr attribute is available, the NRM_CPUUtilNameAttr attribute setting is used to populate the NRM_DeviceCPUUtilizationNames attribute. The names of each instance of the CPU utilization value is set once. If the NRM_CPUUtilizationNameAttr attribute setting changes, you must reconfigure the model to pick up the name change.

- **NRM_CPUAttr_Source**
Contains the source that is currently being used to calculate the normalized CPU utilization. If the intelligence ID is attribute redirection, this attribute says 'Attribute Redirection'. If the intelligence ID is CA - Proprietary, this attribute lists the MIB that DX NetOps Spectrum reads the values from.

The following attributes are used to utilize attribute redirection as the source for calculating the normalized memory utilization for a device:

- **NRM_CPUUtilAttr**
(Required) Points to the attribute that reports CPU utilization in percent. You populate this attribute with the attribute ID of the attribute which reports CPU utilization for the device. The attribute can be either a list or a scalar, and must be one of the following data types: counter, gauge, int, real, or 64-bit long.

  NOTE
  DX NetOps Spectrum does not attempt to adjust invalid results. For example, if an attribute returns 110 percent utilization, DX NetOps Spectrum reports the 110 percent utilization. Verify that the values that are reported in the attribute always yield the correct utilization, once calculated. If negative values are returned, thresholds can indicate a violation, even though a threshold was not exceeded.

- **NRM_CPUUtilNameAttr**
(Optional) Points to the attribute that reports the identifying information for the CPUs. This attribute holds the attribute ID of the attribute which reports the names associated with each instance of CPU utilization for this device.
This attribute can be a scalar or a list, but it must be the same data type as the NRM_CPUUtilAttr attribute and the names must be ordered such that the first element in the list matches the first element in the utilization list. If you do not enter an attribute ID, or if the attribute ID you provide is not valid, the instance ID is appended to “CPU:<*name*>” to create the name for that CPU value. Any data type is accepted.

  NOTE
  OctetStrings are treated as printable text strings.

- **NRM_CPUModelTypeToRead**
(Optional) Lists the model type handle of an application model that the NRM_CPUUtilAttr and the NRM_PUUUtilNameAttr attributes are read from.

Normalized Memory Utilization Attributes

DX NetOps Spectrum uses the following attributes to calculate the normalized memory utilization for a device:

- **NRM_MemoryIntelPref**
Lists possible sources to test when identifying normalized memory utilization. These sources are tested in the order in which they appear in this attribute.
- **NRM_DeviceMemoryUtilization**
Reports the device’s memory utilization. The normalized memory utilization calculation is triggered based on what this attribute reports.
- **NRM_DeviceMemoryUtilizationNames**
Contains the names of each instance of the memory utilization value. By default, the default is displayed as:

`Memory: <instance>`

– ***<instance>***
Is the instance ID of each memory utilization value.

NOTE
If the NRM_MemoryUtilNameAttr attribute is available, the NRM_MemoryUtilNameAttr attribute setting is used to populate the NRM_DeviceMemoryUtilizationNames attribute. The names of each instance of the memory utilization value is set once. If the NRM_MemoryUtilizationNameAttr attribute setting changes, you must reconfigure the model to pick up the name change.

- **NRM_MemAttr_Source**
Contains the source that is currently being used to calculate the normalized memory utilization. If the intelligence ID is attribute redirection, this attribute says 'Attribute Redirection'. If the intelligence ID is CA - Proprietary, this attribute lists the MIB that DX NetOps Spectrum reads the values from.

The following attributes are used to utilize attribute redirection as the source for calculating the normalized memory utilization for a device:

- **NRM_MemoryUtilAttr**
Points to the attribute that reports the memory utilization in percent.
- **NRM_MemoryUsedAttr**
Points to the attribute that reports the used memory in units, for example, bytes, kilobytes, megabytes, gigabytes, and so on.
- **NRM_MemoryTotalAttr**
Points to the attribute that reports the total memory in units, for example, bytes, kilobytes, megabytes, gigabytes, and so on.
- **NRM_MemoryFreeAttr**
Points to the attribute that reports the free memory in units, for example, bytes, kilobytes, megabytes, gigabytes, and so on.

NOTE
To calculate the normalized memory utilization for a device using attribute redirection as the source for the utilization, either NRM_MemorUtilAttr must be populated, or two of the following three attributes must be populated: NRM_MemoryUsedAttr, NRM_MemoryTotalAttr, NRM_MemoryFreeAttr.

- **NRM_MemoryUtilNameAttr**
(Optional) Points to the attribute that provides the memory utilization names.
- **NRM_MemoryModelTypeToRead**
(Optional) Lists the model type handle of an application model that the NRM_MemoryUtilAttr, NRM_MemoryUsedAttr, NRM_MemoryTotalAttr, NRM_MemoryFreeAttr, and the NRM_MemoryUtilNameAttr attributes should be read from.

Calculate Normalized CPU Utilization

You can calculate the normalized CPU utilization for a device whose utilization is not calculated out-of-the-box. You can also recalculate the utilization using different attributes than those attributes that are used by default. You can use different attributes on a per model or a per model type basis. To use different attributes on a per model type basis, use the Attribute Editor or the Model Type Editor to change the default attribute values for the model types.

NOTE
For more information about the Model Type Editor, see the Model Type Editor section.

To determine if the normalized CPU utilization is already calculated for a device, view the Source column in the Thresholds and Watches, Thresholds subview in the Information tab of the Component Details panel.

NOTE
DX NetOps Spectrum does not attempt to adjust invalid results. For example, if an attribute returns 110 percent utilization, DX NetOps Spectrum reports the 110 percent utilization. Verify that the values that are reported in the attribute always yield the correct utilization, once calculated. If negative values are returned, thresholds can indicate a violation, even though a threshold was not exceeded.

Follow these steps:

1. Verify that the device meets the specified requirements.
2. Identify the attribute that reports CPU utilization and place this attribute ID into NRM_DeviceCPUUtilAttr.
3. Identify the attribute that reports the identifying information for all the device CPUs, if the attribute exists.
4. Place the attribute ID into NRM_CPUUtilNameAttr.
5. Identify the origin of the attribute that reports CPU utilization and the attribute that reports the identifying information for the CPUs. If these attributes originate on an application model, enter the model type handle of the application model into NRM_DeviceCPUModelTypeToReadAttr. Otherwise, leave this attribute empty.
   If the DeviceCPUModelTypeToReadAttr is empty, DX NetOps Spectrum attempts to read the specified attribute from the device model. If DeviceCPUModelTypeToReadAttr is populated, DX NetOps Spectrum attempts to find an associated application model with that model type handle. If the associated application model, with the specified model type handle, is not found, or the attributes do not exist on that model, attribute redirection is not considered to be a valid source for calculating the utilization.
6. Reconfigure the device model.
   If attribute redirection fails, DX NetOps Spectrum attempts to test other available sources. If a valid, functioning source is not identified, the source column in the Thresholds and Watches, Thresholds subview displays 'None'. The normalized CPU and normalized memory performance graphs report 'Not available', and no further reads are made to the device. If a valid, functioning source is identified, the source column displays the successful source.

Calculate Normalized Memory Utilization

You can calculate the normalized memory utilization for a device whose utilization is not calculated by default, or for a device whose utilization has not been automatically calculated. You can also recalculate memory utilization using attributes that are not used by default. You can use different attributes for individual models or for selected model types. To use different attributes on a per model type basis, use the Attribute Editor or the Model Type Editor to change the default attribute values for the model types.

Note: For more information about the Model Type Editor, see the Model Type Editor section.

To determine whether the normalized memory utilization is already calculated for a device, view the Source column in the Thresholds and Watches, Thresholds subview in the Information tab of the Component Details panel.

NOTE
DX NetOps Spectrum does not attempt to adjust invalid results. For example, if an attribute returns 110 percent utilization, DX NetOps Spectrum reports the 110 percent utilization. Verify that the values that are reported in the attribute always yield the correct utilization, once calculated. If negative values are returned, thresholds can indicate a violation, even though a threshold was not exceeded.

Follow these steps:

1. Verify that the device meets the specified requirements.
2. Identify the attribute that reports memory utilization, if it exists, and place this attribute's handle into NRM_DeviceMemoryUtilizationAttr. If the device does not support an attribute that reports memory utilization, identify two of the following three attributes:
   - Used Memory
   - Free Memory
   - Total Memory

Populate the related attribute, NRM_Memory*XXX*Attr, where *XXX* is Free, Used, or Total. If more than the required attributes are provided, all the attributes must exist on the same model type.

NOTE
These attributes must report memory utilization in the same unit, for example, bytes, kilobytes, megabytes, gigabytes. However, DX NetOps Spectrum does not verify that each attribute reports the same units.

If more than the required number of attributes are provided, DX NetOps Spectrum uses the following order of precedence to determine which attributes to use:

a. NRM_MemoryUtiliAttr
b. NRM_MemoryUsedAttr and NRM_MemoryTotalAttr
c. NRM_MemoryFreeAttr and NRM_MemoryTotalAttr
d. NRM_MemoryFreeAttr and NRM_MemoryUsedAttr

The first instance that returns a valid set of values is used.

3. Identify where these attributes originate. If these attributes originate on an application model, enter the model type handle of the application model into NRM_DeviceMemoryUtilizationNameAttr. Otherwise, leave this attribute empty. If the NRM_DeviceMemoryUtilizationNameAttr is left empty, DX NetOps Spectrum attempts to read the specified attribute from the device model. If NRM_DeviceMemoryUtilizationNameAttr is populated, DX NetOps Spectrum attempts to find an associated application model with that model type handle. If the associated application model, with the specified model type handle, is not found, or the attributes do not exist on that model, attribute redirection is not considered to be a valid source for calculating the utilization.
4. Reconfigure the device model.
   If attribute redirection fails, DX NetOps Spectrum attempts to test other available sources. If a valid, functioning source is not identified, the source column in the Thresholds and Watches, Thresholds subview displays 'None', the performance graphs report 'Not available', and no further reads are made to the device. If a valid, functioning source is identified, the source column displays the successful source.

Troubleshoot CPU and Memory Utilization Calculation

If DX NetOps Spectrum is returning incorrect or invalid CPU and memory utilization calculation values, reconfigure the model.

The attributes that DX NetOps Spectrum reads, and the model handles that DX NetOps Spectrum reads from, are all cached to verify that the same source is used during the utilization calculation. If a source is no longer available, or has been changed, invalid or incorrect values are reported until the device model is reconfigured.

NOTE
Name attributes are only reevaluated when the model is reconfigured and then cached. Therefore, if instances change, or the names associated with a given instance change, reconfigure the model.

If DX NetOps Spectrum is not selecting the source that you want to use, do the following:

1. Verify that the order of possible sources you want to test is set correctly in the CPU intelligence preference attribute, NRM_CPUIntelPref, and memory intelligence preference attribute, NRM_MemoryIntelPref.
2. Verify that the device supports the source you want to use. For example, if you want to use attribute redirection, confirm that the attributes are supported on the device model or specified application model.

Fault Management

This section describes how you can manage the faults in your network.

Configure Cross-Landscape Fault Correlation

In a distributed SpectroSERVER (DSS) environment, a network administrator may need to model a router from a local landscape in a remote landscape for its connections to participate in fault isolation for the remote landscape. This *proxy* model doesn't need to participate in alarm generation in the remote landscape because it already does so in the local landscape where it is modeled "normally." It is in the local landscape that alarms for the router are tracked and trouble tickets are created.

In such a scenario, Cross-Landscape Fault Correlation can prevent multiple red alarms for the same outage. With the Enable Event Creation attribute set to FALSE in the proxy model's Fault Management subview, DX NetOps Spectrum suspends the creation of events for the model (and any component models such as boards or ports). This effectively disables alarms for the model, but unlike maintenance mode, SNMP communication with the proxy model continues, and so too does its participation in fault isolation.

> **NOTE**
> For more information about distributed network management, see the Distributed SpectroSERVER Administration section.

Designate a Model as a Proxy Model

You can designate a device model as a proxy model from the Information tab of the selected device model. Setting a device model up as a proxy model disables event creation for that model.

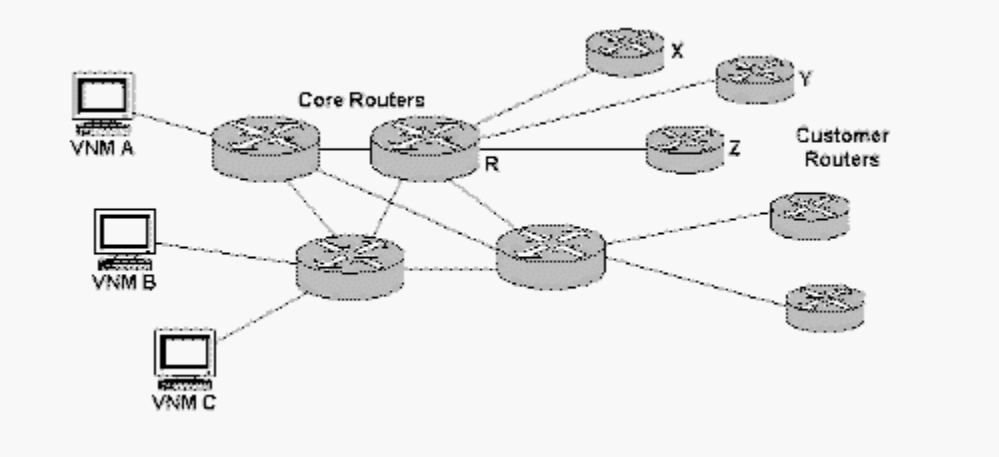
> **NOTE**
> When you have multiple proxy models in a Global Collection topology, you can collapse them to a single icon, merging all connections.

Follow these steps:

1. Select the device model to designate as a proxy model.
2. Click the Information tab, and expand the DX NetOps Spectrum Modeling Information subview.
3. Locate the 'Is a Proxy Model' setting, click 'set,' and select Yes.
   Event creation is disabled for this model. The model now serves as a proxy model.

Cross-Landscape Fault Correlation Example

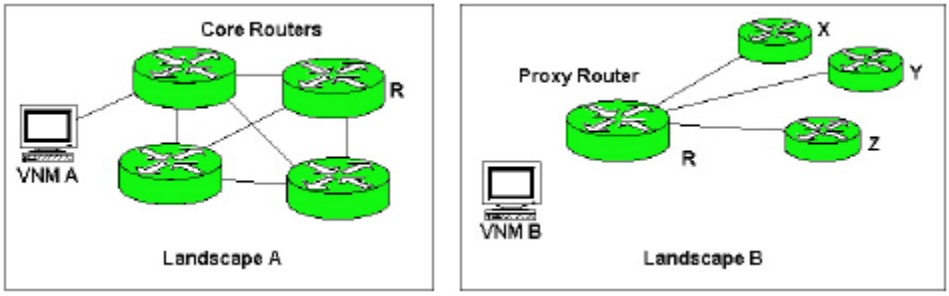
The following diagram provides an example of a network with multiple landscapes:



Landscape A, the local landscape, contains core routers, including Router R. Landscape B, the remote landscape, contains customer routers with the core Router R modeled a second time, this time as a proxy, as shown in the following

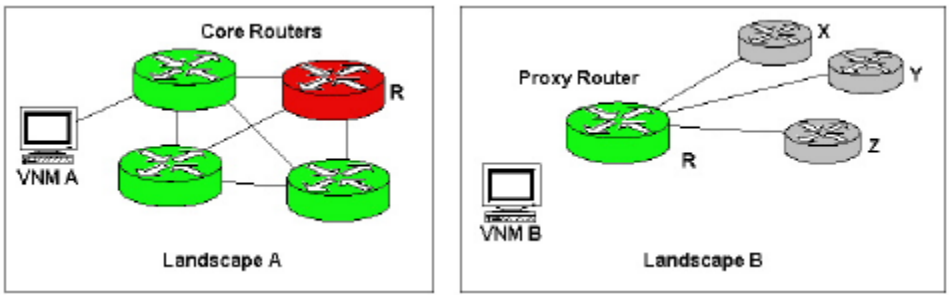
diagram. This proxy model has its IsEventCreationEnabled attribute set to No. The device is being polled, but will not generate events or alarms.

Router R in Landscapes A and B:



If Router R goes down, as shown in the following diagram, Landscape B loses contact with the proxy and customer routers. However, only one red alarm is generated, in Landscape A. The proxy router stays green in Landscape B, where the alarms are suppressed because the proxy model's IsEventCreationEnabled attribute is set to No.

Alarm with Cross-Landscape Fault Correlation:



Configuring Port Status Monitoring

DX NetOps Spectrum provides the following methods of monitoring the status of ports:

- **Link Traps**
  Link traps allow you to monitor the status of ports without the cost of polling. However, traps are not always the most reliable notification mechanism of port status.
- **PollPortStatus**
  The PollPortStatus feature lets you poll the status of a port even if its connectivity is not modeled in DX NetOps Spectrum.
- **Live Pipes**
  Live Pipes let you turn on port status monitoring for individual links. This is a more reliable monitoring method than traps because DX NetOps Spectrum will periodically poll the status of the link (with an increased cost in performance). In addition, Live Pipes let you graphically verify which links are being monitored.
- **WA_Link Port Monitoring**
  WA_Link models automatically enable a live pipe for any connected ports.
- **NetworkLinkType**
  DX NetOps Spectrum automatically maintains the port-level attribute NetworkLinkType based on the model class of the two connected devices. The attribute lets you set up management policies based on the type of link a port is involved in.

  NOTE
  For more information about the NetworkLinkType attribute and management policies in general, see the Policy Manager section.

The possible values for NetworkLinkType include the following:

- 0 = No Link
- 1 = Router Link
- 2 = Switch Link
- 3 = Shared Access Link
- 4 = End Station Link
- 5 = Wide Area Link
- 6 = Internal Link
- 7 = Unknown Link
- 8 = Network Cloud Link

If the connectivity of the port is not modeled, NetworkLinkType will be set to Unknown Link. When the connectivity of the port is modeled, the value of NetworkLinkType is maintained as described in the following table:

Connection	Attribute Value	Link Type
Router > Router	1	Router
Router > Switch Router	1	Router
Router > Switch	1	Router
Router > Hub	1	Router
Router > Workstation Server	1	Router
Switch Router > Switch Router	2	Switch
Switch Router > Switch	2	Switch
Switch Router > Hub	3	Shared Access
Switch Router > Workstation Server	4	End Station
Switch > Switch	2	Switch
Switch > Hub	3	Shared Access
Switch > Workstation Server	4	End Station
Hub > Hub	3	Shared Access
Hub > Workstation Server	4	End Station
Any port connected to a WA_Link model	5	Wide Area
Any backplane connecting inside a hardware device	6	Internal Link
EVPN Discovery is run and Provider_Clouds are created	8	Network Cloud Link

Port Status Polling Criteria

In general, the status of a port is polled when the following criteria are met:

- The PollingStatus (0x1154f) of the port model must be TRUE.
- The Polling_Interval (0x10071) of the port model must be non-zero.
- The PollingStatus of the port's device model must be TRUE.
- Neither the port model nor the port's device model can be in maintenance mode; the isManaged (0x1295d) attribute for both must be set to TRUE.

If this criteria is met, port polling occurs with a frequency equal to the Polling_Interval setting.

However, either of the following two conditions override the default polling frequency:

- The port has been down since it was modeled in DX NetOps Spectrum and the Port Always Down Alarm Suppression attribute is set to Enabled.

  NOTE
  If the Port Always Down Alarm Suppression attribute is set to Disabled, the port will be polled as described above.
- The port is administratively down (that is, ifAdminStatus attribute is set to Down).

If these criteria are met, the polling frequency is reduced to once per hour (every 3600 seconds). Plus, all red alarms on the down ports are suppressed, and a gray condition is asserted. Administratively down ports remain brown.

Port Status Events and Alarms

The port status monitoring engine uses the events and alarms listed in the following table to notify you of a change in status.

Event Description	Event ID	Alarm Description	Alarm ID	Port Condition Color
Port status good	0x10d10	N/A	N/A	Green
Port status bad	0x10d11	BAD LINK	0x1040a	Red
Port status disabled	0x10d12	LINK DISABLED	0x1040b	Brown
Port status unknown	0x10d13	LINK STATUS UNKNOWN	0x1040e	Gray
Port status unreachable	0x10d14	UNREACHABLE LINK	0x1040c	Gray
Port status initial	0x10d15	N/A	N/A	Blue
Port lower layer down	0x10d16	BAD LINK, BUT ALARM WAS SUPPRESSED	0x1040f	Gray
Port up, but linked with down port	0x10d17	LINK MAY NOT BE UP	0x10410	Gray
Port connected to down port or device	0x10d18	PORT ALARM SUPPRESSED	0x10411	Gray
Port status bad, but connected to WA_Link whose LinkFaultDisposition is LinkOnly	0x10d2d	PORT ALARM SUPPRESSED	0x10d2d	Gray

Link Traps

Traps provide a means for network devices to let a management system know that a significant event has occurred on the network. Link Down and Link Up traps are perhaps the most important traps when it comes to port status monitoring. These traps tell the management system that a port has either become inoperable, or has come back up.

When DX NetOps Spectrum receives a Link Down trap, it polls the status of the corresponding port once to verify its status and generates one of the events and alarms listed in Port Status Events and Alarms on the affected port.

NOTE
DX NetOps Spectrum generates a yellow alarm on the device model to allow easy access to vendor-specific trap data, however it no longer generates the trap-specific events and alarms on the affected port model.

Once a Link Down trap is received, DX NetOps Spectrum sets the OutstandingLinkDownTrap attribute on the port to TRUE. This will cause DX NetOps Spectrum to poll the status of the port regardless of the port status polling criteria. When DX NetOps Spectrum receives a Link Up trap for the port, or when the port's status is determined to be up based on a poll, the value of the OutstandingLinkDownTrap attribute is set to FALSE and polling will take place based on the value of the port status polling criteria. For more information about when a port is polled, see Port Status Polling Criteria.

When all of the ports for which DX NetOps Spectrum has received a Link Down trap are back up, the yellow alarm on the device will be cleared.

You can use the following attributes to control how DX NetOps Spectrum handles link traps:

- **AlarmOnLinkDownIfTypes**
  This attribute contains a mapping of ifType values to a value which determines how to handle the trap for that particular ifType and model type (0 for never, 1 for always, and 2 for check admin). This can be customized in the MTE on a per-model type basis. When a port model is created, its AlarmOnLinkDownTrap (0x11fc2) attribute is automatically populated with the value which corresponds to its particular ifType.
  ID: 0x1290f
- **AlarmOnLinkDownTrap**
  This attribute sets the alarm generation behavior for receipt of a LINK DOWN Trap Event. Possible settings are:
  – Never (0) = Do not generate an alarm upon receipt of LINK DOWN trap
  – Check Status (1) = Generate an alarm based on the current Admin Status (UP = Generate a Red alarm, otherwise generate a Brown alarm)
  ID: 0x11fc2
- **AssertLinkDownAlarm**
  This attribute is used to determine if the yellow alarm should be generated on the device model. It is read from the port model for which DX NetOps Spectrum received the trap. This attribute is available from the port model's Attributes tab.
  ID: 0x12957

Interface Trap Configuration

For many device models, you can configure the processing of link down traps received for individual port models through the port model's Interfaces tab, Component Detail view, Attributes tab. Here you can access the attributes that let you suppress link down alarms for the selected port model or its parent device model. Consult the DX NetOps Spectrum management module section for the type of device you are interested in to see if that module supports such trap configuration.

> **NOTE**
> You can also use Locater search to select a set of port models and then the Attribute Editor to update in bulk.

PollPortStatus Feature

The PollPortStatus feature lets you monitor the status of a port even if the port's connectivity is not modeled. The PollPortStatus attribute exists for both Device and Port models with a different attribute ID for each of the two model types. This lets you enable and disable port status polling at the device or port level. By default, PollPortStatus is set to TRUE at the device level and FALSE at the port level.

> **NOTE**
> To reduce network traffic, SNMP reads for polled ports on the same device are grouped together into larger SNMP requests. This provides performance benefits that are most noticeable when many ports are polled by this method in a single SpectroSERVER.

Utilizing PollPortStatus to Watch a Connected Port's Status

The PollPortStatus attribute at the device level (0x12809) controls port status polling on a per-device basis. If TRUE, polling is enabled for that device. If FALSE, no ports will be polled, even if a port model's PollPortStatus attribute is TRUE. When changed to FALSE, alarms will be cleared for any port which is not involved in a live pipe.

The PollPortStatus attribute at the port level (0x1280a) controls polling for each port model. If this attribute is set to TRUE (and PollPortStatus for the device is also set to TRUE), the status of the port will be polled, and alarms will be generated if needed. When changed to FALSE, any alarm on the port will be cleared. The following table shows that a port's status will be polled only if PollPortStatus is TRUE for both a given port model and its device model.

Device Model's PollPortStatus Value	Port Model's PollPortStatus Value	Results
FALSE	FALSE	Port status is not polled for any port on device
TRUE	FALSE	Port status is not polled for this port on device
FALSE	TRUE	Port status is not polled for this port on device
TRUE	TRUE	Port status is polled for this port on device

DX NetOps Spectrum watches the polling interval to determine when to poll port status. When a port is polled, the port's status is determined and an appropriate alarm is generated (RED, BROWN, or GRAY) if necessary.

If a BAD LINK alarm is generated on a port (alarm code 0x1040a), and later polling on that port is disabled by changing the value of PollPortStatus to FALSE and disabling Live Pipes, an event will be generated to automatically clear the BAD LINK alarm.

> **NOTE**
> The PollPortStatus attribute can be set to TRUE while the Live Pipes functionality is enabled. This will not cause redundant network traffic.

Enabling Port Status Polling

You can enable port status polling for all future models of a given type using the Model Type Editor (MTE), or on a current, per-model basis using the Command Line Interface (CLI). For example, use the MTE to set PollPortStatus to TRUE for both device and port model types. Then, when polled, interface models will generate appropriate alarms when needed. PollPortStatus can also be set at both the device and port level using the Global Attribute Editor.

> **NOTE**
> For information about using the CLI to enable or disable PollPortStatus for a single model, see the Command Line Interface *section.*

Fault Isolation Settings

The Fault Isolation subview in the VNM model's Information tab lets you configure various aspects of the DX NetOps Spectrum device fault isolation functionality. It contains the following settings:

- **ICMP Support Enabled**
  Specifies whether an attempt should be made to contact a device using the ICMP protocol when trying to ascertain the fault status of the device. When the ICMP_SUPPORT attribute is enabled (set to TRUE), DX NetOps Spectrum looks at the setting of the ICMP_SUPPORT attribute at the device level. If ICMP support is also enabled on the device, DX NetOps Spectrum attempts to contact the device using the ICMP protocol. However, when ICMP_SUPPORT is disabled (set to FALSE), this setting takes precedence over the setting at the device level and prevents any attempt to contact the device using the ICMP protocol for fault isolation.
  Default: Yes
- **ICMP Timeout (msec)**
  Specifies the amount of time (in milliseconds) DX NetOps Spectrum waits for a response to an ICMP ping. If a response is not received within this period of time, DX NetOps Spectrum assumes the device has timed out.
  Default: 3000 milliseconds (3 seconds)
- **ICMP Try Count**

Specifies the total number of attempts made to contact a device using the ICMP protocol before DX NetOps Spectrum determines the device is down.

- **Lost Device Try Count**
  Specifies the number of retries that DX NetOps Spectrum attempts for each SNMP request sent to a device after contact with the device is lost.
  Default: 1
- **Port Fault Correlation**
  Enables port fault correlation and specifies how it should be configured.
  Default: All Connected Ports
- **Contact Lost Model Destruction**
  Specifies whether a device is automatically destroyed when its CONTACT_STATUS is set to false. When enabled, models that have had their CONTACT_STATUS set to lost for a specified period of time, as determined by the Destruction Delay (sec) setting, are destroyed automatically. When disabled, models will never be automatically destroyed as a result of the value of the CONTACT_STATUS attribute.
  Default: Disabled
- **Destruction Delay (sec)**
  Specifies the length of time (in seconds) that a model must continuously have its CONTACT_STATUS attribute set to lost before it is automatically destroyed.
  Default: 604800 seconds (7 days)
- **Destruction Event Generation**
  This field controls whether an event message is created when a model is automatically destroyed. When this field is set to Enabled, an event will be generated each time a model is destroyed as a result of its CONTACT_STATUS being continuously set to lost for the length of time specified in the Destruction Delay Time field. When this field is set to Disabled, no event message will be generated.
  Default: Enabled
- **Router Redundancy Retry Count**
  Specifies the number of times DX NetOps Spectrum will attempt to contact a router's redundant IP addresses if contact is lost with its primary address. The polling interval setting determines the amount of time between each attempt.
  Default: 2
- **Unresolved Fault Alarm Disposition**
  If information about the connectivity of your network model is incomplete, DX NetOps Spectrum may be unable to find the root cause of a network outage. In this case, the status of all devices affected by the outage is set to gray, and a red unresolved fault alarm is generated. This alarm indicates that DX NetOps Spectrum has lost contact with a group of devices, but was unable to pinpoint the cause.
  All of the devices to which DX NetOps Spectrum has lost contact are listed in the impact scope of the alarm. The model name and other details of the lost devices also appear in the event that generated the alarm.
  The Unresolved Fault Alarm Disposition field lets you control how the unresolved fault alarm is generated. When set to Fault Isolation Model, the alarm will be generated on the Fault Isolation model. When set to Device In Fault Domain, the alarm will be generated on one of the devices with which DX NetOps Spectrum has lost contact. When determining which device to generate the alarm on, DX NetOps Spectrum looks for the device with the highest criticality. If the highest criticality is shared by two or more devices, DX NetOps Spectrum generates the alarm on the first of these devices that it finds. If all devices have the same criticality, then DX NetOps Spectrum chooses the device with the lowest model handle.

  NOTE

  The default behavior is to place Unresolved Fault Alarms on the Fault Isolation model. Most users prefer to have unresolved fault alarms placed on a device in the fault domain, where the problem is more visible. This default behavior can be changed from "Unresolved Fault Alarm Disposition.
- **WA Link Fault Isolation Mode**
  Specifies whether WA_Link models are considered neighbors for fault isolation purposes. Options are Normal and Transparent.
  Default: Normal

Port Fault Correlation

DX NetOps Spectrum lets you customize its fault isolation algorithm to resolve the root cause of a network outage to the port level. This is most desirable in cases where a single physical port, such as a Frame Relay interface, supports multiple logical connections to remote devices. If the physical port goes down, DX NetOps Spectrum can suppress the alarms on all downstream devices in favor of a single red alarm on the physical interface, thus significantly reducing the number of alarms which need attention. The impact severity and scope of the red alarm on the physical interface will contain all downstream devices, as well as the physical interface.

Port Fault Correlation Options

Use the Port Fault Correlation setting in the VNM model's Fault Isolation subview to configure port fault correlation.

- **Disabled**
  Disables port fault correlation. The root cause of a network outage will remain a red alarm on a device model. However, Fault Isolation will still examine all of the device's connected ports to see if they are all in Maintenance Mode. If so, the alarm on the device model will be suppressed.
- **All Connected Ports**
  Port fault correlation will run, examining all ports that exist on "up" neighbors which are connected to the down device as possible root causes of the outage. No additional manual configuration is required.
- **Management Neighbors Only**
  Enables port fault correlation to run but only examine ports which were previously configured manually as management neighbors as possible root causes of the outage.
- **All Connected Ports -- Multiple Devices Only**
  Enables port fault correlation, examining all ports that exist on "up" neighbors which are connected to the down device as possible root causes of the outage. However, DX NetOps Spectrum will only resolve the outage to the port level if there is more than one device model that would have a red alarm which can be correlated to the port alarm. If only one connected device alarm can be correlated to the port alarm, DX NetOps Spectrum will not suppress the device alarm. Instead, both the port and device alarm will be generated.

Port Fault Correlation Criteria

The following criteria must be met for the root cause of an outage to be resolved to the port level:

- The down device must have only one "up" neighbor. If the down device has more than one "up" neighbor, port fault correlation will not be performed. This is done to reduce the number of alarms for a single problem. If multiple up neighbors were a valid criteria, and all connected ports were down, multiple red alarms would exist, all with the same impact severity and scope. If a device has more than one up neighbor, DX NetOps Spectrum assumes the problem lies with the device, not the upstream ports and creates a single red alarm on the device.
- The down device must have at least one connected port (or management neighbor port) on an "up" neighbor that is down.
- If multiple ports on the "up" neighbor connect to the down device (such as link aggregation), all of the ports must be down.
- A port is considered "down" if it is either operationally down, or the port model has been put into Maintenance Mode.
- There must be an alarm on at least one of the down ports. Otherwise, there would be no alarm to which DX NetOps Spectrum could resolve the outage.
- If Port Fault Correlation is set to Management Neighbors Only, management neighbors for the down device must have been configured before the outage occurred.

Port Fault Correlation Caveats

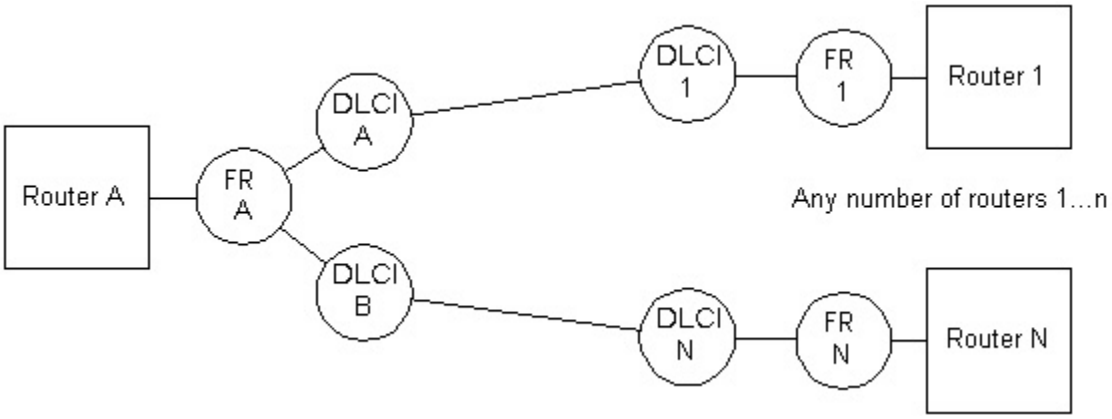
Port Fault Correlation overrides the Suppress Linked Port Alarms setting in the Live Pipes subview. When set to TRUE, this setting suppresses the alarm on an upstream port if it's connected to an unreachable device. If Port Fault Correlation is enabled, and the upstream port is the root cause of an outage, DX NetOps Spectrum forces the upstream port to alarm.

Only the Criticality of the alarmed port will be used in the impact severity and scope calculation of the root cause alarm. The Criticality of any sub-interfaces (such as DLCI ports) will not be included.

Port Fault Correlation is supported by Device models only. Models such as Fanouts and Unplaced do not support this feature. WA_Link models have their own mechanism for supporting port fault correlation, Link Fault Disposition, which is explained in Wide Area Link Monitoring.

If multiple ports on the “up” neighbor connect to the down device (e.g. link aggregation), and all of the ports are down, multiple red alarms will exist as the root causes of the outage. Each red alarm will contain the same impact severity and scope. The root cause of the outage in this case is all of the ports, not just one of them.

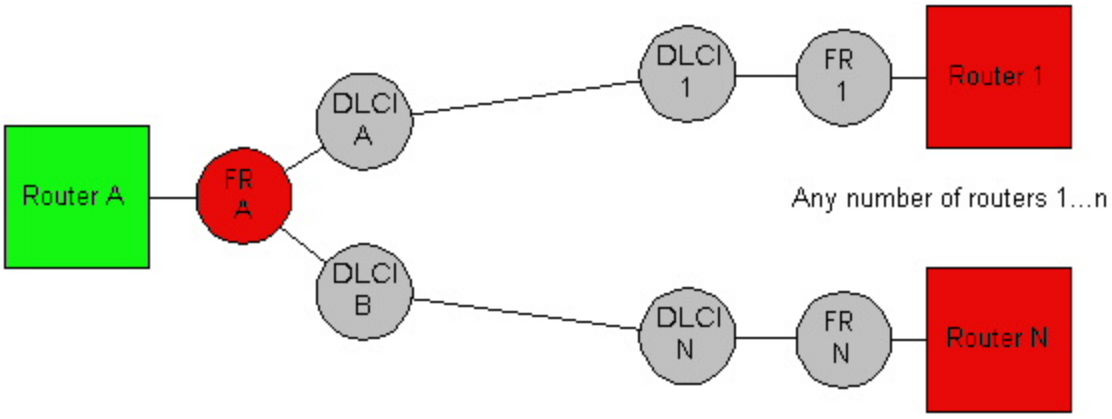
Example Port Fault Correlation Scenario 1



The previous diagram assumes that DX NetOps Spectrum must communicate through Router A to reach Routers 1 through N, and that this is the only means by which DX NetOps Spectrum can reach them. Each remote router is connected to Router 1 using a frame relay link. In DX NetOps Spectrum, this is modeled by connecting each DLCI port model to the other device.

If the physical frame relay interface (FR A) goes down in this scenario, all virtual circuits provisioned on the interface will go down as well. With Port Fault Correlation disabled, the alarms shown in the following diagram will occur.

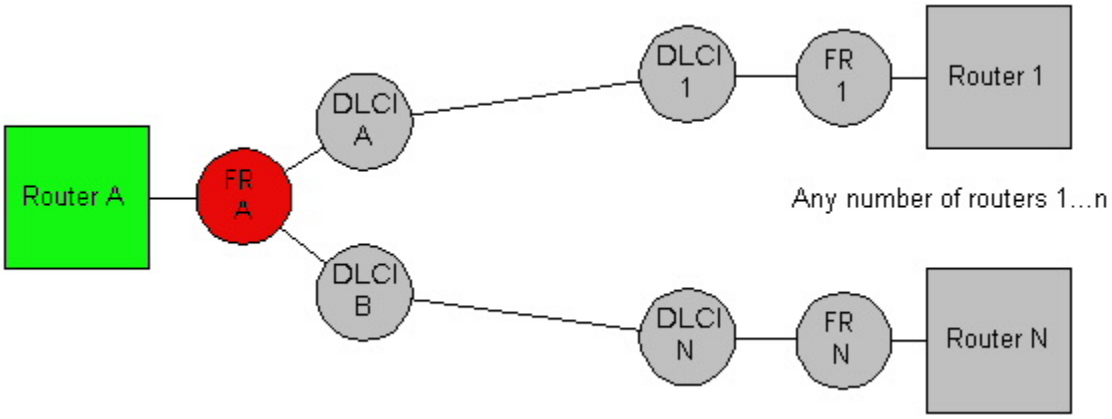
Fault Scenario 1: Alarms without Port Fault Correlation



If a trap is received for FR A going down (or a live pipe is configured to be on), the physical frame relay interface will have a red alarm on it. In addition, all routers connected to the frame relay interface will have a red alarm on them. This could mean multiple red alarms could be generated by DX NetOps Spectrum for a single problem.

Port Fault Correlation reduces the number of alarms generated for this problem to a single alarm without requiring any manual configuration beforehand. The following diagram shows the results with Port Fault Correlation enabled.

Fault Scenario 1: Alarms with Port Fault Correlation



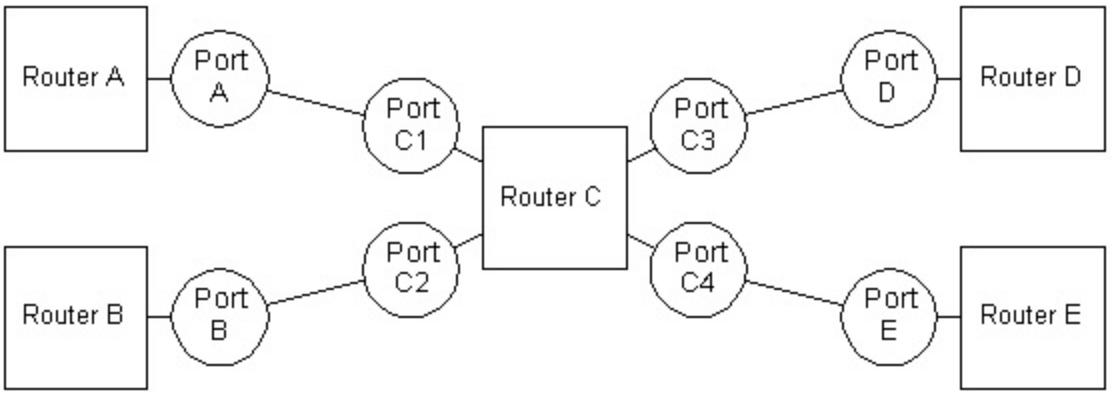
A single red “Bad Link” alarm will be seen in the Alarms tab. That alarm will have an Impact Scope and Severity which contains the following models: FR A, Routers 1 through N, and all unreachable devices that are downstream from Routers 1 through N.

Example Port Fault Correlation Scenario 2

This fault scenario illustrates the benefits of setting the Suppress Linked Port Alarms and Port Fault Correlation attributes as recommended in Suggested Port Fault Settings for Optimal Fault Notification.

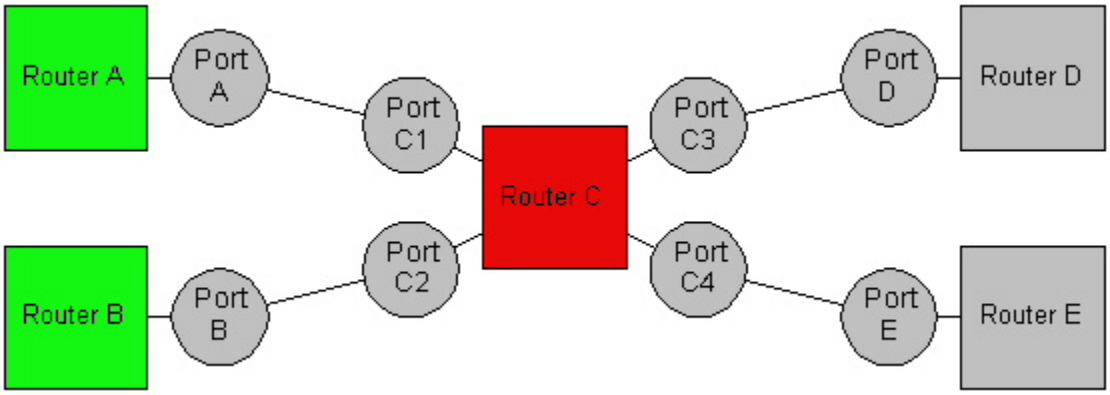
The following diagram assumes that the VNM must communicate through Routers A and B to reach Routers C, D, and E, and that is the only means by which the VNM can reach them. In DX NetOps Spectrum, port-level connectivity is modeled as shown.

Fault Scenario 2: Multiple “Up” Neighbors



In this scenario, Router C goes down, which causes DX NetOps Spectrum to lose contact with Routers C, D, and E, and makes Ports A and B go down as well. If Suppress Linked Port Alarms is set to TRUE, and Port Fault Correlation is set to All Connected Ports, only a single red alarm on Router C will result, as shown in the following diagram:

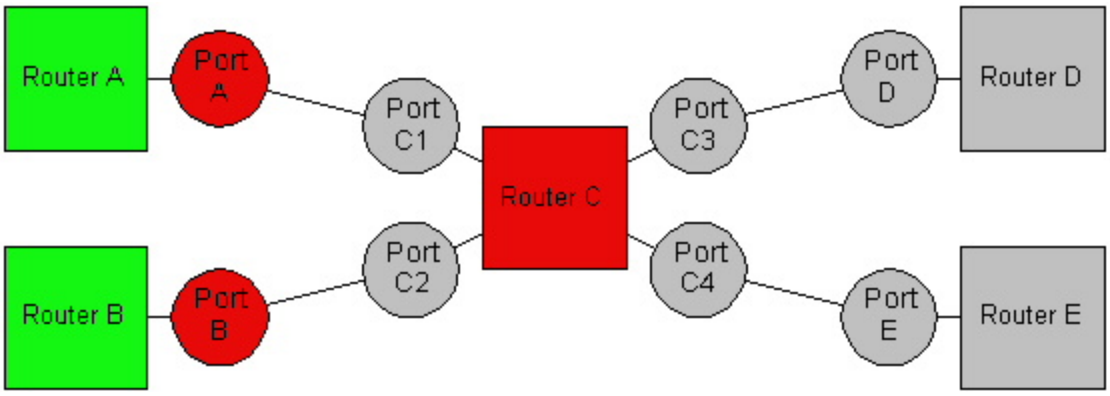
Fault Scenario 2: Multiple “Up” Neighbors



The upstream ports (Ports A and B) have their alarms suppressed because Suppress Linked Port Alarms is set to TRUE. Even though Port Fault Correlation is enabled, Router C has multiple “up” neighbors, so the fault won't be resolved to the port level. When this occurs, DX NetOps Spectrum assumes the fault is with the device itself, not the connected ports.

If you set Suppress Linked Port Alarms to FALSE, and Port Fault Correlation is still set to All Connected Ports, Router C and the upstream ports will be alarmed (if the status of the ports is being polled, or DX NetOps Spectrum receives a LinkDown trap), as shown in the following diagram:

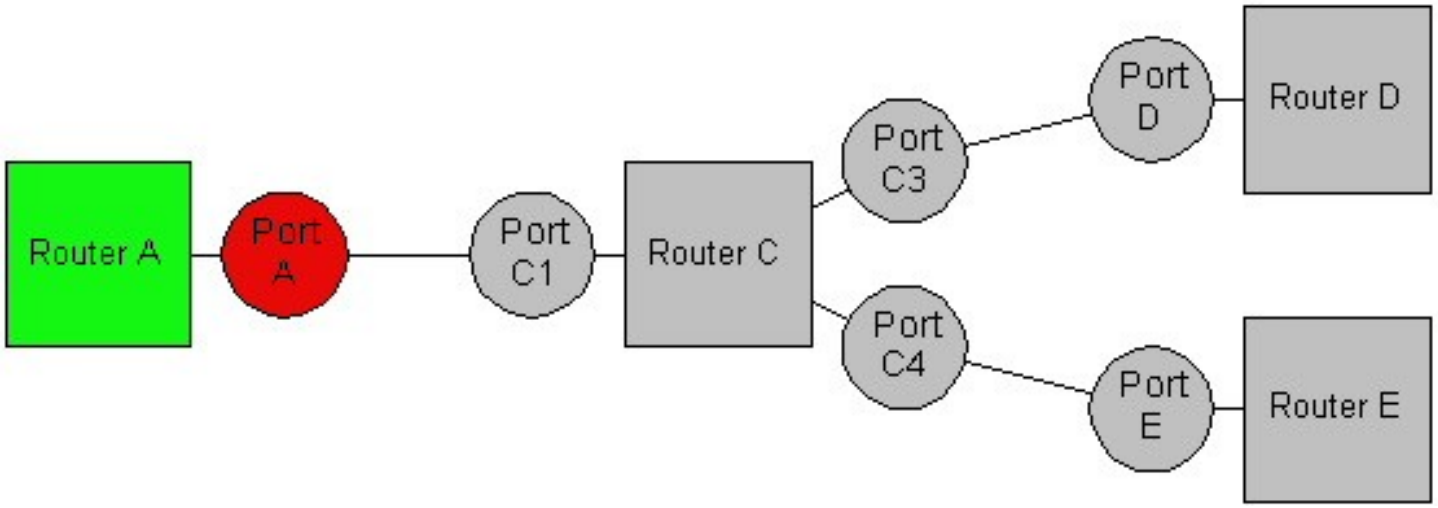
Fault Scenario 2: Multiple “Up” Neighbors



Once again, the fault wasn't resolved to the port level because Router C has multiple “up” neighbors. Since Suppress Linked Port Alarms is disabled, DX NetOps Spectrum will alarm the upstream ports.

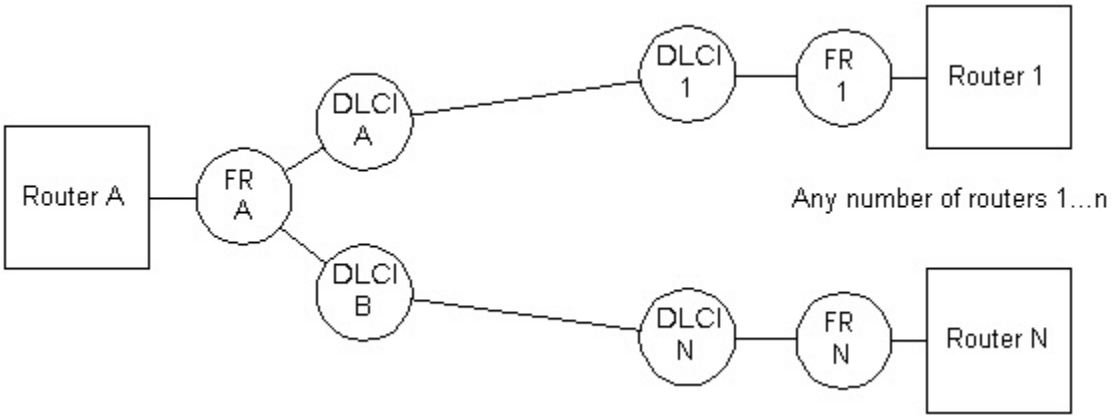
If Router C had only one “up” neighbor, as shown in the following diagram, even if Suppress Linked Port Alarms were set to TRUE (assuming Port Fault Correlation is still set to All Connected Ports), DX NetOps Spectrum will resolve the fault down to the port level. Port Fault Correlation forces the upstream port to be alarmed, and the alarm on Router C is suppressed.

Fault Scenario 2: Single “Up” Neighbor



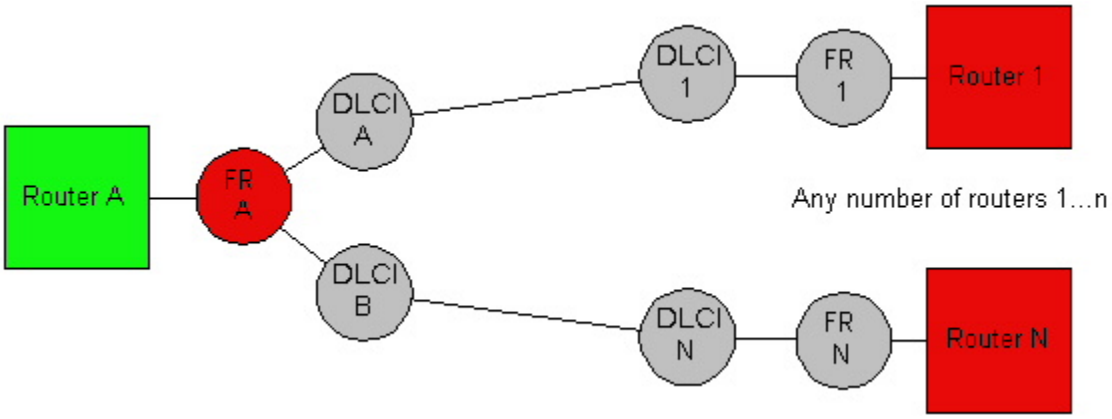
Example Port Fault Correlation Scenario 3

This fault scenario demonstrates what happens when Port Fault Correlation is set to All Connected Ports--Multiple Devices Only. It assumes that DX NetOps Spectrum must communicate through Router A to reach Routers 1 through N, and that this is the only means by which DX NetOps Spectrum can reach them. Each remote router is connected to Router 1 using a frame relay link. This is modeled by connecting each DLCI port model to the other device, as shown in the following diagram:



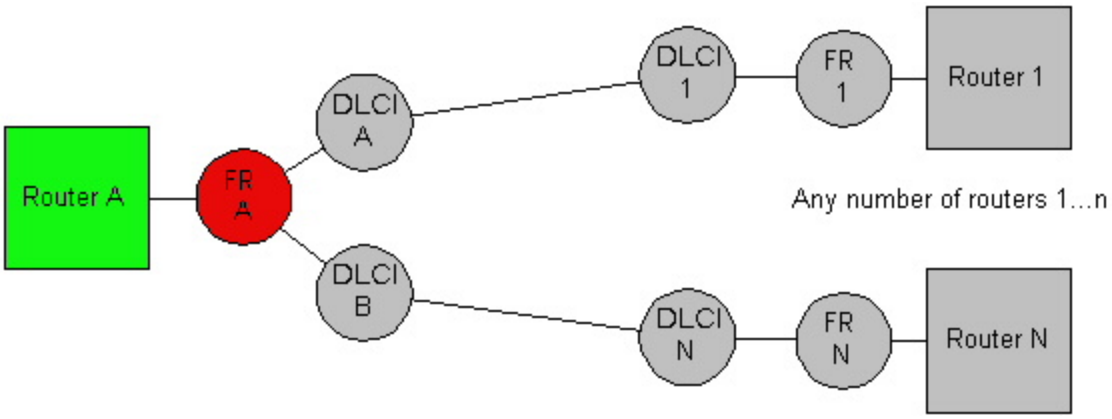
Assume the physical frame relay interface (FR A) goes down. This means that all virtual circuits provisioned on the interface will go down as well. With Port Fault Correlation disabled, the alarms shown in the following diagram will occur:

Fault Scenario 3: Alarms without Port Fault Correlation

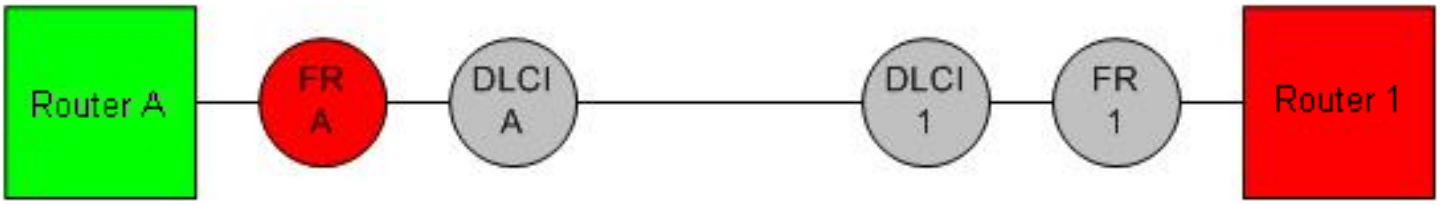


With Port Fault Correlation set to All Connected Ports--Multiple Devices Only, the alarms in the following diagram will occur because multiple devices can be correlated to the frame relay interface.

Fault Scenario 3: Port Fault Correlation Set To “All Connected Ports--Multiple Devices Only”



With Port Fault Correlation set to All Connected Ports--Multiple Devices Only, if there is only one router lost because of a down link, then the alarm on the remote router will not be suppressed.



Port Fault Correlation Anomalies

If a red alarm is generated on a port model as the root cause of an outage, you may then choose to put that port model into Maintenance Mode. If so, the red alarm would be replaced with a brown alarm. The brown alarm will still contain the same impact severity and scope (except the maintenance port will no longer contribute to the impact). If you then decide to take the port out of Maintenance Mode, the red alarm will reappear. It is possible, in this scenario, for the impact scope and severity of the red alarm to be lost.

Wide Area Link Monitoring

DX NetOps Spectrum polls any ports connected to a WA_Link model for status automatically. This polling is controlled by the PollingStatus and Polling_Interval of the WA_Link model.

If the PollingStatus of a WA_Link model is TRUE, and its Polling_Interval is non-zero, DX NetOps Spectrum automatically makes the pipes that are connected to a WA_Link "live" and sets the PollPortStatus for port models to TRUE. The live pipe lets you visually verify that DX NetOps Spectrum is monitoring the status of the connected ports.

If you disable the live pipe but leave the PollingStatus of the WA_Link set to TRUE, the Polling_Interval set to a non-zero number, and the ports' PollPortStatus set to TRUE, DX NetOps Spectrum continues to monitor the status of the ports.

> **NOTE**
> WA_Link models can only represent point-to-point connections, such as T1 and T3 lines. No more than two devices can be connected to it at a time.

LinkFaultDisposition

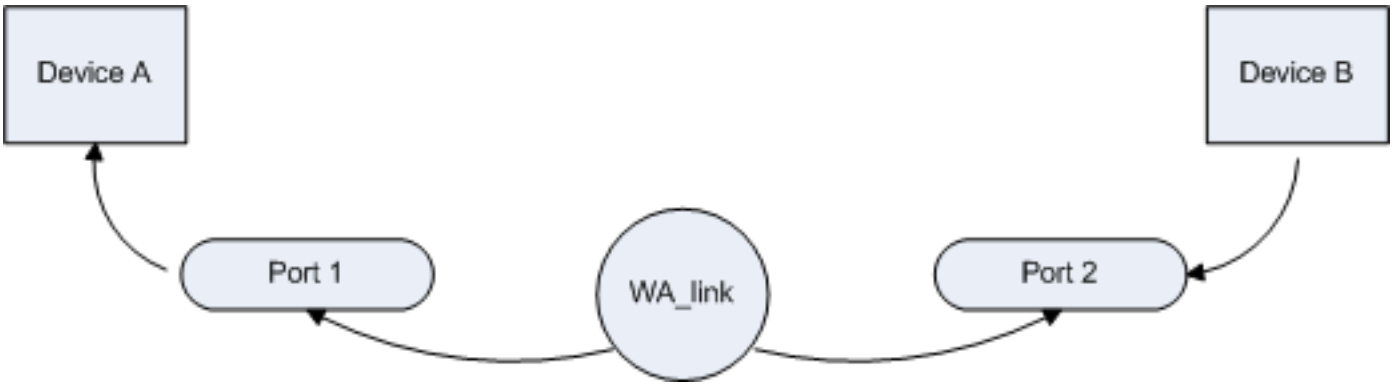
The LinkFaultDisposition setting provides control and flexibility over fault alarming. When a wide area connection goes down, alarms can be generated on ports and on the link model. You can set the LinkFaultDisposition (0x129e2) attribute from the WA_Link model Attributes tab.

LinkFaultDisposition can be set to one of the following three modes:

- **BothPortsAndLink**
  If set to BothPortsAndLink, alarms are generated on both the connected ports and on the link model. This is the default setting.
- **PortsOnly**
  If set to PortsOnly, only the connected ports are alarmed, and the WA_Link is suppressed.
- **LinkOnly**
  If set to LinkOnly, only the WA_Link model will be alarmed, and the ports will be suppressed.

Wide Area Link Monitoring Scenarios

Consider the sample WA_Link network topology shown in the following diagram:



The following tables illustrate two possible WA_Link monitoring scenarios for this topology.

Scenario 1: Link Goes Down, Device B Loses Contact

LinkFaultDisposition	Port 1 Condition	WA_Link Condition	Port 2 Condition
BothPortsAndLink	Red	Red	Gray
PortsOnly	Red	Gray	Gray
LinkOnly	Gray	Red	Gray

NOTE
If the Suppress Linked Port Alarms setting is set to TRUE, then the alarm on the upstream port will be suppressed, even if Link Fault Disposition is set to BothPortsAndLink. If Link Fault Disposition is set to Ports Only, and the Suppress Linked Port Alarms setting is set to TRUE, DX NetOps Spectrum generates an alarm on the Port model.

Scenario 2: Link Goes Down, Device B Remains Reachable

LinkFaultDisposition	Port 1 Condition	WA_Link Condition	Port 2 Condition
BothPortsAndLink	Red	Red	Red
PortsOnly	Red	Gray	Red
LinkOnly	Gray	Red	Gray

NOTE
If the Suppress Linked Port Alarms setting is set to TRUE, then only one of the ports is alarmed (red). The other port will be suppressed (gray). If Link Fault Disposition is set to Ports Only, and the Suppress Linked Port Alarms setting is set to TRUE, DX NetOps Spectrum generates an alarm on the Port model.

Wide Area Link Modeling Best Practices

When you model a Wide Area Link, be sure to supply the IP address for the Network_Address parameter. As a best practice, supply values for the WA_Link model Network_Address and Network_Mask attributes based on the subnet of the connected router interfaces. In a proxy environment, the "real" and "proxy" links must have the same value for Network_Address.

DX NetOps Spectrum relies on the Network_Address (0x12d7f) attribute of a WA_Link to find duplicate WA_Link models and to collapse proxies into a single icon.The Network_Address is the only unique attribute that can be used to find duplicate WA_Links. However, this attribute is not automatically populated by DX NetOps Spectrum unless the WA_Link models are created by Discovery. When you manually create WA_Links, the Network_Address and Network_Mask attributes are not automatically populated, even when they are connected to router interface models with valid IP addresses.

In our testing, we have found that the Global Collection topology view does not collapse proxied WA_Link models correctly if the Network_Address parameter is not configured.

Set the Network_Address attribute of the WA Link model to the network ID of the subnet to which the interface belongs. For example, a serial interface has an IP address of 10.253.9.2 and a subnet mask of 255.255.255.252. Set the Network_Address attribute of the WA Link to 10.253.9.0 (10.253.9.2 with subnet mask 255.255.255.252).

In addition, do not simply draw pipes between the router and WA_Link icons. Proper WA_Links require a nested WA_Segment. In addition, an interface model on each router must be connected to the WA_Segment (and not to the WA_Link). This modeling paradigm enables DX NetOps Spectrum to establish fully resolved connections. It also enables the proper display of pipes in the Global Collection topology view.

Port Layer Alarm Suppression

Devices that support advanced network technologies, such as Frame Relay and Link Aggregation, have logical entries in the ifTable representing higher layer interfaces. DX NetOps Spectrum models these logical layers according to the ifStackTable. If you set the use_if_entity_stacking (0x12a83) attribute to TRUE on a device model in the Attributes tab, DX NetOps Spectrum attempts to use information from RFC2737 (Entity MIB) to model these logical layers if the ifStackTable method fails.

When a monitored higher layer port goes down (such as a Frame Relay DLCI, or logical trunk interface), DX NetOps Spectrum will query the statuses of all lower layer interfaces before alarming the port which went down. If all of the lower layer interfaces are down as well, DX NetOps Spectrum will suppress the higher layer interface alarm. A key example is a

physical Frame Relay interface going down which has multiple circuits provisioned on it. All of the higher layer DLCI port models will be suppressed, and the single red alarm will exist on the physical Frame Relay interface.

Port Criticality

You can assign a relative importance value to port models using the port criticality (0x1290c) attribute. The criticality of a port is used in the Impact Severity calculations of an alarm on any port which may cause a network outage. You can also display the criticality of a port in the Alarms tab to allow prioritization of port alarms. The port criticality attribute can be set for an individual port from the port model's Attributes tab.

Live Pipes and Fault Management

Live Pipes functionality lets you turn on port status monitoring for individual links and display the status of a link by using status color indicators. A link is a connection between two devices that DX NetOps Spectrum has resolved to the port level. Live Pipes display a combined condition color from the two resolved ports representing each side of the link.

When a pipe is deleted, DX NetOps Spectrum removes all of its underlying associations (such as links_with and connects_to). If the pipe being deleted represents more than one link, DX NetOps Spectrum asks you to confirm the deletion.

Enable or Disable Live Pipes System-Wide

Live Pipes are enabled system-wide by default. Without Live Pipes enabled on a system-wide basis, enabling Live Pipes for individual links is not available.

To enable or disable Live Pipes system-wide

1. Expand the Live Pipes subview in the VNM model's Information tab.
2. Click 'set' in the Live Pipes field and select Enabled or Disabled from the drop-down list as desired.

Enable or Disable Live Pipes on Individual Links

Live Pipes for individual links are disabled by default. All individual pipes are gold or silver until Live Pipes are enabled. When an individual live pipe is enabled, the ok_to_poll (0x11dd8) attribute is set to TRUE for both ports that are involved in the link. The status of the linked ports is monitored if ok_to_poll is TRUE and the port status polling conditions in the Port Status Polling Criteria section are met.

You can enable a live pipe for an individual link.

Follow these steps:

1. Right-click the link that you want to enable as a live pipe, and select 'Enable/Disable Live Links.'
2. Select the check box for the link to enable and click OK.
   The Enable/Disable Live Links dialog closes. The link that you selected is enabled as a live pipe.

Receiving Port Alarms

To receive alarms on a port model, the following conditions must be met:

- Live Pipes must be enabled system-wide
- Live Pipes for the link of interest must be enabled separately

> **NOTE**
> If there is no model on the other side of the link, an alarm can still be generated when the status of the link changes by setting a watch on the MIB-II ifOperStatus attribute. When the ifOperStatus attribute returns a

value other than 1, an alarm is generated. With this method, an alarm can still be generated even if the port is intentionally down (the ifAdminStatus attribute has been set to OFF).

You can set the default value of ok_to_poll in the MTE for any port model type. When a port connection is made, DX NetOps Spectrum will set both ports' ok_to_poll attributes to their MTE default values so that the pipe will automatically become live if the you want. When the connection is removed, the value for ok_to_poll remains at the MTE default value.

When DX NetOps Spectrum notices a change in the link's status, it will generate one of the events and alarms listed in Port Status Events and Alarms on the two ports involved in the link, and will also change the color of the live pipe to reflect its new status.

Port Status Monitoring Settings

The settings described in the following table let you to control the service of Live Pipes. These settings appear in the VNM model's Information tab, Live Pipes subview.

Note: The settings described in this section apply to port status monitoring throughout DX NetOps Spectrum, not just ports associated with Live Pipes.

- **Live Pipes**
  Setting this (global) option to Disabled turns off all pipes in the SpectroSERVER and no status polling will be performed for any ports associated with a pipe. However, any port which also has the PollPortStatus attribute set to TRUE will still be polled for status changes.
  Attribute ID: 0x11df9
- **Alarm Linked Ports**
  Setting this option to TRUE will cause ports with a good status to have a gray alarm generated on it when linked with a bad or unreachable port.
  Attribute ID: 0x11fbd
- **Suppress Linked Port Alarms**
  Setting this option to TRUE causes ports with a bad status to suppress their red alarms and generate a gray alarm if either the linked port or the connected device is bad or unreachable. Only one port in the link will be alarmed red. The other will be gray.
  Attribute ID: 0x11fbe
- **Port Always Down Alarm Suppression**
  Enabling this option will cause DX NetOps Spectrum to suppress red alarms and assert a gray condition if a port has always been down since first being modeled in DX NetOps Spectrum.
  Attribute ID: 0x12a03

  NOTE
  Any port status alarm will be automatically cleared by DX NetOps Spectrum if the port's ok_to_poll and PollPortStatus attributes are both set to FALSE.

Monitoring Physical and Logical Connections

DX NetOps Spectrum can monitor the related physical connections of multilink bundles that are resolved to the logical connection via a Live Pipe. When Live Pipes are enabled on the logical connection, the physical ports on one side of the multilink bundle are polled. If Live Pipes are disabled, the polling on the associated physical ports are stopped.

NOTE
You may need to configure the MultiLinkVirtualIfTypes (0x12e3d) attribute to contain the list of ifType values for multilink bundles for which DX NetOps Spectrum should also poll the related physical connections. This attribute is pre-configured with the pppMultilinkBundle (108) ifType.

To avoid creating multiple alarms when a single physical connection goes down, DX NetOps Spectrum only polls the physical connections on one side of the multilink bundle. The side that is polled is determined by reading the Criticality (0x1290c) attribute for the logical connections and choosing the side with the higher value. If the values are equivalent,

the connection with the lowest model handle is chosen. Also, the NetworkLinkType (0x12a79) attribute on the physical port models on the side that is polled is set to the same value of the NetworkLinkType attribute of the multilink virtual interface model.

The polling of the non-resolved physical ports on one side of the multilink bundle results in the following alarm behaviors:

- An alarm is generated on a physical port model whenever a physical connection that is part of a multilink bundle goes down.
- If the logical connection is down and at least one of the related physical connections is up, an alarm is generated on a multilink virtual interface model.
- If all of the physical connections are down and the logical connection also goes down, the logical interface is put into the suppressed (grey) state.

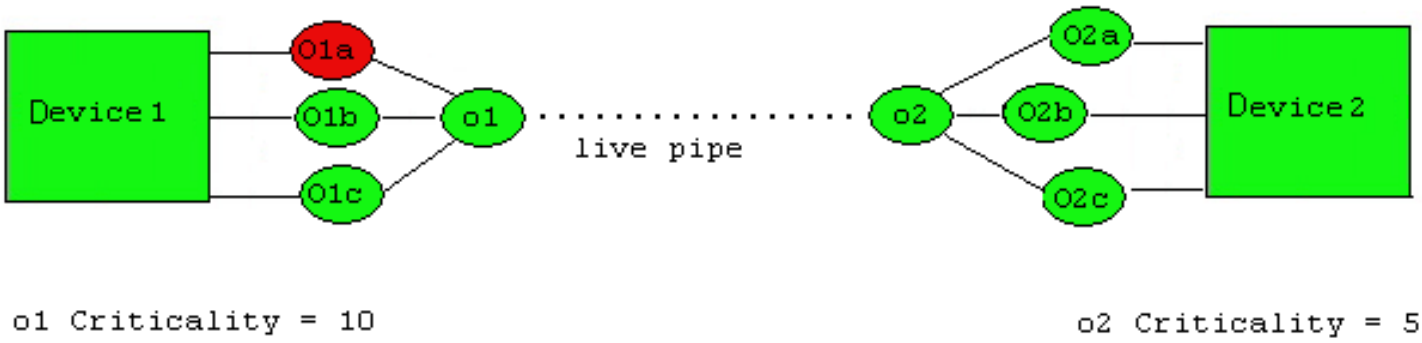
> **NOTE**
> The physical ports on the side that is not being polled remain in the green state at all times, unless some other type of monitoring has been enabled on them.

Examples: Monitor Physical and Logical Connections

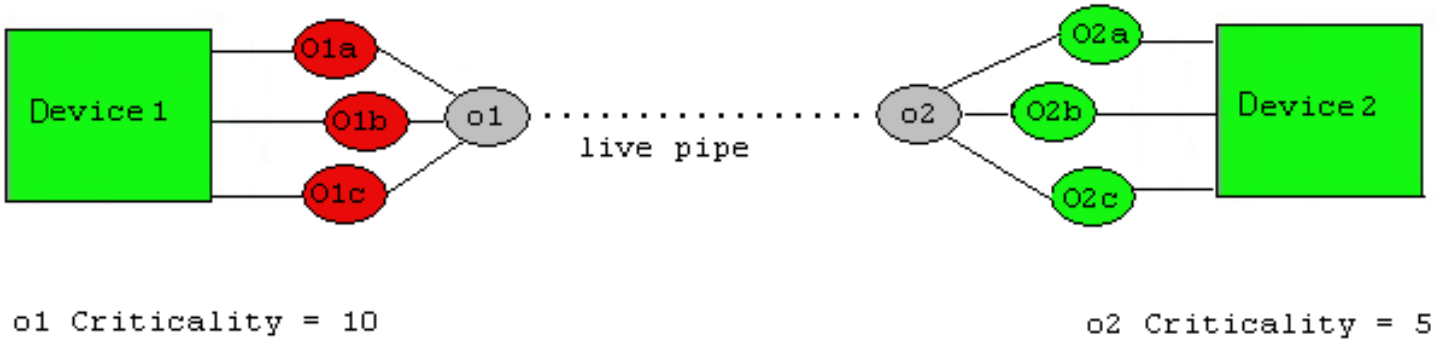
In the following examples, two devices are connected through a multilink bundle of three pairs of physical port links. “O” represents a physical port and “o” represents a logical interface. Live Pipes are enabled on the logical connection between the multilink bundles. There are physical connections between O1a and O2a, O1b and O2b, and O1c and O2c, but these connections are not resolved in DX NetOps Spectrum.

When Live Pipes are enabled on the logical connection between the multilink bundles, the three physical ports on Device 1 (O1a, O1b, O1c) are also polled because o1’s Criticality (10) is greater than o2’s Criticality (5).

If the physical connection between O1a and O2a goes down, an alarm is generated on port O1a and port O2a remains green:



If all three physical connections are down, alarms are generated on ports O1a, O1b, and O1c, ports O2a, O2b, and O2c remain green, and logical connections o1 and o2 are put into a suppressed state:



Suggested Port Fault Settings for Optimal Fault Notification

In SPECTRUM 7.0 and later, the default settings for both Suppress Linked Port Alarms and Port Fault Correlation have changed. The default value of Suppress Linked Port Alarms has changed from FALSE to TRUE. This setting will suppress red alarms on ports that are connected to another down port or unreachable device. The default value of Port Fault Correlation has been changed from Management Neighbors Only to All Connected Ports. This eliminates the need for you to manually configure management neighbors before a fault occurs so that port fault correlation will work properly. If you have not previously used ‘Management Neighbors’ you will not need this setting.

> **NOTE**
> Setting Suppress Linked Port Alarms to FALSE and Port Fault Correlation to Management Neighbors Only will approximate the fault notification behavior of SPECTRUM 6.6 with Service Pack 3.

CA recommends changing the default setting for Link Fault Disposition on WA_Link models. The default setting of BothPortsAndLink will result in multiple alarms if the link fails. Consider changing the setting to Link Only or Ports Only. Link Only is best in environments where the name of the WA_Link models or notes on these models is meaningful. Changing the setting to Ports Only may be better if fault notification consistency is most important. That is, regardless of the topology, you would prefer an alarm on a port model if there is a link failure.

Device Criticality

The Device Criticality setting, accessible from a device model’s Attributes tab, specifies the relative importance of the device within the network being modeled. When DX NetOps Spectrum loses contact with the device, this value is summed for the device itself and all of its downstream neighbors for which a gray condition is now being asserted (because their actual status cannot be determined). The aggregate device criticality value is displayed as the Impact Severity value of the associated alarm in the alarm’s Impact tab. The default value for all devices is “1”; you can increase this value as desired depending on how important you consider the device to be; the higher the number, the more critical the device is to the network.

Configuring Fault Management for Pingables

Device fault isolation is faster and more reliable when device models have knowledge of each other as neighbors. When a fault occurs, each device model that is lost sends an ARE_YOU_DOWN action to all of its neighbor models. Depending on the answers that neighbor device models send, the lost models either turn gray or red.

Establish neighbor relations by creating a Connects_to association between a device model and the port model of another device. The act of pasting a device model on the interface of another device model adds each device model to the other's neighbor list.

Pingable models lack ports. As a result, in older versions of DX NetOps Spectrum, neighbor associations could not be established for Pingable models without the use of an inferred connector, like a Fanout. However, it is a best practice to create a relationship between models that is resolved directly. Placing both neighbor models in a Fanout means that fault resolution occurs indirectly. Fanouts and other inferred connector model types resolve faults differently and less directly during fault isolation.

Connect Pingable Models

You can connect Pingable models to each other in the topology view. Connect models to create a Connects_to association between them and receive more status information. You can connect Pingable models using one of the following methods:

- Establish neighbors by drawing pipes between device models. Drawing a pipe between two Pingable models establishes a Connects_to association between the two models, making them neighbors.
- You can create a Connects_to association between two Pingable models using the DX NetOps Spectrum Command Line Interface. Use the following syntax:

```
./create association rel=Connects_to
lmh=<model handle of Pingable A>
rmh=<model handle of Pingable B>
```

When the Connects_to association is established, you see a gold pipe between the two connected models. When a fault occurs, each Pingable model sends the other an ARE_YOU_DOWN action.

Mapping Traps from Other Models to Pingable Models

You can map traps from multiple IP addresses to a single pingable model using the Command Line Interface (CLI) update command. You create the mapping by adding the IP addresses to the deviceIPAddressList (0x12a53) attribute on the pingable model.

Before you can specify the mapping, you must add the following option to the .vnmrc file if the option is not already included in the file:

```
enable_traps_for_pingables=TRUE
```

You can also remove mappings with CLI, and you can configure OneClick to display IP addresses mapped to Pingable models.

To map traps from other IP addresses to a pingable model

1. Connect to the SpectroSERVER with CLI.

   NOTE
   For more information about using CLI, see the Command Line Interface section.
2. Invoke the update command:

   ```
   ./update
   ```
3. Add additional IP addresses to the deviceIPAddressList attribute (0x12a53) for the Pingable model you want to designate as a trap destination. The following example shows three IP addresses added to the attribute:

   ```
   update mh=<pingable's mh> attr=0x12a53,iid=10.253.8.34,val=0
   update mh=<pingable's mh> attr=0x12a53,iid=10.253.8.65,val=0
   update mh=<pingable's mh> attr=0x12a53,iid=10.253.9.17,val=0
   ```
4. Verify that the IP addresses were added:

   ```
   show attributes attr=0x12a53 mh=<pingable's mh>
   ```

Enable a Device IP Address View for a Pingable in OneClick

If the Device IP Address List category is not included under the Information tab for Pingables, complete the following procedure.

To enable a Device IP Address view for a Pingable in OneClick

1. Open the view-pingabledetails-config.xml file located in the following directory:

   ```
   <$SPECROOT>/tomcat/webapps/spectrum/WEB-INF/topo/config/
   ```
2. Uncomment the following line:

   ```
   <field-subview idref="devipaddrlist-subview-config"/>
   ```
3. Restart OneClick.
   The Device IP Address List category appears under the Information tab for Pingable models. If you map IP addresses to a pingable model, the addresses appear in the list.

Remove an IP Address Mapping from a Pingable Model

When addressing schemes change in your environment, keep model information up to date. Use the DX NetOps Spectrum Command Line Interface (CLI) to remove an IP address mapping from a Pingable model.

Follow these steps:

1. Connect to the SpectroSERVER with CLI.

   NOTE
   See the Command Line Interface section for more information about using CLI.
2. Invoke the update command:
   ```
   ./update
   ```
3. Remove the IP address from the deviceIPAddressList attribute (0x12a53).
   ```
   update mh=pingable mh attr=0x12a53,iid=10.253.8.65,remove
   ```
4. The following example shows one IP address removed from the attribute:
   Verify that the IP address was removed:
   ```
   show attributes attr=0x12a53 mh=pingable mh
   ```

Pingable Model Names

Pingable, or non-SNMP managed, device models are defined in Spectrum as devices capable only of communication through Ping.

The Model Naming configuration that controls how Spectrum determines the names of models it creates is found on the VNM model for each Landscape. It is found in the VNM models Information tab, in the SpectroSERVER Control section.

The primary two configurations that impact model naming are:

- Use Fully Qualified Host Name
- Model Naming Order

User Fully Qualified Host Name has a Yes or No setting. If a devices name is device.company.com, if that is set to Yes, it will be named with, device.company.com

If that is set to No, it will be named with **device**. The default setting is No. Model Naming Order default settings are:

- SysName: SysName is obtained from the MIB Object of the device that lists its SysName value
- IP Address: IP Address is the IP Address of the device
- Name Service: Name Service is the DNS name of the device, also found through the 'nslookup <IP_Address> command.

The default Spectrum Naming configuration for determining Model Names noted above will result in Pingable models being named with IP Addresses. If that order is changed after the Pingable models are created, they will be ignored when the 'Reevaluate All Model Names' function is launched and will not be renamed.

There are two other methods of creating Pingable models. The first, the 'Model by Type' option from the Topology tab will also ignore those naming configurations and will create a model named with IP address if the devices name is not specified when setting up the 'Model by Type' option.

The second, Discovery Configurations launched from the Auto Discovery UI, does honor the Model Naming configuration settings. Some examples of model names when using the Discovery configurations are as follows using the example of the device with Fully Qualified Host Name of 'device.company.com':

Model Naming configuration settings:

Use Fully Qualified Host Name = No
Model Naming Order set to:

- IP Address
- Naming Service
- SysName

Pingable model will be created with IP Address as the models name.

Model Naming configuration settings:
Use Fully Qualified Host Name = No
Model Naming Order set to:

- Naming Service
- SysName
- IP Address

Pingable model will be created with 'device' as the models name.

Model Naming configuration settings:
Use Fully Qualified Host Name = Yes
Model Naming Order set to:

- Naming Service
- IP Address
- SysName

Pingable model will be created with 'device.company.com' as the models name.

If you have already discovered the Pingable models prior to properly configuring the Model Naming configuration options and they need to be changed, we are left with two options:

1. Delete and rediscover, through a Discovery Configuration in the Auto Discovery UI, the Pingable models
2. Manually rename the Pingable models

SNMPv3 Support

> **NOTE**
> SNMPv3 standards require a unique engineID for each SNMP entity (or engine). The SNMP engine/application must have its own unique engineID whether it is a manager or an agent. RFC 3414 and RFC 3418 are the official SNMPv3 standards. See the IETF website (http://www.ietf.org/rfc.html) for more information.

SNMPv3 support includes the following:

- Authentication
- Privacy
- 64-Bit Counters

DX NetOps Spectrummodels and concurrently manages devices that support SNMPv1, SNMPv2c, and SNMPv3.

Support for Diffie-Hellman (DH) Profile on SNMP v3
10.4.1 supports the creation of DH profiles on SNMPv3. This ability provides more robust security mechanism during communication. For more information about how to create a DH profile, see the SNMP v3 Profiles Dialog page.

Secure Domain option in the SNMP v3 profile creation

10.3.1 introduces support for a Secure Domain option in the SNMPv3 profile creation dialog. This feature will ensure privacy and security by restricting v3 profile to the particular SDC specified in a Secure Domain option and preventing users from viewing device profiles belonging to other users. Users have to specify the IP address and configure the secure domain for their devices. For more information about the enhanced support for SNMPV3 Profile, refer to the SNMP v3 Profiles Dialog page.

SNMPv3 Authentication

Starting from 10.3, DX NetOps Spectrum allows '/' and ':' in the snmpv3 username, authentication password, and privacy passwords.

SNMPv3 provides the following levels of security: non-authenticated, authenticated, and authenticated with privacy. Authentication in SNMPv3 uses an algorithm to determine if a message is from a valid source. DX NetOps Spectrum supports the SNMPv3 standard for the authentication of messages. You specify an authentication password for a device model when you create it.

When an SNMP packet is converted to SNMPv3, security parameters are added to the SNMPv3 packet that is sent to the device. The SNMPv3 agent on the device checks the authenticity of the message to verify that the packet came from an authorized source.

SNMPv3 data sent from the device to DX NetOps Spectrum also uses similar security parameters. DX NetOps Spectrum receives the packet and verifies its authenticity.

DX NetOps Spectrum supports the following algorithms for authentication:

- MD5 (Message Digest Algorithm): Produces a 128-bit (16 bytes) message digest. This algorithm is the default. You can model a device configured to use MD5, using ‘Authentication with no Privacy’ or ‘Authentication with Privacy.’
- SHA (Secure Hash Algorithm): Produces a 160-bit (20 bytes) message digest.
- SHA256: Produces a 256-bit (32 bytes) message digest.
- SHA512: Produces a 512-bit (64 bytes) message digest.

Enable SNMPv3 Privacy

Privacy in SNMPv3 uses an encryption algorithm to encode the contents of an SNMPv3 packet to verify that it cannot be viewed by unauthorized entities when routed over the network. DX NetOps Spectrum supports the SNMPv3 standard for the encryption of messages. You specify a privacy password for a device model when you create it.

If configured properly, the SNMPv3 message is sent by DX NetOps Spectrum using the password to encrypt the message before it goes out onto the network. The destination device decrypts the data when it receives it. The return data sent from the device toDX NetOps Spectrumis also encrypted.

DX NetOps Spectrum supports the following encryption algorithms for privacy:

- DES: Data Encryption Standard (DES) is a 64-bit standard that encrypts and decrypts data.
- 3DES: Data Encryption Standard (DES) is a 64-bit standard that encrypts and decrypts data three times.
- AES: Advanced Encryption Standard (AES) is a 128-bit standard, cryptographic algorithm that encrypts and decrypts data.
- AES256: Advanced Encryption Standard (AES 256) is a 256-bit standard, cryptographic algorithm that encrypts and decrypts data.

Follow these steps:

1. In the Topology tab of the Contents panel, click Creates a new model by IP

   The Create Model by IP Address dialog opens.

2. Complete the fields as appropriate.
   - **Network Address**
     Specifies the IPv4 or IPv6 address for the device you want to model.
   - **DCM Timeout (ms)**
     Specifies the timeout between retry attempts (in milliseconds).
     Default: 3000 milliseconds (3 seconds)
   - **DCM Retry Count**
     Type the number of times that the DCM should attempt to send a request to a device that is not responding.
   - **Agent Port**
     Specifies the SNMP agent port.
     Default: 161
3. Select the SNMP v3 option in the SNMP Communications Options section.
   The SNMP Community String field becomes disabled.
4. Click Profiles to create a new SNMPv3 security profile.
   The Edit SNMP v3 Profiles dialog opens.

   NOTE
   The Edit SNMP v3 Profiles dialog is also accessible by clicking Profiles in the Configuration tab in the Discovery Console. For more information, refer to Edit SNMPv3 Profiles dialog.

64-Bit Counters

The SNMPv3 standard provides support for 64-bit counters. DX NetOps Spectrum can access 64-bit counter MIB variables for all SNMPv3 devices that comply with this standard.

SNMPv3 Support Issues

The following are some issues related to SNMPv3 support.

- **get-bulk Command**
  DX NetOps Spectrum support of SNMPv3 does not include the get-bulk command.
- **View Access Control Model (VACM)**
  DX NetOps Spectrum supports the VACM features of SNMPv3, however, VACM is not recommended. DX NetOps Spectrum has features that allow for secure access to devices. If you give DX NetOps Spectrum full view access to all device MIBs, you receive effective monitoring and management performance.
- **Performance and Capacity**
  High processing resources are required for DX NetOps Spectrum to effectively manage SNMPv3 devices. More overhead is consumed using the Authentication and Privacy features due to the time it takes to decrypt and authenticate each message.
  This affects the number of device models that a SpectroSERVER can manage.
- **SNMPv3 Security User Names on SpectroSERVER**
  You cannot use the same user name more than once for the three levels of SNMPv3 (non-authenticated, authenticated, and authenticated with privacy). For example, if you are using the user name “user1” for SNMPv3 level 1 non-authenticated, you cannot use that same user name for SNMPv3 level 2 authenticated or for SNMPv3 level 3 authenticated with privacy.

Edit SNMPv3 Profiles Dialog

The **Edit SNMP v3 Profiles** dialog can be accessed by clicking **Profiles** in the **Configuration** tab in the **Discovery Console** or from the **Create Model** dialogs.

NOTE

For more information on SNMPv3 privacy and authentication options, see SNMPv3 Support.

Configuring the SNMPv3 Profile

1. To add/edit the SNMPv3 profile, do one of the following:
   - From the OneClick Console > Explorer view, right-click **Utilities > Discovery Console** > navigate to the **Configuration** tab > **SNMP Information** section, the select **SNMP v3** option, and click the **Profiles** button.
   - From the OneClick Console > **Contents > Topology** tab, click the create a new model by IP icon  . Select the **SNMPv3** option and click the **Profiles** button.
2. Select the existing profile and click **Modify** to modify a profile, or click **Add** to add a profile.

   NOTE
   This procedure is for non-Diffie-Hellman (DH) profiles creation. For more information about how to create a DH profile on SNMPv3, see the separate section "Support for Diffie-Hellman (DH) Profile on SNMPv3" explained in this article.
3. Enter a name in the **Profile Name** field. This profile name should be unique, for example, for a multitenant configuration, the profile can be <tenantname>_profilename, and in a non-multitenant environment, the profile name can be <SDCIP>_profilename.
4. Enter the same data that has been configured for full MIB access on the device in the **User ID** field.
5. Choose *one* of the following SNMPv3 standard security options from the **Authentication Type** drop-down list:
   - **No Authentication:** Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is not encrypted or authenticated.
   - **Authentication with no Privacy:** Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is authenticated but it is not encrypted.
   - **Authentication with Privacy:** Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is both encrypted and authenticated.

     NOTE
     By default, the MD5 encryption mode option is selected in the **Authentication Protocol** field. If you do not want to use the default option, you can select the SHA, SHA256, or SHA512 encryption option, as appropriate.
6. Select one of the options in the **Authentication Protocol** field:
   - **MD5**
   - **SHA**
   - **SHA256**
   - **SHA512**

     NOTE
     SHA256 and SHA512 are the newly added options in the 10.4.2 release. Ensure that SNMPv3 is enabled on the target device. Also, ensure that the SNMPv3 (SHA256/SHA512) usernames and passwords are created on the target device.
7. Enter a relevant password in the **Authentication Password** field.
8. Re-enter to confirm the password in the **Confirm Authentication Password** field.

   NOTE
   By default, DES authentication option is selected in the Privacy Protocol field. You can select one of the following privacy encryption algorithm options.
9. Select one of the following options in the **Privacy Protocol** field:

- **DES**
- **3DES**
- **AES**
- **AES256**

10. In the **Privacy Password** field, enter the same data that has been configured for a full MIB access on the device.
11. Re-enter to confirm the privacy password in the **Confirm Privacy Password** fields.
12. Click **Add/Modify** to update the profiles list with the new/updated profile you have created.

    NOTE
    10.3.1 introduces support for a secure domain option in the SNMP v3 profile creation dialog. This feature will ensure privacy and security by restricting v3 profile to the particular SDC specified in a secure domain option and preventing users from viewing device profiles belonging to other users. Users have to specify the IP address and configure the secure domain for their devices.
13. Click **OK** to save your changes and close the **Edit SNMP v3 Profiles** dialog.

    NOTE
    Select the **Show Passwords** checkbox to view the authentication password and the privacy password entered for the selected profile.

    WARNING
    If you modify the **User ID** field in the **Edit SNMP v3 Profiles** dialog after your model has connected, you will lose contact with the SNMPv3 device. To regain management of the device, right-click the device model in the **Topology** tab of the **Contents** pane, and click **Reconfiguration, Reset SNMPv3 Authentication**.

The following is an example screenshot:

Support for Diffie-Hellman (DH) Profile on SNMP v3

DX NetOps Spectrum now supports the creation of DH profiles on SNMPv3. This ability provides more robust security mechanism during communication.

Create DH Profiles

To create a DH profile, enable the required option and then provide the relevant information. By default, the option to create a DH profile is not selected.

NOTE
Unmanaged traps are not supported on DH profiles.

Follow these steps:

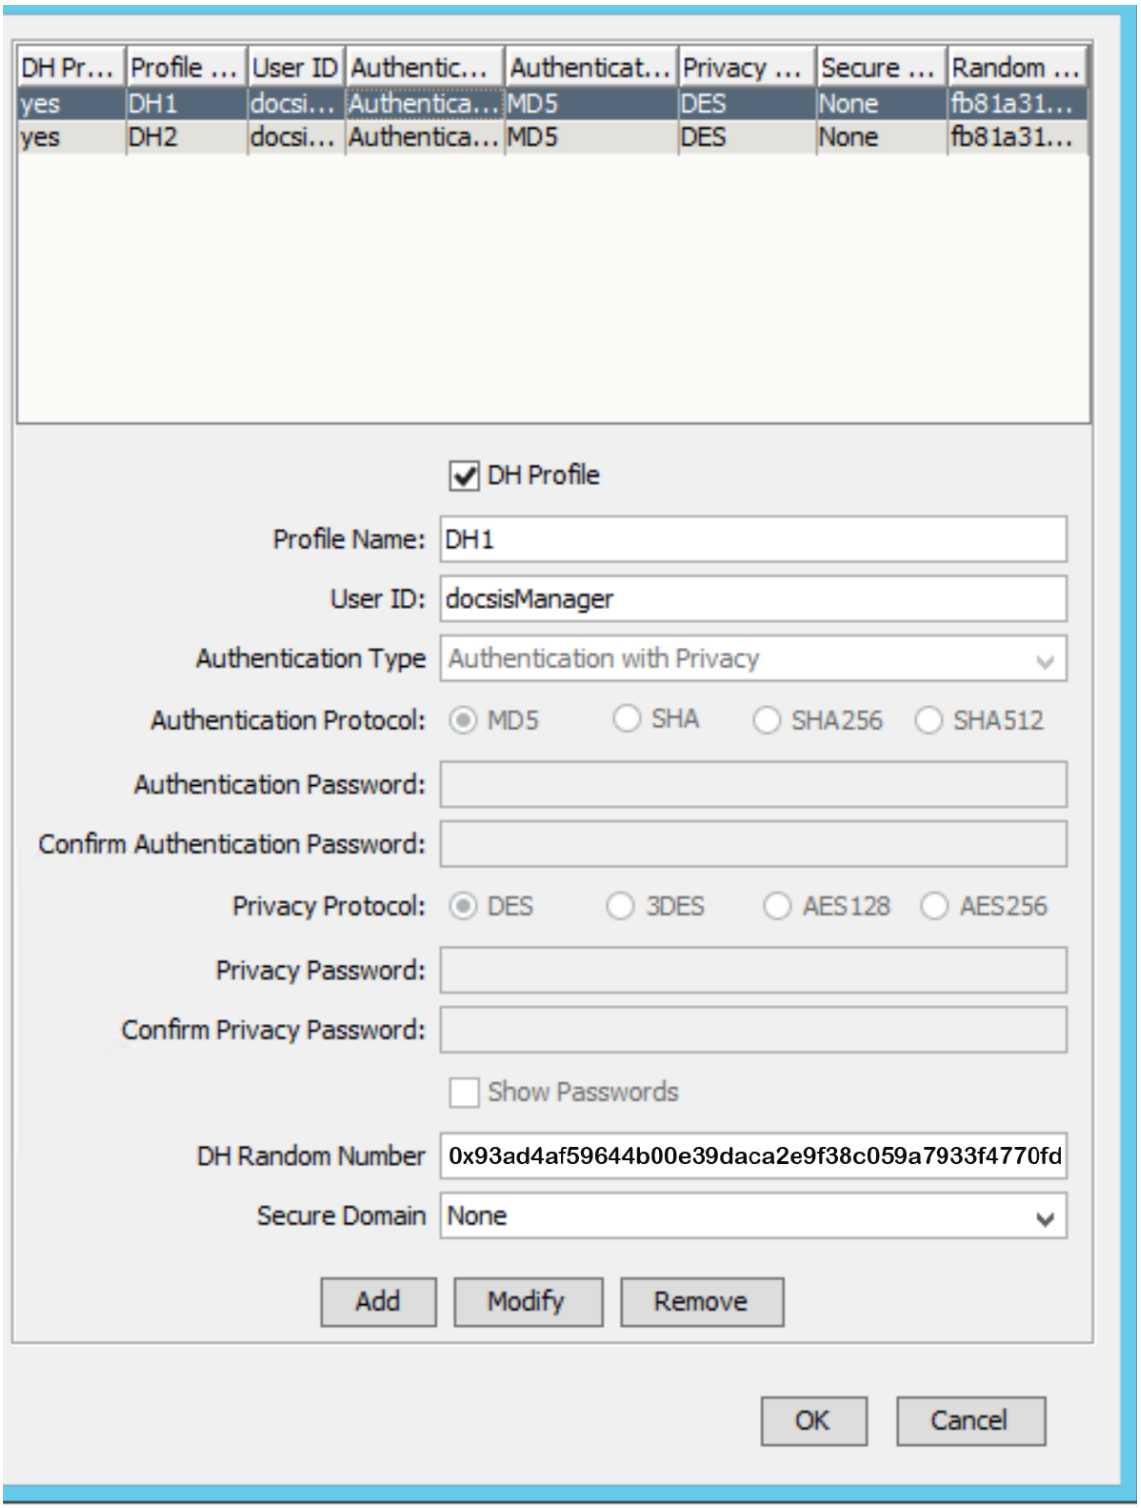
1. In the OneClick Console, click the **Explorer** tab.
2. Right-click in the left pane and select the **Utilities, Discovery Console** option from the context menu.
3. Navigate to the **Configuration** tab, **SNMP Information** section.
4. Select the **SNMP v3** option and click the **Profiles** button.

   NOTE
   When the DH Profile option is enabled, the following fields are disabled and their values are changed automatically:

   - **Authentication Type:** The value is changed to *Authentication with Privacy*.
   - **Authentication Protocol:** The value is changed to *MD5*.
   - **Privacy Protocol:** The value is changed to *DES*.
5. Enable the **DH Profile** option. When this option is enabled, only the following fields are available for entering the information:
   - **Profile Name**
   - **User ID**
   - **DH Random Number**

     NOTE
     The DH random number value must be 256 bits and must start with 0x. An example value is as follows:
     `0x93ad4af59644b00e39daca2e9f38c059a7933f4770fdb648a7e3bcc9c7959c2804cd85f3b4f8a05d70`
   - **Secure Domain**
6. Click **Add** to add the profile
7. Click **OK**.

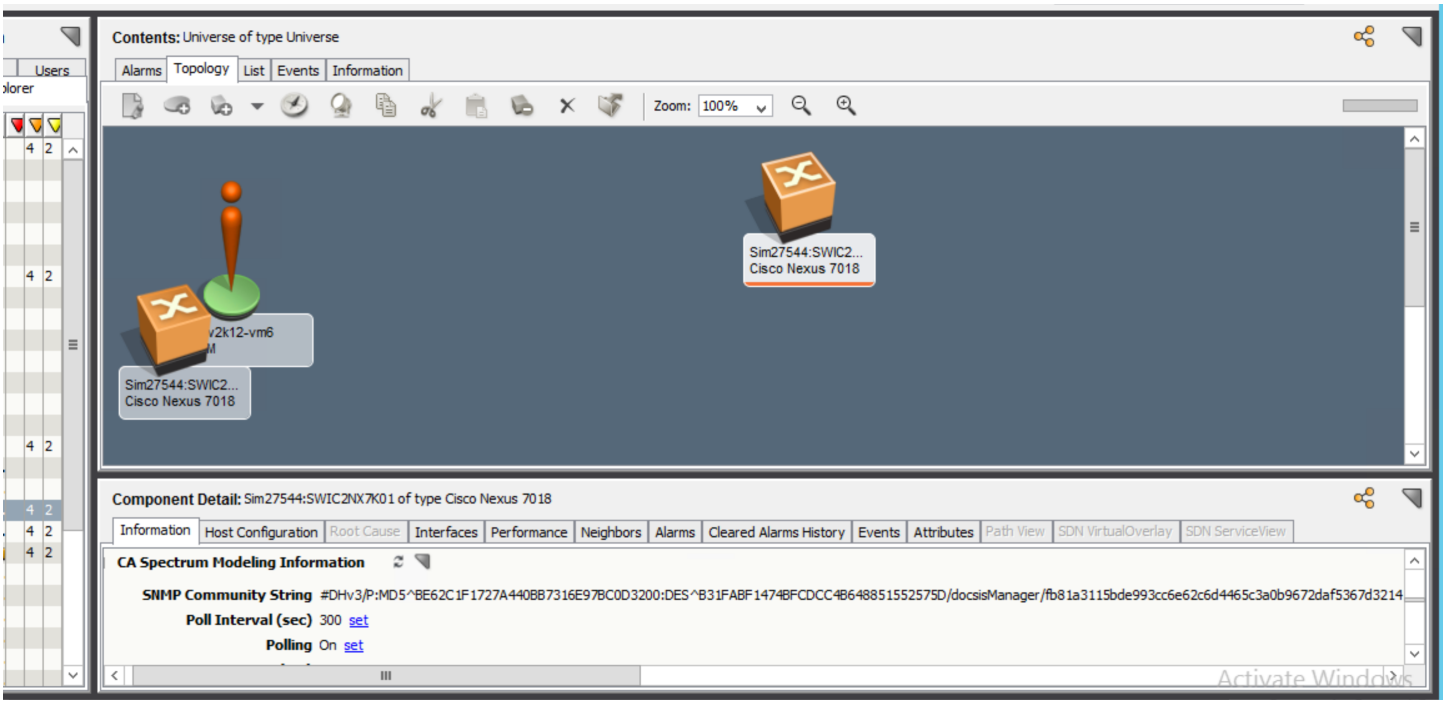
The DH profile is successfully created on SNMP v3. The following 10.4.1 screenshot shows a created DH profile:



After a DH profile device is modeled, the DH SNMPv3 community string will include the following parameters:

- Protocol type (*DH*)
- Authentication type (*MD5*)
- Authentication key
- Privacy protocol (DES)
- Privacy key
- User name
- DH random number

The following screenshot shows the required information:



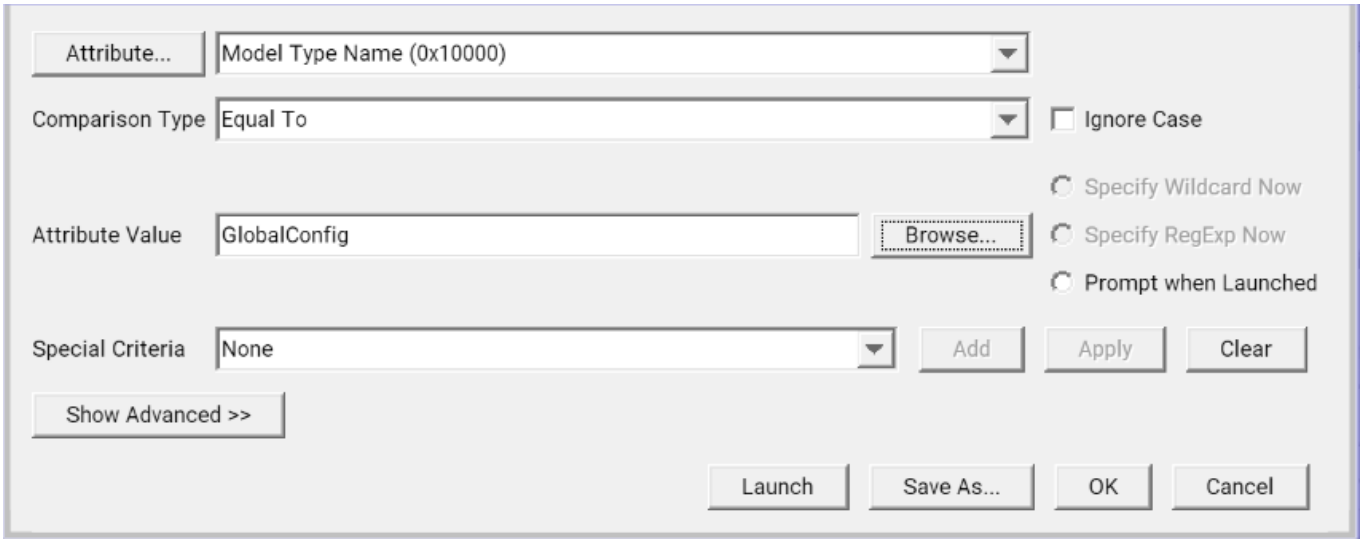
NOTE
If an agent on a device is restarted, then the authentication key and the privacy key will be changed because the public number of the device will get changed. In this case, SpectroSERVER automatically calculates the new authentication key and the privacy key to communicate with the device.

Edit G and P Values on a DH Profile

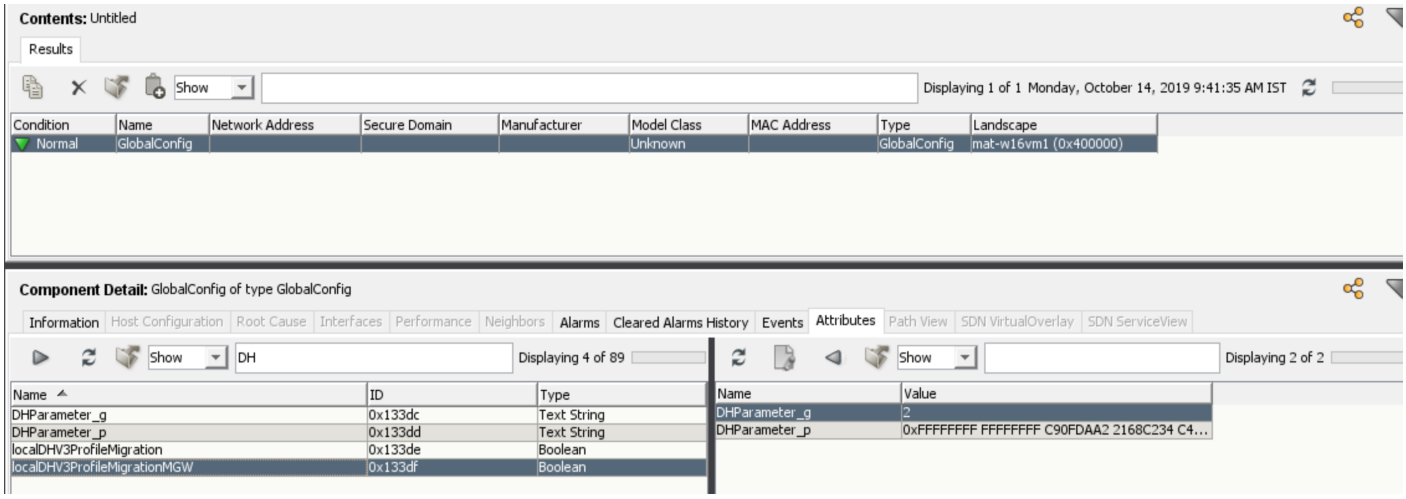
You can edit the G and P values on a DH profile based on your requirements.

Follow these steps:

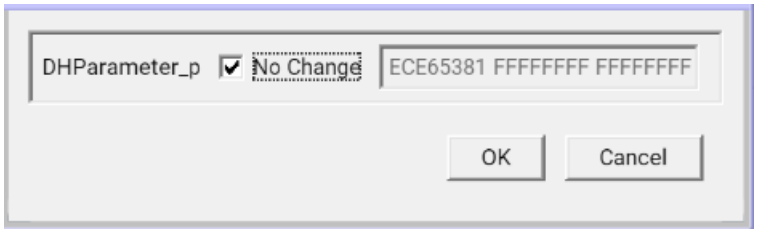
1. Access the OneClick console.
2. Navigate to the **Locater** tab.
3. Click the **Create a new search** icon and enter the information as follows:
   a. Select **Model Type Name (0x10000)** from the **Attribute** drop-down list.
   b. Verify that the value in the **Comparison Type** field is set to **Equal To**.
   c. Select **GlobalConfig** from the **Attribute Value** drop-down list.
   The following screenshot shows the required information:



4. Save the new search.
5. Launch the newly created search.
6. Select the result that is displayed in the **Results** tab in the right pane.
7. Click the **Attributes** tab and search for DHParameter_g and DHParameter_p.
   The parameters are listed in the table. The following screenshot shows the required information:



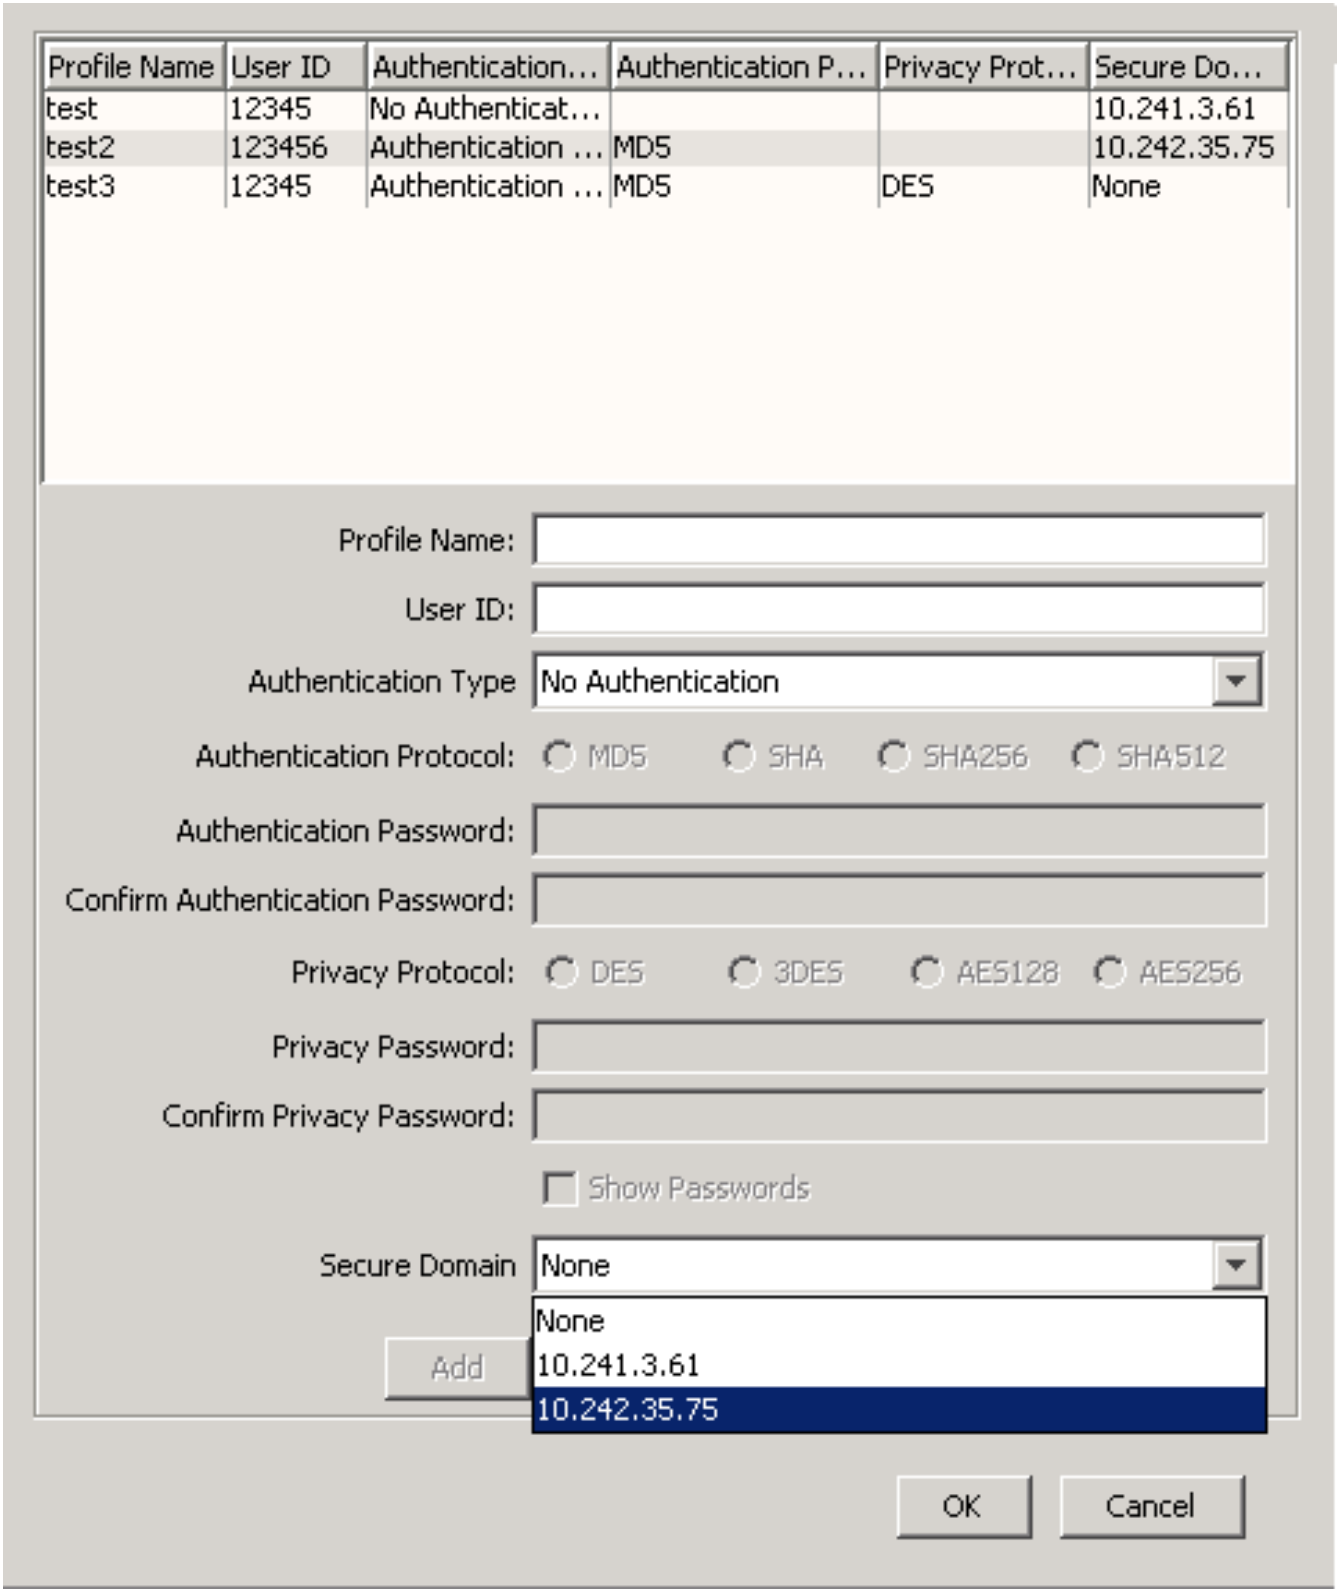
8. Double-click the required parameter (in the right pane) to edit its value and click **OK** to save it. The following screenshot shows the required information:



The values are changed accordingly.

Secure Domain Option

10.3.1 introduces support for a 'Secure Domain' option in the SNMPv3 profile creation dialog. This feature will ensure privacy and security by restricting v3 profile to a particular SDC specified in the **Secure Domain** option and preventing users from viewing device profiles belonging to other users. Users have to specify the IP address and configure the secure domain for their devices. Here is a 10.3.1 screenshot of the SNMPv3 profile creation dialog with the newly added **Secure Domain** option.



To create a v3 profile, specify the IP address of a secure domain along with the other v3 information. If you select **None**, then the corresponding profile pushes all SDCs connected to the landscape. Otherwise, the profile will be unicasted to

a secure domain mentioned in the v3 profile. To model a device with SNMPv3, the selected secure domain option in the CreateModelByIP/ Discovery Console panel should be the same as the secure domain specified in v3 profile.

NOTE

If the selected v3 profile has a secure domain option **None**, then the device can be modeled through any of the selected SDC.

If the SNMPV3 profiles are present in a prior version of the product, then after upgrading to 10.3.1, all these profiles are updated with the **None** option in the **Secure Domain** field. These profiles are broadcasted to all the connected SDCs.

Dump and Reset v3 Profiles at SDC

To dump local and remote profiles at SDC, 0x10337 action can be used on the SDC model handle. Profile details are dumped at “snmpv3profiledump.txt” in the SDConnector/bin folder under SDC. Similarly, to reset all remote profiles at SDC, 0x10336 action can be used.

Troubleshooting

- For unmanaged v3 trap processing, if the trap destination is SDC, then there must be a local profile created at SDC.

Manually Model an SNMPv3 Device

You can manually model SNMPv3 devices and set up new profiles using the Create Model by IP functionality in DX NetOps Spectrum. You cannot model SNMPv3 devices using the Model by Model Type feature in DX NetOps Spectrum.

NOTE
When you discover SNMPv3 devices on Cisco switches with VLANs, you cannot use the community_string@VLAN_ID format to index bridging information for each VLAN. You must create contexts instead. For more information, see the Cisco Device Management section.

Follow these steps:

1. In the Topology tab of the Contents panel, click the Creates a new model by IP icon 
   The Create Model by IP Address dialog opens.
2. Complete the fields as appropriate.
   - **Network Address**
     Specifies the IPv4 or IPv6 address for the device you want to model.
   - **DCM Timeout (ms)**
     Specifies the timeout between retry attempts (in milliseconds).
     Default: 3000 milliseconds (3 seconds)
   - **DCM Retry Count**
     Specifies the number of times that the DCM should attempt to send a request to a device that is not responding.
   - **Agent Port**
     Specifies the SNMP agent port.
     Default: 161
3. Select the SNMP v3 option in the SNMP Communications Options section.
   The SNMP Community String field becomes disabled.
4. Take *one* of the following steps:
   - Select an existing profile from the V3 Profile drop-down list and go to Step 6.
   - Click Profiles to create a new SNMPv3 security profile.

The Edit SNMP v3 Profiles dialog opens.

a. Enter a name in the Profile Name field.
b. Enter the same data that has been configured for full MIB access on the device in the User ID field.
c. Choose *one* of the following SNMPv3 standard security options from the Authentication Type drop-down list:
   No Authentication: Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is not encrypted or authenticated (go to Step 4e).
   Authentication with no Privacy: Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is authenticated but it is not encrypted. Enter the same data that has been configured for full MIB access on the device in the Authentication Password field. Confirm the password (go to Step 4e).
   Authentication with Privacy: Data sent from the DX NetOps Spectrum host system to the SNMPv3 device is both encrypted and authenticated. In the Authentication and Password fields, enter the same data that has been configured for full MIB access on the device (go to Step 4e).
d. Select one of the following options in the **Authentication Protocol** field:
   MD5 (Message Digest Algorithm): Produces a 128-bit (16 byte) message digest.
   SHA (Secure Hash Algorithm): Produces a 160-bit (20 byte) message digest.
e. Enter a relevant password in the **Authentication Password** field.
f. Re-enter to confirm the password in the **Confirm Authentication Password** field.
g. Select one of the following options in the **Privacy Protocol** field:
   - **DES**
   - **3DES**
   - **AES**
   - **AES256**
h. In the **Privacy Password** field, enter the same data that has been configured for full MIB access on the device.
i. Re-enter to confirm the Privacy password in the **Confirm Privacy Password** fields.
j. Click Add to update the Profiles list with the new profile you have created.
k. Click OK to save your changes and close the Edit SNMP v3 Profiles dialog.

5. Select the Discover Connections check box, if appropriate.
6. Click OK in the Create Model By IP Address dialog to accept your selections and close the dialog.
   The model of the SNMPv3 device appears in the Topology tab.

WARNING

If you modify the User ID field in the Edit SNMP v3 Profiles dialog after your model has connected, you will lose contact with the SNMPv3 device. To regain management of the device, right-click the device model in the Topology tab of the Contents panel, and click Reconfiguration, Reset SNMPv3 Authentication.

After you model SNMPv3 devices, you can model the rest of the network using Discovery. Discovery does not overwrite any of the devices that you have already modeled.

Modeling an SNMPv3 Device Using a DX NetOps Spectrum Toolkit

You can use one of the DX NetOps Spectrum toolkits, for example, Modeling Gateway, to create a device model that supports SNMPv3. By default, MD5 is the authentication algorithm that is used and DES is the privacy algorithm that is used. The algorithms can be overridden by the ‘^’ character. Use the following syntax when specifying the SNMP community string for the model.

NOTE

When you want to set the community string with username, authentication and privacy passwords having ':' and '/' following should be used.

Set it using escape(\) for '/' and ':'.
For example if username is Test/user:1, it should be provided as Test\/user\:1 in the community string. Ensure that the profile for Test/user:1 should be already created and existing.

For an SNMP community string that uses both privacy and authentication, use the following syntax:

```
#v3/P:authpassword:privpassword/userid
```

- **authpassword**
  Specifies the authentication password for the device.
- **privpassword**
  Specifies the privacy password for the device.
- **userid**
  Specifies the user ID for the device.

Example 1

```
#v3/P:myAuthPW:myPrivPW/myUserID
```

For an SNMP community string that uses a non-default privacy algorithm (3DES) and a default authentication algorithm, use the following syntax:

```
#v3/P:authpassword:3DES^privpassword/userid
```

- **authpassword**
  Specifies the authentication password for the device.
- **privpassword**
  Specifies the privacy password for the device.
- **userid**
  Specifies the user ID for the device.

Example 2

```
#v3/P:myAuthPW:3DES^myPrivPW/myUserID
```

For an SNMP community string that uses a non-default privacy algorithm (3DES) and a non-default authentication algorithm (SHA), use the following syntax:

```
#v3/P:SHA^authpassword:3DES^privpassword/userid
```

- **authpassword**
  Specifies the authentication password for the device.
- **privpassword**
  Specifies the privacy password for the device.
- **userid**
  Specifies the user ID for the device.

Example 3

```
#v3/P:SHA^myAuthPW:3DES^myPrivPW/myUserID
```

For an SNMP community string that uses authentication only, use the following syntax:

```
#v3/A:authpassword/userid
```

- **authpassword**
  Specifies the authentication password for the device.
- **userid**
  Specifies the user ID for the device.

Example 4

```
#v3/A:myAuthPW/myUserID
```

For an SNMP community string that uses a non-default authentication algorithm (SHA) and no privacy, use the following syntax:

```
#v3/A:SHA^authpassword/userid
```

- **authpassword**
  Specifies the authentication password for the device.
- **userid**
  Specifies the user ID for the device.

Example 5

```
#v3/A:SHA^myAuthPW/myUserID
```

For an SNMP community string that does not use authentication or privacy, use the following syntax:

```
#v3/N/userid
```

- **userid**
  Specifies the user ID for the device.

Example 6

```
#v3/N/myUserID
```

Model an SNMP v2c Device Using a DX NetOps Spectrum Toolkit

To use one of the DX NetOps Spectrum toolkits to create a device model that supports SNMP v2c, use the following syntax when specifying the SNMP community string for the model:

```
#v2/<SNMP community string>
```

- ***<SNMP community string>***
  Specifies the SNMP community string of the device.

Example:

```
#v2/mySNMPcommunitystring
```

Change Security Information for a Device Model

You can change security information for an existing SNMPv3 device model. You can also convert an SNMPv1 device model to an SNMPv3 device model. You must add the appropriate security information to the device model.

Follow these steps:

1. Select the model that you want to modify, and click the Information tab in the Component Detail panel.
2. Expand the DX NetOps Spectrum Modeling Information subview, and click set in the SNMP Community String field.
3. Modify the SNMP Community String using a syntax listed in Modeling an SNMPv3 Device Using a DX NetOps Spectrum Toolkit to create the appropriate string.

   NOTE
   For more information about using CLI commands, see the Command Line Interface section.

Add Context Name Information

You can add the SNMPv3 context name value to be sent with SNMPv3 messages for a particular device.

Follow these steps:

1. Select the model that you want to modify, and click the Information tab in the Component Detail panel.

2. Expand the DX NetOps Spectrum Modeling Information subview, and click set in the SNMP Community String field.
3. Add the context name value to the SNMP Community String field. For example, if the current SNMP community string is:
   ```
   #v3/P:authPass:privPass/myuserid
   ```
4. To insert a context name value of ‘quark,’ add ‘quark’ to the SNMP community string as follows:
   ```
   #v3/P:authPass:privPass/quark/myuserid
   ```

Specify an Authentication Encryption Algorithm on a Per-Model Basis

DX NetOps Spectrum supports both MD5 and SHA authentication encryption, although MD5 is the default. You can specify the alternate encryption algorithm (SHA) by prepending it to the password in the SNMP community string. Prefixing the encryption algorithm on the SNMP community string for a particular device model overrides the default algorithm for that device model only.

To specify a privacy encryption algorithm on a per-model basis

1. In the Topology tab of the Contents panel, click the Creates a new model by IP icon 
   The Create Model by IP Address dialog opens.
2. Complete the fields as appropriate.
   - **Network Address**
     Specifies the IPv4 or IPv6 address for the device you want to model.
   - **DCM Timeout (ms)**
     Specifies the timeout between retry attempts (in milliseconds).
     Default: 3000 milliseconds (3 seconds)
   - **DCM Retry Count**
     Type the number of times that the DCM should attempt to send a request to a device that is not responding.
   - **Agent Port**
     Specifies the SNMP agent port.
     Default: 161
3. Select the SNMP v3 option in the SNMP Communications Options section.
   The SNMP Community String field becomes disabled.
4. Click Profiles to create a new SNMPv3 security profile.
   The Edit SNMP v3 Profiles dialog opens.
5. (Optional) To specify the SHA authentication encryption algorithm, do the following:
   a. Enter a name in the Profile Name field.
   b. Enter the same data that has been configured for full MIB access on the device in the User ID field.
   c. Select Authentication with Privacy from the Authentication Type drop-down list.
   d. Enter the following in the Authentication Password and Confirm Authentication Password field:
      ```
      SHA^<authpassword>
      ```
   e. Enter the privacy password in the Privacy Password and Confirm Privacy Password field.
   f. Click Add to update the Profiles list with the new profile you have created.
   g. Click OK to save your changes and close the Edit SNMP v3 Profiles dialog.
6. (Optional) To specify the SHA authentication encryption algorithm and the 3DES, AES-128, or AES-256 privacy encryption algorithm, do the following:
   a. Enter a name in the Profile Name field.
   b. Enter the same data that has been configured for full MIB access on the device in the User ID field.
   c. Select Authentication with Privacy from the Authentication Type drop-down list.
   d. Enter the following in the Authentication Password and Confirm Authentication Password field:

```
SHA^<authpassword>
```

e. Enter the following in the Privacy Password and Confirm Privacy Password fields:

```
[3DES|AES|AES256]^<privpassword>
```

f. Click Add to update the Profiles list with the new profile you have created.

g. Click OK to save your changes and close the Edit SNMP v3 Profiles dialog.

7. Select the Discover Connections check box, if appropriate.
8. Click OK in the Create Model By IP Address dialog to accept your selections and close the dialog.
   The model of the SNMPv3 device appears in the Topology tab. The authentication and privacy encryption algorithms you specified appear in the SNMP Community String field of the Modeling Information subview for the model. You can also specify a privacy encryption algorithm or an authentication encryption algorithm by clicking set in the SNMP Community field of the Modeling Information subview.

NOTE
The Edit SNMP v3 Profiles dialog is also accessible by clicking Profiles in the Configuration tab in the Discovery Console.

Change the Default Authentication Encryption Algorithm For All Device Models

To change the default authentication encryption algorithm for all device models, modify the ".vnmrc" file.

Follow these steps:

1. Navigate to the following directory:
   <$SPECROOT>/SS/
2. Open the ".vnmrc" file with a text editor.
3. Locate the following line:

```
snmpv3_default_auth_protocol=md5
```

4. To modify the algorithm to use SHA as the default, change the parameter as follows:

```
snmpv3_default_auth_protocol=sha
```

   You have successfully changed the default authentication encryption algorithm.

Specify a Privacy Encryption Algorithm on a Per-Model Basis

DX NetOps Spectrum supports DES, 3DES, AES-128, and AES-256 privacy encryption and uses DES by default. You can specify an alternate encryption algorithm by prefixing it to the password in the SNMP community string. Appending the encryption algorithm on the SNMP community string for a particular device model overrides the default algorithm for that device model only.

To specify a privacy encryption algorithm on a per-model basis

1. In the Topology tab of the Contents panel, click the Creates a new model by IP icon 
   The Create Model by IP Address dialog opens.
2. Complete the fields as appropriate.
   - **Network Address**
     Specifies the IPv4 or IPv6 address for the device you want to model.
   - **DCM Timeout (ms)**
     Specifies the timeout between retry attempts (in milliseconds).
     Default: 3000 milliseconds (3 seconds)
   - **DCM Retry Count**
     Type the number of times that the DCM should attempt to send a request to a device that is not responding.
   - **Agent Port**

Specifies the SNMP agent port.
Default: 161

3. Select the SNMP v3 option in the SNMP Communications Options section.
   The SNMP Community String field becomes disabled.
4. Click Profiles to create a new SNMPv3 security profile.
   The Edit SNMP v3 Profiles dialog opens.
5. To specify the 3DES, AES-128, or AES-256 privacy encryption algorithm, do the following:
   a. Enter a name in the Profile Name field.
   b. Enter the same data that has been configured for full MIB access on the device in the User ID field.
   c. Select Authentication with Privacy from the Authentication Type drop-down list.
   d. Enter the authentication password in the Authentication Password and Confirm Authentication Password field.
   e. Enter the following in the Privacy Password and Confirm Privacy Password fields:
      `[3DES|AES|AES256]^<privpassword>`
   f. Click Add to update the Profiles list with the new profile you have created.
   g. Click OK to save your changes and close the Edit SNMP v3 Profiles dialog.
6. Select the Discover Connections check box, if appropriate.
7. Click OK in the Create Model By IP Address dialog to accept your selections and close the dialog.
   The model of the SNMPv3 device appears in the Topology tab. The privacy encryption algorithm you specified appears in the SNMP Community String field of the Modeling Information subview for the model. You can also specify a privacy encryption algorithm by clicking set in the SNMP Community field of the Modeling Information subview.

NOTE
The Edit SNMP v3 Profiles dialog is also accessible by clicking Profiles in the Configuration tab in the Discovery Console.

Change the Default Privacy Encryption Algorithm For All Device Models

To change the default privacy encryption algorithm for all device models, you must modify the ".vnmrc" file.

To change the default privacy encryption algorithm for all device models

1. Go to the following directory:
   `<$SPECROOT>/SS/`
2. Open the ".vnmrc" file with a text editor and locate the following line:
   `snmpv3_default_priv_protocol=des`
3. Depending on the privacy encryption algorithm you want to set as the default, modify the parameter as follows:
   ```
   snmpv3_default_priv_protocol=3des
   snmpv3_default_priv_protocol=aes (uses AES 128 encryption)
   snmpv3_default_priv_protocol=aes256 (uses AES 256 encryption)
   ```

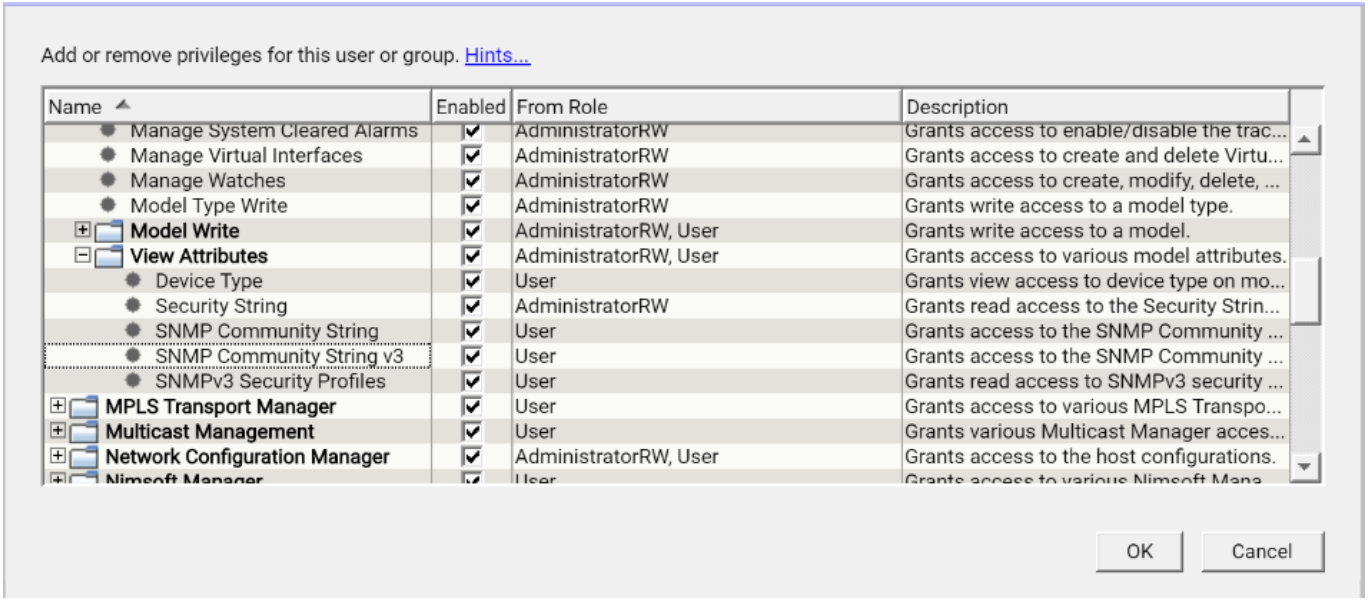
SNMPv3 Community String Access Control

You can control the access to the SNMPv3 community string information on models. You can decide whether you want to display or hide the SNMP v3 community string to specific users. This functionality, therefore, gives you the ability to restrict the display of this information, making it available only to those users who are supposed to view the information.

NOTE
By default, the **SNMPv3 Community String v3** option is enabled. However, if any customization has been done on the options under the **Privileges** section on the lower version of DX NetOps Spectrum for the administrator and operator roles, then after upgrade to 10.4.1, the **SNMPv3 Community String v3** option is displayed as not selected. Furthermore, if no customization has been done, the **SNMPv3 Community String v3** option is displayed as enabled.

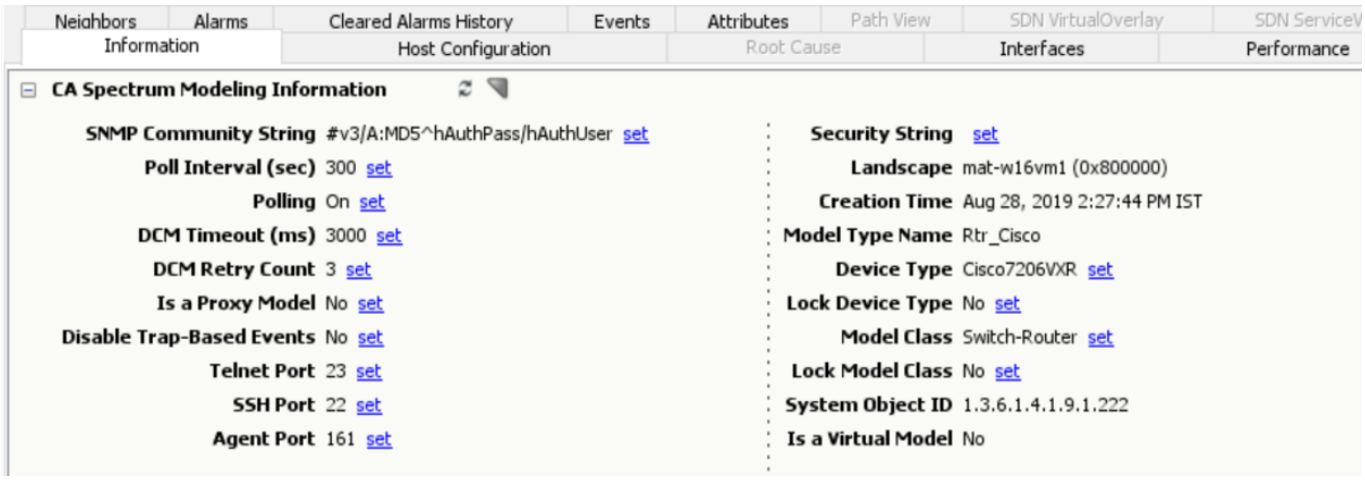
Follow these steps:

1. Access the OneClick interface.
2. Click the **Users** tab in the **Navigation** pane.
3. Locate and select the required user.
4. Click the **Access** tab in the **Contents** pane.
5. Click **Add/Remove** on the **Privileges** tab.
6. Expand **Model Management, View Attributes** to view the options.
   The following screenshot shows the required information:



7. Locate the **SNMPv3 Community String v3** option and perform one of the following actions depending on your requirement:
   – Clear the checkbox.
   This action disables the display of the SNMPv3 community string for the selected user. In this case, the related user cannot see the SNMPv3 community string information; only asterisks (****) are displayed. The following screenshot does not display the community string information:

– Select the checkbox.
This action enables the display of the SNMPv3 community string for the selected user. In this case, the related user can see the information. The following screenshot displays the SNMPv3 Community string information:



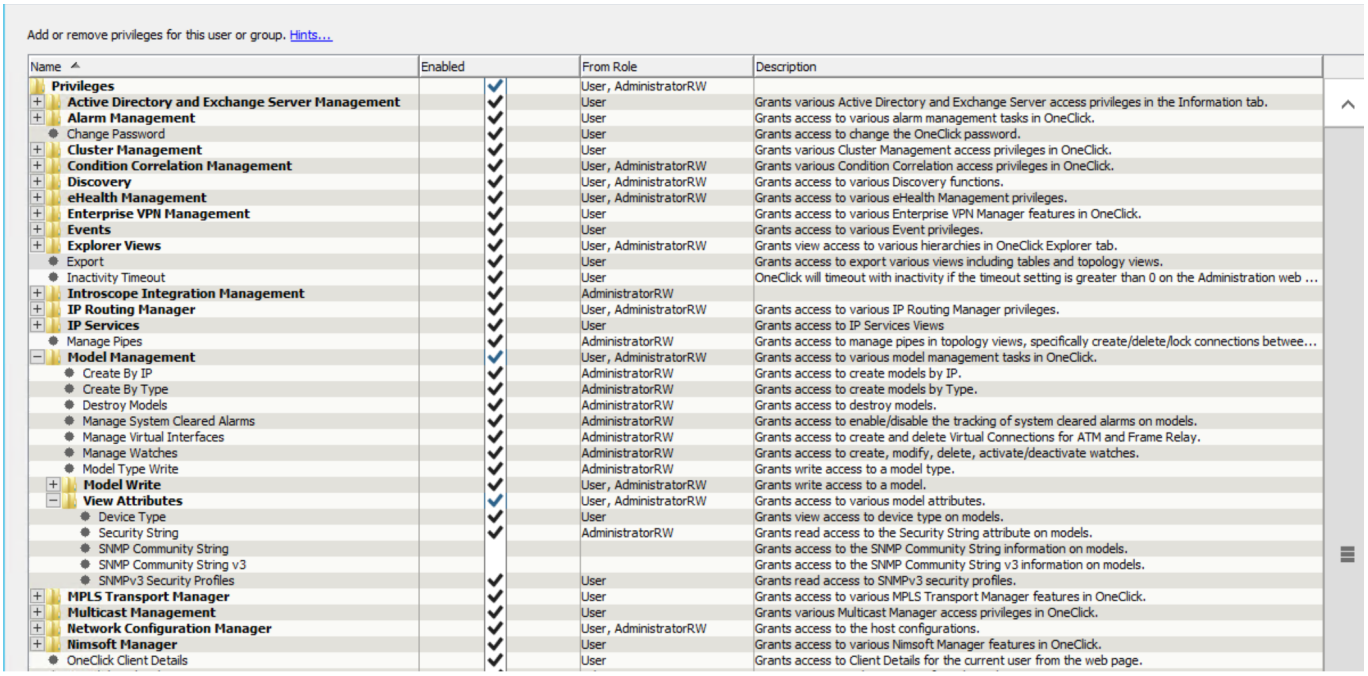
8. Click **OK**.

You have successfully changed the access to the SNMPv3 community string for the required user. Therefore, depending on whether you have enabled or disabled the option, the SNMPv3 community string information is displayed or hidden, as appropriate.

Consideration

If the **SNMP Community String v3** option is disabled (not selected) at the time of upgrading to 10.4.1, then after the upgrade, both **SNMP Community String v3** and **SNMP Community String** will be disabled.

The following screenshot shows the required information. Note that both **SNMP Community String v3** and **SNMP Community String** are not selected:



Troubleshoot SNMPv3 Communication Issues

An error message or alarm is displayed if DX NetOps Spectrum cannot communicate with an SNMPv3 device.

Consider the following:

Is the Device Model's Security Information Correct?

If you changed security information for a particular device model (see), and the new information provided does not match the security information on the device, DX NetOps Spectrum generates an alarm indicating that it cannot contact the device using SNMP.

To troubleshoot this problem, update the security information for the device model to match the information on the device.

What Should I Do When DX NetOps Spectrum Loses SNMPv3 Contact with Cisco Routers After They Have Been Rebooted?

DX NetOps Spectrum can lose communication with Cisco devices, such as Cisco router models like 2621 v12.2 (IOS), 2517 v12.0 (IOS), or 2514 v12.2 (IOS).

SNMPv3 support includes a security feature named replay protection, which guards against SNMPv3 packet deciphering activities over the network. Replay protection checks the following two values on a device whenever a SNMP query is initiated:

- snmpEngineBoots: The number of times the device has rebooted.
- snmpEngineTime: The number of seconds since the snmpEngineBoots counter was last incremented.

DX NetOps Spectrum monitors these values for every device. When SNMP communication is properly occurring, DX NetOps Spectrum and a device are in sync with one another. If a device goes down, DX NetOps Spectrum receives the snmpEngineTime with the value of 0. DX NetOps Spectrum compares the snmpEngineBoots value and, if it has incremented, communication resumes. If the snmpEngineBoots value has not incremented, then DX NetOps Spectrum does not resume communication.

This problem is due to a Cisco IOS firmware bug that will not increment the boot count causing SDManager to stop communication.

To avoid this performance problem, upgrade these routers with the latest Cisco IOS firmware. See http://www.cisco.com for details.

> **NOTE**
> For more information about replay protection, see RFC 3414, section 2.2, Replay Protection.

Previously configured snmpv3 profiles are missing in Spectrum 10.2.2, what is the solution?

Previously configured snmpv3 profiles are missing in the 10.2.2 release, during an upgrade. This issue requires a patch on top of the 10.2.2 version, install the patch to fix the issue. The patch details are **10.02.02.PTF_10.2.208**. The salesforce ID for this issue is 00903607.

Product Intelligence Technology and Capabilities

This section provides information about the various DX NetOps Spectrum Intelligence technology and capabilities:

Inductive Modeling Technology

DX NetOps Spectrum comes with Inductive Modeling Technology™ (IMT), a patented technology that consists of a suite of intelligence circuits which work with the VNM to help configure, manage, and monitor your network.

Static Configuration of Device Models

Many network devices are configured during their manufacturing process and are difficult to modify later. For DX NetOps Spectrum modeling purposes, these devices are considered to have a static configuration--once DX NetOps Spectrum intelligence models these devices, they are not reconfigured. DX NetOps Spectrum creates models for the ports, matching the types of port models to the types of ports on the device, such as T1 or Ethernet. For each port model that is created, an association is established between the port and the device using the HASPART relation and may be viewed within the device model's Interfaces tab. When the model is destroyed, all of the port models associated with the device are also destroyed.

> **NOTE**
> For more information about the Interfaces tab, see the Using OneClick section.

Dynamic Configuration of Device Models

Some network devices can be configured dynamically by removing boards and installing new boards without removing the device from the network. DX NetOps Spectrum intelligence provides for automatic modeling of these devices and their connections upon their creation and then performs verification and remodeling if necessary after each VNM polling cycle. Thus, DX NetOps Spectrum continuously monitors and changes these models to match the actual device on the network.

Whenever a model is created, SpectroSERVER polls the device and creates an appropriate configuration, including the number, type, and order of modules and ports. For each device model created, a relation exists between that model and the parent device via the HASPART model type relation rule. This relation also exists between the boards and any ports on the boards. After each polling cycle, SpectroSERVER re-examines and, if necessary, changes the parent model and its related models to match changes to the device configuration.

Whenever you add a new board to a dynamically configured device, DX NetOps Spectrum creates a model to represent that board and each of the ports on the board. If a board model is destroyed, all of the port models that form part of the board are also destroyed.

Pulled Board List

Creating and destroying models is time consuming. When you remove a board from the device, DX NetOps Spectrum does not destroy the board model, but rather keeps a copy of the board model in a "pulled board list." The board model's HASPART relation to the hub model is removed. DX NetOps Spectrum reassociates this model to the device if you reinstall the old board. If you add a new board to replace the old board, DX NetOps Spectrum associates the new board model to the device and the old board model is placed in the Lost and Found view. If you remove a board model from the pulled board list, the board model is removed from the Lost and Found view and no longer exists.

The following are general pulled board list attributes:

- **Max_Pulled_Bd_Cnt**
  Specifies the maximum number of models allowed to exist in the pulled board list. When this value is exceeded, the oldest model is removed from the list.
- **Pulled_Bd_Cnt**
  Specifies the current number of models in the pulled board list.
- **Pulled_Bd_List**
  Contains a list of board models that have been pulled from a dynamically configured device. When a board is reinstalled in the device, DX NetOps Spectrum removes the board model from the Pulled_Bd_List.

  NOTE
  The Pulled_Bd_List is not readable by the user.

Router Reconfiguration Events

Router reconfiguration actually involves two separate processes: interface reconfiguration, which helps ensure the device's interfaces are properly modeled, and device discovery, which helps ensure proper modeling of other devices, LANs, and so on that are connected to those interfaces. Depending on whether both or either one of these processes occurs, DX NetOps Spectrum generates one of the following events to help you keep track of the configuration changes:

- **ROUTER_RECONFIG_EVENT (0x1001c)**
  This event is generated when a device is reconfigured and both interface reconfiguration and device discovery occur.
- **INTERFACE_RECONFIG_EVENT (0x1001d)**
  This event is generated for a device whenever interface reconfiguration occurs.
- **DEVICE_DISCOVERY_EVENT (0x1001e)**
  This event is generated for a device whenever device discovery occurs such as when connections off the device's interfaces are being rediscovered.

Condition Versus Rollup Condition

DX NetOps Spectrum provides intelligence circuits that let you see changes in your network devices and their performance by simply glancing at the icons that represent them. The icons use color to indicate two different types of status: Condition and Rollup Condition. Condition reflects the contact and alarm status of the modeled device represented by the icon. Rollup Condition is the *composite* status of models that are "children" of the model represented by the icon. (Child models are related to parent models through the "collects" relation in the Topology hierarchy and through the "contains" relation in the Location hierarchy.) The Rollup Condition generally changes as you move up in the hierarchy, because at each level it reflects the blending of the Rollup Conditions from a greater number of individual models.

The location of the Condition and Rollup Condition colors varies according to the type of icon. For device and topology (LAN) icons, Condition is displayed in the diagnostic double-click zone and the Rollup Condition is displayed in the down-

arrow double-click zone for the icon. The circle at the base of location model icons displays either the Condition or the Rollup Condition, whichever is more critical.

The Rollup condition gets updated to the parent models in SDN hierarchy based on the composite condition value. The composite condition is calculated based on alarms on the child models and the configured threshold.

Attributes Determining Condition and Rollup Condition

There is a unique set of attributes that are related to Condition and Rollup Condition. Their values are used in determining Condition and Rollup Condition for models:

- **Condition**
  The Condition attribute value reflects the contact status as well as any more specific alarm in effect for a device model. This value determines the Condition color on topology and location icons as explained in the following table:

Contact Status	Condition	Color	Description
Initial	Initial	Blue	Either the model has not yet established contact with the device it represents, or it represents an insignificant device with which contact has been lost.
Established	Normal	Green	The model has successfully established contact with the device it represents, and the device is functioning normally.
Established	Minor	Yellow	This is the first level of marginal operation. Either the model has successfully established contact with the device it represents but there is an abnormal condition that does not affect overall network operation (perhaps a module has been removed from the device), or the IP address assigned to this model was already assigned to another model.
Lost	Major	Orange	This is the second level of marginal operation. The management agent on the device has failed and is not responding to any communication from DX NetOps Spectrum but the device is still relaying data to its downstream neighbors. This condition occurs only on data-relay type devices such as hubs and is typical of a firmware failure.
Lost	Critical	Red	This condition indicates a total failure of the device and requires management's attention to repair or replace it.

Lost	Suppressed (Unknown)	Gray	Contact has been lost with this device *and* with a device that is upstream from this device (for example, between this device and DX NetOps Spectrum), thus the actual condition of this device is unknown and alarms for the model representing it are suppressed. The gray condition color is also displayed for all models that are downstream from this device. All adjacent (directly connected) models, whether upstream or downstream, will have a contact status of “Lost."
Lost	Maintenance	Brown	DX NetOps Spectrum cannot contact the device because the model has been placed into maintenance mode.

- **Condition_Value**
  Specifies a numeric value that represents a model’s overall condition. This value is passed to a parent model and included in the composite condition. The model’s overall condition is either the condition or the rollup condition, whichever is more severe.

  NOTE
  The condition value indirectly receives the value of the administrator-defined significance level corresponding to a model’s overall condition.

- **Composite_Condition**
  The sum of all condition values for models that are contained by a location model or collected by a topology model.

- **Rollup Condition**
  DX NetOps Spectrum computes the rollup condition attribute value using the administrator-defined rollup threshold and composite condition. The resulting attribute value determines the color that is displayed to indicate the overall condition of models that are contained by a location model or collected by a topology model. The possible colors are:
  - **Green**
    The value of the composite condition attribute for this model’s children is less than the yellow (rollup condition) threshold.
  - **Yellow**
    The composite condition value for this model’s children equals or exceeds the yellow threshold but is less than the orange threshold.
  - **Orange**
    The composite condition value for this model’s children equals or exceeds the orange threshold but is less than the red threshold.
  - **Red**
    The composite condition value for this model’s children equals or exceeds the red threshold.

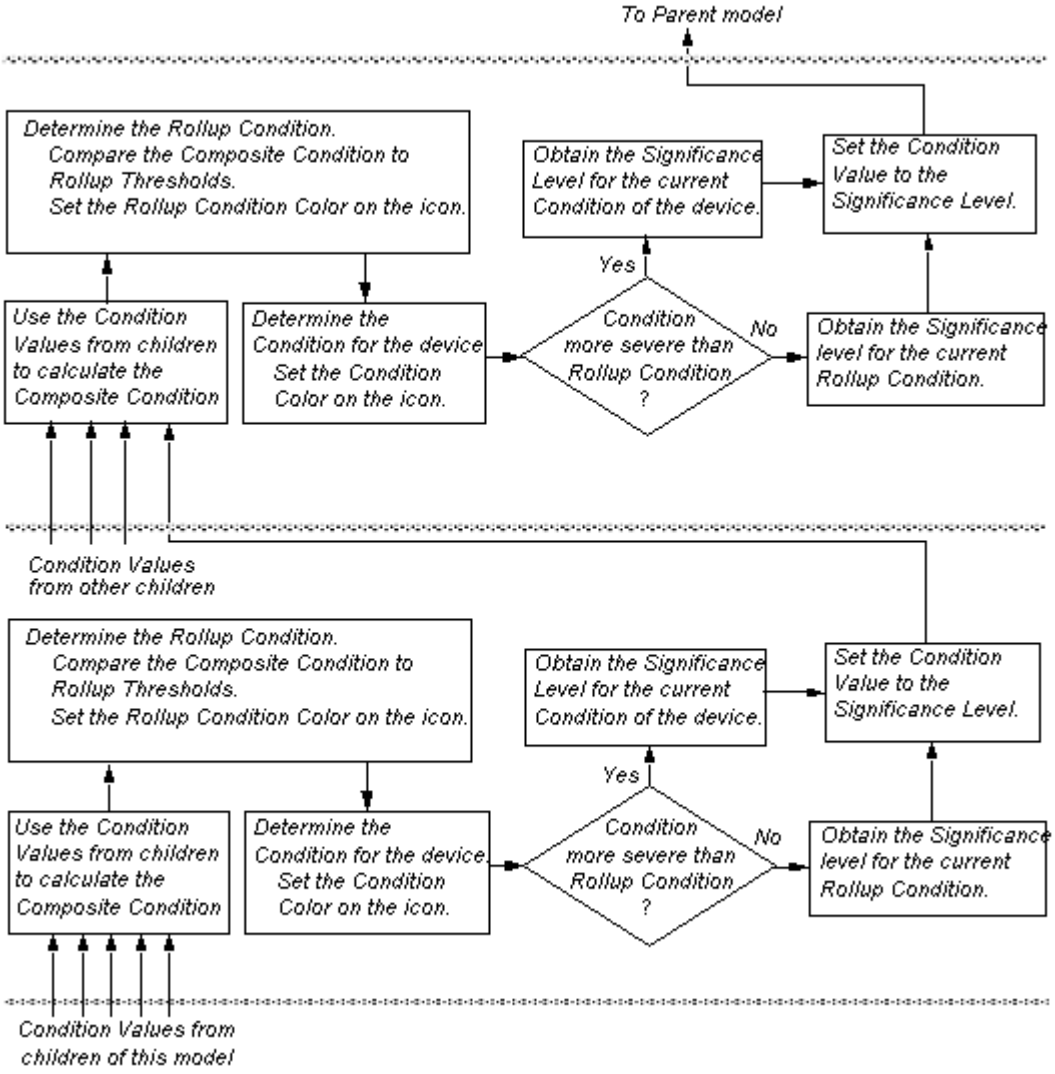
Condition and Rollup Condition Sensitivity

The following two attributes serve as parameters that can be used to emphasize or diminish the impact on rollup condition from the condition values of particular models. By adjusting these attribute values you can control when the rollup condition color changes.

- **Rollup Thresholds**
  The rollup thresholds are the three attributes that control the rollup condition color (yellow, orange, and red) for a model. Rollup thresholds are administrator-defined values that are entered on a model-by-model basis. The composite condition value received from the model's children is compared with these attributes to determine a rollup condition color. For example, if a model's composite condition value is equal to or greater than its orange threshold (but less than its red threshold), the model's rollup condition color is orange.
  The default values for rollup thresholds are:
  – Yellow Threshold = 3
  – Orange Threshold = 6
  – Red Threshold = 10
- **Significance Level**
  The significance level attributes define the numeric value for yellow, orange, and red conditions and rollup conditions. Like rollup thresholds, significance level values are administrator-defined values, and are entered on a model-by-model basis.
  Significance level field labels begin with the words "value when." The default significance level values are:
  – Value_When_Yellow = 1
  – Value_When_Orange = 3
  – Value_When_Red = 7
  Typically, models (devices) are divided into two classes, "significant" or "insignificant." A significant device is any device that requires an administrator's attention for proper network operation. Insignificant devices are typically end-point devices, such as a PC or workstation. Insignificant devices usually toggle between green and blue (Condition Value = 0). Significant models can be made insignificant by changing their Value_When_Red attribute value to 0 (zero).

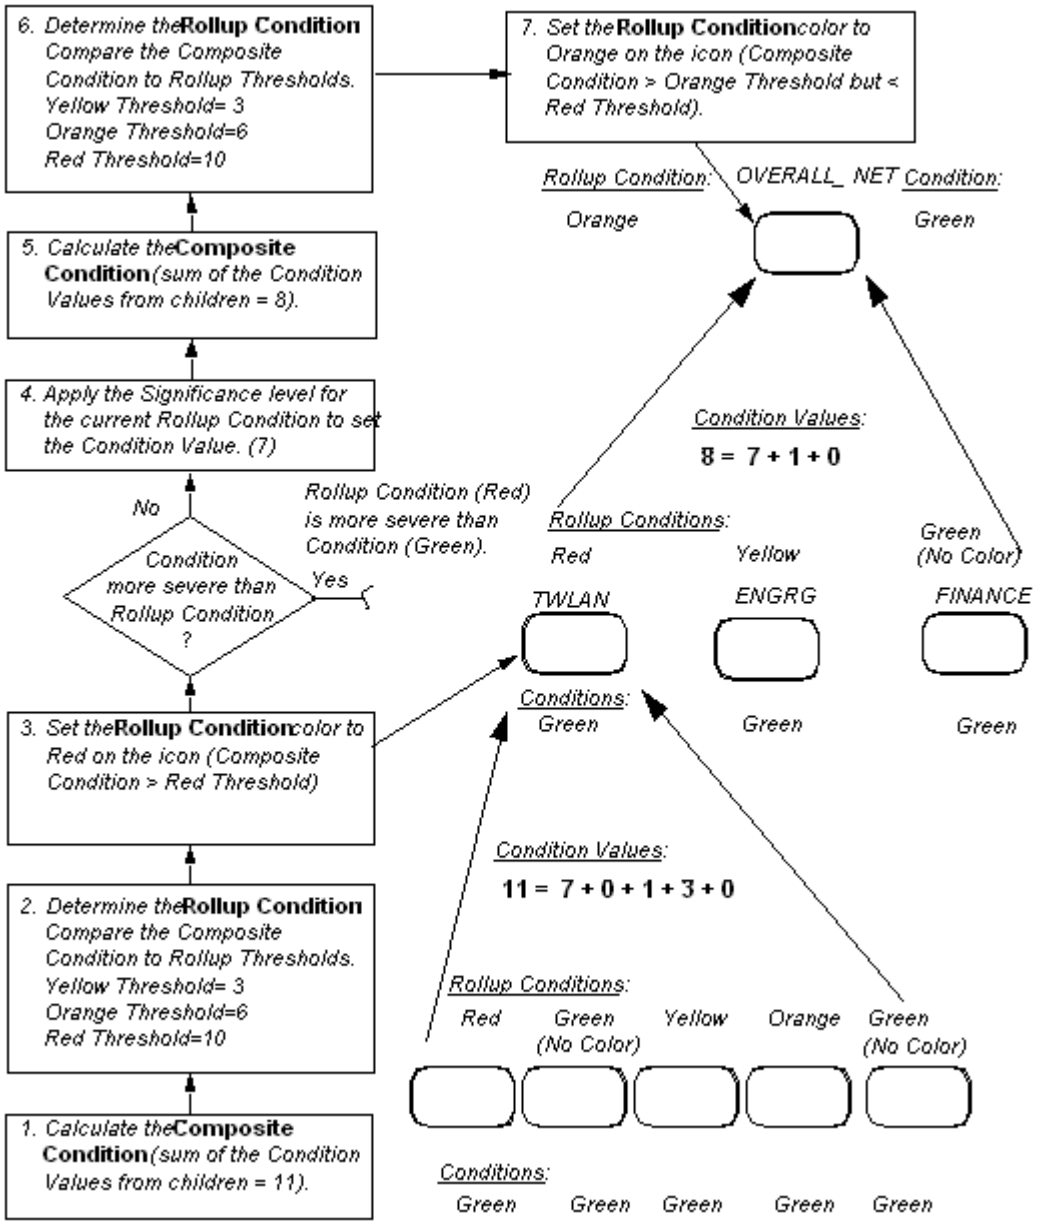
Rollup Condition Flow

An overview of the rollup condition process is illustrated in the following diagram. Read the flow from bottom to top, but keep in mind that it shows a single path in the propagation of rollup condition and that there may be many children passing condition values to a parent model.



Example of Rollup Condition Propagation

The following diagram illustrates the propagation of a rollup condition in the Topology hierarchy.



This example depicts two layers of a Topology hierarchy. The example assumes the use of default Rollup Thresholds and Significance Levels. At the lowest level in the figure there are five devices: two hubs, a router, and two end-point devices. These are contained by TWLAN, a LAN of type 802_3_LAN (as are the two other LANs: FINANCE and ENGRG). The network group model named OVERALL_NET collects these three LAN models.

The following Rollup Conditions and Conditions, at lower levels, determine the top-level Rollup Condition for the network group model OVERALL_NET:

Devices Collected by TWLAN

Hub#1
Condition = Green
Rollup Condition = Red

Condition Value = 7

Hub#2
Condition = Green
Rollup Condition = Orange
Condition Value = 3

Router#1
Condition = Green
Rollup Condition = Yellow
Condition Value = 1

End-Point Devices PC#1 & PC#2
Condition = Green
Rollup Condition = Green
Condition Value = 0

LAN Named FINANCE

Condition = Green
Rollup Condition = Green
Condition Value = 0

LAN Named ENGRG

Condition = Green
Rollup Condition =Yellow
Condition Value = 1

Example Rollup Condition Process

Every model within a Topology view receives its Collects relation from the model that it is collected by. Therefore, all models contribute to the rollup condition of the network group model. The following steps provide a detailed flow of condition values that contribute to the rollup condition for the model named OVERALL _NET shown in the previous example diagram.

1. Determine the Composite Condition for the TWLAN network group model. Composite Condition is the sum of the collected models' Condition Values. In this case, the device models have Condition Values of:
   "Orange" Condition hub model has a Condition Value of 3.
   "Red" Condition hub model has a Condition Value of 7.
   "Green" Condition PC#1 model has a Condition Value of 0.
   "Yellow" Condition router model has a Condition Value of 1.
   "Green" Condition PC#2 model has a Condition Value of 0.
   Therefore, for the TWLAN model:
   Composite Condition = (3 + 7 + 0 + 1 + 0) = 11
2. Determine the Rollup Condition for TWLAN. In this case:
   Composite Value = 11
   TWLAN Yellow Threshold = 3
   TWLAN Orange Threshold = 6
   TWLAN Red Threshold = 10
   Composite Value > Red Threshold
   Therefore:
   Rollup Condition for TWLAN = Red
3. Assign Significance Levels to TWLAN Condition and Rollup Condition. In this case, Significance Levels are:
   Value When Yellow = 1
   Value When Orange = 3
   Value When Red = 7

Therefore:
Rollup Condition = Red Condition = 7

4. Set Condition Value for TWLAN model. In this case:
   Rollup Condition more severe than Condition
   Therefore:
   Condition Value = Rollup Condition Significance Level = 7
   The three network models TWLAN, ENGRG, and FINANCE pass their Condition Values up to the network group model OVERALL_NET. Changes in the Condition or Rollup Condition for the device models at lower levels can produce changes in the topology models further up in the Topology hierarchy. The Rollup Conditions for these three networks produce the following Rollup Condition for OVERALL_NET.
5. Determine the Composite Condition for the OVERALL_NET network group model. Composite Condition is the sum of the collected models' Condition Values. In this case, the network models have Condition Values of:
   Red Condition TWLAN model has a Condition Value of 7.
   Green Condition FINANCE model has a Condition Value of 0.
   Yellow Condition ENGRG model has a Condition Value of 1.
   Therefore, for the TWLAN model:
   Composite Condition = (7 + 0 + 1) = 8
6. Determine the Rollup Condition for OVERALL_NET. In this case:
   Composite Value = 8
   Yellow Threshold = 3
   Orange Threshold = 6
   Red Threshold = 10
   Composite Value > Orange Threshold, but < Red Threshold
   Therefore:
   Rollup Condition for OVERALL_NET = Orange

Fault Isolation

Fault Management is one of the key requirements of network management. A fault is different from an error because it is an abnormal condition that requires management attention and repair. Problems that results in faults could be caused by a bad firmware, a bad hardware, or a bad network. Each of these problems requires a different response from the network manager. Thus the goal is to determine the exact location of the fault and to get the attention of the network administrators as quickly as possible.

DX NetOps Spectrum intelligence is capable of isolating a network problem to the most probable faulty component. To speed up fault isolation and to reduce unnecessary traffic, two actions occur:

- **Are-You-Down Action**
  Upon losing contact with the device it represents, a model sends the Are-You-Down action to all of its neighbors to determine its own condition. If all of the neighbors return a response of TRUE, the condition color of the model turns gray (meaning "my device might be down, but it is impossible to tell because all the neighbors are down"). However, if any of the neighbors return a response of FALSE, the condition color of the model turns red (meaning "my device must be down, because one of the neighbors is up").
- **Are-You-Up Action**
  Upon re-establishing contact with the device it represents, a model sends the Are-You-Up action to its neighbors to speed up the fault isolation. Upon receiving this action, each neighbor returns TRUE if it has an established contact status. If the contact status of the model is lost, and the next-time-to-poll is more than 60 seconds, then the model pings the device for quicker fault isolation.

Every time the status of the model changes, or the information available to DX NetOps Spectrum changes, a new assessment occurs. DX NetOps Spectrum intelligence keeps the topology presentation as current and as accurate as possible, but it depends on correct modeling to accurately assess contact status and determine device failures on the network. Correct modeling includes placing your VNM model in proper relation to the other models that represent your

network; it must have a resolved connection in the Topology view of a model that represents a device to which the VNM host is connected. When the VNM model is properly connected and DX NetOps Spectrum loses contact with a model, the icon representing that model displays a condition color of Gray, Orange, or Red, which helps the network administrators to locate the faults immediately.

Improved Fanout Performance

> **NOTE**
> In 10.4.2, this option is enabled by default; that is, the parameter value is already set to True. In previous releases, the option was not enabled by default.

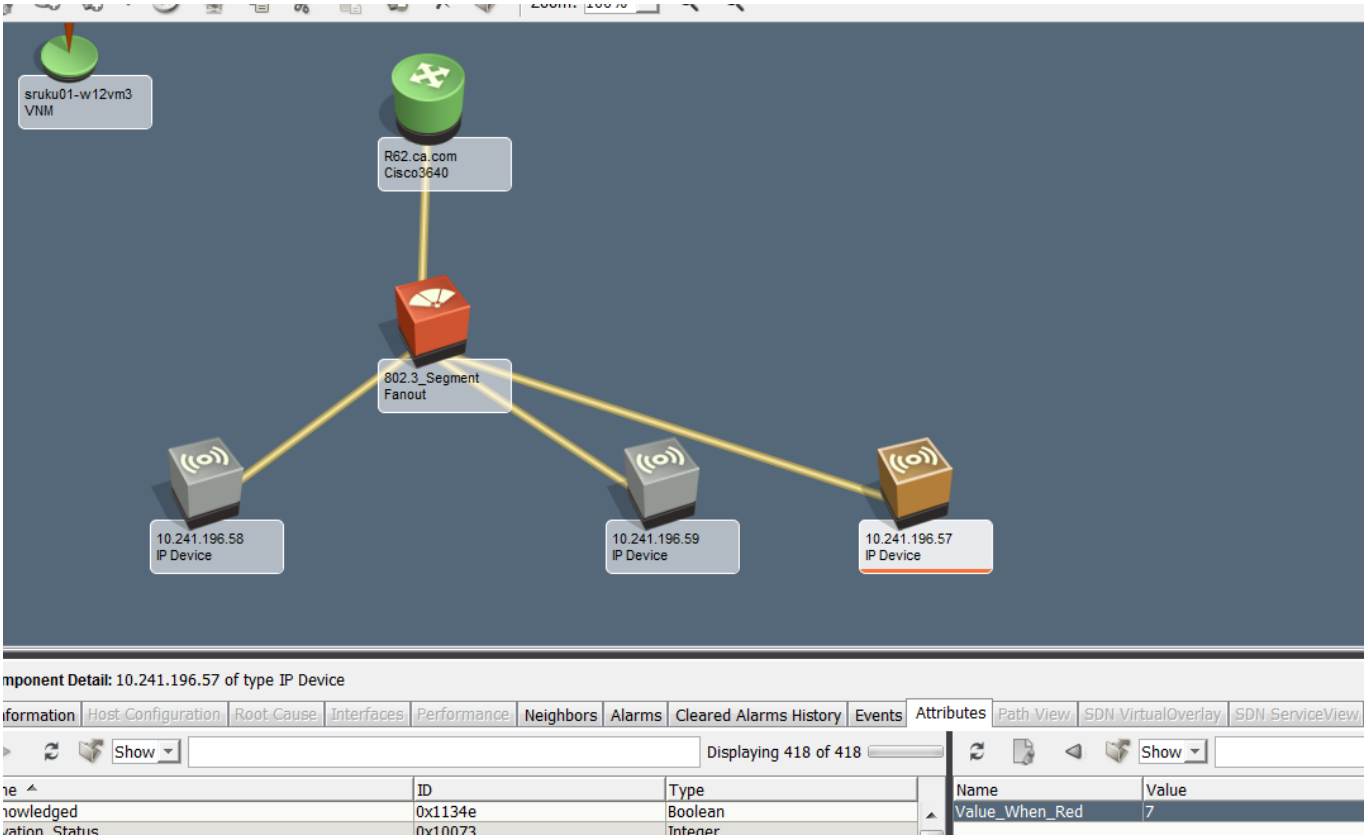
With 10.3.1, the Fanout performance has been improved by propagating the 'Are_You_Down' action to only SNMP-capable neighbors of Fanout. To enable the Fanout performance enhancement, set the parameter attribute 'improve_fanout_performance' to True in the $Specroot\SS\.vnmrc file and restart the SpectroSERVER. By default, this parameter is set to False (in releases prior to 10.4.2). When all the non-SNMP significant device models are down and any SNMP capable device is up, then Fanout condition turns red and the non-SNMP device models are suppressed (shown in Fig.1). To change the non-SNMP insignificant model device to significant model device, refer to the section on How Model Category Affects Contact Status.

Fig.1

NOTE

If a non-SNMP significant device model is in a maintenance mode, then this model is considered as down (shown in Fig.1.1).

Fig.1.1



How Model Category Affects Contact Status

Each fault is associated with a particular condition, which is represented by a particular color that displays on the icon representing the model where the fault occurs. The condition color reflects both the contact status and the alarm status of the model. However, the contact status and condition color asserted for a model also depend upon which of the following categories a model belongs to. The following list summarizes how the categories to which a model and its neighbors belong influences its contact status and condition color.

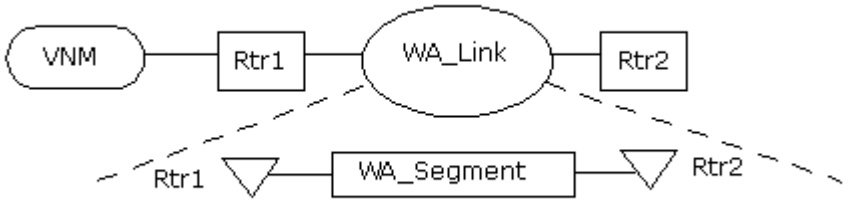
- **Significant Device Models**
  Any device that requires the attention of the administrator for the smooth operation of the network is called a significant device. To change an insignificant model into a significant model change the value of the attribute Value_When_Red (0x1000e) to 7.
- **Insignificant Device Models**
  An insignificant device such as an end-user PC toggles between Blue and Green contact states and does not generate alarms or event messages to get the attention of the administrator. To change a significant model into an insignificant model change the value of the attribute Value_When_Red (0x1000e) to 0.
- **Inferred Connectors**
  These are dumb models that do not poll, but that keep track of a list of their Data Relay neighbors. Possible inferred connectors are: WA_Segment, Fanout, and so on. DX NetOps Spectrum automatically enables Live Pipes for all ports that are connected to a WA_Segment.

  NOTE
  DX NetOps Spectrum intelligence does not expect Fanout models to be connected to each other; thus this configuration results in inaccurate contact status displays. If two Fanouts are connected to each other and each of them is in turn connected to a device with a green contact status, the Fanouts nonetheless turn red.

If two Fanouts are connected to each other with no other devices that are connected to either one, both Fanouts turn gray.

- **Shared Media Link**
  The Shared Media Link is a specialized inferred connector. These models are similar to Fanouts, but the fault management works differently. Unlike a Fanout model, the Shared Media Link model condition is based on configured threshold values.
  Example: If the critical threshold is set to 80, the Shared Media Link turns red when it loses contact with 80 percent of the downstream models.
- **Composite and Discrete Topology Models**
  The contact status of LAN, LAN 802.3, LAN 802.5, and so on, models is determined by the contact status of its collected children. A LAN model with lost contact status turns either red or gray, depending on the condition of its collected models.
- **Wide Area Links**
  Wide Area Links (WA_Links) are modeled with wide area segment (WA_Segment) models. This allows for proper rollup of the Wide Area Link condition. WA_Link models can only represent point-to-point connections, such as T1 and T3 lines, and there can be no more than two devices that are connected to it at a time. Also, you must connect the WA_Segment model to the correct port of the device models.

  NOTE
  WA_Link models can accommodate only one WA_Segment model. If you attempt to paste more than one WA_Segment model into a WA_Link model's Topology view, the second one is destroyed immediately and an alarm is generated.



- **Wide Area Segments**
  WA_Segments poll the InternalPortLinkStatus (IPLS) attribute of each interface model which Connects_To the WA_Segment. This is an active poll, meaning that the IPLS of each connected interface is read at every polling interval rather than simply watched for a change in the attribute. Therefore, DX NetOps Spectrum does not have to lose contact with one of the connected routers for a fault isolation alarm to be generated on a WA_Link.
  The polling of the connected ports' IPLS is regulated by the WA_Link model's Polling_Interval and PollingStatus attributes. When the Polling_Interval changes to zero (0) or PollingStatus goes to FALSE, polling of the connected port's IPLS is stopped.
  If one of the connected interfaces has an IPLS of BAD (for example, Admin Status is ON, but Open Status is OFF), then the WA_Segment's Contact_Status is set to 'lost' and the WA_Segment turns gray. The WA_Link turns red.
  If one of the connected interfaces has an IPLS of 'disabled' (for example, Admin Status is OFF), then the WA_Segment's Contact_Status is set to 'lost' and the WA_Segment turns gray. The WA_Link turns orange. This is because the alarm must be severe enough to be viewed in the Alarms tab, but it is not a "Contact Lost" alarm.
  If the DISABLED interface causes DX NetOps Spectrum to lose contact with the remote router, then the WA_Link turns red. This is the regular InferConnector-type fault isolation working.

Model Category	Connected Models (Neighbors)	Condition Color
Significant Devices (Modeling Hub-types only)	connected to a VNM...	turn Red after losing contact

Significant Devices	with no connections to other models (a zero connector count)...	turn Red after losing contact
Significant Devices	connected to an established Data Relay neighbor...	turn Red after losing contact
Composite and Discrete Topologies	in which all of the collected children have a lost contact status and at least one of those collected children is Red...	turn Red after losing contact
Inferred Connectors	where the Fanout model has lost contact but one of its neighbors is good and the associated port has bad port link status, then it...	turn Red after losing contact
Significant Devices, Inferred Connectors, and WA_Links	where all neighbors have also lost contact status...	turn Gray after losing contact.
Composite and Discrete Topologies	in which all ocs and none of those collected children are Red...	turn Gray after losing contact.
Significant Devices (Modeling Hub-types only)	connected to an end-point neighbor (such as a PC) that has established contact status...	turn Orange after losing contact.
WA_Links	WA_Segment (or Fanout) is good and one of the routers is lost then...	turn Orange after losing contact.
Significant Devices	connected to a model with an Established contact status...	turn Green.
Composite/Discrete Topologies and WA_Links	in which any of the collected children has established contact status, then the LAN will also...	turn Green.
Inferred Connectors	connected to a model with an established contact status where at least one of its neighbors is *Good* and its associated port (port that is connected to the Fanout) status is *Good*...	turn Green.
Significant and Insignificant Devices	not yet connected to other devices...	turn Blue
Composite/Discrete Topologies and WA_Links	when all collected children of a LAN have initial contact status, then the LAN will also have the initial contact status...	turn Blue

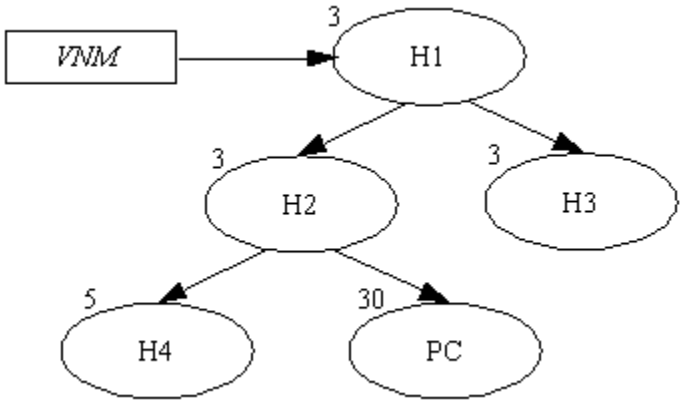
Fault Isolation Examples

The following examples illustrate how DX NetOps Spectrum fault isolation operates with various network configurations and problem scenarios.

Example: Proactive Fault Isolation

This example demonstrates that fault isolation is a proactive mechanism which does not depend upon polling all of the connected models.

Consider a simple network topology as shown in the following diagram. The device H1 is connected to the VNM model. Devices H1, H2, and H3 poll every 3 minutes. H4 polls every 5 minutes. The PC polls every 30 minutes.



Assume that H2 is BAD. As a result H2 turns red, H4 turns gray, PC (insignificant model) turns blue, while H1 and H3 remain green.

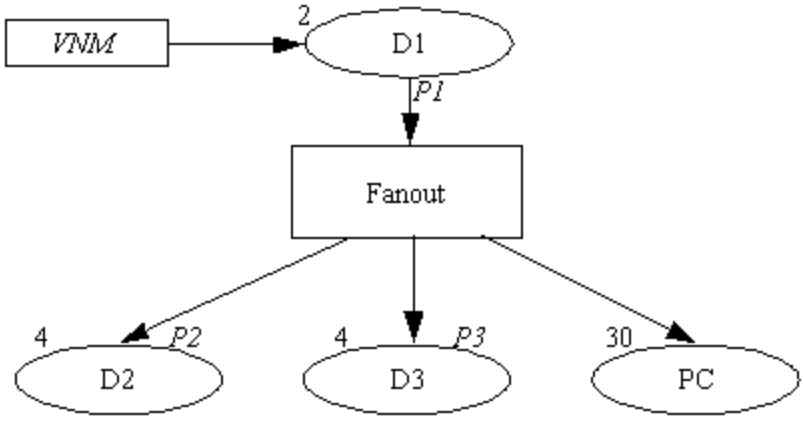
Fault isolation is initiated when H2, H4, or PC polls. If H4 is lost, it sends an Are-You-Down action to H2. If H2 is lost by then, it sends TRUE to H4, otherwise it pings itself and then sends the response to H4. This causes H4 to turn gray.

Now H2 is lost, and it sends Are-You-Down action to H1. Because H1 is established, H2 has to decide between orange and red conditions. H2 pings PC. Since PC cannot respond H2 turns red. The ping from H2 puts PC in a lost state. Since PC is an insignificant device, it turns blue.

Example: Modeling a Fanout.

This example demonstrates fault isolation when modeling a Fanout.

Assume that the Fanout is red and D2, D3, and PC are gray. The following diagram illustrates this scenario.



The Fanout registers a watch on D1's contact status. If D1 goes down, the Fanout turns Gray as a result of the watch trigger.

When D3 eventually polls successfully, D3 has an established contact status and turns Green. D3 then sends an Are-You-Up action to the Fanout. The Fanout reads device P3's (D3's port connection to the Fanout) internal link port status. Assuming the port has a good status, the watch is cleared, and the Fanout turns Green with an established contact status. This means that as long as P1 (D1's port connection to the Fanout) has good internal link port status, the contact status of the inferred connector remains good.

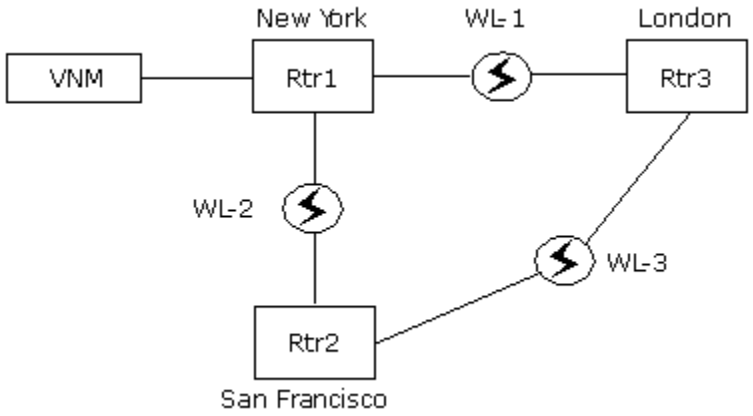
What if D2 goes bad? D2 loses its contact status and sends an Are-You-Down action to the Fanout. The Fanout pings D1, and finds D1 to be good. The intelligence then examines the status of P1. Assuming Link-Status of P1 is good, the Fanout returns FALSE to model D2. This causes D2 to turn Red.

What if P1 is bad? This is the same case as disconnecting the network connection to the Fanout. If D3 polls first, it loses its contact status and sends an Are-You-Down action to the Fanout. The Fanout pings D1 as finds it as a good neighbor. Fanout then reads the internal-port-link-status of the port P1. Because P1 is bad, the Fanout will lose its contact status and turns Red. The Fanout returns TRUE to the model D3. This causes D3 to turn Gray. D2 will also turn Gray in the same way as D3. PC being the insignificant device will turn Blue immediately after losing its contact status.

Example: Redundant Paths Fault Isolation

This example shows how DX NetOps Spectrum manages devices using redundant paths if a link is shut down administratively (i.e., admin-status equals *down*).

The following diagram depicts a network with redundant WA Links. Here VNM manages Rtr3 through link WL-1 and Rtr2 using link WL-2. Assume that the network administrator shuts down the WL-1 link. This causes WL-1 to turn gray. Rtr3 turns red because VNM cannot talk to it through WL-1. The redundancy intelligence of Rtr3 modifies its agent address, so that VNM can talk to it using links WL-2 and WL-3. This causes Rtr3 to turn green again. The link WL-1 still has the gray condition.

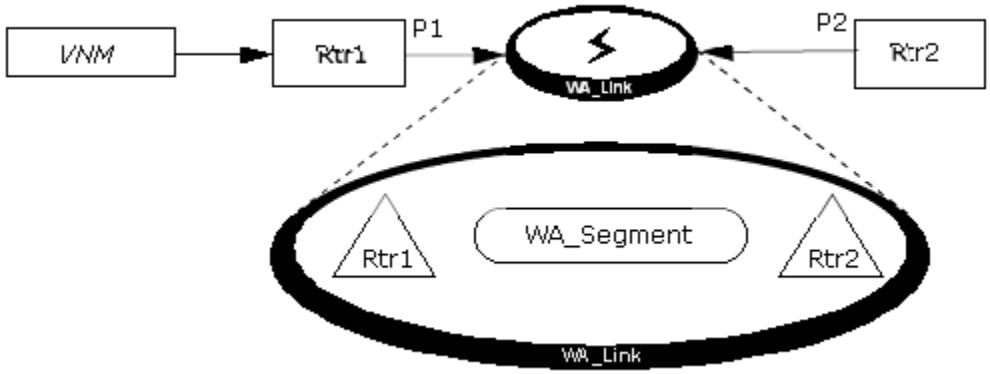


Example: Inferred Connector Fault Isolation

This example demonstrates that fault isolation for an Inferred Connector requires specific modeling. Assume that two routing devices, Rtr1 and Rtr2, are connected at both ends of the WA_Link and that their ports are P1 and P2 respectively.

WA_Link models needs to be associated with a WA_Segment (or Fanout) model through the Collects relation to enable the proper rollup of the WA_Link condition. The devices at either end of the WA_Link needs to be connected to the WA_Segment collected by the WA_Link model. You do this by navigating into the device's Device Topology view and resolving the WA_Segment off-page reference icon to the appropriate port. You can view the connections by navigating into the WA_Segment's view.

This cross-connection is important for fault isolation to work, as shown in the following diagram.



Assume that P1 is the port on Rtr1 and P2 is the port on Rtr2. The routers that are connected to the WA_Segment causes it to behave as described in the following table. Note that the port link status becomes important in determining the status of the WA_Link only when both routers are “contact established.”

Rtr1	Rtr2	WA_Link
Initial	Initial	Blue
Established	Lost	Red
Lost	Lost	Gray
Established	Established	Check Port States*

* If both Rtr1 and Rtr2 have a contact status of *established* then the port status of P1 and P2 determines the condition of the WA_Link. If any port is BAD, the WA_Link turns RED. If any port is DISABLED, the WA_Link turns ORANGE. Otherwise, the WA_Link turns GREEN.

Duplicate Addresses

DX NetOps Spectrum intelligence automatically detects when duplicate IP addresses are entered in the SpectroSERVER database. Although some devices are allowed to have a duplicate IP address, Cabletron hub devices should be configured with only one IP address per device.

DX NetOps Spectrum can model different devices that share IPs, provided that each device has at least one IP that is unique to that device. This modeling policy accommodates certain networking technologies such as load balancing that create identical IP addresses across a range of devices. Devices that share some interface IP addresses can be modeled manually or by using Discovery. However, devices that share all their interface IP addresses in common cannot be modeled manually or by using Discovery.

Alarm condition colors warn you of duplication, as shown here:

- **Same MAC Address & Different IP Address**
  This alarm occurs when there are two or more models with the same MAC address and at least one model with a different IP address.
  Color: Yellow
- **Same IP Address & Different MAC Address**
  This alarm occurs when there are two or more models with the same IP address and at least one model with a different MAC address.
  Color: Orange
- **Same IP Address & Same MAC Address**

This alarm occurs when there are two or more models with the same IP address and the same MAC address (duplicate addresses).
Color: Yellow

- **Duplicate MAC Address**
  The special case alarm for duplicate models where at least one of the models does not have an IP address. Only a Physical_Address model type can have this characteristic.

  NOTE
  Even if the MAC address for two device models is identical, this alarm occurs only when the MAC address of every interface of the two devices is the same.

  Color: Yellow

To get these alarms, a model type needs both the MAC address and the IP address. For example, the model types Pingable and PhysicalAddress do not have both addresses, so you will not see these alarms.

Manually Clear Duplicate Addresses

You can clear duplicate address alarms manually.

Follow these steps:

1. Select the model with the duplicate IP address alarm.
2. Determine whether to allow two devices to have the same IP address. If not, change one of the devices to use a unique IP address, and then use the Update feature to change the IP address within DX NetOps Spectrum.
3. To clear the duplicate, click

   (Clear selected alarms).
   The alarm is cleared. The status color on the model icon returns to a normal green condition unless another alarm is present for the model.

Automatic Naming and Addressing

DX NetOps Spectrum implements an automatic model naming and addressing feature through the AUTO_NAME attribute (attribute ID 0x00011979). The value for this attribute is set to TRUE by default for each model type in your modeling catalog. You can disable automatic naming and addressing on a model type basis using the Model Type Editor (MTE) to set the value to FALSE. Otherwise, the feature functions as described below.

If you create a new model using only the IP address, DX NetOps Spectrum automatically attempts to supply a name for the model in one of three ways:

- Using NIS (Network Information System) or DNS (Domain Naming Service) to get the name from the modeled device
- Checking the local /etc/hosts file for the name associated with the modeled device's IP address
- Using the IP address as the model name

NOTE
The priority order of the source that will be used to supply a name for the model (IP Address, Name Service, or sysName) is dictated by the Model_Naming_Options attribute on the VNM model. This attribute can be modified on the VNM model's control view.

NOTE
For more information about configuring landscapes, see the Distributed SpectroSERVER Administrator section.

Likewise, if you create a new model and supply only a model name, DX NetOps Spectrum will attempt to use NIS, DNS, or the local /etc/hosts file to retrieve the modeled device's IP address.

In either case, as long as the value for AutoName is TRUE for a particular model type, DX NetOps Spectrum will automatically maintain the names for models of that model type as follows: in the event the IP address for a model changes and the original model name was supplied by DX NetOps Spectrum, a new name will be supplied using one of the three methods listed previously. However, if the original name was supplied by the user and differs from the name that would be supplied through automatic naming, then the original name will be preserved.

Board and port models are also automatically named by default, each being assigned the name of the parent device model suffixed with the board/port Instance ID. For example, if a model of model type Hub_CSI_IRM2 is named IRM2_UK, and the modeled device has a port with the Instance ID of 2.5, the name of the port will be IRM2_UK.2.5. If the device name is changed to IRM2_US, then the name of the port becomes IRM2_US.2.5. However, if the device name was user-specified and the user then changes the port name from IRM2_US.2.5 to LAB_PORT, then the automatic naming will not be not used for that port in the event of subsequent IP address changes. Some boards (mainly standalone MIMs) contain their own intelligence. In such cases, setting AUTO_NAME to FALSE as previously described will disable the autonaming intelligence and allow the board's own intelligence to work.

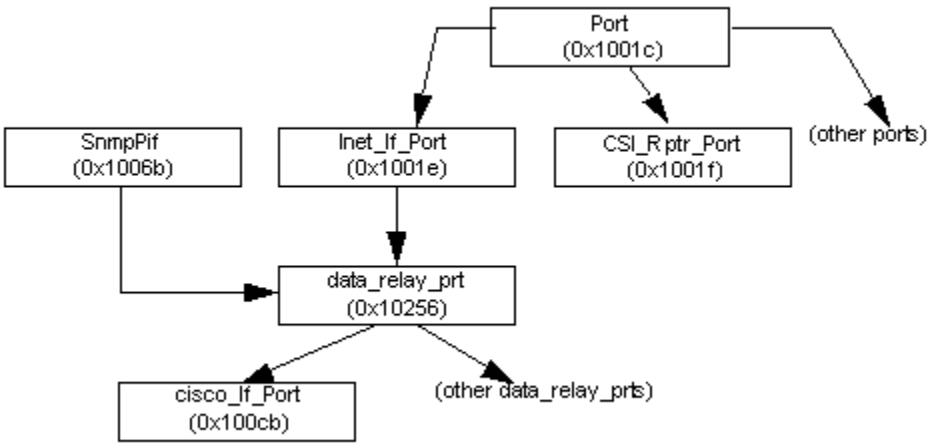
Detection of Firmware Problems

DX NetOps Spectrum allows for automatic detection of problems in some device firmware. Using the connects_to and collects model type relations formed in the Topology views, DX NetOps Spectrum detects if a network management firmware problem exists in the hub device. The connects_to relation denotes that one model is attached or connected to another; for example, a PC model connects to a hub model via a port on the hub. The collects relation denotes that one model collects information from another mode; for example, the Topology view model collects information from the hub devices contained within that view. If DX NetOps Spectrum cannot retrieve management information from a hub device, but can still contact devices connected to this hub, then a hub firmware management problem can be deduced and the hub icon's condition color is set to orange. You should then use the alarm views along with the content in the Impact tab and the Performance tab to help isolate and correct the problem.

Interface Intelligence

Interfaces are ports that have both a physical address and a network address. These types of ports are found on routers and bridges, where network identity is important, unlike a port on a repeater, which might have a physical address, but not a network address.

The following diagram illustrates the derivation of the interface port:



Port is the base model type for all ports. Two basic types of ports are derived from Port: repeater ports and interface ports.

- **Inet_If_Port**
  Derived from Port and Enet Monitor model types. Inet_If_Port is the base class for all interface ports that are potential monitor points for network statistics.
- **Data_relay_prt**
  Derived from Inet_If_Port and SnmpPIf. SnmpPIf is the base class for all model types that communicate with SNMP agents. Data_relay_prt is the base model type for all interface ports that do their own reading and polling. It is an instantiable model type and is used to model a generic interface port. More specific types of interface ports, such as Cisco_If_Port, are derived from data_relay_prt.

The inference handler CsIHInterfaceIntLinkStatus, which computes InternalPortLinkStatus, is attached at Inet_If_Port so that all interfaces inherit the desired functionality.

The intelligence for interfaces that use ifAdminStatus and ifOperStatus are defined in the MIB-II definition of the interface group in RFC 1158. These variables can have the state of ON or OFF, and are defined as follows:

- **ifAdminStatus: desired interface state**
  This is the state that the administrator wants the interface to be in. This attribute shows whether the interface has been shut off. The values of this attribute are ON and OFF.
- **ifOperStatus: current interface state**
  This attribute shows the actual state of the interface. The values of this attribute are UP and DOWN. UP means that the interface is communicating with the network properly. DOWN means the interface has lost connection with the network.

These two variables are used to calculate a DX NetOps Spectrum internal attribute named Internal_Link_Status (IPLS - 0x10f1b). The possible values for this attribute are LINK_STATUS_GOOD (LSG), LINK_STATUS_BAD (LSB), and LINK_STATUS_UNKNOWN (LSU). This attribute is used to create and clear alarms, both on the interface and the device it is part of. It is also used to generate events concerning the attempt to reach of the interface. The following table shows how these variables are calculated.

IfAdminStatus	IfOperStatus	INTERNAL_PORT_LINK_STATUS
ON	ON	LINK_STATUS_GOOD
ON	OFF	LINK_STATUS_BAD
OFF	ON	LINK_STATUS_UNKNOWN
OFF	OFF	LINK_STATUS_UNKNOWN

The INTERNAL_PORT_LINK_STATUS of interface is set to LSU when DX NetOps Spectrum has lost contact with the device.

Interface Alarms

Internal Port Link Status (IPLS) is used to generate alarms for both the device model and the interface model. The only interface alarm is gray. These alarms can only be seen by going into the Alarm Details tab of an interface model. It is interesting to note that the alarm for an interface with an IPLS of LSB have a gray alarm. All models with alarms are displayed in the Alarms tab. This is undesirable for interfaces. Interfaces are considered to be a part of a larger device such as a router. When a router goes down, all its interfaces also go down. A red alarm is generated for the router. It would be confusing to have all of the interfaces also producing red alarms, cluttering the Alarms tab and making it difficult to locate the router.

A device watches the IPLS of each of its interfaces. If any of the interfaces has an IPLS of LSB, then the device generates a yellow alarm with a probable cause of CS_ALARM_CAUSE_PORT_LINK_STATUS_BAD. This alarm, once set, is not be reasserted until it is cleared. Only one alarm is asserted for all ports. The first interface with an IPLS of LSB creates an alarm. The second and successive interfaces with an IPLS of LSB are put into a bad port list. Once the list is clear the yellow alarm is removed.

Each of the interfaces watches its own IPLS. Whenever the interface has an IPLS of LSB or LSU it generates a gray alarm. This alarm only shows up in the interfaces Alarm Details tab.

When the device becomes unreachable, the interface's IPLS is set to LSU. A gray alarm with a probable cause of CS_ALARM_CAUSE_DEV_CONTACT_STATUS_LOST is generated.

When the interface has been administratively shut off the interface's IPLS is set to LSU. A gray alarm with a probable cause of CS_ALARM_CAUSE_ADMIN_SHUT_OFF is generated.

When the interface becomes unreachable, its IPLS is set to LSB. A gray alarm with a probable cause of CS_ALARM_CAUSE_PORT_LINK_STATUS_BAD is generated.

Alarm Configuration

- **Generate Alarm on Port**
  This attribute determines if an event/alarm must be generated on the port for changes to Internal Port Link Status.
- **Generate Alarm on Device** This attribute determines if an alarm should be on device for any port link down traps that are received from the device.

Interface Events

The interface generates two events that deal with its status. The events contain information about the attempts to reach the interface. These events are generated when a device has a yellow alarm due to a bad interface. Each event message contains the interface number and IP address. For example:

```
Tue 20 Jul, 1994 - 13:31:50 Interface 2 (IP   address = 129.128.127.2, type = Gen_IF_Port) on device cisco1 of
  type Rtr_CiscoMIM is unreachable. - (event [00010623])
```

As stated before, IPLS has three possible values. This makes it important to know the last two states of an interface's IPLS to make a proper judgment about its current state. If the interface IPLS is LSB, and it was previously LSU, it is important to know if it was previously LSB or LSG. Due to this, each interface keeps the values of the last two states of IPLS. Events are generated based on these two saved values, and the current value.

Events Generated from IPLS State

The following table shows which states generate events based on the IPLS.

Two Previous	Previous	Current	Event
GOOD	UNKNOWN	GOOD	none
GOOD	UNKNOWN	BAD	UNREACHABLE
GOOD	BAD	GOOD	REACHABLE
GOOD	BAD	UNKNOWN	none
BAD	GOOD	BAD	UNREACHABLE
BAD	GOOD	UNKNOWN	none
BAD	UNKNOWN	GOOD	REACHABLE
BAD	UNKNOWN	BAD	none
UNKNOWN	GOOD	BAD	UNREACHABLE
UNKNOWN	GOOD	UNKNOWN	none
UNKNOWN	BAD	GOOD	REACHABLE
UNKNOWN	BAD	UNKNOWN	none

MPLS Transport Manager

MPLS Transport Manager is a utility that monitors the health of your MPLS core network. Continuously monitoring the MPLS environment can help identify potential performance issues, preventing service interruptions to your customers and helping ensure your customer SLAs are not broken. The MPLS Transport Manager data can also help you pinpoint and effectively troubleshoot problems within your MPLS network by providing the impact of an outage in terms of its affect on the MPLS infrastructure.

A key challenge when monitoring MPLS data is keeping the data accurate. Changes happen dynamically in an MPLS network -- LSPs and their associated Paths can change frequently under certain network conditions. MPLS Transport Manager keeps up with these changes and accurately models the current state of LSPs and Paths. MPLS Transport Manager provides complete visibility into all provisioned LSPs and Paths, and it knows the relationship between an LSP and its primary and secondary Paths.

Access to MPLS Transport Manager is provided in the DX NetOps Spectrum interface. MPLS Transport Manager supports the MPLS implementations of multiple vendors, and both proprietary and standard-based technologies.

Who Should Use MPLS Transport Manager

MPLS is a broad technology defined by hundreds of standards that is continuing to grow, supporting increasingly complex network systems and services. MPLS Transport Manager is intended for TE MPLS environments only. If you have this type of MPLS environment and must adhere to your customer SLAs, you can use MPLS Transport Manager to monitor device outages, their impact on the MPLS network, and effectively troubleshoot these outages.

System Requirements

MPLS Transport Manager is an add-on application that works within DX NetOps Spectrum. In addition to a running SpectroSERVER installation, MPLS Transport Manager requires the following:

- Appropriate MIBs implemented and populated on your MPLS hardware:

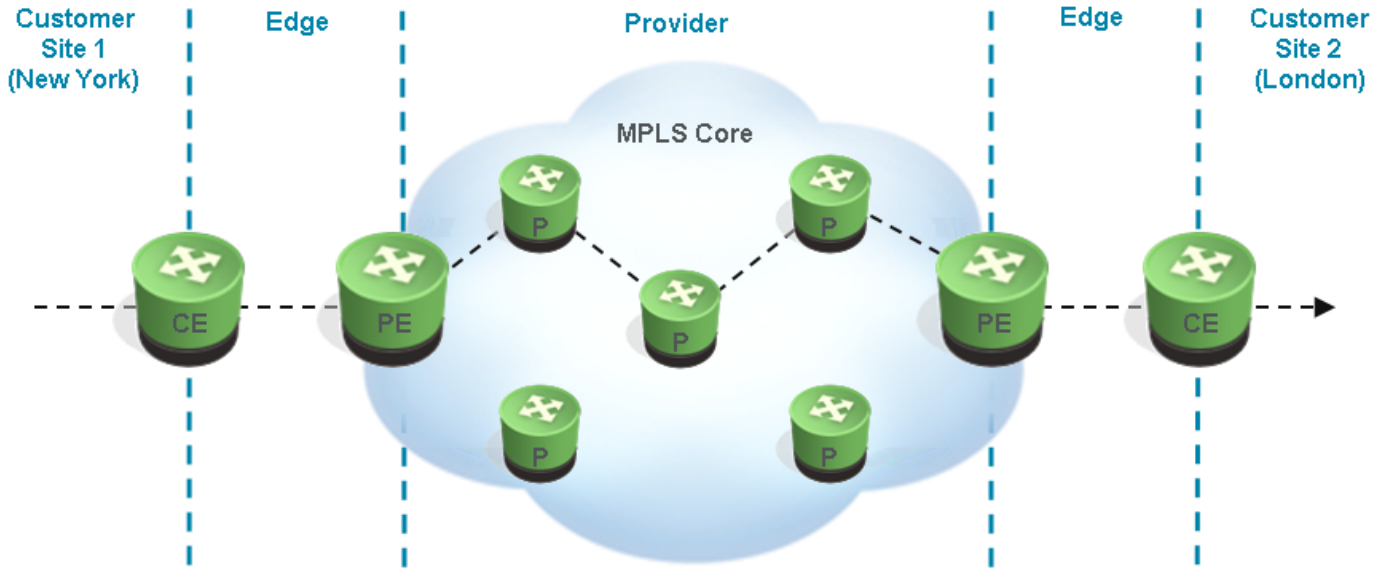
  NOTE
  DX NetOps Spectrum comes with all the required MIBs.

  - MPLS-TE MIB (Cisco devices)
  - Juniper TE MIB (Juniper devices)
  - TIMETRA-MPLS-MIB (Alcatel devices)
- Management module for Cisco, Juniper and Alcatel routers.

  NOTE
  The device models in these modules have the necessary application models needed for discovery of your MPLS environment.

How MPLS Transport Manager Works with MPLS-TE

As a service provider, your goal is to use your MPLS core network to transport data packets from one part of your customer's network to another. For example, your MPLS network may transfer data packets from your customer's New York office to their London office. In this situation, your customer cannot model and monitor their network traffic through your MPLS network, and you, as a service provider, typically cannot model and monitor the client networks in New York or London. The following diagram shows that in this scenario the only interface between the customer network and your MPLS network is the relationship between their Customer Edge (CE) router and your Provider Edge (PE) router:



As shown in the diagram above, a customer communicates from one side of their network to the other using the Provider's MPLS network as follows:

1. A data packet from Customer Site 1 passes through the CE and PE routers on one edge of your MPLS core.
2. Based on its label, the packet passes from router (P) to router through the MPLS core. This route is defined as the primary Path. Each Path is an ordered set of routers through which the packet is passed, moving it from one router (also known as a "hop") to another within the MPLS core. The first device in a Path is the ingress device, and the last one is the egress device.

   NOTE
   Excluding topology changes or load balancing, all subsequent packets with the same source and destination take the same path through the core. If any device along the primary Path becomes inoperable, the packet switches to a secondary Path.
3. A packet passes through each hop in a Path, until it reaches the egress device on the other side of the MPLS core.
4. From the egress device, the packet is passed to its next destination within Customer Site 2.

MPLS Transport Manager models the relationships between the PE routers, Paths, devices, and hops to monitor any changes that can negatively impact the ability to move customer data packets through your MPLS core. For example, if a router goes down, an LSP can change from its primary Path to a secondary Path. Using traps and polling, MPLS Transport Manager is aware of this change -- it logs the event and may trigger an alarm (based on your threshold values) to make sure that you are aware of the change. Knowing that an LSP switched to a secondary Path can help you locate unreachable devices and quickly assess their impact on your clients.

Devices Supported by MPLS Transport Manager

MPLS Transport Manager supports MPLS-enabled Cisco, Juniper, Nokia and Alcatel devices. The following tables describe which features are available and supported by each device.

NOTE
For more information about the Cisco devices, models, and firmware that support MPLS technology, see the MIB Locator on the Cisco website.

MIBs Supported

MIB	Cisco	Juniper
TE-MIB	Yes	No
Juniper MPLS MIB	No	Yes

Functions Supported

Function	Cisco	Juniper
Tunnel/LSP name	Yes	Yes
Tunnel interface	Yes	No
Tunnel primary instance	Yes	No
Total # of paths	Yes	Yes
# of path changes	Yes	Yes
Active path	Yes	Yes
Active path hops	Yes	Yes
Primary path hops	Yes	Yes
Alternate path hops	Yes	Yes*

NOTE
* Some details about Juniper routers may not be immediately available upon discovery. Although the Path model lists all hops for the primary and secondary Paths in the hops table, Juniper routers provide details only when they are included in the active Paths. Therefore, when a secondary Path becomes active, MPLS Transport Manager populates the hops table with details about the Juniper router used in that Path.

Dynamic Discovery Traps Supported

Trap	Cisco	Juniper
Tunnel creation traps	Yes	Yes
Tunnel removal traps	Yes	Yes
Tunnel change traps	Yes	Yes

Configuring MPLS Transport Manager

This section describes how to install and configure MPLS Transport Manager. These are tasks that are typically performed only once per installation by the MPLS Transport Manager administrator.

Install and Configure MPLS Transport Manager

MPLS Transport Manager is included in your DX NetOps Spectrum extraction key. When you install DX NetOps Spectrum, the MPLS Transport Manager components are automatically installed and available for use. However for best results, adjust the configuration settings appropriately.

To install and configure MPLS Transport Manager properly, the administrator must complete these tasks:

1. Install DX NetOps Spectrum.

For existing DX NetOps Spectrum installations, perform an in-place installation to ensure the MPLS Transport Manager components are installed. MPLS Transport Manager supports the distributed SpectroSERVER environment (DSS).

NOTE
For specific installation instructions, see the Installing section.

2. Configure port polling. This option must be enabled for impact to be calculated for ports which are part of an LSP. Although enabled by default, you can disable port polling, if needed.
3. Configure the SpectroSERVER traps. These traps determine how to manage various events that can occur in the MPLS core.
4. Configure impact weight values. These impact weights help to determine which alarms have the greatest impact on your MPLS environment.
5. Configure settings for Path change alarms. These settings help to determine the severity of alarms generated when LSPs switch Paths excessively.

Configure Port Polling on LSPs

"Polling" for LSPs actually refers to polling the devices and interfaces on which the LSP traverses. You can disable polling to limit network traffic, but it comes at the loss of significant functionality in MPLS Transport Manager. Along with traps, the polling mechanism is used to determine the health of the resources that make up the MPLS Paths.

NOTE
Only an administrator performs this task.

To configure port polling on LSPs

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the LSP Discovery subsection.
   LSP discovery options display.
5. Click the 'set' link for the Enable Port Polling option.
   The value for the selected option becomes editable.

   NOTE
   Enabled by default, the polling option must be turned on for impact to be calculated for ports which are part of an LSP.
6. Select the desired value for the field and press Enter.
   MPLS Transport Manager is configured to poll LSPs according to your selection.

Configure SpectroSERVER Processing of MPLS Traps

If your MPLS-enabled devices are properly configured to send traps to the SpectroSERVER host, you can use this trap data to create, delete, or update LSPs. Some environments do not support the use of traps, and you can choose to disable them. However, we recommend that you enable traps when possible, because traps (along with polling) provide the best response to network faults and outages.

NOTE
Only an administrator performs this task.

To configure SpectroSERVER processing of MPLS traps

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.

3. Expand the Configuration section.
4. Expand the LSP Discovery subsection.
   LSP discovery options display.
5. Click the 'set' link for the following trap that you want to configure:
   - **Create LSP on Trap**
     Creates a new LSP when the TunnelUp trap is received and the device model already exists.
     Default: Yes
   - **Delete LSP on Trap**
     Deletes an existing LSP and its associated Path models when the TunnelDown trap is received and the tunnel no longer exists in the device.
     Default: Yes
   - **Update LSP on Trap**
     Deletes all Paths for an LSP and remodels the LSP when the TunnelRerouted trap is received and an LSP model already exists for the LSP.
     Default: Yes
     Example: When an LSP switches from the primary path to the secondary path, the LSP Path models are deleted and remodeled to display the updated Path information.

   The value for the selected option becomes editable.
6. Select the desired value for the field and press Enter.
   The selected trap is configured for SpectroSERVER processing.

Customize Impact Weights for Alarms

You can assign custom impact weights for three types of LSP problems. These impact weights help determine the alarm level for devices and interfaces used in your LSPs, so you can more quickly identify which devices and interfaces must be resolved first.

NOTE
Only an administrator performs this task.

To customize impact weights for your LSP alarms

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the LSP Impact subsection.
   LSP impact options display.
5. Click the 'set' link for the following impact weight options that you want to configure:
   - **Down LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that is reporting all Paths are down.
     Default: 100
     Limits: Integers greater than or equal to 0
   - **Switched LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that has switched from its primary Path to another one.
     Default: 10
     Limits: Integers greater than or equal to 0
   - **At Risk LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that is reporting at least one of its secondary Paths is down.
     Default: 5

Limits: Integers greater than or equal to 0

The value for the selected option becomes editable.

6. Enter the desired value for the field and press Enter.
   The selected impact weight is customized for LSP alarms.

Managing Your LSP Data

This section describes the basic tasks for discovering, viewing, and managing the models associated with your MPLS infrastructure. Although discovery is an administrator-only task, most of the tasks in this section are for general MPLS Transport Manager operators.

Viewing LSP Details

The primary MPLS Transport Manager view is the OneClick Navigation view. MPLS Transport Manager supports the DSS environment. As a result, MPLS Transport Manager is at the global level, not under the landscape level in the navigation pane. As a result, MPLS Transport Manager can discover LSPs across all the landscapes in your distributed SpectroSERVER (DSS) environment.

The following image shows where MPLS Transport Manager fits into the OneClick Navigation view and shows the hierarchy of MPLS information:

```
[+] Configuration Manager
[+] MPLS Transport Manager
    [-] Head-end device 1
       [-] LSP 1
          [-] Path 1
               Device 1
               Device 2
          [+] Path 2
          [+] Path 3
       [+] LSP 2
    [+] Head-end device 2
    [+] Head-end device 3
[-] SpectroSERVER host
   [+] Universe
```

NOTE
Because MPLS Transport Manager is at the global level, the Landscape information is invalid for MPLS Transport Manager, LspHead, Lsp, and MplsPath models. As a result, the Landscape attribute is removed for these models from the Component Detail, Information, DX NetOps Spectrum Modeling Information. Landscape attribute is displayed only for MPLS devices.

An MPLS environment can have hundreds of LSPs, making it difficult to organize and display them logically. Therefore, MPLS Transport Manager groups LSP details under the LSP head-end devices. The LSP *head-end device* is a Provider Edge router device that is used to create the LspHead model in MPLS Transport Manager. This model groups your LSPs by ingress device in the OneClick Navigation panel, making it easier to view and locate data about your LSPs within the MPLS environment.

From the head-end device level, you can expand the navigation tree to view a list of LSPs that begin from the selected head-end device. Expanding these LSPs in the navigation tree displays a list of Paths within the selected LSP, and expanding a Path displays specific devices used in the Path's hops.

Selecting any entry in the navigation tree displays details about the selection within the Contents panel, and selecting items in the Contents panel displays further details in the Component Detail panel.

To help determine the performance of your MPLS environment and your adherence to customer SLAs, you can use the OneClick views to drill into detailed information for each LSP, such as the following:

- Primary and secondary Paths
- Hops for each Path and their order
- Ingress and egress devices for each LSP
- Alarm state for all models, including the severity and impact

If you cannot find the information that you need through the Navigation panel, you can also search the MPLS Transport Manager data using the Locater tab.

Open MPLS Transport Manager

To monitor your MPLS environment, you must first locate the main MPLS Transport Manager page within OneClick. When you open this page, you can access the features used to monitor the status of your MPLS performance.

To open the main MPLS Transport Manager page

1. Open the OneClick Console.
2. Click the Explorer tab in the Navigation panel.
3. Locate and click MPLS Transport Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.

Discover Your LSPs

To monitor your MPLS environment, you must perform a discovery. LSP discovery creates all device, LSP, and Path models, and these models give you a view into the MPLS core that lets you monitor the health of your MPLS infrastructure.

> **NOTE**
> Only an administrator performs this task.

To discover your LSPs

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the LSP Discovery subsection.
   LSP discovery options display.
5. Click the Run button in the Discovery Status field.

> **NOTE**
> In a distributed SpectroSERVER environment, the "Select Landscapes" dialog opens. The "Select Landscapes" dialog lets you include landscapes for which the LSP discovery is performed. The dialog lets you exclude landscapes so that the LSP discovery is not performed against the excluded landscapes. In a standalone SpectroSERVER environment, this dialog is not displayed as the LSP discovery is performed for only one landscape.

DX NetOps Spectrum discovers your MPLS infrastructure and creates all related models. Your MPLS data is ready to view and monitor.

NOTE
Some details about Juniper routers may not be immediately available upon discovery. Although the Path model lists all hops for the primary and secondary Paths in the hops table, Juniper routers provide details only when they are included in the active Paths. Therefore, when a secondary Path becomes active, MPLS Transport Manager populates the hops table with details about the Juniper router used in that Path.

Filter LSP Discovery Results

If you do not want to monitor all LSPs, you can apply a filter that includes or excludes selected LSPs from discovery and modeling. This feature can help save resources by reducing the number of LSPs DX NetOps Spectrum polls.

To filter LSP Discovery

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the LSP Discovery subsection.
   LSP discovery options display.
5. Click Set in the Path Filter Type field and select one of the following options:
   - Exclusive
   - Inclusive
6. Click Add in the Path Filter field.
   The Add dialog opens, prompting you to enter the Path name.
7. Enter the Path name and click OK.
   The Path name is added to the Path Filter list. Depending on the Path Filter Type you select, LSP Discovery is filtered to include or exclude the listed Paths.

Configuring LSP Discovery During Modeling

DX NetOps Spectrum lets you configure Network Services Discoveries, including LSP Discovery for MPLS Transport Manager, during modeling. As a part of modeling configuration, you can specify which Network Service Discoveries to run with the modeling process.

NOTE
For more information, see the Modeling and Managing Your IT Infrastructure section.

Run Discovery on Selected Models

In any OneClick view that lists models, you can select a set of models and run LSP Discovery for those models only. This ability can help you minimize the DX NetOps Spectrum resources required when troubleshooting or verifying changes to the status of only specific devices.

To run Discovery on selected MPLS Transport Manager models

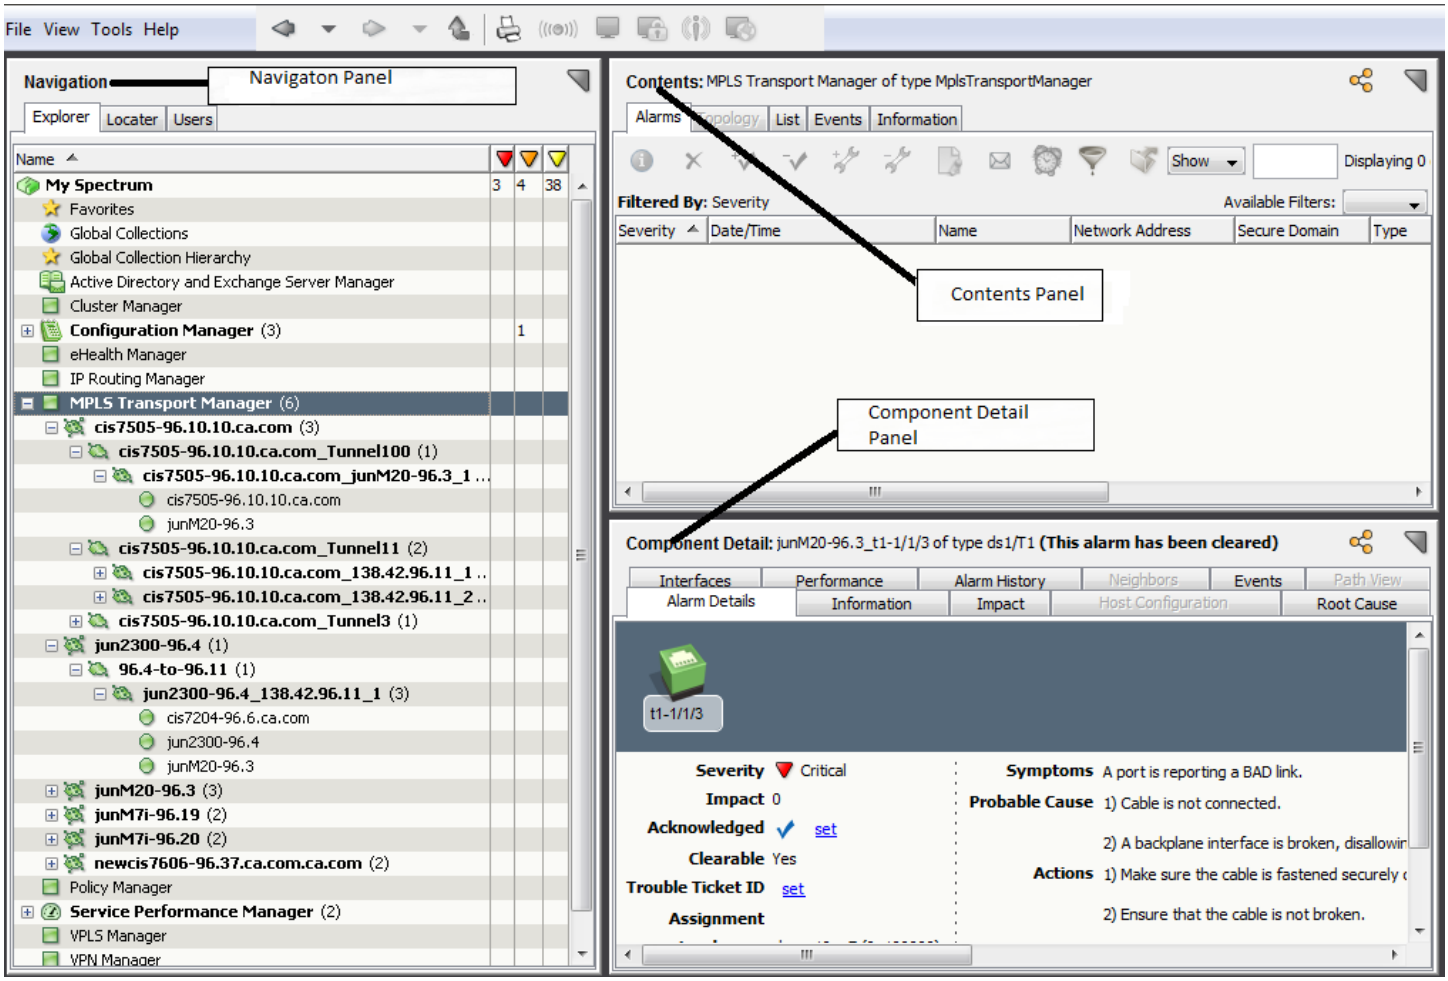
1. Select the models.
2. Click Tools, Utilities, Network Services Discoveries, MPLS Transport Discovery.
   The Discovery process is initiated for the selected models only. You can check the status in the LSP Discovery subview.

Main Window for MPLS

MPLS Transport Manager is integrated into OneClick, and you access the main view through the Explorer tab in the Navigation panel. This tab provides a hierarchical view of the models used to display your MPLS data. This tree structure

helps you manage your customer SLAs and monitor LSP performance by providing a quick way to view details and troubleshoot alarms caused by devices used in your MPLS environment.

When items are selected from the Navigation panel, the item's details display in the Contents panel. When you select items in the Contents panel, additional details display in the Component Detail panel. These three panels are organized as follows:



The Explorer tab in the Navigation panel includes the following items for MPLS Transport Manager information:

- MPLS Transport

Manager

Provides the main access to MPLS models and access to administrator options for configuring the MPLS Transport Manager application. Selecting this item in the navigation tree displays MPLS Transport Manager details in the Content panel on four tabs: Alarms, List, Events, and Information.

Model Class: Application

- *head-end*

device
Groups all LSP models that begin from this device. Selecting a head-end device in the navigation tree displays details in the Content panel on four tabs: Alarms, List, Events, and Information. From these tabs, you can find all LSPs that originate from this device (that is, this device is the LSP's ingress device).
Model Type: LspHead
Example: cisco7505-99.10.xyz.com

- 

LSP
Provides access to LSP details. Selecting an LSP in the navigation tree displays details in the Content panel on four tabs: Alarms, List, Events, and Information. From these tabs, you can view details such as the LSP ingress and egress devices, the LSP's primary and secondary Paths, path change information, and more. You can also select a threshold for path changes.
Model Type: LSP
Example: cisco7505-99.10.xyz.com_Tunnel11

- 

Path
Provides access to Path details. Selecting a Path in the navigation tree displays details in the Content panel on four tabs: Alarms, List, Events, and Information. From these tabs, you can view details such as the Path ingress and egress devices, the Path's hops and their order, the number of unmodeled hops, and more.
Model Type: MplsPath
Example: cisco7505-99.10.xyz.com_cisco7505-99.11.xyz.com_2

View LSP Paths

When analyzing the performance of your MPLS environment, you may need to view the Path details for a specific LSP. You can view details such as how many Paths exist, what is the Path's rank (primary, secondary, and so on), what is the alarm condition for each Path, and more. Viewing this information can help you determine if you are meeting your customer SLAs or can reveal opportunities for improving the performance of your LSP.

To view an LSP Path

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Locate and click the LSP on the Explorer tab in the Navigation panel.
   The LSP details display in the Contents panel.
3. Click the List tab.
   All of the LSP's Paths display in the table, showing details for each.

Static vs. Dynamic Paths

Two path types exist in MPLS environments: static (that is, explicit) and dynamic. A static path is an explicitly engineered path from a source device to a destination device, whereas a dynamic path through the MPLS network is computed by the head-end device, based on resource availability and routing protocols.

When analyzing your LSP Paths, knowing the path type can help reveal weaknesses in your MPLS environment and reveal opportunities to optimize the performance of your Paths.

The Path type is available in two locations:

- The List tab of an LSP's Contents pane
- The Information tab of a Path's Component Details pane

Spotlighting LSP Paths

The spotlighting feature in OneClick lets you isolate and visualize model relationships within your network that are not readily visible from the Topology view. For example, the Topology view does not visually distinguish VLANs, VPNs, or LSP Paths, making it more difficult to picture these relationships within the context of your network. With spotlighting, these model relationships are accentuated, showing you where they appear in the network topology.

Using the spotlighting feature, you can select an LSP Path to view in the Topology view. Viewing LSP Path information from this view can help you more easily understand which devices make up the Path. From this view, you can also see if any alarming devices are impacting the Path's performance.

> **NOTE**
> For more information about how to use spotlighting, see the Topology toolbar section.

View Hops in an LSP Path

When analyzing the performance of your MPLS environment, you may need to view the hops in a specific LSP Path. You can view details such as the order of the hops, the devices used for each hop, what is the alarm condition for each modeled device, and more. Viewing this information can help you troubleshoot alarms that occur for an LSP.

> **NOTE**
> Some details about Juniper routers may not be immediately available upon discovery. Although the Path model lists all hops for the primary and secondary Paths in the hops table, Juniper routers provide details only when they are included in the active Paths. Therefore, when a secondary Path becomes active, MPLS Transport Manager populates the hops table with details about the Juniper router used in that Path.

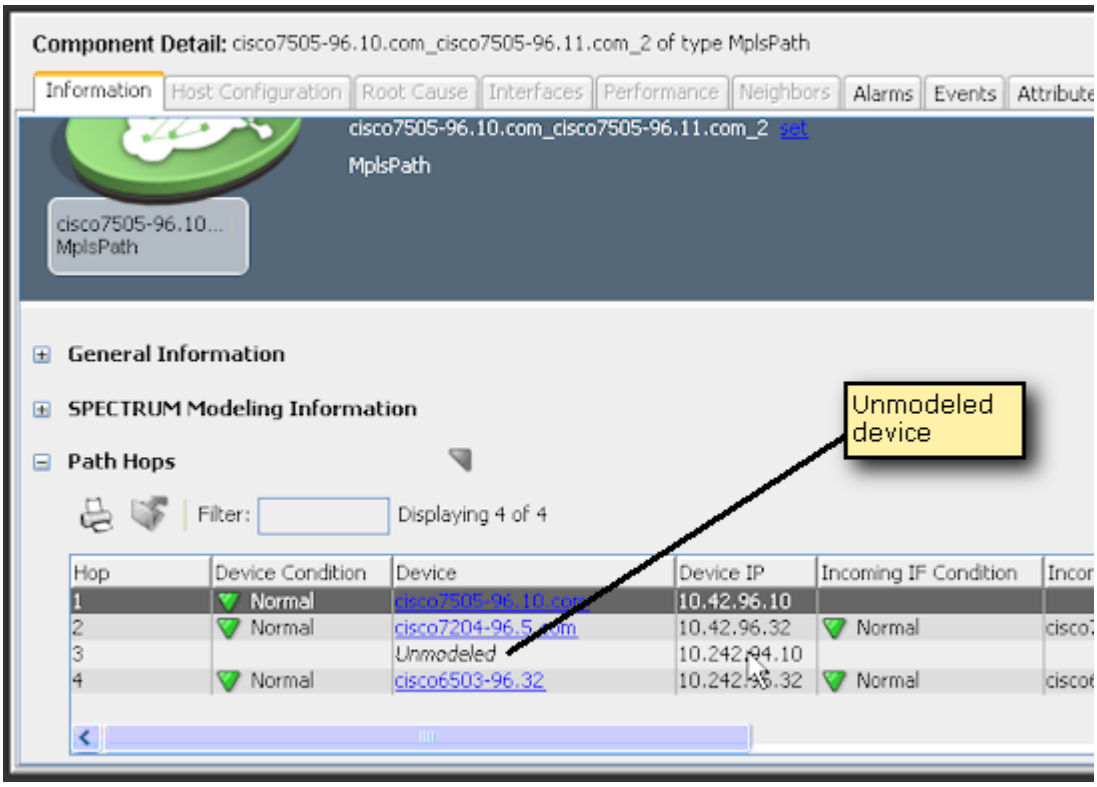
To view hops in a Path

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Locate and click the LSP Path on the Explorer tab in the Navigation panel.
   The LSP Path details display in the Contents panel.
3. Click the Information tab.
4. Expand the Path Hops section.
   All hops for the selected LSP Path are displayed in the table.

> **NOTE**
>
> You can also find a Path's hops on the List tab, but we recommend the list on the Information tab. The Information tab displays the order of the hops and displays the ingress/egress interfaces for each hop.

Unmodeled Hops in MPLS Transport Manager

LSP Paths can contain nodes that appear as unmodeled hops. These unmodeled hops are easily recognized in the Path Hops table on the Component Details Information tab. IPs of any unmodeled hops are provided in the table, as shown:



NOTE
You can find paths with unmodeled hops by searching for all Paths and sorting the results by "Unmodeled Hop Count" in descending order.

Unmodeled hops can exist for any of the following reasons:

- The device is not modeled in DX NetOps Spectrum.
- The device is modeled but with an incorrect community name.

Although MPLS Transport Manager can provide Path and hop information without all devices modeled, DX NetOps Spectrum cannot determine the impact to your MPLS environment and customer SLAs. If the device is not modeled, no alarms appear for that device, making it much harder to figure out the cause of a Path going down. If MPLS traps are not sent to the SpectroSERVER or if these traps are disabled in MPLS Transport Manager, DX NetOps Spectrum may not even detect that the Path is down at all. Therefore, it is always best to model all devices used in your LSP Paths.

How to Add Previously Unmodeled Hops

If an unmodeled device appears in a Path's hops, we recommend that you model that device so that the LSP impact can be calculated for alarms generated by the device. Unmodeled devices do not generate alarms and, therefore, cannot provide impact data, making it more difficult to determine accurately the priority of device outages involving your LSPs.

To get MPLS Transport Manager to display the device details in the Path Hops table, follow these steps:

1. Model the device in OneClick using the IP address provided in the Path Hops table.

NOTE
We recommend that you model all MPLS Path nodes on a single server in a standalone SpectroSERVER environment. In a distributed SpectroSERVER environment, verify that the node is modeled in at least one of the landscapes, with the correct community name.

2. Rebuild the MplsPath model. This task requires the following two steps:
   a. Update the MPLS Path data by searching for and deleting all MplsPath models that contain the unmodeled hop. This step is required because rediscovering MPLS devices does not automatically display the newly modeled device in the list of hops. The MplsPath model must be rebuilt to update that device model information.

      NOTE
      You can find paths with unmodeled hops by searching for all Paths and sorting the results by "Unmodeled Hop Count" in descending order.

   b. Run MPLS Transport Manager discovery. The MplsPath models are recreated, and the newly modeled device information appears in the Path Hop table.

Model Names

During discovery, MPLS Transport Manager uses the following unique model types to model your MPLS environment:

- LspHead
- LSP
- MplsPath

These model types help to determine the names of your MPLS models. For LSP models, MIBs determine the names. Therefore, these names are not editable within MPLS Transport Manager. For LspHead models, the model name is initially patterned after the LSP head-end device during discovery, using the device model name as a prefix. Likewise, the MplsPath model name is patterned after the LSP name. This naming scheme helps to identify the relationships between these MPLS models and their related devices.

If a device or LSP model name changes and the corresponding LspHead or MplsPath model name uses its prefix, the LspHead or MplsPath model name automatically changes to match. For example, if you have a head-end device named "juniper2300," the LspHead model name could be "juniper2300.example.com." If the device name changes to "juniper2300_03," the LspHead model name becomes "juniper2300_03.example.com."

However, you may want to apply a unique name, such as a name that corresponds to a primary customer or region for the LSP. You can edit the LspHead and MplsPath model names manually, and these names do not change automatically. For example, you can manually rename the LspHead model name from "juniper2300_03.example.com" to "Router_NY_03." If the name of the device in this example changes, the LspHead model name will not.

Modify an LspHead or MplsPath Model Name

The LspHead model name is initially patterned after the LSP head-end device during discovery, and the MplsPath model name is patterned after the LSP name. However, you can apply a unique name, such as a name that corresponds to a primary customer or region for the LSP. You can edit the LSP Head and Path model names manually, and these names will not change automatically.

NOTE

The LSP model names are not editable, because MIBs determine these names.

To modify an LspHead or MplsPath model name

1. Open the main MPLS Transport Manager page.
   The main MPLS Transport Manager details page opens in the Contents panel.

2. Locate and click the LSP Head-End or Path on the Explorer tab in the Navigation panel.
   The details display in the Contents panel and Component Detail panel.
3. Click the Information tab in the Component Detail panel.
4. Click the 'set' link for the model name that you want to modify.
   The current name becomes editable.
5. Type the desired model name into the field and press Enter.
   The selected model name is modified.

Deleting Models

Models can be deleted from OneClick at any time for several reasons, and deleting these models can have various implications. First, deleting a head-end model also deletes all models underneath in the MPLS Transport Manager model hierarchy. An MPLS rediscovery is required to restore those models, if needed.

Second, an administrator who does not monitor your MPLS environment can decide that a router in his landscape does not need monitoring, so the administrator deletes the device model for that router. If that device model is the ingress router for one or more LSPs, the LspHead model is deleted. In this case, all LSP and Path models below it are also deleted, as described in the first scenario.

Some of these deleted models may have been used in LSPs or Paths, and the MPLS Transport Manager administrator can decide to restore those models. For example, a device model that appears in a Path's hops can be deleted and appear as an unmodeled hop, making it difficult to monitor the performance of the LSP that includes that Path.

Monitoring Performance and SLAs

This section explains the information you need to monitor the performance of your MPLS infrastructure and check your adherence to customer SLAs using MPLS Transport Manager. This section is intended for general MPLS Transport Manager operators.

Monitoring SLAs for MPLS Environments

For an ISP, continuity of service is crucial for each customer, which is why client SLAs are often established. Although all service outages are not avoidable, the customer relies on the ISP to keep the outages to a minimum, adhering to the terms agreed upon in their SLA.

Monitoring an MPLS environment for adherence to customer SLAs can be difficult. MPLS Transport Manager makes this task easier by monitoring the performance of the MPLS devices and providing a way to view the relationship of those devices to your LSPs and Paths. Depending on your needs, you can monitor SLAs in one of the following ways:

- Analyze your LSPs for performance
- Determine if LSP service is interrupted
- Determine which customers are affected by outages or poor performance
- Search for a customer's LSPs to monitor their health

Some of these monitoring tasks are proactive (such as searching for specific LSPs) and some are the result of an alarm triggered by a device in your MPLS environment.

Although SLA information is not maintained in MPLS Transport Manager, you can use the information you have about your SLAs, such as the specific traffic-engineered LSPs used by a client, to determine which customers are impacted by an alarm involving an MPLS device.

Analyzing LSP Performance

To measure the performance of your MPLS environment and the LSPs in the environment, you must analyze the devices and interfaces used by the LSPs. Their status helps to determine the overall health of your MPLS environment and to decide if you must make changes to improve the performance.

The areas that you can monitor for LSP performance include the following:

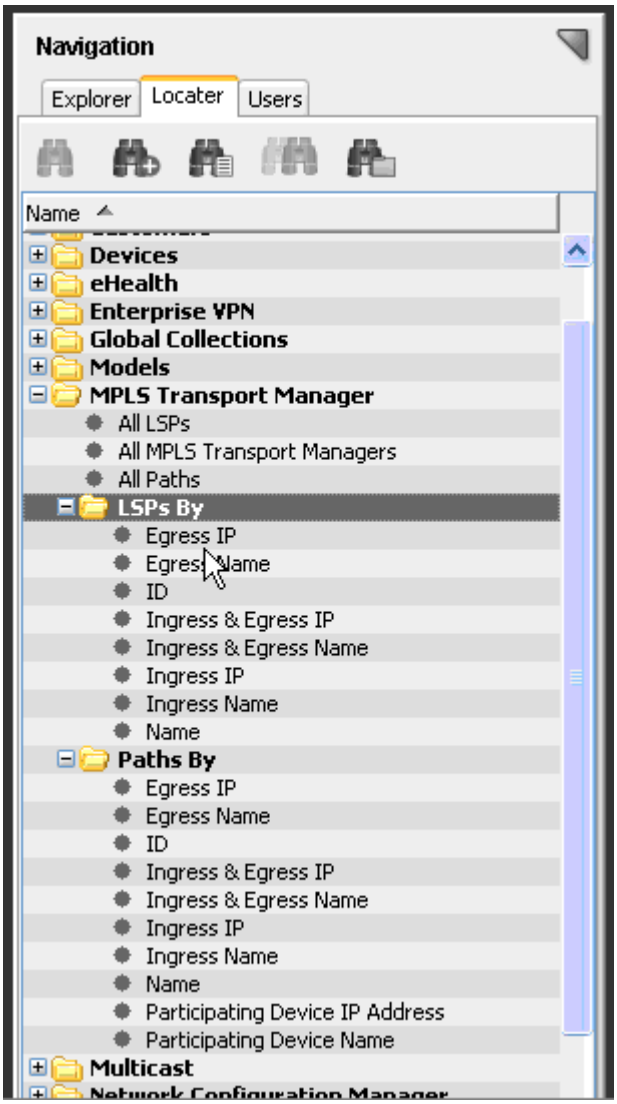
- **Path changes** -- Excessive Path changes can indicate a problem with a device or network connection in your LSP. For example, an LSP may switch to the secondary path 90 percent of the time because a router on the primary path is continually at maximum capacity. In this case, you can analyze the devices and interfaces in the Path to determine the cause and troubleshoot the problem before a service outage occurs on that LSP. MPLS Transport Manager lets you specify a maximum threshold of Path changes for an LSP. If the threshold is breached, an alarm is generated.
- **Device outages** -- If a device outage occurs and causes an alarm, you need to know quickly if the outage has affected any LSPs in your environment. If these devices are modeled in MPLS Transport Manager, the alarm details display information about which LSPs are affected.
- **Alarms** -- All alarms generated from the MPLS environment can provide insight into performance glitches. The impact of alarms generated for device and interface models that affect LSPs is determined by a combination of information, such as which LSP paths are affected (that is, primary, secondary, and so on) and the number of LSPs impacted by the alarm. These alarms can help you drill into the LSP details required to analyze performance issues.

  NOTE
  Only device and interface alarms provide impact weight information. Alarms against the Paths, LSPs, and LspHeads do not have the LSP impact values.

Searching

MPLS Transport Manager does not provide a topology view of your MPLS environment, so using the search feature can help you find details that help you monitor the performance. Searches can locate specific components of your MPLS core, such as locating LSPs by ingress IP or all Paths that use a specific device. These types of searches can help you investigate information related to a specific customer, because you can use details associated with your customer SLAs in your searches, such as specific device or Path names.

The search options are grouped under the MPLS Transport Manager folder, as shown:



For example, if you know the IP address or name of a specific router, you can search for all LSP Paths that use it. Using the list of Paths affected by the router can be useful when performing scheduled maintenance. You can change your Paths to use a different router, or be sure that at least one secondary Path is provided for each LSP before the maintenance. Also, you can give prior notice to any customers affected by those Paths.

Search the MPLS Environment

When analyzing the performance of your MPLS environment, you can quickly locate a specific LSP, Path, or find a group of LSPs, such as all LSPs by ingress IP. These searches help you to view only the details required to effectively monitor the performance of your MPLS network or monitor your customer SLAs.

To search within your MPLS environment

1. Click the Locater tab in the OneClick Navigation panel.
2. Expand the MPLS Transport Manager folder and double-click the type of search you want to perform.
   If no additional search criterion is required, the search results display in the Contents panel. If more criteria is required, a Search dialog opens.
3. Enter your search criteria and click OK.

The search results display in the Contents panel.

Locater Tab for MPLS

In addition to navigating your MPLS environment details on the Explorer tab, you can also perform MPLS Transport Manager searches using the Locater tab in the OneClick Navigation panel. Detailed searches can help you investigate information related to a specific customer, because you can use details associated with your customer SLAs in your searches, such as specific device or Path names.

The Locater tab in the Navigation panel includes the following searches for MPLS Transport Manager information:

- **All LSPs**
  Locates all LSPs that have been modeled in the DX NetOps Spectrum database for the network. Although MPLS Transport Manager does not include the distributed intelligence provided in DX NetOps Spectrum, this option searches multiple landscapes by letting you select multiple SpectroSERVERs in the search parameters.
- **All MPLS Transport Managers**
  Locates all MPLS Transport Manager installations in a list of landscapes you select for the search.

  NOTE
  There can never be more than one MPLS Transport Manager per landscape.
- **All Paths**
  Locates all Paths that have been modeled in the DX NetOps Spectrum database for the network.
- **LSPs By**
  Locates specific LSPs that meet the search criteria for the following search types:
  - Egress IP
  - Egress Name
  - ID
  - Ingress & Egress IP
  - Ingress & Egress Name
  - Ingress IP
  - Ingress Name
  - Name
- **Paths By**
  Locates specific Paths in your LSPs that meet the search criteria for the following search types:
  - Egress IP
  - Egress Name
  - ID
  - Ingress & Egress IP
  - Ingress & Egress Name
  - Ingress IP
  - Ingress Name
  - Name
  - Participating Device IP Address
  - Participating Device Name

Responding to Alarms

This section explains the types of alarms generated for MPLS Transport Manager devices and how to manage them. Although configuring impact weights is an administrator-only task, most of this section is intended for general MPLS Transport Manager operators.

MPLS Transport Manager Alarms

To alert you to problems within your monitored networks, DX NetOps Spectrum generates alarms. When monitoring your MPLS environment, your MPLS Transport Manager models display an alarm state for the following conditions:

- **A device or interface used within an LSP is down**
  Device or interface models generate these alarms when they are reported as down. The impacted LSPs and Paths also display an alarm color and details on the Alarm tab to help you identify the source of the problem. Likewise, the device or interface alarm displays LSP impact details on the Impact tab, such as the following:
  – The number of LSPs affected
  – The total LSP impact of the alarm (that is, the LSP impact value without other types of impact, such as service impact or management lost impact)
  – A few details about the affected LSPs, such as their name, condition, ID, and so on
  In MPLS Transport Manager, the LSP impact weight settings determine how much impact value is added to a device or interface alarm's total impact when an LSP uses that device or interface. Adding these weight values can help determine the priority of your devices or interfaces.

  NOTE
  Only device and interface alarms provide impact weight information. Alarms against the Paths, LSPs, and LspHeads do not have the LSP impact values.

- **Paths are switching too frequently**
  An LSP that is switching Paths too frequently can indicate a network problem for you to address. In MPLS Transport Manager, there are two types of Path change alarms:
  – Aggregate Path change alarms -- The LSP head-end model generates these alarms when the Paths in the LSPs grouped under that head-end model collectively exceed a threshold value for Path changes. The aggregate Path change alarm settings help to determine the threshold value that triggers an alarm for these Path changes.
  – Per LSP (that is, non-aggregate) Path change alarms -- An individual LSP model generates these alarms when Path changes for the LSP exceeds a threshold number within a specified time interval. You can configure the Path change alarm settings for each LSP to determine when the LSP triggers an alarm.

View the LSP Impact of an Alarm

When devices or interfaces used in an LSP trigger an alarm, you can view the impact of the alarm on your LSP. Knowing which LSPs are affected by an alarm can help you determine if a customer SLA is in jeopardy and determine which alarms have the highest priority. To view the impact to your LSPs, you have the following options:

- From an LSP Path model, view the devices or interfaces in an alarm state that are causing it to perform poorly.
- From a device or interface model, view a list of LSPs affected by an alarm.

This procedure describes the first option -- how to view impact details from the LSP Path model.

To use the LSP model to view the impact of an alarm in your MPLS environment

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Locate the alarming LSP Path on the Explorer tab in the Navigation panel.
   The LSP Path details display in the Contents panel.
3. Click the Alarms tab.
   Alarms related to the selected LSP Path are displayed.
4. Select an alarm from the table.
   Details about the alarm are displayed in the Component Detail panel.
5. Click the Impact tab.
   The impact details for the selected alarm are displayed.

NOTE
The state of devices on the Impact tab may not reflect the current device state.

How Impact is Determined

Deciding which device and interface alarms cause the greatest impact to your LSPs can be difficult, because the impact depends on how the device or interface is used within your LSP Paths. For example, problematic devices used in an LSP's primary path are much more significant than problematic devices in a secondary path.

The goal of the MPLS Transport Manager impact system is to evaluate and rank device and interface outages in respect to LSPs. For example, a device outage can affect a number of LSPs which would make that device outage more serious than a device outage which affects only one LSP, assuming all LSPs are equal.

NOTE
In the impact calculation, MPLS Transport Manager does not prioritize one LSP as being more important than another. If your SLAs are prioritized, you may need to further calculate the alarms priority by considering your SLA data outside of DX NetOps Spectrum.

To help prioritize the alarms affecting your LSPs, you can assign impact weights for the following situations:

- All LSP Paths are down
- An LSP has switched from using the Primary Path to a secondary Path
- At least one secondary LSP Path is down

When these situations occur, a corresponding impact weight is added to the total impact value for the device or interface alarm. The model with the highest total impact weight shows which alarm has the most impact on the LSPs in your MPLS environment.

NOTE
Only device and interface alarms provide impact weight information. Alarms against the Paths, LSPs, and LspHeads do not have the LSP impact values.

Assuming that you use the default impact weight values, the following example shows how MPLS Transport Manager calculates the LSP impact weights for down devices that are used in your LSPs:

1. Device A is used in the primary Path of only LSP 1. When it goes down, it causes LSP 1 to switch to a secondary Path. The default Switched LSP Weight value (10) is added to the total impact value for the device alarm. The total LSP impact value added for this situation is 10.
2. Device B is used in two secondary Paths for LSP 1. The default At Risk LSP Weight value (5) is added only *once*, even though the device appears in *two* secondary Paths. Only one value is counted per LSP, which is always the most severe impact weight value. So the total LSP impact value added for this situation is 5.
3. Device C is used in a secondary Path for LSP 1 and LSP 2. The default At Risk LSP Weight value (5) is added twice to the total impact value for the device alarm (one for each affected LSP). So, the total LSP impact value added for this situation is 10.
4. Device D is used in the primary Path for LSP 1 and one secondary Path for LSP 2. LSP 1 switches to an unaffected secondary Path, which adds impact weight for the Switched LSP Weight (10). The At Risk LSP Weight value (5) is added for the affected secondary Path for LSP 2. So, the total LSP impact value for this scenario is 15.
5. Device E is used in all Paths for LSP 1, which includes the primary Path and two secondary Paths. Because all Paths are down, the default Down LSP Weight value (100) is added to the total impact value for the device alarm. So, the total LSP impact value added for this situation is 100.

In this scenario, Device E would have the highest priority, because it causes the highest total LSP impact value.

NOTE
LSP impact weights are only one factor contributing to the total impact weight for an alarm. The total impact value for an alarm can include additional impact values caused by other conditions *not* related to your LSP.

Customize Impact Weights for Alarms in LSP

You can assign custom impact weights for three types of LSP problems. These impact weights help determine the alarm level for devices and interfaces used in your LSPs, so you can more quickly identify which devices and interfaces must be resolved first.

> **NOTE**
> Only an administrator performs this task.

To customize impact weights for your LSP alarms

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the LSP Impact subsection.
   LSP impact options display.
5. Click the 'set' link for the following impact weight options that you want to configure:
   - **Down LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that is reporting all Paths are down.
     Default: 100
     Limits: Integers greater than or equal to 0
   - **Switched LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that has switched from its primary Path to another one.
     Default: 10
     Limits: Integers greater than or equal to 0
   - **At Risk LSP Weight**
     Defines the value added to a device or interface alarm's total impact weight when that device or interface is used within an LSP that is reporting at least one of its secondary Paths is down.
     Default: 5
     Limits: Integers greater than or equal to 0

   The value for the selected option becomes editable.
6. Enter the desired value for the field and press Enter.
   The selected impact weight is customized for LSP alarms.

How Path Change Alarms Work

An LSP that is switching Paths too frequently can indicate a network problem to address. MPLS Transport Manager can monitor the number of Path changes for each LSP, and it can monitor the aggregate Path changes for all LSPs grouped under an LSP head-end device. Understanding the difference between the Per LSP (that is, non-aggregate) and the aggregate method for monitoring Path changes can help you determine which method you prefer for your MPLS environment.

When monitoring **Per LSP Path change alarms**, the individual LSP generates the alarms. This method works as follows:

1. For each LSP you want to monitor, the administrator configures the Path Change Information, which includes specifying the Path Changes Window interval and the Path Changes Threshold value.
2. For each Path Changes Window interval, MPLS Transport Manager performs these steps:
   a. Counts how many times a Path within the LSP switches Paths, either from the primary Path to a secondary Path or vice versa.
   b. Notes the total number of changes at the end of the interval.

NOTE
The number is also added to the # Path Changes field, which represents the number of Path changes since the head-end device was last booted. This value is not used when calculating the Path change alarms.

c. Compares the # Path Changes field with the threshold value selected.
d. Triggers a critical alarm if the number of Path changes is greater than the threshold value.

3. MPLS Transport Manager repeats step 2 for each Path change interval and adjusts the alarm, as needed. Therefore, if subsequent intervals *do not* exceed the threshold value, the alarm is cleared. However, an event is recorded to the event history for each Path change alarm.

When monitoring **aggregate Path change alarms**, the LSP head-end device generates the alarms. This method can generate more than one alarm severity and works as follows:

1. For each LSP head-end device that you want to monitor, the administrator configures the Aggregate Path Change Alarms settings for the MPLS Transport Manager installation. These settings include threshold percentages for three alarm severities and the Path Change Window interval.
2. For each Path Change Window interval, MPLS Transport Manager performs these steps:
   a. Counts the number of Path switches for all LSPs grouped under an LspHead device.
   b. Calculates the percentage of Path changes as follows:
      ```
      (Total Path changes ÷ Total LSPs in the LspHead) x 100 = Percentage of Path changes
      ```
   c. Compares the percentage to the threshold values for each alarm severity.
   d. Triggers an alarm with a severity that corresponds to the highest threshold breached.

      NOTE
      If multiple thresholds are configured with the same value, the highest level of alarm is generated.
3. MPLS Transport Manager repeats step 2 for each Path change interval and adjusts the alarm as needed. Therefore, if subsequent intervals breach a lower alarm threshold, the alarm severity is adjusted accordingly. Also, if Path changes in an interval do not exceed any threshold values, the alarm is cleared. However, events are recorded in the event history for all Path change alarms.

Customize Aggregate Path Change Alarm Settings

LSP Path changes are common, but excessive changes cause an alarm that can indicate a performance problem to address. Customizing the aggregate path change alarm percentages can help you sort these Path change alarms by severity.

To customize aggregate alarm settings for excessive LSP Path changes

1. Open the main MPLS Transport Manager page.
   The main details page opens in the Contents panel for the selected MPLS Transport Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration section.
4. Expand the Aggregate Path Change Alarms subsection.
   Path change alarm options display.
5. Click the 'set' link for the following options that you want to configure:
   – **Minor Threshold %**Defines the threshold percentage for Path changes that triggers a minor alarm. The percentage of Path changes refers to the ratio of Path changes to the total number of Paths within an LspHead model during a single Path Change Window interval.
   Default: 3
   Limits: Integers 0-100

   NOTE
   A value of 0 causes any Path changes to generate an alarm with this severity.

- **Major Threshold %**
  Defines the threshold percentage for Path changes that triggers a major alarm. The percentage of Path changes refers to the ratio of Path changes to the total number of Paths within an LspHead model during a single Path Change Window interval.
  Default: 5
  Limits: Integers 0-100

  NOTE
  A value of 0 causes any Path changes to generate an alarm with this severity.
- **Critical Threshold %**
  Defines the threshold percentage for Path changes that triggers a critical alarm. The percentage of Path changes refers to the ratio of Path changes to the total number of Paths within an LspHead model during a single Path Change Window interval.
  Default: 10
  Limits: Integers 0-100

  NOTE
  A value of 0 causes any Path changes to generate an alarm with this severity.
- **Path Change Window (sec)**
  Defines the time interval in seconds for which the percentage of Path changes is calculated.
  Default: 60
  Limits: Integers greater than or equal to 30

  NOTE
  Only one alarm is generated for a Path change window interval, even if multiple threshold values are set to the same number. For example, if the Minor Threshold % and Major Threshold % values are both set to 5, only a major alarm is generated if the threshold value is breached. The minor alarm is not created.

The value for the selected option becomes editable.

6. Enter the desired value for the field and press Enter.
   The selected Path change alarm setting is customized.

Customize Per LSP Path Change Alarms

LSP Path changes are common, but excessive changes cause an alarm that can indicate a performance problem to address. Customizing the path change alarm settings for each LSP model determines when the LSP triggers an alarm.

To customize Per LSP alarm settings for excessive LSP Path changes

1. Locate and select an LSP in the OneClick Navigation panel.
   Details for the selected LSP appear in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Path Change Information section.
   Path change alarm options display.
4. Click the 'set' link for the following options that you want to configure:
   - **Path Changes Threshold**

Defines the threshold number of Path changes allowed for an LSP. If the number of Path changes exceeds this value within the path change window interval, the LSP generates a critical alarm.
Default: 5
Limits: Integers greater than or equal to 0

NOTE
A value of 0 causes any Path changes to generate an alarm with this severity.

– **Path Change Window (sec)**
Defines the time interval in seconds for which the percentage of Path changes is calculated.
Default: 60
Limits: Integers greater than or equal to 30
The value for the selected option becomes editable.

NOTE
The # Path Changes field is informational only. It is a non-configurable field that specifies the total number of Path changes since the LSP ingress device was last booted. This number can give you an idea of the frequency of the Path changes.

5. Enter the desired value for the field and press Enter.
The selected Path change alarm setting is customized.

Dynamic MPLS Correlation

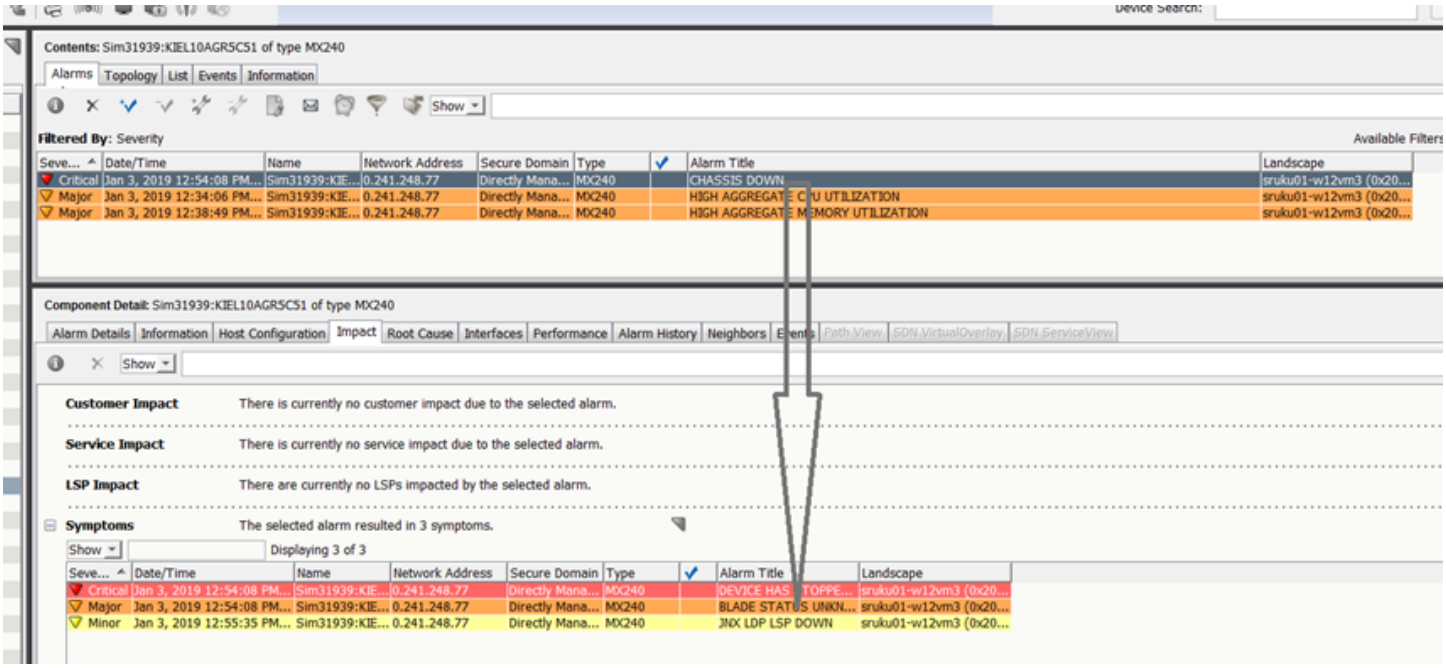
10.3.1 introduces support to address wrongful SNMP trap that is generated when the LSP goes down (as shown in **Fig.1)**. A 'jnxLdpLspDown' trap is received usually when a Juniper device is down, however this trap is generated on the neighboring devices instead of the device it was meant to be generated for. The occurrence has been identified by Spectrum users and now rectified in this new release. This fix ensures that the 'Fec' trap is forwarded from the neighboring device to the rightful device which is down and multiple events concurrent under that trap only, are appropriately displayed.

A 'jnxLdpLspDown’ trap is received in Spectrum when an LSP goes offline. This trap contains the following objects: jnxLdpLspFec jnxLdpRtrid jnxLdpLspDownReason jnxLdpLspFecLen jnxLdpInsta 'jnxLdpLspFec' value contains the device IP which is down and a 'jnxLdpLspDown’ trap is forwarded to the device IP & LSP down alarm is asserted on this device. Device down alarm & LSP down alarm is correlated. There is an LSP down alarm correlation when the chassis goes down.

NOTE

With this change the traps jnxLdpLspUp & jnxLdpLspDown will be processed only if JnprLdpApp is present.

Fig.1.This image describes the prevalent issue which has been fixed in this release:



VPN Manager

VPN Manager lets you discover, model, and monitor Virtual Private Networks (VPNs) within the network environment. VPN Manager provides VPN and Site discovery and modeling, VPN connectivity status, SNMP trap handling, monitoring of Virtual Routing and Forwarding (VRF) conditions, and performs calculation of and alarming on VPN conditions. VPN Manager is a distributed application.

VPN Manager discovers all of the Provider Edge (PE) routers and interfaces that are forwarding traffic for a particular VPN. Based on this discovery, DX NetOps Spectrum creates VPN models representing each unique VPN. These VPN models can then be polled for their current operational status (Up or Down).

In addition, VPN Manager supports VRF Ping and VRF Path Tracing, which enables you to monitor the status of the paths between the sites in each of the modeled VPNs. You can configure threshold alarms to alert you when path changes exceed the configured tolerance.

VPN Manager provides searches that let you quickly find a particular VPN or all VPNs. Search results contain a list of the current VPNs configured within the environment and their current status. You can drill into a single VPN to see the current list of PE interfaces participating within that VPN as well as the current status of the VPN.

VPN Topologies Supported

The common topologies for MPLS Layer 3 VPNs include Full Mesh, Hub and Spoke, and Overlapping VPNs. MPLS VPN Manager supports the following two topologies:

- **Full Mesh** -- The service provider provisions the service so that all customer sites communicate directly with each other. Customer sites are members of the same single VPN. This topology is the most common VPN topologies, and it is generally used by enterprise customers to establish their corporate intranet.
- **Overlapping VPNs** -- Sites can be members of multiple VPNs. Scenarios requiring sites with multiple memberships include the following:

- Establishing a management VPN to customer edge devices
- Establishing a shared service across VPNs
- Implementing an extranet-based service

Overlapping VPN Considerations and Limitations

For overlapping VPN topologies, consider the following notes and limitations when using MPLS VPN Manager:

- Configurations based on route-map statements are not reflected in the mplsVpnVrfRouteTargetTable. DX NetOps Spectrum does not discover or model these configurations.
- The scale of Service Assurance tests in overlapping VPNs becomes more critical because of the greater possibility that connectivity spans multiple VPNs. We recommended enabling Service Assurance tests incrementally to evaluate the performance and resource impacts.
- VPN Sites impact the health of all VPNs in which it has membership. A single VPN Site outage can cause the generation of several alarms (that is, one alarm for each VPN in which the VPN Site has membership). DX NetOps Spectrum does not correlate (that is, suppress) the alarms. Areas affected include:
  - VPN condition calculation
  - VRF test results
  - Aggregate VPN performance (bandwidth usage added to each VPN)
- There is no mechanism to detect when new Route Targets are added, removed, or modified in existing VPNs. There is no background discovery mechanism, and this information is not captured by traps.
- When VPN Sites read some of their configuration from their parent VPN, unexpected behavior can occur when VPN Sites are in multiple VPNs. Configure VPNs similarly for the following options:
  - Enable VRF ping and trace
  - Enable site alarms
  - Model security

MIB Support and Device Compatibility

The MPLS VPN Manager supports:

- Cisco's – MPLS Virtual Private Networks MIB (MPLS-VPN-MIB). Cisco's MPLS-VPN-MIB is based on Draft 3 of the IETF draft MPLS/BGP VPN MIB.
- Juniper’s – Juniper Enterprise VPN MIB; and partially supports Draft 4 of the IETF MPLS/BGP VPN MIB.

From 9.4.1 onwards, – The MPLS VPN Manager supports MPLS-L3VPN-STD-MIB (RFC4382)

NOTE

- – If a CISCO device supports both Draft MIB and MPLS-L3VPN-STD-MIB, MPLS VPN Manager considers the latter for modeling.
  – If a Juniper device supports Draft MIB, as well as the MPLS-L3VPN-STD-MIB. The L3 VPN MIB will take precedence over the MPLS VPN Draft MIB

If models supporting only MPLS-L3VPN-STD-MIB exist in 9.4 or earlier, you need to manually reconfigure those models after upgrading to 9.4.1. This enables the MPLS VPN Manager to discover those VPNs which were not discovered earlier.

For devices which support both Draft MIB and the MPLS-L3VPN-STD-MIB, there is no change in existing functionality. However, we recommend reconfiguring the existing models as it enables the VPN Manager to read the information from the MPLS-L3VPN-STD-MIB.

These MIBs provide access to the following configuration information for VPNs configured on PE router interfaces:

- Virtual Routing/Forwarding (VRF) Instance Table (mplsVpnVrf/mplsL3VpnVrf) - Contains the VPN name and the Route Descriptors (RD) for each VRF.
- VPN Interface Configuration Table (mplsVpnInterfaceConf/mplsL3VpnIfConf) - Associates entries in the ifTable with a VRF.

MPLS VPN Manager uses the following MIBs to support the VRF Ping and the VRF Trace functionality:

- Cisco- RTTMON MIB
- Juniper- RFC2925, Juniper Ping MIB, and Juniper Traceroute MIB

MPLS VPN Manager supports the following tables in the Juniper Enterprise VPN MIB:

- Table of Configured VPNs (jnxVpnTable)
- Table of VPN Interfaces (jnxVpnIfTable)

MPLS VPN Manager functionality is supported by Cisco GSR 12000 and 7500 Series routers running Cisco IOS 12.2(15) T8 or higher in networks with properly configured MPLS VPNs. Juniper support is for JunOS 6.1 or later.

MPLS VPN Manager Interface

Open MPLS VPN Manager

To view the VPNs modeled in your networking environment, open MPLS VPN Manager in OneClick.

To open MPLS VPN Manager in OneClick

1. Open OneClick.
2. Click the VPN Manager node on the Explorer tab in the Navigation panel.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.

MPLS VPN Manager Hierarchy

MPLS VPN Manager can be directly accessed from the Explorer tab of the Navigation panel. Expanding the VPN Manager node displays all of the VPNs managed by the MPLS VPN Manager. Expanding each VPN displays the VPN Sites contained in the VPN.

NOTE
Each VPN Site displays under the VPN in which it has membership. In an overlapping VPN topology, a specific VPN Site may show up under multiple VPNs.

The following graphic is an example of the MPLS VPN Manager hierarchy in the Navigation panel:

NOTE

You can no longer view Devices listed under VPN Site models in the VPN Manager Explorer view.

The Contents panel displays the Alarm list for the modeled element that you have selected in the Navigation panel. The Component Detail panel displays the Alarm details for the Alarm selected in the Alarm list shown in the Contents panel. If the Alarm list is empty, the Component Detail panel displays the Information view for the modeled element selected in the Navigation panel.

Using VPN Search options in Locater Tab

The Locater tab includes specific predefined searches for VPNs. These searches support cross-server device modeling.

The Locater tab in the Navigation panel includes the following searches:

- **VPN**
  - **All Route Targets**
    Locates all Route Targets that are modeled in the DX NetOps Spectrum database for the selected landscape (Main Location Server, by default) through their Route Target information.
  - **All Sites**
    Locates All Sites that are modeled in the DX NetOps Spectrum database for the selected Landscape.
  - **All VPN Managers**
    Locates all VPN Managers in a list of landscapes that you select for the search in a distributed implementation.

    NOTE
    There can never be more than one VPN manager per landscape.
- – **Site By**
    Locates specific sites that meet the search criteria for the following search types:
  - **Interface**
    Locates and lists all VPN Sites modeled in the DX NetOps Spectrum database based on their interface
  - **Name**
    Locates all VPN Sites modeled in the DX NetOps Spectrum database based on site names
  - **PE Router IP**
    Locates and lists all VPN Sites modeled in the DX NetOps Spectrum database based on the specific IP addresses of the PE Router which you specify in the Search> Site By dialog box.
  - **PE Router Name**
    Locates and lists all VPN Sites modeled in the DX NetOps Spectrum database based on the specific PE Router Name which you specify in the Search> Site By dialog box.
  - **VPN Model Names**
    Locates and lists all VPN Sites modeled in the DX NetOps Spectrum database based on the specific Model Name(s) which you specify in the Search> Site By dialog box.
    If you wish to list the sites present in multiple VPNs, enter the relevant VPN model names (as comma separated values) in the Search > Site By Dialog box.
  - **VPN By**
    Locates specific sites that meet the search criteria for the following search types:
  - **Exported Route Target**
    Locates and lists VPNs based on their Exported Route Target information
  - **Imported Route Target**
    Locates and lists VPNs based on their Imported Route Target information
  - **Interface**

Locates and lists VPNs based on their Interface information

- **Name**
  Locates and lists VPNs based on their VPN Names.
- **PE Router Name**
  Locates and lists VPNs based on their PE Router Name
- **Site Model Names**
  Locates and lists VPNs based on their Site Model Names. A list of common VPNs where there is an intersection of more than one site is displayed.
  If you wish to list the common VPNs with overlapping sites, enter the relevant Site model names (as comma separated values) in the Search > Site By Dialog box.

Follow these steps, to search your MPLS VPN Manager environment:

1. Open OneClick.
2. Click the Locater tab in the Navigation panel.
   The search options are grouped under the VPN folder on the Locater tab, as shown:

3. Expand the VPN node and double-click the type of search you want to conduct.
   A relevant Search dialog opens, based on the parameter selected in a list of landscapes that you select for the search.
4. Follow these steps in the Search dialog box:
   a. For a specific query, enter relevant values in the text box for the search option selected
   b. For multiple searches,
      click 

   c. Follow these steps: in the List of Values dialog:
      - Click Import to import a list
      - Enter a list of values

5. Click OK.
   The search results appear in the Contents panel.

Discovering and Modeling VPNs

To manage the VPNs on your network, you must run VPN Discovery before you can use MPLS VPN Manager. VPN Discovery discovers each VPN and VPN Site currently configured on devices modeled in DX NetOps Spectrum.

Discovery Prerequisites

For VPN Discovery to complete successfully, devices must meet the following prerequisites:

- VPN devices must support the correct MPLS-VPN MIBs.
- You must model the physical components of your network in DX NetOps Spectrum before using the VPN Discovery functionality. You can model the physical components using one of these methods: Discovery, manual modeling, or the Modeling Gateway.

  NOTE
  For instructions about using these mechanisms to model your network, see Modeling and Managing Your IT Infrastructure and Modeling Gateway Toolkit .
- The devices must have MPLS-VPN properly configured.

Configure VPN Discovery Options

Before modeling your MPLS VPN Manager environment, you can select several VPN Discovery options. These options determine how DX NetOps Spectrum finds and models the VPNs in your environment.

To configure the VPN Discovery options

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, VPN Discovery subview.
4. Click set in the following fields to select your configuration settings:
   - **Model Inactive VPNs**
     Determines whether inactive VPNs in your network environment are discovered and modeled by VPN Discovery.
     Default: No
   - **Enable Dynamic Discovery**
     Determines whether to start the VPN Discovery automatically when a new PE router is modeled. Starting VPN Discovery automatically helps to keep the VPN information current when new devices are added to the network.

     NOTE
     As the MPLS VPN Manager application is running, VPN sites may be created or destroyed when certain traps are received.**Default:** No
   - **Use RD instead of VRF name**
     Determines whether to use the VRF name or Route Distinguisher information from the MIB as the unique identifier when determining VPN membership. This information is used when discovering and naming your VPN site models. By default, DX NetOps Spectrum uses the VRF name. However, if your routers use different VRF names for the same VPN route target, DX NetOps Spectrum creates a separate VPN site model for each new name. In this case, you can avoid multiple models for the same VPN site by configuring DX NetOps Spectrum to use the Route Distinguisher (RD) from the MIB to model your VPN sites.

Default: No

- **VRF/RD Name Filter Type**
  Determines if the VRF/RD names in the 'Global VRF/RD Name Filter' field are included or excluded from modeling. This feature can save unnecessary resources by limiting the number of VPN sites that require monitoring. Options include the following:
  - Exclusive
  - Inclusive
- **Global VRF/RD Name Filter**
  Specifies the VRF/RD names to be included or excluded from modeling. This field is used together with the 'VRF/RD Name Filter Type' field.
- **Default Ping Mode**
  By default, the Ping Mode is set as NoPinging. However, you can select DestinationPinging as the Default Ping Mode for VPN discovery using this feature.

  NOTE
  This option is applicable only to newly discovered sites. This will not update the Ping mode property of existing sites.

You have successfully configured VPN Discovery options.

IfExclusionList

Contents

IfExclusionList is an attribute of the VpnManager (attribute ID: 0x4940185) and is not listed with the VPN Discovery configuration options. This attribute is a text attribute with the default value of 24,131. This value means that by default MPLS VPN Manager does not create VpnSite models for loopback interfaces (ifType=24) and tunnel interfaces (ifType=131).

This attribute can be modified to include additional interface types by using the Attribute Editor in OneClick and adding IfExclusionList as a User Defined attribute.

NOTE
Use the Global_IfExclusionList attribute in Distributed SpectroSERVER environment to apply the changes to all SpectroSERVERs.

Update VPN Models for Overlapping VPN Topology

VPN models created prior to 9.2.1 do not support overlapping VPN topology. DX NetOps Spectrum does not automatically update existing VPN models to support overlapping VPNs. To properly manage your overlapping VPNs in DX NetOps Spectrum, you must manually migrate the existing VPN models.

To update VPN models to use overlapping VPN topology

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the List tab.
   The table lists all existing VPN models.
3. Select all VPN models, right-click, and select Delete.
   DX NetOps Spectrum deletes all VPN models and their associated VPN Site models.
4. Run VPN Discovery.
   DX NetOps Spectrum updates your VPN models by recreating the VPN models. These new models support overlapping VPN topologies.

Run VPN Discovery

VPN Discovery is the simplest method of modeling your network. Before you run an on-demand VPN Discovery, ensure that you meet the prerequisites.

WARNING

Before you run VPN Discovery, be sure that all Provider Edge devices are modeled in DX NetOps Spectrum with the read/write community name. MPLS VPN Manager cannot locate your VPNs without these Provider Edge models in the SpectroSERVER.

Follow these steps:

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, VPN Discovery subview.
   The VPN Discovery options and configurations display.
4. Click Run.
   The Select Landscapes dialog opens, requesting the landscapes on which you want to run VPN Discovery.
5. Select the landscapes and click OK.
   VPN Discovery runs. When complete, the VPN Discovery field status indicator lists the status. Also, a tooltip on this field lists the number of discovered MPLS-VPN devices (single SpectroSERVER) or servers (distributed SpectroSERVER).

Configuring VPN Discovery During Modeling

DX NetOps Spectrum lets you configure Network Services Discoveries including VPN Discovery, during modeling. As a part of modeling configuration, you can specify which Network Service Discoveries to run with the modeling process.

NOTE
For more information, see Modeling and Managing Your IT Infrastructure .

Run VPN Discovery on Selected Models

VPN Discovery is one of the Network Services Discovery options, which are available for models in various OneClick views. Instead of modeling all VPNs in your networking environment, this option lets you quickly model VPNs that are related to selected models in your networking environment.

To run VPN Network Services Discovery on selected models

1. Open OneClick.
2. Select device models related to your VPN environment.
3. Right-click the models and select Tools, Utilities, Network Services Discoveries, VPN Discovery.
   The VPN Discovery process is initiated for the selected models only. You can check the status in the Configuration, VPN Discovery subview for MPLS VPN Manager.

Run VPN Discovery based on Route Target

Overview

You can run the VPN Discovery based on Route Target. Route Target is an identifier that is defined in VRFs for sharing the routes between the VRFs.

Route Target based Discovery benefits:

1. Sites are discovered based on its association with the Route Target. So, VPN Manager recognizes incorrect Route Target usage/ Route Target-Site configuration.
2. Overlapping VPN calculation is done considering both VRF/Site and Route Target/Site associations. This action avoids huge number of sites getting wrongly associated with VRFs.

NOTE

Hub/Spoke configuration functionality is not supported with Route Target based Discovery.

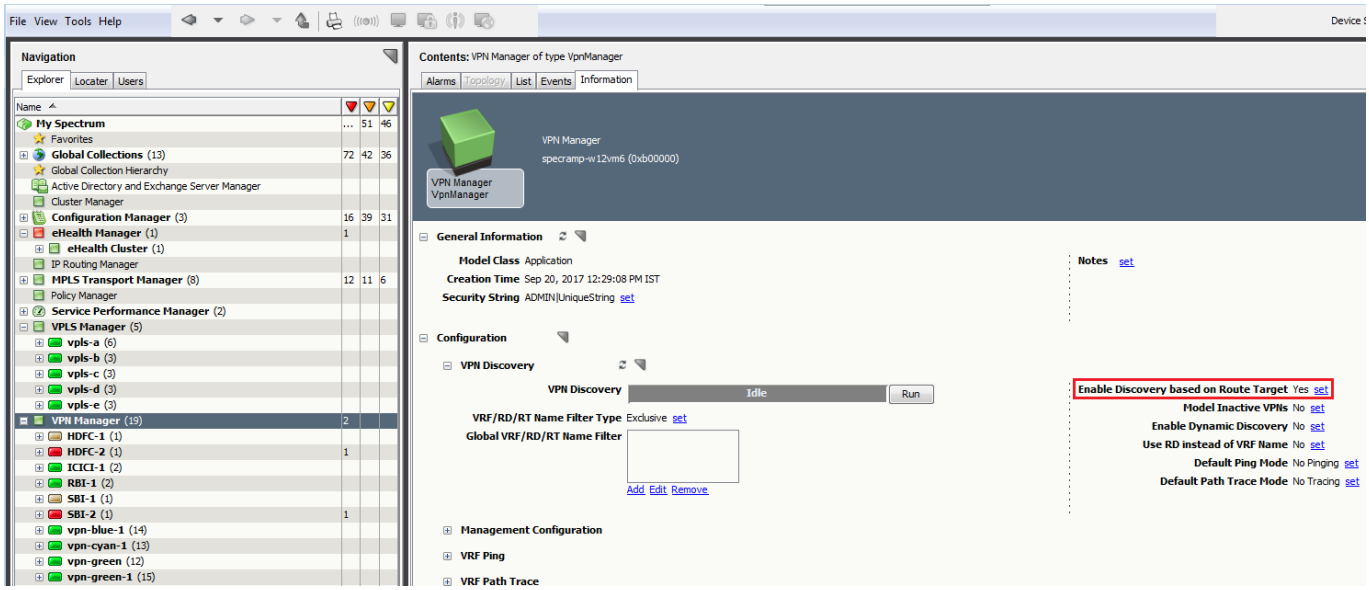
Enable Discovery based on Route Target

You can configure the Route Target based discovery by enabling the 'Enable Discovery Based on Route Target' option in the VPN Discovery sub-view.

When you enable this option, the VPN Manager collects the sites in a Route Target Container based on Route Target/Site association. Associations between VRF and sites are also created based on the Route Target definitions.

Follow these steps:

1. Open OneClick.
2. Click the VPN Manager node on the Explorer tab in the Navigation panel.
3. Click the Information tab in the Contents panel.
   Expand the Configuration, VPN Discovery sub-view.



4. Click 'Set' for the 'Enable Discovery based on Route Target' option.
   Your VPN Discovery option is configured.

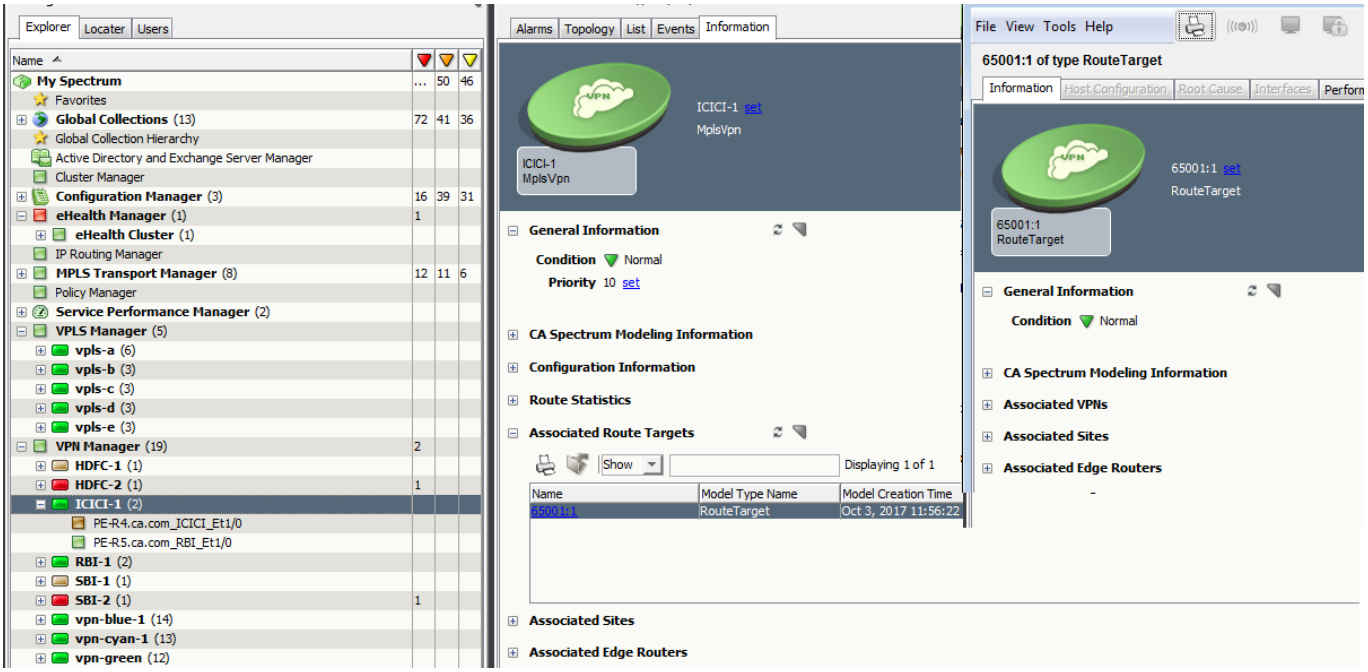
NOTE

You must delete all the VPN Manager models before running a Discovery when the 'Enable Discovery based on Route Target' option is enabled or disabled to switch between the Discoveries.

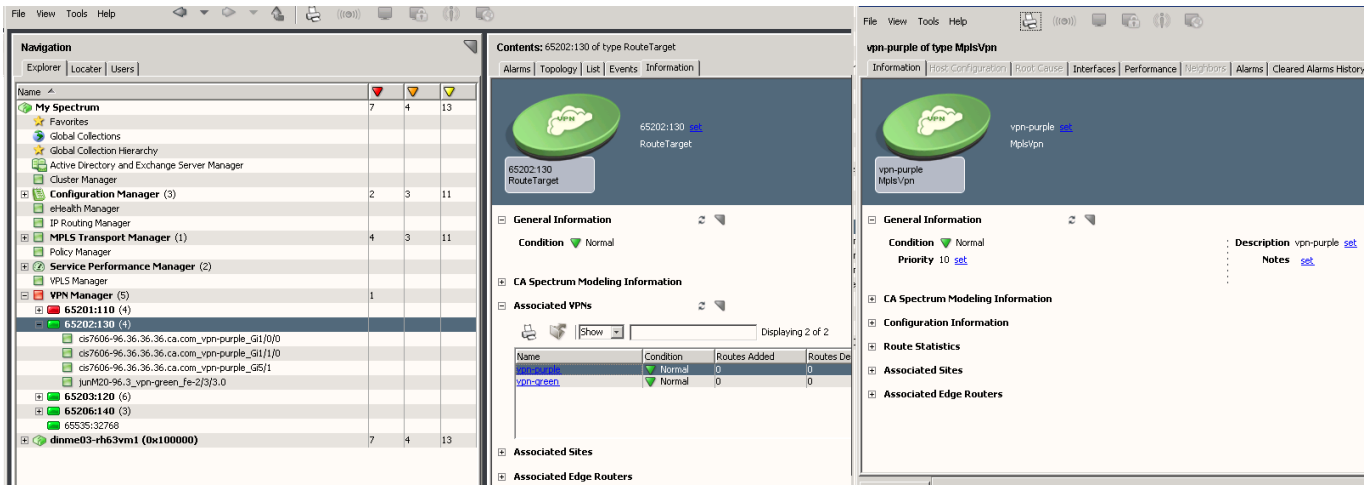
Route Target Model

Starting from the 10.2.2 release, the VPN Manager hierarchy for Route Target based discovery is modified in the Explorer view. The Explorer view now lists the VPN models in the navigation tree instead of Route target models. This

enhancement, the VPN condition alarms that are being asserted on the VPN Manager model are asserted on the VPN model. The VPN Manager hierarchy displays VPN models and associated Route Targets. When a VPN model is selected, the Information tab contains all the information for a selected VPN model. In the Information Tab, 'Associated Route Targets' sub view lists the Route Target type associated with the VPN model as links. When you click the Route Target links, the Component Detail view of the selected Route Target is displayed.



(For 10.2.1 release) The VPN Manager hierarchy displays Route Target Name and associated Sites. When a Route Target (RT) model is selected, the Information tab contains all the information for a selected Route Target model. In the Information Tab, 'Associated VPNs' sub view lists the VPNs associated with the Route Target as links. When you click the VPN links, the Component Detail view of the selected VPN is displayed.



When you select an RT model, the Information tab contains sub-menus which are described in the following sections.

General Information

The General Information section provides you with some basic information about the Route Target model.

Condition

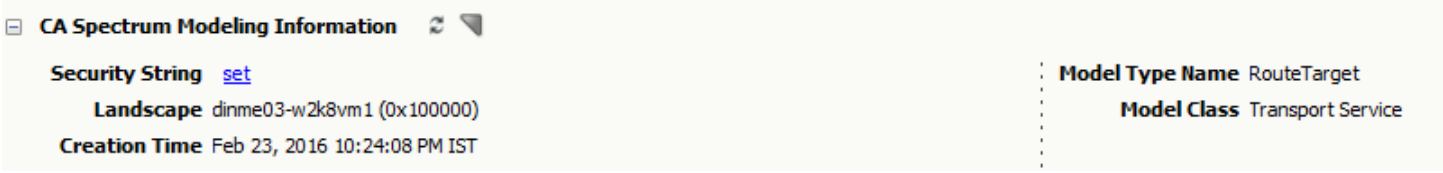
The current condition of the RT.

Notes

You can use this field to save notes about the RT model. Click set, type the notes into the field that is provided, and click Save to save the notes.

Modeling Information

The Modeling Information section provides you with RT modeling information in DX NetOps Spectrum.



Security String

The security string for the RT model.

Landscape

The DX NetOps Spectrum landscape to which the RT model belongs.

Creation Time

The date and time that the RT model was created.

Model Type Name

The RT model name.

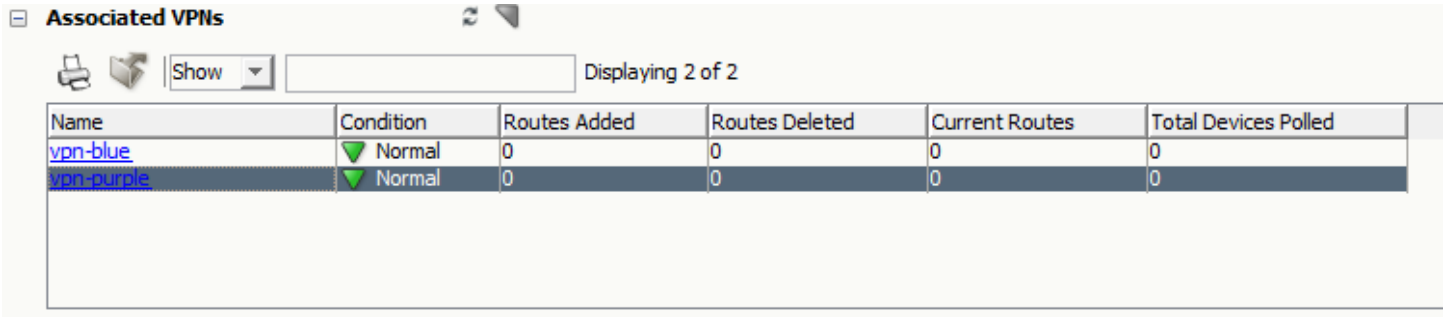
Model Class

The model class of the RT model.

Associated VPNs

The Associated VPNs section provides you with information about the VPNs which are associated with the selected Route Target Model.

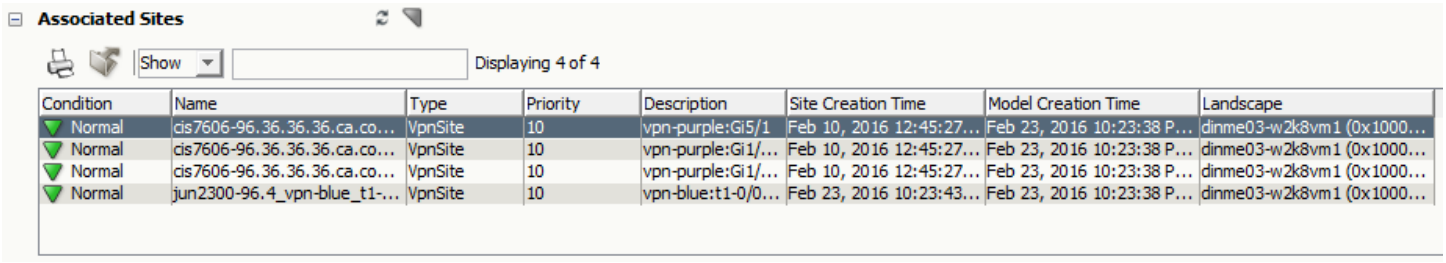
This table lists the VPNs and their information that is associated with the selected RT Model.



Associated Sites

The Associated Sites section provides you with information about the Sites which are associated with the selected RT Model.

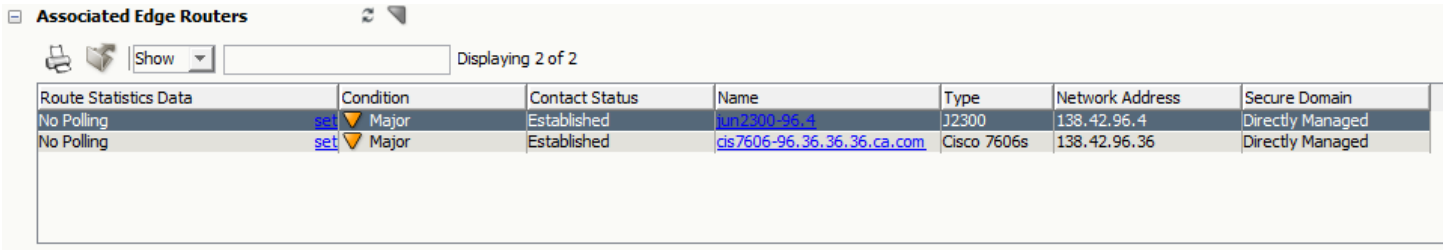
This table lists all the Site models that are associated with the selected RT Model.



Associated Edge Routers

The Associated Edge Routers section provides you with information about the Edge Routers which are associated with the selected RT Model.

This table lists all the Edge Routers that are used by the selected RT Model.



Calculating the Condition of a Route Target

MPLS VPN Manager calculates condition of Route Target based on the following conditions.

1. When condition of site associated with the Route Target model changes, condition of the VPN associated with site changes based on the threshold configuration. VPN condition is then rolled up to the Route Target model and “RT Condition change” (0x4940524) event is generated which has VPN name from which condition is rolled up to the Route Target model
2. VPN condition is rolled up to the Route Target model only during the Site Up/Down condition rollup.
3. VPN condition changes due to VRF Pings are not rolled up to the Route Target model

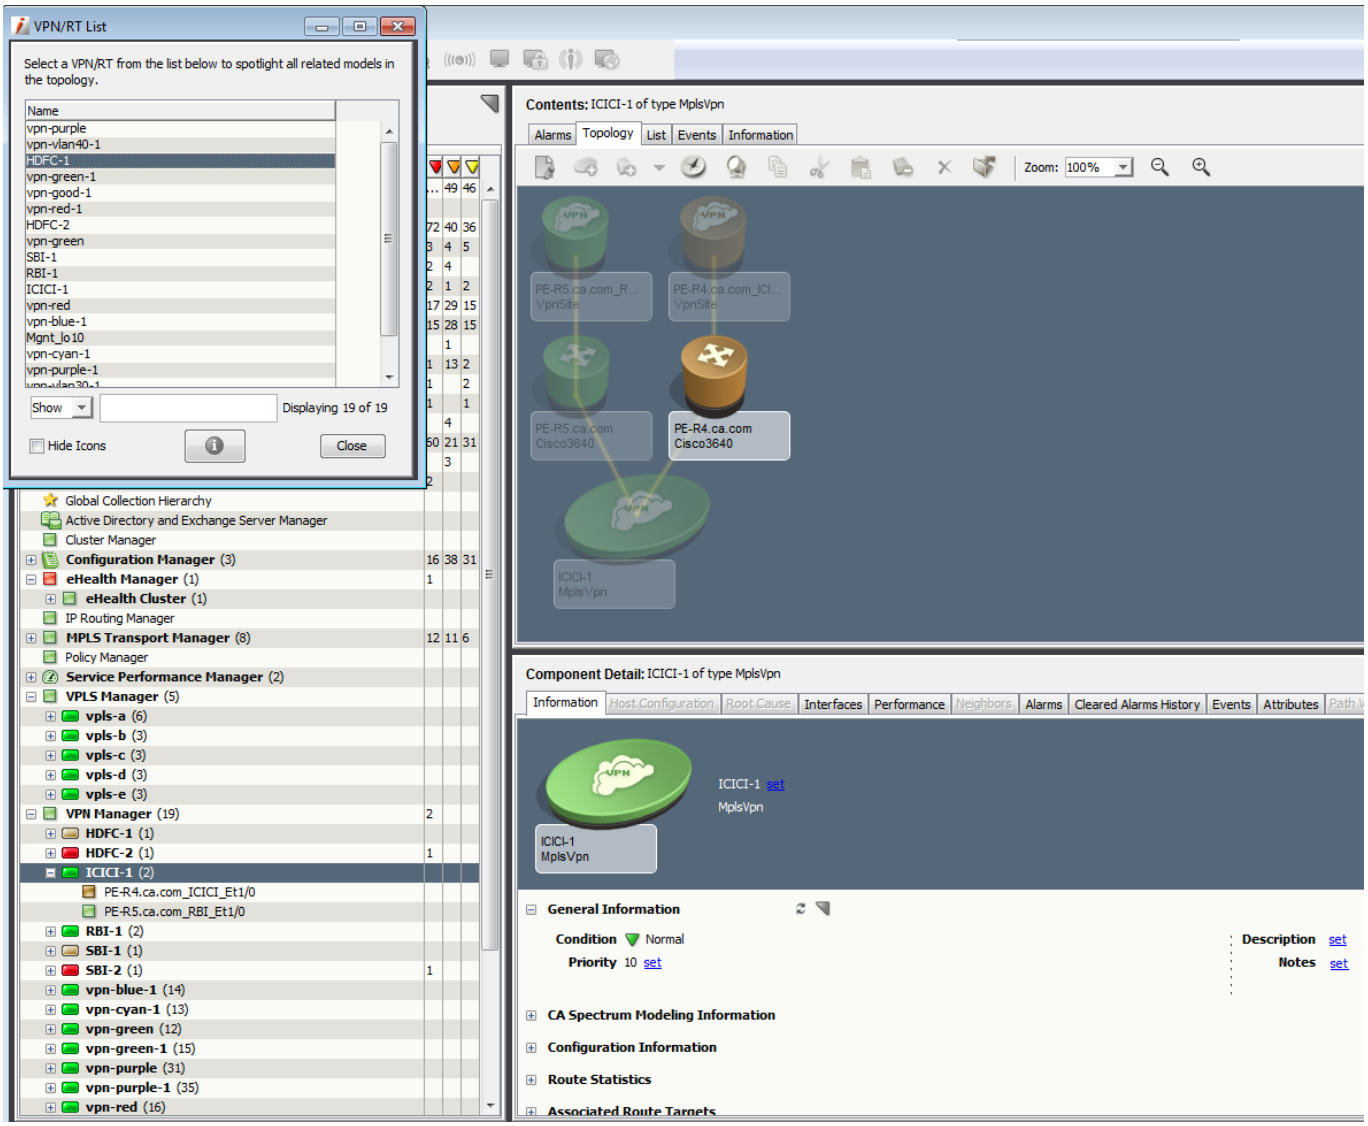
Spotlighting a Route Target

Use the OneClick Spotlight feature to see all models that are related to a Route Target in the Topology view. Spotlighting Route Target in the Topology view helps you more easily determine relationships between Route Target models and the network devices.

Follow these steps:

1. Open OneClick.
2. Expand the desired landscape on the Explorer tab and select Universe.
   Details about the selected Universe appear in the Contents panel.
3. Click the Topology tab.
4. Click (Spotlight View) and select VPN/RT List.
   The VPN List dialog is displayed.
5. Select a VPN or RT from the list.

DX NetOps Spectrum spotlights the selected devices that are configured with selected VPN/RT. Other models are greyed-out in the topology view.



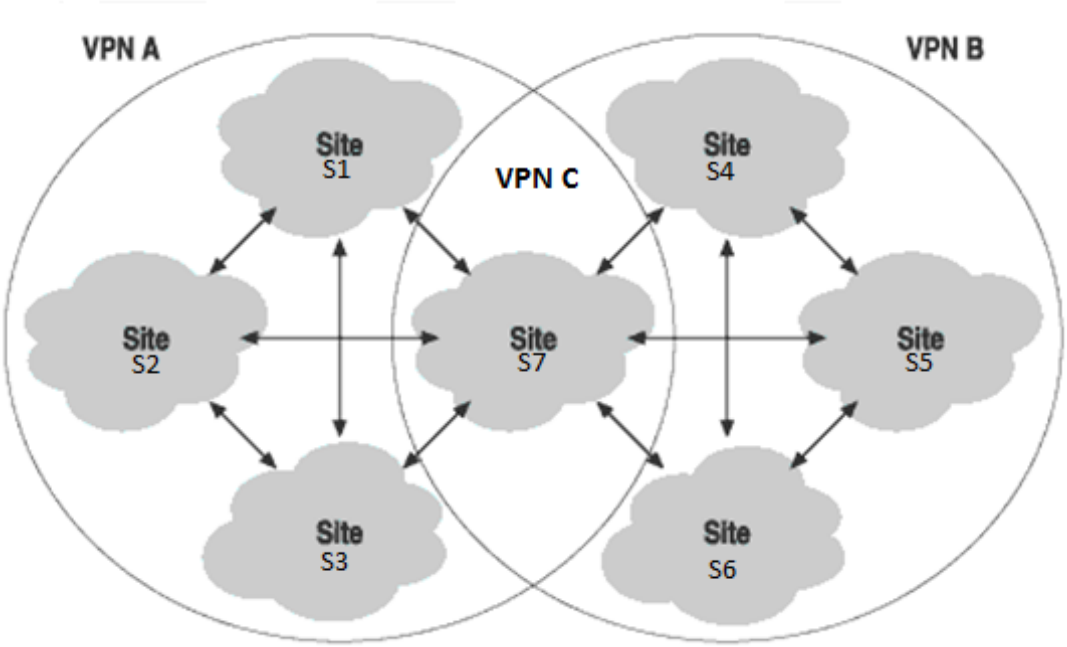
Example Scenario

This section describes a sample configuration and how Spectrum discovers VRF, RT, and Sites when Route Target based discovery is enabled. The following configuration is taken for three devices.

DEVICE 1	DEVICE 2	DEVICE 3

VPN A
{
S1
S2
S3
vrf-import 111:11
vrf-export 111:11
}
	VPN B
	{
	S4
	S5
	S6
	vrf-import 222:22
	vrf-export 222:22
	}
		VPN C
		{
		S7
		vrf-import 111:11
		vrf-import 222:22
		vrf-export 111:11
		vrf-export 222:22
		}

For the preceding configuration, the VPN topology looks as the following image:



Associations between Route Target and Site

Associations are created as shown in the following table are based on the following statements.

- When a Site belongs to VRF that has Route Target defined for importing/exporting the routes, it is considered that the site is using that Route Target.
- When a Site is using more than one Route Target, it is considered as an overlap site for all associated Route Targets.

Route Target	Sites Associated
111:11	S1,S2,S3,S7
222:22	S4,S5,S6,S7

Associations between VRF and Site

Associations are created as shown in the following table are based on the following statements.

- If a VRF (VPN A) has only one Route Target (111:11) defined, all sites in VRF are considered as the own sites of the VRF.
- If a VRF (VPN A) has only one Route Target (111:11) defined, and if that Route Target (111:11) is used by any other VRF (which has more than one Route Target defined i.e.; (VPN C)); then sites from VPN C are added as overlapped sites to VPN A.
- VPN B has only on Route Target (222:22) defined and that is used by VPN C, so sites from VPN C is added as overlapped sites to VPN B.

VRF	Sites Associated
VPN A	S1,S2,S3,S7
VPN B	S4,S5,S6,S7
VPN C	S7

VPN Naming and VPN/Site associations based on Route Target definition

During Route Target based VPN Discovery, VPN sites are associated with VPN models based on the VPN/Route Target association. The following cases are identified to explain how the models and associations are created.

Case 1:

VRF Name	VPN A	VPN A
Site Associated	S1	S2
Route Target Associated	RT-105	RT-110

If VRFs with the same name (VPN A) and different Route Target association (RT-105 and RT-110) are discovered, different model handles for VPN A (RT-105) and VPN A (RT-110) are created. VPN A (RT-105) is named as VPN A and VPN A (RT-110) is named in the format 'VRF name-numerical index' (For example, VPN A-1) as the name VPN A already exists. Respective sites are associated accordingly to VPN models created.

Case 2:

VRF Name	VPN A	VPN Z
Site Associated	S1	S2
Route Target Associated	RT-105	RT-105

If VRFs with different name (VPN A and VPN Z) and same Route Target association (RT-105) are discovered, single model handle is created and named either VPN A or VPN Z based on order of discovery. All sites are associated with the single VPN model handle.

Case 3:

VRF Name	VPN X	VPN Z
Site Associated	S1	S2
Route Target Associated	RT-105 RT-110 RT-220	RT-105 RT-220 RT-110

If VRFs are associated with more than one Route Target, and if the route target definitions are same, single model handle is created and sites from both VRFs are associated with it. For this example, single model handle is created and named either VPN X or VPN Z based on order of discovery. All sites from VPN X and VPN Z are placed under the newly created model handle.

NOTE

When the Route Target definitions are changed on the device, there is no automatic notification like trap to Spectrum about the specific Route Target configuration changes. There is no parameter in MIBS to identify the change in the route target configuration. VPN discovery should be run again so that the VPN models and associations are created/deleted based on the new Route Target configuration read from device MIB.

MPLS-VPN Model Types

DX NetOps Spectrum creates several model types during VPN Discovery to represent different aspects of the MPLS/BGP VPN MIB in MPLS VPN Manager.

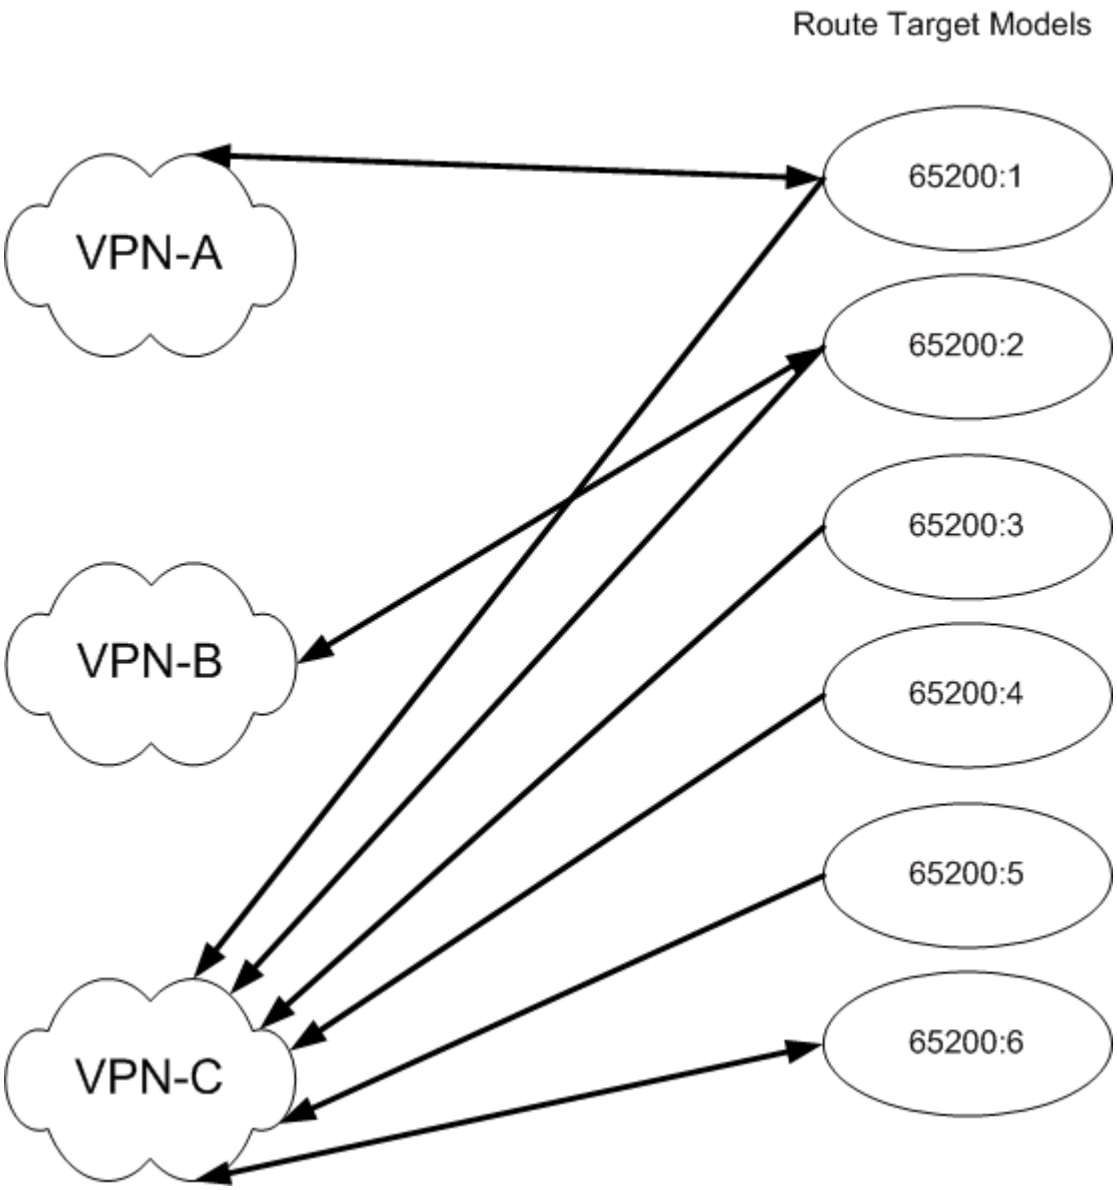
The MPLS VPN Manager model types include the following:

- **VPN Manager**

Represents the MPLS VPN Manager component installed with DX NetOps Spectrum that manages your VPN networking environment. The DX NetOps Spectrum model type for MPLS VPN Manager is VpnManager. This model cannot be destroyed.

- **VPN Site**
  Represents each unique VPN Site that DX NetOps Spectrum discovers during VPN Discovery. DX NetOps Spectrum creates the VPN Site model on the same SpectroSERVER as its associated PE Router. The Model Class attribute for the VPN Site model is set to Transport Service. The DX NetOps Spectrum model type is VpnSite.

  NOTE
  MPLS VPN Manager assumes that each VPN Site is connected to a given PE by a single interface. By default, DX NetOps Spectrum does not create VpnSite models for loopback and tunnel interfaces.
- **VPN Application**
  Represents a modeled device that supports the appropriate MPLS-VPN MIB. This application model must be present for VPN Discovery to successfully discover MPLS-VPN information. The DX NetOps Spectrum model types are MplsVpnApp (for Cisco devices), JNPR_VPN_App (for Juniper devices) and AlcatelMpls_App (for Alcatel). The Model Class attribute is set to Application for these models.
- **VPN**
  Represents each unique VPN that DX NetOps Spectrum models. The Model Class attribute for the VPN model is set to Transport Services. The DX NetOps Spectrum model type is MplsVpn.
- **Route Target**
  Represents the Import and Export of Route Targets. Models of this type do not display in the Navigation view. Instead, they are created on the Main Location Server (MLS). The following diagram shows the Route Target Models created for an overlapping VPN topology scenario:



VPN Site Names

DX NetOps Spectrum generates unique names for VPN Sites during Discovery based on the PE model name, VPN name, and IfName of the interface to which the VPN Site is connected. Using these values helps ensure the VPN Site names in DX NetOps Spectrum are unique.

The VPN Site name follows this structure:

```
ModelName_VPNname_IfName
```

- ***ModelName***
  Represents the name of the PE Router model to which the VPN Site is connected.
  Example: 172.19.38.40
- ***VPNname***
  Represents the name of the VPN to which the VPN Site is connected.

Example: vpn-blue

- ***IfName***
  Represents the IfName of the interface to which the VPN Site is connected.

Example: VPN Site name

DX NetOps Spectrum creates the following VPN Site name when the VPN Site is connected to a VPN named "vpn-blue," a PE Router model named "172.19.38.40," and the interface IfName value is "Fa2/0":

```
172.19.38.40_vpn-blue_Fa2/0
```

VPN Site Model Deletion

A VPN Site model can be deleted in any of the following ways:

- VPN Site models can be manually deleted from the Explorer tab.
- VPN Site models automatically delete when the associated VPN model or Provider Edge (PE) Router model is deleted.

  NOTE
  When a VPN is deleted in an overlapping VPN environment, DX NetOps Spectrum cannot delete the associated VPN Sites with multiple memberships. DX NetOps Spectrum deletes a VPN Site with multiple memberships only when the last VPN referencing the site is deleted.
- VPN models automatically delete when all associated VPN Site models are deleted.
- VPN Site models automatically delete when DX NetOps Spectrum receives an mplsVrfIfDown/ mplsL3VpnVrfDown SNMP trap from the associated PE Router model and the same VRF entry was removed from the PE Router's VRF Table.
- A VPN site model can be associated with multiple device ports.
- A device port model can be associated with multiple VPN site models.
- A VPN Site model will be deleted only if it is not associated with any interface.
- In 10.4.2, stale VPN site models are automatically deleted when no port models are associated with them.

  NOTE
  Previously, such stale VPN site models were not getting deleted. Therefore, if you load a previous database that has stale VPN site entries under VPN Manager, then you need to run the following command from the CLI to delete those entries:

  ./update.exe action=0x4940053 mh= <VPN Manager>

Configuring MPLS VPN Manager

After VPN Discovery, you can configure MPLS VPN Manager to manage the VPN environment effectively. MPLS VPN Manager provides configuration options for VPN Manager models, the individual VPN models, and for VPN Site models, as follows:

- The VPN Manager model configuration lets you specify parameters for all of the VPNs managed by the specified VPN Manager. You can configure VRF Ping and VRF Trace parameters that check on the connectivity of the VPNs in your network and you can configure other parameters relating to how traps and alarms are processed.
- VPN configuration parameters let you set threshold values and other alarm specifics for the VPN Sites within that VPN.
- VPN Site configuration lets you set Trace Mode and Ping Mode, which determine how VRF Path Tracing and VRF Ping should operate within the VPN.

This section describes how to access and set configuration options for MPLS VPN Manager.

Distributed SpectroSERVER Configuration

In a distributed SpectroSERVER (DSS) environment, you can model your PE Routers from any SpectroSERVER. A VPN Site model is created on the SpectroSERVER that its associated PE Router is modeled on. All of the discovered VPNs appear in the VPN Manager area of the OneClick Console. You can enable cross-server Path Tracing and Ping tests to determine the condition of the VPNs that you are managing. The local SpectroSERVERs must have a connection to the Main Location Server (MLS) to support this distributed configuration.

WARNING
An implementation requirement of the distributed VPN Manager is that all MplsVpn models must reside on the SpectroSERVER that is on the MLS machine. When you change the MLS, the MplsVpn and VpnSite models become invalid and are deleted by each SpectroSERVER in the DSS environment.

NOTE
For more information about changing the MLS, see the procedures in Distributed SpectroSERVER Administration .

VPN Manager Configuration

The VPN Manager model manages a set of VPNs on a given DX NetOps Spectrum landscape. The following options are controlled by the VPN Manager model:

- Port polling
- Default model priority
- Traps
- VRF pinging
- VRF path tracing

Configure Port Polling

Port polling must be enabled to update the condition of VPN Site models. But, polling can impact your MPLS VPN Manager performance. To help you optimize your MPLS VPN Manager performance, you can control port polling.

To configure port polling for MPLS VPN Manager

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, Management Configuration subview.
4. Click set in the following field, select your configuration setting, and click Save:
   – **Enable Port Polling**
   Determines whether MPLS VPN Manager polls ports.
   Default: Yes
   Your port polling option is configured.

Control Default Model Priority

Each model MPLS VPN Manager creates has a priority value. Using priority values, you can quickly sort a list of VPNs or VPN Sites to list those with higher priorities first. During VPN Discovery, DX NetOps Spectrum assigns a default priority value. You can configure the default priority value assigned to new VPN and VPN Site models.

To control the default model priority

1. Open MPLS VPN Manager.

MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, Management Configuration subview.
4. Click set in the following fields, select your configuration setting, and click Save:
   - **Default VPN Priority**
     Defines the default priority value assigned to newly created VPN models in MPLS VPN Manager. This value lets you sort VPNs in order of their priority to your work.
     Default: 10
     Limits: 0 - 4 billion
   - **Default Site Priority**
     Defines the default priority value assigned to newly created VPN Site models in MPLS VPN Manager. This value lets you sort VPN Sites in order of their priority to your work.
     Default: 10
     Limits: 0 - 4 billion

   Your default model priority values are configured, and VPN Discovery assigns these values to newly created models.

Configure Trap Options

Traps sent from VPN devices can signal MPLS VPN Manager when a VPN device is newly available or no longer available for management in DX NetOps Spectrum. Based on your needs, you can enable or disable these traps from creating or deleting VPN device models.

To configure trap options

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, Management Configuration subview.
4. Click set in the following fields, select your configuration settings, and click Save:
   - **Create on Trap**
     Determines whether the receipt of a mplsVrfIfUp/ mplsL3VpnVrfUp or jnxVpnIfUp trap results in a new VPN Site or VPN being discovered and modeled by MPLS VPN Manager.
     Default: Yes
   - **Delete on Trap**
     Determines whether the receipt of a mplsVrfIfDown/ mplsL3VpnVrfDown or jnxVpnIfDown trap results in a VPN Site or VPN being deleted from MPLS VPN Manager.
     Default: Yes

   Your trap options are configured.

Configure VRF Ping

MPLS VPN Manager can enable or disable cross-server pinging. Enabling cross-server pinging between domains that are not very related is not recommended. For example, conducting a VRF ping between service customer domains that are highly segmented can reduce performance on the PE Routers. Configuring your VRF ping options lets you optimize your MPLS VPN Manager performance.

To control the default model priority

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, VRF Ping subview.

Click set in the following fields, select your configuration settings, and click Save:

- **Enable VRF Ping**
  Determines whether MPLS VPN Manager sends VRF pings to monitor VPN connectivity. When set to Yes, MPLS VPN Manager sends VRF pings using RTTMON for Cisco devices and Juniper RFC2925, and using Juniper's Ping extension MIB for Juniper devices and for Alcatel, it is TIMETRA-ICMP-MIB. When set to No, MPLS VPN Manager infers VPN condition from the VPN Site condition.
  Default: Yes
- **VRF Ping Interval**
  Determines the time interval between VRF pings. Setting this value to a higher number reduces network traffic.
  Default: 1200
- **VRF Ping Timeout**
  Determines the time (milliseconds) to wait for a VRF ping to complete.
  Default: 5000
- **Enable Cross-VPN Ping Tests**
  Controls whether VRF pings test connectivity across overlapping VPN boundaries. For example, a VPN Site from vpn-blue normally does not communicate with a VPN Site from vpn-red. If vpn-blue imports the route target from vpn-red, then they *may* communicate. This attribute (EnableTransVpnPing) determines whether MPLS VPN Manager attempts this Service Assurance (SA) test.
  Default: Yes
- **Enable Cross-server VRF Ping Tests**
  Determines whether site-to-site connectivity test occur across multiple SpectroSERVERs. When set to No, site-to-site tests occur on a single SpectroSERVER only.
  Default: No
- **Collapse Bidirectional Ping**
  Determines whether MPLS VPN Manager performs a bidirectional VRF ping. Setting this value to Yes limits the VRF ping to one direction only. Unidirectional VRF pinging works based on the assumption that if one site can successfully receive a response from another, then the network between them is functioning properly. Unidirectional VRF pinging can reduce network traffic by eliminating potentially redundant ping tests.

  WARNING
  Before changing the value of this field, you must stop VRF pings by setting the Enable VRF Ping option to No. After changing the Collapse Bidirectional Ping option, restart VRF pings by setting the Enable VRF Ping option to Yes.

  Default: Yes

Your VRF ping options are configured.

Configure VRF Path Trace

MPLS VPN Manager can enable or disable cross-server path traces. Enabling cross-server path traces between domains that are not very related is not recommended. For example, conducting a VRF path trace between service customer domains that are highly segmented can reduce performance on the PE Routers. Configuring your VRF path tracing options lets you optimize your MPLS VPN Manager performance.

To configure VRF Path Trace options

1. Open MPLS VPN Manager.
   MPLS VPN Manager opens, and the Contents panel populates with information about the selected VPN Manager.
2. Click the Information tab.
3. Expand the Configuration, VRF Path Trace subview.
4. Click set in the following fields, select your configuration settings, and click Save:
   – **Enable Path Trace**

Enables all of the path tracing features for all VPN models managed by the selected VPN Manager model. Setting this option to No disables path tracing.
Default: No

- **Path Trace Interval (seconds)**
  Determines the time interval between invocations of site-to-site path tracing.
  Default: 1200
- **Path Trace Timeout (msec)**
  Determines the time (milliseconds) to wait for a VRF path trace to complete.
  Default: 25000
- **History Limit**
  Defines the maximum number of paths to be remembered between any pair of VPN Sites. To limit memory usage, the maximum History Limit value is 12.
  Limits: 1 - 12
  Default: 5
- **Enable Cross-VPN Path Traces**
  Controls whether VRF path traces cross overlapping VPN boundaries. For example, a VPN Site from vpn-blue normally does not communicate with a VPN Site from vpn-red. If vpn-blue imports the route target from vpn-red, then they *may* communicate. This attribute (EnableTransVpnTrace) determines whether MPLS VPN Manager attempts this Service Assurance (SA) test.
  Default: Yes
- **Enable Cross-server Path Traces**
  Determines whether site-to-site connectivity tests occur across multiple SpectroSERVERs. When set to No, site-to-site tests occur on a single SpectroSERVER only.
  Default: Yes
- **Enable Path Change Alarms**
  Determines whether DX NetOps Spectrum generates alarms when the number of path changes exceeds the thresholds defined by the Critical, Major, and Minor Threshold % values.
  Default: No
- **Critical Threshold %**
  Defines the critical threshold for the percentage of path changes in a given poll cycle. If this value is set to zero, MPLS VPN Manager generates alarms for any path changes.
  Default: 10
- **Major Threshold %**
  Defines the major threshold for the percentage of path changes in a given poll cycle. If this value is set to zero, MPLS VPN Manager generates alarms for any path changes.
  Default: 5
- **Minor Threshold %**
  Defines the minor threshold for the percentage of paths changed in a given poll cycle. If this value is set to zero, MPLS VPN Manager generates alarms for any path changes.
  Default: 3

NOTE
MPLS VPN Manager uses these threshold values for VRF path tracing functionality only.

Your VRF path trace options are configured.

Global Configurations and Local Overrides

In a distributed SpectroSERVER (DSS) environment, the configuration options set on the MLS VPN Manager are applied to the VPN Managers on remote SpectroSERVERs by default. You can override a global configuration on a remote VPN Manager.

NOTE
Use caution when making overrides. Whenever possible, update the model information on the MLS as a best practice and use local overrides for any changes required on a specific SpectroSERVER.

Overriding Global Configurations

You can override a global configuration value by setting a local override on a remote VPN Manager.

To override global configuration values for select VPN Manager

1. Search using the All VPN Managers predefined search.
   The search results appear in the Contents panel.
2. Select the VPN Manager model you want to configure.
   Details about the selected VPN Manager appear in the Component Detail panel.
3. Click the Information tab.
4. Expand the Configuration subview and locate the configuration value to override.
5. Click set for the configuration option.
   The Local Override Panel displays. The Global value is the value set on the MLS VPN Manager.
6. Change the Local value to the desired value, unselect the 'Use global value' check box, and click Save.

   NOTE
   The 'Use global value' check box appears only when the selected value differs from the Global value.

   The global configuration settings are overridden for the selected VPN Manager.

NOTE
When a local override is being used, the attribute value will have an asterisk appended to the end of it in the Configuration subview.

VPN Model Configuration

For each VPN model, you can configure VPN condition alarms. These settings turn alarming on, determine how MPLS VPN Manager generates information about the VPN models, and determine the alarm severity, based on threshold settings. Each threshold is based on the percentage of VPN Sites that are part of the VPN that are “Down.” VPN Sites are determined to be in a “Down” condition either through VRF ping tests or by analyzing the aggregate VPN Site condition for a VPN.

Configuring VPN Condition Alarms

The Component Detail panel's Information tab for a selected VPN model contains the Configuration Information section. Use this section to set the thresholds that determine what, if any, VPN Condition alarms are generated.

NOTE
These threshold values are used for both VRF Ping and the Condition value associated with the VPN Site models. These thresholds are not used by the VRF Trace functionality.

Before accessing the VPN configuration options, you must find the appropriate VPN model. To do this:

1. Perform an All VPNs search or select a VPN model in the Explorer tab and skip step 2.
2. In the Contents panel, select the VPN model you want to configure from the Results list.

Once you have selected the appropriate VPN model, the Component Detail panel's Information tab shows all of the configuration options for the VPN Model. Each of these options are explained in the following section.

To change any configuration value, click the value's set link, change the value, and press Enter.

- **Critical Threshold %**

This value is the percentage of down (unreachable) VPN Sites that will result in the generation of a critical alarm for the model.
default: 15%

- **Major Threshold %**
  This value is the percentage of down (unreachable) VPN Sites that will result in the generation of a major alarm.
  default: 10%
- **Minor Threshold %**
  This value is the percentage of down (unreachable) VPN Sites that will result in the generation of a minor alarm.
  default: 5%
- **Response Time Threshold (msecs)**
  The event threshold for the response time of a successful Ping test.
  default: 250 milliseconds
- **Enable VPN Alarms**
  Enable VPN Alarms is set to Yes by default. Thus when the condition of the VPN model changes, an alarm is generated. When this value is set to Yes and contact is lost to a VPN (with traps properly configured), an event triggers an alarm that is asserted against the VPN Model. When this value is set to No and contact is lost to a VPN, the VPN model turns red, but no alarm is created.
  default: Yes
- **Enable Site Alarms**
  Enable Site Alarms is by default set to No. With this default setting, no alarm is generated when the condition of the VPN Site model changes to critical. When this attribute is set to Yes, an alarm is generated when the condition of the VPN Site changes to Critical.
  default: No

  NOTE
  If a site is participating in multiple VPNs then you need to Enable Site Alarms on the VPN (VRF) which is configured on that site.

- **VPN Manager Path Tracing Active**
  This parameter reflects the value set for the VPN Manager Enable Path Trace parameter.
- **Participate in Path Tracing**
  This parameter enables path tracing for all of the sites in the selected VPN. VPN Manager Path Tracing Active and Participate in Path Tracing must be set to yes in order for path tracing to be active.
- **Enable Path Change Alarms**
  When this parameter is set to Yes, MPLS VPN Manager generates alarms when the number of path changes exceed the thresholds defined in the VPN Manager's VRF Path Trace configuration.

  NOTE
  If you use VRF ping connectivity tests instead of an analysis of the VPN's aggregate VPN Site condition to determine the VPN condition, the number of site-to-site VRF ping test failures is used in place of the percentage of VPN Sites down to define threshold violations. For example, a VPN condition of Good is reported when the number of site-to-site VRF ping test failures is less than the Minor threshold.

VPN Site Model Configuration

VRF Path Tracing and VRF Ping are mechanisms for monitoring your VPNs.

Configure the individual site models within each VPN to be a Source, Destination, Source/Destination, or none of the above. Selecting the most appropriate mode will optimize the communication process to more closely match the role of the sites on your network.

For example, if all sites were placed into SrcDest this would generate a great deal of traffic. For a VPN with 100 sites, there would be tests that are initiated to and from every site resulting in a full mesh of 10,000 tests. A more network-

efficient deployment would be to identify key sites that house critical application servers such as mail, web, or database servers and set only those to Destination.

Configure VRF Path Trace Source and Destination

There are four possible values for Trace Mode:

- **NoTracing**
  Tracing is not enabled for this site.
- **SourceTracing**
  This site can originate a path trace.
- **DestinationTracing**
  This site can receive a path trace from a source.
- **SrcDestTracing**
  This site can either originate or receive a path trace.

The Trace Mode option allows you to select the extent to which a site participates in the automated traceroute functionality. By default all sites are set to NoTracing. Tracing starts only when at least one site is enabled as SourceTracing and another site is enabled as DestinationTracing. These VPN Site models must be members of the same VPN.

You can set the value of the Trace Mode attribute for a particular VPN Site using two methods:

Method 1: Using the Contents Panel

1. Perform an All Sites search.
   When the search is complete, the list of VPN Sites is shown in the Results tab of the Contents panel.
2. Right-click the heading row to display the Table Preferences dialog. Ensure that Trace Mode is checked and click OK.
   The Trace Mode column appears in the list of VPN Sites.
3. Click set to select the value of the Trace Mode.

Method 2: Using the Associated Sites List

1. Select the desired VPN Manager from the Explorer tab.
2. In the Component Details panel, select the Information tab.
3. Select the Associated sites section.
4. Right-click the heading row to display the Table Preferences dialog. Ensure that Trace Mode is checked and click OK.
   The Trace Mode column appears in the list of VPN Sites.
5. Click set to select the Trace Mode.

Configure VRF Ping Source and Destination

There are four possible values for Ping Mode:

- **NoPinging**
  Pinging is not enabled for this site.
- **SourcePinging**
  This site can originate a ping.
- **DestinationPinging**
  This site can receive a ping from a source.
- **SrcDestPinging**
  This site can either originate or receive a ping.

The Ping option allows you to select the extent to which a site participates in the automated ping functionality. By default all sites are set to NoPinging. Pinging starts only when at least one site is enabled as SourcePinging and another site is enabled as DestinationPinging. These VPN Site models must be members of the same VPN.

NOTE
A Default Ping Mode feature has been added to the VPN Discovery Configuration options, you can select the default ping mode from the options in the list.

You can set the value of the Ping Mode attribute for a particular VPN Site using two methods:

Method 1: Using the Contents Panel

1. Perform an All Sites search.
2. When the search is complete, the list of VPN Sites is shown in the Results tab of the Contents panel.
3. Right-click the heading row to display the Table Preferences dialog. Ensure that Ping Mode is checked and click OK. The Ping Mode column appears in the list of VPN Sites.
4. Click set to select the value of the Ping Mode.

Method 2: Using the Associated Sites List

1. Select the desired VPN from the Explorer tab.
2. In the Component Details panel, select the Information tab.
3. Select the Associated sites section.
4. Right-click the heading row to display the Table Preferences dialog. Ensure that Ping Mode is checked and click OK. The Ping Mode column appears in the list of VPN Sites.
5. Click set to select the Ping Mode.

Managing VPNs

This section contains the following topics:

- The VPN Manager Model
- The VPN Site Model
- VPN and VPN Site Performance
- Spotlighting VPNs
- Checking the Status of VPN Paths with VRF Path Tracing
- Calculating the Condition of a VPN
- Trap Support
- Automatically Creating and Deleting VPN Sites
- Threshold Traps

The VPN Manager Model

The VPN Manager model manages a set of VPNs on a given DX NetOps Spectrum landscape. Each of these VPNs contains a series of VPN Sites which are also modeled and managed within the VPN Manager hierarchy. The following steps show you how to view all of the VPNs known to a specific VPN Manager:

1. Perform an All VPNs search.
2. In the Contents panel, VPN Manager displays a list of all VPNs currently known.

Each of these VPNs contain VPN Sites. Both the VPN Models and the VPN Site models display valuable information to assist you in managing the VPNs on your network. The sections in this chapter explain the information available for both VPN and VPN Site models.

The VPN Model

When a VPN model is selected, the Information tab contains all of the configurable options for a selected VPN model. The Information tab contains submenus which are described in the following sections:

General Information

The General Information section provides you with some basic information about the VPN model.

- **Condition**
  The current condition of the VPN.
- **VPN Model Name**
  The VPN model name.
- **Model Class**
  The model class of the VPN model.

  NOTE
  For more information about DX NetOps Spectrum model classes, see SpectroSERVER and DX NetOps Spectrum Databases Overview .
- **Creation Time**
  The date and time that the VPN model was created.
- **Security String**
  The security string for the VPN model.
- **Landscape**
  The DX NetOps Spectrum landscape to which the VPN model belongs.
- **Priority**
  The priority value used for the condition calculation.
- **Description**
  A description of the VPN model that is appropriate to your network. Click set, type the description in the field provided, and press Enter.
- **Notes**
  You can use this field to save notes about the VPN model. Click set, type the notes into the field provided, and click Save to save the notes.

Configuration Information

This section enables you to configure how the VPN monitors certain threshold values that contribute to alarms and the condition of the VPN.

Route Statistics

The route statistics show how many routes have been added to the selected VPN. MPLS VPN Manager calculates these statistics from reading the mplsVpnVrfPerfRoutesAdded, the mplsVpnVrfPerfRoutesDeleted, and the mplsVpnVrfPerfCurrNumRoutes parameters from each device on the VPN. These parameters are added together to produce a VPN-wide total.

For example, when a site is added to a VPN, the mplsVpnVrfPerfCurrNumRoutes and the mplsVpnVrfPerfRoutesAdded parameters are incremented.

These statistics provide a measurement of the current capacity of usage of the VPN.

Associated Sites

This table shows all of the VPN Site models associated with the selected VPN model.

Associated Edge Routers

This table lists all of the edge routers used by the selected VPN model.

The VPN Site Model

When a VPN site model is selected, the Information tab contains all of the configurable options for a selected VPN model. The Information tab contains submenus which are described in the following sections.

General Information

Condition

The current condition of the VPN Site.

Priority

The priority value used for the condition calculation.

Model Class

The model class of the VPN Site model.

> **NOTE**
> For more information about DX NetOps Spectrum model classes, see the Getting Started section.

Model Creation Time

The date and time that MPLS VPN Manager created the VPN Site model.

Security String

The security string for the VPN Site model.

Description

A description of the VPN Site model.

Site Creation Time

The date and time that MPLS VPN Manager created the VPN Site.

Landscape

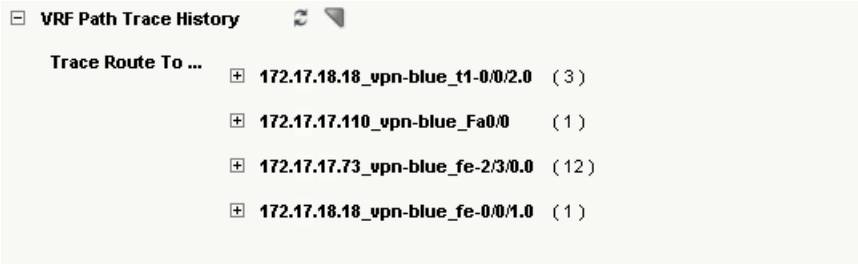
The DX NetOps Spectrum landscape to which the VPN Site model belongs.

Notes

You can use this field to save notes about the VPN model. Click set, type the notes into the field provided, and click Save.

VRF Path Trace History

This section shows the history of all path trace tests from this Site to all peer Sites within the VPN.



Click the + symbol to find specific information about a path trace to the specific site listed as shown in the following graphic.

This menu shows the date and time that the path trace occurred and also shows the IP address of the two VPN sites involved in the path trace. The chart shows specific details about the path between the two VPN sites.

Next Hop Addr

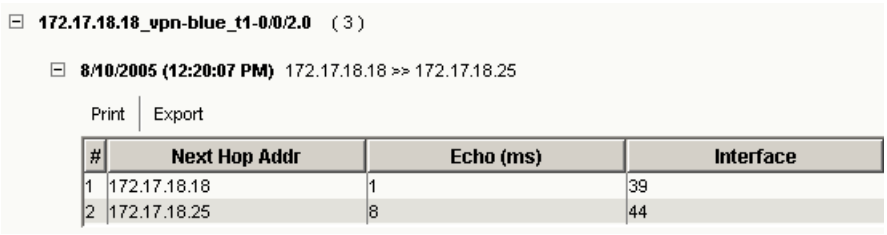
This shows all of the IP addresses of the devices on the path from the originating site to the destination site.

Echo (ms)

The time in milliseconds for the path trace results to be returned.

Interface

The IfIndex value used by the path trace for the device shown in the Next Hop Addr column.



#	Next Hop Addr	Echo (ms)	Interface
1	172.17.18.18	1	39
2	172.17.18.25	8	44

BGP Statistics

The BGP Statistics subview displays details about the BGP peer session involving the selected VPN site device. Details include the following:

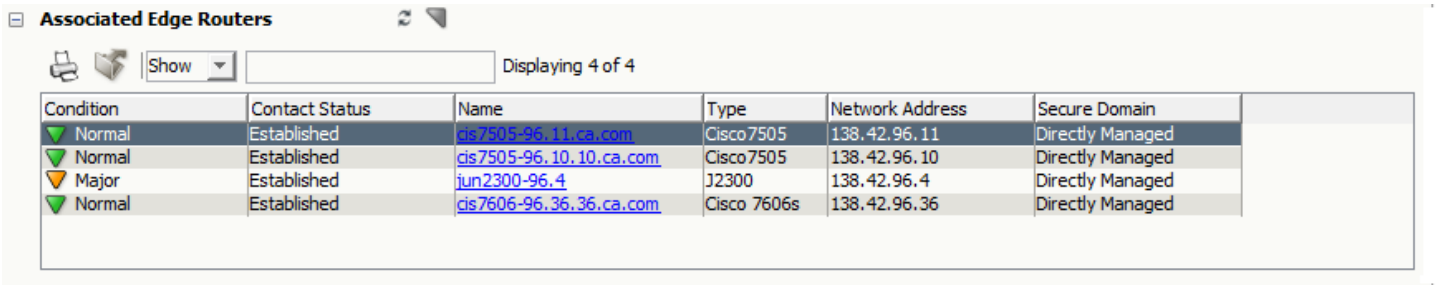
- Local Peer ID
- Remote Peer ID
- Peer State
- Peer Keep Alive
- Peer Hold Time
- Remote AS

NOTE

For more information about BGP peer session monitoring, see Modeling and Managing Your IT Infrastructure.

Associated Edge Routers

The Associated Edge Routers chart shows the edge routers associated with the selected VPN site.

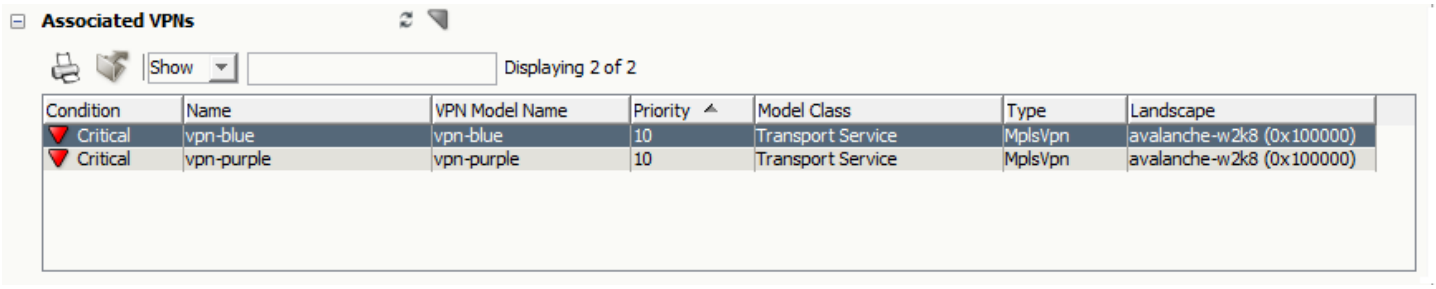


NOTE

If you click the hyperlink in the Name column, you will be redirected to the device location in the respective SpectroSERVER universe.

Associated VPNs

The Associated VPNs chart shows the VPNs associated with the selected VPN site.



VPN and VPN Site Performance

The Performance tab displays performance information for a selected VPN Site or VPN Site Performance. For a selected VPN Site, the performance information is based only on the traffic across the single interface to which the VPN Site is connected. VPN Site performance is a real-time value resulting from the polling of the following interface statistics:

- Bytes In Rate
- Bytes Out Rate
- Out/In Unicast Packet Rate
- Out/In Broadcast Rate
- Out/In Multicast Rate

NOTE

VPN performance data for a selected VPN is an aggregation of the performance data of the component VPN Sites in a VPN.

Spotlighting VPNs

Use the OneClick Spotlight feature to see all models related to a VPN in the Topology view. Spotlighting VPNs in the Topology view helps you more easily determine relationships between VPNs and your network, and between VPNs and other models on your network.

NOTE

When spotlighting in either the VPN or VPN Site Topology views, you can select only a single VPN.

To spotlight a VPN

1. Open OneClick.
2. Expand the desired landscape on the Explorer tab and select Universe.
   Details about the selected Universe appear in the Contents panel.
3. Click the Topology tab.
   The topology of the Universe is displayed.
4. Click the Spotlight View
   icon  .
5. Select VPN List.

   The VPN List dialog opens.
6. Select a VPN.
   DX NetOps Spectrum spotlights the selected VPN by dimming all models in the topology that are not part of the selected VPN.

   NOTE

   To view information about the selected VPN, click the View the Component Detail icon on the VPN List dialog.

Checking the Status of VPN Paths with VRF Path Tracing

MPLS VPN Manager lets you monitor paths within a VPN in two ways. You can enable background path monitoring, which allows paths to be monitored consistently at a preset interval. You can also issue a path trace command on demand to check the path between two VPN sites.

WARNING
You must use a read/write community string when modeling devices in DX NetOps Spectrum for VRF Path Tracing to function properly.

Background Path Monitoring

Background path monitoring traces the paths between VPN Sites based on the configuration options you have chosen. The results of the path traces appear in the VPN Site model's VRF Path Trace History menu.

To use background path monitoring, you must configure the following parameters:

- In the configuration for the VPN Manager model, you must configure the VRF Path Trace parameters. Each of these parameters is explained in the section on VRF Path Trace.
- In the configuration for the VPN model, you must configure the VPN to participate in path tracing, and, if desired, turn on alarms relating to VRF path tracing threshold violations.
- In the VPN Site list, you must configure each VPN Site's trace mode. For instructions see VPN Site Model Configuration.

The VPN Path Trace history results are shown in the VPN Site model's VRF Path Trace History menu in the Information tab.

On-Demand Path Monitoring

An on-demand path trace traces a path between two VPN sites that you have selected. The two VPN sites must belong to the same VPN.

To initiate an on-demand path trace

1. Perform an All Sites search, or locate the desired VPN Site model from the Explorer tab in the Navigation panel and skip step 2.
2. In the Contents panel, locate the VPN Site model you want to configure from the Results list.
3. Right-click the VPN Site model from which you would like to initiate the path trace.
4. Select Select Vrf Trace Start Point.
5. Right-click the VPN Site model that is the destination of the path trace and select Vrf Trace From <VpnSite>. This starts the on-demand path trace.
   The results of the path trace appear in a dialog after the path trace finishes.

Calculating the Condition of a VPN

The overall condition of a VPN is of critical importance to providers of VPN services. VPN Sites impact the health of all VPNs in which it has membership. MPLS VPN Manager provides the following two mechanisms to calculate the VPN condition:

- VRF Ping to determine the state of connectivity
- Condition values determined by alarm threshold values set on each VPN Site model and rolled up to the VPN model

You can choose either mechanism. However, DX NetOps Spectrum cannot use both at the same time. When enabled, VRF Ping takes precedence over the VPN Site condition rollup method. To use the condition rollup method, make sure VRF Ping is disabled.

A single VPN Site outage can cause the generation of several alarms (that is, one alarm for each VPN in which the VPN Site has membership). DX NetOps Spectrum does not correlate (that is, suppress) the alarms. Areas affected include the following:

- VPN condition calculation
- VRF test results
- Aggregate VPN performance (bandwidth usage added to each VPN)

Calculating the VPN Condition using VRF Ping

By default, MPLS VPN Manager uses the state of connectivity between the VPN sites to determine the condition of the VPN. VRF Ping connectivity tests calculate condition for a VPN Site from information obtained from the VRF Table. Using Cisco's VRF Aware Ping (configured through the RTTMON-MIB) and the Juniper Ping MIB extensions to RFC2925, the PE Router can initiate and send pings to any VPN Site on the network. Each entry in the VRF table has information pertaining to one unique Site.

> **NOTE**
> If you use VRF ping connectivity tests instead of an analysis of the VPN's aggregate VPN Site condition to determine the VPN condition, the number of site-to-site VRF ping test failures is used in place of the percentage of VPN Sites down to define threshold violations. For example, a VPN condition of Good is reported when the number of site-to-site VRF ping test failures is less than the Minor threshold. This option is applicable only to newly discovered sites. This will not update the Ping mode property of existing sites.

To ensure that MPLS VPN Manager can use VRF Ping to test for connectivity

1. Verify that you have modeled in DX NetOps Spectrum the devices that are part of the VPN network.
2. Verify that you have used a read/write community string when modeling devices in DX NetOps Spectrum.
3. Verify that Enable VRF Ping is set to Yes on the VPN Manager model.
4. Verify VRF Pings are being run on the device by examining the appropriate MIB on the VPN device (RTTMON for Cisco devices, Juniper Ping MIB extensions to RFC2925 for Juniper device and TIMETRA-ICMP-MIB for Alcatel devices.

5. Verify that the condition of the VPN and VPN Site models is updated correctly and that VRF Pings are successful.
6. Verify the appropriate VPN sites are set as Ping Sources and Destinations.

Calculating the VPN Condition using VRF Ping Response Time Threshold

The result of a VRF Ping test alone informs you of the success or failure of the Ping test. Adding a Response Time Threshold to your VRF Ping tests provides more detailed results than just success or failure.

To ensure that MPLS VPN Manager can use VRF Ping Response Time Threshold

1. Verify you satisfy the requirements listed in Calculating the VPN Condition using VRF Ping.
2. Verify the Response Time Threshold parameter is set to the appropriate value.
3. Verify your Minor, Major and Critical Alarm Threshold % attributes are set to the appropriate values.

Scalability of Ping Tests

The scalability of Ping tests should be considered in large environments where fully meshed testing is performed. Performance testing has shown that full mesh testing beyond 50 sites greatly increases network traffic. The number of Ping tests and the resource requirements can be efficiently managed by organizing your Ping tests.

We recommend that you select a relatively small number of important sites to perform Ping testing. One approach, when the number of sites or remote offices is beyond 50, is to have larger regional offices test back to corporate headquarters or among themselves. For example, in an environment that consists of several regional offices and a corporate headquarters, configuring your corporate headquarters as Ping to Site and your larger regional offices as Ping from Site reduces the network load.

Calculating the VPN Condition using the VPN Site Condition

If you disable VRF Ping by setting the VPN Manager's Enable VRF Ping parameter to No, MPLS VPN Manager can calculate VPN condition based on an analysis of the VPN's aggregate VPN Site conditions. If the Condition value for every Site is “Good,” then the VPN condition is “Good.”

A VPN Site model can have one of four conditions: Initial, Maintenance, Down, or Good. Each of these conditions is explained in the following table. The following values are used to compute the Condition value for a Site:

- Value of ifOperStatus for the physical interface
- Contact status of the PE Router
- Receipt of an mplsVrfIfUp/ mplsL3VpnVrfUp or mplsVrfIfDown/ mplsL3VpnVrfDown trap

VPN Site Condition	Calculation
Initial	No associated IF or IF is initial.
Maintenance Condition	The associated router is in maintenance mode.
Down	IFOperStatus is Down.
Good	All associated IFs are Up.

The condition of the VPN Model is determined by the condition of all of the VPN Sites contained in the VPN. The following list shows how the condition of a VPN is determined.

- **Initial**
  No VPN Sites are modeled or all VPN Site models are “Initial.” The percentage of VPN Sites that are “Initial” is greater than the Minor Threshold.
- **Maintenance Condition**
  All the VPN Site models are in maintenance mode.
- **Minor**

The percentage of VPN Sites down (Site Rollup condition) is greater than the Minor Threshold and less than the Major Threshold.

- **Major**
  The percentage of VPN Sites down is greater than the Major Threshold and less than the Critical threshold.
- **Critical**
  The percentage of VPN Sites down is greater than the Critical Threshold.
- **Good**
  The percentage of VPN Sites down is less than the Minor Threshold.

You can set threshold values for each VPN Model that control whether the VPN Manager generates VPN Condition alarms.

Trap Support- MPLS VPN Manager

The following table lists the MPLS-VPN MIB SNMP traps supported by MPLS VPN Manager. Receipt of either an mplsVrfIfUp/ mplsL3VpnVrfUp trap or an mplsVrfIfDown/ mplsL3VpnVrfDown trap typically results in a change of the VPN Site condition. Events are created based on changes in condition.

NOTE
Each device must be configured to send SNMP traps to the DX NetOps Spectrum VNM machine.

SNMP Trap	Result of Receiving Trap
mplsVrfIfUp/ mplsL3VpnVrfUP	If the VPN Site model already exists, a change in status is reported. Otherwise, a new VPN Site model is created.
mplsVrfIfDown/ mplsL3VpnVrfDown	If both the VPN Site model and the VPN Site on the device sending this trap exist, a change in status is reported. Otherwise, the VPN Site model is deleted.
mplsNumVrfRouteMidThreshExceeded	Event/Alarm
mplsNumVrfRouteMaxThreshExceeded	Event/Alarm
mplsNumVrfSecIllegalLabelThreshExceeded	Event/Alarm
mplsL3vpnVrfRouteMidThreshExceeded	Event/Alarm
mplsL3vpnVrfNumVrfRouteMaxThreshExceeded	Event/Alarm
mplsL3VpnNumVrfSecIllglLblThrshExcd	Event/Alarm
mplsL3vpnNumVrfRouteMaxThreshCleared	Event/Alarm

The following table lists the Juniper traps supported by MPLS VPN Manager.

Trap	Result of Receiving Trap
jnxVpnIfUp	If the VPN Site model already exists, a change in status is reported. Otherwise, a new VPN Site model is created.
jnxVpnIfDown	If both the VPN Site model and the VPN Site on the device sending this trap exist, a change in status is reported. Otherwise, the VPN Site model is deleted.

The following table lists the Alcatel traps supported by MPLS VPN Manager:

Trap	**Result of Receiving Trap**
vRtrMplsLspUp	If the VPN Site model already exists, a change in status is reported. Otherwise, a new VPN Site model is created.
vRtrMplsLspDown	If both the VPN Site model and the VPN Site on the device sending this trap exist, a change in status is reported. Otherwise, the VPN Site model is deleted.
vRtrMplsLspPathUp	If the VPN Site model already exists, a change in status is reported. Otherwise, a new VPN Site model is created.
vRtrMplsLspPathDown	If both the VPN Site model and the VPN Site on the device sending this trap exist, a change in status is reported. Otherwise, the VPN Site model is deleted.

Automatically Creating and Deleting VPN Sites

Currently, MPLS VPN Manager creates a new VPN Site model if a mplsVrfIfUp/ mplsL3VpnVrfUp or jnxVpnIfUp trap is received from a device and a VPN Site model does not already exist for that VPN Site. If a VPN Site model does exist for that VPN Site, MPLS VPN Manager reports a change in its status.

Conversely, if MPLS VPN Manager receives a mplsVrfIfDown/ mplsL3VpnVrfDown or jnxVpnIfDown trap from a device and the VPN Site is already modeled and it exists on the device sending the trap, MPLS VPN Manager reports a change in the status of that VPN Site. If the VPN Site no longer exists on the device that sent the trap, then MPLS VPN Manager deletes the applicable VPN Site model.

NOTE
These actions also depend on the configuration settings for MPLS VPN Manager.

Threshold Traps

MPLS VPN Manager supports threshold traps by creating events and alarms. These traps can be used to monitor the utilization of a PE router:

- mplsNumVrfRouteMidThreshExceeded
- mplsNumVrfRouteMaxThreshExceeded
- mplsNumVrfSecIllegalLabelThreshExceeded
- mplsL3vpnVrfRouteMidThreshExceeded
- mplsL3vpnVrfNumVrfRouteMaxThreshExceeded
- mplsL3VpnNumVrfSecIllglLblThrshExcd
- mplsL3vpnNumVrfRouteMaxThreshCleared
  As the number of VPN Sites increases, these traps indicate that the PE router is approaching its capacity. The mplsNumVrfSecIllegalLabelThreshExceeded threshold trap is used to detect configuration or security violations, such as a PE-CE interface mis-configuration or an attempted VPN break-in using spoofed labels.

The VPN model can be configured to generate alarms based on the condition of the VPN model or VPN Site model.

Model	**Attribute**	**Alarms**
MplsVpn	EnableVpnAlarms	04940405 (Minor) 04940406 (Major) 04940407 (Critical) 04940422 (Maintenance)

MplsSite	EnableSiteAlarms	04940403 (Critical)

Model	Event Condition
MplsVpn	Initial, Maintenance, Minor, Major, Critical, Good
MplsSite	Initial, Down, Good

Troubleshooting MPLS VPN Manager

Common problems and solutions of MPLS VPN Manager are described in the following table:

Description	Solution
MPLS VPN Manager does not currently support the creation of a customer model or the entering of customer VPN information.	You can name a VPN with an associated customer name.
The condition of the VPN Site model may not be updated correctly.	Ensure that Port Polling is enabled in MPLS VPN Manager and that the connections between ports have been resolved by DX NetOps Spectrum. Additionally, traps may be used to determine the condition of a VPN Site. The device must be configured to send traps to DX NetOps Spectrum on behalf of interfaces and VPNs.
A VPN Site alarm is not cleared in cases where the network cable is unplugged and then plugged back in, even though traps are enabled. The mplsVrfIfUp trap is not being sent when the cable is plugged back into the router.	This is a Cisco IOS firmware issue. The mplsVrfIfUp trap is sent in other cases when a VPN Site goes back online (as when the interface is Administratively set to “down” and then back to “up” or when the interface is turned off and then on using Cisco IOS).
A description is added to the VRF configuration on a router after its associated VPN Site has been modeled by MPLS VPN Manager. When you view information for the site in MPLS VPN Manager, the new description is not displayed in either the Description column of a site search Results list or in the Description field of the Component Detail panel's General Information section.	Destroy the VpnSite model, then run a new VPN Discovery that models the site. MPLS VPN Manager then displays the VRF description where appropriate.
A VRF Path Trace will time out with the error message Trace Failed.	Increase the Path Trace Timeout value.
MPLS VPN Manager does not create VpnSite models for each unique VRF entry on Juniper M-Series devices running JUNOS 8.2 R1.7.	Upgrade to JUNOS 8.2 R2.4 or later.
The current implementation creates only a single test model for each source site. This could lead to latency problems (at high site counts) because each test takes a fixed amount of time (typically 5 seconds). With a default poll time of 1200 seconds the system would support approximately 240 sites / vpn. In such cases the number of ping failures might change from one poll cycle to the other.	Increase the VRF Poll interval based on the number of destination sites

Support for Dynamic VPN (DMVPN)

DMVPN (Dynamic Multipoint VPN) is a routing technique that is used to build a VPN network with multiple sites without having to statically configure all devices. It is effective solution for dynamic secure overlay networks. It is a “hub and spoke” network where the spokes communicate with each other directly without having to go through the hub. As a Spectrum user you can now discover, model, visualize the DMVPN topology in Spectrum and Spectrum processes all the DMVPN related traps.

Topology

Spectrum identifies whenever there is a change in the DMVPN topology like a hub or a spoke added to the topology. The DMVPN is a partial dynamic mesh. There are two basic topologies that can be used in the DMVPN networks. The discovered DMVPN networks are modeled under the 'VPN Manager' and on clicking the DMVPN network, the topology displays the hubs and spokes associated with the network.

To discover the DMVPN networks:

1. Navigate to the VPN Manager
2. Run the discovery.

Spectrum will discover the permanent tunnels between the hubs and spokes. The dynamic spoke to spoke tunnels will not be discovered and modeled. The hubs will be positioned on the top and the spokes at the bottom. The label 'Hub' is on the hubs. If there is any hub or spoke added to the DMVPN network, re-run the VPN discovery so that it is visible. Following is the screenshot of the DMVPN topology for a device family.

NOTE

There is no exclusion on the tunnel interface from the VPN Manager.

DMVPN Trap Support

The DMVPN tunnel up and down events will be processed by Spectrum and events will be generated. You will have to configure the devices to send traps to Spectroserver. From the screenshot below, you can see the tunnel up events are received on the Hub device and from the Spoke devices.

Following is a screenshot of the DMVPN Trap Support:

Multicast Manager

Overview

Multicast Manager lets you manage multicast traffic within your network environment. This includes the identification and monitoring of all multicast groups, sources, receivers, and other critical sources like rendezvous point (RP) routers.

Multicast Manager discovers and models Cisco and Juniper devices that support Multicast traffic. Once these devices are discovered, Multicast Manager provides several views which let you monitor the connectivity and performance of these Multicast elements. These views offer details relating to Multicast groups, sources, receivers, routers, and RPs and their relationships to each other.

The information provided in the Multicast Manager views makes troubleshooting Multicast-related outages much more efficient. You can isolate a problem quickly because you can determine the group a receiver belongs to, the RP of the group, the source for the group, the routers and interfaces that a group uses, and the configuration and bandwidth limits of these interfaces. Based on this information, you can prioritize your troubleshooting efforts should multiple problems occur.

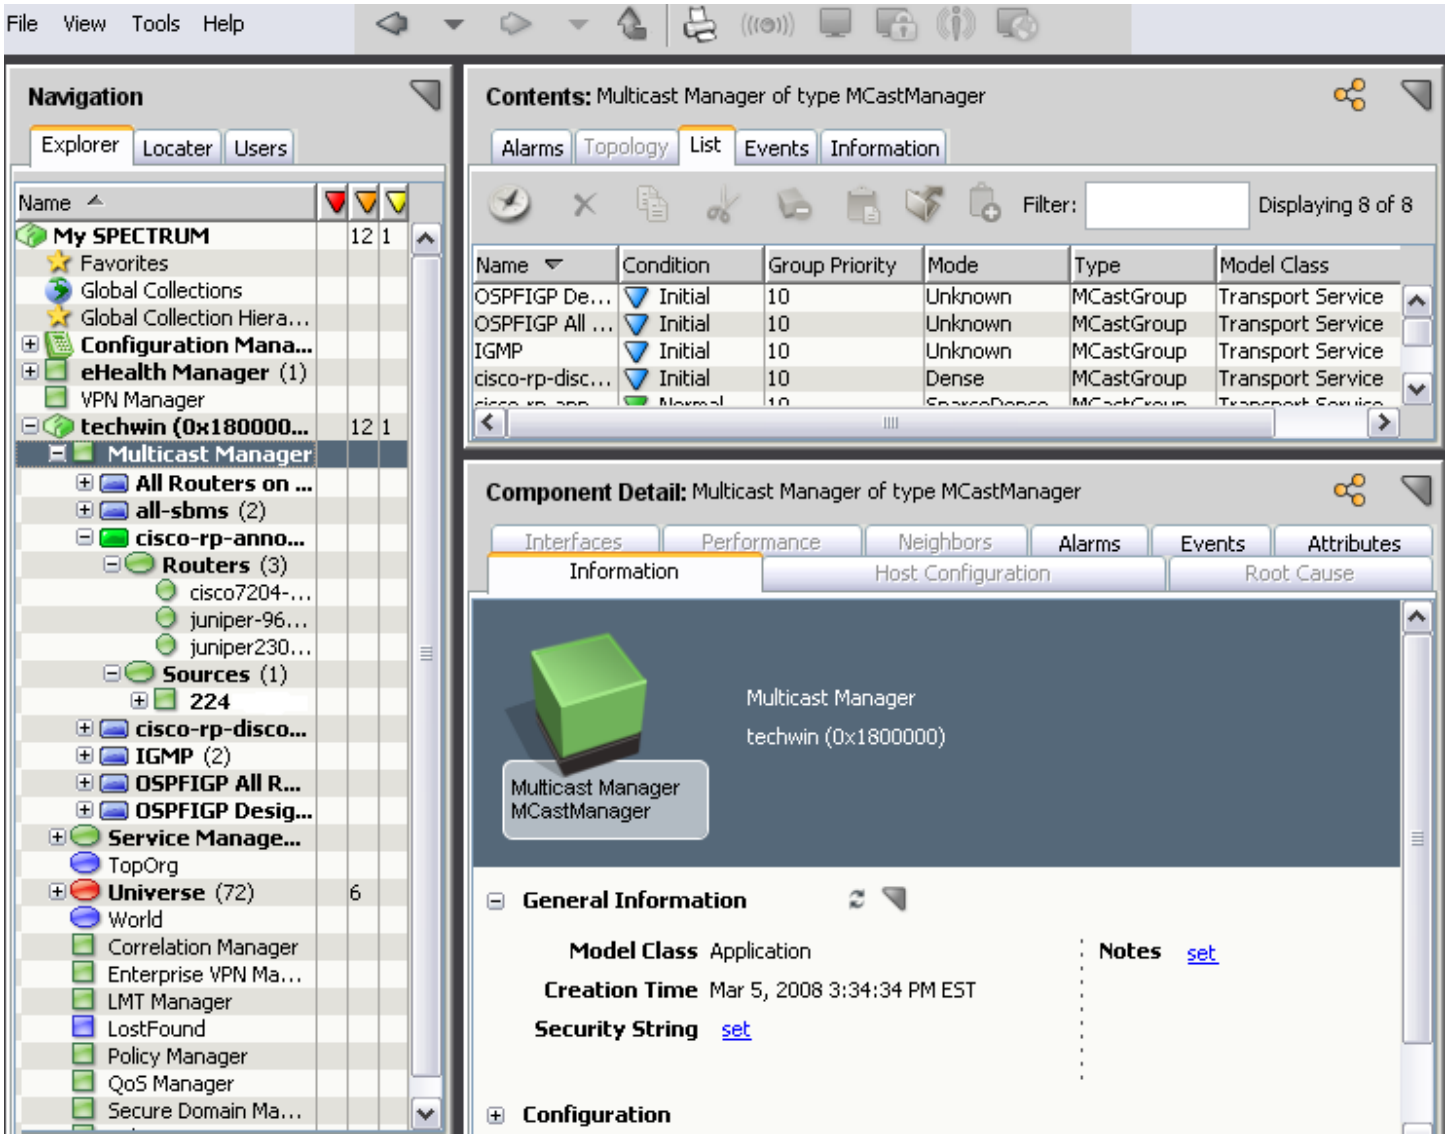
If you purchase a multicast service or a data feed from an external service and you do not have access to the source to obtain its status, Multicast Manager provides you with the ability to create a proxy to the source or you can configure Multicast Manager to exclude the unmanageable source's status in group condition calculation.

Multicast Manager View

You can access Multicast Manager from the Explorer tab of the Navigation panel in the OneClick Console. When you expand the Multicast Manager folder, all of the groups managed by Multicast Manager are listed. When you expand each group, the routers and sources contained in the Multicast Group are listed.

Once the physical components of your multicast network are modeled in DX NetOps Spectrum, you can use Multicast Manager to discover your multicast devices. You can then navigate to or search for these multicast elements in OneClick. The Contents panel and Component Detail panel provide configurations, alarms, events, and other information for a selected Multicast element.

The following shows the Multicast Manager view:



NOTE

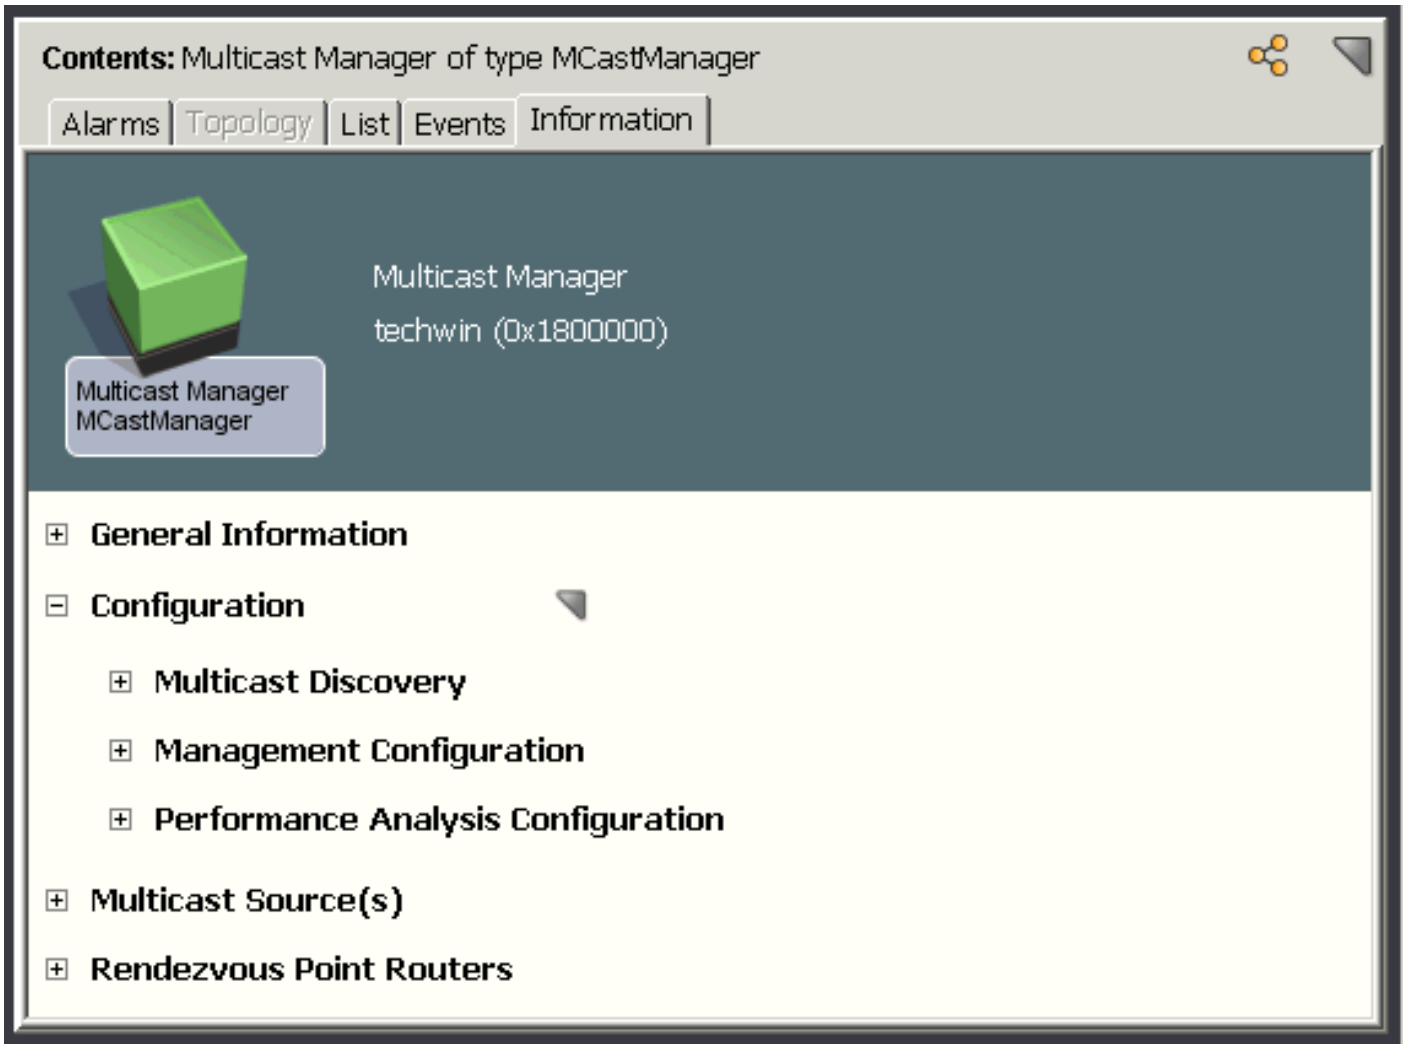
For more information about modeling your network, see the Modeling and Managing Your IT Infrastructure .

Multicast Manager Configuration

The Multicast configuration parameters are available to all users with administrative privileges.

To access Manager configuration parameters

1. Expand the desired landscape from the OneClick Explorer tab and select the Multicast Manager.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration node to display the following options:



Multicast Discovery Subview

You can set the following parameters in the Multicast Discovery subview:

- **Discovery Status**
  Runs a Multicast discovery and displays status.
- **Group Address Filter Type**
  Specifies the addresses that you want to exclude or include. You can select one of the following options to set the filter type:
  - **Inclusive**
    Filters and saves the Multicast addresses that the Group Address Filter specifies.
  - **Exclusive**
    Filters and saves the Multicast addresses except those addresses that the Group Address Filter specifies.
- **Group Address Filter**
  Specifies the Multicast addresses to be saved when the Multicast Discovery is run.

NOTE
The addresses are not filtered and saved if you do not add them in the Group Address Filter. So, even if the Group Address Filter Type is inclusive and the Group Address Filter is empty, all addresses are discovered.

- **Background Create Group Models**
  Creates models for the new Multicast groups, sources, or routers that are discovered from a background discovery.

  NOTE
  The Enable Background Discovery parameter must be set to Yes.
- **Model Sources as Pingables**
  It may not be possible for you to model the device representing the Source of the Multicast traffic because of the IT infrastructure in your particular network environment. You can set one of the following options:
  – Yes (default)
    Creates a model using the pingable model type for each Multicast Source that does not have a corresponding device model. Multicast Manager automatically assigns a model name to this pingable model using the convention <IPAddress>_mcast. The models that are created by running Multicast Discovery are placed in the Multicast Pingables Generic Container in the landscape topology view.
  – No
  – Only if reachable by ICMP ping
    Creates a model only if it gets a response from an ICMP packet.

  NOTE
  By default, Multicast Manager determines the default gateway for the Source model. A correct default gateway is necessary for calculating performance and view in the topology.
- **Enable MSDP Discovery**

  NOTE
  Enables MSDP Discovery when set to yes.
- **Create Groups without Source**
  Creates a group when the source is not manageable. This behavior occurs when the source is initiated outside the network. If there is no manageable source to the group, the group stays in the initial condition and no fault management information is computed. When Create Groups without Source attribute is set to No, Multicast Manager does not create groups for sources that are not manageable.

  NOTE
  Default: Yes
- **Discovery Polling Interval (sec)**
  Determines how often (in seconds) Multicast Manager polls the attribute in the CiscoIPMRoute MIB during a background discovery. This polling determines if new multicast groups, sources, or routers exist.
- **Enable Background Discovery**
  Creates events when new multicast groups, sources, or routers become active on the network. Events for new groups and sources are asserted on the Multicast Manager model. Events for new multicast routes are asserted on the applicable device model.

  NOTE
  Before you enable background discovery, run a manual discovery to find and model the RP routers to be associated with discovered groups.

  To determine if a new entity has become active, Multicast Manager polls an attribute in the Cisco IPMRoute MIB which counts the number of entries in the Multicast routing table.

Management Configuration Subview

You can set the following parameters in the Management Configuration subview:

- **Default Group Priority**
  Sets the priority value given to a group when it is created. This value defines the relative importance of the group and can be used by the network operator to prioritize troubleshooting resources when there are problems with multiple groups.
- **Enable Port Polling**
  If this parameter is set to Yes, when Multicast Discovery is run, it enables port polling on all interfaces associated with group models. This lets port status contribute to the overall group condition.
  Default: Yes
- **Topology Display Units**
  Selects the units displayed in the Topology graph. You can select *one* of the following:
  – % Throughput
  – Pkts/s or Bits/s

  NOTE
  The Topology Display Unit is Pkts/s or Bits/s based on the Performance Collection Type option set under Performance Analysis Configuration.
- **Global Enable Multicast Path Change Detection**
  Enables or disables Multicast Manager's ability to detect topology changes in the Multicast distribution tree. It does this by identifying changes in the device interface receiving Multicast traffic. By default, it is set to No. You can also enable or disable this feature on a group model basis.
- **Total Groups (modeled/known)**
  Shows the number of groups that are modeled and known by Multicast Manager. The number of groups modeled is the number of multicast groups that have been discovered and are presently modeled by Multicast Manager. The number of groups known reflects the number of groups discovered by Multicast Manager via the discovery process, but that are not currently modeled; that is, they have been deleted.
- **Group Count Threshold**
  Displays the group count threshold. This parameter generates a critical alarm on the Multicast Manager model if it is exceeded.
- **Total Sources (modeled/known)**
  Shows the number of sources that are modeled and known by Multicast Manager. The number of sources modeled is the number of multicast sources that have been discovered and are presently modeled by Multicast Manager. The number of sources known reflects the number of sources discovered by Multicast Manager via the discovery process, but that are not currently modeled; that is, they have been deleted.
- **Source Count Threshold**
  Displays the source count threshold. This parameter generates a critical alarm on the Multicast Manager model if it is exceeded.

Performance Analysis Configuration Subview

You can set the following parameters in the Performance Analysis Configuration section:

- **Device Performance Alarms**
  Enables or disables the generation of Multicast performance based alarms on the device; these alarms are asserted in addition to those on the Multicast Group model. If enabled, alarms are produced on the device models in the Group causing the threshold violation.
  Default: Disable
- **Performance Analysis**
  Enables or disables the entire Multicast Performance Monitoring system. You can also enable or disable performance monitoring on a group model basis.
  Default: Enable

NOTE
Performance Analysis must be enabled for performance information to be displayed in the Multicast Topology view.

- **Collection Interval (sec)**
  Determines the interval at which the devices are sampled to obtain performance and IfIndex information. Lowering the interval may have a negative impact on the overall SpectroSERVER performance.
  Default: 300 seconds (5 minutes)
- **Performance Collection Type**
  Sets the performance collection type. You can select Packets/s or Bits/s.
  Default: Bits/s

Multicast Manager Discovery and Modeling

Contents

Multicast Network Modeling

DX NetOps Spectrum discovers and models the physical network infrastructure using Discovery, manual modeling, or the Modeling Gateway. Before using the Multicast Discovery functionality in Multicast Manager, you must first model the physical components of your network in DX NetOps Spectrum using one of these methods.

NOTE
For more information about using Discovery, manual modeling, or the Modeling Gateway to model your network, see the Modeling and Managing Your IT Infrastructure and the Modeling Gateway Toolkit .

Multicast Discovery

Once the physical network components have been discovered, network elements which implement the Multicast MIBs supported by Multicast Manager can be discovered and modeled. This discovery is based on the MIBs specified within Device Support. These MIBs provide the information required to identify all the primary multicast components.

Multicast Manager models multicast groups, sources, and receivers. To do this, Multicast Manager uses group, source, and receiver model types.

Group models represent a domain-wide multicast data stream. The source and receiver models represent the producer and consumer of information in a multicast network. The RP represents the meeting point for sources and receivers in a multicast network.

Run On-Demand Multicast Discovery

You must log in with administrator privileges to run Multicast Discovery.

To run Multicast Discovery

1. Expand the desired landscape from the OneClick Explorer tab and select the Multicast Manager.
   Information and Configurations display in the Contents panel.
2. Select the Information tab in the Contents panel, expand the Configuration folder and then expand the Multicast Discovery node.
   Multicast Discovery controls and configurations display.
3. Set the appropriate Discovery parameters.
4. Click Run next to the Discovery Status field to begin Multicast Discovery.
   The Discovery Status field shows the status of the discovery process.

Run Multicast Discovery on Selected Models

You can configure the Multicast Network Services Discovery from the OneClick views that display models.

To run Multicast Discovery on selected models

1. Select the models.
2. Click Tools, Utilities, Network Services Discoveries, Multicast Discovery.
   The Discovery process is initiated. You can check the status in the Configuration subview.

Configuring Multicast Discovery During Modeling

DX NetOps Spectrum lets you configure Network Services Discoveries, including Multicast Discovery, during modeling. As a part of modeling configuration, you can specify which network service discoveries to run with the modeling process.

> **NOTE**
> For more information, see the Modeling and Managing Your IT Infrastructure .

Multicast Source Discovery Protocol

DX NetOps Spectrum supports the Multicast Source Discovery Protocol (MSDP). If you create a device model using OneClick Discovery, AutoDiscovery, or manual modeling, DX NetOps Spectrum automatically discovers MSDP information on network devices that support the MSDP protocol. This information is used during the Multicast Discovery process to identify Multicast network elements only visible from your network domain through MSDP.

Delete Device Models

You can delete a device model by right-clicking the device and selecting Delete. If a device model is deleted, any associated multicast group, source, or receiver model is also deleted.

Managing the Multicast Network

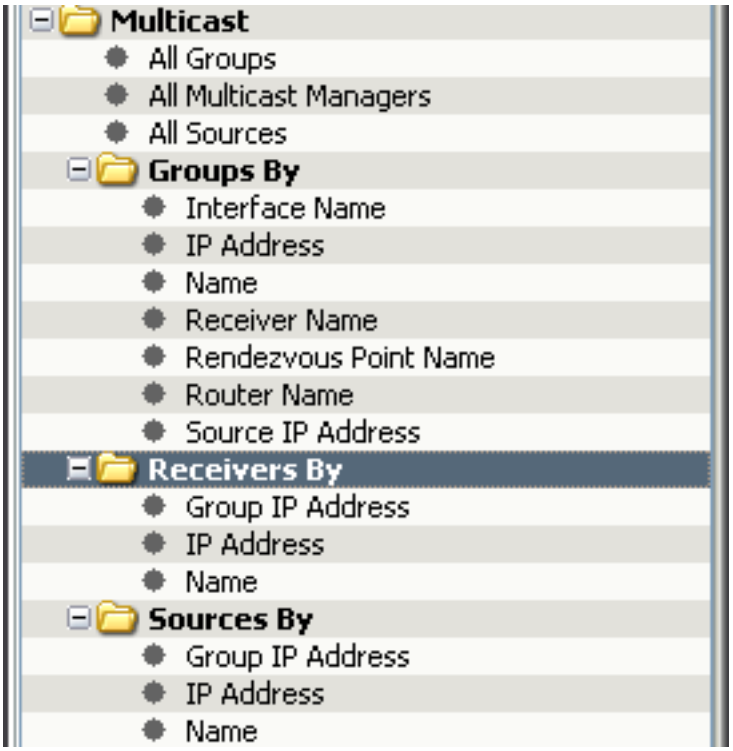
This section about how to manage your multicast network.

Search for Modeled Multicast Elements

Multicast searches, located in the Locater tab on the Navigation panel, lets you search your distributed network for Multicast Managers, multicast groups, multicast receivers, and multicast sources using criteria that you specify. You can use the search results to access a number of views which present management and performance information.

Search results appear in the Contents panel. Detailed information about the modeled device selected in the Contents panel is shown in the Component Detail panel.

The following shows the available multicast searches:



To search for modeled multicast elements

1. Select the Locater tab in the OneClick Navigation panel.
   All available OneClick searches display.
2. Expand the Multicast folder.
   All available Multicast searches display.
3. Double-click a search, enter the appropriate criteria, and click OK.

   NOTE
   Search criteria is case sensitive.

   The search results appear in the Contents panel.
4. (Optional) Use the Filter field in the Contents panel to filter your results.

   NOTE
   For more information about running searches, see the Network Searches .

Group Search Results

The results of group searches are displayed in the Contents panel. Use the Filter field in the Contents panel to filter your results. The following information displays for each group search:

- **Name**
  Indicates the name of the group. This may be the actual name or the IP address of the group.
- **Condition**
  Indicates the overall health of the group. It is calculated based on the condition of the RP routers, source, interconnecting routers, and router interfaces within the group. There are five possible conditions: Initial (blue), Normal (green), Degraded (orange), Maintenance (brown), and Down (red).
  If the condition of the group is either Degraded or Down, an alarm will be generated on the Group model.
  The condition displayed is based on the values in the following table.

NOTE
For Multicast Manager to determine the condition of a group, the group's sources and RP must be modeled in DX NetOps Spectrum and must be contained in the same DX NetOps Spectrum landscape.

- **Group Priority**
  Indicates the relative importance of the group. It can be used to prioritize troubleshooting resources when there are problems with multiple groups. The smaller the number the higher the level of priority.
- **Mode**
  Indicates the multicast mode of the group. The value can be either sparse or dense.
- **Type**
  Indicates the model type of the model that represents the device.
- **Model Class**
  Indicates the model class of the model that represents the device.

NOTE
For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

The condition that is displayed for the overall health of a group is based on the values in the following table:

Group Condition	Performance Monitor Alarm Condition	RP Modeled	RP Contact Status isEstablished	Source Modeled	Source Contact Status is Established	Interface Contact Status is Established	Router Contact Status is Established
Good	Good	Y	Y	Y	Y	Y	Y
Minor	Minor	Y	Y	Y	Y	Y	Y
Major	Major	Y	Y	Y	Y	Y	Y
Critical	Critical	Y	Y	Y	Y	Y	Y
Good	Initial	Y	Y	Y	Y	Y	Y
Minor	Good	Y	Y	Y	Y	N	N
Minor	Minor	Y	Y	Y	Y	N	N
Major	Major	Y	Y	Y	Y	N	N
Critical	Critical	Y	Y	Y	Y	N	N
Minor	Initial	Y	Y	Y	Y	N	N
Critical	Good	Y	N	Y	N	Y	Y
Critical	Minor	Y	N	Y	N	Y	Y
Critical	Major	Y	N	Y	N	Y	Y
Critical	Critical	Y	N	Y	N	Y	Y
Critical	Initial	Y	N	Y	N	Y	Y
Good	Good	N	N/A	N	N/A	N/A	N/A
Minor	Minor	N	N/A	N	N/A	N/A	N/A
Major	Major	N	N/A	N	N/A	N/A	N/A
Critical	Critical	N	N/A	N	N/A	N/A	N/A
Initial	Initial	N	N/A	N	N/A	N/A	N/A

NOTE

A Multicast group will be put into maintenance mode if any of the following occur:

If there are any RPs within the Multicast group and they are all in maintenance.

- If there are Multicast sources within the Multicast group and they are all in maintenance.
- If there are any devices within the Multicast group and they are all in maintenance.
- If there are any interfaces within the Multicast group and they are all in maintenance.

Receiver Search Results

The results of receiver searches are displayed in the Contents panel. Use the Filter field in the Contents panel to filter your results. The following information displays for each receiver search:

- **Name**
  Indicates the name of the receiver. This may be the actual name or the IP address of the receiver.
- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Type**
  Indicates the model type of the model that represents the device.
- **IP Address**
  Indicates the IP address of the receiver.
- **Model Class**
  Identifies the model class of the receiver.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

Source Search Results

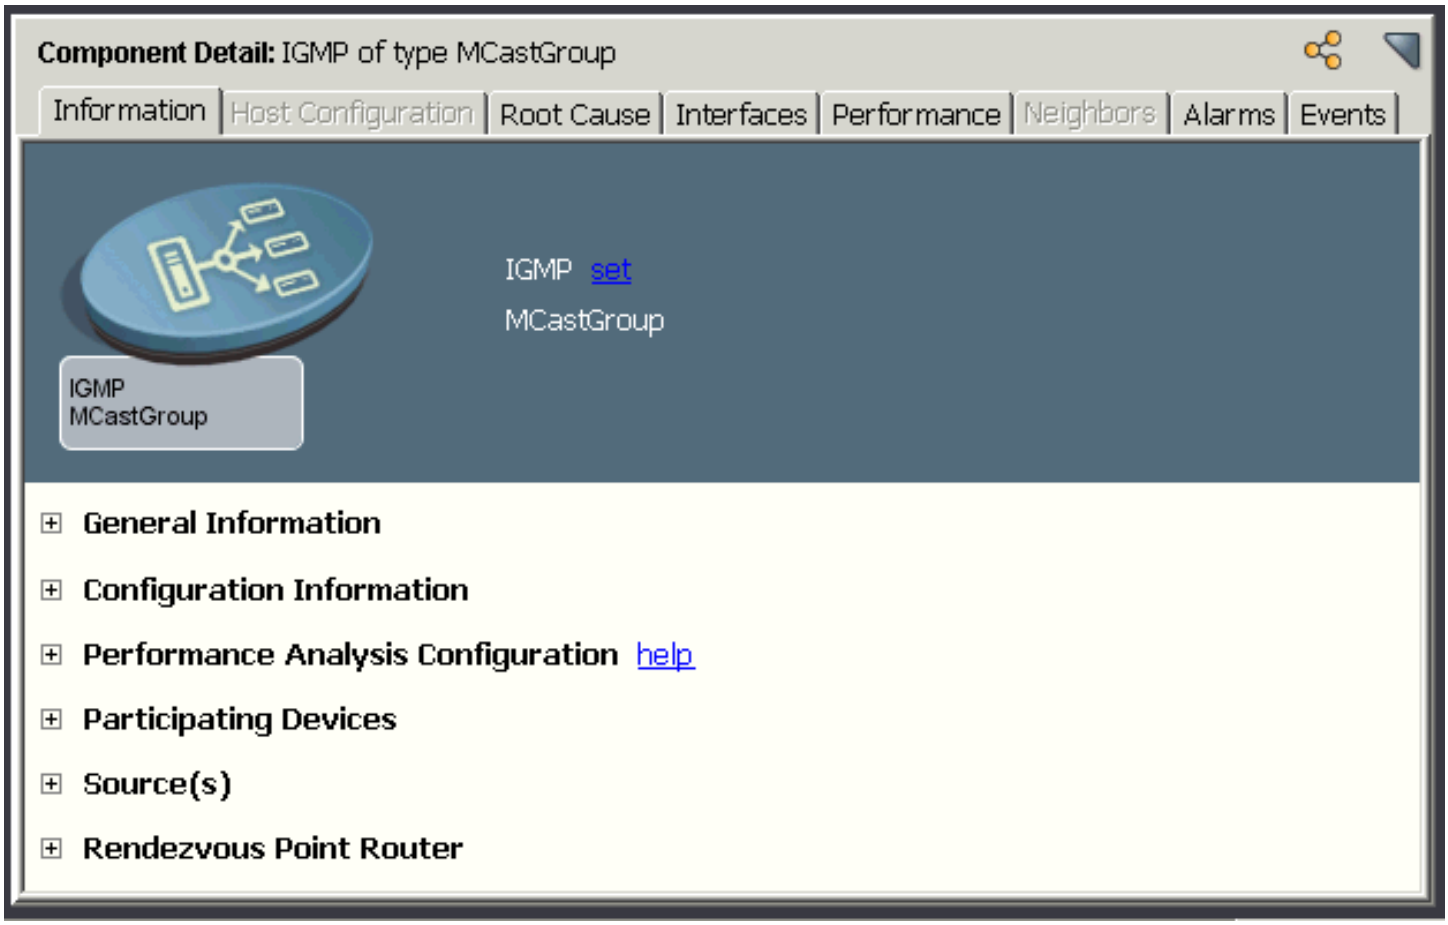
The results of Source searches are displayed in the Contents panel. Use the Filter field in the Contents panel to filter your results. The following information displays for each source search:

- **Name**
  Identifies the name of the source. This may be the actual name or the IP address of the source.
- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Type**
  Indicates the model type of the model that represents the device.
- **Source Address**
  Identifies the IP address of the source.
- **Model Class**
  Identifies the model class of the source.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

Multicast Groups

The Component Detail panel contains tabs that let you view multicast information about a selected group. The Information tab provides a number of subviews for the group.



General Information Subview for Multicast Groups

You can set the following parameters for a group model in the General Information subview:

- **Group Address**
  Indicates the IP address of the group.
- **Group Priority**
  Indicates the relative importance of the Group. It can be used by the network operator to prioritize troubleshooting resources when there are problems with multiple Groups. The lower the value of Group Priority for a given Multicast Group, the higher its priority. If you are logged in as an administrator, you can edit this field by clicking set.
- **Model Class**
  Indicates the model class of the model that represents the device.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .
- **Creation Time**
  Indicates the creation date and time of the Group model.
- **Security String**

Indicates the SNMP community string or password for the device. If you have the appropriate permissions, you can modify the security string. Click set, enter the security string into the available field, and press Enter.

- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.
- **Notes**
  Indicates notes or comments about the group. To add a note, click Set and then enter the appropriate information. When you have finished entering the note, click Save. If you do not want to save the note that you entered, click Cancel.

Configuration Information Subview

You can set the following attribute in the Configuration Information subview:

- **Ignore initial/unmodeled sources in group condition**
  Lets you choose (on a per-group basis) whether or not to include the status of the source model in the group condition calculation. If you purchase a Multicast service or a data feed from an external service, you may not have access to the source to obtain its status. You can use this option to exclude the source's status in the group condition calculation. If you do own and have access to the source of the multicast stream, you should include the source status in the group status configuration.

Performance Analysis Configuration Subview for Multicast Groups

Performance analysis shows you important information about the flow of multicast traffic on your network. In a properly functioning multicast network, each point of the network (where multicast is enabled for that group) should experience the same traffic flow in packets per second or bytes per second.

Any deviation from the traffic level as measured at the source could indicate one or more of the following scenarios:

- A change in group membership.
- A change in routing where multicast traffic is taking a different path due to load balancing, a redundant failover, or a change from shared to source mode.
- A change in the network's multicast configuration where multicast has been disabled on an interface or device.
- A change in interface status.
- Device or link instabilities.

You can configure how Multicast Manager analyzes the performance of the group model selected. A graphical representation of source traffic is also available. You can set the following parameters in the Performance Analysis Configuration subview:

- **Global Group Performance Analysis**
  Indicates whether the entire Multicast Performance Monitoring system is enabled or disabled. It can be set in the Multicast Manager model's Performance Analysis Configuration. The value of this parameter must be set to enable for the Group Performance Analysis to function.
- **Group Performance Analysis**
  Enables performance monitoring for each Group. This value must be enabled for performance information to be displayed in the Multicast Topology view.
- **Percent Degradation Threshold**
  Defines the percent variation allowed in the monitoring of Group performance. For example, if the source is measured at 100 pps, all other points in the network receiving this Group should be within this percent threshold (+/-). Otherwise, a threshold violation is noted for the Group on that device. The default value is three percent.
- **Enable Multicast Path Change Detection**
  When this parameter is set to Yes, the Multicast Group looks for changes in the interface receiving multicast traffic. If a change is detected, an event is generated on the offending device. This event gives information about the device

that generated the event, the interface receiving the traffic, and the group to which the device belongs. By default, this parameter is set to No.
The following scenarios can cause a change in path to be detected:
  – A router performs a routine load balancing operation and redirects the multicast traffic to be routed around the network by a different path. This does not necessarily indicate a failure.
  – A router along the path of the multicast traffic goes down. In this case a topology change will occur and the device receiving the multicast traffic will detect that the interface sending the information has changed.
- **Enable Path Change Alarms**
  If this parameter is set to Yes, Multicast Manager generates a yellow (minor) alarm when a change in path is detected. For this parameter to operate correctly, Enable Multicast Path Change Detection must be set to Yes.
- **Group Performance Alarms**
  Enables Multicast Manager to create an alarm in response to the violation of performance thresholds defined in the Minor, Major, and Critical Alarm Threshold parameters.
- **Minor Alarm Threshold**
  Sets the Minor Threshold Percent. This value determines the severity of threshold violations on a Group. For example, a Group may have 100 interfaces sampled in the network. If more than the Minor Alarm Threshold percentage and less than the Major Alarm Threshold percentage of those samples are in violation of the Performance Degradation Threshold, a Minor event (and an alarm if Group Performance Alarms is set to enable) is generated.
- **Major Alarm Threshold**
  Sets the Major Threshold Percent. This value determines the severity of threshold violations on a Group. For example, a Group may have 100 interfaces sampled in the network. If more than the Major Alarm Threshold percentage and less than the Critical Alarm Threshold percentage of those samples are in violation of the Performance Degradation Threshold, a Major event (and an alarm if Group Performance Alarms is set to enable) is generated.
- **Critical Alarm Threshold**
  Sets the Critical Threshold Percent. This value determines the severity of threshold violations on a Group. For example, a Group may have 100 interfaces sampled in the network. If more than the Critical Alarm Threshold percentage of those samples are in violation of the Performance Degradation Threshold, a Critical event (and an alarm if Group Performance Alarms is set to Enable) is generated.
  – **Minimum Rate (Bits/sec)**
    Sets the minimum rate for critical alarm threshold.
    Default: 0 Bits/ sec
  – **Maximum Rate (Bits/sec)**
    Sets the maximum rate for critical alarm threshold.
    Default: 4294967295 Bits/ sec

    NOTE
    The Minimum Rate and Maximun Rate for alarm threshold apply only when Performance Collection Type is set to Bit/Sec. Thus these alarms should not occur unless the user inputs something for these values.

Participating Devices Subview

The Participating Devices subview provides information for all of the devices that participate in the multicast group. You can set the following parameters in the Participating Devices subview:

- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Name**
  Indicates the name of the participating device model.
- **Network Address**
  Identifies the network address of the device.
- **Manufacturer**

Indicates the manufacturer of the device that the model represents.

- **Model Class**
  Identifies the model class of the device model.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

- **MAC Address**
  Indicates the MAC address of the device.
- **Type**
  Indicates the model type of the model that represents the device.
- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.

Sources Subview

The Sources subview lists all of the sources for a multicast group. You can set the following parameters in the Sources subview:

- **Condition**
  Identifies the status of the source model. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), unknown (gray), and maintenance (brown).
- **Name**
  Identifies the name of the source model. This may be the actual name or the IP address of the source.
- **Type**
  Identifies the model type of the source model.
- **Model Class**
  Identifies the model class of the source model.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.

Rendezvous Point Router

The Rendezvous Point Router subview lists the RP router for the Multicast Group. You can set the following parameters in the Rendezvous Point Router subview:

- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Name**
  Indicates the model name of the model that represents the device.
- **Network Address**
  Identifies the network address of the device.
- **Manufacturer**
  Indicates the manufacturer of the device that the model represents.
- **Model Class**
  Indicates the model class of the model that represents the device.
- **MAC Address**

Indicates the MAC address of the device.

- **Type**
  Indicates the model type of the model that represents the device.
- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.

Group Interfaces Information

You can access information about the interfaces associated with a selected multicast group by selecting a group model and then selecting the Interfaces tab on the Component Detail panel. The following information displays for the interface model:

- **Name**
  Indicates the model name of the model that represents the device.
- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Status**
  Indicates the contact status of the link between this interface and the interface to which it is connected.
- **PIM Status**
  Indicates the configured mode of this PIM interface.
- **Mode**
  Indicates the PIM mode of the interface. This value can be sparse, dense or sparseDense.
- **IGMP Version**
  Indicates the version of IGMP that is running on this interface.

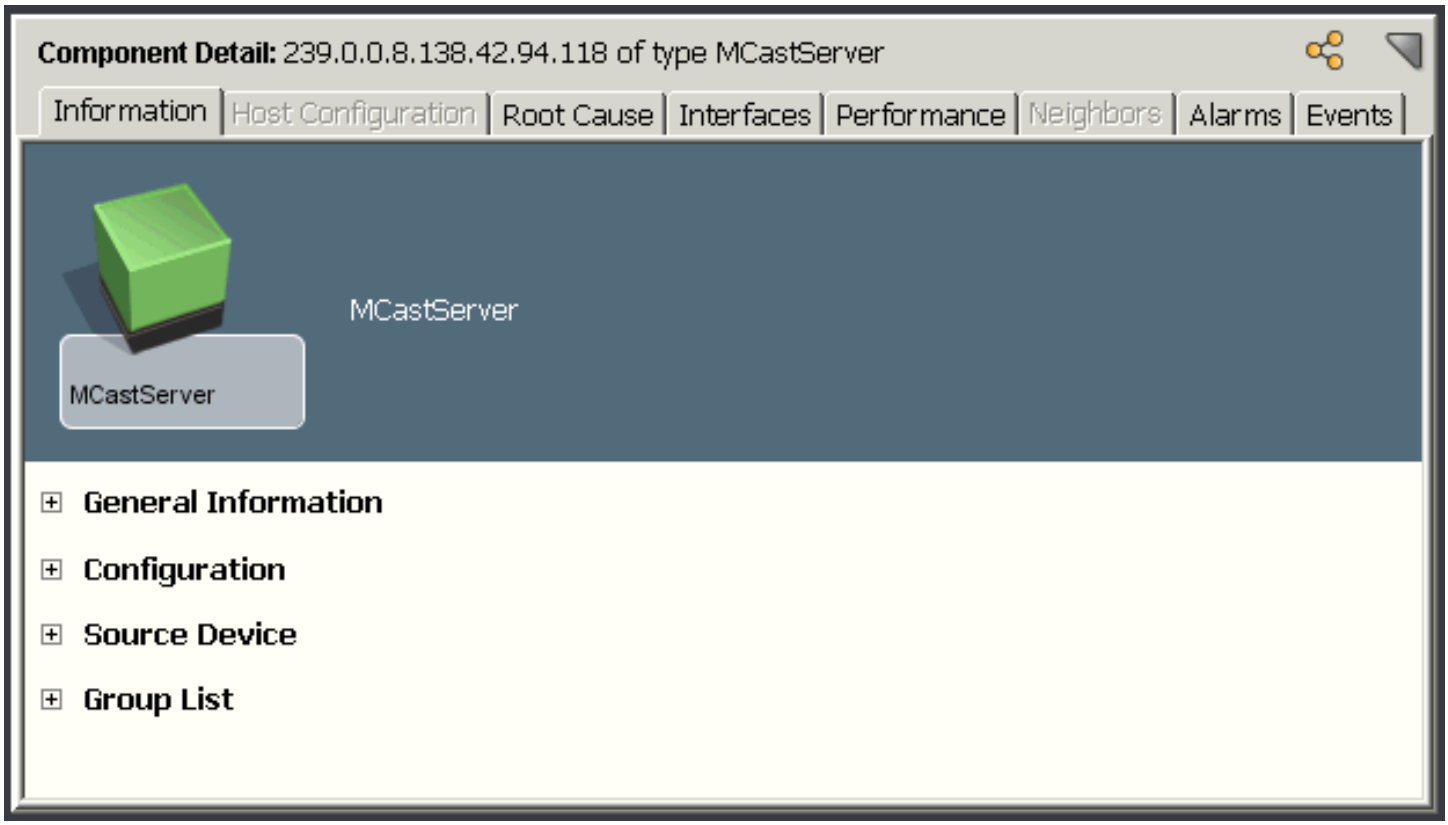
NOTE
If an interface does not participate in a particular protocol, the columns pertaining to that protocol for that interface will not contain any data.

Group Event Information

You can access the Event view for a group by selecting a group model and then selecting the Events tab on the Component Detail panel. The Events tab displays event information for events that occur on the group model.

Multicast Source Management

The Component Detail panel contains tabs that let you view additional information about a source selected from the search results list in the Contents panel. The Information tab provides a number of subviews for the source, as shown in the following example:



NOTE
If a multicast source is unmanageable, you can define a source proxy.

General Information Subview for the Multicast Source Model

You can set the following parameters for the multicast source model in the General Information subview:

- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Source Address**
  Indicates the IP address of the source.
- **Model Class**
  Indicates the model class of the model that represents the device.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .
- **Creation Time**
  Identifies the creation date and time of the source model.
- **Security String**

Indicates the SNPMP community string or password for the device. If you have the appropriate permissions, you can modify the security string. Click set, enter the security string into the available field, and press Enter.

- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.

Configuration Subview

The Configuration subview lets you define a proxy to reach the selected source and reconfigure the Default Gateway. You can set the following parameters for a proxy in the Configuration subview:

- **Default Gateway**
  Indicates the IP Address of the device DX NetOps Spectrum should poll to obtain base-line performance statistics for a multicast group. This value will generally be the IP address of the default gateway for the Multicast Source. By default, Multicast Manager determines the default gateway. The default gateway must be correct to utilize the Multicast Performance and Topology views. Click Set to modify the IP address.
  When the default gateway is set to the Virtual IP address of a Hot Standby Routing Protocol (HSRP) group, for Multicast Performance Analysis to work properly, it is necessary to configure the HSRP member routers to send HSRP related SNMP Traps to DX NetOps Spectrum. This lets DX NetOps Spectrum continue to obtain multicast performance statistics when the Active HSRP router changes.
- **Proxy IP**
  Indicates the IP Address of the proxy for an unmanageable multicast source. This lets you compute condition and gather performance data for an unmanageable source using the information from the closest ingress router to the unmanageable source.

Source Device Information

The following information is shown about the source device for a multicast source model.

- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Name**
  Indicates the model name of the model that represents the source.
- **Network Address**
  Identifies the network address of the device.
- **Manufacturer**
  Indicates the manufacturer of the device that the model represents.
- **Model Class**
  Indicates the model class of the model that represents the source.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

- **MAC Address**
  Indicates the MAC address of the source device.
- **Type**
  Indicates the model type of the model that represents the source device.
- **Landscape**
  Indicates the DX NetOps Spectrum landscape on which the device is modeled.

Group List Subview

The Group List subview displays information about group models to which the source model sends information. You can set the following parameters for a group model in the Group List subview:

- **Condition**
  Indicates the status of the model that represents the device. Possible conditions are initial (blue), normal (green), minor alarm (yellow), major alarm (orange), critical alarm (red), gray (unknown), and maintenance (brown).
- **Name**
  Indicates the model name of the model that represents the device.
- **Group Priority**
  Indicates the relative importance of the group. It can be used to prioritize troubleshooting resources when there are problems with multiple groups. The smaller the number the higher the level of priority.
- **Mode**
  Indicates the multicast mode of the group. The value can be either sparse or dense.
- **Type**
  Indicates the model type of the model that represents the device.
- **Model Class**
  Indicates the model class of the model that represents the device.

  NOTE
  For more information about model classes, see the SpectroSERVER and DX NetOps Spectrum Databases Overview .

Source Event Information

You can access the Event view for a source by selecting a source model and then selecting the Events tab on the Component Detail view. The Events tab displays event information for events that occur on the source model.

Source Performance Information

Real-time multicast performance statistics can be obtained for a multicast source by selecting the Performance tab in the Contents panel. The Performance view provides a real-time graphical view of source traffic. The information provided in the Performance view is useful for monitoring multicast performance and faults within the multicast environment in a graphical format.

You can select *one* of the following:

- Multicast Source Octet Traffic
- Multicast Source Packet Traffic
- Multicast Source Bit Traffic

For the graph to function properly, the following must be true:

- If you are able to create a physical device model of the source, you should model it as an SNMP host. You can choose one of the following host model types:

  - Host_Compaq
  - Host_Dell
  - Host_Sun
  - Host_systemEdge
  - Host_Device
  - GnSNMPDev
- If you are not able to create a physical device model of the source, you should model the source as a pingable. The Multicast Discovery process creates pingable models automatically for all multicast sources that do not have a corresponding physical device model.
- DX NetOps Spectrum must be able to communicate with the source.
- The default gateway for the source must be modeled in DX NetOps Spectrum using the appropriate router model type.
- If you model the source as a pingable, the default gateway must be correct in the source model's Configuration view.
- DX NetOps Spectrum must be able to communicate with the default gateway for the source.
- The default gateway must support one of the IPM Route MIBs (draft or RFC).
- The routers in a Hot Standby Routing Protocol (HSRP) group must be set to send HSRP traps to the SpectroSERVER for Multicast Manager performance monitoring to work properly, and for performance graphs to show traffic statistics when the active router in the HSRP group has changed because of a failover.

Define a Proxy for an Unmanageable Source

Multicast Manager lets you define a proxy to monitor an unmanageable source. Examples of an unmanageable source (or multicast stream) are groups which originate outside of your network. These could be feeds which traverse the Internet to get to this location or dedicated services like financial data streams which are purchased to feed trading applications.

The proxy should ideally be the ingress router where the multicast stream enters the network. Since you cannot monitor the source, you can configure the ingress router where the multicast stream enters the network to represent the unmanageable source for performance comparisons.

To define a proxy for an unmanageable source

1. Conduct a Multicast Search for the unmanageable source model.
   The Contents panel displays the results of the search.
2. Select the unmanageable source model from the results list.
   Information and configurations display in the Information tab of the Component Detail panel.
3. Expand the Configuration subview.
   The Default Gateway and Proxy IP configuration parameters display.
4. Click set next to Proxy IP and enter the IP Address of the ingress router where the Multicast Stream from the unmanageable source enters your network and press Enter.
   The IP Address of the unmanageable source's proxy displays.

Alarm List

The Contents panel displays the Alarms list for the modeled element that you select in the Navigation panel.

To know more about an alarming element, you can click **Alarm Detail** on the Alarm tab of the Component Detail panel.

If the Alarm list in the Contents panel is empty, the Component Detail panel displays the Information tab for a selected element.

Multicast Receiver Information

Information about multicast receivers modeled as pingables is available in the Multicast Information subview of the pingable model. Expand the Associated Multicast Servers subview to display the receiver's associated multicast servers

and their condition. Expand the Associated Multicast Groups subview to display the receiver’s associated multicast groups and their condition.

View Multicast Topology Information

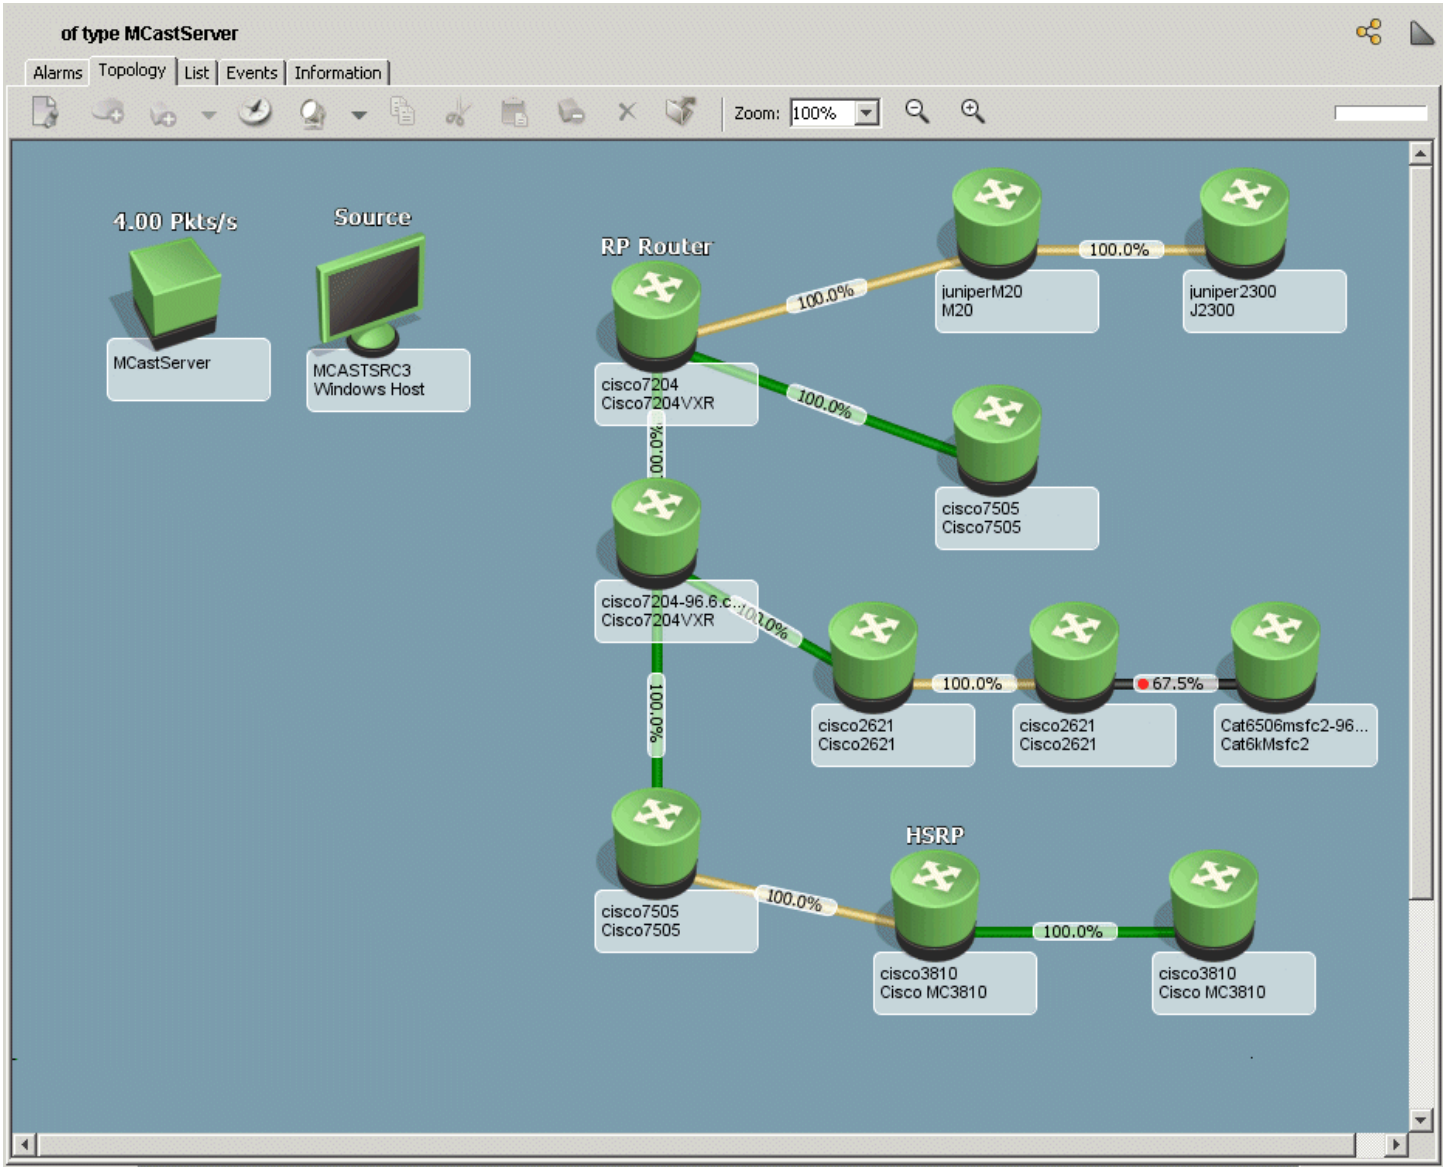
The Multicast Topology view provides a graphical representation of the data flow from a multicast source through the associated devices, and allows you to more easily troubleshoot and gauge the overall impact of traffic flow changes and outages within your environment. You can access a topology view for each source within a multicast group that Multicast Manager has discovered and modeled. The performance information for each segment of the traffic distribution tree displays the percentage of source traffic reaching that segment. The percentage is calculated by comparing the baseline traffic from the source.

Performance Analysis must be enabled on the Multicast Manager model and for any multicast group you want performance information to be displayed for in the Multicast Topology view.

The path structure and performance data displayed is based on the latest poll. It may not necessarily reflect the current state.

To view multicast topology information

1. Expand the appropriate Multicast Manager Group node from the Navigation panel.
2. Expand the Source folder, select the desired source, and select the Topology tab in the Contents panel. Multicast Manager displays a Topology view.



NOTE
Use the Topology Display Units attribute to choose the desired units to display in the topology.

Trap Support by Multicast Manager

The Multicast Manager supports the handling of traps specified by the CISCO-PIM-MIB. The following table describes the supported traps and their information.

Supported Traps	OID	Event Generated	Alarm Generated	Default Alarm Severity
ciscoPIMRPMappingChange	1.3.6.1.4.1.9.9.184.2.0.3	0x2104a5	None	NA
ciscoPIMInvalidRegister	1.3.6.1.4.1.9.9.184.2.0.4	0x2104a6	None	NA
ciscoPIMInvalidJoinPrune	1.3.6.1.4.1.9.9.184.2.0.5	0x2104a7	None	NA

In addition to supporting traps specified by the CISCO-PIM-MIB, Multicast Manager supports the trap specified by the CISCO-HSRP-MIB. Multicast Manager can perform multicast performance monitoring on the active router in a HSRP group when the active router has changed due to a failover.

The following table describes the HSRP trap.

HSRP Traps	OID	Event Generated	Alarm Generated	Default Alarm Severity
cHsrpStateChange	1.3.6.1.4.1.9.9.106.2.6.1	0x0021091e 0x0021091f	0x0021091e 0x0021091e	Minor NA

Devices Supported by Multicast Manager

Cisco and Juniper M Series Devices

Multicast Manager supports the discovery, modeling, and viewing of devices that support multicast traffic using the MIBs specified in the following table:

Supported MIBs	Cisco 12.0	Cisco 12.2 or later
ipMRoute - Cisco	Y	Y
ipMRoute - Experimental	Y	Y
ipMRoute - Standard	N	N
PIM - Cisco	Y	Y
PIM - Experimental	Y	Y
PIM - Standard	Y	Y
IGMP - Experimental	Y	N
IGMP - Standard	N	Y
Functions		
Group Discovery	Y	Y
Source Discovery	Y	Y
Receiver Discovery	Y	Y
RP Discovery	Y	Y
Group Performance	Y	Y
Traps		
Neighbor Loss	N	N
PIM Interface Up	N	N
PIM Interface Down	N	N
RP Mapping Change	Y	Y
Invalid Register	Y	Y
Invalid Join Prune	Y	Y
Dynamic Discovery Traps		
Groups/Sources	N	N

Multicast Manager depends on functionality provided by DX NetOps Spectrum in the Cisco Router management module. Therefore, you must install the Cisco Router management module before or during the Multicast Manager installation.

NOTE

For more information about Cisco management modules, see the Cisco Device Management *section.*

Multicast Manager also supports Juniper M series devices using JunOS releases 6.1 and greater. The Juniper M series management module (SM-JPR1000) must be installed for Multicast Manager to discover and support multicast-enabled, Juniper devices.

NOTE
For more information about Juniper M series devices, see the Device Management Reference *section.*

Troubleshooting Multicast Manager

The Group Condition Is Displayed Incorrectly

Symptom:

The group condition is being displayed incorrectly even though the source is down.

Solution:

If the source has not been modeled by DX NetOps Spectrum, when the physical device goes down there is no way to associate that status with a group on which it depends. Normally, a source down should produce a group down condition but, without the source modeled, the group shows a degraded condition.

Verify that the source is active and modeled by DX NetOps Spectrum, or that you have modeled third-party sources as pingable models.

The Group Condition Is Not Calculated Correctly

Symptom:

The group condition is not being calculated correctly when the model representing the RP is deleted after Multicast Discovery is run.

Solution:

Delete all of the groups and rerun Multicast Discovery.

Symptom:

The group condition is not being calculated correctly when the device representing the RP is not modeled.

Solution:

Model the RP, then rerun Multicast Discovery.

Changes Are Not Reflected in Performance Graphs

Symptom:

I added and removed some multicast sources and so I had to re-run Multicast Discovery. However, my changes are not immediately reflected in the performance graph.

Solution:

Restart the OneClick client.

New Group Models Staying in Initial Condition

Symptom:

New group models stay in Initial condition after a background discovery is run.

Solution:

No RPs will be discovered if a background discovery is run without previously running a manual discovery. Run a manual Multicast Discovery first.

Downward Spikes Display in a Group Performance Graph

Symptom:

When I display a group performance graph during an HSRP switchover, and the HSRP routers are configured to send HSRP traps to the SpectroSERVER, I see a downward spike to 0 for one polling cycle.

Solution:

After the switchover, the graph begins displaying the performance of the new active gateway.

No Data Is Displaying in Performance Graphs

Symptom:

No data is displayed for Group Performance Graph involving routers that are configured for HSRP.

Solution:

The likely cause is that the standby HSRP router has become the active router, and DX NetOps Spectrum was not notified of the change using the HSRP trap. Verify that the HSRP routers are configured to send the HSRP trap to the SpectroSERVER.

Performance Graphs Displaying Last Known Data Points After Contact is Lost

Symptom:

The Performance Graph view for a multicast group model displays the last known data point when contact with the default gateway is lost.

Solution:

This only happens for devices that do not support the IPMRoute MIB. For devices that support the IPMRoute MIB, the Performance Graph view displays a “0” data value until contact with the device is re-established.

Performance Statistics are Displaying as N/A

Symptom:

Performance statistics are displayed as N/A in the Multicast Topology view.

Solution:

The topology cannot gather data from the default gateway. If the performance information remains unavailable for an extended period, verify that the default gateway setting is set to a contactable multicast enabled router within this source’s traffic topology tree.

Use Case Scenarios

This section contains information about common use cases of network management.

Analyze Impact of a Device Alarm on Customer Multicast Traffic

Symptom:

Two unrelated trouble tickets against two core routers are generated at nearly the same time. Consider the following:

- The trouble tickets are routed based on the device class. They are sent to the level 2 operations Group. This Group focuses solely on maintaining the core routing infrastructure.
- The company's network management application has identified the routers in question and their offending components.
- The level 2 support group currently has a backlog of 25 open tickets for a variety of issues.
- The operators are currently using their knowledge of the core network to make decisions regarding issue prioritization.

Assume the following:

1. The customer has previously installed and configured Multicast Manager.
2. The customer has completed a discovery of their physical network.
3. The customer has completed a Multicast Discovery.
4. All multicast services have been modeled with DX NetOps Spectrum.
5. There are a couple of outages and the operator must analyze how these outages affect the multicast topology.
6. There is currently only one network administrator available to handle trouble tickets.

Solution:

1. The first router in the network goes down and is detected by DX NetOps Spectrum. Very shortly after this, the second router goes down.
2. DX NetOps Spectrum generates an alarm for each of the routers that has gone down.
3. The network management system (NMS) operator receives the alarms in the OneClick console and verifies the DX NetOps Spectrum alarms by pinging the routers and not receiving a response.
4. The NMS operator receives an alarm generated on one of the multicast groups modeled by Multicast Manager.
5. The NMS operator selects the multicast group in the OneClick console Alarms tab.
6. The NMS operator opens the Participating Devices subview of the Group’s Information tab and sees that one of its routers has a Down (Red) condition. This router is one of the routers that an alarm was generated on in step 2 above. The network operator now understands that this router is critical to the operation of this multicast group, and of a higher priority than the other router issue.
7. The network operator creates a trouble ticket for the router which is impacting the multicast group. This ticket will show that the problem is a high impact outage and will include information on the impacted groups and applications. The network operator assigns the ticket to the network administrator.
8. The network administrator receives the trouble ticket and begins troubleshooting this high impact problem.
9. The network operator creates a trouble ticket for the second router outage that does not affect the multicast topology and assigns it to the network administrator.
10. The network administrator receives the second trouble ticket and will begin work on it after the multicast problem is resolved. DX NetOps Spectrum has allowed the troubleshooting process to be prioritized to the most critical fault.

An Individual User Is Not Receiving Multicast Traffic

Symptom:

When the stock market opens every day, a multicast feed is established to send real time market data to all the brokers on the company's network. The multicast group uses PIM Sparse mode to communicate to the traders who are widely dispersed throughout the company's operations. Today one broker is not receiving the market data feed but is receiving other multicast traffic.

Assume the following:

1. The customer has previously installed and configured Multicast Manager.
2. The customer has completed a discovery of their physical network.
3. The customer has completed a Multicast Discovery.
4. All multicast services have been modeled with DX NetOps Spectrum.
5. The broker has reported that he is no longer receiving the market data feed.

Solution:

1. The operator sees a DX NetOps Spectrum alarm in the OneClick console indicating that the router port has failed.
2. A trouble ticket is created and the operator begins troubleshooting the router port issue.
3. As part of his troubleshooting procedure the operator uses the Multicast Manager “Groups by Interface” search.
4. This view shows all the affected groups and their priority. Groups 1-3 are affected by this router.
5. In addition, a broker reports that he is no longer receiving the multicast data feed for Group 2.
6. The operator can tell the broker that he is part of the affected group (due to the router failure). A second trouble ticket does not need to be created.
7. The operator fixes the router interface.
8. The router interface is working and market data is now being received by the broker reporting an outage.
9. The operator confirms multicast traffic is being received by the broker and closes the trouble ticket.

Multiple Users Are Not Receiving Multicast Traffic

Symptom:

At the same time each day, a single multicast stream is started. Today the source is started, but none of the users are seeing the multicast traffic, and consequently the business application they use is not functioning.

Assume the following:

1. The customer has previously installed and configured Multicast Manager.
2. The customer has completed a discovery of their physical network.
3. The customer has completed a Multicast Discovery.
4. All multicast services have been modeled with DX NetOps Spectrum.

Solution:

1. Several users contact the network operator to report that they are not receiving their daily service information.
2. The operator brings up Multicast Manager in the OneClick console and does a search on “All Groups”.
3. The results of the search are shown in the Contents panel and all groups have a red condition.
4. The operator examines the source for each group in the Information tab of the Component Detail panel.
5. The operator finds no errors; all sources are operating properly.
6. The operator checks the RP Router for each group.
7. The operator finds that the condition of one of the RP routers is red, indicating that it is down.
8. The operator searches through open trouble tickets and finds a trouble ticket for a router, which is the RP for the group in question.
9. The operator reboots the RP router and the alarm is cleared.
10. Multicast traffic is restored to the network. The operator confirms that the users have service and the trouble ticket is cleared.

A Threshold Violation Has Occurred

Symptom:

At 10:00 A.M., users stop receiving Multicast traffic, consequently, the business application needed by these users is not functioning.

Assume the following:

1. The customer has previously installed and configured Multicast Manager.
2. The customer has completed a discovery of their physical network.
3. The customer has completed a Multicast Discovery.
4. All multicast services have been modeled with DX NetOps Spectrum.
5. The performance monitor configuration has been set up to generate alarms when a performance threshold is violated.
6. The Multicast Manager Device Performance Alarms parameter must be set to Enable.

Solution:

1. Several users contact the network operator to report that their daily service information is broken.
2. The operator brings up Multicast Manager in the OneClick console and does a search on “All Groups”.
3. One of the Groups shows an Orange condition, indicating a major alarm on one of the elements of the Group.
4. The operator checks each of the devices in the Group and finds an alarm on one of the routers. This alarm is also shown in the OneClick alarm console.
5. A trouble ticket is created. The operator begins troubleshooting the router issue and discovers that one of the interfaces on the router is dropping packets. This generated the alarm on the group model, because the traffic tracked by the performance monitor had fallen below the assigned threshold.
6. The operator resolves the port issue and closes the trouble ticket.
7. Multicast traffic is restored to the network.
8. The operator confirms that service has been restored with users.

Network Configuration Manager

Access Network Configuration Manager

To access Network Configuration Manager from the OneClick Console, select Configuration Manager from the Explorer tab. Then, expand the Configuration Manager node; the Device Families, Policies, and Tasks views appear.

From 10.4.2.1, When the privileged role of the user Allow Load Firmware on Multiple Devices is disabled and load firmware task is attempted on more than one device, an error popup should be thrown with the message Restricted Load firmware for a single device, Select the single device to load firmware. when the privileged role of the user **Allow Load Firmware on Multiple Devices** is disabled and load firmware task is attempted on GC with more than one device, an error popup should be thrown with the message Restricted Load firmware for a single device, maintain single device per GC to load firmware.

> **NOTE**
>
> For more information about OneClick, see the Using OneClick section.

Network Configuration Manager Capabilities

Configuration management is the process of identifying and monitoring configurations of single devices and device families that comprise a network. Devices include routers, hubs, and switches.
Using the DX NetOps Spectrum Network Configuration Manager ensures the following benefits:

- Increases the network uptime by reducing the time to resolve network issues.
- Reduces the network support costs by reducing the occurrence of network issues that require reactive troubleshooting and fixes.
- Reduces the network operational costs by reducing the time to administer system-wide changes.

Each device on the network is configured to provide specific services. Details about how a device operates and how it has been customized are contained in its configuration.
Network Configuration Manager lets you perform the following tasks:

- Manage configurations for supported devices that are modeled in DX NetOps Spectrum or OneClick.
- Capture network device configurations and store them in the DX NetOps Spectrum database.
- Compare running and startup configurations.
- Upload Perl configuration scripts.
- Load firmware.
- Export configurations.
- Load and merge the configurations to one or more devices of the same family type.

  NOTE

  Merging content appends information to an existing file (it does not overwrite or restore).
- Verify that the correct configuration is running on a device.
- Set up a schedule of automatic captures and policies to ensure reliable device configurations.
- Detect performance problems by verifying device configurations.
- Maintain a history of network device configurations for comparison and troubleshooting.
- Create policies to monitor content in configurations and verify that device content is compliant.
- Update NCM one device at a time (From 10.4.2.1)

Introduction

Key Terms

The following terms are important for understanding the Network Configuration Manager.

- **Approval Workflow**
  Lets you require configuration changes that are initiated through the Network Configuration Manager to receive approval before being implemented. An approval workflow can be set up to use CA Service Desk tickets or DX NetOps Spectrum authorization privileges for the approval process.
- **Bulk Task**
  Bulk tasks are tasks that you can run on multiple devices. The following bulk tasks are available: Upload, Sync, Save to Startup, Load Firmware task, Reload, and Cancel Reload.
- **Device Family**
  A group of devices that share common methods to access device configurations. Devices that Network Configuration Manager supports out-of-the-box are automatically placed in a device family. You can use the Extension Utility to create more device families.
- **Global Synchronization Task**
  Gathers running configurations for all devices on your network for which Network Configuration Manager is enabled using a schedule. Select a time period and a recurrence frequency to capture configurations from all network-wide supported devices. By capturing the configurations for all devices on your network, you maintain a running configuration history.
- **Load Firmware Task**
  Uploads the firmware to Cisco IOS and the Cisco IOS - SSH Capable devices.
- **Network Configuration Manager Policy**

Monitors content in configurations and verifies that device content is compliant. Policies specify a certain aspect of a device host configuration. A policy is checked and compared every time a host configuration file is captured for a device. Devices that violate the policy can generate an alarm and can be semi-automatically repaired. A policy is checked for the compliance when a configuration change occurs on a device.

- **Reference Configuration**
  A device configuration that serves as a baseline for reference purposes. You can compare other configurations against the reference configuration. You can have an alarm asserted on the device if the current configuration differs from the reference.
- **Reload Task**
  Reloads a device after firmware has been uploaded. This task is available for Cisco IOS and Cisco IOS - SSH Capable devices.
- **Reusable Task**
  A task that persists after it has been executed and can be run again multiple times without being redefined. You can also create a recurring schedule to run a reusable task at predetermined times.
- **Save to Startup Task**
  Writes a current running configuration to the startup configuration of one or more selected devices. A device saves its configuration in the NVRAM (Nonvolatile Random Access Memory). You can run this task on multiple devices.
- **Single Device**
  Representation of a device in your network that DX NetOps Spectrum is monitoring. Configuring a single device overrides all global device family configurations.
- **Sync Task**
  Captures and verifies policy-compliant device configurations for selected devices on your network and shows the results in real time. When a Sync task captures device configuration, it verifies the configuration against all policies pertaining to the device. You can run this task on multiple devices.
- **Upload Task**
  Merges new content into the running configurations of one or more selected devices. You can run this task on multiple devices.

Types of Configurations

The following sections describe the different configurations for a device.

Running Configuration

A running configuration is a version of a configuration that is loaded on a device and defines how the device currently operates. A running configuration only valid for the current run-time session.

Startup Configuration

A startup configuration is the backup version of a configuration that is stored on a device. The startup configuration is used when the device is rebooted. Some devices have primary and secondary startup configurations. A device replaces the previous running configuration with a copy of the startup configuration when it is rebooted.

Configuration File

A configuration file contains a subset of attributes from a running configuration by device manufacturers. Many devices let Network Configuration Manager capture complete configuration files. You can edit captured configuration files.

Supported Devices

Network Configuration Manager supports the device families of the following vendors out-of-the-box:

- Cisco
- Enterasys
- Enterasys
- Riverstone SSR
- Extreme
- Foundry
- Juniper
- Lancom
- Nortel (Baystack and Passport)

Devices that do not fall into one of the out-of-box supported device families can be configured using the Network Configuration Manager Extension Utility. For the full list of NCM supported devices, refer to Devices Supported by Network Configuration Manager.

Device Families

To receive Network Configuration Manager support, a device must be associated with a device family. Devices that are supported out-of-the-box are automatically assigned to the proper device family. A device can only belong to a single device family.

A Network Configuration Manager device family provides a central place to configure access methods. The access methods are used to access device configurations from other family members. You can override Device family settings at the local device. For more information, see Configure a Device Family.

The Network Configuration Manager Extension Utility lets you create more device families on demand, extending Network Configuration Manager to support more devices and vendors. For more information about manually creating more device families and manually moving devices to user-created device families, see Extension Utility.

How Network Configuration Manager Determines Device Families

Network Configuration Manager automatically determines the device family for devices that are supported out-of-the-box. Typically, this determination is made based on the vendor. For more information, see Supported Devices.

Cisco IOS Devices

The following device families exist for the Cisco IOS devices:

- Cisco IOS - SSH Capable (supports SSH/SCP communication mode)
- Cisco IOS (does not support SSH/SCP communication mode)

To place a device into the Cisco IOS - SSH Capable family, the following conditions must be met:

- The device descriptor must indicate a firmware version of 12.2 (18) or greater.
- The feature set must contain letters "K9" indicating the device has the necessary encryption functionality that is needed for SCP.
- SSH access for the device must be unblocked at the time of discovery.

> **NOTE**
> If SSH access to the device is blocked (for example, with a firewall) at the time of discovery, put the device in the Cisco IOS device family.
> For example, a device with the following description is placed in the Cisco IOS - SSH Capable family:
> Cisco IOS Software, 7200 Software (C7200-JK9S-M), Version 12.3(14)T6, RELEASE SOFTWARE (fc2)Technical Support: http://www.cisco.com/techsupportCopyright (c) 1986-2006 by Cisco Systems, Inc.Compiled Thu 05-Jan-06 05:36 by dchih
> A device with the following description is placed in the Cisco IOS family and is not capable of obtaining configurations using SSH/SCP:

Cisco Internetwork Operating System SoftwareIOS (tm) C2600 Software (C2600-J1S3-M), Version 12.3(17a), RELEASE SOFTWARE (fc2)Technical Support: http://www.cisco.com/techsupportCopyright (c) 1986-2005 by cisco Systems, Inc.Compiled Mon 12-Dec-05 1

Cisco NX OS Devices

The Cisco NX OS devices are supported through scripts that use the Net::SSH::Expect modules. The Perl area must be set up with these modules for an out-of box support for Cisco NX OS devices.
For information about setting up your Perl environment, see Perl Modules (see page).

Juniper JUNOS Devices

(For 10.4.1 and earlier) Network Configuration Manager utilizes the JUNOScript API to communicate with the JUNOS devices. Specifically, the JUNOScript API merge command is used to accomplish uploads, as follows:

<load-configuration format="text" action="merge">

JUNOScript support was developed using JUNOScript version 6.3R1. The new releases of JUNOScript API are typically backward compatible.

The JUNOScript API commands differ from the JUNOS CLI commands. As a result, Network Configuration Manager uploads must use the correct format for the upload to succeed.

For more information, see the documentation website of the Juniper on the JUNOScript API.

Example: Using JUNOScript API Format

The following example illustrates how a command entered from the JUNOS CLI command line differs from the JUNOScript API. The command deletes the snmp location field from a device.

A test device has the following block of configuration text, which sets the snmp location field value to 'Boston':

snmp {
name jun2300-96.4;
description "Juniper J2300 w/ JUNOS 9.0R4 built 2008-11-18 18:55:38 UTC";
location Boston;

The following command can be used from the JUNOS CLI command line to delete the snmp location field on this device:

admin@jun2300-96.4# delete snmp location

The following Network Configuration Manager upload deletes the snmp location field from a device:

snmp {
delete: location;
}

Both operations are equivalent; however, the JUNOScript API syntax must be used with Network Configuration Manager uploads.

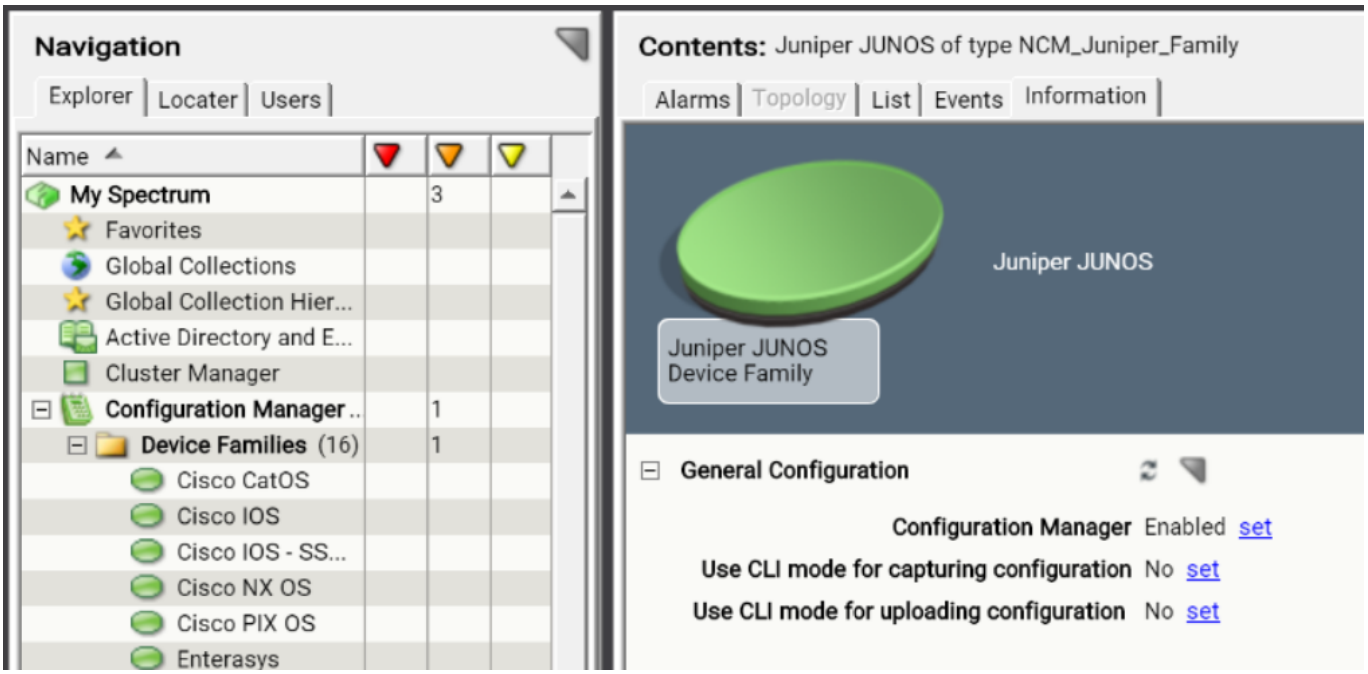
Using CLI Mode for NCM Operations on Juniper JUNOS Device Family

The 10.4.2 release provides the following two new configuration settings in OnceClick for the Juniper JUNOS device family:

- Use CLI mode for capturing configuration
- Use CLI mode for uploading configuration

When you enable these options, NCM starts using the CLI mode to perform the NCM operations (capture and upload) on the Juniper JUNOS devices. Previously, only XML RPC was available for executing the NCM operations on the JUNOS device family. Now, users can decide whether they want to use XMP RPC or CLI mode.

The CLI mode options are disabled by default. Therefore, XML RPC is the default option for the NCM operations on Juniper JUNOS device family. The following screenshot shows that the settings are set to **No** by default:



If you want to use the CLI mode, you can do so by enabling the required configuration settings as follows:

> **NOTE**
> The CLI mode improves the performance as it does not consume high CPU resources while performing the NCM operations.

1. Access the **Explorer** tab in the OneClick UI.
2. Navigate to **Configuration Manager**, **Device Families**, **Juniper JUNOS**.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **General Configuration** section.
5. Locate the **Use CLI mode for capturing configuration** option for the capture operation and the **Use CLI mode for uploading configuration** option for the upload operation.
6. Click **Set** and change the value to **Yes**.

You have successfully enabled the CLI mode for the NCM operations (capture and upload) on the Juniper JUNOS device family.

Extension Utility

The Network Configuration Manager Extension Utility lets you extend the functionality of Network Configuration Manager beyond its out-of-box support. With the Extension Utility, you can do the following tasks:

- Create more device families on demand. These additional device families can then be configured to extend the Network Configuration Manager functionality on more devices by using Perl scripts. For more information about creating device families, see Create a Custom Device Family. For more information about configuring scripts, see Extension Utility Script Configuration.
- Manage more devices and vendors by using Perl scripts for any of the operations Network Configuration Manager executes on a device. The operations such as capturing or writing a startup configuration. The operations also include capturing or uploading a running configuration; and uploading device firmware, reloading a device, and canceling the reload operation on a device. Scripts can be configured within Network Configuration Manager for each of

these operations. For more information about using customized scripts to perform these operations, see Network Configuration Manager Extension Utility.

NOTE
From 10.4.2, you can use Perl scripts to perform NCM operations on the SDC-modeled devices, too.

- Create customized trap settings for your installation which can be used to correlate the configuration change event information. For more information, see Configure Notification Trap Settings.

Network Configuration Manager Prerequisites

To run Network Configuration Manager and actively maintain a running history of device configurations on the managed network, take the following steps:

- Model devices with read/write community strings if you are using SNMP. For more information, see the Modeling and Managing Your IT Infrastructure section.
- Verify that devices are SCP-enabled if you are using SSH. For more information, see Communication Modes.

Communication Modes

The following table lists communication mode support for devices that are supported in Network Configuration Manager. An 'X' in a column indicates that the communication mode is supported for that device family. When a Perl script is the only way to communicate with the device, you are notified about the method that the script uses.
See Configure a TFTP Server to enable configuration capture and loading for devices that use the SNMP/TFTP communication mode.

Device Family	SNMP/TFTP	Telnet/FTP	SSH/SCP	SSH/TFTP	Perl
Cisco CatOS	X				X
Cisco IOS	X	X			X
Cisco IOS-SSH Capable	X	X	X		X
Cisco NX OS					SSH
Cisco PIX OS					Telnet
Enterasys	X				X
Enterasys/ Riverstone SSR	X				X
Extreme	X				X
Foundry	X				X
Juniper JUNOS			X		X
Lancom LCOS					TFTP/Telnet
Nortel Baystack				X	X
Nortel Passport 8600	X				X
Nortel Passport L3	X				X

SSH v2 Support

Network Configuration Manager supports SSH v2 only. Network Configuration Manager does not support SSH v1. The Cisco devices that support SSH v1 only are not automatically placed in the Cisco IOS-SSH Capable family.
Network Configuration Manager does not support the Juniper devices that support only SSH v1.
To support SSH v2, install or update the firmware on a Cisco or Juniper device. Add the device by following the steps in Place a Device in a Device Family.

Cisco Devices and SCP

The Cisco devices must have Secure Copy (SCP) enabled to use the SSH communication mode.
For more information about SCP, see the documentation for the Cisco IOS Secure Copy feature at http://www.cisco.com.

Unsolicited Notifications of Device Configuration Changes

Network Configuration Manager attempts to capture device configurations immediately after any change occurs. An unsolicited notification of configuration change can be either traps or MIB objects that are sent from the device where the change occurred.

Some devices send SNMP traps when their configuration has changed. The SpectroSERVER then performs a capture and saves the configuration in the database to provide updated configuration data. Network Configuration Manager policies are tested against the most recent configuration captures. For more information, see Device Traps.

Selected information can be parsed from these configuration trap notifications and shown in the Host Configuration table. For more information, see Configure Notification Trap Settings.

Instead of or in addition to sending an SNMP trap, some devices update MIB attributes to signal configuration changes. SpectroSERVER then polls the MIB and captures new configurations when it recognizes changes in the attributes. For more information, see Device MIB Objects (see page).

Network Configuration Manager monitors notifications on a subset of supported devices. You can extend Network Configuration Manager to monitor more traps and MIB objects from other supported devices.

Enabling Unsolicited Notifications of Device Configuration Changes provides the most recent and up-to-date configuration captures for devices in your network. You can disable this feature to avoid unnecessary captures, which involve TFTP transfers that can degrade network performance. For more information, see Configure General Configuration (see page) and Configure Unsolicited Device Configuration Captures on a Single Device.

Device Traps

Network Configuration Manager supports the following two traps:

- Cisco: ciscoConfigManEvent 1.3.6.1.4.1.9.9.43.2
- Juniper: jnxCmCfgChange 1.3.6.1.4.1.2636.4.5

When either of these traps are received, DX NetOps Spectrum generates event 0x00821029. This event then triggers Network Configuration Manager to perform a capture. If you want to trigger a capture for other supported devices, map more configuration change traps to that event.

Device MIB Objects

When any configuration changes occur, the Network Configuration Manager polls MIB objects through the model attributes to determine. This feature is supported on Cisco and Juniper devices that support the following MIB objects:

- CISCO-CONFIG-MAN-MIB: ccmHistoryRunningLastChanged 1.3.6.1.4.1.9.9.43.1.1.1
- JUNIPER-CFGMGMT-MIB: jnxCmCfgChgLatestTime 1.3.6.1.4.1.2636.3.18.1.2

You can extend the attribute polling mechanism to other supported devices. Use the Model Type Editor to create the attribute to poll for configuration change notifications, making it a polled attribute. Then, set the value of the Config_Change_AttrID attribute (0x12bf8) to the attribute ID of the newly created polled attribute. Network Configuration Manager then monitors this attribute for the notification of configuration changes and performs a capture.

Global Collections

A global collection lets you organize views of network devices. A global collection contains devices from multiple vendors. The global collections are useful when executing bulk tasks or creating the Network Configuration Manager policies.

For more information about Global Collections, see the Modeling and Managing Your IT Infrastructure section.

Maintenance Mode

Network Configuration Manager is disabled for any device that is in maintenance mode. To verify whether the device is in maintenance mode, select the device from the Explorer tab and then click the Information tab. Under the General Information view, see the In Maintenance option. If this option is set to "yes", the device is in maintenance mode.

Network Configuration Manager Report Packs

Network Configuration Manager report options are included under the Network Configuration Management report pack in DX NetOps Spectrum Report Manager. Report Manager provides numerous report content, format, and report organization options. You can generate reports with the appropriate type and scope of information for different audiences in your organization who are interested in device configuration changes.
For more information, see Network Configuration Manager Reports from Report Manager and the Report Manager section.

NCM Script Mode Enhancement

From 10.4.2, DX NetOps Spectrum uses the NCM Service (ncmservice) instead of the SRAdmin process to perform the NCM script operations. This implementation helps scale up the NCM script operations. The NCM Service configuration file (config.xml) is available in the <SPECROOT>/NCM folder.

Review the following considerations:

- (For SpectroSERVER) With the PERL script execution, if the upload task fails with a timeout error, try to keep the timeout values low in the script for the `upload_timeout_in_seconds` and `login_timeout_in_seconds` parameters, and increase the thread timeout value in the ../NCM/config.xml file. Change the thread timeout value of the following parameter:
  `<thread-timeout-value type="java.lang.Integer">3600</thread-timeout-value>`
  NOTE
  This parameter specifies the maximum time for which the NCM Service waits for the completion of the script execution. If the script execution takes longer time, increase the value. The default value of this parameter is 300 seconds.
- (For SDC) With the PERL script execution, if the upload task fails with a timeout error, try to keep the timeout value low in the script for the `upload_timeout_in_seconds` and `login_timeout_in_seconds` parameters, and increase the thread timeout value in the ../NCM/config.xml file on SDC. Change the thread timeout value of the following parameter:
  `<thread-timeout-value type="java.lang.Integer">3600</thread-timeout-value>`
  Also, try to increase the Secure Domain timeout value under the Secure Domain Manager configuration field, which should not be more than 10 minutes.

Network Configuration Manager Configurations

Configure Network Configuration Manager

This section describes the fundamental configurations for Network Configuration Manager.

Perform General Configuration

Select some initial settings to determine how Network Configuration Manager performs configuration captures and correlates change events.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and settings appear in the Information tab of the Contents panel.
2. Expand the General Configuration subview.
   The General Configuration options appear.
3. Modify the following General Configuration options as needed:
   - **Unsolicited Device Configuration Captures**
     Enables or disables Network Configuration Manager from capturing the configuration of a device when it receives an unsolicited notification from a device. An unsolicited notification of configuration change can be either traps or MIB objects that Network Configuration Manager is monitoring for changes.
   - **Correlation Event Period (seconds)**
     Specifies the amount of time during which configuration change events are correlated. All configuration change events for a particular device that occur during this period is combined into a single event.
     Default: 120
   - **Capture Newly Modeled Device's Configuration**
     Specifies how to handle newly modeled devices on your network at a global level. The available values are:
   - **On Next Global Sync**
     a. Captures newly modeled devices according to the global synchronization schedule.
   - **Do Not Capture**
     a. Disables Network Configuration Manager on the newly modeled device. To enable the Network Configuration Manager functionality, manually enable Network Configuration Manager on the device.
   - **Immediately**
     a. Captures newly modeled devices immediately (once they have been modeled) rather than waiting for the global synchronization to run.
   - **Task Work Queue Size**
     Specifies the maximum number of devices that are processed in parallel on each SpectroSERVER.
     When manually stopping a task that is running, all devices currently in the queue are processed after the stop command is received.
     Default: 10
     Maximum: 40 (in 10.4.2), 100 (in 10.4.2.1), and 200 (10.4.2.2 and above)

Select Configuration History Settings

The following procedure describes how to control the storage of captured configurations. You can maintain captured configurations either by the number of configurations that are kept per device or by a length of time.

> **WARNING**
> When specifying how to store captured configurations, consider the impact on the SpectroSERVER database. If too many configurations are retained, it is possible to fill the SpectroSERVER database with configuration file models.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the Configuration History subview.
   The options that are used to control how captured configurations are stored appear.
3. Select one of the following options:
   - **Specify maximum number of configurations to be stored per device.** This option stores captured configurations per device that is based on a specified number.
     - **Maximum Stored Configurations Per Device**

Specifies the maximum number of stored configurations per device. For example, a number of 25 indicates that the latest 25 configurations for each device reside in the DX NetOps Spectrum database.
Default: 25

- **Specify maximum number of days configurations to be stored.** This option stores captured configurations that are based on a length of time.
  - **Maximum Days Host Configuration Stored**
    Specifies the maximum number of days a host configuration is stored before being destroyed.
    Note: Depending on how frequently configurations are captured, specifying a large time period may cause the SpectroSERVER database to fill with configuration file models.
    Default: 30 (days)
  - **Minimum Stored Configurations Per Device**
    Specifies the minimum number of host configurations that are stored per device. Configurations are maintained even if they have aged out to remain at this minimum value.
    Default: 5

Select Configuration Change Alert Settings

Configuration Change Alert settings control which configuration change events trigger alarms and the types of alarms that are generated. You can select Configuration Change Alert settings to determine the alarms that you see.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the Configuration Change Alert subview.
   The Configuration Change Alert options display.
3. Modify the following Configuration Change Alert options as needed:
   - **Alert Mode**
     Specify the events that trigger an alarm.
     - **Alarm On Any Changes**
       An alarm is generated for configuration changes only.
     - **Alarm On Any Reference Violations**
       An alarm is generated for reference configuration violations only.
     - **Alarm On Any Reference Violations or Changes**
       An alarm is generated for both reference configuration violations and configuration changes.
     - **No Alarm**
       No alarms are generated for any configuration changes.

     Default: No Alarm
   - **Reference Violation Alert Type**
     Specify the type of alarm or event that is asserted when a reference configuration violation occurs. The existing comparison mask is used to determine significant differences between current and reference configurations. Reference violation alarms are automatically cleared when the current configuration matches the reference configuration.
     For information about setting a reference configuration, see Specify a Reference Configuration.
     Valid values are critical, major, and minor alarms and events only.
     Default: Event Only
   - **Configuration Change Alert Type**Specify what type of alarm or event only is asserted when any configuration change occurs.
     Valid values are critical, major, and minor alarms and events only.
     Default: Event Only

Approval Workflows

Approval workflows let you require configuration changes that are initiated through Network Configuration Manager to receive approval before being processed. Approval workflows can be set up to use CA Service Desk tickets or DX NetOps Spectrum authorization privileges for the approval process.

This section describes how to configure approval workflow options. It also describes how to approve tasks if the OneClick approval workflow mode is enabled.

For information about initiating configuration changes using tasks, see Network Configuration Manager Device-Level Tasks, and Network Configuration Manager Bulk Tasks.

> **NOTE**
>
> For more information, see the DX NetOps Spectrum and CA Service Desk Integration.

Configure Workflow Options

Approval workflows let you require configuration changes that are initiated through Network Configuration Manager to receive approval before being processed. Configure approval workflow options to determine how approvals are requested and processed.

Follow these steps:

1. Select Configuration Manager in the Explorer tab. Information and configurations display in the Information tab of the Contents panel.
2. Expand the Workflow subview to open the approval workflow options.
3. Modify the following approval workflow settings as needed:
   Approval Workflow Mode

Specifies whether approval is required for all operations that modify a device. These operations include Upload, Save to Startup, Load Firmware, Reload, and the Cancel Reload tasks.

Disabled Specifies that configuration changes initiated in Network Configuration Manager do not require approval.

ServiceDesk
Specifies that configuration changes initiated in Network Configuration Manager must gain approval through CA Service Desk. When a task is created, a CA Service Desk ticket is generated. If approved, the task is placed into a state in which it can be processed.

If this option is selected, the Configure button is enabled. Click the Configure button to invoke the ServiceDesk Workflow Configuration page, where you can set the initial values for the following fields:
Error Type - Error type values are configured in Service Desk for integrated use with DX NetOps Spectrum. For more information about these values, see the CA Service Desk Implementation section.
Approved Status, Denied Status, Canceled Status, Awaiting Approval Status - Different status values are available depending on the error type. The Status values are configured in CA Service Desk for integration with DX NetOps Spectrum. For information about setting up these values, see the DX NetOps Spectrum and CA Service Desk Integration.

> **NOTE**
>
> If Service Desk approval is enabled and the user who creates the task has Task Approver privileges, CA Service Desk approval is optional. For more information, see Network Configuration Manager Privileges.

OneClick
Specifies that configuration changes that are initiated in Network Configuration Manager can be processed only if initiated or approved by a user with the Task Approver permission. **Default:** Disabled

Include Configuration Changes in Approval Process
Specifies whether configuration content is included in the approval request.
Default: No

NOTE

A user must have the Hide Configuration Changes from Approval Requests permission for this option to take effect. For more information, see Network Configuration Manager Privileges.

Approve a Task in OneClick

If the OneClick approval workflow mode is enabled, a user having the Task Approver permission must approve the tasks from the OneClick console.

NOTE

You can also approve or deny a task from an email notification. When approval is requested for a task, an email is generated and sent to the task approver for approval. Included in the email are links to let you approve or deny the task. Select the appropriate link. The State is updated to reflect whether the task is Approved or Denied.

Follow these steps:

1. Select 'task' in the Tasks folder under the Configuration manager in the Explorer tab.
   The available tasks appear in the List tab of the Contents panel.
2. Right-click the task and select Approve Task, Deny Task, or Cancel Approval Request, as appropriate, from the right-click menu.
   The task State is updated to reflect whether the task is Approved, Denied, or Canceled, respectively.

Configure a TFTP Server

This section describes how to start a Trivial File Transfer Protocol (TFTP) server on a SpectroSERVER system. TFTP transfers configuration files. This process consists of two steps:

- Setting up your system as a TFTP server. This step varies by platform.
- Specifying the TFTP Configuration settings in OneClick.

If you have a distributed SpectroSERVER (DSS) environment, the TFTP servers must be running on every SpectroSERVER to enable Network Configuration Manager functionality.

See Communication Modes for supported device family communication modes.

NOTE
Verify that each device in your network is properly modeled using the appropriate community name (read or write).

Set Up System as TFTP Server

This section describes how to set up your system as a TFTP Server. Instructions vary by platform.

NOTE
Your TFTP server can run on a system other than the SpectroSERVER host system. But the SpectroSERVER computer must be able to access the root directory of the TFTP server, and the root directory on the SpectroSERVER computer must be shared with the TFTP server. For more information, see Considerations When Using Remote TFTP or FTP Servers.

1. Verify that the /etc/services file contains a TFTP entry. To search for the entry, enter the following commands:
   ```
   cd /etc
   grep tftp services
   ```
   You see the following entry in the /etc/services file:
   ```
   tftp          69/udp
   ```
   If this entry does not appear, edit the services file and add it to the “Host specific functions” section.

2. In the /etc/inetd.conf file, find the following line and uncomment it by deleting the pound character (#) from the beginning of the line:
   ```
   #tftp dgram udp6 wait root /usr/sbin/in.tftpd in.tftpd -s /tftpboot
   ```
3. Verify that the entry ends with the -s /tftpboot option. The ending specifies the tftp directory (in this case, /tftpboot).
4. Run the inetconv command.
5. Verify that the tftp service is enabled:
   ```
   svcs | grep tftp
   ```
   The following response is diplayed:
   ```
   online Apr_10 svc:/network/tftp/udp6:default
   ```
6. When your system is set up as a TFTP server, verify that devices are modeled with the read/write community string for TFTP transfer to work.
7. Configure the TFTP settings in OneClick as described in TFTP Configuration Settings.

Configure a Linux System to Support TFTP

The following procedure sets up your Linux system to support TFTP.

Follow these steps:

1. Log in as root.
2. Verify that a TFTP server is installed on your system by running the following command:
   ```
   %rpm -q tftp-server
   ```
   The following message indicates that the TFTP server is installed:
   ```
   tftp-server-<version>.EL3.1
   ```
   If this message does not appear, a TFTP server is not installed. Take the following steps:
   a. Download the TFTP package from the Red Hat website at http://www.redhat.com.
   b. Run the following command:
      ```
      % rpm -i <package.rpm>
      ```
   c. Follow the instructions for installing the rpm package from the Red Hat website.
3. Create the /tftpboot directory and give all users read/write permission to the directory using the following commands:
   ```
   mkdir /tftpboot
   chmod 777 /tftpboot
   ```

   NOTE
   Your TFTP server can run on a system other than the SpectroSERVER host system. But the SpectroSERVER computer must be able to access the root directory of the TFTP server, and the root directory on the SpectroSERVER computer must be shared with the TFTP server. For more information, see Considerations When Using Remote TFTP or FTP Servers.
4. Change to the /etc/xinetd.d directory.
5. Edit the file named tftp as follows:
   ```
   Set disable=no
   ```
6. Save and close the file.
7. Run *one* of the following commands to restart xinetd services:
   – % service xinetd restart
     The following message appears:
     ```
     Stopping xinetd  OK
     Starting xinetd  OK
     ```
   – % killall -HUP xinetd
8. Verify that the TFTP server is running.

NOTE
One method of verification is to run a Network Configuration Manager capture. If you receive a TFTP timeout error /event 0x821001, it indicates that TFTP is not running.

9. Configure the TFTP settings in OneClick as described in TFTP Configuration Settings.

TFTP Servers on Windows

A TFTP server is not typically available on Windows. If you use the TFTP communication mode for any device family, set up a TFTP server. Multiple free or commercial applications are available.

With a TFTP Server on a remote host, see Considerations When Using Remote TFTP or FTP Servers to use that server with Network Configuration Manager.

To configure your Windows system to support TFTP, complete the procedure that is described in TFTP Configuration Settings. The steps in this procedure are applicable to any TFTP server that you install.

Configure a TFTP Server on Windows

This section describes how to configure TFTP settings in OneClick.

NOTE
Before you perform this procedure, make sure that your system has been configured as a TFTP server. For more information, see Set Up a System as a TFTP Server.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the TFTP Configuration subview.
   The TFTP Configuration table appears.
3. Modify the following as needed. Click set to edit a particular field, and press Enter when you have finished.
   - **Default TFTP Host**
     TFTP server IP address for the landscape, by default, the host system running the SpectroSERVER.
     This field lets you change the IP address for the TFTP server globally. For considerations when using a remote host, see Considerations When Using Remote TFTP or FTP Servers.

     NOTE
     The attribute DefaultTftpHost can be configured in the Attribute Editor.
   - **Default TFTP Directory**
     Pathname where TFTP is running. Click set, and enter a valid TFTP server path, such as:
     - For Unix systems, /tftpboot
     - For Windows, C:\win23app\SPECTRUM\NCM\tftp

     NOTE
     Your TFTP server can run on a system other than the SpectroSERVER host system. But the SpectroSERVER computer must be able to access the root directory of the TFTP server, and the root directory on the SpectroSERVER computer must be shared with the TFTP server. For more information, see Considerations When Using Remote TFTP or FTP Servers.

Configure an FTP Server

Configure Network Configuration Manager to use a local FTP server on a SpectroSERVER system (see Communication Modes for supported device family communication modes).

If you are deploying devices that use FTP for file transfers, configure an FTP server. We recommend installing and configuring a native FTP server for your platform. For the Windows platforms, the following links describe how to install and configure the native FTP service.

- Windows Server 2012: http://www.c-sharpcorner.com/UploadFile/cd7c2e/how-to-install-ftp-server-on-windows-server-2012/
- Windows Server 2016: https://www.avoiderrors.com/install-configure-ftp-server-server-2016/

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the FTP Configuration subview.
   The FTP Configuration table appears.
3. Modify the following settings as needed. Click set to edit a particular field and then press Enter.
   - **Default FTP Host**
     FTP server IP address for the landscape. By default, the SpectroSERVER runs on this host system.
     This field lets you change the IP address for the FTP server globally. For more information, see Considerations When Using Remote TFTP or FTP Servers.

     NOTE
     The attribute DefaultFtpHost represents this value, which can be configured in the Attribute Editor.
   - **FTP Username**
     FTP username.
   - **FTP Password**
     FTP password.
   - **Default FTP Directory**
     Pathname where FTP is running.
     Note: Your FTP server can run on a system other than the SpectroSERVER host system. But certain requirements apply to the directory. For more information, see Considerations When Using Remote TFTP or FTP Servers.
   - **Landscape**
     DX NetOps Spectrum landscape (for display only).

Considerations When Using Remote TFTP or FTP Servers

By default, the host system running the SpectroSERVER is also the host system for both the TFTP and FTP servers. However, you can set up your TFTP or FTP server to run on a different host system.

To set up your TFTP or FTP server to run on a different host globally, use the Default TFTP/FTP Host and Default TFTP/FTP Directory fields as described in TFTP Configuration Settings and Configure an FTP Server. You can also override the default values for the host by using the Attribute Editor as described in Specify TFTP or FTP Server for a Single Device.

NOTE
Although you can override the TFTP and FTP server host system by device, TFTP and FTP directory settings apply to the entire landscape.

When using a remote host for the TFTP or FTP server instead of the local system where the SpectroSERVER runs, consider the following points:

- Both the specified TFTP and FTP directories must be locally accessible from the DX NetOps Spectrum host system. Share the root directory of the TFTP or FTP server with the computer running the SpectroSERVER.
  - For Unix systems, the remote directory must be mounted using read/write nfs mount.
- When specifying the pathname, use the UNC paths only; local variables or locally mapped directories are not allowed. For example, to access the shared folder 'tftpboot' on the host 'tftpserver', specify the UNC path of \\tftpserver\tftpboot as the default TFTP directory.
- On the Windows systems, the UNC path cannot require a username and password and requires read and write privileges.

NOTE
Because mapped drives are not supported, mapping the network drive and providing a username and password do not circumvent the requirement.

Specify TFTP or FTP Server for a Single Device

The following procedure describes how to specify a separate host system for the TFTP or FTP server at the device level.

NOTE
To set the TFTP or FTP host globally for the landscape, use the Default TFTP Host and Default FTP Host fields, as described in TFTP Configuration Settings and Configure an FTP Server, respectively. Although you can override the TFTP and FTP server host system by device, TFTP and FTP directory settings apply to the entire landscape.

Follow these steps:

1. Select the devices that will use the TFTP or FTP servers on the separate host in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices.
3. Select Utilities from the Tools menu, and select Attribute Editor.
   The Attribute Editor opens.
4. Select the User Defined folder, and click Add.
   The Attribute Selector window appears.
5. Enter “host” in the Filter field of the Attribute Selector window. Select the NCM_FTP_Host and NCM_TFTP_Host attributes and click OK.
   These two attributes now appear under the User Defined folder.
6. Select both the NCM_FTP_Host and NCM_TFTP_Host attributes and click the add arrow.
   Values that you can modify appear in the right pane.
7. Modify the following values for each attribute:
   - **No Change**
     Clear the check box to enable the remaining fields.
   - **IP address**
     Enter the IP address of the host system running the TFTP and FTP protocols.

     NOTE
     If using NAT, use the public IP address.
   - **Set As Default**
     If selected, all newly created devices automatically inherit this value.
8. Click OK. If a confirmation dialog opens, click Yes.
   The Attribute Edit Results page shows the results of the change.
9. Click Close.

Select Settings for Device Configuration Export

You can configure Network Configuration Manager to export device configurations to a text file for historical archiving purposes. You must manually manage this file system outside of DX NetOps Spectrum and OneClick.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations appear in the Information tab of the Contents panel.
2. Expand the Export Configuration subview.
3. Click set next to Export Configuration. The default is “Do Not Export.” Select one of the following options:
   - **Export Unique Configurations Only**

Export device configurations only if they differ from previously captured configurations.

- **Export Unique and Global Sync Configurations**
  Export device configurations only if they differ from previously captured configurations or on a global synchronization. For example, one file per device is generated each day if you have configured a global synchronization to run on a daily basis. See About Global Synchronization for more information.

The export configuration displays next to Export Configuration.

4. Click set in the Export Directory column. Then specify a local directory in the SpectroSERVER in which to export configuration text files for Linux and/or Windows. The export files are named with a device name and a timestamp. If you want to export configuration text files to a network share, specify the UNC path to the directory. For example, \ \Shared_Server\Export\ExportFiles.
5. Press Enter.
   The export directory appears.

Configure a Device Family

The device family provides a central location to configure Network Configuration Manager interactions with devices in the device family. Configurations that are made to a device family take effect on all devices that are contained within the family. Device family settings can be overridden at the local device level. For more information, see Configure a Single Device to Override Device Family Settings.

To access the configurations for a device family, select a device family from Device Families in the Explorer tab. Then select the Information tab in the Contents panel. Device family configurations are shown.

The Extension Utility lets you configure a Perl script to handle device interaction for any of the supported Network Configuration Manager operations. For more information, see Network Configuration Manager Extension Utility.

Configure Device Family General Settings

The General Configuration subview contains the Configuration Manager settings. Configuration Manager lets you disable tasks for an entire device family. When Configuration Manager is set to disabled, Network Configuration Manager operations are not performed on any of the devices that are contained by this device family.

> **NOTE**
> Configuration Manager can also be disabled at the local device level if any devices in the Device Family require it. For more information, see Configure a Single Device to Override Device Family Settings.

Follow these steps:

1. Navigate to device family configurations as described in Access Network Configuration Manager Device Family Configurations and expand the General Configuration subview.
   The general configurations for the selected device family appear.
2. Click set next to Configuration Manager to enable or disable Network Configuration Manager tasks and functionality for the device family. Configuration Manager is enabled by default.
   The status of device family communication with Network Configuration Manager displays next to Configuration Manager.

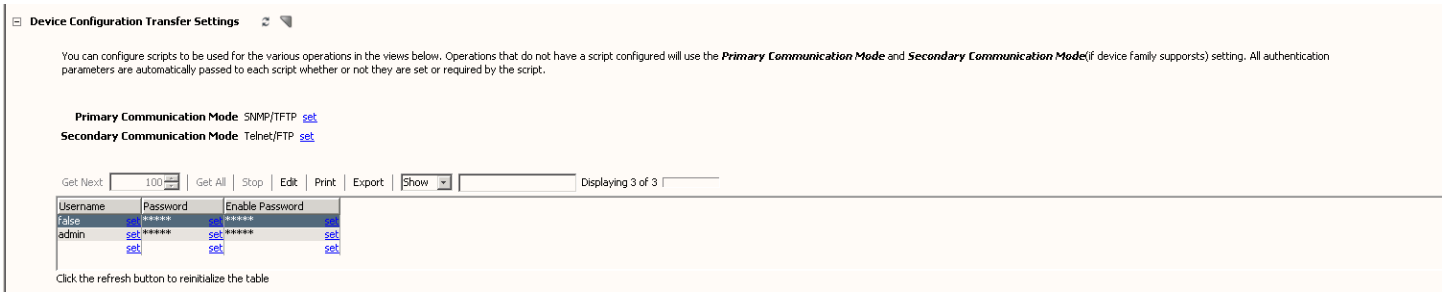
> **NOTE**
> In 10.4.2, two new configuration settings (Use CLI mode for capturing configuration and Use CLI mode for uploading configuration) have been provided in the General Configuration subview for the Juniper JUNOS device family. When you enable these options, Network Configuration Manager (NCM) starts using the CLI mode to perform the NCM operations (capture and upload) on the Juniper JUNOS devices. Previously, only XML RPC was available for executing the NCM operations on the JUNOS device family. Now, users can decide whether they want to use XML RPC or CLI mode. For more information, see the "Using CLI Mode for NCM Operations on Juniper JUNOS Device Family" section in Network Configuration Manager Introduction.

Configure Device Family Communication Mode

All device families that are supported out-of-the-box have a communication mode that determines how Network Configuration Manager (NCM) interacts with the associated devices. Some device families with the default support let you select from multiple communication modes. Depending on the communication mode that is selected, the device username, password, and enable password can be required.

If not all devices in the family can be accessed using the same username, password, and enable password, you can override the usernames and passwords at the local device. For more information, see Configure a Single Device to Override Device Family Settings.

The following image shows the Primary Communication Mode and Secondary Communication Mode setting, which appears in the Device Configuration Transfer Settings subview:



Follow these steps:

1. Select a device family from **Device Families** in the **Explorer** tab, and then select the **Information** tab in the **Contents** panel.
2. Expand the **Device Configuration Transfer Settings** subview to view the communication mode configurations for the device family.
3. Select the primary and secondary communication mode for the selected device family.
   The selected communication mode displays next to Communication Mode.

Modify the following fields as needed:

> **NOTE**
>
> You can set multiple (maximum three) Usernames and Passwords.

- **Username**
  Specifies the user name for accessing the devices.
- **Password**
  Specifies the password for accessing the devices.
- **Enable password**
  Specifies the second password for configuring the devices (supported for Cisco IOS, Cisco IOS-SSH Capable, and Foundry devices only).

The communication mode for the selected device family is configured.
When you perform a capture or upload capture or operations that are supported by NCM, the action tries with Primary Communication Mode and the first Username, Password combination. If the combination fails, it tries with the remaining Username, Password combinations. If all the Username, Password combinations fail with Primary Communication Mode, then it tries with the Secondary Communication Mode with all the Username and Password combinations till the action is success.

NOTE

- If the primary or secondary communication consists of any incorrect username or password, then the device stops responding to the next available credentials it supports. This behavior is due to the connections limit per minute value in the device configuration.
- By default, the communication retries value in DX NetOps Spectrum is set to 5 attempts and the retry attempts in devices also set to 5. To make the communication mode work and try with the next correct credentials, you need to either reduce the retries value in DX NetOps Spectrum or increase the retries value in devices configuration.
- To update the retries value in DX NetOps Spectrum, open $SPECROOT/NCM/config.xml, then add the 'tries type' attribute under the 'root' tag and close the xml file. For example, <tries type="java.lang.String">3</tries>.
- To update the retries value in device configuration, refer to the documentation provided by the device vendor.
- If the script is configured to capture the configuration for the out-of-the-box device family, then primary and secondary communication modes will be ignored.
- If some of the devices are not capturing the configuration with the primary and secondary communication modes, then create a custom family and move the devices from the out-of-the-box family to the custom family. Configure the script and try to capture the configuration.

Configure Device Family Masks

Configure device family masks to exclude device configuration content from configuration comparisons or to hide sensitive information from unauthorized users. Mask configurations are discussed in the following sections.

Device Family Comparison Mask

The Comparison Mask is a list of regular expressions that conceal device configuration content during a comparison with a historical configuration. Any line in the device configuration file that matches a regular expression in the Comparison Mask is ignored during comparisons of configuration files. Network Configuration Manager provides a list of predefined masks that are displayed in the window next to Comparison Mask.

You can add or remove masks.

The mask setting can be overridden at the local device level. For more information, see Configure a Single Device to Override Device Family Settings.

Add a Device Family View Mask

The View Mask is a list of regular expressions that conceal device configuration content from users who lack the OneClick privilege to view the entire device configuration file. The View Unmasked Configurations privilege is required to view the contents of the View Mask field. Use this setting to hide passwords or other content from unauthorized users. You can override a mask setting at the local device level.

Follow these steps:

1. Select Add under Comparison Mask or View Mask.
   The Add dialog opens.
2. Type the mask for the selected device family. For example, for comment lines, enter: [!#]. Supply any regular expression.
3. Click OK.
   The content that you entered for the mask appears. You have set a mask for all devices in the device family.
4. Repeat the previous steps to enter more masks.

For more information about overriding device family settings at the local device, see Configure a Single Device to Override Device Family Settings.

Enter a Mask

You can enter a mask that applies to all devices in a device family.

Follow these steps:

1. Select Add under Comparison Mask or View Mask.
   The Add dialog opens.
2. Enter the mask for the selected device family. For example, for comment lines, enter: [!#] or enter any regular expression.
3. Click OK.
   The content that you entered for the mask displays. You have now set a mask for all devices in the device family.

Configure Notification Trap Settings

You can configure DX NetOps Spectrum to automatically capture device configuration based on trap notifications from a device. You can customize these trap settings for your installation. Specify the information that is parsed from the configuration change trap notifications from the device and displayed in the Host Configuration table. Network Configuration Manager uses these settings to correlate configuration change event information so that events are combined for a particular device.

> **NOTE**
> The Unsolicited Device Configuration Captures setting controls the automatic configuration capture for a device. For more information about this feature, see Unsolicited Notifications of Device Configuration Changes.

Trap format information varies by device family. Out-of-the-box support is provided for Cisco CatOS, Cisco IOS, Cisco IOS - SSH Capable, and Juniper JUNOS device families. The following example shows the Syslog traps that are defaults for the Cisco IOS - SSH Capable device family:

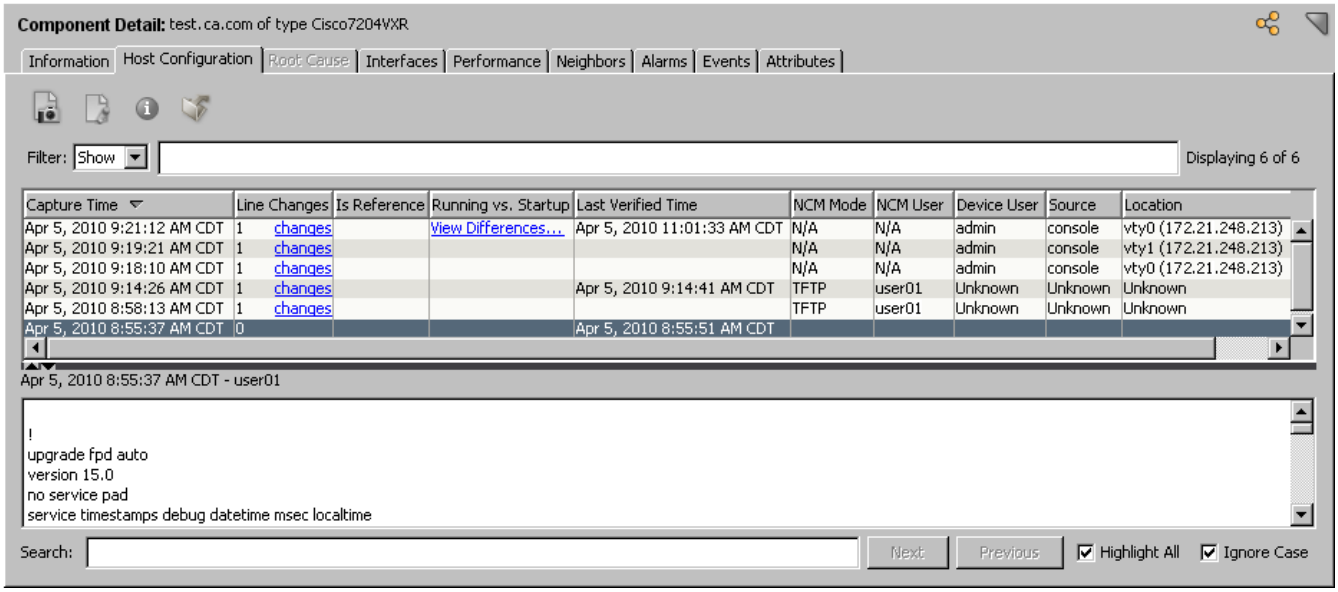
```
Configured from {SOURCE} by {USER} on {LOCATION}
Configured from {LOCATION} by {SOURCE}
```

The following variables represent information that is parsed out from the trap message and shown in the Host Configuration table:

- **SOURCE**
  Corresponds to Source column in the Host Configuration table.
- **USER**
  Specifies the user who was logged in on the device when the changes were made. This value corresponds to the Device User column in the Host Configuration table.
- **LOCATION**
  Corresponds to the Location column in the Host Configuration table.

You can also specify additional message formats if trap messages from the Syslog server are in non-default formats.

The following image shows the Host Configuration table for a Cisco IOS - SSH Capable device, including the table columns:



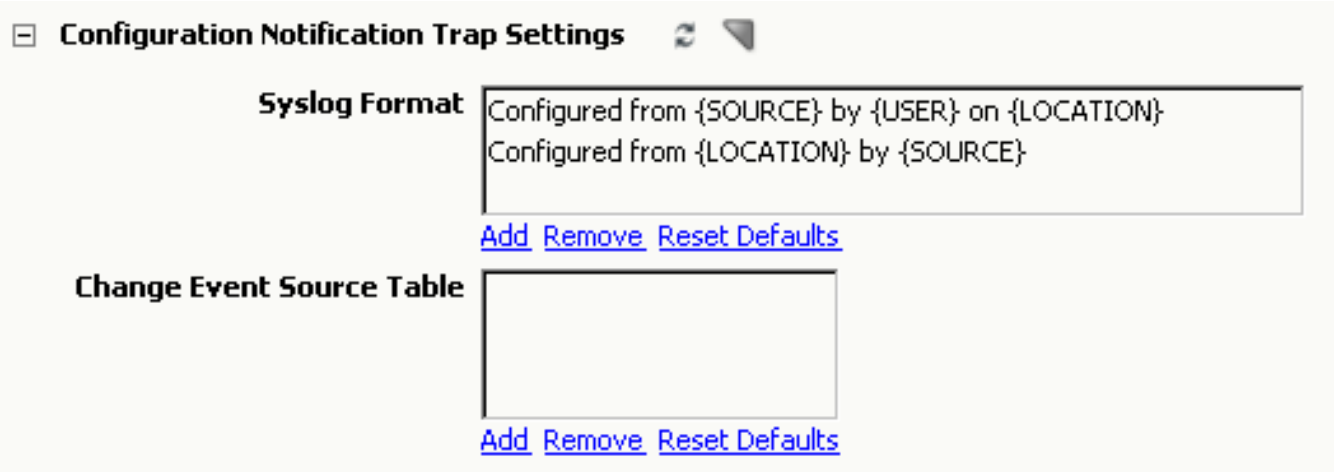
Information is correlated based on device traps, Syslog traps and events, Network Configuration Manager internals, and any other trap that is mapped to the generic change event. Correlation Event Period parameter in Network Configuration Manager General Configuration determines the amount of time during which configuration change events are correlated. For more information, see Configure General Configuration.

For more information about event messages, see Network Configuration Manager Events.

Configure notification trap settings for a device family.

Follow these steps:

1. Navigate to device family configurations as described in Access Network Configuration Manager Device Family Configurations and expand the Configuration Notification Trap Settings subview.
   The configuration notification trap settings for the selected device family appear. This subview is configured with the basic formats of the traps that are received from the Syslog server. The following image shows the default settings for the Cisco IOS device family:



- To add a Syslog format, take the following steps:
  a. Click Add below the Syslog Format box.
     The Add dialog opens.

b. Enter the format of the trap message with any column-specific information that can be parsed out from the message in {}, and click OK.

The new Syslog format is added to the box.

- To add an entry to the Change Event Source Table, take the following steps:
  a. Click Add below the Change Event Source Table box.
  The Add dialog opens.
  b. Enter a Source index entry, and click OK.
  The new entry is added to the table.

Configure a Single Device to Override Device Family Settings

This section describes how to configure a single device to override the configuration of its associated device family. Most device family settings can be overridden at the local device level

Access Network Configuration Manager Settings on a Single Device

Network Configuration Manager settings for a single device are available in the Network Configuration Manager subview.

Follow these steps:

1. Select a device in the Explorer tab.
   Information and configurations appear in the Information tab of the Contents panel.
2. Scroll down the page and expand the Network Configuration Manager subview.
   The Network Configuration Manager device configuration options appear.
   The settings that you select here override the device family settings.

Enable or Disable Network Configuration Manager on a Single Device

All Network Configuration Manager operations can be disabled at the local device. Network Configuration Manager must be enabled on the associated device family for this setting to affect a device. For more information, see Configure Device Family General Configuration.

Follow these steps:

1. Expand the Network Configuration Manager subview as described in Access Network Configuration Manager Settings on a Single Device.
   The Network Configuration Manager device configuration options display.
2. Click set next to Configuration Manager to enable or disable Network Configuration Manager tasks and Network Configuration Manager functionality.

   NOTE
   Configuration Manager is enabled by default.

   The current state of communication with Network Configuration Manager displays next to Configuration Manager.

Configure Unsolicited Device Configuration Captures on a Single Device

Unsolicited Device Configuration Captures can be enabled or disabled at the local device.

NOTE
Unsolicited Device Configuration Captures must be enabled globally for this local setting to have an effect.

For more information, see Unsolicited Notifications of Device Configuration Changes.

Follow these steps:

1. Expand the Network Configuration Manager subview as described in Access Network Configuration Manager Settings on a Single Device.
   The Network Configuration Manager device configuration options appear.
2. Click set next to Unsolicited Device Configuration Captures to enable or disable automatic device captures.
   The value displays next to Unsolicited Device Configuration Captures.

Specify Configuration Change Alert Settings on a Single Device

Configuration Change Alert settings can be enabled or disabled at the local device.

Follow these steps:

1. Expand the Network Configuration Manager subview as described in Access Network Configuration Manager Settings on a Single Device.
   The Network Configuration Manager device configuration options appear.
2. Expand the Local Configuration Change Alert subview.
   The Local Configuration Change Alert options appear.
3. Click set next to 'Use Local Configuration Change Alert Settings' to override the global settings.
   The value appears next to 'Use Local Configuration Change Alert Settings'.
4. Modify the following Configuration Change Alert options as needed:
   - **Alert Mode**
     Lets you specify the events that trigger an alarm.
     - **Alarm On Any Changes**
       Triggers an alarm for configuration changes only.
     - **Alarm On Any Reference Violations**
       Triggers an alarm for reference configuration violations only.
     - **Alarm On Any Reference Violations or Changes**
       Triggers an alarm for both reference configuration violations and configuration changes.
     - **No Alarm**
       Ensures that no alarms are triggered for any configuration changes.

     Default: No Alarm
   - **Reference Violation Alert Type**
     Specifies the type of alarm or event that is asserted when a reference configuration violation occurs. The existing comparison mask is used to determine significant differences between current and reference configurations. Reference violation alarms are automatically cleared when the current configuration matches the reference configuration.
     See Specify a Reference Configuration for information on setting a reference configuration.

Valid values are critical, major, and minor alarms and events only.

Default: Event Only

- **Configuration Change Alert Type**
  Specifies the only type of alarm or event that is asserted when any configuration change occurs.

Valid values are critical, major, and minor alarms and events only.

Default: Event Only

Configure Communication Mode on a Single Device

All out-of-the-box supported devices have a communication mode that determines how Network Configuration Manager interacts with the device. Some out-of-box supported devices let you select from among multiple communication modes.

Depending on the selected communication mode, the device user name, password and enable password may be required.

For more information about configuring the communication mode for a device family, see Configure Device Family Communication Mode.

The following image is an example of the Local Communication Configuration subview:

Configure the communication mode on a single device.

Follow these steps:

1. Expand the Network Configuration Manager subview as described in Access Network Configuration Manager Settings on a Single Device.
   The Network Configuration Manager device configuration options appear.
2. Expand the Local Communication Configuration subview.
   The Local Communication Configuration options appear. The available options depend on the device type.
3. Modify the Communication Configuration options as needed:
   - **Use Local Communication Mode Settings**
     Specifies whether to override the device family communication mode with the Local Default Communication Mode.

     NOTE
     The Local Default Communication Mode is not used for an operation if a script is configured for that operation on the device family.
   - **Local Default Communication Mode**
     Specifies the communication mode if your device lets you choose from multiple communication modes.
   - **Use Local Authentication Settings**
     Specifies whether to override the device family authentication settings. When enabled, the values that are specified in the Local Username and Password fields are used.
   - **Local Username**
     Specifies the user name for accessing the device.
   - **Local Password**
     Specifies the password for accessing the device.
   - **Local Enable Password**
     Specifies the second password for configuring the device (supported for Cisco IOS, Cisco IOS-SSH Capable, and Foundry devices only).

The local communication configuration options for the selected device are set.

Configure a Mask on a Single Device

Configure masks to exclude script content from configuration comparisons or to hide sensitive information from unauthorized users. Masks configured at the local device level override the mask settings of the device's associated device family. Mask configurations on a single device are discussed in the following sections.

Comparison Masks

The Comparison Mask is a list of regular expressions that conceal device configuration content during comparison with a historical configuration. Any line in the device configuration file that matches a regular expression in the Comparison Mask is ignored during configuration file comparisons. Network Configuration Manager provides a list of predefined masks that are displayed in the window next to Comparison Mask. Masks on local devices override the mask settings of the device family.

View Masks

The View Mask is a list of regular expressions that conceal device configuration content from users who lack the OneClick privilege to view the entire device configuration file. Content in the View Mask field is only accessible to operators with the View Unmasked Configurations privilege. Use the mask to hide passwords or other content from unauthorized users. Masks on local devices override the mask settings of the device family.

For more information about the View Unmasked Configuration privilege, see Network Configuration Manager Privileges.

Enter a Mask on a Single Device

You can enter a mask for a single device.

Follow these steps:

1. Expand the Network Configuration Manager subview as described in Access Network Configuration Manager Settings on a Single Device.
   The Network Configuration Manager device configuration options display.
2. Expand the Local Mask Configuration subview.
   The local comparison and view masks options display.
3. Click set next to Use Local Comparison Mask or Use Local View Mask to override the device family settings.
   The value displays next to the option.
4. Select Add under Local Comparison Mask or Local View Mask.
   The Add dialog opens.
5. Enter the mask for the selected device. For example, for comment lines, enter: [!#] or enter any regular expression.
6. Click OK to accept your entries.
   The content that you entered for the mask displays. You have now set a mask for the selected device.
7. Repeat Step 4 to Step 6 to enter more masks.

Network Configuration Manager Extension Utility

The Network Configuration Manager Extension Utility lets you extend the basic functionality of Network Configuration Manager. You can create device families and can manage extra devices and vendors by using Perl scripts for the operations that Network Configuration Manager executes on a device. You can customize trap settings and can use them to correlate configuration change event information.

The following sections describe how to use the Extension Utility to expand Network Configuration Manager support.

Supported Operations

The Network Configuration Manager Extension Utility lets you use Perl scripts to extend Network Configuration Manager to extra devices and vendors. Network Configuration Manager can be extended by providing Perl scripts for any, or all, of the operations Network Configuration Manager performs on a device. The following list summarizes these operations:

- **Capture Startup Configuration**
  Capture device startup configuration.
- **Capture Running Configuration**
  Capture device running configuration.
- **Upload Running Configuration**
  Upload and merge specified content into the device running configuration.
- **Write Startup Configuration**
  Write the device current running configuration to its startup configuration.
- **Reload Device**
  Reboot a device.
- **Cancel Reload**
  Cancel the scheduled reboot of a device.
- **Load Device Firmware**
  Initiate a load of the specified firmware image on the device.

  NOTE
  In 10.4.2, you can use Perl scripts to execute these NCM operations on SDC-modeled devices also.

Scripts can be configured for each of these operations within device families that are created on demand. Any operation that lacks a script is handled as an unsupported operation for the given Device Family and all devices that are contained within it.

The Cisco PIX OS out-of-box device family provides an example of how scripts are used to extend Network Configuration Manager support. (Within these example scripts, the Net::Telnet perl module does *not* support IPv6.)

The utility also lets you use Perl scripts to alter Network Configuration Manager interactions with devices that belong to out-of-the-box device families.

OpenSSH Device Family

The OpenSSH Device Family supports the Network Configuration Management functionality, which you can use to capture and upload device configurations. This OpenSSH functionality includes the Perl scripts to support OpenSSH.

Follow these steps to add any OpenSSH supported devices to this device family:

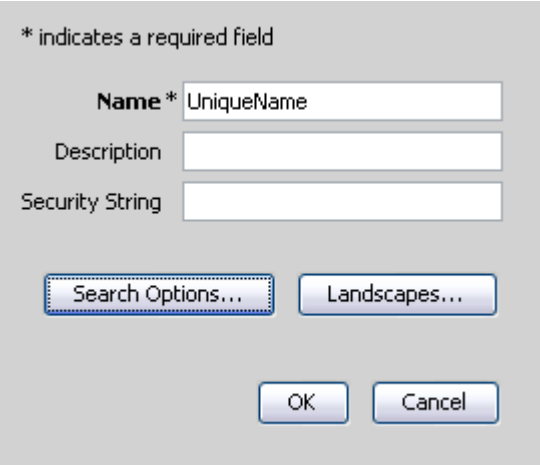
1. Select the device that you want to add to the OpenSSH Device Family
2. Right click the device, then select **Add to**, **Device Family**.
3. Select the NCM OpenSSH Device Family.

Create a Custom Device Family

Network Configuration Manager supports Cisco, Enterasys, Enterasys/Riverstone SSR, Extreme, Foundry, Juniper, Lancom, Nortel Baystack, and Nortel Passport device families out-of-box. The Network Configuration Manager Extension Utility lets you create custom device families.

Follow these steps:

1. Expand Configuration Manager in the Explorer tab of the Navigation panel.
2. Right-click Device Families, and select Create Device Family.
   The Create Device Family dialog opens as shown in the following image:



3. Enter a unique name in the Name field.
4. (Optional) Enter a description and security string.
5. (Optional) Click the Landscapes button to select the Landscapes where you want to place the device family.
6. Select the Search Options button to search for specific devices.
   The Search Options dialog opens. Like a Global Collection, a device family can have both static members that are manually added to the family, and dynamic members that are automatically added using specified search criteria. For more information, see the OneClick Administration section.

   NOTE
   A device can belong to only one device family. If multiple device families contain search criteria that apply to the same device, the first device family to execute the search contains the device.
7. Select OK when you have finished.
   The device family is created and appears under Device Families in the Explorer tab of the Navigation panel. Static members can now be added.

Place a Device in a Device Family

Network Configuration Manager automatically assigns out-of-the-box supported devices to the family. A device that is associated with a device family must be manually moved to a user-created device family. Manually created device families that contain search criteria to define membership do not pull in devices that already belong to a device family. For the search criteria to pull in a new device, the device must not currently be a member of any device family.

You have several options for placing a device in a device family. You can manually make the association.

Follow these steps:

1. Locate the device.
2. Right-click the device and select Add To, Device Family.
   The Select Device Family dialog opens.
3. Select the device family that you want to associate with the selected device.
   If a suitable device family is not displayed, create a custom device family by clicking Create. See Create a Custom Device Family for more information.
   The device is now associated with the selected device family.

   NOTE
   Add `cisco_ssh_check=9K` in the `<SPECROOT>/SS/.vnrmc` file and restart the SpectroSERVER, to place the Cisco 9300 series devices in the correct device family.

You can force a manually created device family to update using its defined search criteria.

Follow these steps:

1. Right-click the device family in the Navigation panel.
2. Select Update Device Family.
   The device family searches for and adds all devices that meet the search criteria if they do not currently belong to a device family.

For more information about device family search criteria, see Create a Custom Device Family.

You can also restore a device to one of the out-of-box supported device families.

Follow these steps:

1. Right-click a device that is not currently associated with a device family.
2. Select Reconfiguration, Reevaluate NCM Device Family.

   WARNING
   Cisco PIX devices do not support the Reevaluate NCM Device Family function.

   Network Configuration Manager reevaluates the device to determine whether it should belong to an out-of-the-box device family.
   If Network Configuration Manager determines that the placement is appropriate, the device is added to the device family.

   NOTE
   The Reevaluate NCM Device Family action on a device that is currently in a manually created device family has no effect.

   NOTE
   For more information about out-of-the-box supported device families, see Supported Devices.

Extension Utility Script Configuration

Perform all interactions with Network Configuration Manager scripts using OneClick. Network Configuration Manager handles all script administration within the DX NetOps Spectrum environment. The available scripting options are discussed in the following sections.

NOTE
The end of line character in each line must be in UNIX format.

Scripting Considerations

When a script is configured for a Network Configuration Manager operation, the script is used for all devices in the family. For example, if scripts are configured for all of the supported operations in the Cisco IOS SSH Capable device family, the Communication Mode setting at the device family and any overridden Communication Mode settings at local devices have no effect. In this example, the scripts for all Network Configuration Manager operations on all devices that are contained in the Cisco IOS SSH Capable Device Family are used.

In the case where only a subset of the Network Configuration Manager operations has scripts that are configured, the Network Configuration Manager uses the Communication Mode that is selected at the device family or overridden at the local device for the operations for which no script is configured.

Username, Password, and Enable Password are always sent to the scripts as command line parameters. The values that are specified in the device family are used unless they are overridden at the local device in which case the locally overridden values are used.

Default Script Command Line Parameters

By default Network Configuration Manager provides the following parameters, in the order shown, to every script. If the script does not make use of these parameters, the script must still be written to accept them.

- Device IP.
- Absolute filename of file containing content to upload. (Upload operation only).
- Device Username.
- Device Password.
- Device Enable Password.

Additional Script Command Line Parameters

Optionally, unlimited additional command line parameters can be configured for each of the supported operations. The parameters are passed on the command line to the script after the default set of parameters. The parameters are passed in the order they are shown in the Additional Script Parameters list.

Upload Running Configuration and Load Device Firmware operations can have additional command line parameters that are configured in such a way that the user is prompted for a value at runtime. A label and default value can also be displayed when prompting at runtime.

Error Code Mappings

Network Configuration Manager provides the ability to map non-zero integer values that are returned by the script to a textual error message which displays in OneClick if the error occurs. This enables script creators to provide detailed information about the failure mode.

Script Error Handling

For Network Configuration Manager to report success of a script-based operation, the script must return a value of zero. Network Configuration Manager assumes that the operation failed if a non-zero value is returned by the script.

Additional Error Detail Returned in STDERR Buffer

If a script returns a non-zero value, in addition to the error mapping above, Network Configuration Manager also looks for any output that is returned by the script in the STDERR buffer. If content is found, it displays in OneClick as additional error information.

Enter a Configuration Script

Network Configuration Manager can use Perl scripts for the following operations:

- **Capture Startup Configuration**
  This script must return the device startup configuration in the STDOUT buffer. All content that is returned in the buffer is considered to be the device startup configuration.
- **Capture Running Configuration**
  This script must return the device running configuration in the STDOUT buffer. All content that is returned in the buffer is considered to be the device running configuration.
- **Upload Running Configuration**
  This script reads the file that is identified by the Absolute Filename parameter (for more information, see Default Script Command Line Parameters). It then uploads and merges the content of the file to the device running configuration.
- **Write Startup Configuration**
  This script causes the device running configuration to be written to its startup configuration.
- **Reload Device**

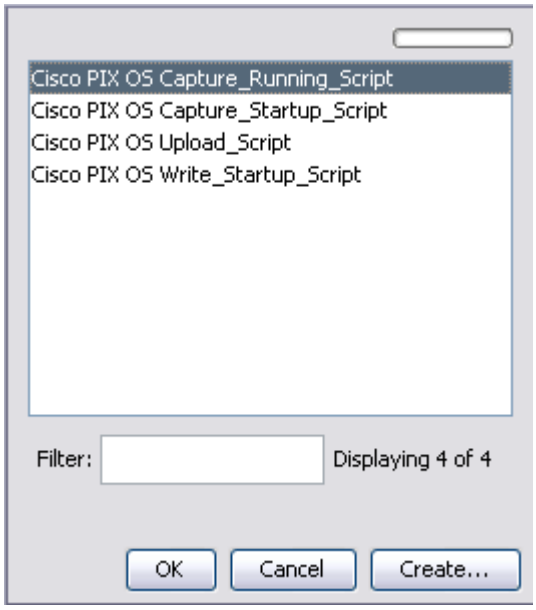
This script reboots a device.

- **Cancel Reload**
  This script cancels a pending or scheduled reboot of a device.
- **Load Device Firmware Configuration**
  This script uploads a new firmware image onto a device and executes all necessary operations to reload the device using this firmware image.

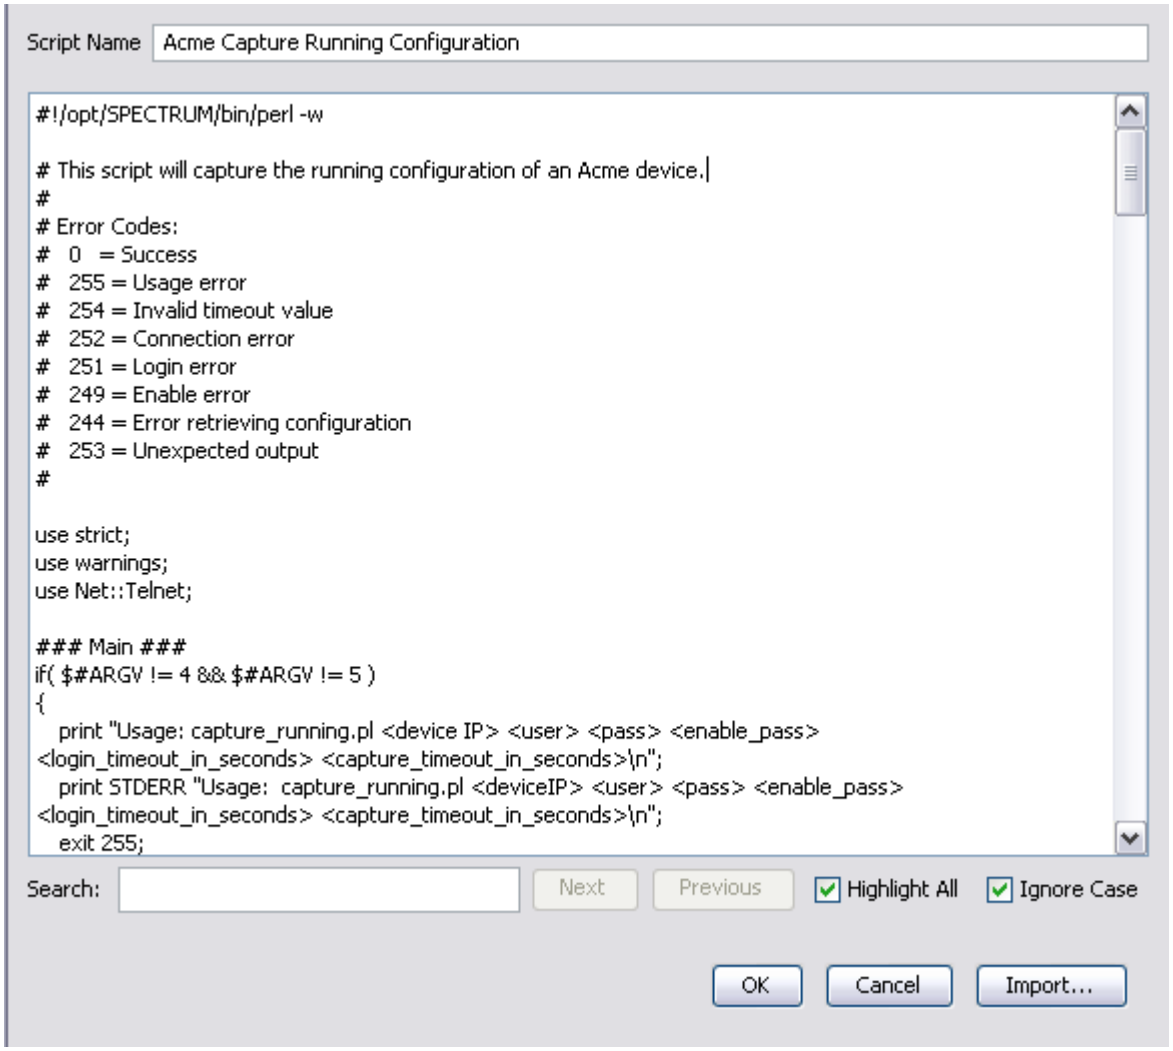
You can select a configuration script for these operations.

Follow these steps:

1. Select a device family from the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the Device Configuration Transfer Settings subview.
   The script operation subviews appear.
   Note: For the Cisco IOS and Cisco IOS - SSH Capable device families, the Load Device Firmware Script resides in the Device Firmware Transfer Settings subview.
3. Expand the appropriate script operation subview.
   The available script configuration fields display.
4. Select set next to the script name.
   The Select Script dialog opens as shown in the following example:

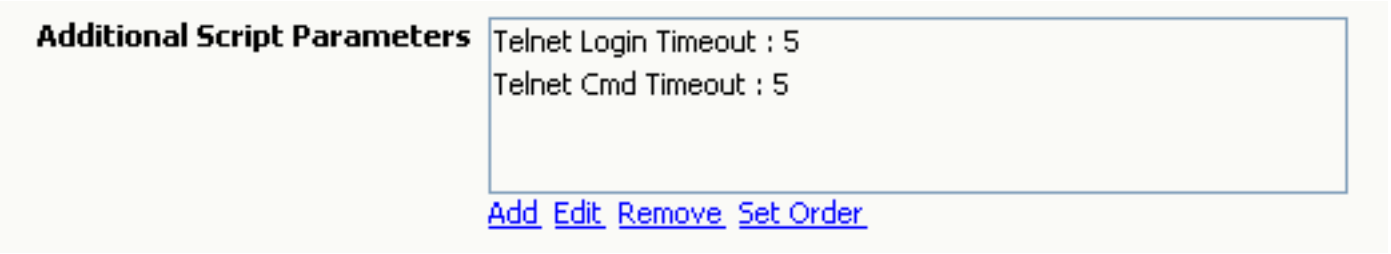


5. Take one of the following steps:
   – If a script that you want to use is available, select the script, select OK, and go to Step 10.
   – If you have not yet created a script for the selected device family, select Create to upload or create one.
6. Supply a unique name for the script in the Script Name field. Paste the script into the field under Script Name, or select Import to import a configuration file that is saved locally on your system.
   The script content appears in the field under the Script Name field, as shown in the following example:

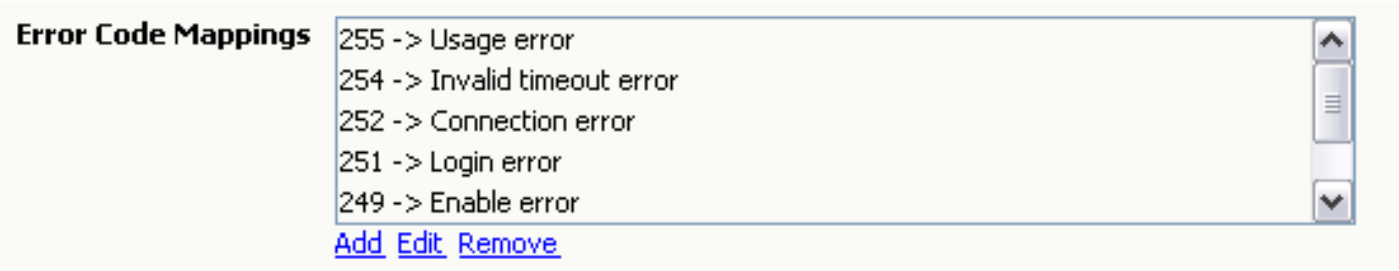


7. (Optional) Edit script content if necessary. Or enter criteria in the Search field to locate specific lines in the script file.
8. Select OK when you have finished importing and configuring the script.
   The script name appears in the Select Script dialog.
9. Select the script, and select OK.
   The script is loaded and is visible in the Script Content field.
10. Add any additional script parameters.

    NOTE
    For more information, see Additional Script Command Line Parameters.
11. Select Add under the Additional Script Parameters field.
    The Add dialog opens.
    a. Enter the parameter name and value. If the operation is Upload, or the task is Load Firmware, you can configure the parameter to prompt you at run time for a value.
    b. Select OK.
       The parameter appears in the Additional Script Parameters field, as shown in the following example:



12. Add any error code mappings. For more information, see Error Code Mappings.
13. Select Add under the Error Code Mappings field.
    The Add dialog opens.
14. Enter the error code in the Error Code field and the corresponding message in the Error Message field, and select OK.
    The error code appears in the Error Code Mappings field, as shown in the following example:



The configuration script is ready to run.

Configuration for Non-Root User on RHEL 8

For a non-root user on RHEL 8, to execute NCM script operations, you must create a configuration with the required entries (as shown in the example) under `/usr/userid/.ssh/` with the appropriate permissions (`chmod 600 ~/.ssh/config`).

Example

```
cat /usr/home/myuser/.ssh/config

     Host *

        StrictHostKeyChecking no

        UserKnownHostsFile=/dev/null

        KexAlgorithms +diffie-hellman-group1-sha1

        Ciphers aes128-ctr,aes192-ctr,aes256-ctr,aes128-cbc,3des-cbc,aes128-cbc,3des-
cbc,aes192-cbc,aes256-cbc
```

NOTE
This behavior is also applicable for non-root SpectroSERVER and non-root SDC.

NCM Support for SSH using Jsch libraries

This release of DX NetOps Spectrum NCM supports SSH using Jsch libraries to perform NCM Captures and uploads for CISCO and Juniper devices only using SSH configuration.

Follow these steps to enable NCM SSH to use JSCH mode:

1. Goto $SPECROOT\NCM\config.xml
2. Set the 'ssh-library type' value to 'jsch' (the default value is 'mindterm')
   <ssh-library type="java.lang.String">mindterm</ssh-library>
   to
   <ssh-library type="java.lang.String">jsch</ssh-library>

For large configuration devices (>8K lines), Jsch sometimes throws the capture failure/capture file does not work error. To fix this, increase the output wait time.

Follow these steps:

1. Goto $SPECROOT\NCM\config.xml
2. Change the jsch-read-datawait type value:
   <jsch-read-datawait type="java.lang.Integer">4</jsch-read-datawait>
   to
   <jsch-read-datawait type="java.lang.Integer">7</jsch-read-datawait>

> **NOTE**
>
> **Information!** DX NetOps Spectrum by default uses MindTerm SSH libraries for NCM activities. In some cases, MindTerm libraries throw premature EOF error, then the user should shift to other libraries such as JSCH or OpenSSH.
> For Windows platform, user can shift to only JSCH libraries. For Linux platforms user can shift to either JSCH libraries or Perl Script using the OpenSSH.
>
> In this release of DX NetOps Spectrum, NCM supports JSCH for CISCO and Juniper device family only. Once the configuration is set to leverage JSCH libraries, all the NCM activities use JSCH SSH API instead of default SSH API (mindterm).

Perl Modules

DX NetOps Spectrum ships all Perl Modules (for the Windows platforms) required to run the Perl scripts that are provided out-of-box. That includes:

- Net::Telnet

In addition, DX NetOps Spectrum also comes with certain perl modules that may be useful in developing scripts for the Extension Utility. These include:

- Net::OpenSSH
- Net::SSH
- Net::SSH::Expect
- Expect
- Net::TFTP
- Net::SCP
- Net::FTP

Perl modules that ship with DX NetOps Spectrum can be viewed at:

```
/opt/SPECTRUM/lib/perl5
```

WARNING
Perl modules that are not compiled and installed correctly may result in failure or other undesirable behavior.

RESTRICTION
NCM OpenSSH is not supported in the Windows platform.

Using SSH-based Perl Scripts for Network Configuration Manager Operations

DX NetOps Spectrum's out-of-the-box scripts-based support for Network Configuration Manager operations is based on the Net::Telnet module. If you want to use SSH-based scripts for Network Configuration Manager operations:

- **Windows**-- DX NetOps Spectrum includes a complete perl install and the Net::SSH::Expect module.
- **Linux** -- You must install perl to a separate location on your system and must configure DX NetOps Spectrum to use that perl.

This Perl installation and configuration on DX NetOps Spectrum is to be done on a per landscape basis in a DSS. You will have to set up perl for each landscape on which you have devices that are modeled to use SSH-based scripts.

NOTE
If you want to continue to use DX NetOps Spectrum's out-of-box scripts once you have configured DX NetOps Spectrum to use your custom Perl install, then your custom Perl area must have the Net::Telnet perl module installed. You can download and install this module from www.cpan.org. Otherwise, DX NetOps Spectrum's out-of-box scripts fail.

To set up SSH-based scripts, follow the instructions specific to your platform.

On Windows

1. Install Perl.
   DX NetOps Spectrum ships with Cygwin's complete version of Perl, so you are not required to install anything more if you want to use scripts based on the Net::SSH::Expect module.
   If you want to use scripts based on some other module, complete one of the following depending on the module you are using:
   - If the perl module is compatible with a version of Perl other than Cygwin, then we recommend that you install that specific Perl onto your SpectroSERVER machine, then install your specific perl module, and then configure DX NetOps Spectrum to use your particular Perl install. (See Configuring DX NetOps Spectrum to Use a Custom Perl Install.)
   - If the perl module that you want to install is only compatible with Cygwin's perl, and is a change module (i.e., it does not require compilation of C libraries), then you can add it to the DX NetOps Spectrum Perl install. Simply place the <Module_Name>.pm file in $SPECROOT/NT-Tools/SRE/lib/perl5/site_perl/5.8
   - If the perl module that you want to install is only compatible with Cygwin's perl and also requires C libraries to be compiled, then this module has to be compiled and shipped with DX NetOps Spectrum. Contact DX NetOps Spectrum support for this enhancement request.
2. Install SSH-based perl modules and SSH program.
   DX NetOps Spectrum ships with the Net::SSH::Expect (and its required) modules and the ssh program (that is required by Net::SSH::Expect). For instructions on how to develop scripts using this module, select the documentation for Net::SSH::Expect on www.cpan.org.
3. Configure DX NetOps Spectrum to use the custom Perl install.
   Because DX NetOps Spectrum's perl is set up for this purpose, you do not have to configure DX NetOps Spectrum to use a custom perl installation.

On Linux

1. Install Perl.
   The OS already has Perl that is installed (check /usr/bin/). This pre-installed Perl can be used for Network Configuration Manager scripts.
2. Install SSH-based perl modules and the SSH program.

You need to download and install the Net::SSH::Expect module, its dependent modules, and the ssh utility.
The dependency tree for Net::SSH::Expect looks like:
Net::SSH::Expect -> Expect -> IO::Pty
where the '->' represents a "requires" relationship.
You can download all of these modules from www.cpan.org
Be sure to install these modules to the custom Perl area you installed above.
This can be done by specifying the full-path of the perl binary when you are installing the modules such as:

```
<PERL_FULL_PATH>/perl Makefile.pl
```

NOTE
Some Perl modules are dependent on C/C++ code libraries. To install such modules, you have to install the gcc compiler so that you can link against the libraries. You can install the gcc compiler by using RPM to add the latest gcc package.

3. Install SSH-based perl modules and the SSH program.
   You need to download and install the Net::OpenSSH module, its dependent modules, and the ssh utility.
   The dependency tree for Net::OpenSSH looks like:
   Net::OpenSSH -> IO::Pty -> File::Path
   where the '->' represents a "requires" relationship.
   You can download all of these modules from www.cpan.org
   Be sure to install these modules to the custom Perl area you installed above.
   This can be done by specifying the full-path of the perl binary when you are installing the modules such as

   ```
   <PERL_FULL_PATH>/perl Makefile.pl
   ```

   NOTE
   Some Perl modules are dependent on C/C++ code libraries. To install such modules, you have to install the gcc compiler so that you can link against the libraries. You can install the gcc compiler by using RPM to add the latest gcc package.
4. Configure DX NetOps Spectrum to use the custom Perl install.
   See Configuring DX NetOps Spectrum to Use a Custom Perl Install and point DX NetOps Spectrum to the perl install area from Step 1 above.

Configuring DX NetOps Spectrum to Use a Custom Perl Install

DX NetOps Spectrum is configured by default to use the Perl that is shipped with it. If you want to use additional perl modules that are not shipped with DX NetOps Spectrum, and have installed them to a perl area, you can configure DX NetOps Spectrum to use your custom perl installation. To set this up, select the Configuration Manager model in the Explorer tab in OneClick. In its Information view, expand the Perl Configuration subview. You find a table that contains the Perl directory configuration per landscape.

Note that the Use Custom Perl option has to be set to Enabled to be able to specify a custom perl directory. Otherwise, the default Perl that comes with DX NetOps Spectrum is used. You can point DX NetOps Spectrum to a custom Perl location that you have installed on a particular SpectroSERVER system.

Follow these steps:

1. On a given landscape, set the Use Custom Perl to Enabled.
2. Once you have enabled the use of a custom Perl area, specify the Custom Perl Directory.

   NOTE
   The Custom Perl directory must contain the full pathname of the directory that contains the perl.exe (Windows) or the perl program (Linux).

For example, if the perl program is located in /usr/local/bin/, specify Custom Perl Directory as /usr/local/bin.

NOTE
You can continue to use the DX NetOps Spectrum default scripts once you have configured DX NetOps Spectrum to use your custom Perl install. But your custom Perl area must have the Net::Telnet perl module installed. You can download and install this module from www.cpan.org. Otherwise, the DX NetOps Spectrum default scripts fail.

You can also disable the use of your custom Perl area and use the default DX NetOps Spectrum Perl.

NOTE
Set the Use Custom Perl to disabled (use CA Spectrum default). Note that when you disable the use of a custom Perl area, the Custom Perl Directory cannot be seen or edited. But when you enable Use Custom Perl again, your previously specified Custom Perl Directory is restored.

Using Additional Perl Modules

If you want to use scripts based on your preferred perl module, you must install the perl module to the area that will be used.

On Windows

Depending on the module that you want to use you have three options:

- If the perl module is compatible with a version of Perl other than Cygwin, then we recommend that you install that specific Perl onto your SpectroSERVER machine, then install your specific perl module and then configure DX NetOps Spectrum to use your particular Perl install. (See Configuring DX NetOps Spectrum to Use a Custom Perl Install).
- If the perl module that you want to install is only compatible with Cygwin's perl, and is a text-based module (i.e., it does not require compilation of C libraries), then you can add it to the DX NetOps Spectrum Perl install. Simply place the <*Module_Name*>.pm file in $SPECROOT/NT-Tools/SRE/lib/perl5/site_perl/5.8
- If the perl module that you want to install is only compatible with Cygwin's perl and also requires C libraries to be compiled, then this module has to be compiled and shipped with DX NetOps Spectrum. Contact DX NetOps Spectrum support for this enhancement request.

On Linux

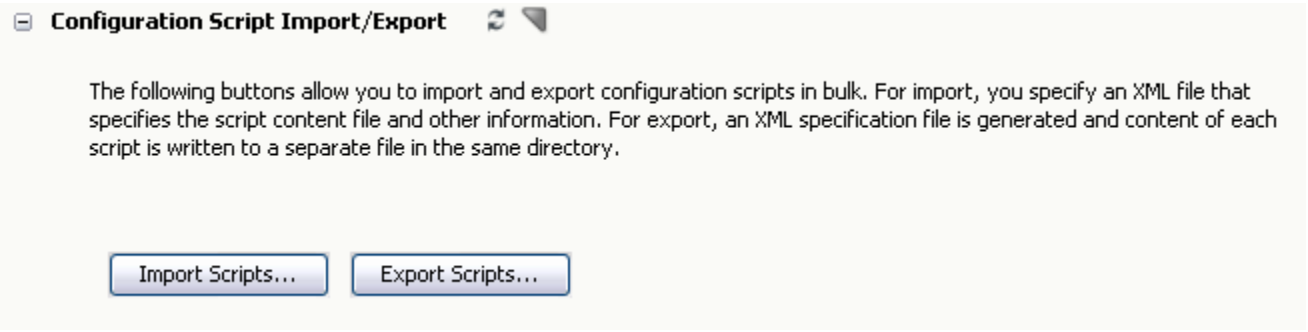
It is required that you install Perl to a separate area on your SpectroSERVER, then install the required perl modules using that Perl and configure DX NetOps Spectrum to use the Perl install area. Once you have installed Perl, refer to the installation instructions of the specific perl module that you want to install. Then refer to Configuring DX NetOps Spectrum to Use a Custom Perl Install. You may refer to the Using SSH-based Perl Scripts for Network Configuration Manager Operations for details about how to use scripts based on the Net::SSH::Expect module but you may use the procedure as a guideline for integrating any perl module.

Import and Export Scripts

Network Configuration Manager lets you import and export scripts in bulk. The scripts are exported to or imported from the file system of the host server that is running the OneClick client.

Follow these steps to export scripts:

1. Select Configuration Manager in the Navigation panel.
2. Select the Information tab in the Contents panel.
   Information and configurations display.
3. Expand the Configuration Script Import/Export subview.
   The Import Scripts and Export Scripts buttons display.



1. Select Export Scripts.
   The Select Scripts To Export dialog opens.
2. Select the script to be exported. Or select multiple scripts.
   The Save as dialog opens.
3. Select the location to save, and supply a name for the XML specification file that is automatically generated during export. The export process generates a file for each selected Perl script using its designated name and the .pl extension. The export process also generates the XML specification file that contains the list of scripts that were exported and the error-mapping information for each. The XML specification file can then be used to import the scripts on the same or different DX NetOps Spectrum environment.
   The selected Perl scripts are exported to the location that you specified.

Follow these steps to import scripts:

1. Select Configuration Manager in the Navigation panel.
2. Select the Information tab in the Contents panel.
   Information and configurations display.
3. Expand the Configuration Script Import/Export subview.
   The Import Scripts and Export Scripts buttons display.
4. Select Import Scripts.
   The open dialog opens.
5. Select the XML specification file that describes the Perl scripts to be imported into Network Configuration Manager. If you are importing scripts that were previously exported from DX NetOps Spectrum, you can use the XML specification file that was generated during that export.
   The XML specification file may also be generated manually by following the format that is shown in the following example.

```
<scripts>
  <script>
    <file-name>ABC_Vendor_Capture_Running_Configuration.pl</file-name>
    <display-name>ABC Vendor Capture Running Configuration</display-name>
    <error-message errorCode="255">Usage</error-message>
    <error-message errorCode="99">Invalid Enable Password</error-message>
    <error-message errorCode="98">Unexpected Response</error-message>
    <error-message errorCode="97">Illegal Telnet Timeout Value</error-message>
  </script>
  <script>
    <file-name>XYZ_Vendor_Capture_Running_Configuration.pl</file-name>
    <display-name>XYZ Vendor Capture Running Configuration</display-name>
    <error-message errorCode="255">Usage</error-message>
    <error-message errorCode="99">Response Timed out</error-message>
    <error-message errorCode="50">Connection Error</error-message>
  </script>
  <script>
```

```
    <file-name>XYZ_Vendor_Capture_Startup_Configuration.pl</file-name>
    <display-name>XYZ Vendor Capture Startup Configuration</display-name>
  </script>
</scripts>
```

- **file-name**
  The name of the Perl file to be imported. This file must exist in the same directory as the XML specification file at the time of import.
- **display-name**
  The name that is used in OneClick to identify this script.
- **error-message**
  (Optional) Describes a mapping of an error code that is returned by the script to a textual error message that is displayed in OneClick if the error occurs. Multiple error-message elements can be specified for each script.

The Perl script XML is imported. The scripts are available when configuring Network Configuration Manager operations on device families.

> **NOTE**
> The import process does not associate the scripts with a device family.

Maintaining a Script Backup and History

Scripts are stored as models in the DX NetOps Spectrum database and therefore are backed up each time DX NetOps Spectrum performs a backup. The script export feature provides an additional backup and means of tracking the history of Network Configuration Manager scripts that is easily accessed and imported back into DX NetOps Spectrum if desired.

Customized Traps

You can extend the functionality of Network Configuration Manager by configuring customized trap settings for your installation. These settings are used to correlate configuration change event information so that events are combined for a particular device. These settings are configured at the device family level. For more information, see Configure Notification Trap Settings.

Capture Huge Configurations

10.3.1 allows you to capture huge configuration files using the 'Capture' function of the Network Configuration Manager by configuring the 'thread-timeout-value' settings. To capture large configuration files, increase the thread-timeout-value as described here:

Follow these steps:

1. Navigate to the **$SPECROOT>NCM>config.xml** file and find the 'thread-timeout-value type'.
2. By default this value is set to 300 as shown here:
   ```
   <thread-timeout-value type="java.lang.Integer" ><300>< / thread-timeout-value>
   ```
3. Change the setting and increase the value as shown here:
   ```
   <thread-timeout-value type="java.lang.Integer" ><increased value in seconds>< /
    thread-timeout-value>
   ```

NCM Enhancement - Configuration Search

10.3.2 introduces 'Configuration Search' a new search filter for NCM devices, which is based on parsing a sub-string value to span all device configurations from a device family and/or from a global search. This enhancement address challenges for regular search operations for configurations, route, interface description, or other global parameters such as Log settings, AAA, SNMP, ACL, and others.

The **Configuration Search** feature includes two major search categories and subcategories, as described:

1. **Search Device Models by Sub-string Search In**: This search criteria contacts SpectroSERVER to fetch device model information. This search criteria fetches configurations including input string in the running configuration, startup configuration, running configuration difference result and the startup configuration difference result.
   a. Startup Configuration: Devices that are configured and captured using the startup command can be identified using a sub-string under this category.
   b. Running Configuration: Devices that are configured and captured using the running command can be identified using a sub-string under this category.
   c. Startup Configuration Difference Result: Users can utilize this search option to find the difference in the configuration of the same device that is configured and captured under the startup configuration.
   d. Running Configuration Difference Result: Users can utilize this search option to find the difference in the configuration of the same device that is configured and captured under the startup configuration.
2. **Search Host Configuration Models by Sub-string Search In**: This search criteria contacts SpectroSERVER to fetch the host configuration models containing input string in its configuration. This search criteria fetches configurations including input string in the running configuration, startup configuration, running configuration difference result and the startup configuration difference result.
   a. Startup Configuration: Host configuration models configured and captured using the startup command can be identified using a sub-string under this category.
   b. Running Configuration: Host configuration models configured and captured using the running command can be identified using a sub-string under this category.
   c. Startup Configuration Difference Result: Users can utilize this search option to find the difference in the host configuration of the same devices that are configured and captured under the startup configuration.
   d. Running Configuration Difference Result: Users can utilize this search option to find the difference in the host configuration of the same devices that are configured and captured under the startup configuration.

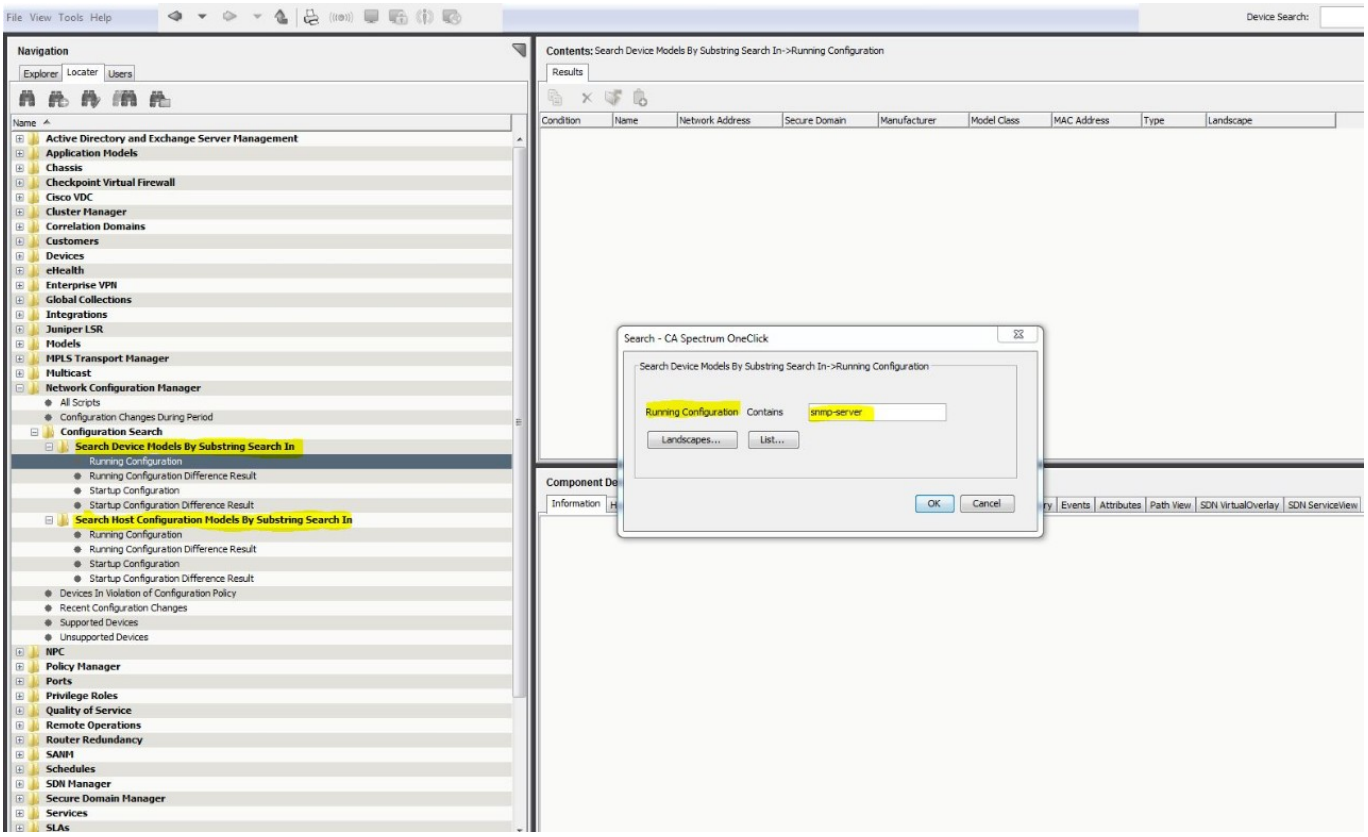
      NOTE

      Right-click on the 'Host Configuration' menu and select the 'Location' option to redirect to the corresponding device model.

      NOTE

      Until the Host Configuration model is added to any of one or more GCs or CorrelationDomains etc., it remains disabled.

This is a screenshot displaying the new Configuration Search feature with the two categories and other subcategories. For example the screenshot displays the Running Configuration window contains the snmp-server sub-string value in the device family.



Global Synchronization Task

This section describes how to set up the Global Synchronization task on your network with Network Configuration Manager. When you run the Global Synchronization task, Network Configuration Manager captures and saves all device configurations.

> **NOTE**
> We recommend that you capture device configurations prior to configuring Network Configuration Manager policies.

About Global Synchronization

A Global Synchronization task gathers running configurations for the devices on your network that have Network Configuration Manager enabled. You can schedule this task to run regularly. You select a time period and recurrence frequency to capture configurations from all network-wide supported devices. For example, capture device configurations after 9 PM and no later than 5 AM on a daily basis. By capturing the configurations for all devices on your network, you maintain a running configuration history.

You can set Global Synchronization to verify whether the startup configurations are the same as the running configurations. If they differ, you can configure Network Configuration Manager to generate an alarm. A Global Synchronization captures the startup configuration and compares it to the running configuration to detect changes. See Types of Configurations for descriptions of startup and running configurations.

NOTE
You can also gather running configurations for selected devices on your network and view the results in real-time by creating an automatic Sync task. See Create Sync Task for details.

About Enterasys/Riverstone SSR Devices

Configuration captures performed on Enterasys/Riverstone SSR devices provide the startup configuration and not the running configuration. Therefore, the device configuration history maintained by Network Configuration Manager is a history of the startup configurations on SSR devices. See Determine How an Enterasys/Riverstone SSR Device Responds to an Upload Task for details about how SSR devices handle Network Configuration Manager configuration uploads.

Configure Global Synchronization

Configure settings for Global Synchronization, such as a schedule. Global Synchronization is performed by the Global Sync Task, which appears under Tasks in the Explorer tab.

Follow these steps:

1. Select Configuration Manager in the Explorer tab.
   Information and configurations display in the Information tab of the Contents panel.
2. Expand the Global Synchronization subview.
   Global Synchronization options appear.
3. Modify the following options as needed:
   - **Global Synchronization Schedule**
     Specify a schedule for the Global Sync Task. Click the Schedule button to access the Select Schedule dialog from which you can select a default schedule or create a custom one. More information on scheduling the Global Sync Task is available in Schedule Global Synchronization.
   - **If Sync Task Not Completed in Allotted Time, Assert Task Alarm**
     Specify a minor, major, or critical alarm if you want to be notified by alarm if the global synchronization task did not complete properly. If you manage many devices and run a scheduled global sync task periodically, a Sync task stops at the end of the scheduled period because capturing configurations can consume bandwidth on slow links.
   - **Include Devices and Device Families on which NCM has been Disabled**
     Specify whether to include in the Failed Device List those devices for which Network Configuration Manager has been disabled.
     Default: Yes
   - **Verify Startup Equals Running Configuration**
     Enable this option if you want to compare a startup configuration against a currently running configuration for devices in your network.
   - **When Startup Differs, Assert Device Alarm**
     Specify a minor, major, or critical alarm if you want to generate an alarm for devices with startup configurations that differ from running configurations.

Schedule Global Synchronization

You can schedule a global synchronization to gather running configurations for all devices on your network. Devices are processed in random order.

If a scheduled global synchronization does not complete in the allotted time, the next execution first randomly processes the unprocessed devices from the previous execution. All remaining devices are then processed in random order.

WARNING
Do not schedule a “one-shot” global synchronization if DX NetOps Spectrum landscapes exist in multiple time zones. Performing this type of task causes the global synchronization to run only in the earliest time zone.

Follow these steps:

1. In Explorer, select Global Sync Task in the Tasks folder.
2. Select the List tab in the Contents panel.
3. Click the Schedule button in the toolbar.
   The Select Schedule dialog opens.
4. Take one of the following steps:
   – Select a default schedule and click OK.
   – Create a custom schedule. Click Create, specify schedule options, and click OK.
   The custom schedule is added to the list of available schedules. Select the new schedule and click OK.

   The Global Sync Task is now scheduled. The schedule appears in the Schedule column of the List table, and the schedule icon appears next to the task in the Tasks folder.

Run an On-Demand Global Sync Task

Run a Global Sync task to gather running configurations for all devices on your network. Devices are processed in random order.

Follow these steps:

1. In Explorer, select Global Sync Task in the Tasks folder.
2. Select the List tab in the Contents panel.
3. Click the Start Selected Task icon.
   The Sync Task Results dialog shows a list of processed devices and the results of the Global Sync.

View Configuration History for a Single Device

You can view the configuration history for a single device in OneClick. For details about uploading configurations to network devices, see Manually Upload Configurations to a Single Device.

Follow these steps:

1. Select a device in the Explorer tab.
2. Verify that the List tab is selected in the Contents panel, and select the Host Configuration tab in the Component Detail panel.
   The following details appear in the Host Configuration table:
   – **Capture Time**
   Lists the time (M-DD-YYY HH:MM:SS) that configuration in this row was first captured on the device.
   – **Captured By**
   Identifies the DX NetOps Spectrum OneClick user who configured the task.
   – **Line Changes**
   Lists the number of relevant changed lines when compared with the previous configuration on the device. Relevant changes include added lines, removed lines, and changed lines. Irrelevant changes are any lines that match the comparison mask. The comparison mask is managed in Mask Configuration settings for the device family. For more information, see Configure Device Family Masks.
   – **Total Line Changes**
   Lists the total number of changed lines (relevant and irrelevant) when compared with the previous configuration on the device. Displays the changes hyperlink if any changes are detected.
   – **Is Reference**
   Indicates the reference configuration for this device.
   – **Running vs. Startup**
   Shows configuration differences in the startup and running configuration files (if applicable). Displays the View Differences hyperlink if differences exist.
   – **Last Verified Time**

Lists the last time (M-DD-YYY HH:MM:SS) Network Configuration Manager verified that the configuration still existed on the device.

- **Last Verified User**
  Identifies the last user to have accessed the device.
- **NCM Mode**
  Identifies the method that was used to transfer new configuration content to the device when a change was initiated with Network Configuration Manager.
- **NCM User**
  Identifies the DX NetOps Spectrum user who initiated the configuration change on the device using Network Configuration Manager.
- **Device User**
  Identifies the user who accessed the device and made the configuration change.
- **Source**
  Identifies the source of the configuration change.
- **Location**
  Identifies the location of the configuration change.
- **Violated Policies**
  Identifies policies that were in violation after this configuration change.
- **Compliant Policies**
  Indicates policies that were compliant after this configuration change.

A new row is created when one or more changes are detected by Network Configuration Manager.

3. Select a row in the Host Configuration table.
   The captured host configuration content appears in the box below the table.
4. (optional) Click the changes hyperlink (if applicable) in the Line Changes column in the Host Configuration table to view added, removed, changed, and irrelevant lines in the configuration of the selected device.
   The Configuration Differences dialog opens. The highlighted text uses the following colors to indicate status:
   - **Green --** These lines were added.
   - **Red --** These lines have been removed.
   - **Blue --** These lines have changed.
   - **Grey --** These lines are irrelevant. Irrelevant changes are lines that match the comparison mask.

     NOTE
     Click Next or Previous to navigate through the differences in the file.
5. (optional) Click the View Differences hyperlink (if applicable) in the Running vs. Startup column in the Host Configuration table to view added, removed, changed, and irrelevant lines.
   The Running vs. Startup dialog displays differences in running and startup configuration files for the captured device. The startup configuration appears in the right column. The highlighted text uses the colors listed in the previous step to indicate status.

Compare Any Two Configurations

You can compare any two host configurations, even if they belong to different devices.

Follow these steps:

1. Select a device in the Explorer tab.
2. Verify the List tab is selected in the Contents panel and select the Host Configuration tab in the Component Detail panel.
3. Right-click a configuration in the Host Configuration table that you want to compare and select Start Compare.
4. Select the second configuration to include in the comparison. Select a configuration for the same device, or select a different device in the Explorer tab. Verify that its configuration information is displayed in the Host Configuration table.

5. Right-click the second configuration to include in the comparison in the Host Configuration table, and select Compare With <*name_of_first_configuration*>.
   The Configuration Differences dialog opens. The highlighted text uses the following colors to indicate status:
   - **Green --** These lines were added.
   - **Red --** These lines have been removed.
   - **Blue --** These lines have changed.
   - **Grey --** These lines are irrelevant. Irrelevant changes are lines that match the comparison mask.

     NOTE
     Click Next or Previous to navigate through the differences in the file.

Specify a Reference Configuration

You can specify a reference configuration for a device with an associated alarm. An alarm can be generated on the device whenever Network Configuration Manager determines that the current configuration differs significantly from the reference.

NOTE
For more information about alarm settings, see Configure Configuration Change Alert.

Follow these steps:

1. Select a device or device family in the Explorer tab.
   Verify the List tab is selected in the Contents panel.
2. Select one or more devices in the List tab whose most recent configuration you want to set as a reference.
3. Right-click the selection and select Set NCM Reference Configuration.
   A confirmation dialog opens.
4. Select Yes.
   The most recent configuration is set as reference for each device selected. The 'Is Reference' field in the Host Configuration table displays a check and the user who set the reference.

You can also manually specify a reference configuration.

Follow these steps:

1. Select a device in the Explorer tab.
   Verify the List tab is selected in the Contents panel and select the Host Configuration tab in the Component Detail panel.
2. Right-click the configuration to use as reference and select Set Reference.
   The configuration is designated as the reference configuration for this device. A check and the user who set the reference appear in the Is Reference field in the Host Configuration table.

You can change or remove a reference configuration specification after you set it. Only one configuration can be set as the reference configuration for a device. If you use the Set Reference or the Set NCM Reference Configuration option on another configuration when one is already set, the original one is automatically cleared, and the new one becomes the designated reference configuration. To clear a reference configuration, use the Unset Reference command from the right-click menu for the configuration in the Host Configuration table.

Configuration Alarms

You can specify alarms to be triggered when certain configuration changes occur. This section describes how to view the differences between configurations that triggered an alarm.

For more information about determining when configuration change alarms are triggered, see Configure Configuration Change Alert and Specify Configuration Change Alert Settings on a Single Device.

View Reference and Running Configuration Differences

You can view and compare reference and current running differences for a single device from the Alarm Details tab.

Follow these steps:

1. Select a device, a device family, or a global collection from the Explorer tab.
2. Select the Alarms tab in the Contents panel.
   Alarms for the selected item are displayed.
3. Select an alarm that displays “Reference and Current Running Configurations are Different” in the Alarm Title column.
4. Select the Alarm Details tab in the Component Detail panel.
   Alarm details are displayed.
5. Click the View Differences hyperlink.
   The Configuration Differences screen displays differences in the reference and current running files for the captured device. The reference configuration appears in the right column.

View Startup and Running Configuration

You can view and compare startup and running configuration for a single device from the Alarm Details tab.

Follow these steps:

1. Select a device, a device family, or a global collection from the Explorer tab.
2. Select the Alarms tab in the Contents panel.
   Alarms for the device, device family, or global collection are displayed.
3. Select an alarm that displays “Startup and Running Configurations are Different” in the Alarm Title column.
4. Select the Alarm Details tab in the Component Detail panel.
   Alarm details are displayed.
5. Click the View Differences hyperlink.
   The Running vs. Startup screen displays differences in running and startup configuration files for the captured device. The startup configuration appears in the left column.

View Global Sync Task Results

You can view lists of devices for which global synchronizations failed and succeeded.

> **NOTE**
> You can control whether to include devices with Network Configuration Manager disabled in the Failed Device List. For more information, see Configure Global Synchronization.

Follow these steps:

1. Expand Configuration Manager, and select Tasks in the Explorer tab.
2. Select the Global Sync Task.
   Information and results appear in the Information tab of the Contents panel.
3. Enter a name, type, condition, or device family in the Filter field to filter the results lists.

Network Configuration Manager Reports from Report Manager

Network Configuration Manager report options are included under the Network Configuration Management report pack in Spectrum Report Manager. Report Manager provides numerous report content, format, and report organization options. As a result, you can generate reports with the appropriate type and scope of information for different audiences in your organization who are interested in device configuration changes.

Report Manager Options

Report Manager provides you with multiple options for generating and managing your Network Configuration Manager reports:

- Generate reports on demand to view the most recent test results.
- Schedule test report generation on a one-time or periodic basis.
- Specify how long you want Report Manager to retain scheduled test reports or how many reports to retain.
- Specify email recipients for scheduled test reports.
- Schedule test reports for other Report Manager users.
- Publish reports in PDF, text, and spreadsheet formats.

NOTE
For detailed information about Report Manager features, see the Report Manager section.

The following reports are available:

- **Configuration Changes: All**
  Displays a summary of changes for all devices that have configuration changes. Each row represents a device to be associated with data that describes its configuration changes.
- **Configuration Changes: Group**
  Displays a summary of changes for devices in a given global collection. Each row represents a device to be associated with rolled up statistics describing its configuration changes.
- **Configuration Changes: Individual Device**
  Displays a list of configuration changes on a given device. Each row displays the time of the change, who made the change, and how many lines were changed. In addition, each row contains a web link to a Java applet that displays the difference between the current configuration and the previous configuration.
- **Detailed Configuration Event Log: All**
  Displays a reverse chronological list of events for all devices and models within DX NetOps Spectrum with Network Configuration Manager activity. Each entry in the list includes the IP address (if applicable), event text, event code, and event creator.
- **Detailed Configuration Event Log: Group**
  Displays a reverse chronological list of events for all devices and models with Network Configuration Manager activity for a specified global collection. Each entry in the list includes the IP address (if applicable), event text, event code, and event creator.
- **Detailed Configuration Event Log: Selected Device or Model**
  Displays a reverse chronological list of events for a specified device or model with Network Configuration Manager activity. Each entry in the list includes the IP address (if applicable), event text, event code, and event creator.
- **Top-N Configuration Changes: All**
  Displays a summary of changes for the "Top-N" devices that have configuration changes, where "Top-N" is defined as the maximum number of records based on the current sorting criteria. Each record represents a device to be associated with rolled-up statistics that describe its configuration changes.
- **Top-N Configuration Changes: Group**
  Displays a summary of changes for the "Top-N" devices that have configuration changes in a global collection. The "Top-N" is defined as the maximum number of records based on the current sorting criteria. Each record represents a device to be associated with rolled-up statistics that describe its configuration changes.

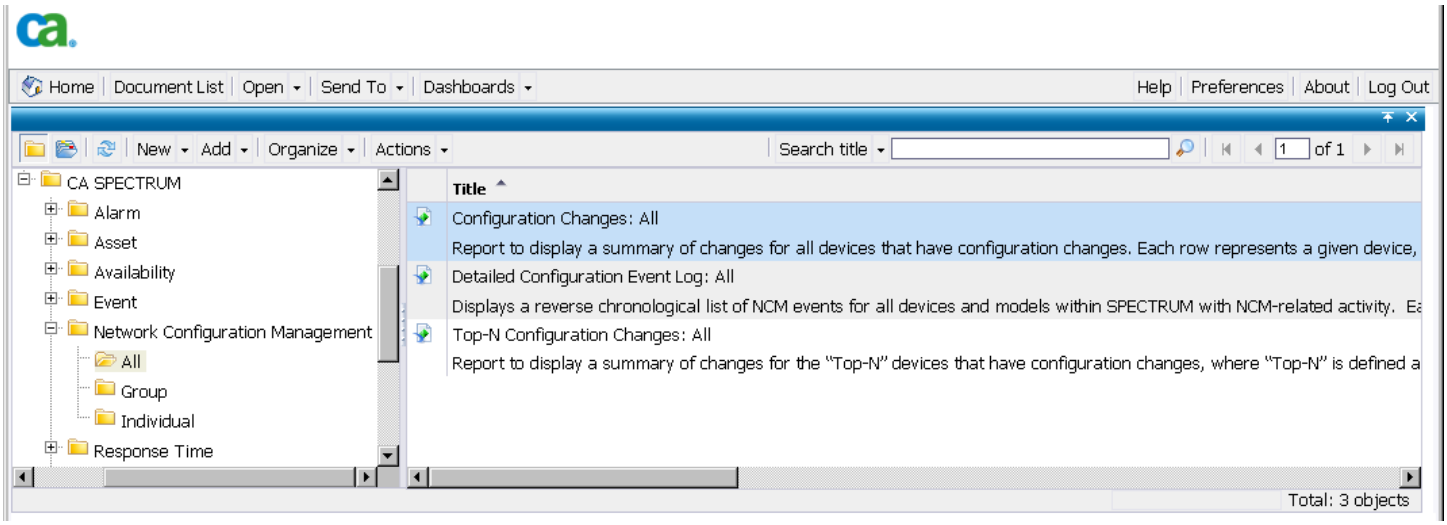
Generate Network Configuration Management Reports with Report Manager

You can generate Network Configuration Management reports using the Spectrum Report Manager.

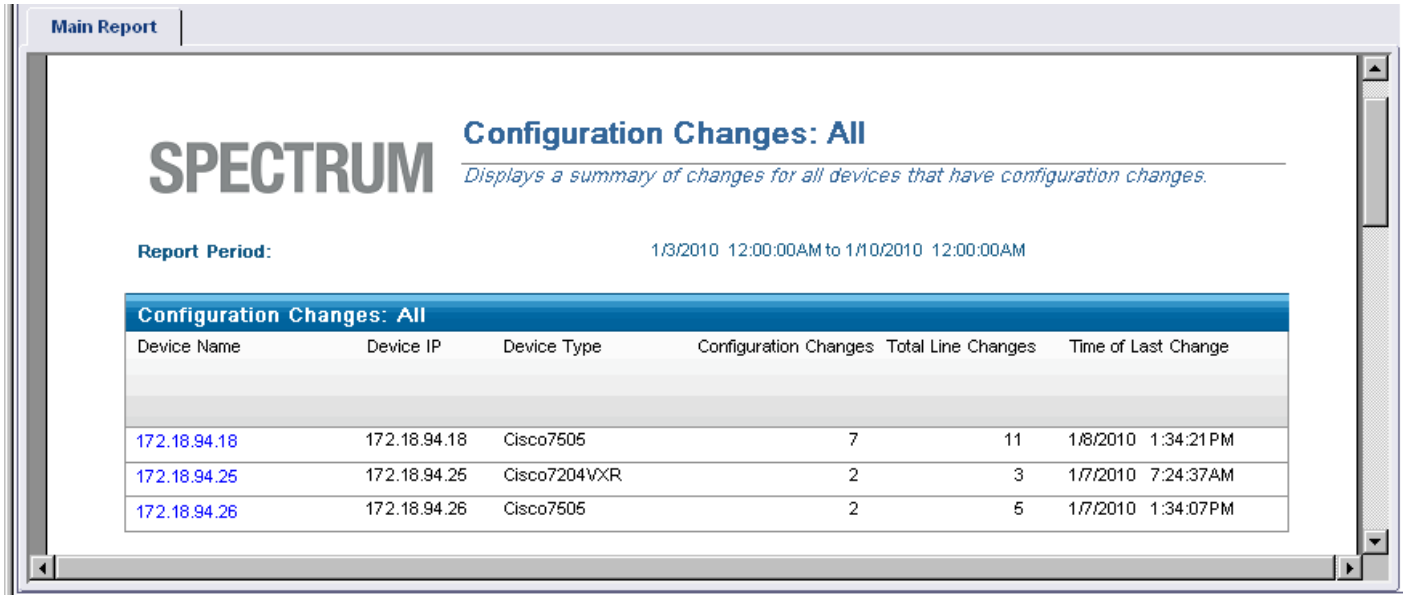
NOTE
The following example only provides an overview of the Network Configuration Management reports and features available in Report Manager. For more information, see the Report Manager section.

Follow these steps:

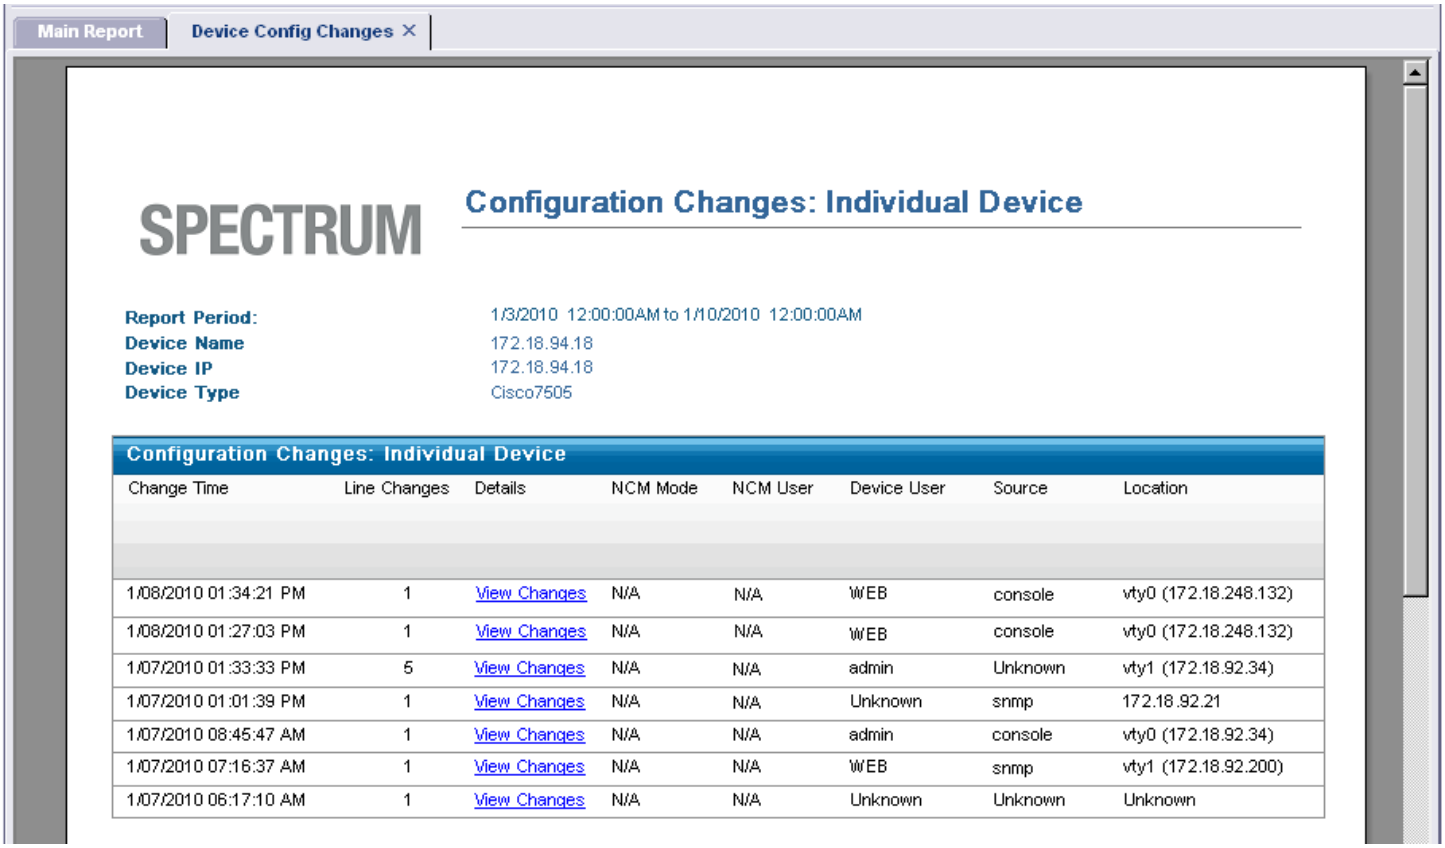
1. Select the type of test to generate.
   The following image shows the Network Configuration Management report options:



1. Configure the report. Select options for date and time range, supply a report title and subtitle, and select the landscape.
2. Click View Report to generate the report.
   The report displays. The following image shows an example of report results:



3. Click a Device Name hyperlink to examine results at the device level.
   The following image shows an example. From this view, you can click the View Changes hyperlink to view added, removed, changed, and irrelevant lines in the configuration of the selected device.



Network Configuration Manager Device-Level Tasks

This chapter describes how to manually capture, export, and upload configurations for devices in your network using Network Configuration Manager.

Manually Capture Configurations

Network Configuration Manager attempts to capture device configurations immediately after any change occurs. An unsolicited notification of configuration change can be either traps or MIB objects that are sent from the device where the change occurred. When it receives an unsolicited notification, the SpectroSERVER performs a capture and saves the configuration in the database to provide updated configuration data. You can also manually capture device configurations in OneClick.

Follow these steps:

1. Select a single device in the Explorer tab.
   The device appears in the List tab of the Contents panel.
2. Select the Host Configuration tab in the Component Detail panel.
   The results of any previous captures display.
3. Click the Capture Configuration icon.
   The results of the capture appear. Either a new configuration appears in the list or the last verified time is updated for the current configuration.

Manually Upload Configurations to a Single Device

You can manually upload a configuration file to a single device on your network. When you upload a configuration file, you merge it into the existing configuration file. You can use this feature to bring a newly installed device or a replacement/ standby remote device quickly online.

When uploading to a device in the Juniper JUNOS device family, use JUNOScript API format. For more information, see Juniper JUNOS Devices.

NOTE
You can upload configurations and view the results in real time by creating a bulk Upload task. For more information, see Create Upload Task.

Approval Not Required

The process to upload a device configuration to a single device varies depending on whether approval workflow is enabled. The following procedure describes the process when approval is not required.

NOTE

For information on workflow approval options, see Configure Workflow.

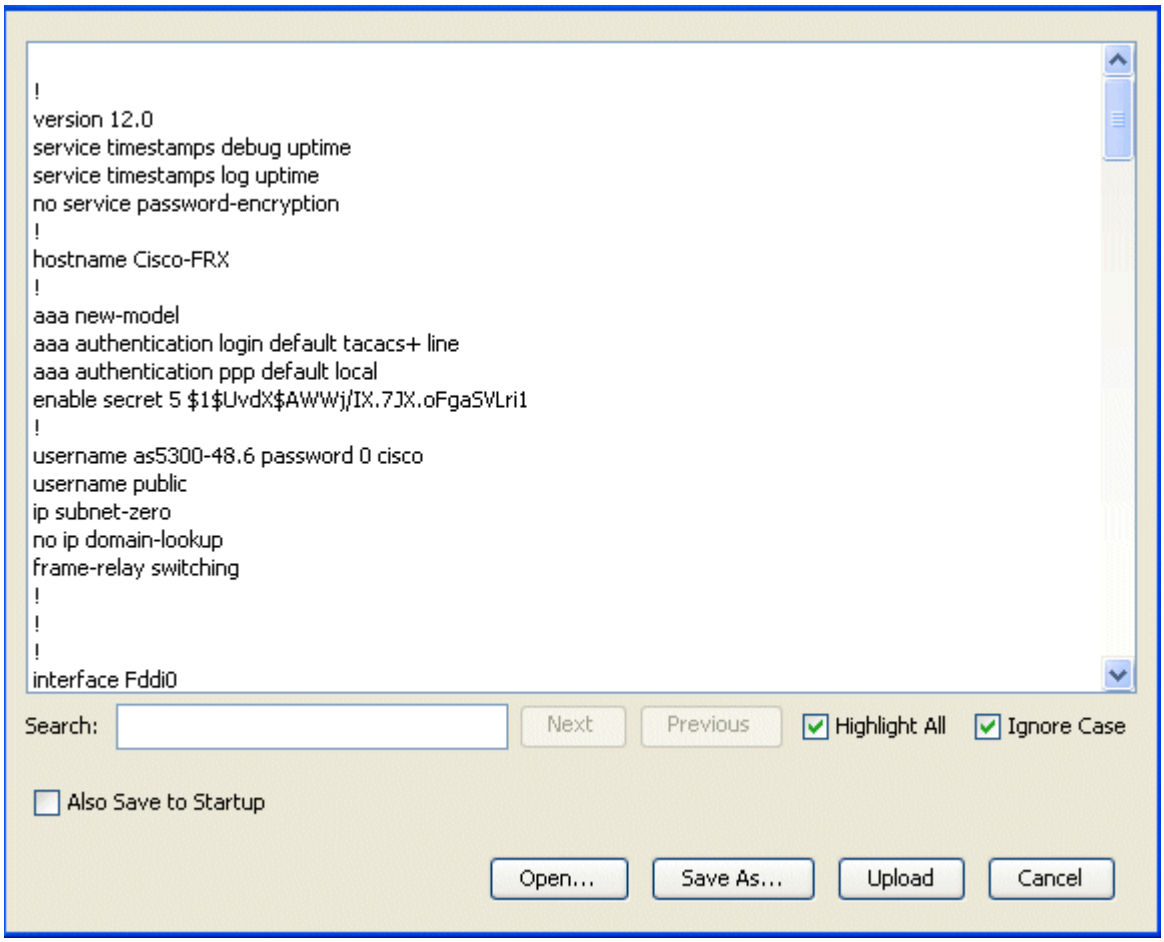
Follow these steps:

1. Select a single device or device family in the Explorer tab.
   The device or devices associated with the selected device family appear in the List tab of the Contents panel.
2. Select the Host Configuration tab in the Component Detail panel.
   The results of any previous captures display.
3. Click the Upload icon.

   NOTE

   If approval is required, the Approval Required dialog appears. Go to Approval Required to create a request for approval.

   The Upload Configuration screen appears with the last known configuration information for the selected device as shown in the following example:



4. Perform any of the following optional steps:
   - Edit configuration content as desired.
   - Enter criteria in the Search field to locate specific lines in the configuration file to change content or to verify content prior to an upload.
   - Select Also Save to Startup to write this configuration to the startup configuration. This will cause the configuration file to be loaded into the device when rebooted.

     NOTE
     This feature is only supported for Cisco, Foundry, and Nortel Passport L3 devices.
   - Click Open to import a previously exported configuration file that is saved locally on your system.
   - Click Save As if you want to save and export this configuration file in txt or html format.
5. Click Upload to upload the configuration file to the selected device.
   The message “The configuration upload succeeded” appears when the procedure is complete.

   NOTE
   Scheduling tasks is an available feature of bulk tasks. If you want to schedule your Upload task, see Network Configuration Manager Bulk Tasks.

Upload Configurations to a Single Device (Approval Required)

If approval workflow is enabled, your configuration changes must be approved before they can be processed. This is accomplished by creating a task for the upload request which can then be run after approval.

NOTE

For information on approval workflow options, see Configure Workflow.

Follow these steps:

1. Select a single device or device family in the Explorer tab.
   The device or devices associated with the selected device family appear in the List tab of the Contents panel.
2. Select the Host Configuration tab in the Component Detail panel.
   The results of any previous captures display.
3. Click the Upload icon.
   The Approval Required dialog appears.
4. Click Yes to continue.
   The Create NCM Task appears.
5. Create the task as follows:
   a. Enter a unique name in the Name field.

      NOTE
      Network Configuration Manager provides a default name (<*task type*>.YY-MM-DD_HH:MM.<*user name*>). For example, Upload.2006-10-17_15:48:04.Administrator.

   b. Enter a description for the task in the Description field.
   c. Select Reusable Task if you want the task to be available after it has run.
   d. Click Edit to specify content for uploading and merging into the device configuration in the Upload Content box. You can also click Open to import content from a text file. After you have made changes, you can click Save As to save and export this configuration file in txt or html.
   e. (optional) Enter criteria in the Search field to locate specific lines in the configuration file.
   f. Select Commit to Startup (if applicable) to copy the entire running configuration to the startup configuration after new content is merged.
   g. Select Alarm device on failure to generate an alarm on each device on which the task fails.
   h. Click Request Approval.

   The Approval Required dialog appears.
6. Select a user and enter an email address for a Task Approver, enter a task description (optional), and click OK to generate the request.
   A confirmation dialog appears indicating the request creation was successful. An email is sent to the Task Approver and the generated task appears in the Tasks folder in the Explorer tab.

   NOTE
   For email configuration information, see the OneClick Administration section.
7. Check approval status and run the task as described in Start a Task.

Network Configuration Manager Bulk Tasks

This chapter describes how to create an on-demand bulk Upload task, Sync task, and Save to Startup task with Network Configuration Manager. These tasks interact with devices by capturing and uploading host configurations. You can create a task to run anytime on a single device or on a list of devices. These on-demand tasks are useful if you want to roll out the same configuration (with minor differences such as IP addresses) to multiple devices on your network.

A task can be defined as reusable. A reusable tasks persists after execution and can be run again. If a task is not reusable, once it is run on a device or global collection, it is sent to the Lost and Found view and purged within 24 hours.

Create Upload Task

Create an automatic Upload task to perform bulk configuration uploads. A bulk Upload task merges new content into the running configurations of one or more selected devices. Devices are processed in random order.

WARNING
If you are uploading to Enterasys/Riverstone SSR devices, see Determine How an Enterasys/Riverstone SSR Device Responds to an Upload Task before continuing with this task. If you are uploading to a device in the Juniper JUNOS device family, you must use JUNOScript API format; for more information, see Juniper JUNOS Devices.

Follow these steps:

1. Select a single device, device family, global collection, a search result entry, or a container (such as Universe) in the Explorer tab.
2. Click the List tab and select the devices for the Upload task.
3. Select Upload Task from the Create NCM Task icon on the toolbar.
   The Upload Task dialog opens.

   NOTE
   If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or lack the necessary privileges.
4. Click Continue.
   The Create Task dialog appears.
5. Enter task information as follows:
   a. (Optional) Enter a unique name in the Name field.

      NOTE
      Network Configuration Manager provides a default name (<*task type*>.YY-MM-DD_HH:MM.<*user name*>). For example, Upload.2006-10-17_15:48:04.Administrator.
   b. (Optional) Enter a description for the task in the Description field.
   c. Select Reusable Task to make the task reusable.
   d. Click Edit to specify content for uploading and merging into the device configuration in the Upload Content box. You can also click Open to import content from a text file. After you have made changes, you can click Save As to save and export this configuration file in txt or html.
   e. Enter criteria in the Search field to locate specific lines in the configuration file.
   f. Select Commit to Startup (if applicable) to copy the entire running configuration to the startup configuration after new content is merged.
   g. Select Alarm device on Failure to generate an alarm on each device on which the task fails.
6. If approval is required (as indicated by the Request Approval button), take the following steps:
   a. Click Request Approval.
      The Approval Required dialog appears.
   b. Select a user and enter an email address for a Task Approver, enter a task description (optional), and click OK to generate the request.
      A confirmation dialog indicates that the request was created successfully. An email message is sent to the Task Approver ,and the generated task appears in the Tasks folder in the Explorer tab.

      NOTE

      For email configuration information, see the OneClick Administration section.
   c. Check approval status and run the task as described in Start a Task.

      NOTE
      For information on approval workflow options, see Configure Workflow.

7. If approval is not required (as indicated by the Save button):
   a. Click Save.
      The Task Saved dialog appears.
   b. Take one of the following steps:
      - Click Upload to upload the task to the selected device.
        The Upload Task Results dialog appears, and the generated task appears in the Tasks folder in the Explorer tab. For more on the results dialog, see View Task Results in Real Time.
      - Click Schedule to schedule the task for future execution. Scheduling is described in Schedule a Task.
        The task is saved and runs according to its schedule.
      - Click Close to save the task; it is available to run at a future time. You can edit and run the task by selecting it from Tasks in the Explorer tab under Configuration Manager.

Determine How an Enterasys/Riverstone SSR Device Responds to an Upload Task

Enterasys/Riverstone SSR devices do not respond consistently to configuration uploads. Some of these devices replace both the running and startup configurations with uploaded content. Others merge the uploaded content into both the running and startup configuration. Configuration captures performed on Enterasys/Riverstone SSR devices provide the startup configuration and not the running configuration. Therefore, we recommend testing devices that are running Enterasys firmware to verify the running and startup configurations.

Follow these steps:

1. Select a single SSR device from a search result or container (such as Universe) in the Explorer tab.
2. Click the List tab in the Contents panel.
3. Click the Host Configuration tab in the Component Detail panel.
   Previously captured configurations display.
4. Select the Capture Configuration icon to capture the current configuration of the selected device.
5. Select the Upload icon.
   The Upload Configuration screen appears. The content of the current startup configuration displays in the bottom pane.
6. Edit the existing configuration in the Upload Configuration screen. For example, remove the location line value (or remove a line):
   ```
   system set location "value"
   ```
7. Select the Upload icon again to upload the modified device configuration. Select the Capture Configuration icon again to capture the new configuration from the device.
   If the location is not present in the newly captured configuration, it indicates that the device is replacing (not merging) both the running and the startup configuration with the uploaded content.

Create Sync Task

Create an automatic Sync task to capture and verify policy-compliant device configurations for selected devices on your network and view the results in real time. When a Sync task captures device configuration, it checks the configuration against all policies pertaining to the device and, if specified, against the device startup configuration. Devices are processed in random order.

See Network Configuration Manager Policies for details about Network Configuration Manager policies.

See About Global Synchronization for details about running global sync tasks in background mode.

Follow these steps:

1. Select a single device, device family, global collection, a search result entry, or a container (such as Universe) in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices that you want to include in the Sync task.

3. Click Sync Task from the Create NCM Task icon on the toolbar.
   The 'Select device(s) for Sync Task' dialog opens.

   NOTE
   If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or do not have necessary privileges.
4. Enter task information as follows:
   a. Enter a unique name in the Name field.

      NOTE
      Network Configuration Manager provides a default name (<*task type*>.YY-MM-DD_HH:MM.<*user name*>). For example, Sync.2010-09-09_15:48:04.Administrator.
   b. Enter a description for the task in the Description field.
   c. Select 'Alarm on device if startup differs' and appropriate severity to generate an alarm on each device where the captured configuration differs from its startup configuration.
   d. Click Edit Schedule to schedule the task for future execution. Scheduling is described in Schedule a Task.
   e. Select Reusable Task to make the task reusable.
5. Take one of the following steps:
   – Click Save to save the task; it is available to run at a future time. You can run the task by selecting it from Tasks in the Explorer tab under Configuration Manager.
   – Click Run Sync Task Now.
   The Sync Task Results dialog opens, and the generated task appears in the Tasks folder in the Explorer tab. For more information, see View Task Results in Real Time.

Create a Save to Startup Task

Create an automatic Save to Startup task to write a current running configuration to the startup configuration of one or more selected devices. A device saves its configuration in NVRAM (Nonvolatile Random Access Memory).

Devices are processed in random order.

Follow these steps:

1. Select a single device, device family, global collection, a search result entry, or a container (such as Universe) in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices to upload.
3. Click Save to Startup Task from the Create NCM Task icon on the toolbar.
   The Save to Startup Task dialog opens.

   NOTE
   If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or lack the necessary privileges.
4. Enter task information as follows:
   a. (Optional) Enter a unique name in the Name field.

      NOTE
      Network Configuration Manager provides a default name (<task type>.YY-MM-DD_HH:MM.<user name>). For example, WriteStartup.2006-10-17_15:48:04.Administrator.
   b. (Optional) Enter a description for the task in the Description field.
   c. Select Reusable Task to make the task reusable.
5. If approval is required (as indicated by the Request Approval button), take the following steps:
   a. Click Request Approval.
      The Approval Required dialog appears.

b. Select a user and enter an email address for a Task Approver, enter a task description (optional), and click OK to generate the request.
A confirmation dialog indicates that the request was created successfully. An email is sent to the Task Approver and the generated task appears in the Tasks folder in the Explorer tab.

NOTE

For email configuration information, see the OneClick Administration section.

c. Check approval status and run the task as described in Start a Task.

NOTE
For information about approval workflow options, see Configure Workflow.

6. If approval is not required, take any of the following steps:
   – Click Schedule to schedule the task for future execution. Scheduling is described in Schedule a Task.
   – Click Save.
   The task is saved for future execution.
   – Click Run Save to Startup Task Now.
   The Save to Startup Task Results dialog opens, and the generated task appears in the Tasks folder in the Explorer tab. For more information, see View Task Results in Real Time.

NOTE
Any “Startup Versus Running Configurations are Different” alarms on task devices are automatically cleared by this task. For more information, see View Startup and Running Configuration Differences.

Firmware Upload

This section describes how to upload firmware for Cisco IOS and Cisco IOS - SSH Capable devices. Uploading firmware can be accomplished by either of two methods:

- Using the Load Firmware task
- Using Extension Utility scripting

WARNING
Uploading firmware is an advanced user feature and requires an expert level of knowledge. Modifying device firmware incorrectly may leave the device in an inoperative state.

About Firmware Upload

Firmware Upload is supported in that if a script is present it will use the script. If no script is present and the device supports the CISCO-FLASH-MIB, the MIB will be used.

Firmware Upload must accomplish certain tasks successfully and in a specific order for the transfer to be successful. This section describes these tasks and the firmware upload process.

NOTE
These tasks are handled by the Load Firmware Task, which is described in Create Load Firmware Task, or by a custom script.

These tasks are:

1. **Upload firmware image from the server to the device.** The device must be instructed to load the firmware image from a well-known server (the image server) to a specified flash or file system name. This upload can take minutes to hours to complete depending on the size of the image file and the network bandwidth.
2. **Upload boot command configuration to the device.** This occurs in three steps:
   a. Capture configuration. The configuration must be captured so that the new command can be inserted into the current configuration.

b. Upload change.
c. Write to NVRAM. The modified configuration must be written to startup so that the device will reload the specified image at boot time.

3. **Run reload script.** The reload command is written directly to enable mode and is not part of the configuration.

The system will use the default protocols or an override script for each phase as appropriate.

> **WARNING**
> If an error occurs in any of these steps, there is no rollback. The device is left in the last successful state.

Privileges

When uploading firmware as described in these sections, the following Network Configuration Manager privileges may be required:

- Load the Device Firmware
- Reload Device
- Schedule a Reload

For more information, see Network Configuration Manager Privileges.

Configure Device Firmware Transfer Settings

The section describes how to configure the protocol and server settings used to transfer the firmware image to the device. These settings are made at the device family level and reside in the Device Firmware Transfer Settings subview, which is available for the Cisco IOS and Cisco IOS - SSH Capable device families only. The devices in these device families support the CISCO-FLASH-MIB.

> **NOTE**
> Firmware Upload is supported out-of-box for Cisco IOS and Cisco IOS - SSH Capable device families only. For all other devices, the Extension Utility may be used to specify a Load Device Firmware script. See Network Configuration Manager Extension Utility for more information.

Follow these steps:

1. Select the Cisco IOS or Cisco IOS - SSH Capable device family from Device Families in the Explorer tab. Information and configurations appearin the Information tab of the Contents panel.
2. Expand the Device Firmware Transfer Settings subview.
   Firmware transfer options let you configure a firmware image transfer from a server or provide a custom script.
3. Take one of the following steps:
   – Modify the Firmware Image Transfer Protocol as needed.
   – Enter a Load Device Firmware script. For details on entering a script, see Enter a Configuration Script.

> **WARNING**
> If a script is present, the script is used, regardless of what is specified for the Firmware Image Transfer Protocol.

Display Cisco Flash Partition Information

In order to successfully upload a new firmware image to a device, you must have enough disk space available to support the image. This section describes a convenient way to review the available resources on a device before attempting a firmware upload.

> **NOTE**
> You can also display partition information for the device when creating the Load Firmware Task using the View Partitions button on the Create NCM Task dialog. For more information, see Create Load Firmware Task.

To display Cisco flash partition information

1. Select a device from either the Cisco IOS or Cisco IOS - SSH Capable device families in Device Families in the Explorer tab.
   Information and configuration settings for the device display in the Information tab of the Contents panel.
2. Expand the Cisco Flash Partitions subview.
   The following information appears:
   - **Name**
     Partition name.
   - **Number of Files**
     Number of files within the partition.
   - **Free Space**
     Amount of space available in the partition. There must be enough free disk space to support the new firmware image to be uploaded.
   - **Total Space**
     Total amount of space allocated to the partition.

Create Load Firmware Task

This section describes how to create a Load Firmware task, which is used to upload firmware to Cisco IOS and Cisco IOS - SSH Capable devices.

> **NOTE**
> To complete this task, you need to specify where on the device to upload the new firmware image. The target location must have enough space available to support the new image. To review the available resources on the device before creating the task, see Display Cisco Flash Partition Information.

Follow these steps:

1. Select a device from either the Cisco IOS or Cisco IOS - SSH Capable device families in Device Families in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices for the Load Firmware task.
3. Select Load Firmware Task from the Create NCM Task icon on the toolbar.
   The Select Device(s) for Load Firmware Task dialog opens.

   > **NOTE**
   > If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or do not have necessary privileges.
4. Click Continue.
   The Create NCM Task dialog appears.
5. Create the task as follows:
   a. Enter a unique name in the Name field.

      > **NOTE**
      > Network Configuration Manager provides a default name (<*task type*>.YY-MM-DD_HH:MM.<*user name*>). For example, LoadFirmware.2006-10-17_15:48:04.Administrator.

   b. Enter a description for the task in the Description field.
   c. Select Reusable Task to make task reusable.
   d. Enter Image Information:
      - **Firmware Image Name**
        The file name of the firmware image on the image server.
      - **Destination**

The file name of the image as it will be on the device. Often this is the same name as that on the server and the value will auto-fill.

- **Boot Command**
  The name of the image to boot from. This will auto-fill with the destination name.
  Default: boot system flash
- **Backup Boot Command**
  The name of the image to boot from if an error occurs. This should be set to the current bootable image on the device. This will auto-fill with the destination name.
  Default: boot system flash
- **Reload the device after firmware upload**
  If selected, the Reload Information fields are enabled and the device will be reloaded after the firmware upload is successful.
- **View Partitions**
  Click View Partitions to display the Device Partitions dialog, which displays the available resources on the device. The target location must have enough space available to support the new image.

e. Enter Reload Information (if applicable):

- **Reload Immediately**
  Select Reload Immediately to reload the device immediately after firmware upload is successful. If this option is not selected, use the Timing fields to schedule the reload.
- **Save to Startup (if modified)**
  If the running configuration has been modified but not saved, indicate whether to copy it to startup before the reload begins.
- **Telnet Login Timeout**
  The timeout value (in seconds) to be used for the telnet connection while attempting to log in to the device.
- **Telnet Command Timeout**
  The timeout value (in seconds) to be used while attempting to execute commands over the telnet connection.

f. Click Server Settings and enter the following on the Edit Server Settings dialog to override transfer settings set at the device family level:

- **Protocol**
  The protocol to be used.
- **Server Address**
  The image transfer server address from which the device will copy the firmware image.
- **Time out (seconds)**
  The time out period before the device will fail the copy from the firmware image server.
- **Image Dir**
  The subdirectory on the image transfer server from which the file will be served.
  Note: This may be required if the images are not served from the root directory of the image server.
- **User Name**
  The user name required by the image transfer server.

  NOTE

  This may not be required by the specified protocol.
- **Password**
  The password required by the image transfer server.

  NOTE

  This may not be required by the specified protocol.

6. If approval is required (as indicated by the Request Approval button), take the following steps:
   a. Click Request Approval.
   The Approval Required dialog opens.

b. Select a user, and enter an email address for a Task Approver.
c. (Optional) Enter a task description, and click OK to generate the request.
A confirmation dialog indicates that the request was created successfully. An email message is sent to the Task Approver and the generated task appears in the Tasks folder in the Explorer tab.

NOTE

For information about email configuration, see the OneClick Administration section.

d. Check approval status and run the task as described in Start a Task.

NOTE
For information on approval workflow options, see Configure Workflow.

7. If approval is not required (as indicated by the Save button):
a. Click Save.
The Task Saved dialog opens.
b. Do one of the following:
- Click Upload Firmware to process the task.
The Load Firmware Task Results dialog opens, and the generated task appears in the Tasks folder in the Explorer tab. For more information, see View Task Results in Real Time.
- Click Schedule to schedule the task for future execution. Scheduling is described in Schedule a Task.
The task is saved and runs according to schedule.
- Click Close to save the task; it is available to run at a future time. You can edit and run the task by selecting it from Tasks in the Explorer tab under Configuration Manager.

Create Reload Task

Create a Reload task to reload a device after firmware has been uploaded. This task is available for Cisco IOS and Cisco IOS - SSH Capable devices.

NOTE
The functionality provided by the Reload task is also optionally available in the Load Firmware task.

Follow these steps:

1. Select a device from either the Cisco IOS or Cisco IOS - SSH Capable device families in Device Families in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices for the Reload task.
3. Select Reload Task, Reload Task from the Create NCM Task icon on the toolbar.
The Select Device(s) for Reload Task dialog opens.

NOTE
If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or lack the necessary privileges.

4. If approval is required (as indicated by the Request Approval button), take the following steps:
a. Click Request Approval.
The Approval Required dialog opens.
b. Select a user, and enter an email address for a Task Approver.
c. (Optional) Enter a task description, and click OK to generate the request.
A confirmation dialog indicates that the request was successfully created. An email message is sent to the Task Approver, and the generated task appears in the Tasks folder in the Explorer tab.
Note: For information about email configuration, see the OneClick Administration section.
d. Check approval status and run the task as described in Start a Task.
When you start the task after it has been approved, the Reload Task dialog appears

NOTE
For information on approval workflow options, see Configure Workflow.

5. If approval is not required, click Run Reload Task Now.
   The Reload Task dialog appears.
6. Create the task as follows:
   a. Enter Reload Information:
      - **Reload Immediately**
        Select Reload Immediately to reload the device immediately. If this option is not selected, use the Timing fields to schedule the reload.
      - **Warm**
        Reload Warm (skip copying the image to NVRAM and uncompressing it).
      - **Save to Startup (if modified)**
        If the running configuration has been modified, indicate whether to copy it to startup before the reload begins.
      - **Telnet Login Timeout**
        The timeout value (in seconds) to be used for the telnet connection while attempting to log in to the device.
      - **Telnet Command Timeout**
        The timeout value (in seconds) to be used while attempting to execute commands over the telnet connection.
   b. Click OK.
      The Reload Device Task Results dialog opens, and the generated task appears in the Tasks folder in the Explorer tab. For more information, see View Task Results in Real Time.

Create Cancel Reload Task

A Cancel Reload task is used to cancel a pending reboot that has been scheduled on a device. This task is available for Cisco IOS and Cisco IOS - SSH Capable devices.

Follow these steps:

1. Select a device from the Cisco IOS or Cisco IOS - SSH Capable device family in Device Families in the Explorer tab.
2. Click the List tab in the Contents panel and select the devices for the Reload task.
3. Select Reload Task, Cancel Reload Task from the Create NCM Task icon on the toolbar.
   The Select Device(s) for Cancel Reload Task dialog appears.

   NOTE
   If the selected devices do not appear in the Allow tab, click Disallow to display devices that are either disabled from Network Configuration Manager tasks or do not have necessary privileges.
4. If approval is required (as indicated by the Request Approval button), take the following steps:
   a. Click Request Approval.
      The Approval Required dialog opens.
   b. Select a user and enter an email address for a Task Approver.
   c. (Optional) Supply a task description.
   d. Click OK to generate the request.
      A confirmation dialog indicates that the request was successfully created. An email message is sent to the Task Approver, and the generated task appears in the Tasks folder in the Explorer tab.

      NOTE

      For information about email configuration, see the OneClick Administration section.
   e. Check approval status and run the task as described in Start a Task.

      NOTE
      For information about approval workflow options, see Configure Workflow.
5. If approval is not required, perform any of the following tasks:

- Click Schedule to schedule the task for future execution. Scheduling is described in Schedule a Task.
- Click Save.
  The task is saved for future execution. Exit this procedure.
- Click Run Cancel Reload Task Now.
  The Cancel Reload Device Task Results dialog opens, and the generated task appears in the Tasks folder in the Explorer tab. For more information, see View Task Results in Real Time.

Load Device Firmware Script

The Load Device Firmware Script can be used to initiate a load of the specified firmware image on a device as an alternative to the internal MIB-based support for Load Firmware Task (only for the Cisco devices that support CISCO-FLASH-MIB). For more information on using scripts, see Network Configuration Manager Extension Utility.

Managing Tasks

Associating Tasks with Global Collections

Tasks can be associated with global collections. By associating a task with a global collection, the task runs on all members of the collection that support the task type at execution time. Associating a task with a global collection can occur during initial task creation or after the task already exists.

> **NOTE**
> The 'Include Global Collection in NCM Task' privilege is required for a user to associate a task with a global collection. For more information on privileges, see Network Configuration Manager Privileges.

Associate a New Task

You can associate a task with a global collection when you create the task.

Follow these steps:

1. Select the Global Collections node in the Explorer tab.
   A list of defined global collections appears in the List tab of the Contents panel.

   > **NOTE**
   > If no global collections exist, you must create one before you can continue. For more information, see the Modeling and Managing Your IT Infrastructure section.

   On the List tab, select the global collection with which to associate a task.
2. The global collection is highlighted and the Create NCM task icon is enabled.
3. Click the Create NCM task icon and select the task that you want to create and associate with this global collection.
   The 'Select device(s)' dialog for the task appears.
4. Continue with the creation of the task as described in Network Configuration Manager Bulk Tasks or Firmware Upload, depending on the task.
   When you have finished:
   - The new task appears in the NCM Tasks subview on the Information tab for the global collection.
   - The new task appears in the Tasks folder in the Explorer tab. When viewing the Information tab for the task, the global collection with which the task is associated appears in the Global Collections subview.

   When the task is executed, it runs on all members of the global collection that support the task type at the time of execution.

Associate an Existing Task

You can associate an existing task with a global collection, and you can also perform the association while creating the task. The following procedure can be used to add another global collection to an existing task or to remove a collection.

Follow these steps:

1. Select the task from the Tasks folder under Configuration Manager in the Explorer tab.
   Information for the task appears in the Information tab of the Contents panel.
2. Expand the Global Collections subview.
   Any global collections that are associated with the selected task appear in the table.
3. Click the Add or Remove Global Collections icon above the table.
   The Task Members Editor dialog opens.
4. Select global collections from the Available Global Collections pane (on the right). Use the arrows to move them into the Associated Global Collections pane (on the left) to be associated with this task.
   Global collections that are in the Associated Global Collections pane will be associated with this task.
5. Click Save, and then Yes in the subsequent confirmation dialog.
   The associated global collections appear in the table. When the task is executed, it will run on all members of the associated global collections that support the task type at the time of execution.

Scheduling Bulk Tasks

Bulk tasks can be scheduled. Scheduling can be accomplished either at the time of creation of a task or after the task has run (in the case of reusable tasks).

The following tasks can be scheduled: Upload Task, Sync Task, Save to Startup Task, Load Firmware Task, and Cancel Reload Task.

> **NOTE**
> Reload tasks cannot be scheduled through this mechanism; instead, the internal scheduling mechanism of a device is used. If you define a script to accomplish the reload operation, the script must leverage the scheduling mechanism of the device to schedule reload tasks. For more information, see Enter a Configuration Script.

A task can be associated with only one schedule. If a task already has an existing schedule when a new schedule is specified, the previous schedule is removed. You must manually delete recurring tasks; no automatic cleanup is performed.

Tasks are essentially distributed. Each "local" task runs at the scheduled time, based on the local time zone of the local landscape. The recommended best practice is to have all SpectroSERVERs working with the same time zone setting. The Time Completed column in the Succeeded Device List and Failed Device List tables show at what time the task operation was attempted on a particular device. This capability can help determine the time when a task is run in a DSS with multiple landscapes in different time zones.

> **NOTE**
> The Network Configuration Manager Schedule NCM Tasks privilege is required to schedule bulk tasks.

Reusable Tasks

Defining a task as reusable allows you the ability to save and run a task multiple times without having to redefine it. You can also create a recurring schedule to automatically run the task at predetermined times.

For information on scheduling a task, see Schedule a Task.

> **NOTE**
> A task with a recurring schedule will automatically be created as a Reusable task.

A task is designated as reusable when the Reusable Task option is specified during task creation.

The task is identifiable as reusable in following areas:

- In the Reusable field in the List table in the Contents panel
- Within General Task Information in the Information tab in the Component Detail panel

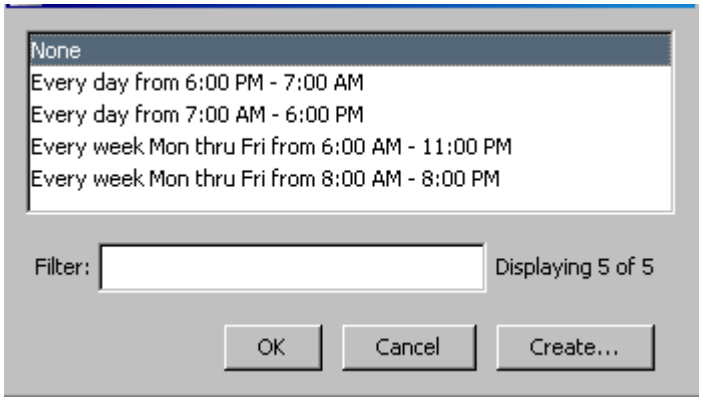
Schedule a Task

Scheduling a task lets you define a task and then specify a future date and time when it runs. Schedule a task to run one time only or on a recurring basis. You can set up the schedule at the time of task creation. Use the Schedule or Edit Schedule button. Or, for reusable tasks, you can set up a schedule at any time.

Note: Tasks run from the Host Configuration tab cannot be scheduled.

Follow these steps:

1. Follow the procedures outlined in Network Configuration Manager Bulk Tasks and Firmware Upload to create any of the following tasks: Upload Task, Sync Task, Save to Startup Task, Load Firmware Task, and Cancel Reload Task. The Schedule or Edit Schedule button appears on the creation dialog where it is available.
   Note: If Approval Workflow is enabled, the Schedule button is not available during task creation; only approved tasks can be scheduled. You must set up a schedule after the task has been created. See below for the procedure.
2. Select the Schedule or Edit Schedule button.
   The Select Schedule dialog appears as shown in the following image:



3. Take one of the following steps:
   – Select a default schedule, and click OK.
   – Create a custom schedule: click the Create button, specify schedule options, and click OK.
   The custom schedule is added to the list. Select the new schedule and click OK.

   The task is now scheduled. The schedule appears next to the Schedule button.

   NOTE
   To remove the schedule for a task, select the default schedule of None.
4. If you want to run this task multiple times, select Reusable Task. If you specified a recurring schedule in the previous step, the task should be created as a reusable task.

   NOTE
   Reusable tasks will not be cleaned up automatically.
5. Take one of the following steps:
   – Save task. If you have specified a schedule and want to run the task from the List tab in the Tasks folder at a later time, click the Save button. The task is created with the associated schedule (if any).
   – Run task. If you want to run the task right away, click the Run button.

   The task is saved and appears in the Tasks folder in Explorer with the Scheduled Task icon
   Schedule information is available in the Schedule field in the List table in the Contents panel and within General Task Information in the Information tab in the Component Detail panel.

You can also create or modify a schedule after task creation for any of the following reasons:

- Before setting up the task to run on a recurring basis, you want to test the task thoroughly.
- Because a task that requires approval cannot be scheduled until after it has been approved, you must first create the task and then wait for the approval.
- Site situations have changed, requiring schedule modification.

Follow these steps:

1. Select Tasks in Explorer and the List tab in the Contents panel.
   All defined tasks appear.
2. Select a task whose schedule you want to create or modify. The following conditions must be met for a task to be eligible for scheduling:
   – Task must be eligible to be run. Either it is a reusable task (Reusable = Yes) or if it is not reusable, then it has not been run yet (Inactive state).
   – If Approval Workflow is enabled, task must be in Approved state.
   The Schedule button in the toolbar is enabled for the task if it can be scheduled.

   NOTE
   If the Schedule button is not enabled, verify that the eligibility conditions are met.
3. Click the Schedule button.
   The Select Schedule dialog opens.
4. Select or create a schedule.

Starting and Stopping Tasks

This section describes how to start, stop, resume, and delete tasks.

Start a Task

This procedure describes how to start a task that has already been created. Tasks can be started if they are not already running and they are reusable tasks or, if they are not reusable tasks, have not been run at all. If approval is enabled, then the tasks have to be in the Approved state.

NOTE
Any configuration change task that requires approval must be approved before it can be run.

Follow these steps:

1. Select the task from the Tasks view under Configuration Manager in the Explorer tab.
2. Select the List tab in the Contents panel.
   Information about the task displays in the List table. A value of Awaiting Approval in the State column indicates the request has been generated but not yet approved; a value of Approved indicates the request has been approved and can be run.
3. Select a task to start.
   The Start button is enabled if the task can be started.
4. Click the Start Selected Task icon to run the task.
   If information is required for a task, refer to the section for that task. Otherwise, the task starts and the Task State value is updated.
   Depending on the task, a results dialog can appear. For more information, see View Task Results in Real Time.

Stop a Task

You can stop a task while it is running.

Follow these steps:

1. Select Tasks under Configuration Manager in the Explorer tab.
2. Click the List tab in the Contents panel, and select a task.

   NOTE
   Only tasks with a State of Running can be stopped.
3. Click the Stop Selected Task icon in the toolbar.
   The task stops, and the Task State value is updated.

Resume a Task

A task can be resumed if it has been stopped and has devices left in the Remaining Device List. When you resume a task, Network Configuration Manager only attempts to run the operation on those devices in the Remaining list. The operation is not reattempted on those devices that previously succeeded or failed and were removed from the Remaining list.

Follow these steps:

1. Select Tasks under Configuration Manager in the Explorer tab.
2. Click the List tab in the Contents panel and select a task to be resumed.

   NOTE
   Only tasks that have devices remaining, as represented by a positive value in the Remaining column, can be resumed.
3. Click the Resume Selected Task icon in the toolbar.
   The task starts, and the State value is updated.

Delete a Task

You can delete tasks in OneClick.

NOTE
Tasks that are running or locked for edit cannot be deleted.

Follow these steps:

1. Select Tasks under Configuration Manager in the Explorer tab.
2. Click the List tab in the Contents panel and select a task for deletion.
3. Click the Delete selected tasks icon in the toolbar.
   The Confirm Delete dialog appears.
4. Click Yes to delete.
   The selected task is deleted.

Viewing Task Information

This section describes how to view information for tasks that have been created and that have been run.

View Task Results in Real Time

After you have started an Upload, Sync, Save to Startup, Load Firmware task, Reload, or Cancel Reload task, a results dialog opens. The name, condition, type, and status (Pending, Failed, or Succeeded) of the task are shown in the Results tab. If Failed, the results appear in the Cause of Failure field.

Note: The task statistics are updated on a 10-second poll cycle.

While the task is running, you can do the following on the results dialog:

- Click the Content tab to view the content that you are uploading.

NOTE
The Content tab is available on the Upload Task Results dialog and Load Firmware Task Results dialog only.

- Click Stop to cancel the task. The task finishes processing any devices that are in progress. It then stops processing any remaining devices.
- Click Close to run the task in the background.

View Critical Statistics on All Bulk Tasks

You can view critical statistics for all bulk tasks simultaneously.

Follow these steps:

1. Select Tasks under Configuration Manager in the Explorer tab.
2. Select the List tab in the Contents panel.
   Statistics for all bulk tasks display.

View Detailed Statistics for a Bulk Task

Take different steps to view detailed statistics for a single bulk task.

Follow these steps:

1. Select a task from Tasks folder in the Explorer tab.
2. Click the Information tab in the Contents panel.
   Information on the task displays.

Task State and Status Values

The Task State (State) and Task Status values identify the current stage of execution for the task. The Task State (State) and Task Status are available when viewing task results or statistics. To access these views, see Viewing Task Information.

Task State

The following are possible Task State (State) values:

Approved
Approval workflow mode has been enabled for this task. The task has been approved by the appropriate Task Approver and can be run.

Awaiting Approval
Approval workflow mode has been enabled for this task. A request for this task has been generated but not yet approved.

Completed
The task has run successfully and is reusable. A task that is on a recurring schedule and has run at least once will have this state.

Completed awaiting Destroy
The task has run and is not reusable. The task will be purged within 24 hours.

Denied
Approval workflow mode has been enabled for this task. A request for this task was generated and has been denied by the appropriate Task Approver.

Inactive
The task has been scheduled but not yet run.

Initializing

Task preparation within DX NetOps Spectrum has started.

Running
The task is currently running. Tasks in this state can be stopped.

Stopping
The task started and then was stopped by the user.

Task Status

The following are possible Task Status values:

Failed
The task did not complete successfully. The results are displayed in the Cause of Failure field.

Pending
The task is currently running. Tasks in this state can be stopped.

Succeeded
The task has completed successfully.

Network Configuration Manager Policies

This chapter describes how to create and configure Network Configuration Manager policies. Network Configuration Manager policies monitor content in configurations and verify that device content is compliant.

> **NOTE**
> We recommend that you have configurations captured prior to setting up Network Configuration Manager policies. See Global Synchronization Task to set up a global synchronization task on your network.

About Network Configuration Manager Policies

A Network Configuration Manager *policy* defines criteria that are used to monitor content for a device host configuration. A policy is checked and compared every time a device host configuration file is captured. Devices that violate the policy can generate an alarm and can receive remediation.

Policies can be created and applied to devices, device families, and to global collections. When it is applied to a global collection, the policy is enforced on all global collection members of the selected device families in that global collection. See Network Configuration Manager and Global Collections for details about setting up global collections.

You can create two types of policies: single-line policies and multi-line block policies. They are described in the following sections.

> **NOTE**
> Configuration captures that are performed on Enterasys/Riverstone SSR devices provide the startup configuration and not the running configuration. Therefore, the startup configuration is used when determining whether a device is compliant with Network Configuration Manager policies. See Determine How an Enterasys/Riverstone SSR Device Responds to an Upload Task for information about how SSR devices handle Network Configurations Manager configuration uploads.

Single Line Policies

A single line policy compares the currently defined host configuration to the policy definition one line at a time. Each line of data in the host configuration is analyzed against the policy. This type of policy is useful when checking for the existence of a single command throughout the entire configuration.

Example

Suppose that your site has a regulation that all switches must have http enabled. A switch is brought online with the following in its configuration:

```
#http configuration
set ip http server disable
set ip http port 80
```

For this device to comply with site regulations, "set IP HTTP server disable" should be "set IP HTTP server enable". To identify and correct this situation, you can create a single line policy to check if the configuration has the line "set IP HTTP server enable". If this line is missing from the configuration, you can specify that an alarm is generated so that the condition can be repaired. From the alarm, the policy violation can be viewed and you then have the option to repair the device by scheduling a task to upload the corrected content.

Multi-line Block Policies

A multi-line block policy compares the currently defined host configuration to the policy a block at a time. The policy attempts to match corresponding blocks between the policy and the current host configuration. A block is designated by start and end tags; only data within qualifying blocks is analyzed by the policy. This type of policy is useful when monitoring settings for a block of configuration text such as an interface configuration. Most devices have multiple interfaces where unique settings for individual interfaces appear in the same configuration file.

There are two options available when enforcing a block policy: the configuration content can be compared to a pre-defined set of policy criteria, or it can be compared with the previous configuration or reference configuration in the configuration history.

When comparing with a previous or reference configuration, lines that have been changed, added, or removed are identified. Comparing with a previous or reference configuration is useful for highlighting changes that occur in the context of the block; changes that occur outside of a designated block will be shown as masked or irrelevant changes.

Example

Suppose that you want to shut down certain interfaces that have been identified by the word "shutdown" appearing in their descriptions. You can identify such devices by defining multi-line block policies in the following ways:

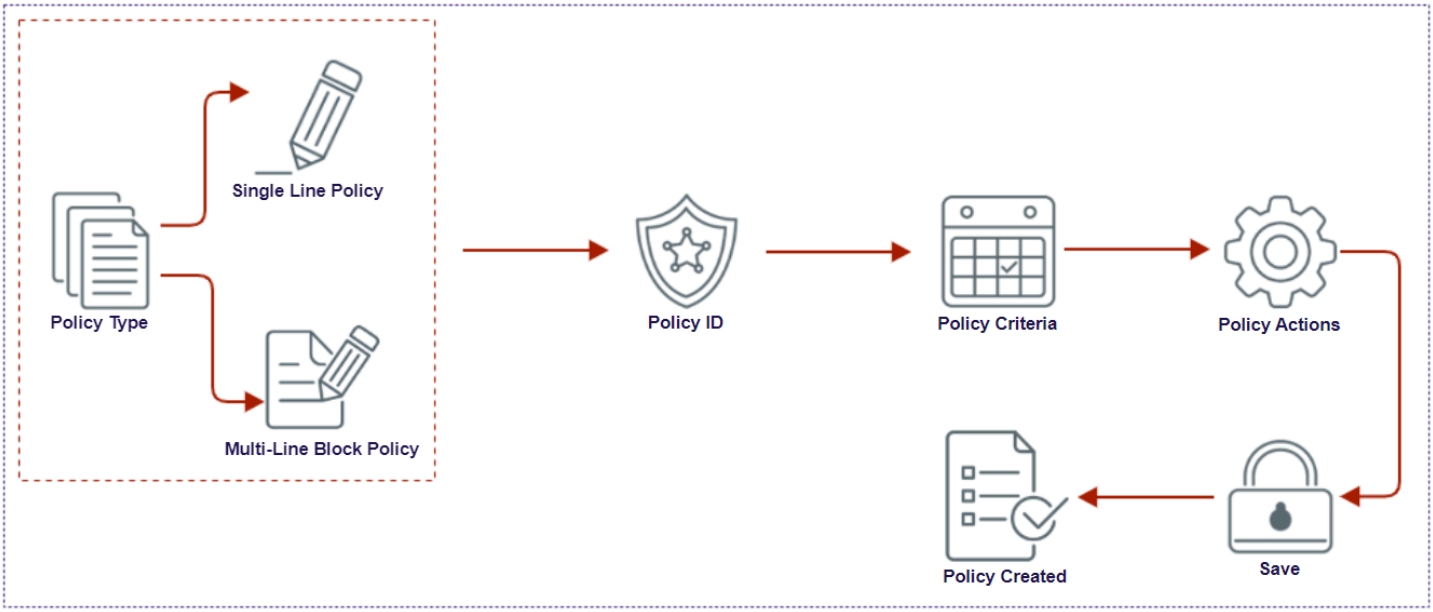
- By comparing to specified contents
- By comparing content with a script
- By comparing to another configuration

After the devices are identified, the shutdown command can then be issued easily for those interfaces that are marked for shutdown as part of the recommended upload for corrective action.

For the detailed implementation of this example of multi-line block policy, see Multi-line Block Policy Example.

Policy Creation Process

The following illustration outlines the high-level policy creation process:



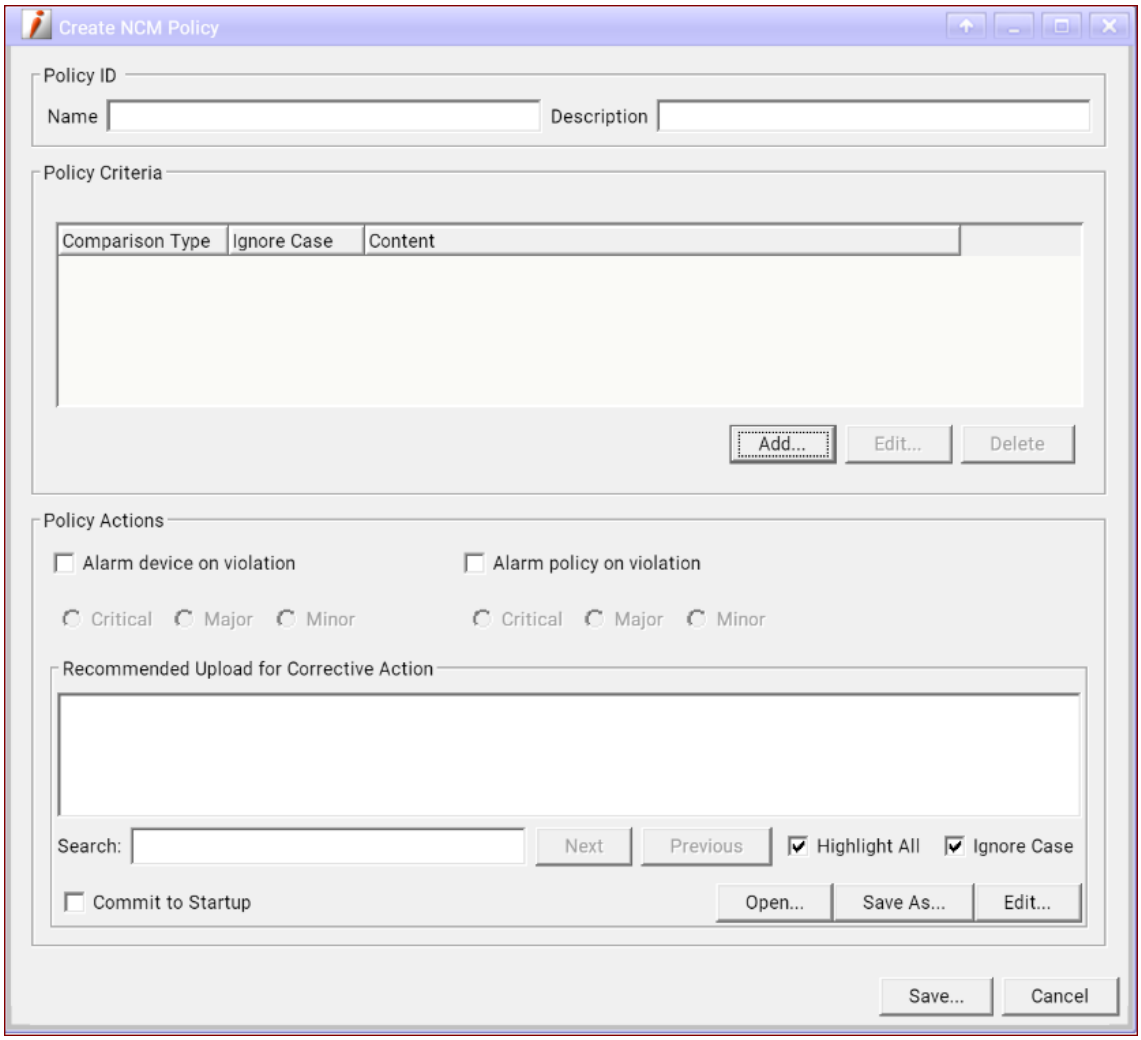
Create a Policy

A policy defines criteria that are used to monitor content for a device host configuration. You can create two types of policies: single-line policies and multi-line block policies. The following procedure describes how to create a Network Configuration Manager policy.

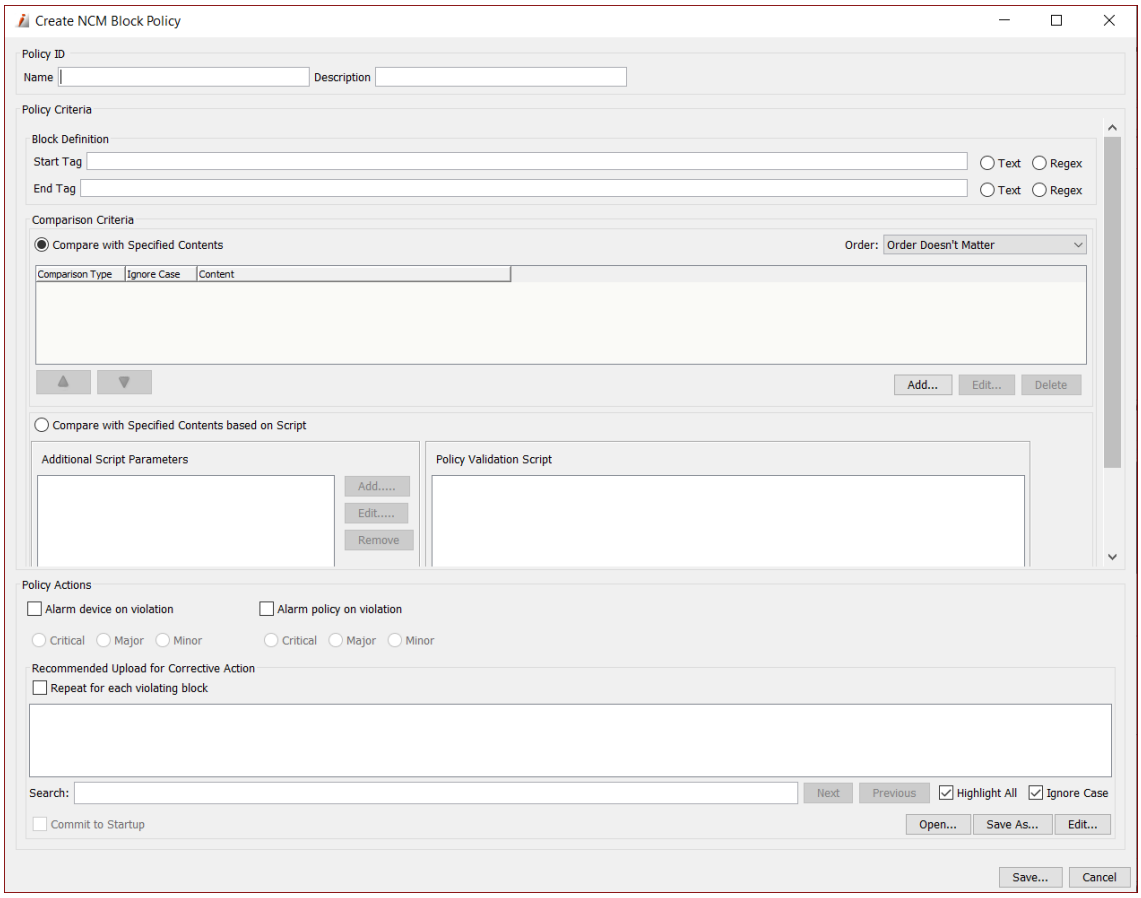
> **NOTE**
> An example is provided in the Multi-line Block Policy Example.

Follow these steps:

1. Access the **Explorer** tab in the OneClick UI.
2. Navigate to **Configuration Manager, Policies**.
3. Click the **List** tab in the **Contents** pane.
4. Select the "Create policy" icon.
   The **Select Policy Type** dialog appears.
5. Select the type of policy you want to create:
   – **Single Line Policy.** Creates a policy where only a single line of configuration is compared at a time. The **Create NCM Policy** dialog opens. The following screenshot shows the single-line policy options:



– **Multi-line Block Policy.** Creates a policy where a host's configuration is compared by qualifying blocks. The **Create NCM Block Policy** dialog opens. The following screenshot shows the multi-line block policy options:



6. In the **Policy ID** section, enter a name and description for the policy.

   NOTE
   In 10.4.2, there is no device family association section in the UI. In previous releases, this section was available.

7. In the **Policy Criteria** section of the dialog, configure policy criteria as follows:
   - For single-line policies, see Single Line Policy Criteria.
   - For multi-line block policies, see Multi-line Block Policy Criteria.
8. In the **Policy Actions** section of the dialog, do the following:
   a. Enter the alarm criteria as follows:
      - **Alarm device on violation**
        Indicates whether to alarm a device when a device is non-compliant with this policy. This is a single alarm on each non-compliant device, viewable in the Alarms tab. You can also select the severity of the alarm (Critical, Major, or Minor). You must enable the policy for this option to take effect.
      - **Alarm policy on violation**
        Indicates whether to alarm the policy when at least one device is non-compliant. This is a single alarm on a single policy, viewable in the Alarms tab. You can also select the severity of the alarm (Critical, Major, or Minor). You must enable the policy for this option to take effect.

   b. Enter a recommended upload for corrective action.
      - For single-line policies, see Single Line Policy Corrective Action.
      - For multi-line block policies, see Multi-line Block Policy Corrective Action.

   c. Select the **Commit to Startup** option to indicate whether to copy the entire running configuration to the startup configuration after the new content is merged.
9. Click **Save**.

The **Save NCM Policy** or **Save NCM Block Policy** dialog appears.

10. Click **Back** if you want to make any edits to the policy or click **Exit** to save the policy.

You have successfully created and saved a policy.

Policy Criteria

The types of policy criteria that you can specify differs between single line and multi-line block policies. This section describes how to specify policy criteria according to the type of policy you have defined. This section contains the following topics:

- Single Line Policy Criteria
- Multi-line Block Policy Criteria
- Policy Criteria Dialog

Single Line Policy Criteria

Use the following procedure to specify the comparison criteria for a single line policy.

To specify criteria for a single line policy

1. On the **Create NCM Policy** dialog in the **Policy Criteria** section, select **Add** to create criteria for comparison.
   The **Policy Criteria** dialog opens.
2. Configure policy criteria as described in Policy Criteria Dialog.
   After the **Policy Criteria** dialog is completed, the new criteria for comparison appears in the table.
3. To add more criteria or to modify existing criteria, use the **Add**, **Edit**, and **Delete** buttons.

The remainder of this dialog, including saving of the policy, is described in Create a Policy.

Multi-line Block Policy Criteria

When defining a multi-line block policy, you must specify two types of criteria: block definition criteria and comparison criteria. Block definition criteria define what constitutes the start and end of a block; comparison criteria define content that is used to compare against the current host configuration.

This section describes how to define this criteria and contains the following topics:

- About Blocks
- Specify Multi-line Block Policy Criteria
- Compare with Specified Contents
- Compare with Specified Contents based on Script
- Compare with Matching Block from Reference or Previous Configuration

About Blocks

When using multi-line block policies, you need to know what constitutes a block in the host configuration file for your device. In the following example for a Cisco IOS - SSH Capable device, a block similar to the following exists for each interface. This block would be delimited by the line "interface *name*" and the comment character "!":

```
interface Loopback0
 description "test 123"
 ip address 138.42.96.6 255.255.255.255
 ip pim sparse-dense-mode
 no ip route-cache cef
 no ip route-cache
 ipv6 address 2002:8A2A:5E12:8A2A:6006::1/128
 ipv6 enable
```

```
  ipv6 rip IPv6-1 enable
 !
```

This information is used when defining the policy. In block policy terminology, this block would be defined by:

1. **Start Tag:** interface *name*
2. **End Tag:** !

You can use either text or regular expressions to define what constitutes the start and end of a block. The following describes how the two options differ when determining what qualifies as a start or end tag.

> **NOTE**
> The values that are defined as Start Tag and End Tag is included as part of the block.

Using Text

When using text, the entire line that contains the matching text is matched to that field. For example, if you use "interface" of Text type as the start tag, this matches every line that contains the word "interface" and regards it as the starting line for a block.

Using Regular Expressions (Regex)

When using regular expressions, only an exact match of the regular expression pattern (and not the entire line) is matched to that field. For example, if you specify "interface abc" as the end tag, then only content up to "interface abc" will be considered as the end of the block. If, instead, you specified "interface abc.*" (where ".*" is a wildcard pattern in regular expressions that matches any characters in a line), then the entire line that matched "interface abc" would be considered as the end of the block.

Specify Multi-line Block Policy Criteria

The following procedure describes how to specify criteria for a multi-line block policy.

Follow these steps:

1. On the **Create NCM Block Policy** dialog in the **Policy Criteria** section, specify the following **Block Definition** criteria. You can use either text or regular expressions to define what constitutes the start and end of a block. For additional explanation on how the two options differ, see About Blocks.

   > **NOTE**
   > The values that are defined as Start Tag and End Tag are included as part of the block.
2. In the Comparison Criteria section, select one of the following options:
   - **Compare with Specified Contents**
     Specifies that the policy compares the current host configuration against user-defined content that is specified in this policy. For more information, see Compare with Specified Contents
   - **Compare with Specified Contents based on Script**
     Specifies that the policy compares the current host configuration against the provided script. For more information, see Compare with Specified Contents based on Script.
   - **Compare with Matching Block from Previous Configuration**
     Specifies that the policy compares the current host configuration to content from a previous or reference configuration. For more information, see Compare with Matching Block from Reference or Previous Configuration.

The remainder of this dialog, including saving of the policy, is described in Create a Policy.

Compare with Specified Contents

When defining a multi-line block policy, you can specify explicitly what content to check for in each block of the current configuration. This procedure describes how to set up user-defined criteria in a multi-line block policy.

To set up user-defined comparison criteria

1. On the Create NCM Block Policy dialog with the 'Compare with Specified Contents' option that is selected, specify the Order. The following are available options:
   - **Order Doesn't Matter**
     Indicates that the order of the criteria is not considered when comparing with the current host configuration. The policy is violated based on content only.
   - **Preserve Order (Allow Extra Lines)**
     Indicates that the specified content must appear in the order that is specified to comply with the policy; however, additional content that is interspersed between what is specified is allowed. The policy will be violated if some of the specified content does not exist in the configuration or if it exists in a different order. The policy ignores unmatched lines.
   - **Preserve Order with No Extra Lines**
     Indicates that the specified content must appear both in the order that is specified and contiguously to comply with the policy. The policy is violated if the configuration block does not match exactly with the specified content; any extra lines in the block content that were not explicitly defined by the specified content violates the policy.
2. Select Add to create criteria for comparison.
   The Policy Criteria dialog appears.
3. Configure policy criteria as described in Policy Criteria Dialog.
   After the Policy Criteria dialog is closed, the new criteria for comparison appears in the table. The order of the criteria in the table will be used if you have specified that order is preserved when comparing to the host configuration.
4. To add more criteria or to modify existing criteria, use the Add, Edit, and Delete buttons.

Compare with Specified Content Based on Script

When defining a multi-line block policy, you can explicitly set a script to validate content for each block of the current configuration. You define custom scripts to validate the content. DX NetOps Spectrum provides a default script for reference. By default, the bash prompt is used to execute the script. You can change the default program using the `verify-block-script-program-type` tag in the `$SPECROOT\NCM\config.xml` file.

Follow these steps:

1. Select **Compare with Specified Content based on Script** in the **Create NCM Block Policy** dialog.
2. Specify the script content and additional parameters to execute the script.
   A temporary file with validating block content is created in the `$SPECROOT\NCM\cache` folder and passed as the first argument to the script.

   NOTE
   The script rewrites TRUE or FALSE (to STDOUT)
   TRUE means Violated
   FALSE means NOT Violated
3. Select **Set** to select the predefined block policy scripts.
4. (Optional) Select **Edit** to modify the script.
   You can change the policy level content, but the script template cannot be changed once defined.
5. (Optional) Use **Clear** button to clear the content of the script.
6. Use the **Additional Script Parameters** field to capture additional parameters for the execution of the script.

For the detailed implementation, see Multi-line Block Policy Example.

Compare with Matching Block from Reference or Previous Configuration

When defining a multi-line block policy, you can specify that the policy compares the current host configuration to the previously captured configuration or to content saved as a reference configuration. Content is compared block by block. This procedure describes how to set up the policy to compare content to either a reference or the previously captured configuration.

NOTE
A reference or previous configuration must exist for the device when testing the policy; otherwise, a Policy Status of Untestable will result.

To compare content with reference or previous configuration

1. On the Create NCM Block Policy dialog with the 'Compare with Matching Block from' option that is selected, specify the type of configuration with which to compare content. The following are available options:
   - **Previous Configuration**
     Indicates that the current host configuration will be compared, block by block, to the most recent captured configuration.
   - **Reference Configuration**
     Indicates that the current host configuration will be compared, block by block, to the configuration designated as reference. For information about setting a reference configuration, see Specify a Reference Configuration.
   - **Reference or Previous Configuration**

     NOTE
     Indicates that the current host configuration is compared, block by block, to a saved configuration. First, the policy looks for a reference configuration. If a reference configuration has not been set for a particular device, then block content is compared against the previous known configuration.

     NOTE
     If a reference or previous configuration does not exist for the device when testing the policy, a Policy Status of Untestable will result.
2. (Optional) Do the following steps to specify a block identifier.
   The block identifier is used to match corresponding blocks between two configurations. You can pick out specific text from within a block and can use it as a block identifier. For example, to compare interfaces that are labeled "interface Loopback*n*" between two configurations, you must identify 'interface Loopback.*' as the block identifier.
   If a block identifier is not specified, the first line of the block is used as the block identifier. This default is sufficient usually to identify the matching block between two configurations.
   a. Select **Advanced**.
      The Specify Block Identifier dialog opens.
   b. Specify the **Block** Identifier and whether the value is Text or RegEx.
      The following is an example of a regular expression that will match corresponding lines that begin with "interface":
      ```
      (?m)^interface .*
      ```
      The following is an example of a regular expression that represents "interface *name*", where only the name of the interface (as opposed to the entire line) will be used to match corresponding blocks:
      ```
      (?m)^interface ([a-z||A-Z||0-9||/]*)
      ```
      NOTE
      When using regular expressions, regular expression capturing groups are leveraged to pick out the block identifier. This is an advanced regular expression concept. Capturing Group 1 is used as the block identifier when using regular expressions. In this example, Group 1 is ([a-z||A-Z||0-9||/]*), which identifies the name of the interface.

      For more information about using text and regular expressions in multi-block policies, see About Blocks.
   c. Select OK.
      The Block Identifier dialog closes.

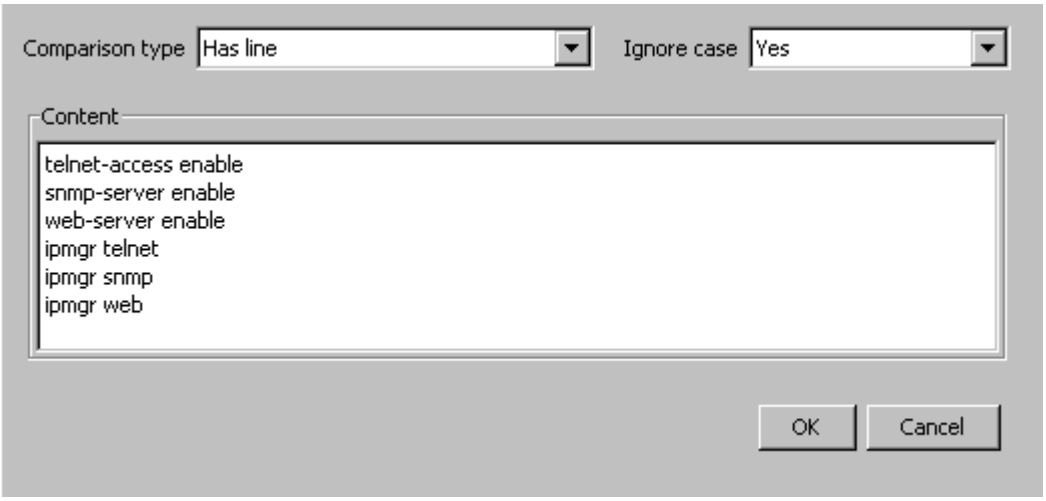
Policy Criteria Dialog

This procedure describes how to complete the Policy Criteria dialog, which is used for defining comparison criteria for single line and multi-line block policies. The content that you specify will be checked and compared every time a device's host configuration file is captured. The Policy Criteria dialog is invoked from the Create NCM Policy dialog.

To define criteria using the Policy Criteria dialog

1. Select a comparison type for the policy. Available comparison types are:
   - **Has line**
     Indicates that the host configuration file contains all lines that are specified. If met, the policy is compliant and passes.
   - **Does not have line**
     Indicates that the host configuration file does not contain the lines that are specified. If met, the policy is compliant and passes.
   - **Contains**
     Indicates that the host configuration file contains these words or symbols. If met, the policy is compliant and passes.
   - **Does not contain**
     Indicates that the host configuration file does not contain these words or symbols. If met, the policy is compliant and passes.
   - **Contains regular expression**
     Indicates that the host configuration file matches these regular expressions. If matched, the policy is compliant and passes.
   - **Does not contain regular expression**
     Indicates that the host configuration file does not match these regular expressions. If not matched, the policy is compliant and passes.
2. Specify whether to ignore upper or lowercase for the content that you enter.

   NOTE
   This setting is not available when using regular expressions.
3. Select in the **Content** box and enter content (full line, sub-string, or regular expression). The following is an example:



4. Select **OK**.
   The **Policy Criteria** dialog closes and you return to the **Create NCM Policy** or**Create NCM Block Policy** dialog, where the new criteria appears in the table.

Recommended Upload for Corrective Action

The setup for recommended upload for corrective action differs slightly between single line and multi-line block policies. This section describes how to configure corrective action according to the type of policy you have defined. This section contains the following topics:

Single Line Policy Corrective Action

The recommended upload for corrective action for a single line policy involves specifying content that once merged into the running configuration makes the device compliant with the policy. This procedure describes how to set up this content.

To enter corrective action for a single line policy

1. Select Edit under the Recommended Upload for Correction Action group.

   NOTE
   You can also select Open to import content from a text file.

   The Edit Corrective Action dialog opens.
2. Enter one or more lines that repair a non-compliant device. This is the content that once merged into the running configuration makes the device compliant with this policy.
3. Select OK.
   The Edit Corrective Action dialog closes and the corrective lines are displayed.

Multi-line Block Policy Corrective Action

The recommended upload for corrective action for a multi-line block policy involves specifying content that once merged into the running configuration makes the device compliant with the policy. Because block policies by nature deal with multiple blocks or occurrences of non-compliant data, you must set up the corrective action to handle this accordingly. This procedure describes how to set up this content.

To enter corrective action for a multi-line block policy

1. Select 'Repeat for each violating block' if you want the corrective action to be effected for each block where a violation occurs. If unchecked, the corrective action is uploaded as-is for the first violating block only.
2. Select Edit under the Recommended Upload for Correction Action group.

   NOTE
   You can also select Open to import content from a text file.

   The Edit Corrective Action dialog opens.
3. Enter one or more lines that repair a non-compliant device. This is the content that once merged into the running configuration makes the device compliant with this policy. Use the Insert Extracted Content button to insert the <extracted_text> tag into your corrective action, which will be replaced by block-specific content when the policy runs. The following shows an example corrective action:

   ```
   interface <extracted_text>
   description "policy violation detected on <extracted_text> by Spectrum"
   !
   ```

   WARNING
   The repair text must be a valid and complete device configuration statement, especially when the repair action is repeated. For example, if the "!" is omitted from the end of the previous example, the corrective action may not be implemented properly, and unexpected results may occur. This is because the statement is not ended correctly: a description needs to end with a new line character or a new line with a "!" character.
4. Select Configure Extracted Content.
   The Edit Extracted Content dialog opens.
5. Enter content to be extracted from each block, and select whether it is Text or a regular expression (RegEx).

- If text, this value is inserted wherever the <extracted_text> tag is found in the corrective action.
- If regular expression, the value that is returned from evaluating the regular expression will be inserted wherever the <extracted_text> tag is found in the corrective action.

The following is an example of a regular expression that represents "interface *name*":

```
(?m)^interface ([a-z||A-Z||0-9||/]*)
```

Using this example, the policy extracts the name of the interface from each block and will insert it into the corrective action.

For more information about using text and regular expressions in multi-block policies, see Multi-line Block Policies.

6. Select OK.
   The Edit Corrective Action dialog closes and the corrective lines are displayed.

View Violations

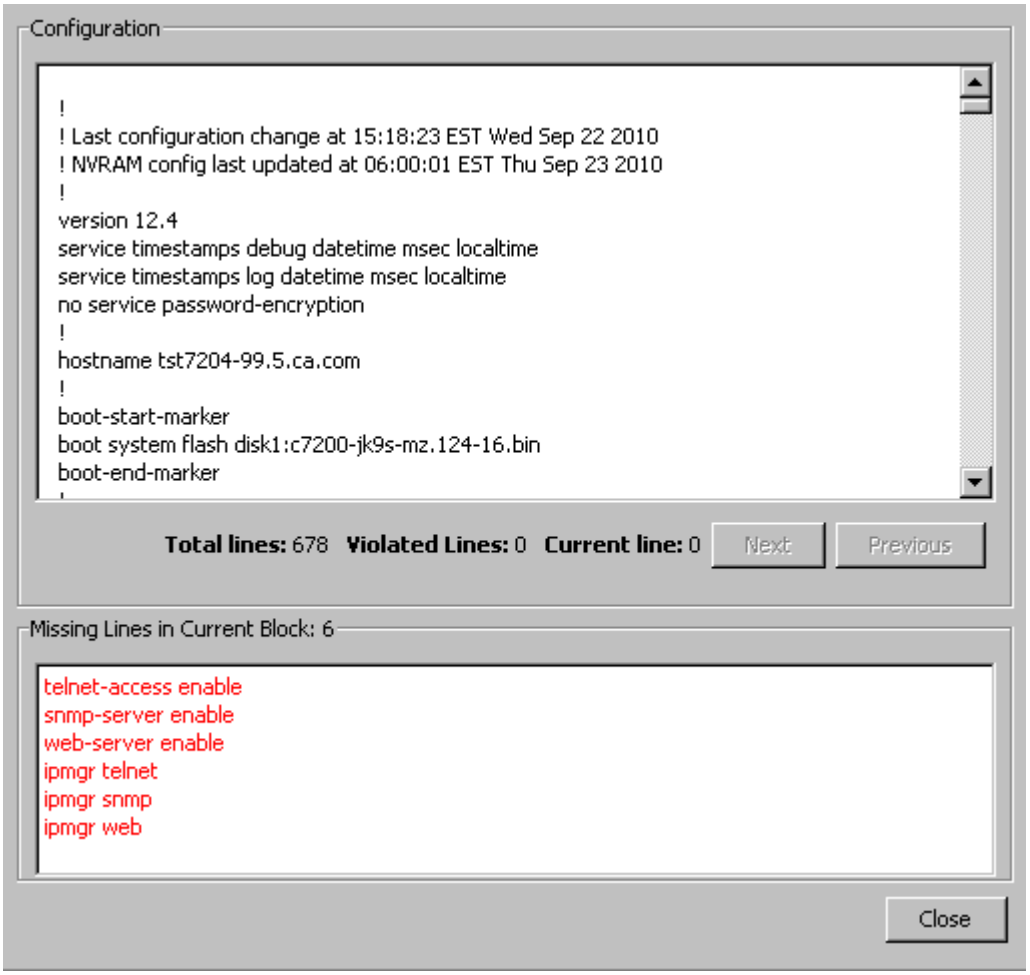
When a device is non-compliant, a View Violations dialog provides information as to the reason why. The dialog that is invoked and the information presented varies based on the policy definition. This section contains the following topics:

- Single Line Policy Violations
- Multi-line Block Policy Violations

Single Line Policy Violations

Violations for all single-line policies are displayed in the View Violation dialog.

The following example shows certain required commands that are missing in the configuration for the device and thus the policy is violated.



The View Violation dialog for all single-line policies contains the following information:

- **Configuration**
  Displays the captured host configuration in its entirety with any violated lines highlighted.
- **Total lines**
  Provides the total number of lines in the configuration file.
- **Violated Lines**
  Provides the total number of lines that violate the policy.
- **Current line**
  Provides the current location within the configuration file.
- **Next**
  Allows you to quickly advance to the next violation.
- **Previous**
  Allows you to move back to the previous violation.
- **Missing Lines in Current Block: *total_number_of_lines***
  Displays those lines that are defined in the policy that were not found in the configuration file.

  NOTE
  For single line policies, there is only one block.

Multi-line Block Policy Violations

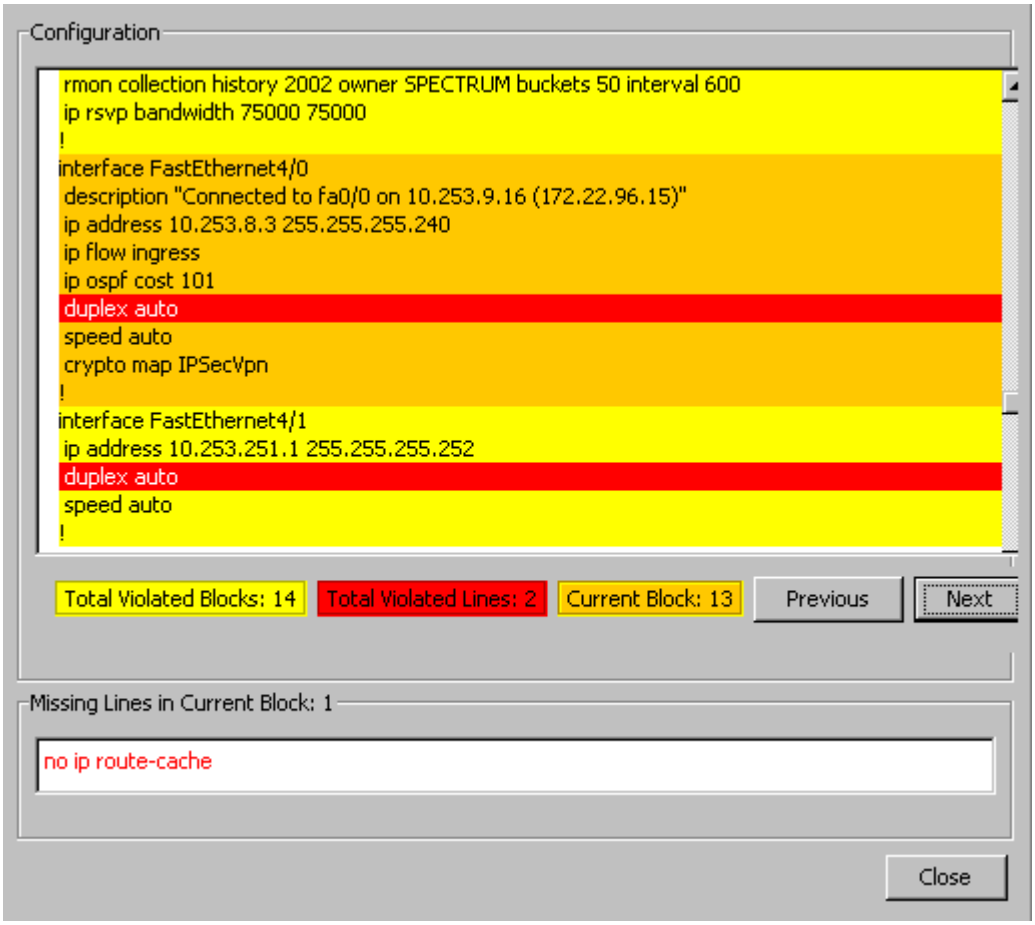
There are two types of criteria that can be used for comparison in a multi-line block policy: user-defined criteria and content from a saved configuration. Because of this, the view violation dialog that appears will be different depending on the violation content to be displayed.

Violations when Compared with Specific Contents

When user-defined criteria is used for comparison in a multi-line block policy, violations are shown on the View Violation Blocks dialog.

The following are examples of View Violation Blocks dialogs for multi-line block policies where the current host configuration is compared to user-defined criteria.

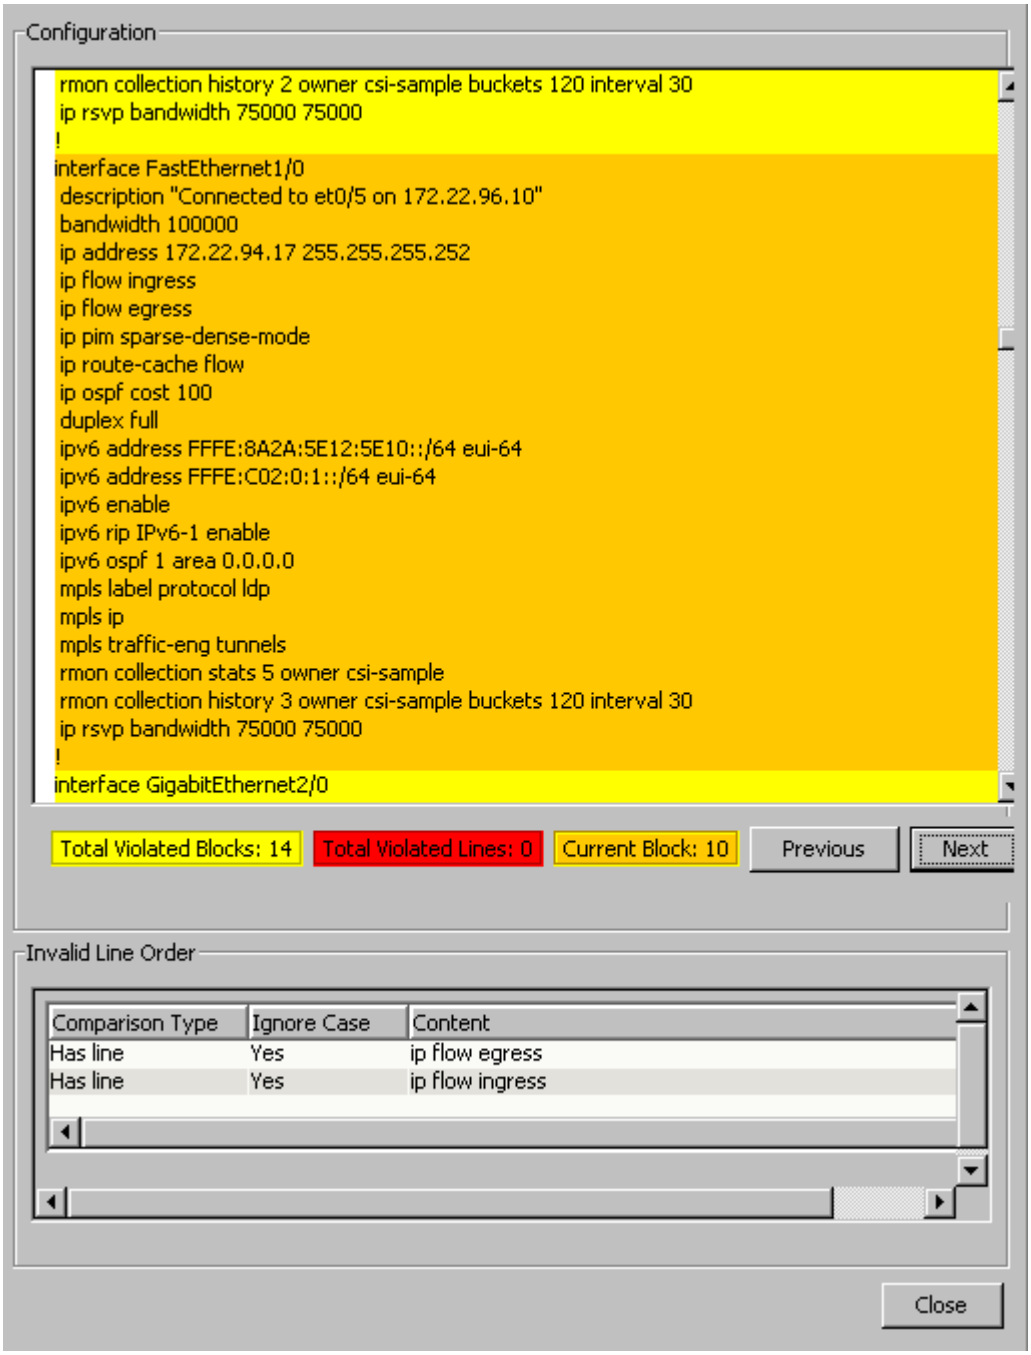
In this example, a policy has been set up to check that 'duplex auto' is not present and 'no ip route-cache' is present for each interface configuration. The violations are identified as follows:



In the next example, a policy has been set up to so that a configuration is compliant if the following commands appear and that they appear in the following order:

```
ip flow egress
ip flow ingress
```

The current configuration violates this policy because although the commands appear, they are not in the correct order, as shown in the following image:



The View Violation Blocks dialog may contain the following information, depending on the violation:

- **Configuration**
  Displays the captured host configuration in its entirety with any violated lines highlighted:
  - **Red --** These lines contain violations.

  Blocks are distinguishable by color:
  - **Orange --** These lines constitute the current block.
  - **Yellow --** These lines are included in a block other than the current block.
- **Total Violated Blocks**

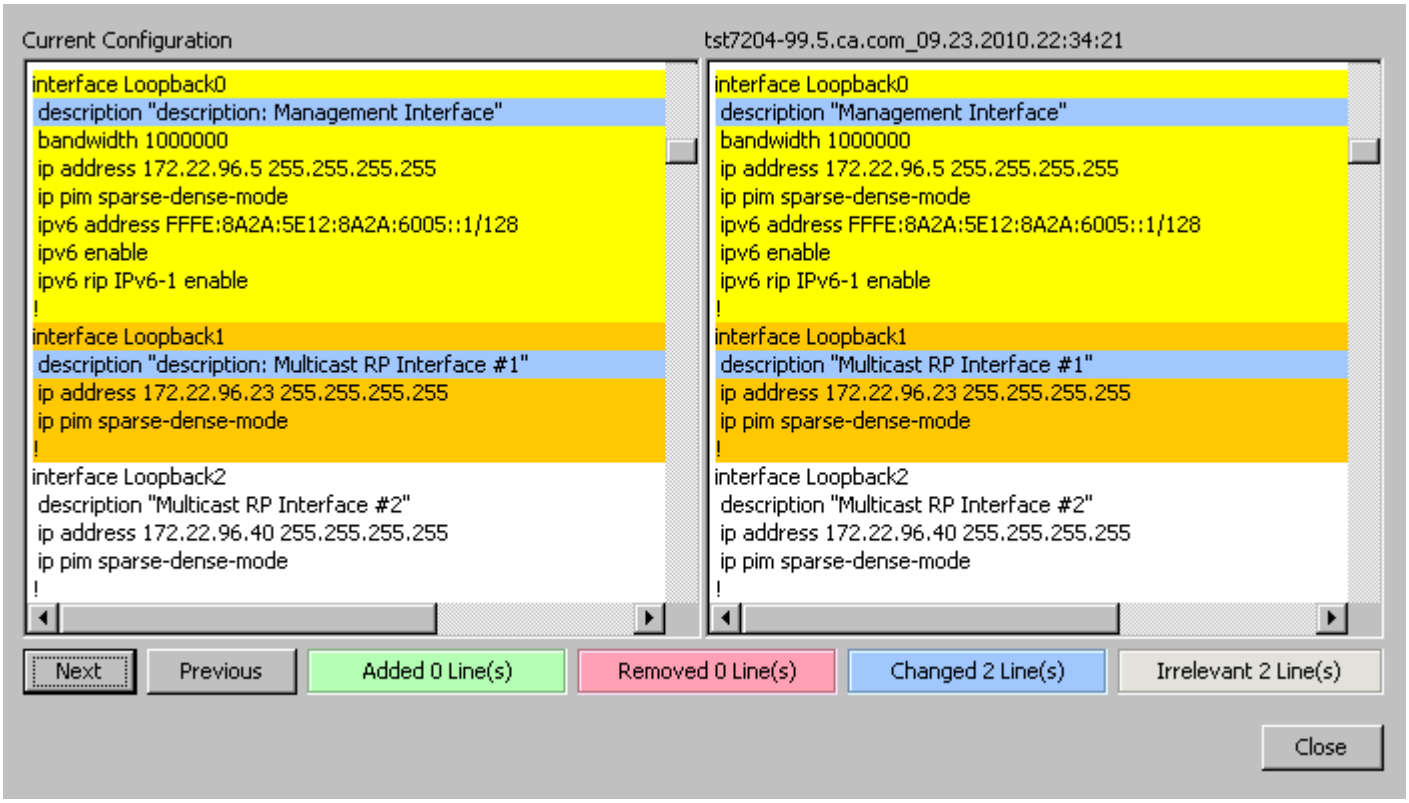
Provides the total number of blocks that contain violations.

- **Total Violated Lines**
  Provides the total number of lines that violate the policy.
- **Current Block**
  Provides the current location within the configuration file. Distinguishable blocks are numbered for identification.
- **Previous**
  Allows you to move back to the previous block containing a violation.
- **Next**
  Allows you to quickly advance to the next block containing a violation.
- **Missing Lines in Current Block: *total_number_of_lines***
  Displays those lines that are defined in the policy that were not found in the configuration file.
- **Invalid Line Order**
  Displays content criteria that has been violated due to its order of appearance in the configuration file.

Violations when Compared with Another Configuration

When a saved configuration is used for comparison in a multi-line block policy, violations are shown on the View Policy Violation dialog.

The following is an example of a View Policy Violation dialog for a multi-line block policy where the current host configuration is compared to a reference configuration and lines have changed; thus, the policy is violated.



The current host configuration is in the left pane and the reference configuration is displayed in the right. Differences between the two configurations are highlighted according to the following key.

Blocks containing differences are highlighted in their entirety and distinguishable by color:

- **Yellow --** These lines constitute a block where a violation occurs.
- **Orange --** These lines constitute a block where a violation occurs.

Individual lines denoting differences are identified as follows:

- **Green --** These lines were added.
- **Red --** These lines have been removed.
- **Blue --** These lines have changed.
- **Grey --** These lines differ but are outside of a qualifying block.

Select Next or Previous to navigate through the differences in the file.

Repair Non-Compliant Devices

In addition to repairing non-compliant devices when setting up policies, you can also initiate repair of non-compliant devices after violations occur. This section contains the following topics:

- Repair Non-Compliant Devices from the Policy Table
- Repair Non-Compliant Devices from a Policy Violation Alarm

Repair Non-Compliant Devices from the Policy Table

You can check and repair policies from the policy table by selecting a device, device family, or global collection. For example, you can repair a non-compliant device.

Follow these steps:

1. Select a device, device family, or global collection that has a configured policy in the **Explorer** tab.
2. Select the **Information** tab in the **Contents** panel.
   Information about the device, device family, or global collection appears.
3. Expand **Network Configuration Policies**.
   The **Network Configuration Policies** table appears. Policies with non-compliant devices have a non-zero value in the **Violators** column.
4. Select a policy that has a non-compliant device, and select the 'Launch repair dialog' icon.
   The **Repair Devices in Violation** dialog appears.
5. Select the **Content** tab to view the content to be uploaded to perform the repair.
6. Select**View Violation** to view the violation of each device.
7. Select **Repair**.
   The **Creating Task** status box appears. The **Upload Task Results** dialog shows the results of the operation.

   NOTE

   You can automate and minimize the above process by running a Jar executable through AlarmNotifier. Contact DX NetOps Spectrum support team to get the executable file and the steps to use it.

Repair Non-Compliant Devices from a Policy Violation Alarm

You can view a violation and can upload or merge the correct content to the device to make it compliant with the policy from the **Alarm Details** tab. Repair a non-compliant device directly from a policy violation alarm.

Follow these steps:

1. Select a device, device family, or global collection that has a configured policy, or a policy (from the Policy node) in the **Explorer** tab.
2. In the **Alarms** tab in the **Contents** panel, select an alarm with “NCM Policy Violated” in the **Alarm Title** column.
3. Select **View Violation Details** in the **Alarm Details** tab in the **Component Detail** panel.
   The**Repair Devices in Violation** page opens.
4. Select **Content** to view the content to be uploaded to perform the repair. Select **View Violation** to view the violation of each device.

The **View Violation** page appears.

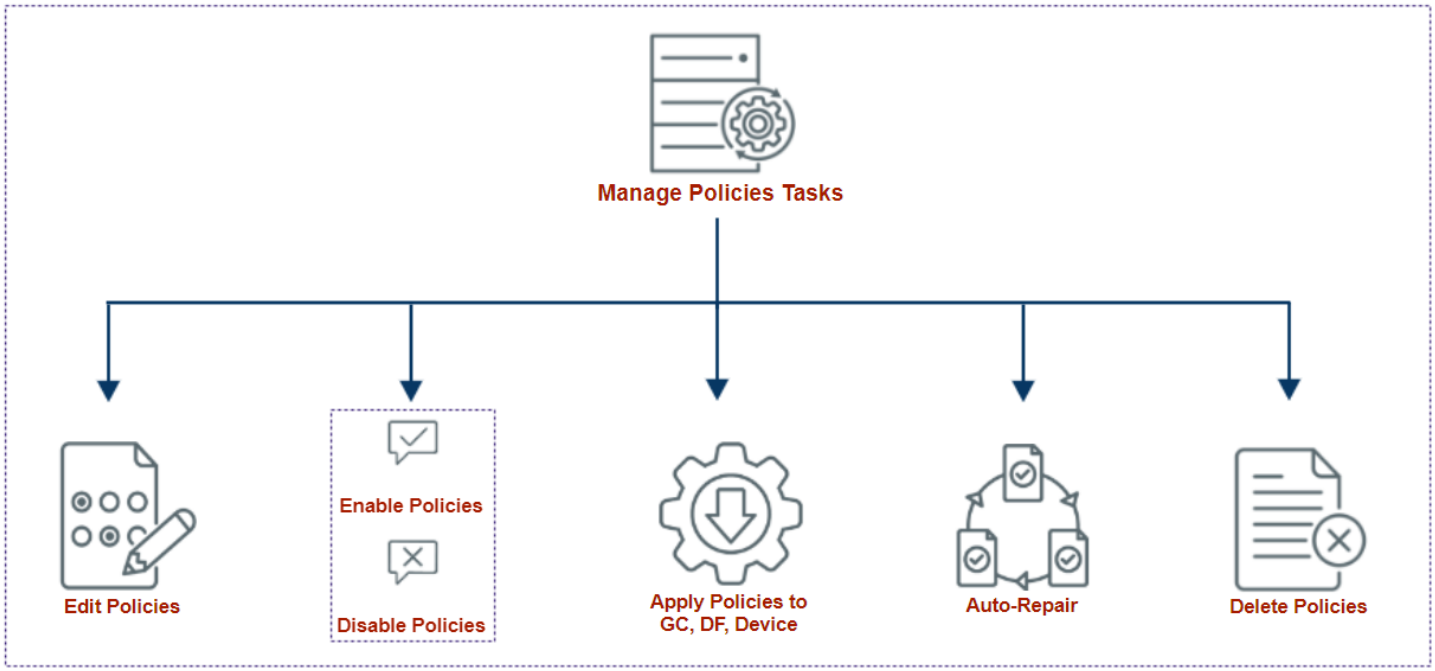
5. Select **Repair**.
   The **Creating Task** status box appears, followed by the **Upload Task Results** page.

Manage Policies

After a policy has been created, you can perform various operations on it. For example, you can edit, enable, disable, or delete it. You can also apply it to devices, device families, or global collections.

Manage Policies Tasks

The following diagram provides an overview of the tasks that help you manage your policies:



Edit Policies

You can edit an existing Network Configuration Manager policy. After you edit a policy, you must save and enable it.

To edit a policy

1. Select a policy under the **Policies** node in the **Explorer** tab.
2. Select the **List** tab in the **Contents** panel.
   A list of policies appears.
3. Select the policy and click the Edit selected policy icon in the toolbar.
4. Select **Yes** on the message confirmation dialog.
   The **Edit NCM Policy** dialog appears.
5. Make changes as necessary and click **Save**.
   The policy is disabled. Enable the policy as explained in Enable and Disable Policies from the Policy Table.

> **NOTE**
> Optionally, for a global collection, you can edit a policy by selecting the global collection, clicking the **Information** tab, and editing the associated policy. For a device, you can select the individual device, click

the **Information** tab, click **Network Configuration Policies**, and edit the associated policy. For a device family, select a device family, click the **Information** tab, click **Network Configuration Policies**, and edit the associated policy.

Enable and Disable Policies

You can enable and disable Network Configuration Manager policies from the policy table.

Follow these steps:

1. Select a policy under the **Policies** node in the **Explorer** tab.
2. Select the **List** tab of the **Contents** panel.
   A list of policies appears.
3. Select a policy and click the 'Enable selected policies' icon to enable the policy.
   Enabling a policy causes any specified alarms to immediately appear for all non-compliant devices and violated policies.
4. (Optional) Select a policy and click the 'Disable selected policies' icon to disable that policy.
   Disabling a policy immediately clears any existing alarms on non-compliant devices and violated policies.

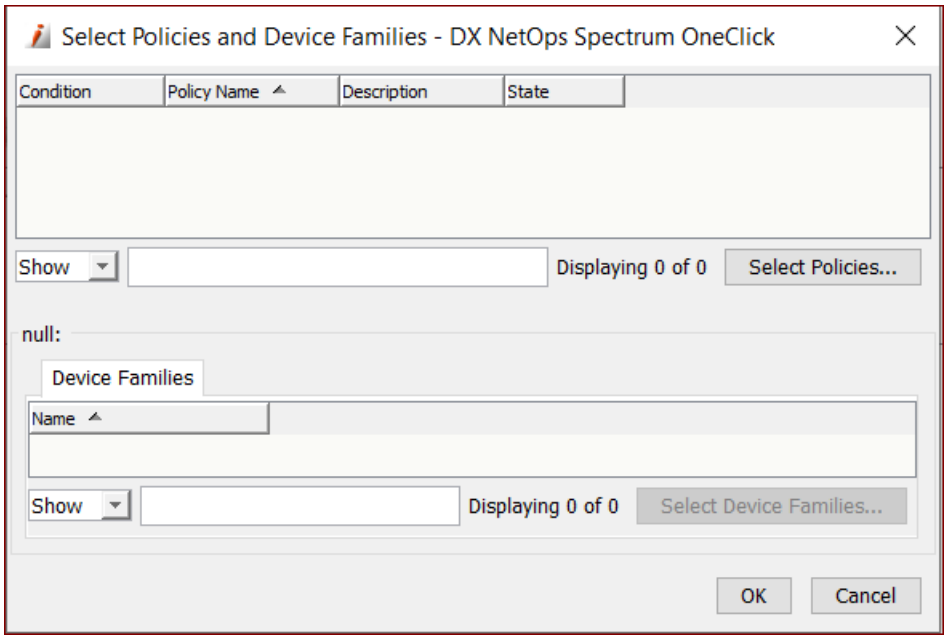
   NOTE
   You can also enable and disable a policy by selecting a global collection, device family, or device. Use the **Information** tab to manage the associated policy.

Apply Multiple Policies to a Global Collection

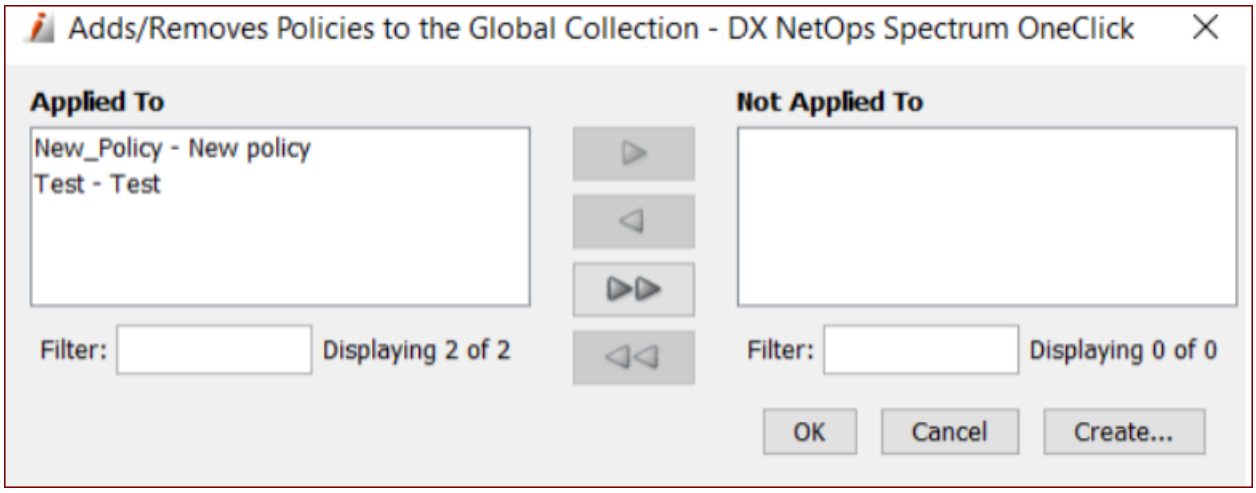
After policies are created, they can be applied to a global collection. When the policies are applied to a global collection, the policies are then enforced to all the global collection members of the selected device families (in that global collection).

Follow these steps:

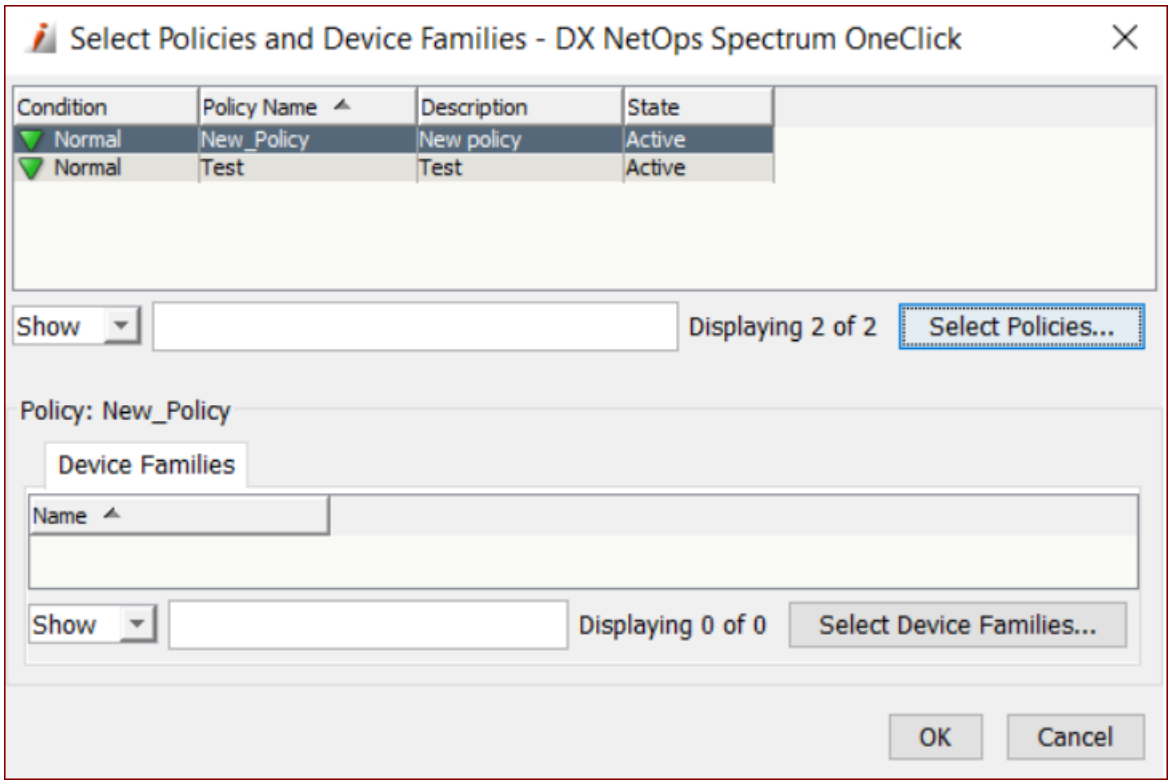
1. Select a global collection in the **Explorer** tab.
   Information for the global collection appears in the **Information** tab of the **Contents** panel.
2. Expand the **Network Configuration Policies** subview.
   The Network Configuration Policies table appears.
3. Click the 'Add/Remove policies to/from the global collection' icon.
   The **Select Policies and Device Families** dialog appears.



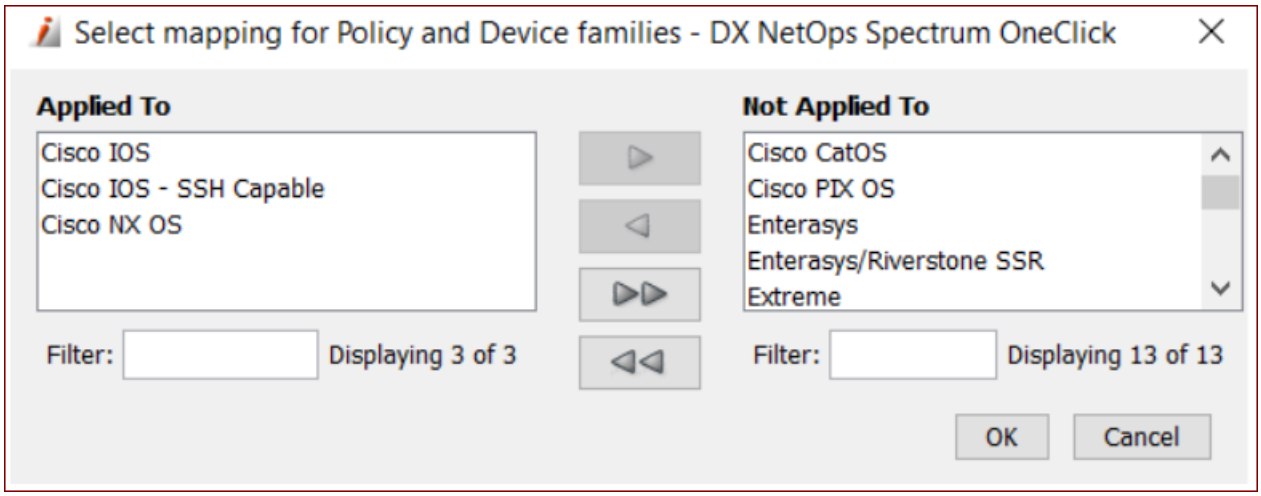
4. Click the **Select Policies** button to select the policies that you want to apply on the global collection. The **Adds/ Removes Policies to the Global Collection** dialog appears.
5. Select the required policies from the **Not Applied To** area and move them to the **Applied To** area. The following screenshot shows the required information that the two policies have been applied to this global collection:



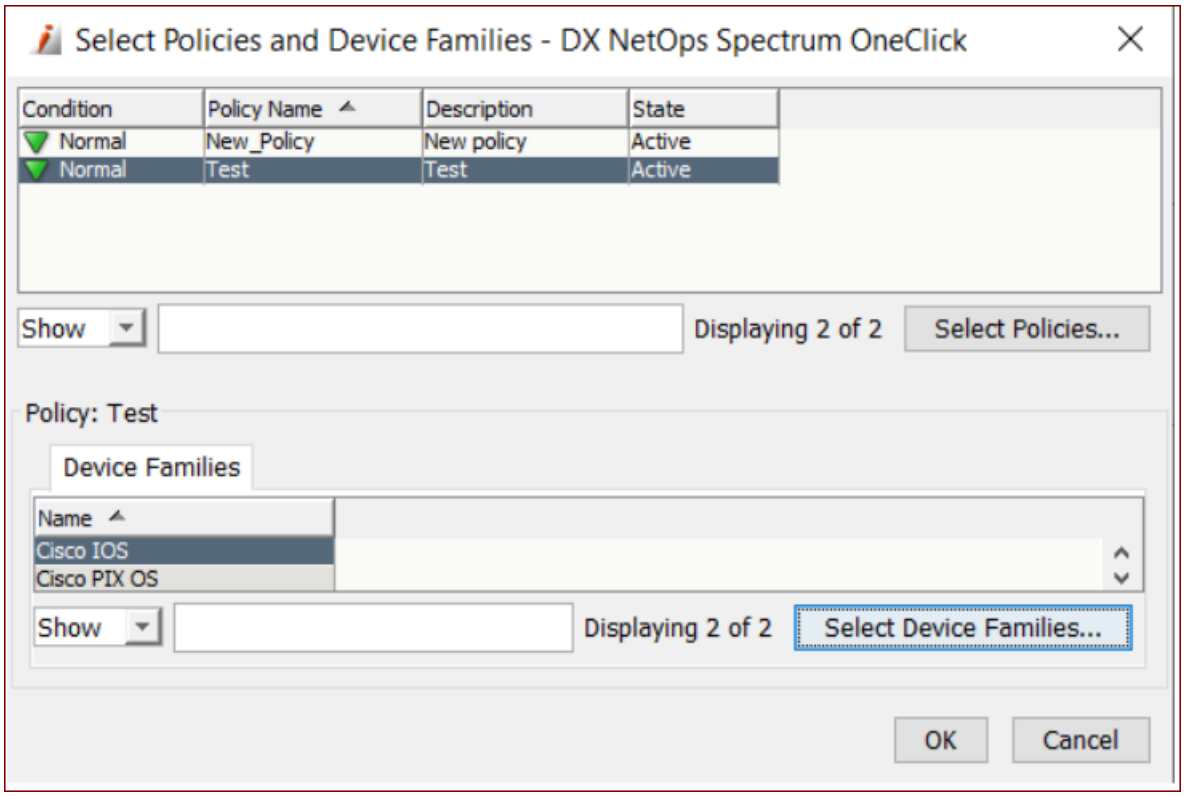
6. Click **OK**. The added policies appear in the table as follows:



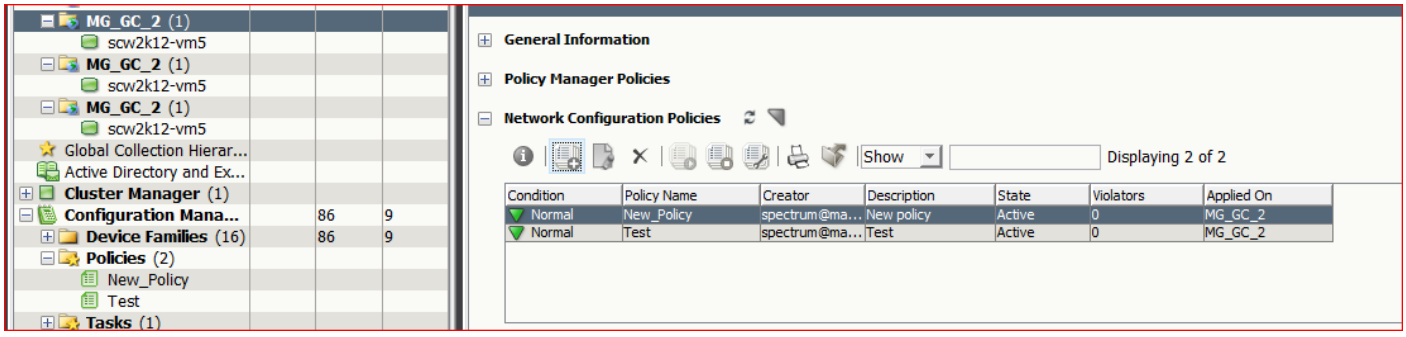
7. Select a policy from the table.
8. Click the **Select Device Families** button to select the device families that you want to associate with the selected policy.
9. Select the required device families from the **Not Applied To** area and move them to the **Applied To** area. The following screenshot shows the required information:



10. Click **OK**. The selected device families appear in the **Device Families** section of the dialog and get associated with the selected policy. The following screenshot shows the required information:



11. Click **OK**.
    The applied policies appear in the **Network Configuration Policies** table. The following screenshot shows the required information:



12. Repeat the steps to associate the remaining policies with the device families. The added policies will be enforced on all the global members based on the associated device families (in that global collection).

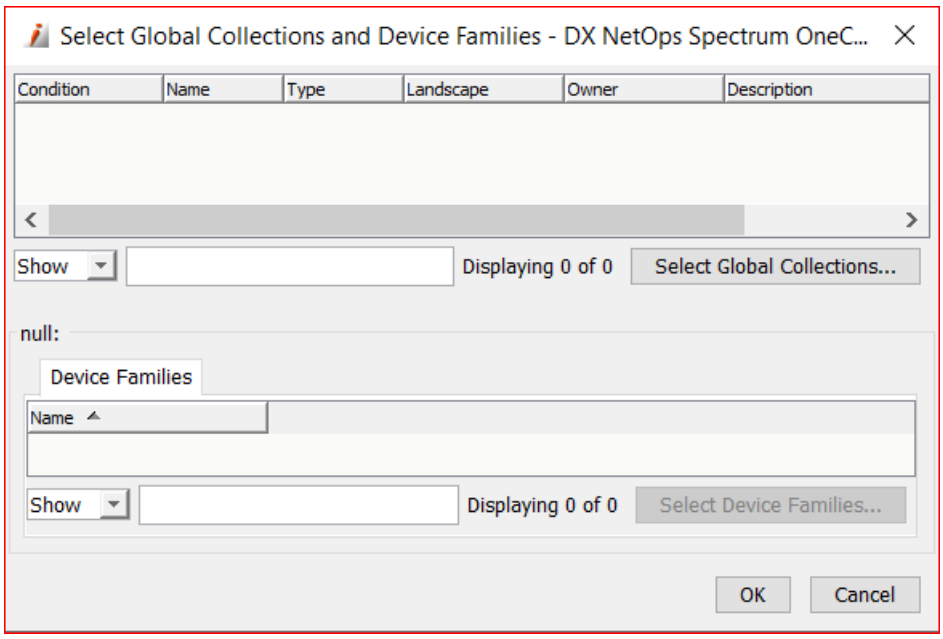
Apply a Single Policy to Multiple Global Collections

You can also apply a single policy to multiple global collections.

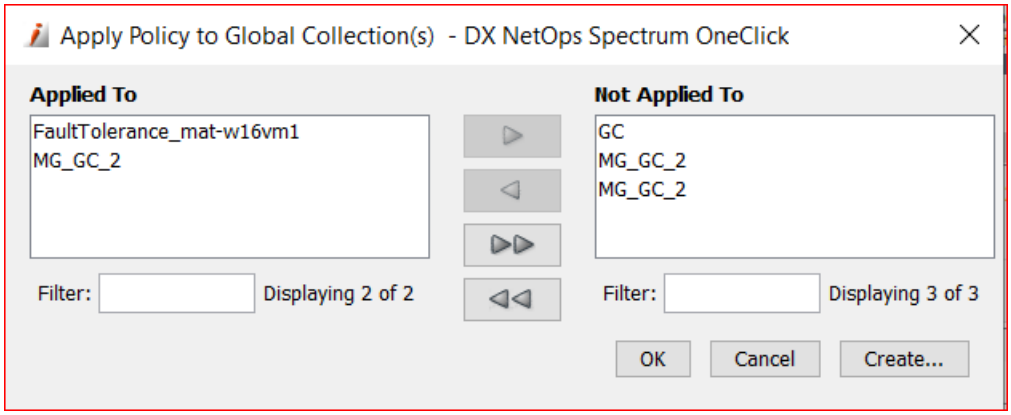
Follow these steps:

1. Navigate to the **Policies** node in the **Explorer** tab.
2. Select the **List** tab of the **Contents** panel.
   A list of policies appears.
3. Select the policy that you want to apply to multiple global collections.
4. Click the 'Apply policy to global collection(s)' icon.

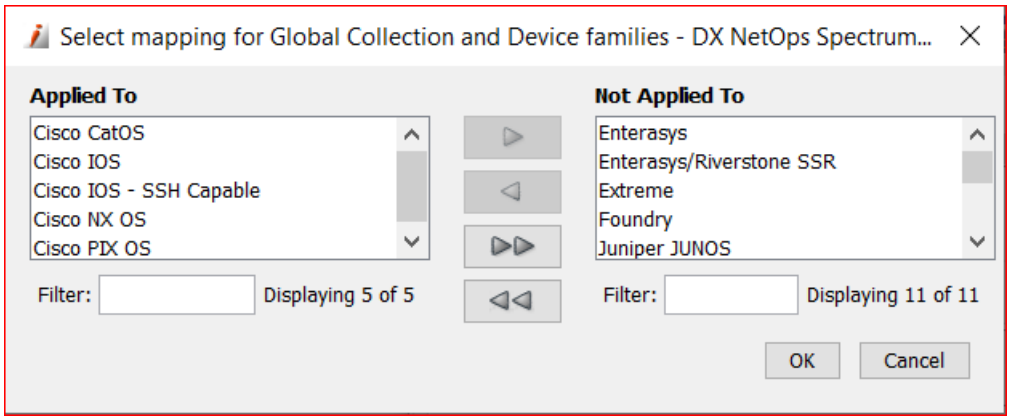
The **Select Global Collections and Device Families** dialog appears:



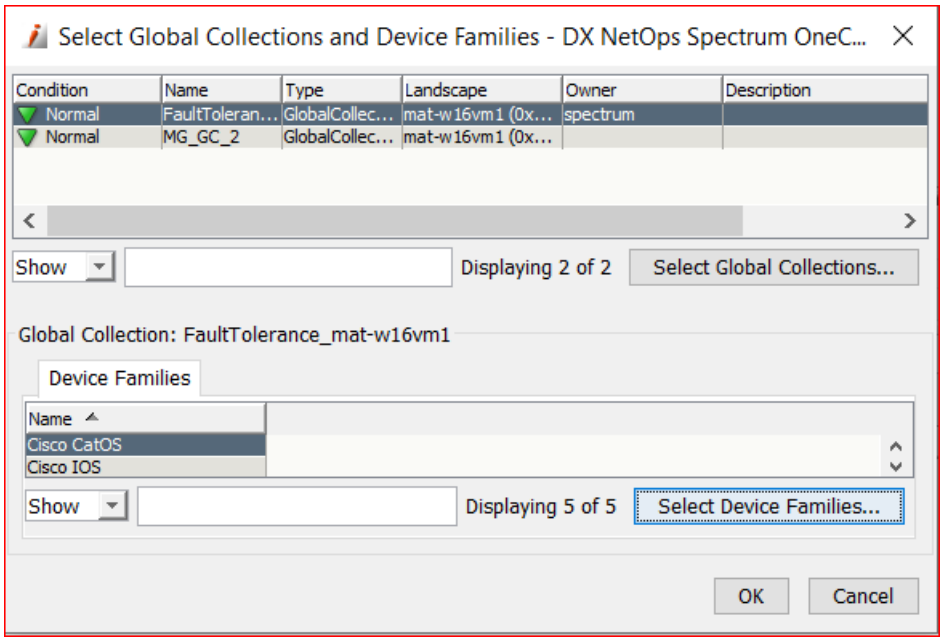
5. Click the **Select Global Collections** button to choose the global collections on which you want to apply the policy. The **Apply to Global Collection(s)** dialog appears.
6. Select the required global collections from the **Not Applied To** area and move them to the **Applied To** area. The following screenshot shows the required information:



7. Click **OK**. The selected global collections are added to the table.
8. Select the global collection in the table and then click the **Select Device Families** button. The **Select Mapping for Global Collection and Device Families** dialog appears. In this dialog, you select the required device families that you want to associate with the policy selected for the global collection.
9. Select the required device families from the **Not Applied To** area and move them to the **Applied To** area. The following screenshot shows the required information:



10. Click **OK**. The selected device families are added to the **Device Families** section of the dialog:



11. Follow the same steps to select device families for other global collections that you have added.
12. Click **OK**.

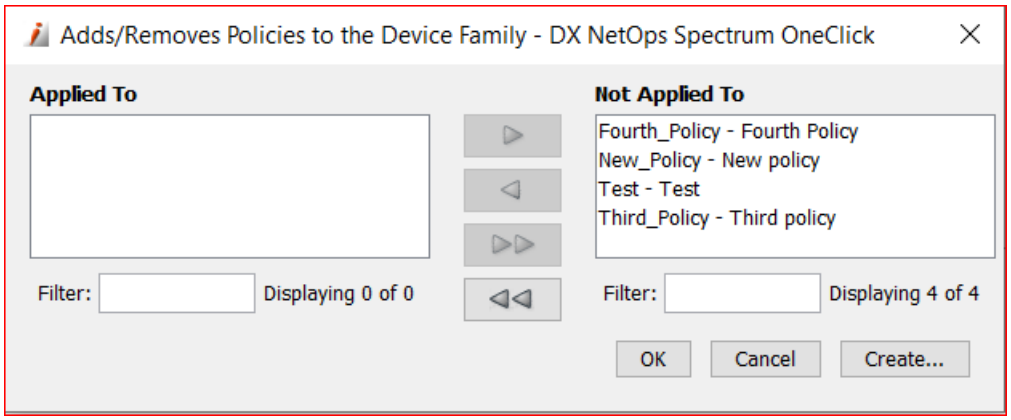
You have successfully applied a policy to multiple global collections. You have also selected the required devices families for the global collections. Therefore, the policy is applied to only those device families in the global collection, not to the other device families in that global collection.

Apply Multiple Policies to a Device Family

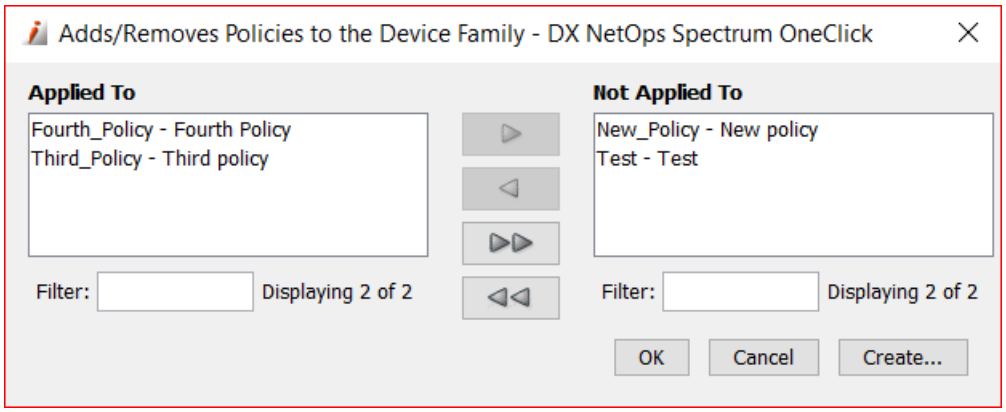
After policies are created, they can be applied to a device family. When multiple policies are applied to a device family, the policies are then enforced on all members of the selected device family.

Follow these steps:

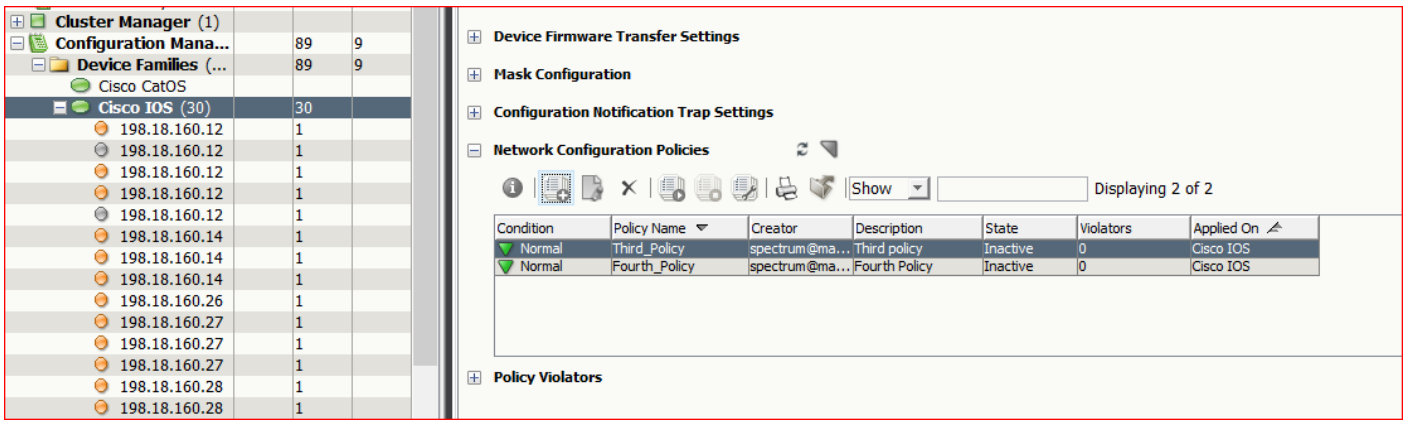
1. Select a device family in the **Explorer** tab.
   Information for the device family appears in the **Information** tab of the **Contents** panel.
2. Expand the **Network Configuration Policies** subview.
   The **Network Configuration Policies** table appears.
3. Click the 'Create policy' icon.
   The **Adds/Removes Policies to the Device Family** dialog appears:



4. Select the required policies (which you want to apply to the device family) from the **Not Applied To** area and move them to the **Applied To** area:



5. Click **OK**.
   The applied policies appear in the **Network Configuration Policies** table and will be enforced on all the members of the selected device family.



Apply a Single Policy to Multiple Device Families

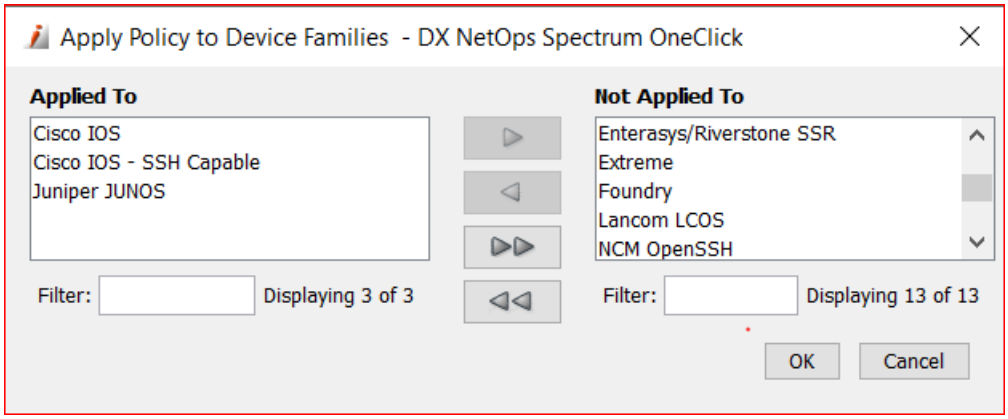
Similarly, you can apply a single policy to multiple device families.

Follow these steps:

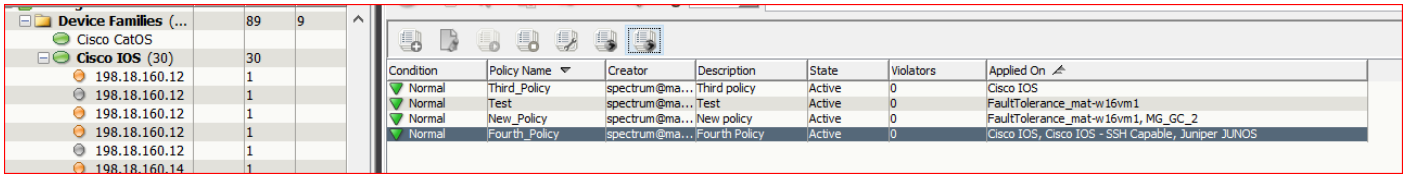
1. Navigate to the **Policies** node in the **Explorer** tab.
2. Select the **List** tab of the **Contents** panel.

A list of policies appears.

3. Select the policy that you want to apply to multiple device families.
4. Click the 'Apply policy to device families' icon. The **Apply Policy to Device Families** dialog appears. In this dialog, you select all the device families to which you want to apply the selected policy.
5. Select the required device families from the **Not Applied To** area and move them to the **Applied To** area.



6. Click **OK**. The policy is associated with the selected families.



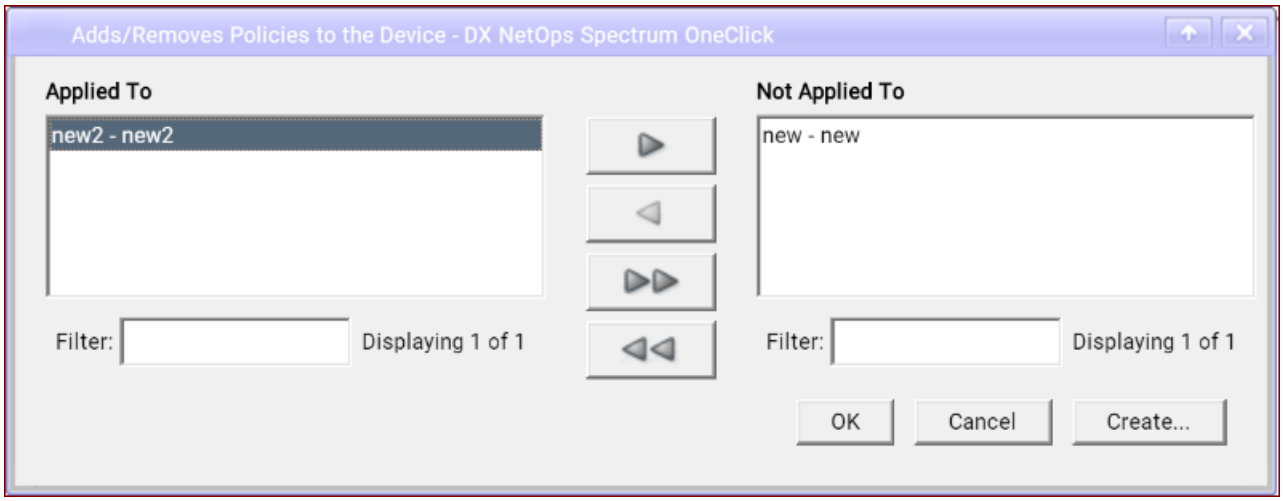
You have successfully applied a single policy to multiple device families.

Apply a Policy to an Individual Device

You can also apply a policy to an individual device.

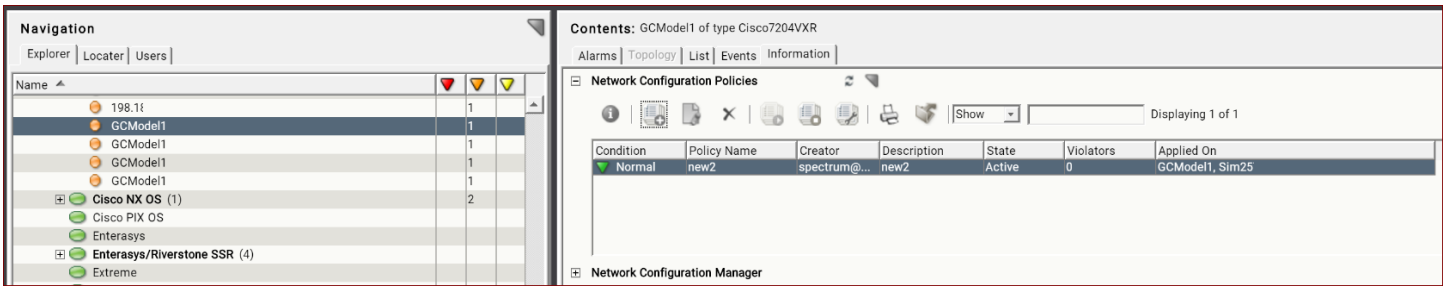
Follow these steps:

1. Select a device to which you want to apply a policy in the **Explorer** tab.
2. Click the **Information** tab in the **Contents** pane.
3. Expand the **Network Configuration Policies** subview.
4. Click the Create policy icon.
5. Move the required NCM policy that you want to apply from the **Not Applied To** area to **Applied To** area.



6. Click **OK**.

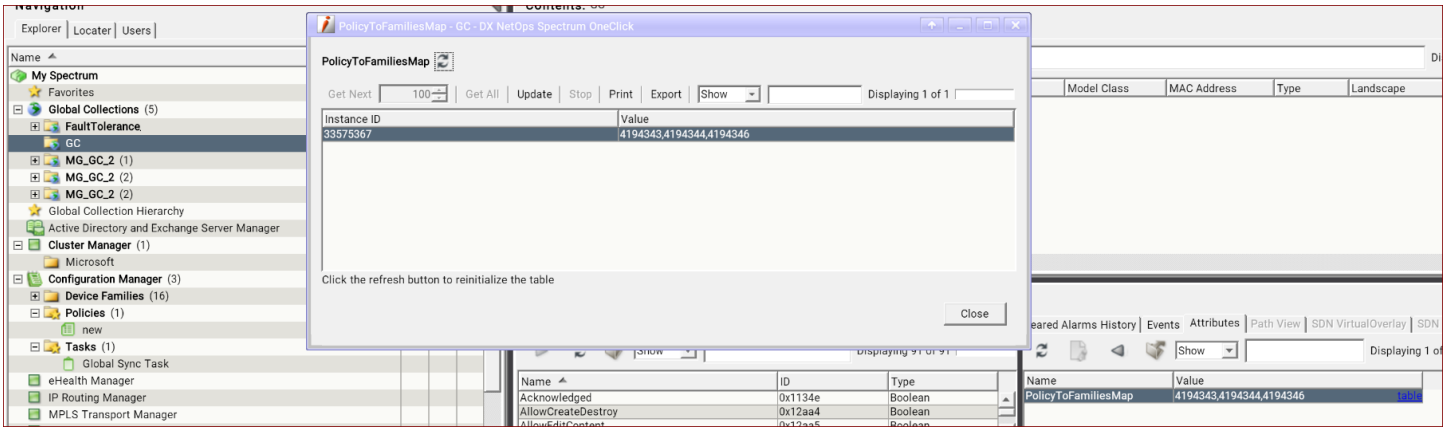
The policy is added to the Network Configuration Policies table.



If you see the **Applied On** column in this table, you can find the device on which you have applied the policy is also listed there. If you review the same table for other devices in this family, you will find that the policy is not applied to them; it is applied only to the selected device.

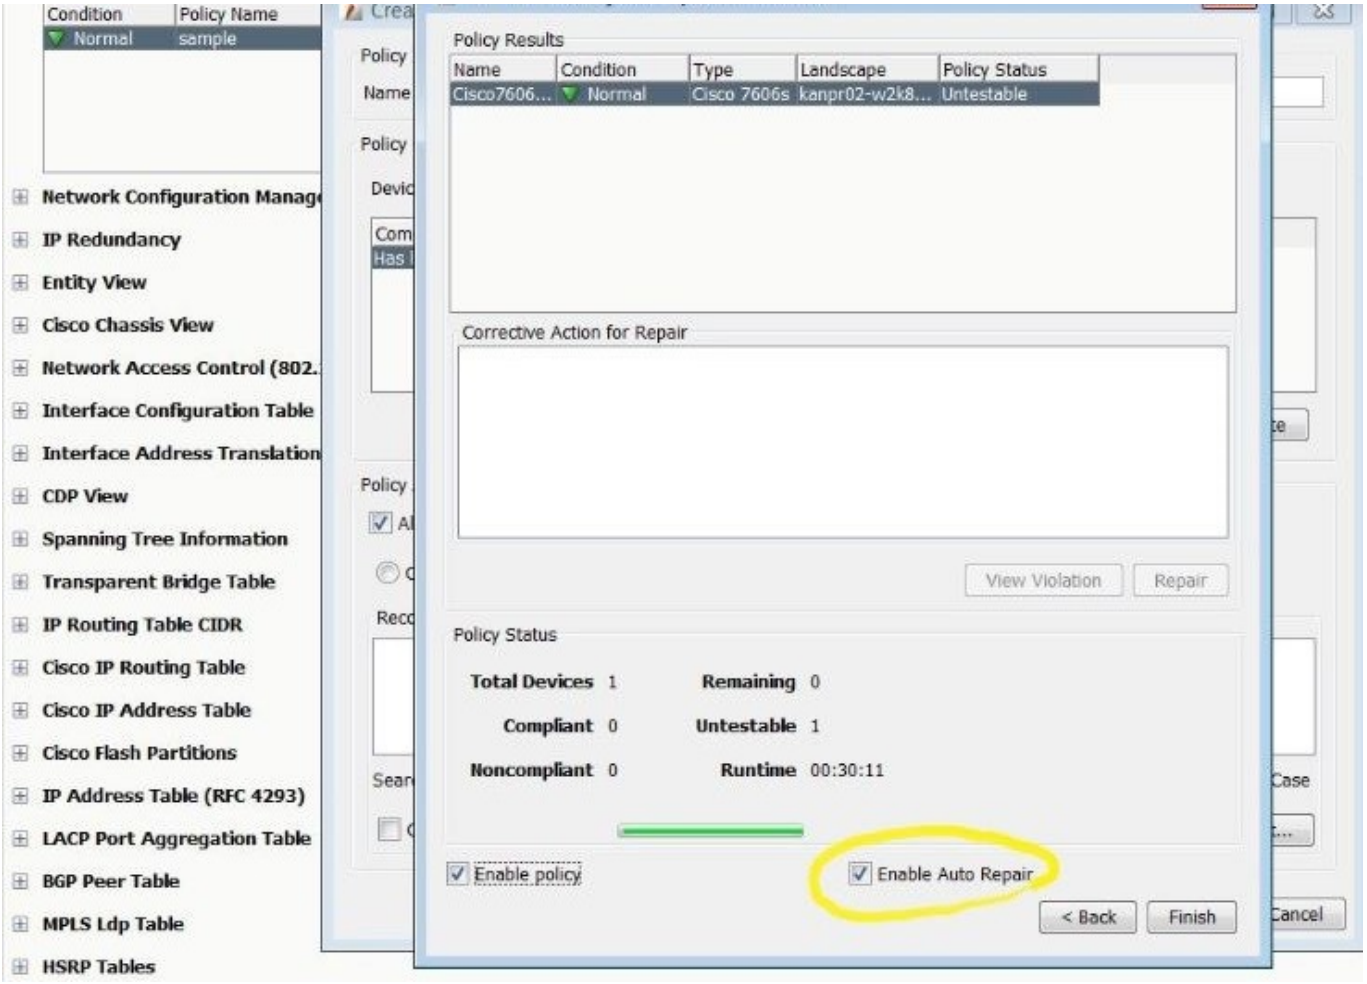
PolicyToFamiliesMap Attribute in Global Collection

The PolicyToFamiliesMap attribute stores mapping between the applied NCM policy (key) and the list of device families (value) in global collection. In each entry, the key is the home model handle of the NCM policy applied to that global collection. The value is the home model handles of the device families (comma separated). The following screenshot shows the required information:



Auto-Repair Functionality

Previously, Alarm Notifier's set script triggered the auto repair functionality and repaired all the violated policies configurations. From 10.3, auto-repair functions work independent of the Alarm Notifier. Select the check box next to the **Enable Auto Repair** option on the NCM Policy dialog. Here is a screenshot displaying the new Auto-Repair functionality for NCM devices.



Delete Policies

To delete a policy that you no longer need, right-click the policy under **Policies** in the **Explorer** tab and select **Delete**.

> **NOTE**
> Optionally, you can delete a policy by selecting a global collection, clicking the **Information** tab, and deleting the associated policy. You can also select an individual device or device family, click the **Information** tab, click **Network Configuration Policies**, and delete the associated policy.

Troubleshooting

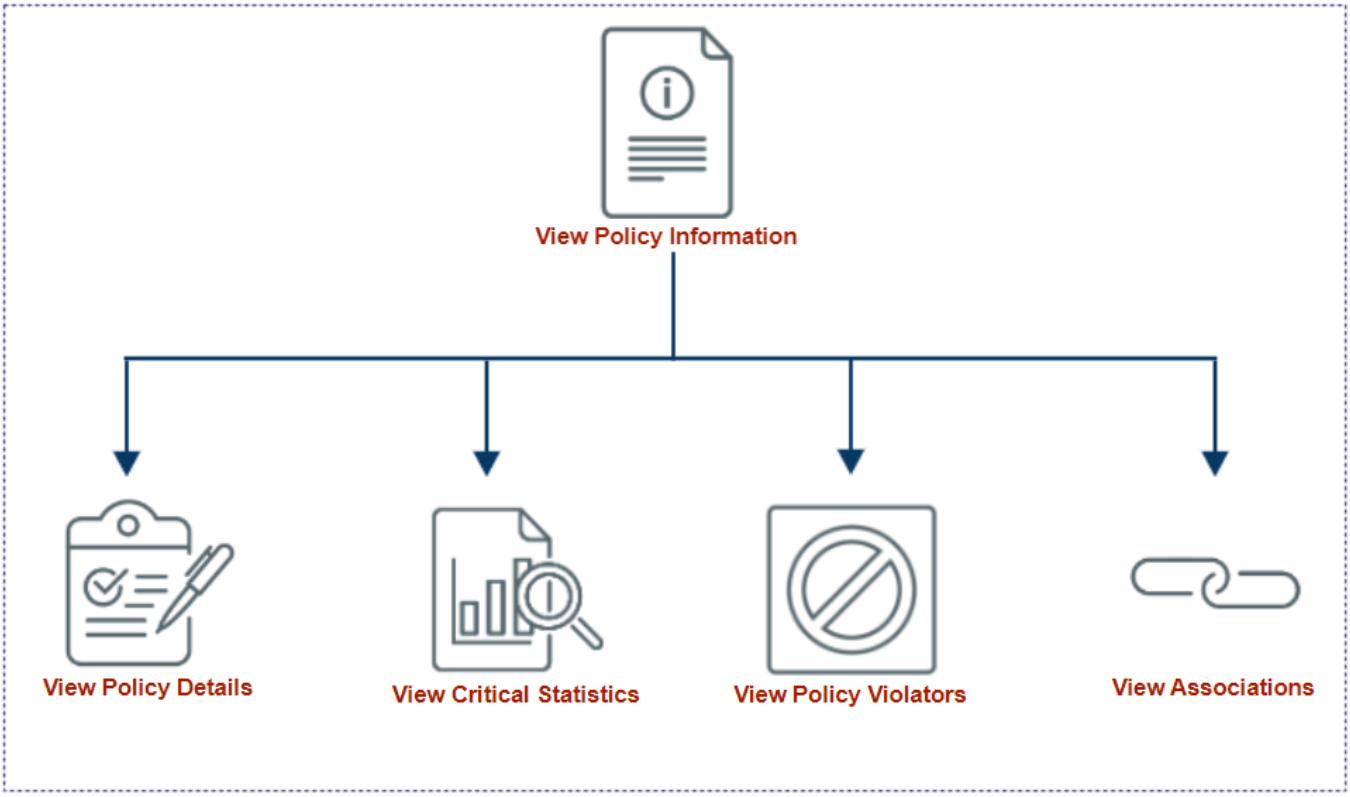
Review the following troubleshooting information:

- If a policy is violated, then the violation alarms are asserted on the device model, policy model, or both. If the same policy is not applied, then the corresponding alarms are cleared.
- If a policy that is applied to a global collection is violating for a device under that global collection, then the violation alarm is raised as expected. If the device is removed from the global collection, then the policy violation alarm is cleared. The same behavior holds good for the policy that is applied to a device family.
- If a policy is applied to a global collection and the expected violation alarm is not created on the device models, then verify that the PolicyToFamiliesMap attribute is updated properly with the policy and the families home model handles.

View Policy Information

This section describes how to view policy information and includes the following topics:

The following diagram shows the high-level tasks that help you view the information related to policies:



View Policy Details

You can view component details for Network Configuration Manager policies.

Follow these steps:

1. Select a device, device family, or global collection in the **Explorer** tab that has an associated policy.
2. Click the **Information** tab in the **Contents** panel.
   Information and configurations for the selected device, device family, or global collection appear.
3. Expand **Network Configuration Policies**, and click 'View the Component Detail for the selected model'.
   The **Component Detail** panel for the selected policy appears.

   NOTE
   You can also access this screen by selecting a policy from **Policies** in the **Explorer** tab.

View Critical Statistics for All Policies

You can view critical statistics for policies by selecting **Policies** under **Configuration Manager** in the **Explorer** tab and selecting the **List** tab in the **Contents** panel.

Statistics for all policies appear.

View Critical Statistics for All Policies Applied to a Device

You can view critical statistics for policies that are applied to a device.

Follow these steps:

1. Select a device, and then click the **Information** tab.
   Information about the device appears.
2. Select **Network Configuration Policies**.
   Statistics for all policies applied to a single device appear.

View Critical Statistics for Policies Applied to a Global Collection

You can view critical statistics for policies that are applied to a global collection.

Follow these steps:

1. Select an existing Global Collection from the **Explorer** tab.
2. Select the **Information** tab of the **Contents** panel.
   Information appears in the **Contents** panel.
3. Select **Network Configuration Policies**.
   Statistics for all policies that are applied to a collection appear.

View Critical Statistics for Policies Applied to a Device Family

You can view critical statistics for policies that are applied to a device family.

Follow these steps:

1. Select an existing device family from the **Explorer** tab.
2. Select the **Information** tab of the **Contents** panel.
   Information appears in the **Contents** panel.
3. Select **Network Configuration Policies**.
   Statistics for all policies that are applied to a device family appear.

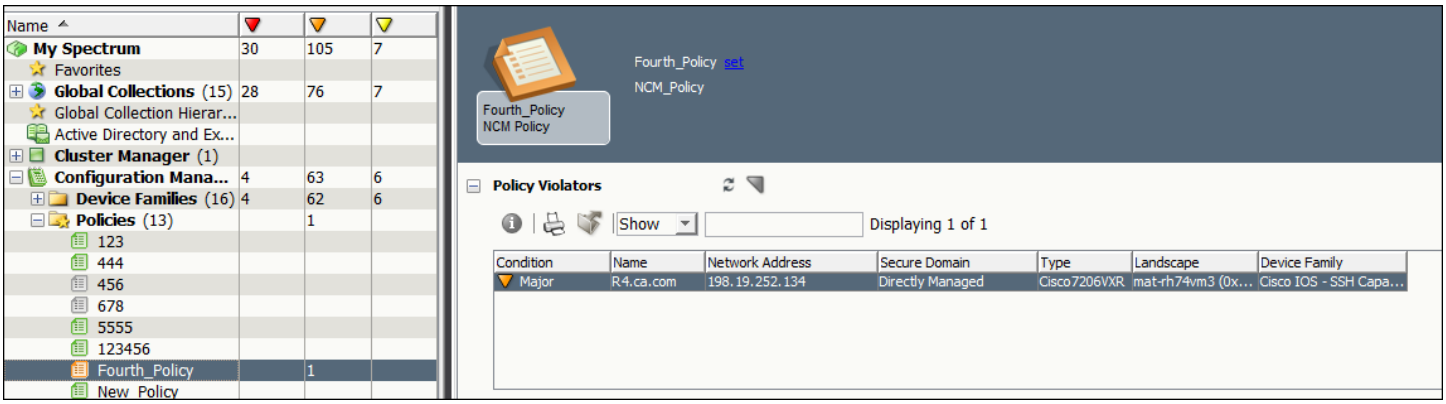
View Policy Violators

If any device violates the policy, you can view the list of such devices in the Policy Violators table at the policy level, global collection level, and at the device family level. With this information, you can quickly identify the violators and take appropriate actions.

(Policy Level) Follow these steps:

1. Navigate to the **Configuration Manager**, **Policies** node in the **Explorer** tab.
2. Select the required policy under the **Policies** node.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **Policy Violators** subview.
5. Review the list of policy violators in the table.

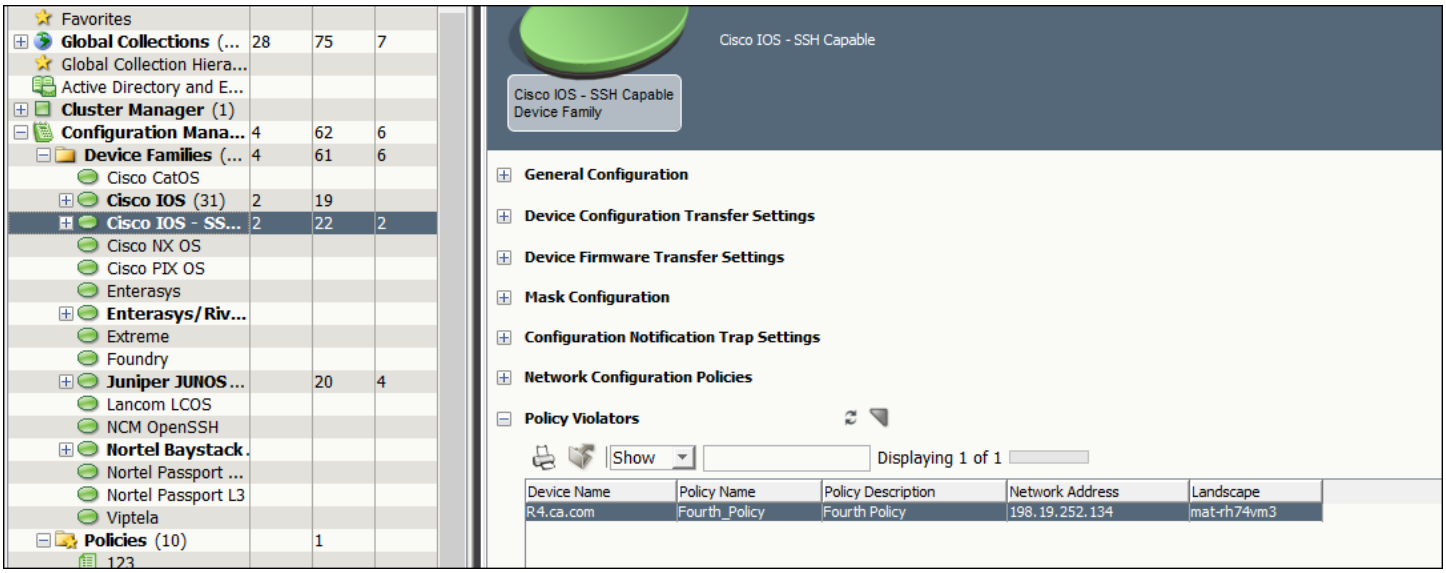
The following screenshot shows the required information at the policy level:



(Device Family Level) Follow these steps:

1. Navigate to the **Configuration Manager**, **Device Families** node in the **Explorer** tab.
2. Select the required device family under the **Device Families** node.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **Policy Violators** subview.
5. Review the list of policy violators in the table.

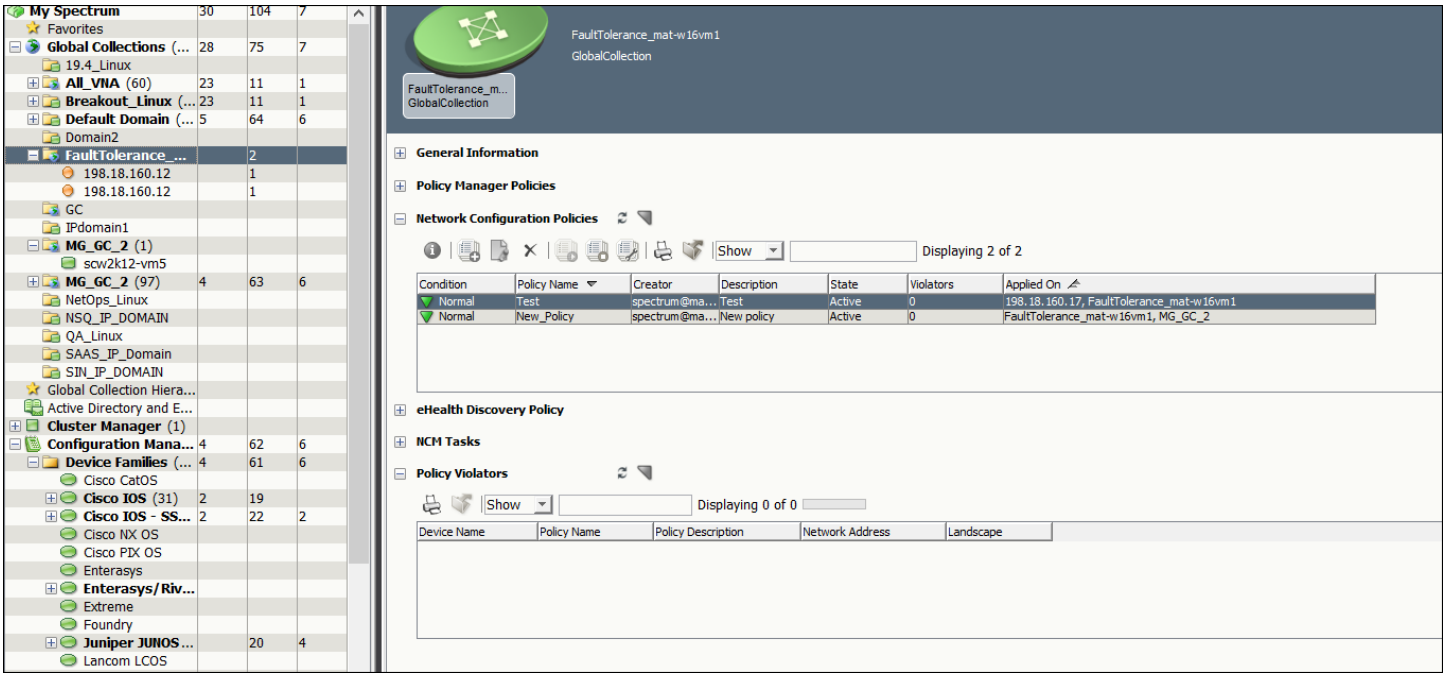
The following screenshot shows the required information at the device family level:



(Global Collection Level) Follow these steps:

1. Navigate to the **Global Collection** node in the **Explorer** tab.
2. Select the required global collection under the **Global Collection** node.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **Policy Violators** subview.
5. Review the list of policy violators in the table.

The following screenshot shows the required information at the global collection level:



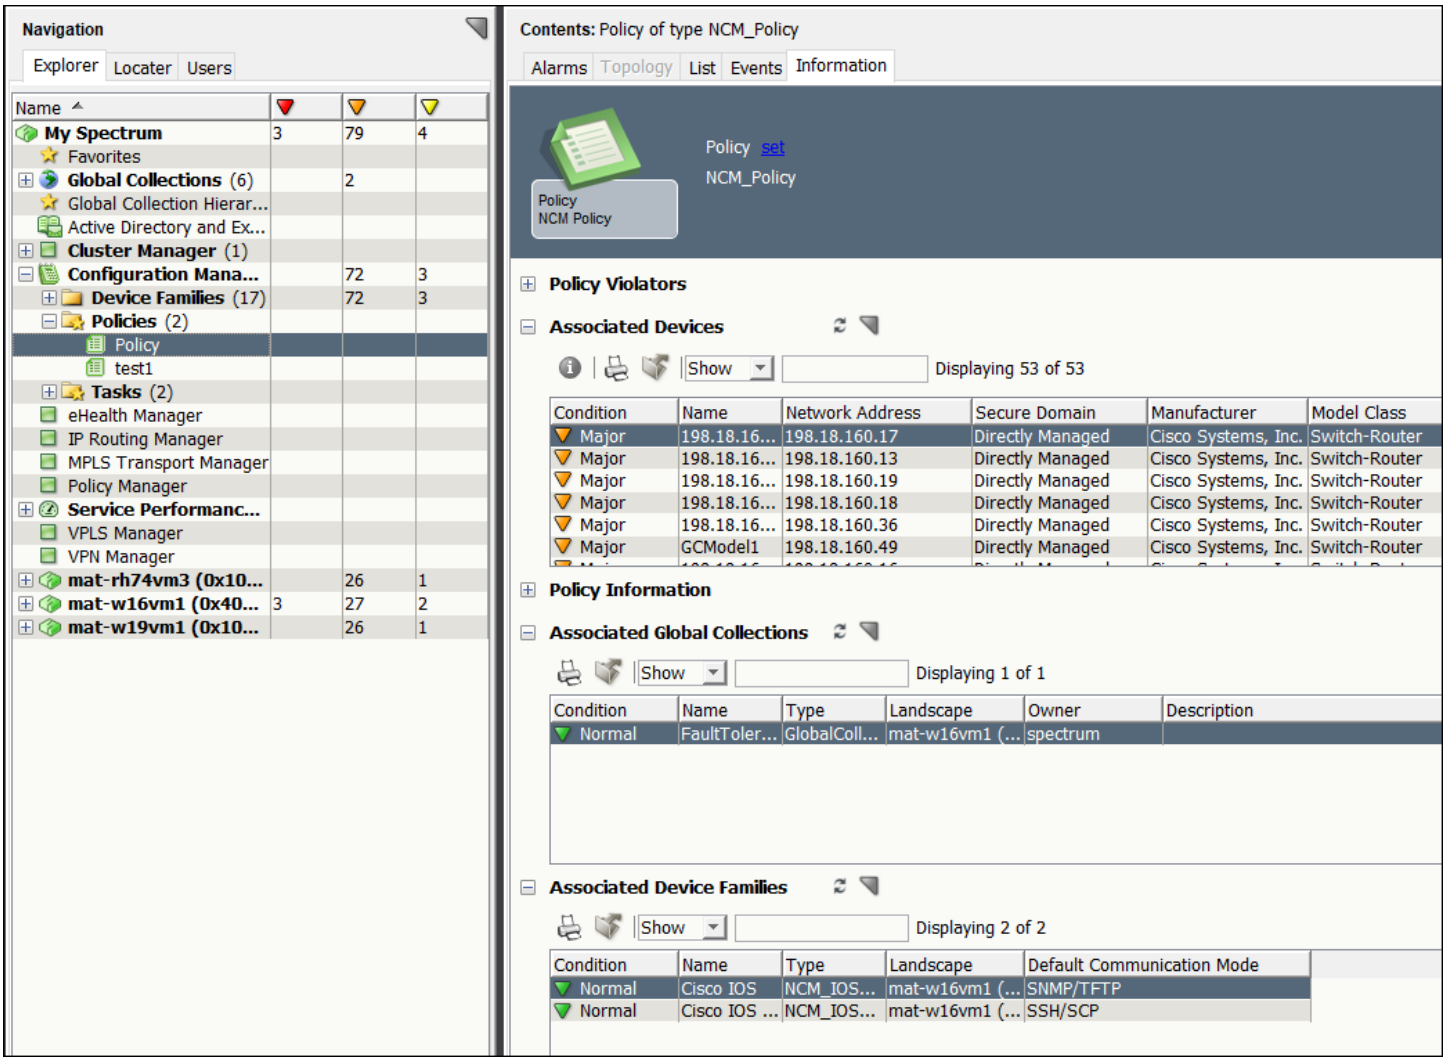
View Associated Devices, Device Families, and Global Collections

You can view the devices, device families, and global collections that are associated with a specific policy. This information helps you quickly get an overview of how the policy is associated with different items.

Follow these steps:

1. Navigate to the **Configuration Manager**, **Policies** node in the **Explorer** tab.
2. Select the required policy under the **Policies** node.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **Associated Devices, Associated Global Collections, Associated Device Families** subviews.
5. Review the list of associations in the tables, as required.

The following screenshot shows the required information:



Multi-line Block Policy Example

This section provides an example of how to use multi-line block policies. The same use case is implemented in two different ways: by comparing to specified contents, and by comparing it to another configuration.

> **NOTE**
> The content provided in this section is intended to provide a sample use case at a high level. For additional information on any of the concepts or items referenced in this section, please refer to the appropriate parent topic.

Scenario

Suppose you want to shut down certain interfaces that have been identified by the word "shutdown" appearing in their descriptions. You can identify such devices by defining multi-line block policies in the following ways:

- **By comparing to Specified Contents:**. You can search for all interfaces that do not contain "shutdown" in the description as the policy definition. This will highlight all the interfaces that *do* contain "shutdown" in the description as violators of the policy.
- B**y comparing to Specific Content with Script:** You can search for all interfaces that do not contain "shutdown" in the description as the policy definition. This will highlight all the interfaces that *do* contain "shutdown" in the description as violators of the policy.
- **By comparing it to Another Configuration:** You can monitor content by comparing newly captured configurations to a reference configuration every time a capture occurs. When "shutdown" is added to the description for an interface, it will be highlighted as a violator of the policy because it does not match the reference configuration.

After the devices are identified, the shutdown command can then be issued easily for those interfaces marked for shutdown as part of the recommended upload for corrective action.

Getting Started

Before you begin defining a policy, you must do the following:

- Identify what constitutes a block.
- Establish a reference configuration (if comparing to a reference configuration).

You can gather this information by reviewing captured host configurations for the device. Configurations are captured using the Global Sync task, the Sync task, and the Capture Configuration icon.

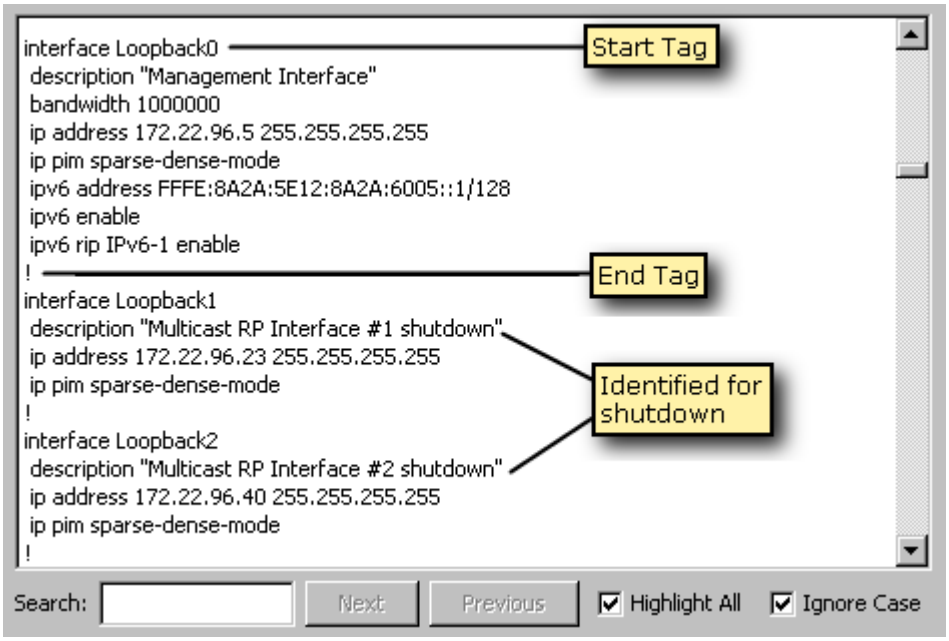
To view a captured host configuration for a device

1. Select a device in the **Explorer** tab.
2. Verify the **List** tab is selected in the **Contents** panel and select the **Host Configuration** tab in the **Component Detail** panel.
3. Click the row in the **Host Configuration** table for the captured host configuration that you want to view.
   The captured host configuration appears in the box below the table.

   NOTE
   For more information, see View Configuration History for a Single Device.

Identify What Constitutes a Block

The following image shows a portion of the configuration file for a device. You can see that each interface on this device has a similar format and is delimited by a start tag and an end tag. Also, notice the appearance of "shutdown" in the descriptions for a couple of interfaces.



In block policy terminology, each block in this example would be defined by:

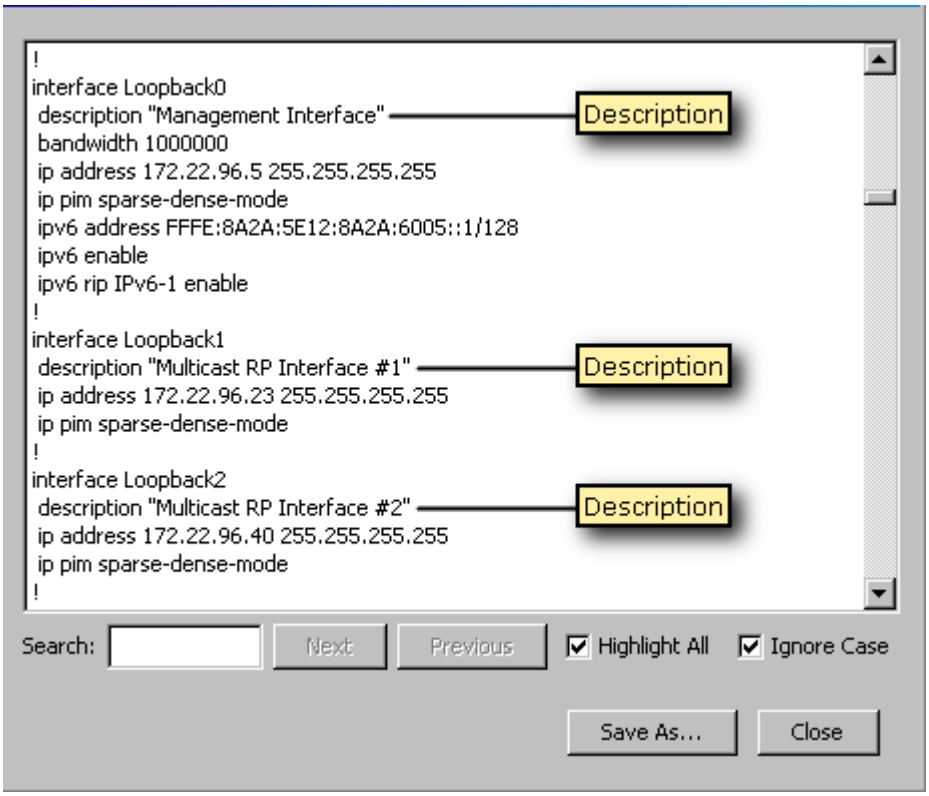
1. **Start Tag:** interface
2. **End Tag:** !

Establish a reference configuration (if comparing to a reference configuration)

Use the procedure outlined in "To view a captured host configuration for a device" to identify a host configuration that contains ideal settings for the device, and specify this configuration as its Reference Configuration. For information on setting a reference configuration, see Specify a Reference Configuration.

> **NOTE**
> You can also use the last captured configuration for comparison instead of the reference configuration.

The following image shows a portion of the configuration file that will be used as the reference configuration. Notice that this configuration does not contain "shutdown" in the description for any of the interfaces.



Defining the Policy

After you have established what constitutes a block and have specified a reference configuration (if applicable), the multi-line block policy can be defined.

Refer to the steps outlined in Create a Policy to create a multi-line block policy and subsequently invoke the Create NCM Block Policy dialog, which contains the following sections:

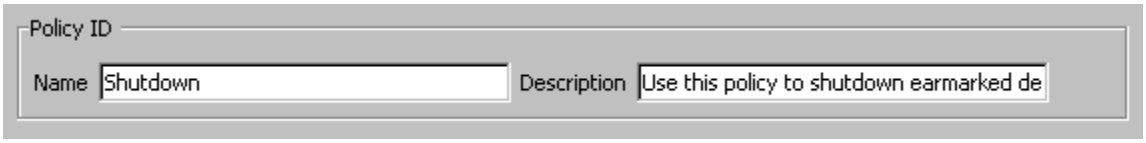
- Policy ID
- Policy Criteria
- Policy Actions

Each of these sections will be described separately.

> **NOTE**
> Additional detailed information for each of the fields mentioned in this section is available in the Create a Policy section.

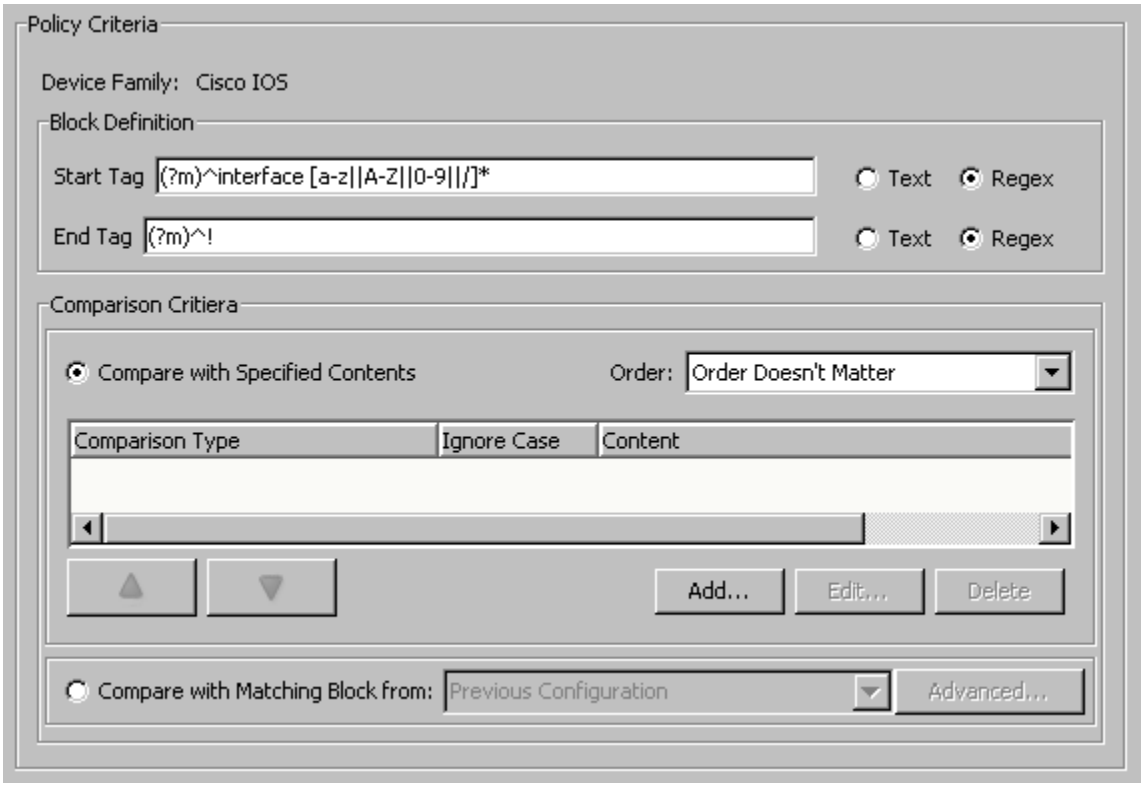
Policy ID

Policy ID information identifies the policy. Use these fields to name the policy according to standards in place at your site.



Policy Criteria

The Policy Criteria information defines the block-delimiting fields and the comparison criteria, which are described following the image. In 10.4.2, the **Device Family** option is not available. This option is applicable only for previous releases. The following screenshot is for a previous release.

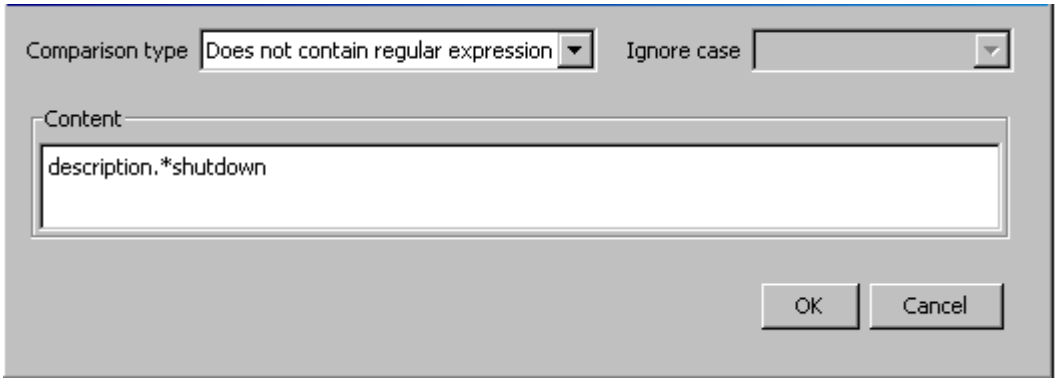


- **Block Definition.** The Start Tag and End Tag fields define strings that are used to identify the beginning and end of a block. In this example, regular expression values are used to designate that each block begins with the string "interface *name*" and ends with the character "!". These values are included as part of the block.

Comparison Criteria

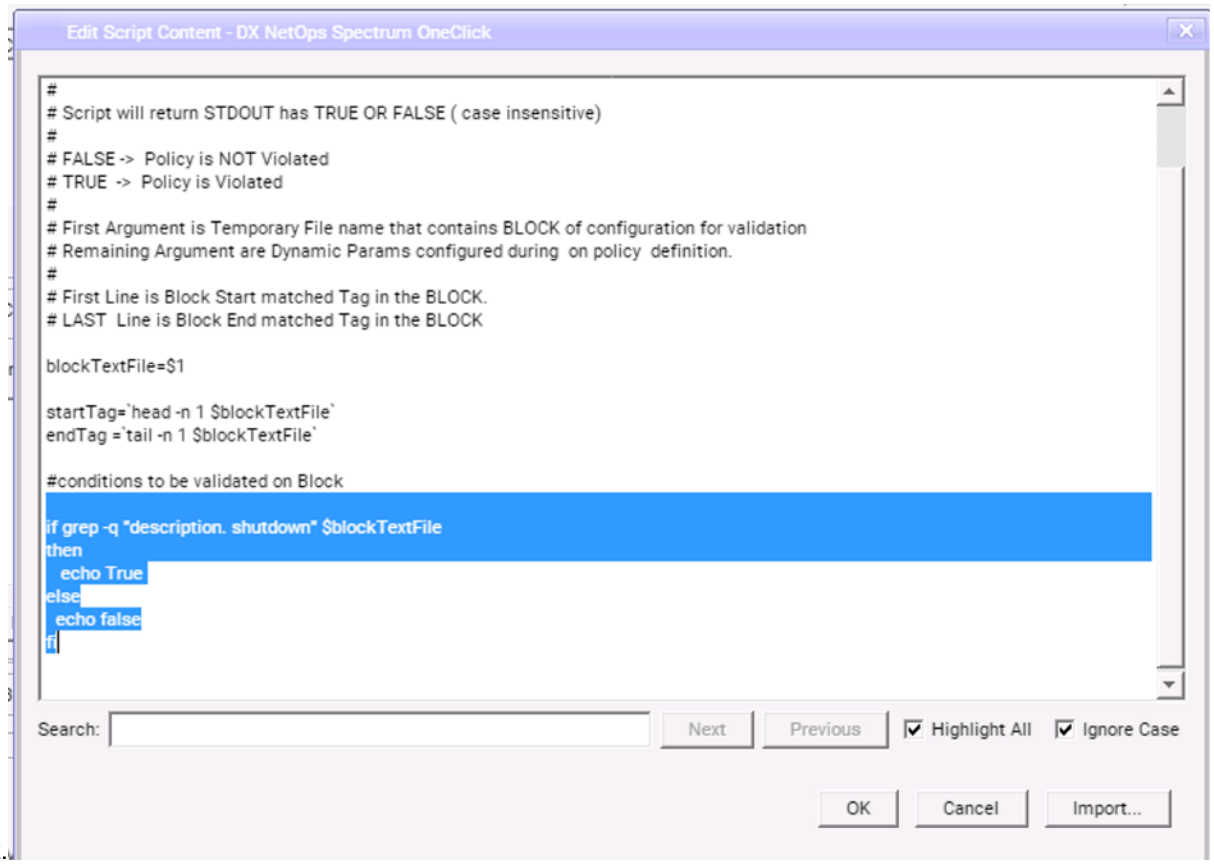
This section controls the method by which a newly captured configuration is evaluated against the policy. You can specify whether to compare the configuration against specific, user-defined criteria, specific content with a script, or against another configuration.

Compare with Specified content:



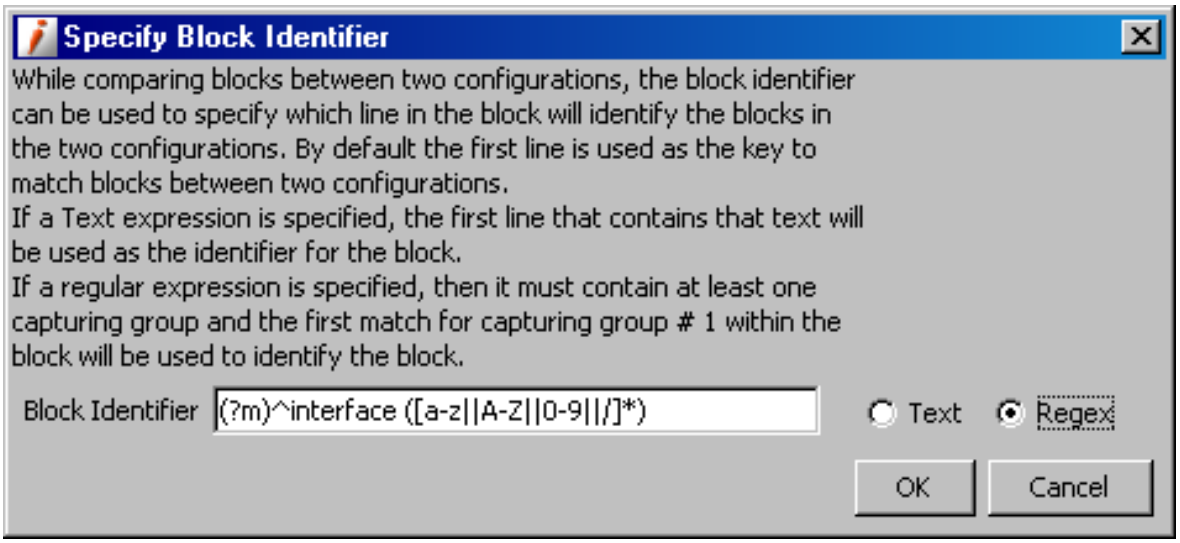
NOTE
Only one set of criteria can be included in a single policy. Both sets of criteria are shown here for demonstration purposes only.

Compare Specified content with Script:
Set the default script using the Set button and modify it to validate the condition. You can create a new script with a custom validation condition. In this example, we are modifying the script content at the policy level. In the following illustration, we can see the implementation of the same example we used for comparison with specified content, using the compare specified content with the script.



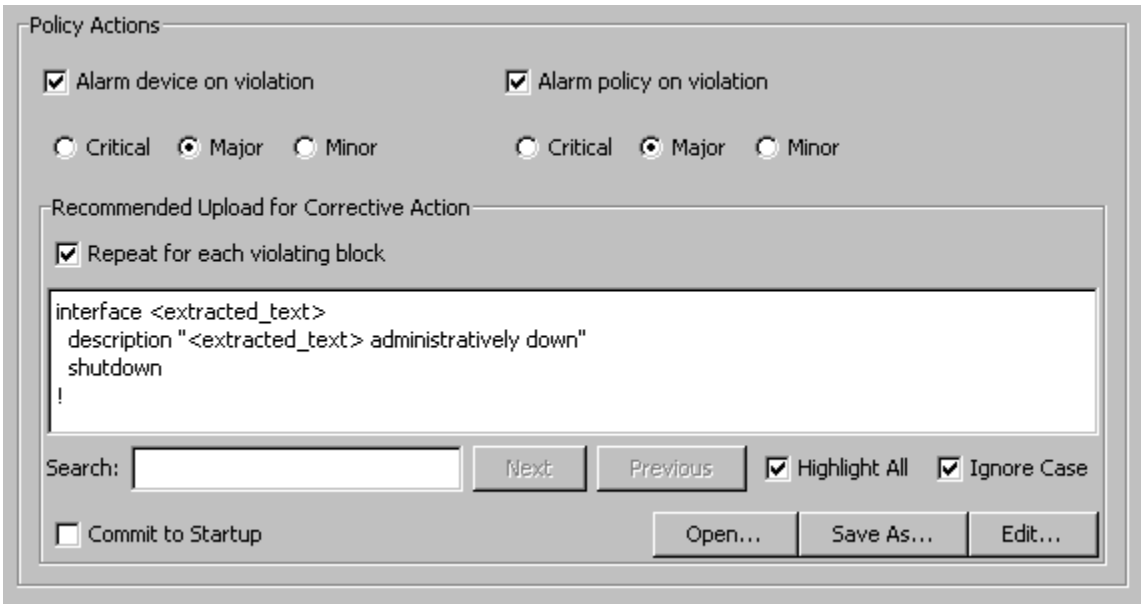
NOTE
The end of line charcter in each line must be in UNIX format.

Compare with Reference Configuration:
The option to 'Compare with Matching Block from Reference Configuration' indicates that each configuration that is captured after the policy is enabled will be compared to the configuration that has been designated as the Reference Configuration for the device. Click the Advanced button to specify the Block Identifier, which is used to match corresponding blocks between the current configuration and the reference (or previous, if specified) configuration. The following example will match up based on "interface *name'":*

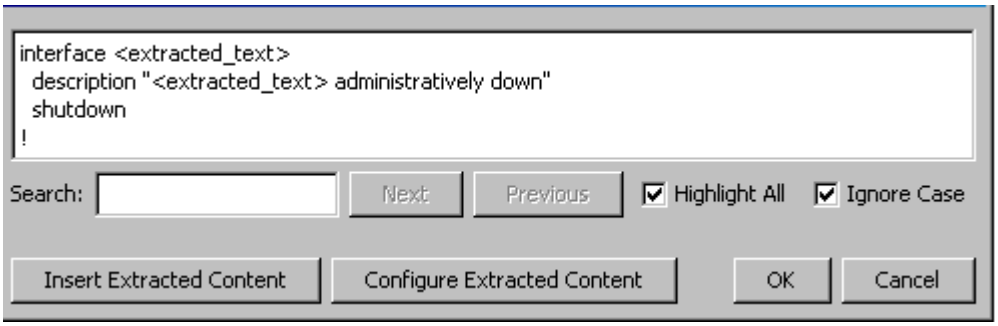


Policy Actions

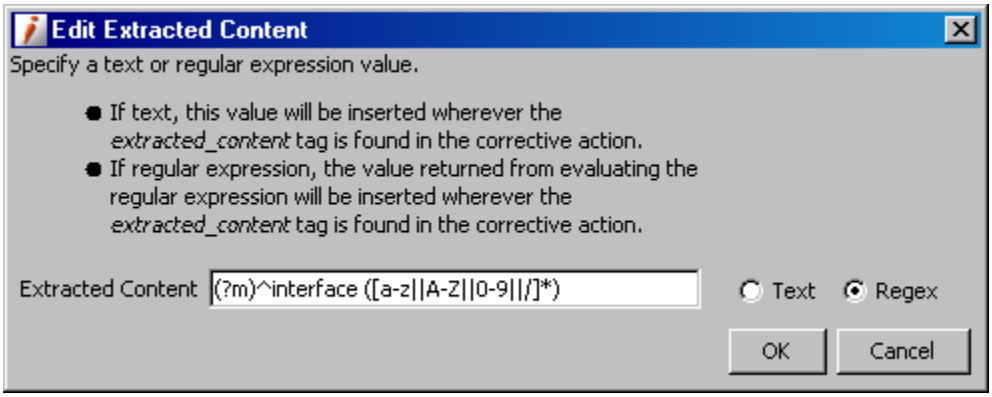
The Policy Actions options define how alarms should be generated and the corrective action to be uploaded should non-compliance occur. The following image shows this section (already populated) and will be described subsequently:



- Specify alarm preferences for when a violation occurs. Alarms can be associated with the device, the policy, or both.
- To define the 'Recommended Upload for Corrective Action,' click the Edit button to display the Edit Corrective Action dialog. In the box, enter the content that will be uploaded to the device. The following image shows content that will upload a modified description and the shutdown command to the device:



In this example, the <extracted_text> tag will be replaced by block-specific content when the policy runs. To insert this tag into your corrective action, use the Insert Extracted Content button. To configure what will be used to replace the tag, click the Configure Extracted Content button, which opens the following dialog:



In this example, the name of the interface will be extracted from each block and used to create corrective action content.

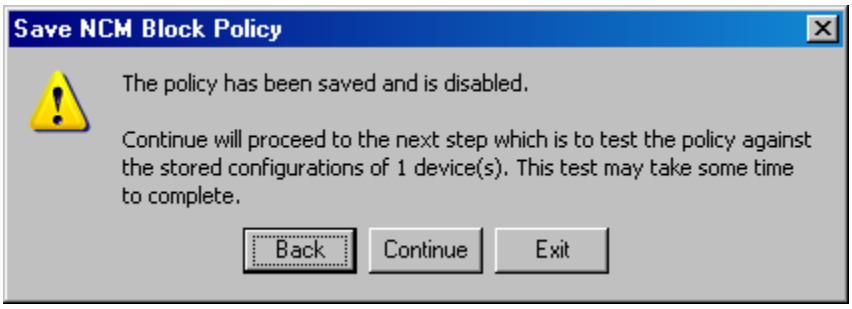
After the corrective action content is defined, it appears in the Recommended Upload for Corrective Action box. Select the 'Repeat for each violating block' option if you want this change to be made for each occurrence of a violation; if it is left blank, the change will only be made for the first occurrence.

Saving and Testing the Policy

After the policy is initially defined, it should be tested before being enabled to make sure it operates as expected.

To proceed with testing of the policy, click Save on the Create NCM Block Policy dialog to save your settings. On the ensuing Save dialog, shown in the next image, click Continue to test the policy.

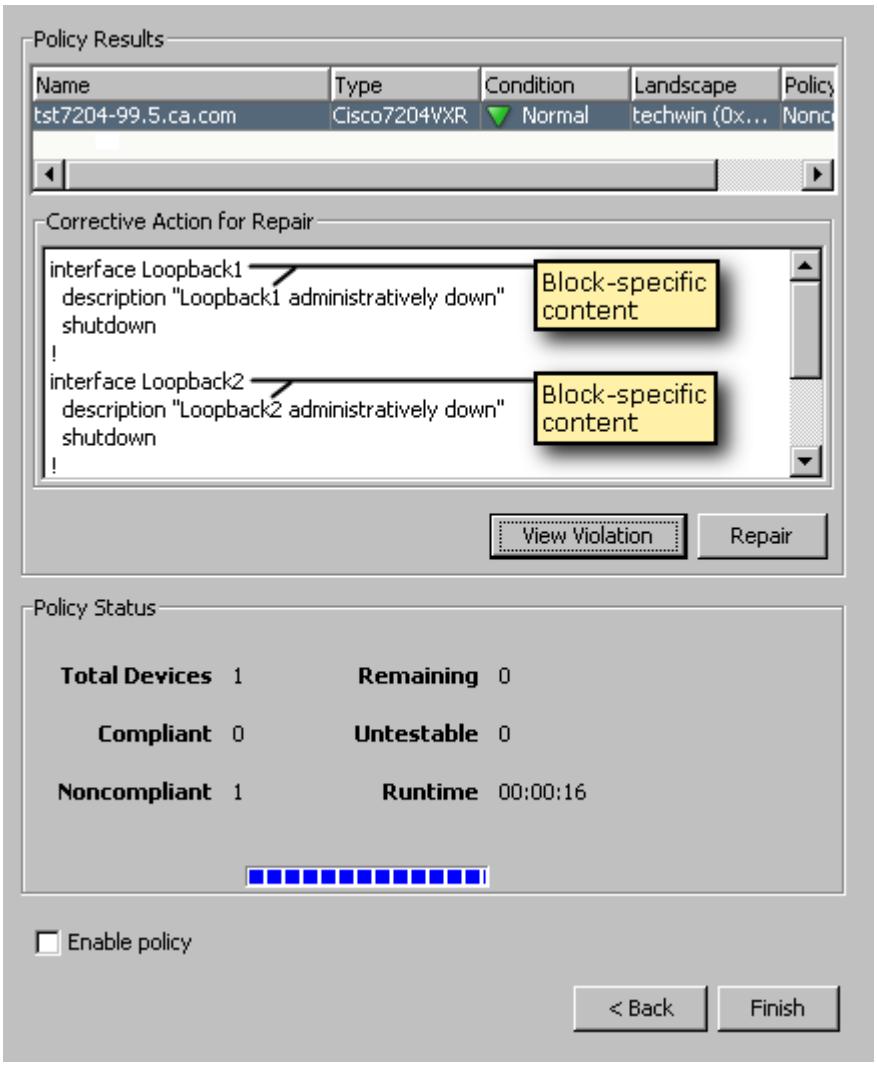
> **NOTE**
> You can also select Back to make additional changes to the policy definition. If you click Exit, the policy is saved but disabled.



The Test NCM Block Policy dialog opens, the test begins, and the status bar indicates its progress. During the test, current configurations are captured and compared to criteria specified in the policy. Blocks are matched based on the block identifier and the contents of corresponding blocks are compared.

NOTE
Depending on the number of devices included, the test may take a while to complete.

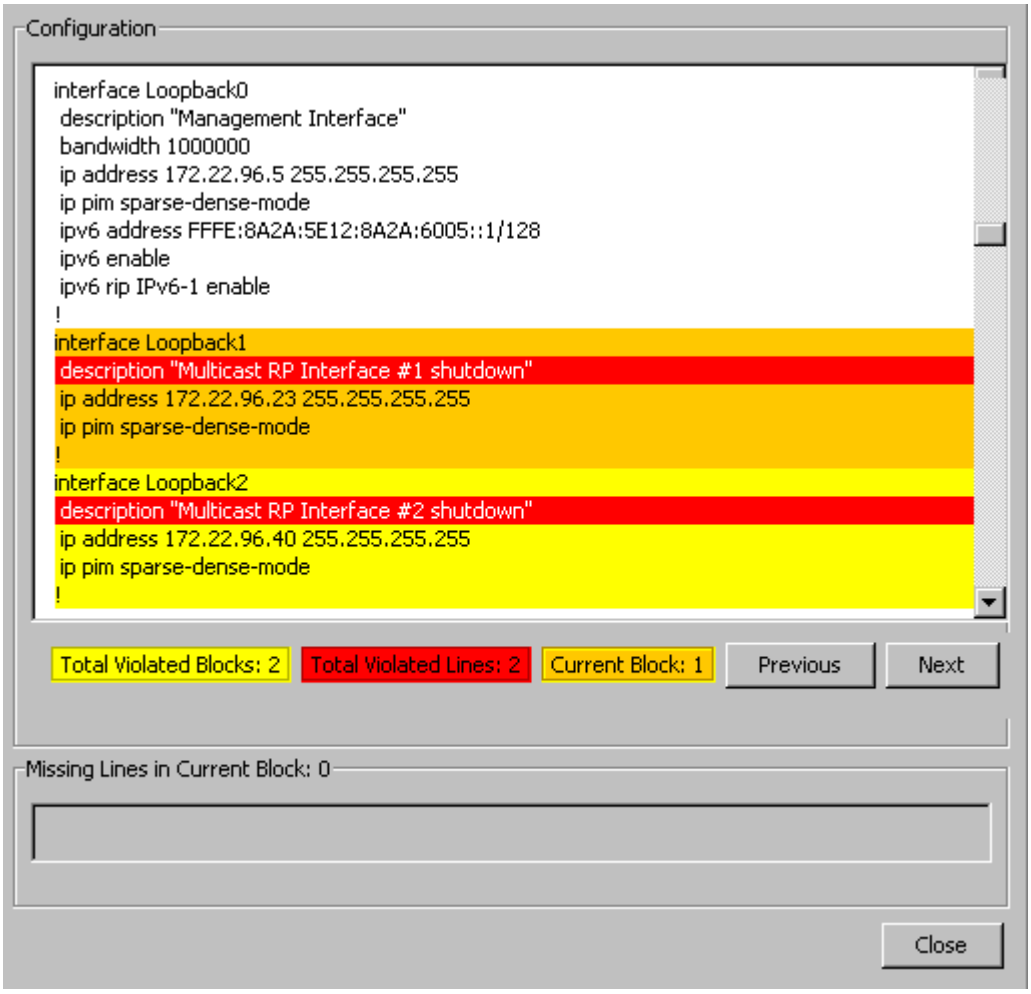
When testing of the policy is complete, the policy results are displayed, as follows:



When non-compliancy is detected, as in this example, the number of devices affected is reported in the Policy Status section, and, if it has been defined, corrective action is displayed as well. Notice that the <extracted_text> tag has been replaced with block-specific content.

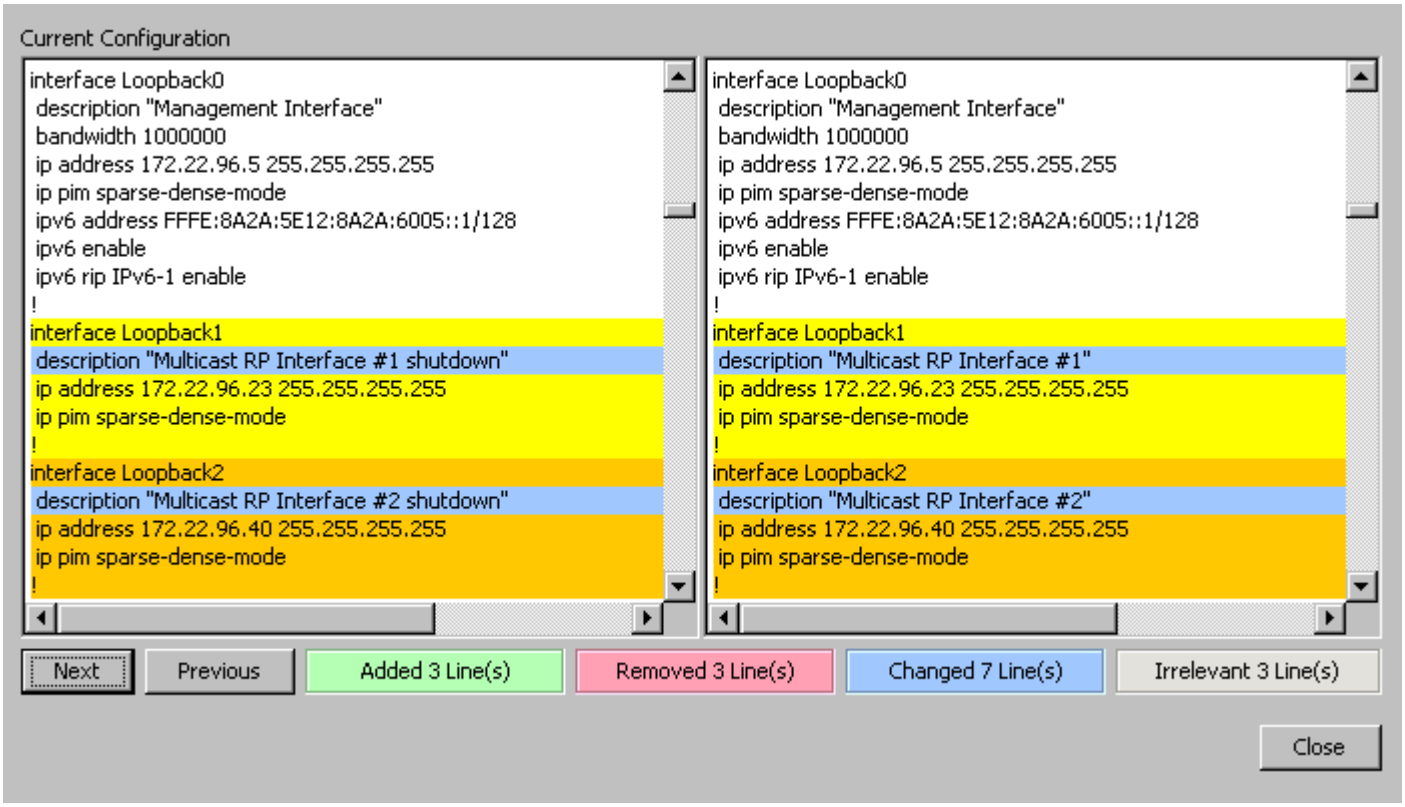
After the test is complete, you can do the following from the test dialog:

- To view the policy violations, click View Violation. A dialog appears that shows the violations.
  - If you used specified contents for comparison criteria, the View Violation Blocks dialog appears, as in the following image. Each block is distinguished by color and the violated lines are highlighted. In this example, the lines beginning with "description" and containing "shutdown" are identified as violations. You can scroll through the violations using the Next and Previous buttons.



If you used another configuration for comparison criteria, the View Policy Violation dialog appears, as in the following image. Each block is distinguished by color and the differences are highlighted. In this example, the description content for two of the interfaces does not match what was defined as the reference. You can scroll through the violations using the Next and Previous buttons.

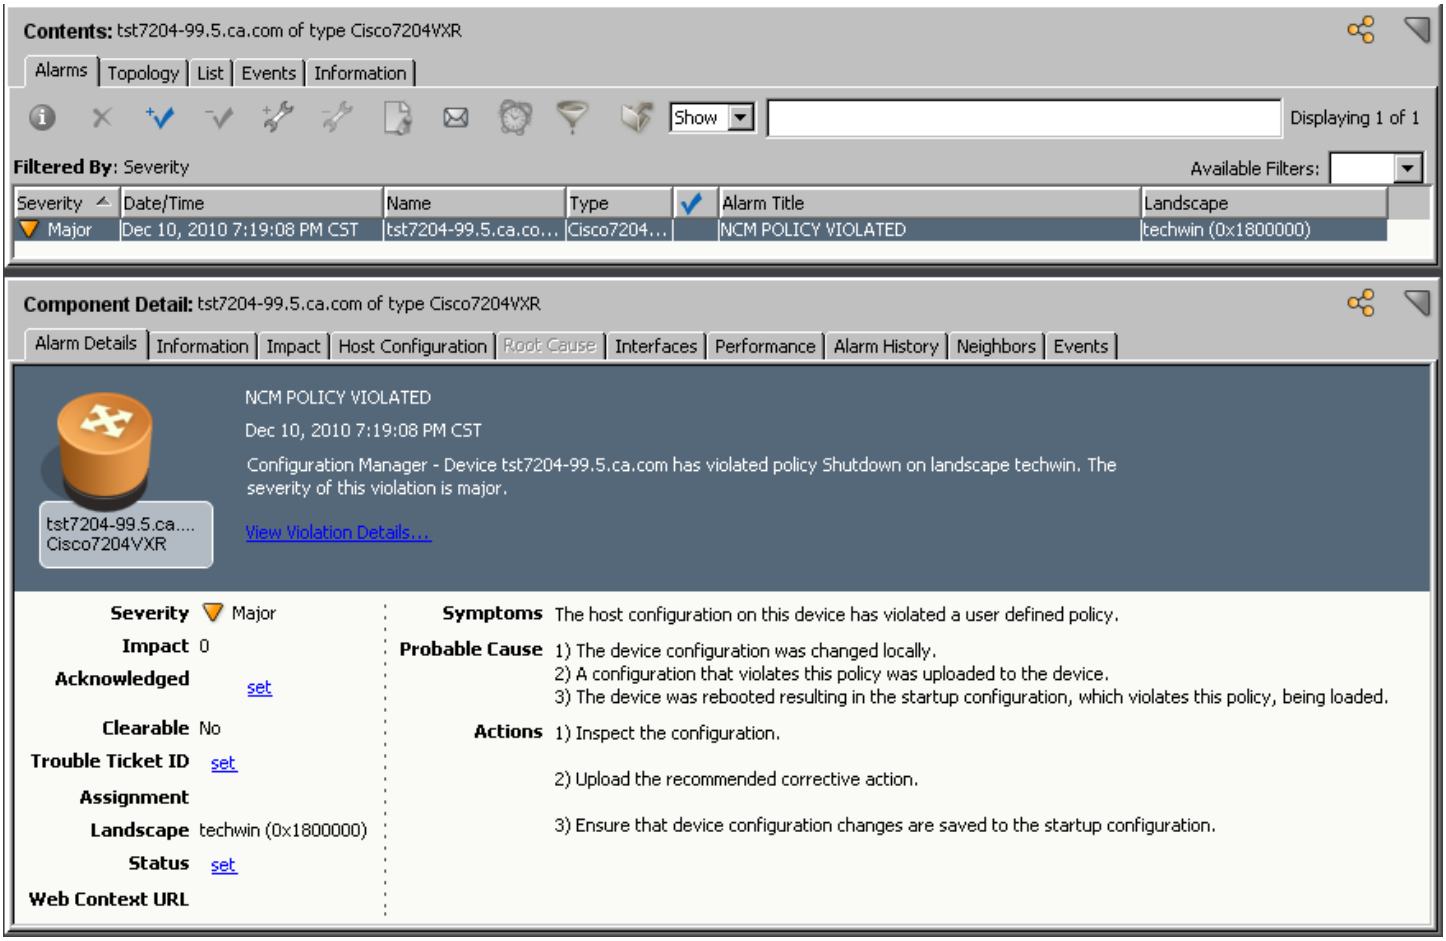
WARNING
When comparing against a reference configuration, be sure to review each of the differences found so that you do not inadvertently execute a corrective action where it does not apply.



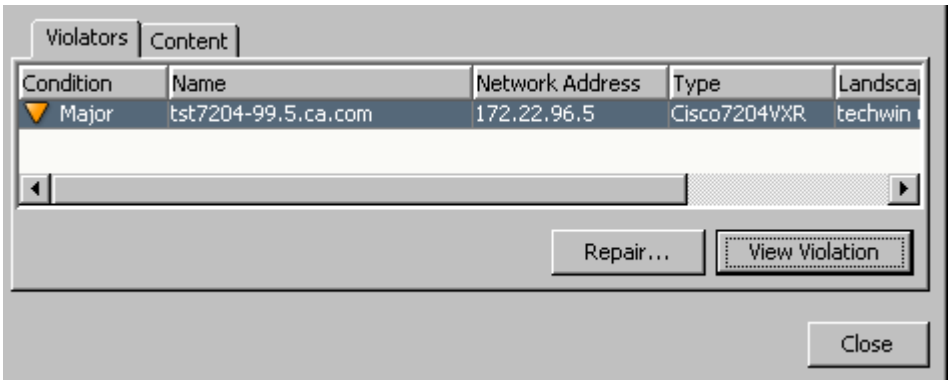
- To correct the policy violation and thereby make the device compliant, click Repair to upload the content as outlined in the 'Corrective Action for Repair' box. An Upload task is created and executed, with the results of the task displayed in the 'Upload Task Results' dialog.
- If you are satisfied with the results of the test, select the 'Enable policy' option to start automatic monitoring and alarm generation based on this policy; otherwise, you can click Back and modify the policy definition. If you click Finish, the policy will be saved but not enabled.

Monitoring Violations

After a policy has been enabled, it monitors configurations that are captured and will alert you to any violations based on the actions you have specified. An alarm generated by a policy violation has an alarm title of 'NCM Policy Violated.' The following image shows an alarm generated based on this example policy:



From the alarm details, you can click View Violation Details, which will open the Repair Devices in Violation dialog as follows:



From this dialog, you can use the available buttons to view violations or repair the non-compliant devices as described when testing the policy.

NOTE
You can also launch this dialog from the Network Configuration Policies table in the Contents panel for the non-compliant device. For more information, see Repair Non-Compliant Devices from the Policy Table.

Devices Supported by Network Configuration Manager

Cisco Devices

The DX NetOps Spectrum Network Configuration Manager supports the following Cisco devices. For a list of supported Catalyst devices, see Cisco Supported Catalyst Devices. For a list of PIX firewall devices, see Cisco Supported PIX Firewall Devices.

The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

When a Perl script is the only means of communication with the device, the script method is provided.

Cisco Supported PIX Firewall Devices

The DX NetOps Spectrum Network Configuration Manager supports the following Cisco devices. For a list of supported Catalyst devices, see Cisco Supported Catalyst Devices.

The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

When a Perl script is the only means of communication with the device, the script method is provided.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
PIX Firewall	1.3.6.1.4.1.9.1.227	no	no	no	Telnet
PIX 506 Firewall	1.3.6.1.4.1.9.1.389	no	no	no	Telnet
PIX 515 Firewall	1.3.6.1.4.1.9.1.390	no	no	no	Telnet

Cisco NX OS Supported Devices

The following table lists Cisco NX OS devices supported by DX NetOps Spectrum Network Configuration Manager.

NOTE
Cisco NX OS devices are supported through scripts that utilize the Net::SSH::Expect modules. The Perl area must be set up with these modules for out-of box support for Cisco NX OS devices.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
Cisco Nexus 1000V VSM	1.3.6.1.4.1.9.12.3.1.3.840	no	no	no	yes
Cisco Nexus 2000	1.3.6.1.4.1.9.12.3.1.3.820	no	no	no	yes
Cisco Nexus 5000	1.3.6.1.4.1.9.12.3.1.3.719	no	no	no	yes
Cisco Nexus 7000	1.3.6.1.4.1.9.12.3.1.3.612	no	no	no	yes

Enterasys Supported Devices

The following table lists Enterasys devices supported by DX NetOps Spectrum Network Configuration Manager. The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support

Foundry Supported Devices

The following table lists Foundry devices supported by DX NetOps Spectrum Network Configuration Manager. The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
BigIronMG8Sw	1.3.6.1.4.1.1991.1.3.32.1	FOUNDRY-SN-AGENT-MIB	no	no	yes

M7i	1.3.6.1.4.1.2636.1.1.1.2.10	no	no	*yes	yes
M10	1.3.6.1.4.1.2636.1.1.1.2.4	no	no	*yes	yes
M10i	1.3.6.1.4.1.2636.1.1.1.2.11	no	no	*yes	yes
M20	1.3.6.1.4.1.2636.1.1.1.2.2	no	no	*yes	yes
M40	1.3.6.1.4.1.2636.1.1.1.2.1	no	no	*yes	yes
M40e	1.3.6.1.4.1.2636.1.1.1.2.8	no	no	*yes	yes
M160	1.3.6.1.4.1.2636.1.1.1.2.3	no	no	*yes	yes
M320	1.3.6.1.4.1.2636.1.1.1.2.9	no	no	*yes	yes
T320	1.3.6.1.4.1.2636.1.1.1.2.7	no	no	*yes	yes
T640	1.3.6.1.4.1.2636.1.1.1.2.6	no	no	*yes	yes
TX	1.3.6.1.4.1.2636.1.1.1.2.17	no	no	*yes	yes

*Device must support SSH V2

Lancom Supported Devices

The following table lists Lancom devices supported by DX NetOps Spectrum Network Configuration Manager. Supported devices must be running firmware LCOS 7.58.0045 or above. The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

When a Perl script is the only means of communication with the device, the script method is provided.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
LANCOM 1721 VPN	1.3.6.1.4.1.2356.500.4.1721	no	no	no	Telnet/ TFTP
LANCOM 1751	1.3.6.1.4.1.2356.1000.1.1751	no	no	no	Telnet/ TFTP
LANCOM 7111	1.3.6.1.4.1.2356.500.2.7111	no	no	no	Telnet/ TFTP
LANCOM 8011	1.3.6.1.4.1.2356.500.2.8011	no	no	no	Telnet/ TFTP

Nortel Baystack Supported Devices

The following table lists Nortel Baystack devices supported by DX NetOps Spectrum Network Configuration Manager. The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
BayStack450-24T	1.3.6.1.4.1.45.3.35.1	no	no	*yes	yes

BayStack380-24T	1.3.6.1.4.1.45.3.45.1	no	no	*yes	yes
BayStack420	1.3.6.1.4.1.45.3.43.1	no	no	*yes	yes
BayStack460-24T	1.3.6.1.4.1.45.3.49.1	no	no	*yes	yes
BayStack470-48T	1.3.6.1.4.1.45.3.46.1	no	no	*yes	yes
BayStack425-24T	1.3.6.1.4.1.45.3.57.2	no	no	*yes	yes
BayStack470-24T	1.3.6.1.4.1.45.3.54.1	no	no	*yes	yes
BayStack5510-24T	1.3.6.1.4.1.45.3.52.1	no	no	*yes	yes
BayStack5510-48T	1.3.6.1.4.1.45.3.53.1	no	no	*yes	yes
BayStack5520-24T-PWR	1.3.6.1.4.1.45.3.59.1	no	no	*yes	yes
BayStack5520-48T-PWR	1.3.6.1.4.1.45.3.59.2	no	no	*yes	yes
Nortel ERS 5530-24TFD	1.3.6.1.4.1.45.3.65	no	no	*yes	yes

* Device must support SSH V2

Nortel Passport Supported Devices

The following table lists Nortel Passport devices supported by DX NetOps Spectrum Network Configuration Manager. The table provides examples. For the most up-to-date information on device support, access the CA Device Certification database.

Device Name	Sys OID	SNMP/TFTP Support	Telnet Support	SSH Support	Perl Support
Passport1424T	1.3.6.1.4.1.2272.42	SWL2MGMT-MIB	no	no	yes
Passport1648	1.3.6.1.4.1.2272.43	SWL2MGMT-MIB	no	no	yes
Passport1612	1.3.6.1.4.1.2272.44	SWL2MGMT-MIB	no	no	yes
Passport1624	1.3.6.1.4.1.2272.45	SWL2MGMT-MIB	no	no	yes
Passport8610	1.3.6.1.4.1.2272.30	RAPID-CITY MIB	no	no	yes
Passport8606	1.3.6.1.4.1.2272.31	RAPID-CITY MIB	no	no	yes
Passport8110	1.3.6.1.4.1.2272.32	RAPID-CITY MIB	no	no	yes
Passport8106	1.3.6.1.4.1.2272.33	RAPID-CITY MIB	no	no	yes
Passport8610	1.3.6.1.4.1.2272.37	RAPID-CITY MIB	no	no	yes
IntrWanPE100	1.3.6.1.4.1.2272.40	RAPID-CITY MIB	no	no	yes
Passport8006	1.3.6.1.4.1.2272.280887558	RAPID-CITY MIB	no	no	yes
Passport8010	1.3.6.1.4.1.2272.280887562	RAPID-CITY MIB	no	no	yes

Network Configuration Manager Events

About Network Configuration Manager Events

Events are generated when a configuration change occurs on a device. All events for a particular device during a specified Correlation Event Period, which is set in Configuration Manager General Configuration, are combined. See Configure General Configuration for more information.

Information is correlated based on device traps, Syslog traps and events, Network Configuration Manager internals and any other trap that is mapped to the generic change event. This information varies by device family. Out-of-box support is provided for Cisco CatOS, Cisco IOS, Cisco IOS - SSH Capable, and Juniper JUNOS device families. See Configure Notification Trap Settings for more information on customizing traps for your installation.

Events Generated on the Device

Configuration Change

Event0082101b:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Configuration change detected on device {m} of type {t} on landscape {S 3}. (event [{e}])

Event00821029:{d "%w- %d %m-, %Y - %T"} Configuration Manager - A configuration change notification was received from device {m}. (event [{e}])

Event0082105e:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The running configuration of device {m} on landscape {S 2} is changed. (event [{e}])

Event0082105f:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The running configuration of device {m} on landscape {S 2} is changed. An alarm will be generated on this model. (event [{e}])

Correlation of Configuration Change Events

Event0082105a:{d "%w- %d %m-, %Y - %T"} Configuration Manager - A configuration change notification was received from device {m} of type {t} on landscape {S 1}.

Device trap(s) provided:

1. Device User: {S 2}
2. From: {S 3}
3. On: {S 4}

The following information was provided by SPECTRUM:

Device User: {S 2}

1. Spectrum User: {S 5}
2. NCM Communication Mode: {S 6}
3. Capture Succeeded: {S 7}
4. Capture Error Message: {S 8}
5. Total Number of Line Changes: {I 9}
6. Relevant Number of Line Changes: {I 10}
7. Violated Policies: {S 11}
8. Compliant Policies: {S 12}
9. Model handle of current configuration model: {H 13}
10. Model handle of previous configuration model: {H 14}

Startup and Running Configurations Same/Differ

Event00821024:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The startup configuration of device {m} on landscape {S 3} differs from its running configuration. (event [{e}])

Event00821025:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The startup configuration of device {m} on landscape {S 3} differs from its running configuration. A minor alarm will be generated on this model. (event [{e}])

Event00821026:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The startup configuration of device {m} on landscape {S 3} differs from its running configuration. A major alarm will be generated on this model. (event [{e}])

Event00821027:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The startup configuration of device {m} on landscape {S 3} differs from its running configuration. A critical alarm will be generated on this model. (event [{e}])

Event00821028:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The startup configuration of device {m} on landscape {S 3} is equal to its running configuration. (event [{e}])

Reference and Running Configuration Same/Differ

Event0082105b:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The reference running configuration of device {m} on landscape {S 2} differs from its current running configuration. (event [{e}])

Event0082105c:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The reference running configuration of device {m} on landscape {S 2} differs from its current running configuration. An alarm will be generated on this model. (event [{e}])

Event0082105d:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The reference running configuration of device {m} on landscape {S 2} is equal to its running configuration. (event [{e}])

Device Compliant/Noncompliant with Policy

Event00821016:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} is compliant with policy {S 1} on landscape {S 3}. (event [{e}])

Event00821017:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} is not compliant with policy {S 1} on landscape {S 3}. (event [{e}])

Event00821051:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Unable to verify policy compliance of host configuration on device {m} of type {t} on landscape {S 1}.
Specific error: {S 2} (event [{e}])

Event00821055:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} is no longer in violation of policy {S 1} because the device has been removed from global collection {S 2} on landscape {S 3}. (event [{e}])

Event00821056:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} is no longer in violation of policy {S 1} because the device has been removed from device family {S 2} on landscape {S 3}. (event [{e}])

Event00821057:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} on landscape {S 2} is no longer in violation of policy {S 1} because the policy has been deleted. (event [{e}])

Device Noncompliant with Policy Alarm Generating Events

Event00821020:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} has violated policy {S 1} on landscape {S 3}. The severity of this violation is minor. (event [{e}])

Event00821021:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} has violated policy {S 1} on landscape {S 3}. The severity of this violation is major. (event [{e}])

Event00821022:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} has violated policy {S 1} on landscape {S 3}. The severity of this violation is critical. (event [{e}])

Capture Succeeded/Failed

Event00821000:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Capture succeeded for host configuration file from device {m} of type {t} on landscape {S 1} initiated by user {S 2}. (event [{e}])

Event00821001:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Capture failed for host configuration file from device {m} of type {t} on landscape {S 1} initiated by user {S 2}.
Specific error: {S 3} (event [{e}])

Event00821049:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Capture succeeded for host startup configuration file from device {m} of type {t} on landscape {S 1} initiated by user {u}. (event [{e}])

Event00821050:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Capture failed for host startup configuration file from device {m} of type {t} on landscape {S 1} initiated by user {u}. Specific error: {S 3} (event [{e}])

Upload Succeeded/Failed

Event00821002:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Load succeeded for host configuration on device {m} of type {t} on landscape {S 1} initiated by user {S 2}. (event [{e}])

Event00821003:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Load failed for host configuration on device {m} of type {t} on landscape {S 1} initiated by user {S 2}.
Specific error: {S 4} (event [{e}])

Upload Failed Alarm Generating Events

Event00821035:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Load failed for host configuration on device {m} of type {t} on landscape {S 1} initiated by user {S 2}.
The severity of this failure is minor. (event [{e}])

Event00821036:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Load failed for host configuration on device {m} of type {t} on landscape {S 1} initiated by user {S 2}.
The severity of this failure is major. (event [{e}])

Event00821037:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Load failed for host configuration on device {m} of type {t} on landscape {S 1} initiated by user {S 2}.
The severity of this failure is critical. (event [{e}])

Write to Startup Succeeded/Failed

Event00821018:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Successfully wrote the running configuration to the startup configuration on device {m} of type {t} on landscape {S 1} initiated by {S 2}. (event [{e}])

Event00821019:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The attempt to write the running configuration to the startup configuration on device {m} of type {t} failed on landscape {S 1}. This operation was initiated by {S 2}. Specific Error: {S 3}. (event [{e}])

NCM Enabled/Disabled on Device

Event0082102f:{d "%w- %d %m-, %Y - %T"} Configuration Manager - NCM has been disabled for device {m}. (event [{e}])

Event00821030:{d "%w- %d %m-, %Y - %T"} Configuration Manager - NCM has been enabled for device {m}. (event [{e}])

NCM Disabled, Operation Not Performed

Event00821032:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The requested NCM operation was not performed on model {m} because NCM is disabled on the models device family. (event [{e}])

Event00821033:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The requested NCM operation was not performed on model {m} because NCM is disabled on this model. (event [{e}])

Event00821034:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The requested NCM operation was not performed on model {m} because this model is a proxy model. (event [{e}])

Device Firmware Load

Event00821053:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Firmware load completed successfully on device {m} of type {t} on landscape {S 1}. Firmware script was executed with command line parameters: {S 3} This operation was initiated by {u}. (event [{e}])

Event00821054:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Firmware load failed on device {m} of type {t} on landscape {S 1}. Specific error: {S 2} Firmware script was executed with command line parameters: {S 3} (event [{e}])

Device Added/Removed from Device Family

Event00821058:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} has been added to device family {S 2} on landscape {S 1}. (event [{e}])

Event00821059:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Device {m} of type {t} has been removed from device family {S 2} on landscape {S 1}. (event [{e}])

Events Generated on Policies

Policy Enabled/Disabled

Event00821014:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} been enabled by {u}. (event [{e}])

Event00821015:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} been disabled by {u}. (event [{e}])

Event00821023:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {S 1} has been disabled. Any alarms previously generated by violations of this policy have been cleared. (event [{e}])

Policy Modified

Event00821011:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} has been modified by {u}. (event [{e}])

Policy has Violators

Event00821012:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} has a violator on landscape {S 1}. (event [{e}])

Event00821013:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} no longer has a violator on landscape {S 1}. (event [{e}])

Violated Policy, Alarm Generating Events

Event0082101d:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} has a violator on landscape {S 1}. The severity of this violation is minor. (event [{e}])

Event0082101e:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} has a violator on landscape {S 1}. The severity of this violation is major. (event [{e}])

Event0082101f:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Policy {m} has a violator on landscape {S 1}. The severity of this violation is critical. (event [{e}])

Events Generated on Tasks Global Sync, Capture, Upload and Write to Startup

Task Scheduled/Unscheduled

Event00821040:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Scheduled - Task {m} of type {t} has been scheduled for {S 1} on landscape {S 2}. (event [{e}])

Event00821041:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Unscheduled - Task {m} of type {t} has had the schedule removed on landscape {S 1}. (event [{e}])

Task Started, Stopped, Completed, Partially Completed

Event00821042:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Started - Task {m} of type {t} has been started by {S 1} on {I 2} devices on landscape {S 3}. (event [{e}])

Event00821043:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Stopping - Task {m} of type {t} was stopped by {S 1} on landscape {S 3}. (event[{e}])

Event00821045:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Completed - Task {m} of type {t} has completed with all devices processed on landscape {S 1}. Out of a total of {I 2} devices, {I 3} succeeded and {I 4} failed. (event [{e}])

Event00821044:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Partially Completed - Task {m} of type {t} completed with {I 5} unprocessed devices on landscape {S 1}. For a total of {I 2} deivces, {I 3} succeeded, {I 4} failed and {I 5} devices remained unprocessed. (event [{e}])

Task Partially Completed Alarm Generating Events

Event00821046:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Partially Completed - Task {m} of type {t} completed with {I 5} unprocessed devices on landscape {S 1}. For a total of {I 2} devices, {I 3} succeeded, {I 4} failed and {I 5} devices remained unprocessed. A minor alarm has been generated. (event [{e}])

Event00821047:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Partially Completed - Task {m} of type {t} completed with {I 5} unprocessed devices on landscape {S 1}. For a total of {I 2} devices, {I 3} succeeded, {I 4} failed and {I 5} devices remained unprocessed. A major alarm has been generated. (event [{e}])

Event00821048:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Task Partially Completed - Task {m} of type {t} completed with {I 5} unprocessed devices on landscape {S 1}. For a total of {I 2} devices, {I 3} succeeded, {I 4} failed and {I 5} devices remained unprocessed. A critical alarm has been generated. (event [{e}])

Events Generated on the Configuration Manager Application

Event0082101a:{d "%w- %d %m-, %Y - %T"} Cannot connect to Configuration Manager - Cannot connect to the NCM secure communication daemon on landscape {S 1}. (event [{e}])

Event0082101c:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Cannot create file in Archive Directory. Unable to archive a device configuration. Could not create a file in the archive directory {S 1} on landscape {S 2}. (event [{e}])

Event00821052:{d "%w- %d %m-, %Y - %T"} Configuration Manager - Connection to the ncmservice daemon has been restored. (event [{e}])

Global Unsolicited Notification

Event0082102b:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The ability to respond to unsolicited notifications of configuration change has been globally disabled on all landscapes. (event [{e}])

Event0082102c:{d "%w- %d %m-, %Y - %T"} Configuration Manager - The ability to respond to unsolicited notifications of configuration change has been globally enabled on all landscapes. (event [{e}])

Events Generated on Device Families

Event0082102d:{d "%w- %d %m-, %Y - %T"} Configuration Manager - NCM enabled/disabled for device family {m}. (event [{e}])

Event0082102e:{d "%w- %d %m-, %Y - %T"} Configuration Manager - NCM has been enabled for device family {m}. (event [{e}])

Network Configuration Manager Privileges

This section lists Network Configuration Manager privileges for OneClick users. By default, each privilege is enabled.

> **NOTE**
> See the OneClick Administration section for details about configuring privileges.

- **Network Configuration Manager**
  Allows the administrator to configure the Network Configuration Manager application. This includes configurations performed in the Information tab views from the Configuration Manager node, Device Family nodes, and Network Configuration Manager configuration performed at the individual device level. This also includes the ability to schedule a global synchronization task.
- **Capture Host Configuration**
  Allows the operator to create a bulk capture task or an on-demand capture from the Host Configuration tab.
- **Hide Configuration Changes from Approval Requests**
  Allows the user to decide whether to include configuration content in a workflow approval request.
- **Include Global Collection in NCM Task**
  Allows the user to associate Network Configuration Manager tasks with Global Collections. By having access to a collection, a user will implicitly have access to all members within the collection. With this access, the user can perform any of the tasks, including uploading configurations and loading firmware, on these devices.
- **Load device firmware**
  Allows the operator to upload firmware to devices.
- **Manage NCM Tasks**
  Grants access to the Network Configuration Manager Tasks folder. Access to this folder provides global access to all Network Configuration Manager tasks on all DX NetOps Spectrum landscapes and the ability to start, stop, edit and delete them all.
- **Reload Device**
  Allows operator to reload firmware configuration to a device.
- **Repair Device**
  Allows the operator to upload the specified repair content for a policy with non-compliant devices.
- **Save Host Configuration to Startup**
  Allows the operator to create bulk Save to Startup tasks.
- **Schedule a Reload**
  Allows operator to schedule reload firmware configuration to a device.
- **Schedule NCM Tasks**
  Allows the operator to schedule bulk tasks.
- **Task Approver**
  Controls approval authorization for approval workflow.
  - **ServiceDesk**
    If Approval Workflow Mode is set to ServiceDesk and the user has this privilege, acquiring approval through Service Desk is optional.
  - **OneClick**
    If Approval Workflow Mode is set to OneClick and the user has this privilege, the user can approve his own tasks or tasks that are initiated by others.
- **Upload Host Configuration**
  Allows the operator to create a bulk Upload task or an automatic Upload from the Host Configuration tab.
- **Use Cached Device Authentication**
  Allows the operator to use the username and password as specified in the device family and single device override configurations. The user does not have to enter a username and password each time a task is initiated if this privilege is enabled. When initiating a task (for example, Upload or Save to Startup), the user will be prompted for device authentication if this privilege is disabled.

NOTE
When performing a bulk task, such as an Upload or Save to Startup, without this privilege, the operator is prompted for device authentication once. This same authentication data is then used for all devices for which the bulk operation is performed.

- **View Host Configuration**
  Allows the operator access to host configurations.
- **View NCM Policies**
  Grants access to the Network Configuration Manager Policies folder. Access to this folder provides global access to all Network Configuration Manager policies on all DX NetOps Spectrum landscapes and the ability to edit, enable, disable and delete them all.
  - **Create/Edit NCM Policies**
    Allows the operator ability to create a new policy or edit an existing policy. This privilege does not allow the user to enable a policy.
  - **Enable/Disable NCM Policies**
    Allows the operator to enable, disable, and delete a Network Configuration Manager Policy.
- **View Unmasked Configurations**
  Allows the operator to view content that is blacked-out by the View Mask. The View Mask is on a Device Family and can be overridden at the local device.

Network Configuration Manager Self Certification

From 10.3.1 release, the Network Configuration Manager feature is enhanced to support capturing and managing network configurations for your custom device families by using simple SSH commands. Previously, enabling NCM support for devices did not come with an out of the box NCM support. With this enhancement, users can now enable NCM support for any SSH enabled device by using custom device family and by providing commands in the OneClick view without having to use scripts. You can use the SSH commands to capture and upload the configurations for custom devices which are SSH capable. The SSH commands for respective devices can be obtained from an administrator of the network.

NOTE

We recommend running the bash -login, as a prerequisite, to create the .ssh folder which is required to run the NCM scripts.

The following NCM operations are supported using the SSH commands:

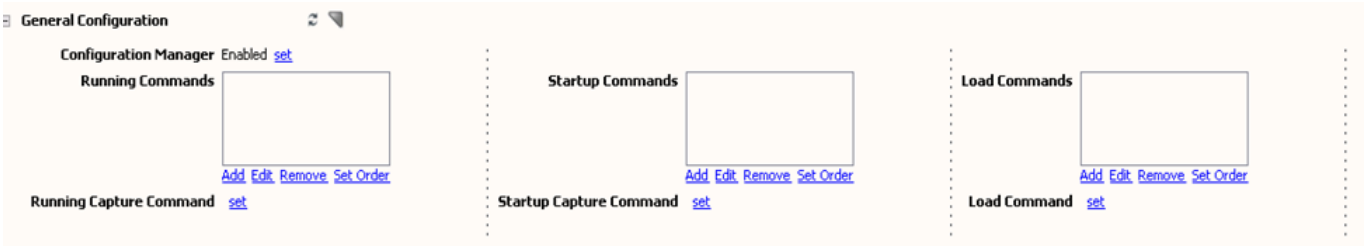
- Capture Startup Configuration
- Capture Running Configuration
- Upload Configuration

NOTE

The existing Perl script mode of configuration is also supported for enabling NCM support for custom devices. Using the SSH-based Perl scripts mode of configuration takes precedence over the SSH commands configuration. For more information about Perl Scripts functionality in NCM, see Using SSH-based Perl Scripts for Network Configuration Manager Operations.

General Configuration for SSH Commands

The following view is added in Spectrum OneClick to support SSH commands. When you select a custom device family in the Explorer tab, you can see the General Configuration section for the respective device family in the Information tab of the Contents panel. Using the General Configuration section, you can configure SSH commands to capture running, startup configurations and upload the modified or saved configurations for a custom device family.



NOTE

For custom devices (which are not supported out-of-the-box), create a custom device family and assign the devices to the family. A device can only belong to a single device family. For instructions, see Create a Custom Device Family section.

General Configuration View

Using the General Configuration view, you can add, edit, or remove commands for running, startup and upload configurations. These commands are also displayed in corresponding attributes of the device family in the Attributes table view of Component Detail panel.

- **Running Commands and Running Capture Command:** The **Running Commands** option allows you to perform the following tasks:
  - Add - To add a command for capturing the running configuration of a device family.
  - Edit- To edit a command.
  - Remove- To remove commands from the running commands box.
  - Set Order- To define the sequence for running the running configuration commands. When you select this option, Set Order pop-up window appears. Select a command and use the up and down arrows to set the order for that command.

  The **Running Capture Command** option allows you to set the command to capture the running conflagration of the selected device family. When you select the Set link, it converts into a drop-down list and allows you to select the command from the list.
- **Startup Commands and Startup Capture Command:** The **Startup Commands** option allows you to perform the following tasks:
  - Add- To add a command for capturing the startup configuration of a device family.
  - Edit- To edit a command.
  - Remove- To remove commands from the startup commands box.
  - Set Order- To define the sequence for running the startup configuration commands. When you select this option, Set Order pop-up window appears. Select a command and use the up and down arrows to set the order for that command.
  - The **Startup Capture Command** option allows you to set the command to capture the startup conflagration of the selected device family. When you select the Set link, it converts into a drop-down list and allows you to select the command from the list.
- **Load Commands and Load Config Start Sequence:** The **Load Commands** option allows you to perform the following tasks:

  - Add- To add a command for capturing the upload configuration of a device family.
  - Edit- To edit a command.
  - Remove- To remove commands from the upload commands box.
  - Set Order- To define the sequence for running upload configuration commands. When you select this option, Set Order pop-up window appears. Select a command and use the up and down arrows to set the order for that command.
- The **Load Config Start Sequence** option allows you to set the command sequence to upload the changed configurations. Spectrum executes sequence of commands until this value (this command is executed before uploading the configuration) and upload the changed configuration to the device then perform the remaining sequences.

Enable NCM Support for Custom Device Families

The following procedure provides end to end scenario to enable NCM support for custom devices (which are not supported out-of-the-box).

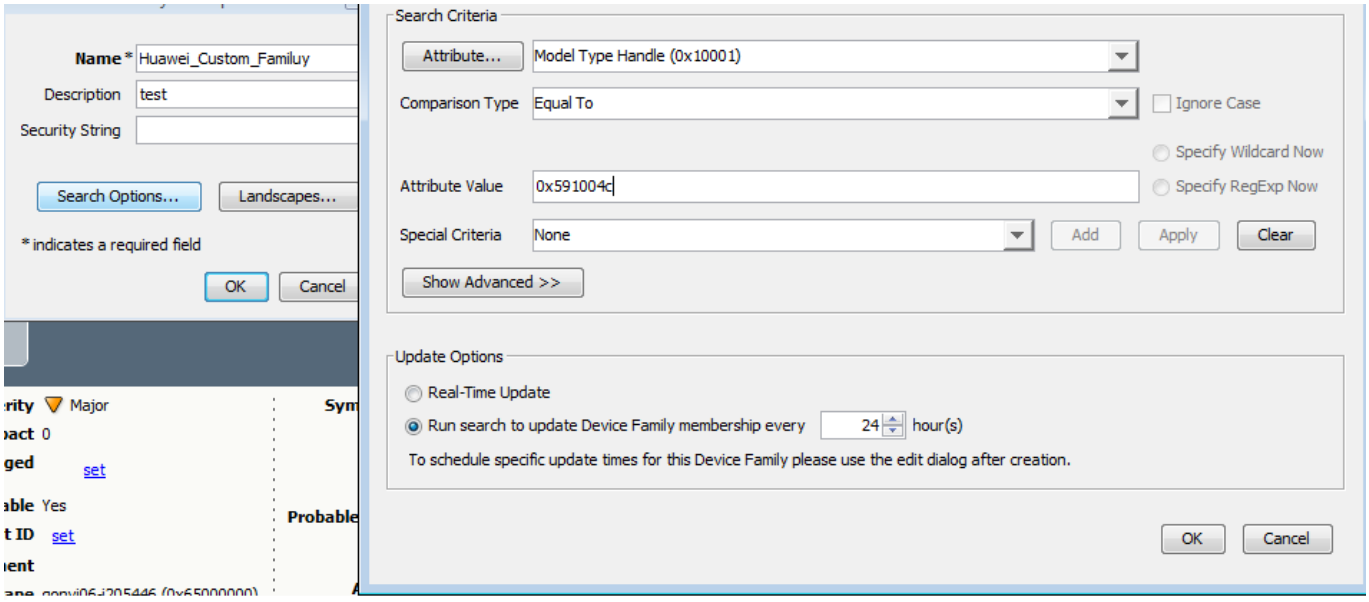
Prerequisites:

- List of commands for running, startup, and upload configurations for a specific device family.
- Create a Custom Device Family based on the model type.

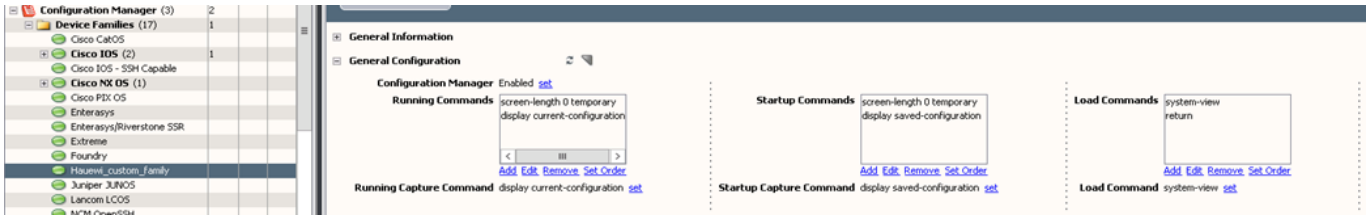
How to enable the support:

Following is an example to explain a step-by-step procedure to enable NCM support for Huawei device model type (0x591004c).

1. Ensure all the prerequisites are met.
2. Create a Custom Device Family based on the model type. In the Create Device Family window, select the Search Options to provide the search settings for the custom device family. This procedure is the same as the search settings for the global collection.
   The following screen explains the search criteria for Huawei model type (0x591004c).

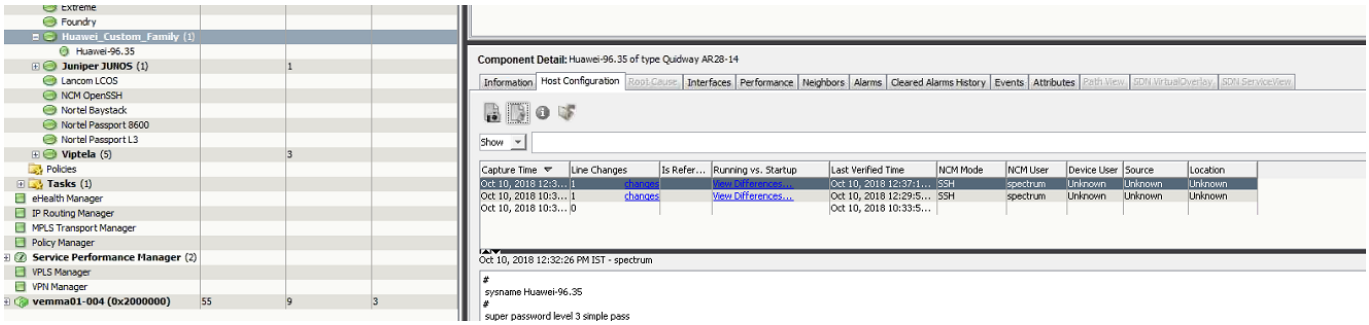


3. Provide the running, startup, and load commands list and corresponding values.



After successfully configuring the commands, Spectrum will enable the NCM support for the selected model type devices.
The default communication mode/primary communication mode is selected as SSH. To know more about communication mode, see Configure Device Family Communication Mode section.

4. Use the Host Configuration tab in the Component Details panel, to capture, and upload the configurations for selected host. The capture functionality gets the commands from the Information tab and executes them in the sequence that is defined there. For more details, see Network Configuration Manager Device-Level Tasks.



NOTE

To compare a startup configuration against a currently running configuration (Running vs Startup) for devices in your network, enable the **Verify Startup Equals Running Configuration** option in the Information tab at the Configuration Manager level.

Migrate devices from out-of-box NCM families

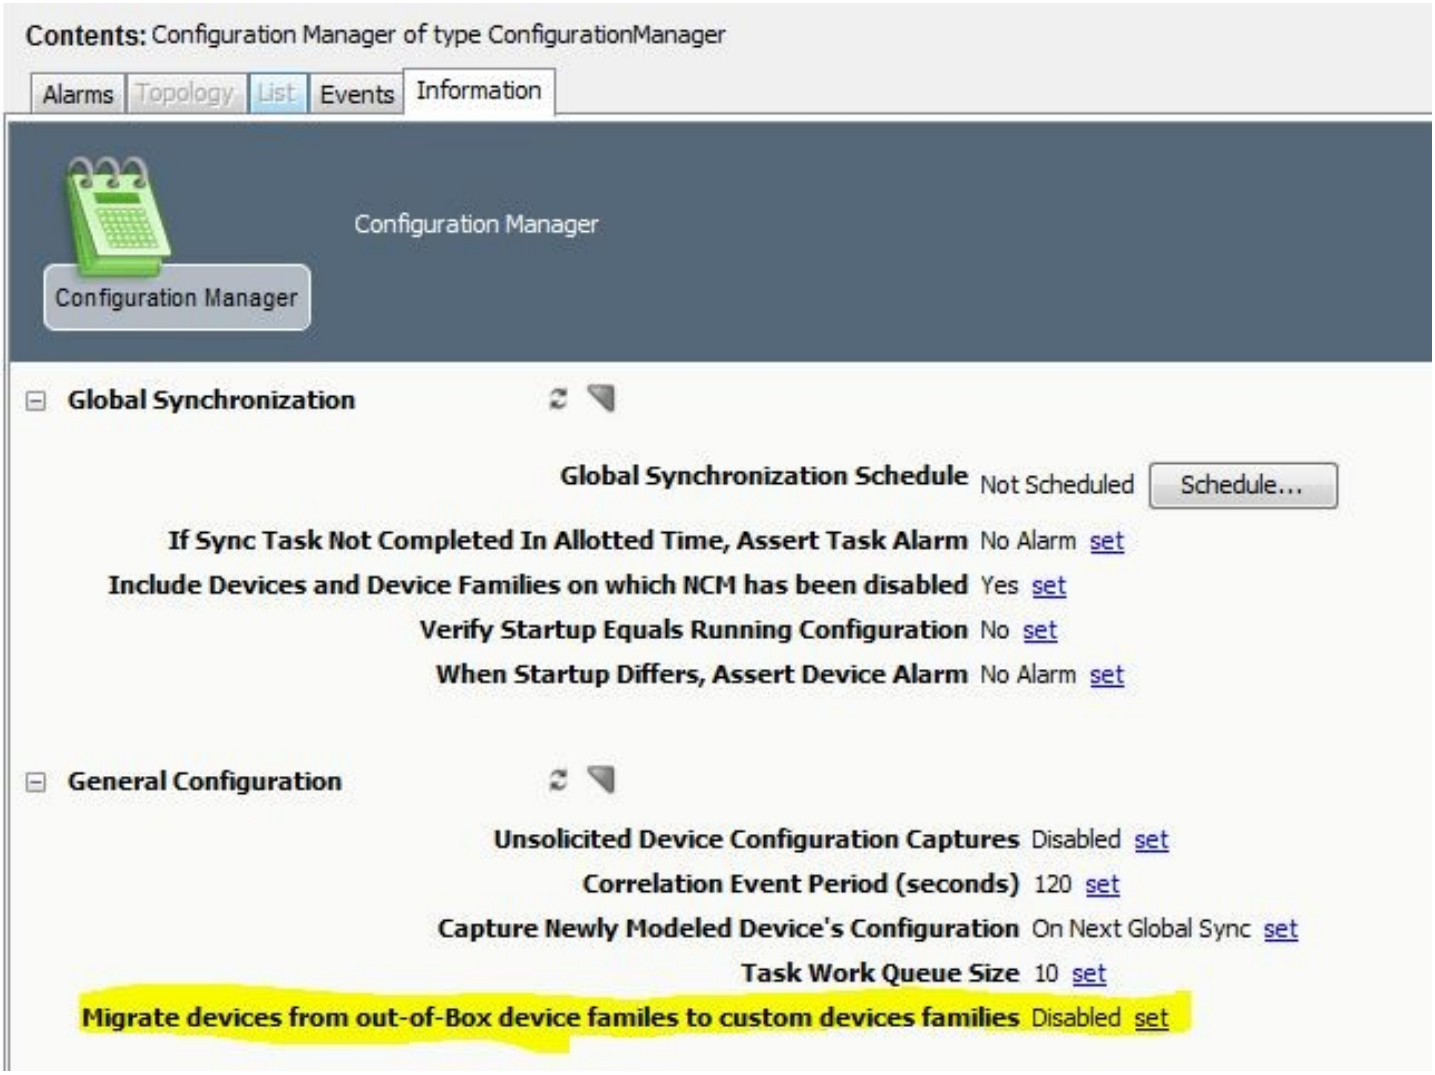
NOTE

Now migrate devices from out-of-box device families to custom device families, with Spectrum 10.3.2 !

This release introduces a new field to migrate out-of-box device families to the custom device families (as shown in the screenshot). To migrate devices from out-of-box device families to custom device families:

1. On the OneClick Console, navigate to the Configuration Manager>Information tab>General Configuration>Migrate devices from out-of-box device families to custom device families.
2. Set this option to 'enable', to use this feature. By default this feature is 'disabled'.

Optimize search settings for these devices by adding attributes and attribute value, when creating their device families. Changing the search criteria moves the existing devices back to the old families and the devices that satisfy the new search criteria are moved to the custom device families.



Non-Persistent Connections Manager

Contents

Getting Started with Non-Persistent Connections

This chapter provides an overview of the non-persistent connections functionality available in DX NetOps Spectrum OneClick and describes the types of links you can manage.

You can manage transient communications links using OneClick's non-persistent connections functionality. Non-persistent connections generally remain in an inactive state and are activated only under certain conditions. They can be activated manually as needed to serve as normal dialup type communications links, or they can be configured to activate automatically in either of the following two scenarios:

- To serve as a backup when failure of a primary connection occurs
- To provide load balancing or extra bandwidth for another overloaded communications link

Non-persistent connections let you see:

- When a link is activated
- Whether a link has failed to activate
- How long a particular link has been active

Events and alarm conditions are generated and logged to maintain accurate link usage statistics. Also, you can view the links as icons so that you can differentiate between normal connections and non-persistent connections and determine a connection's current status at a glance. Within DX NetOps Spectrum these non-persistent connections are represented by the Dialup_Link model type.

Non-Persistent Connection Types

When you create a Dialup_Link model, you choose the type of connection that best suits your needs. The Dialup_Link model type provides functionality for the following three distinct types of non-persistent connections:

- **Dial Backup Link (DBL)**
  A Dial Backup Link (DBL) provides a redundant link if a primary link fails. This type of link provides monitoring support for a one-to-one relationship between primary and secondary links and it provides support for multiple primary and secondary link configurations. Each DBL model can provide monitoring capabilities for multiple primary links using a common secondary interface. This is useful when many remote sites use one phone number at a central site (common interface) to support a non-persistent connection.
- **Bandwidth on Demand Link (BODL)**
  A Bandwidth on Demand Link (BODL) provides extra bandwidth for connections experiencing congestion problems. Links of this type may or may not be active in conjunction with the primary link. BODLs provide the same redundant capabilities as Dial Backup Links.
- **Primary on Demand Link (PODL)**
  A Primary on Demand Link (PODL) is not a redundant connection of any type. These links are activated manually when needed and function as a primary connection. There is no primary-secondary relationship involved.

Create Dialup_Link Models

This section explains how to create a Dialup_Link model to represent a non-persistent connection. Create one Dialup_Link model for each telephone number that remote routers can dial to create a non-persistent connection. Create Dialup_Link models manually. If the remote router can dial one number that one of several host routers or host router interfaces can pick up, one Dial_Up link model represents this connection.

Follow these steps:

1. In the Explorer tab of the OneClick Navigation panel, locate the Universe topology view where the devices involved in the non-persistent connection reside.
   The selected Universe topology view appears in the Topology tab of the Contents panel.
2. In the Topology tab toolbar, click the Create a Model by Type icon 
   The Select Model Type dialog opens.
3. Click the All Model Types tab.
   A list of model types opens.
4. Type **Dialup_Link** in the Filter text box to filter the list to show the Dialup_Link model type only.
5. Select the Dialup_Link model type and click OK.
   The Create Model Of Type Dialup_Link dialog opens.
6. In the Create Model Of Type Dialup_Link dialog, complete the following fields, which describe the device model type that you are modeling.

- **Name**
  Specifies a unique name for the Dialup_Link device you are modeling. This name appears in the Topology view with the icon.
  Limits: 1 to 16 ASCII characters
- **Security String**
  Specifies a DX NetOps Spectrum Security String for this Dialup_Link model.

  NOTE
  For more information, see the OneClick Administration section.
- **Dialup Link Type**
  Specifies the functional type of the Dialup_Link. Possible types are Dial Backup Link, Primary on Demand Link, and Bandwidth on Demand Link.
- **Dialup Protocol Type**
  Specifies the protocol type to use on the Dialup_Link. Possible protocol types include Analog, Switch-56, ISDN, Frame_Relay, and Other. The type appears in the Topology view with the icon.
- **Activation Grace Period (Min)**
  Specifies the time, in minutes, for the secondary link to become active after a primary link failure. If this time period expires before the secondary link is active, a red alarm is generated.
  Default: 3 minutes
- **Deactivation Grace Period (Min)**
  Specifies the time, in minutes, for an active secondary link to deactivate after the failed primary link reactivates. If the secondary link is still active after this grace period expires, a yellow alarm is generated.
  Default: 3 minutes
- **Active Time Until Yellow (Hours)**
  Specifies the number of hours a backup link can be active before a yellow alarm is generated.
- **Active Time Until Orange (Hours)**
  Specifies the number of hours a backup link can be active before an orange alarm is generated.
- **Active Time Until Red (Hours)**
  Specifies the number of hours a backup link can be active before a red alarm is generated.

7. Click OK to create a modeled device icon for the specified device and close the dialog.
   The Dialup_Link model appears in the selected Topology view.

   NOTE
   When first created, the model is in a normal inactive state and has a brown condition.
8. (Optional) Click the Edit mode button in the Topology tab toolbar to move the device icon to a more appropriate location in the Topology view.

   NOTE
   For more information, see the Modeling and Managing Your IT Infrastructure section.

Configuring Non-Persistent Connections

Configuring non-persistent connections involves identifying primary and secondary interfaces on the appropriate remote and host router or routers. Remote routers initiate dialup links. Host routers answer dialup calls from remote routers to establish the link. Management information is obtained by monitoring the remote router or routers.

Dial Backup Links (DBLs) and Bandwidth on Demand Links (BODLs) involve the redundant relationship between a primary link and a secondary link or links. The Dialup_Link model representing a DBL or a BODL monitors a primary link for a possible failure; it also monitors a related secondary link to verify its activation in a backup or supporting role if the primary link fails.

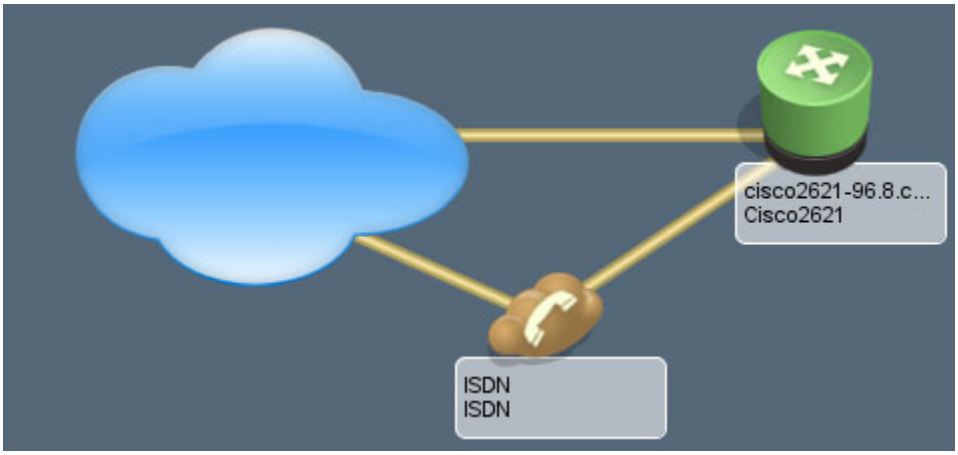
In general, the process to follow for configuring these types of links is as follows:

1. Configure the secondary interface or interfaces on the remote router or routers. This involves resolving the Dialup_Link model to the secondary interface.
   This is the interface that will serve as the dialing end of the dialup connection.
2. Configure the primary interface or interfaces on the remote router or routers.
   If all the primary interfaces go down, the dialup connection is used.
3. If known, configure the secondary interface or interfaces on the host router that will serve as the receiving end of the dialup connection.

> **NOTE**
> Primary on Demand Links (PODLs) are non-persistent connections that are used as transient primary links. You configure these links using this same process, however, since this type of link model does not need to monitor a primary interface, you can ignore the second step.

Basic Non-Persistent Connections

The Non-Persistent Connection solution requires that the primary and secondary interfaces reside on the same remote router. This leads us to the following most basic supported scenario in which only one end of the connection is known:

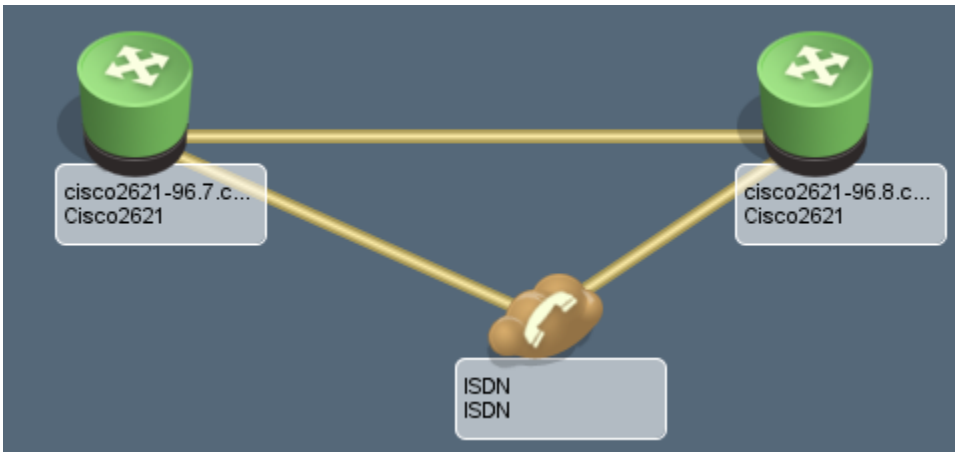


As illustrated by the previous image, in this case, only the remote (dialing) side of the redundant setup is known. As such, you would set up this scenario as described in the following procedure.

To model a basic non-persistent connection when only one end is known

1. Right-click the primary interface on the router and select 'Non-Persistent Connection Setup, Identify NPC Backup For This Interface.'
2. Right-click the backup interface which should be activated if the primary interface is unavailable and select 'Non-Persistent Connection Setup, NPC Backup For *<primary interface>*.'
   The Create Model of Type Dialup_Link dialog appears.
3. Create a Dialup_Link model.

Another basic non-persistent connection is one in which both the initiating and the receiving routers involved in the dialup connection are known, as illustrated by the following image:



To model a basic non-persistent connection when both ends are known

1. Complete all the steps in the previous procedure, "To model a basic non-persistent connection when only one end is known."
2. Right-click the interface model on the remote router that is initiating the dial backup link and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
3. Right-click the interface model on the host router interface that is on the receiving end of the dial backup link and select 'Non-Persistent Connection Setup, Connect With *<interface from step 2*>.'
   This creates a link between the Dialup_Link model and the host router interface on the receiving end of the non-persistent connection.

Dialer Map-Based Dial-on-Demand Routing (DDR) Configurations

This section discusses modeling a non-persistent connection that uses a Dial-on-Demand Routing (DDR) configuration that is map-based.

A DDR configuration that is map-based (often referred to as a legacy DDR configuration) associates a call specification for a single destination and a particular physical interface configuration. The physical interface contains all the configuration information that relates to receiving or making calls, and the bearer channels inherit the physical interface's configuration.

Modeling a Map-Based DDR Configuration

To model a DDR configuration that is map-based, create the appropriate number of Dialup_Link models and then configure the connection for each Dialup_Link model.

To model a map-based DDR configuration

1. Create one Dialup_Link model for each phone number that the remote router or routers could dial to create the non-persistent connections.

   NOTE
   If the remote router can dial one number that can be picked up by one of several host routers or host router interfaces, you can use just one Dial_Up link model to represent this connection.
2. Associate each Dialup_Link model you created with one of the secondary (dialing) interfaces on the remote router:
   a. Right-click the Dialup_Link model and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
   b. Right-click the associated secondary (dialing) interface on the remote router and select 'Non-Persistent Connection Setup, Connect With *<Dialup_Link model>.'*

3. Specify a primary interface for each Dialup_Link model. In the event that the primary interface goes down, the secondary link represented by the Dialup_Link model will activate:
   a. Select the Dialup_Link model and then click the Information tab in the Component Detail panel.
   b. Expand the Primary and Secondary Interface Information subview.
   c. In the Primary Interfaces table, click
      Add  .
   d. Select one or more primary interfaces in the resulting dialog and then click Add.
   e. Repeat for each Dialup_Link model that is part of this non-persistent connection configuration.
4. Associate each Dialup_Link model to the secondary (receiving) interfaces on the host router or routers.
   a. Right-click the Dialup_Link model and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
   b. Right-click the appropriate secondary (receiving) interface on the host router and select 'Non_Persistent Connection Setup, Connect With <*Dialup_Link model*>.'
   c. Repeat for each Dialup_Link model that is part of this non-persistent connection configuration.

Map-Based DDR Connections with Multilink Secondary Interfaces

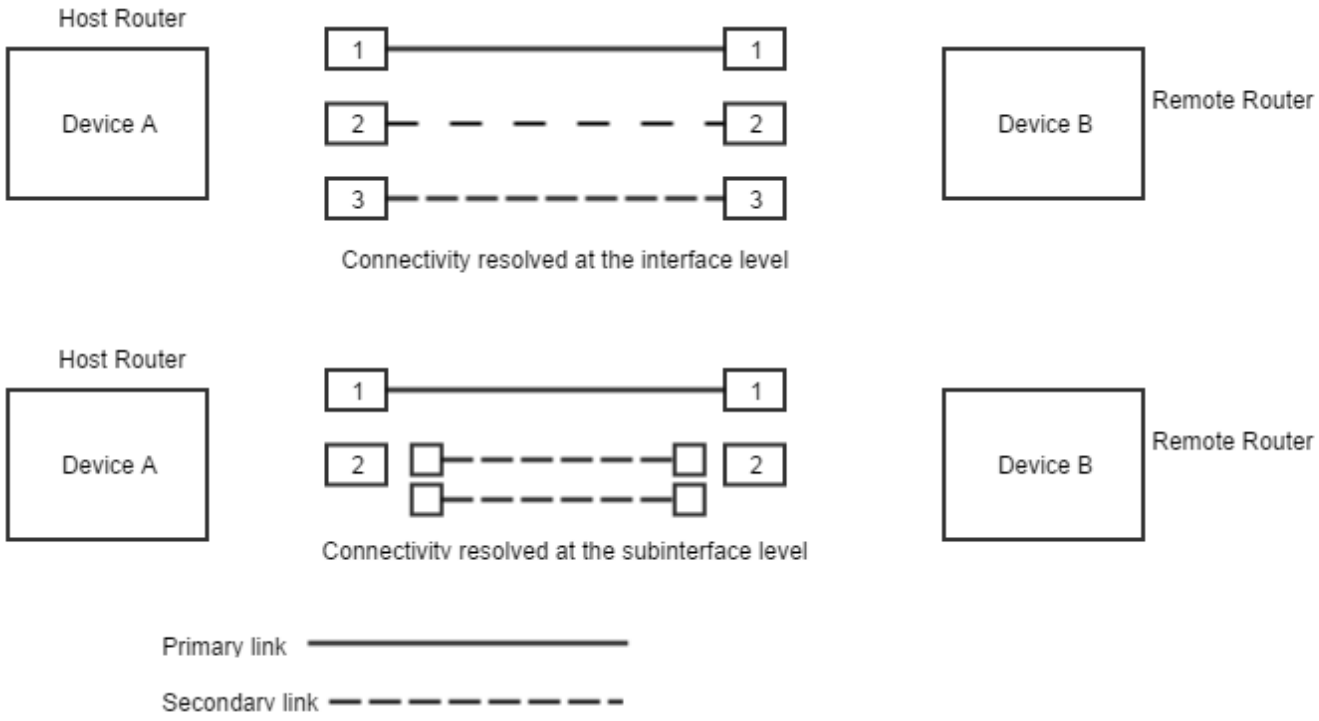
This section discusses modeling a non-persistent connection that uses one Dialup_Link model to specify a secondary link consisting of multiple interfaces that make up one logical link. This secondary link can be initiated by one or more ports on the remote router.

Modeling DDR Map-Based Connections with Multilink Secondary Interfaces

You can use one Dialup_Link model to support multiple secondary interfaces on a single remote router. For example, if your dialup connection uses a Multilink PPP over ISDN BRI configuration, you could associate a single Dialup_Link model with each PPP interface associated with the ISDN bearer channel connections.

The following diagram shows a remote router that has two connections to a host router. Since these two connections make up one logical link, you can use one Dialup_Link model to represent the link. Depending on the type of connectivity you are using, you can resolve the Dialup_Link model at the interface or the subinterface level.

Figure 76: Remote router



To model DDR map-based connections with multilink secondary interfaces on a remote router

1. Right-click the primary interface on the remote router and select 'Non-Persistent Connection Setup, Identify NPC Backup For This Interface.'
2. Right-click one of the the backup interfaces that should activate when the primary interface is unavailable and select 'Non-Persistent Connection Setup, NPC Backup For *<primary interface>*.'
   The Create Model of Type Dialup_Link dialog opens.
3. Create a Dialup_Link model.
4. Repeat Step 2 for the remaining secondary interfaces.
5. Right-click the Dialup_Link model and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
6. Right-click one of the receiving interfaces on the host router and select 'Non-Persistent Connection Setup, Connect with *<Dialup-Link model>*.'
7. Repeat Step 6 for each secondary (receiving) interface on the host router.

Secondary Groups

When a Dialup_Link model is associated with more than one interface on the same device, these interfaces will form a secondary group. DX NetOps Spectrum determines the status of the connection by looking at the state of the group. The DevSecGrpActiveCriteria attribute lets you change how DX NetOps Spectrum determines the state of the secondary group. This attribute has a default value of AnySecondaryIFActive (0), meaning that the group will be active if any member of the group is up and dormant only if all members of the group are down. The other possible value for this attribute is AllSecondaryIfsActive (1). If this is the value, the secondary group is considered active only if all members of the group are up, and is considered inactive if one member goes down. You can change the value of this attribute in the Dialup_Link model's Attributes tab.

NOTE
For more information about modifying attributes, see Modeling and Managing Your IT Infrastructure section.

Dialer Profile DDR Configurations

This section discusses modeling a non-persistent connection that uses a DDR configuration with dialer profiles.

In DDR Configurations that are dialer map-based, each physical interface can have only one set of configuration characteristics. When using a DDR configuration with dialer profiles, physical interfaces take on different characteristics based on incoming or outgoing call requirements. This is possible because dialer profiles separate logical configurations from the physical interfaces that receive or make calls. This lets interfaces such as ISDN, asynchronous modems, or synchronous serial connections be shared by multiple dialer profile configurations. The logical and physical interfaces are associated dynamically on a per call basis.

A dialer profile is made up of three main components:

- **Dialer Interface**
  Logical interfaces that represent a call to a particular destination. The dialer interface configuration contains all configuration settings specific to the destination. A router can have one or more dialer interfaces. Each interface references a group of physical interfaces called a dialer pool.
- **Dialer Pool**
  A group of physical interfaces that are associated with a dialer profile. A physical interface can belong to multiple dialer pools.
- **Physical Interface**
  Each physical interface is able to determine the dialer pool to which it belongs. Interfaces in a dialer pool are configured for encapsulation parameters and each dialer profile supports PPP and HDLC encapsulation.

Representing a Dialer Interface with DX NetOps Spectrum

DX NetOps Spectrum uses a logical interface model to represent a dialer interface; the logical interface model represents a call to or from a particular destination. This model is automatically created when DX NetOps Spectrum discovers a DDR dialer profile configuration on a device.

For example, if DX NetOps Spectrum discovers a dialer profile configuration on a Cisco router, the following logical interface model is used to represent a dialer interface. If there are multiple dialer interfaces configured on the router, multiple logical interfaces are created.

Modeling a Dialer Profile Connection

To model a connection that makes use of dialer profiles, create the appropriate number of Dialup_Link models and then configure the connection for each Dialup_Link model. Dialer profiles can be used on the remote router, on the host router, or both. Create one Dialup_Link model for each phone number that the remote router could dial to create the non-persistent connection.

If the remote router can dial one number that can be picked up by one of several host routers or host router interfaces, one Dial_Up link model is used to represent this connection.

To model a dialer profile DDR connection

1. Create a Dialup_Link model for each phone number the remote routers could dial.
2. Associate each Dialup_Link model with one of the secondary (dialing) interfaces on the remote router:
   a. Right-click the Dialup_Link model and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
   b. Right-click the associated secondary (dialing) interface on the remote router (or the logical interface representing the dialer profile) and select 'Non-Persistent Connection Setup, Connect With <*Dialup_Link model*>.'

NOTE
If you are making use of a dialer profile on the remote router, use the logical interface model representing the dialer. If you are not using a dialer profile on the remote router, use the interface model that represents the dialing interface.

3. Specify a primary interface for each Dialup_Link model. In the event that the primary interface goes down, the secondary link represented by the Dialup_Link model will activate:
   a. Select the Dialup_Link model and click the Information tab in the Component Detail panel.
   b. Expand the Primary and Secondary Interface Information subview.
   c. In the Primary Interfaces table,

      click Add 
   d. Select one or more primary interfaces in the resulting dialog and click Add.
   e. Repeat for each Dialup_Link model that is part of this non-persistent connection configuration.
4. Associate each Dialup_Link model to the secondary (receiving) interfaces on the host router or routers.
   a. Right-click the Dialup_Link model and select 'Non-Persistent Connection Setup, Start Non-Persistent Connection.'
   b. Right-click the appropriate secondary (receiving) interface on the host router and select 'Non_Persistent Connection Setup, Connect With <*Dialup_Link model*>.'
   c. Repeat for each Dialup_Link model that is part of this non-persistent connection configuration.

Monitoring a Dialer Profile Connection

The logical interface model may behave in different ways when a call is activated. This behavior is often dependent on the particular router supporting the given dialer profile.

The status indicator on the logical interface model icon may display OFF even when the connection is live. The logical interface model icon may also move from the physical layer of the device topology view and stack itself on the PPP encapsulation layer interface model. You can locate the model by drilling down from the physical interface, to the bearer channel layer, to the PPP encapsulation layer, and then to the dialer interface. All of these behaviors are normal, but may differ depending on the device modeled. Therefore, you should rely on the Dialup_Link model status and the views presented in Monitoring Non-Persistent Connections to monitor your connection.

Multiple Dial Backup Links

This section discusses modeling a non-persistent connection that lets you have variable or unspecified links between a remote router and a host router. There could be multiple remote routers linking to a single host router or a single remote router linking to multiple host routers.

A single Dialup_Link model can support configurations that include multiple secondary links. Only one Dialup_Link model is needed to monitor multiple secondary connections, because only a single active secondary connection can exist between the host router and the remote router at one time.

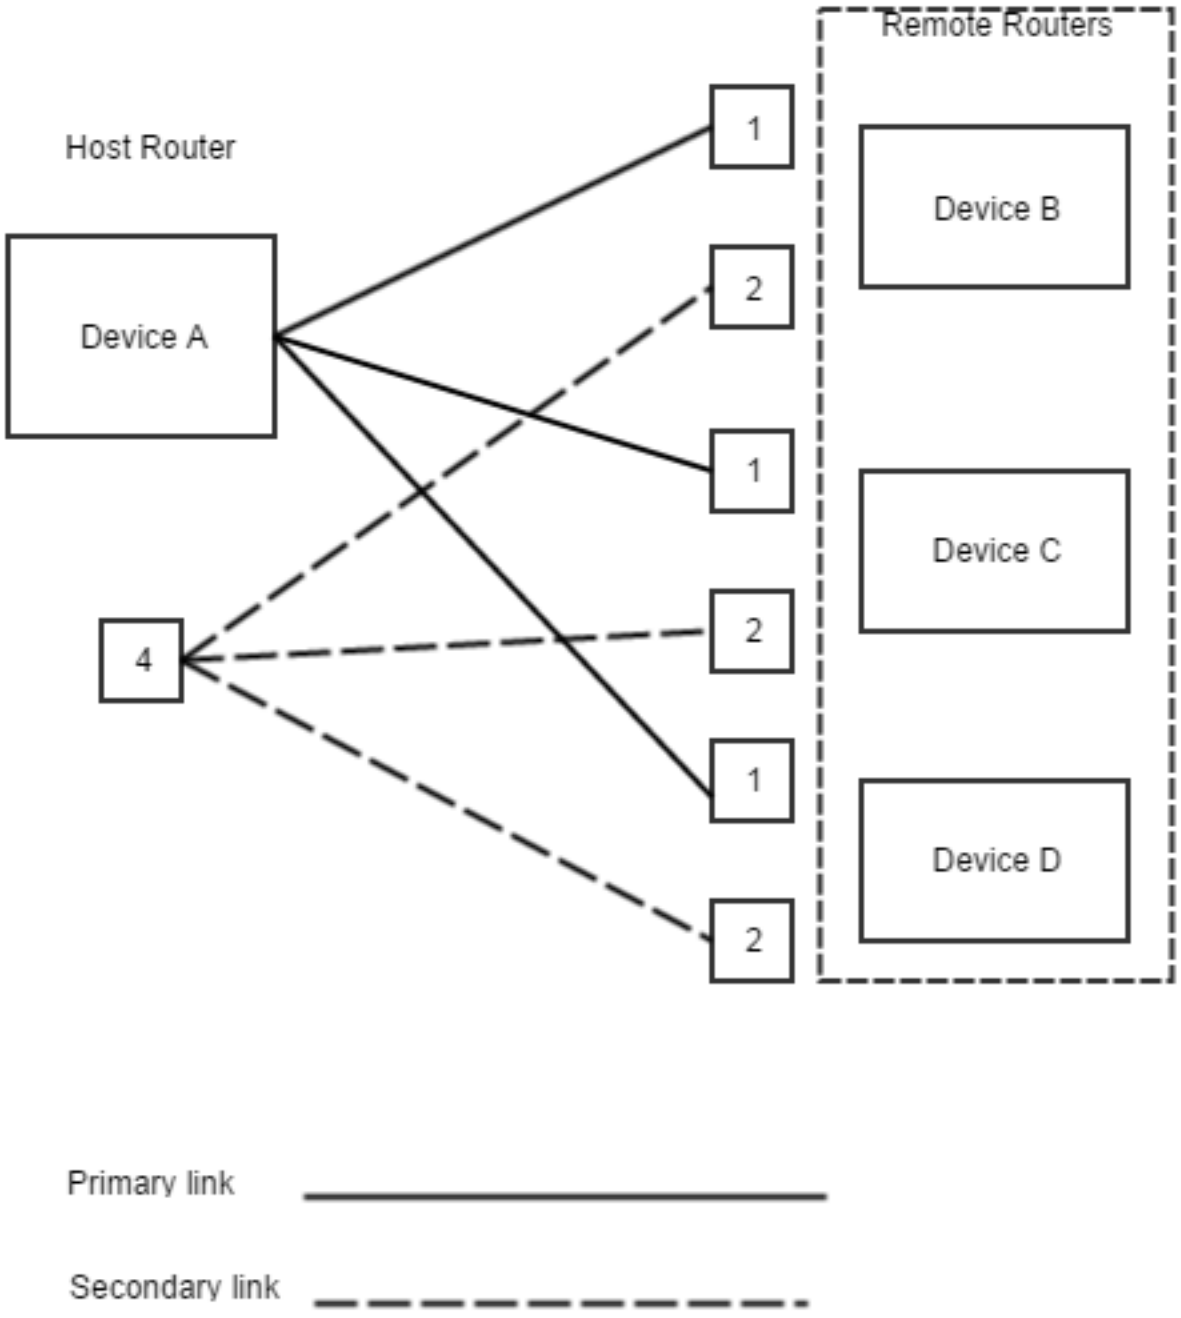
Multiple Dial Backup Links (MDBLs) are used in either of the following scenarios:

- Multiple remote routers each with a dial backup link that connects to a common host router.
- A single remote router with a dial backup link that could connect to one of several host routers.

How to Model Multiple Remote Routers to a Common Host Router

The following image shows three remote routers (devices B, C, and D) using one interface on a host router (Interface 4 of Device A) to provide redundant support for their primary links.

Figure 77: Multiple Remote Routers to a Common Host Router



There are three main tasks involved in creating this configuration:

1. Configure the secondary interfaces on the remote routers by resolving the the Dialup_Link model to the secondary interfaces on each remote router.
2. Configure the appropriate primary interfaces. When you configure a primary interface, you associate the secondary link to the primary link or links it is supporting. This is done in the Dialup_Link model's Primary Interfaces subview in the Component Detail panel.

NOTE
DX NetOps Spectrum automatically affiliates the secondary interface configured on a device with the primary interface configured on the device, so that if this primary interface fails, the proper secondary connection will be monitored.

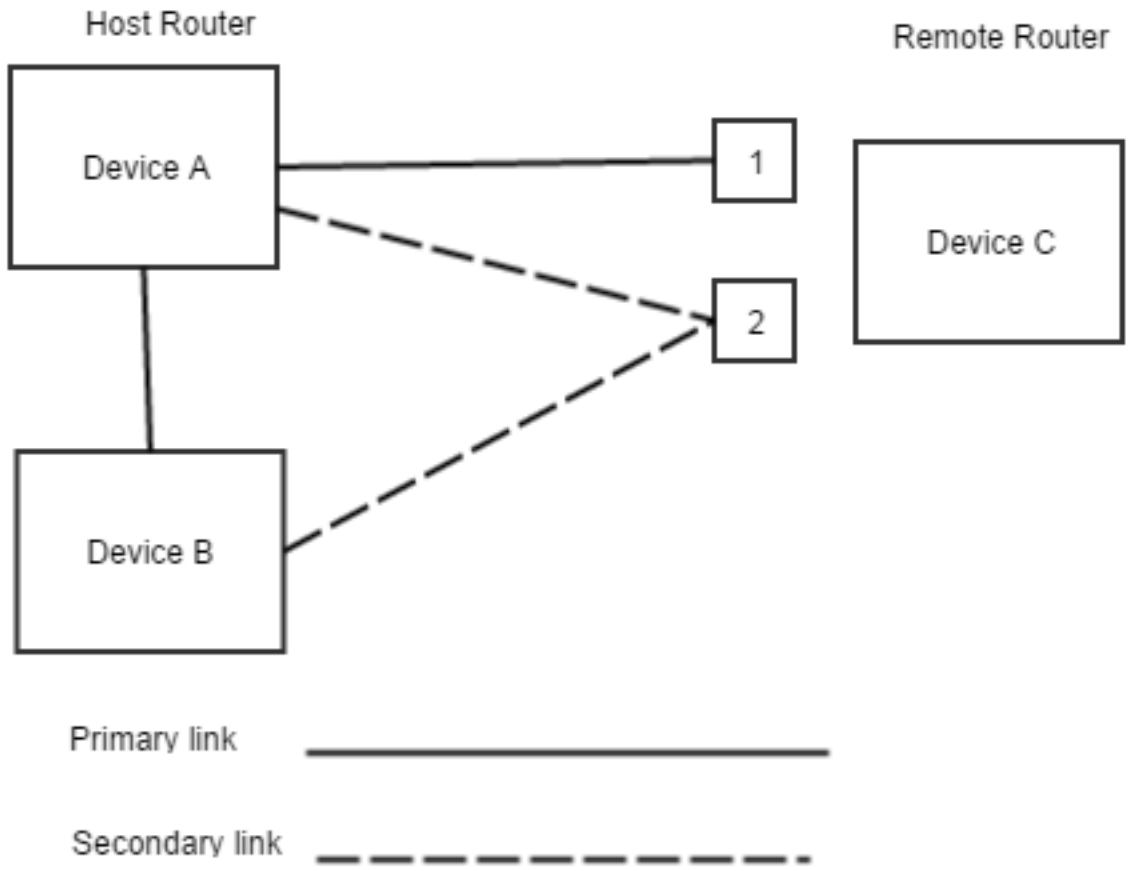
3. Configure the fixed secondary interface on the host router. This involves resolving the Dialup_Link model to the secondary interface of the host router.

How to Model a Single Remote Router to Multiple Host Routers or Host Router Interfaces

The following diagram shows a remote router (device C) which has secondary links established with two host routers (devices A and B) to provide redundant support for the primary link between device A and device C. When the secondary link becomes active, it will connect with either router A or router B. Before the connection is actually made, you cannot determine which of these routers the link will connect to.

The same scenario exists if the redundant link could connect to one of several interfaces on a host router or routers. In all of these cases, the connection to the host routers is resolved at the device level.

Figure 78: Single Remote Router to Multiple Host Routers



There are three main tasks involved in creating this configuration:

1. Configure the secondary interface on the remote router. This involves resolving the Dialup_Link model to the secondary interface.

2. Configure the appropriate primary interface. When you configure a primary interface, you associate the secondary link to the primary link it is supporting. This is done in the Dialup_Link model's Primary Interfaces subview in the Component Detail panel.
3. Configure the connection to the host router. This involves resolving the Dialup_Link model to the secondary interface on the host router. If it is unknown which host router or host router interface the remote router will connect to, resolve the dialup connection to the device level rather than the interface level.

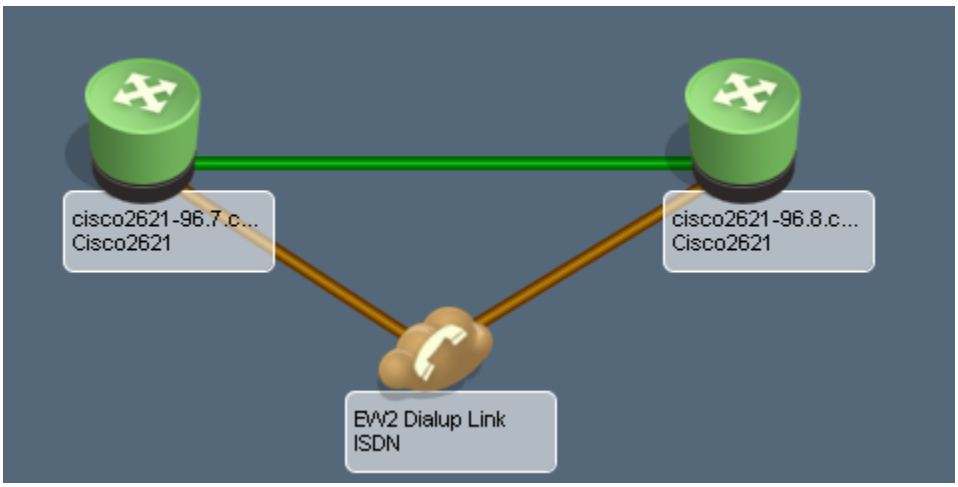
Monitoring Non-Persistent Connections

This section contains information about monitoring non-persistent connections.

Viewing Dialup_Link Model Information

Once you have configured the Dialup_Link model connections and specified the interface on the remote router for the primary connection, the Dialup_Link model is fully integrated into the current modeling scheme and reacts according to the type of link it represents. The Topology view containing the Dialup_Link model shows live pipes connecting the Dialup_Link model to the remote and host routers.

These live pipes will have a brown condition when the dialup link is inactive. If the modeled primary link and secondary links involve the same two devices, the topology configuration involving the host and remote routers should look similar to the following image:



You access information about the creation, current settings, and status of the Dialup_Link model by selecting the model and then clicking the Information tab in the Component Detail panel. The Information tab displays the following views for Dialup_Link models:

- General Information
- Thresholds and Watches
- Primary and Secondary Interface Information:
  - **Primary Interfaces**
    The Primary Interfaces list includes all currently configured primary interfaces on all devices associated with this Dialup_Link model.
  - **Secondary Interfaces**
    The Secondary Interfaces list includes all currently configured secondary interfaces on all of the devices associated with this Dialup_Link model.

The Primary and Secondary Interface Information view contains the Primary Interfaces view and the Secondary Interfaces view.

- **Primary Interfaces**
  Contains information about the primary interfaces set up on this Dialup_Link model. This is a left/right list that lets you select interfaces on the devices associated to the Dialup_Link model. Ideally, this list should contain only interfaces on the dialing/remote device.

  NOTE
  If more than one primary interface on a single remote router has been configured, these interfaces will be treated as a group. The status of the group of primary interfaces is determined by the healthiest group member. The backup interface will activate only if all of the primary interfaces in the group fail.
- **Secondary Interfaces**
  Contains information about the secondary interfaces setup on this Dialup_Link model.

The tables in both of these views display the following information by default:

- **Name**
  Specifies the name of the interface.
- **Condition**
  The contact status for the device, in addition to any alarm conditions in effect for the device model. Specifies the current condition of the interface.
- **Status**
  Indicates whether the interface is operational or non-operational. An interface may be non-operational for a variety of reasons including being administratively disabled. Some of the possible values include up, down, off, and dormant.
- **Type**
  Specifies the physical layer interface standard that the interface uses, such as ppp, ethernet, frameRelay, and so on.
- **Description**
  Describes whether the interface is physical or logical, and the interface ID, such as et.2.1.
- **Device Connected**
  The name and status (green for up or red for down) of the device that the current interface is connected to. The device name is a hyperlink that displays the Information tab for the connected device.
- **Port Connected**
  Specifies the name of the port on the device that the current port is connected to. The port name is a hyperlink that displays the Interfaces tab for the device that the current port is connected to.
- **QoS Policy**
  Specifies the QoS policy name that applies to this interface.
- **Index**
  Specifies the value of the index object in the standard RFC or proprietary MIB that uniquely identifies this interface within the device.
- **Board.Port**
  Identifies the board and port number on the device for the corresponding port. For example if the port is port 4 on a module in the device's third slot, the Board.Port value is 3.4.

Searching for Non-Persistent Connections

From the Locater tab, you can run the following two searches specific to non-persistent connections:

- **Active Non-Persistent Connections**
  The Active Non-Persistent Connections search returns a list of all Dialup_Link models that are currently active in a landscape.
- **All Non-Persistent Connections**

The All Non-Persistent Connections search returns a list of every Dialup_Link model in the landscape, even if they are currently inactive.

Each results list contains the following information:

- **Condition**
  Identifies the current condition of the Dialup_Link model.

  NOTE
  See Modeling and Managing Your IT Infrastructure section for more information about condition colors.
- **Name**
  Specifies the name of the Dialup_Link model.
- **Dialup From**
  Specifies the name of the remote router model.
- **Dialup To**
  Specifies the name of the host router model.
- **Link Activation Start Time**
  Indicates at what time the Dialup_Link model became active, or whether it is inactive. For example, when the Dialup_Link model was connected to the appropriate interfaces.
- **Link Activation Duration**
  Indicates the length of time that the connection has been active.
- **Dialup Link Type**
  Specifies the type of link between the two points. Possible types are Backup (DBL), Primary (PODL), and Bandwidth (BODL).
- **Dialup Protocol Type**
  Specifies the protocol type to used by the Dialup_Link. Possible protocol types include Analog, Switch-56, ISDN, Frame_Relay, and Other.

Determining the Status of Multiple Primary or Secondary Links

You can model non-persistent connections using multiple primary or secondary interfaces. When multiple primary interfaces are used, the status of the group is always determined using the following rule: If any of the interfaces are up, then the group is up; otherwise, the group is down.

Multiple secondary links use the DecSecGrpActiveCriteria attribute to determine the status of the group. If the value is AnySecondaryIFActive, and at least one of the secondary interfaces is up, then the group is considered to be up. Otherwise, the group is considered to be down.

Multiple primary links operate in the same way. If the value of the DecSecGrpActiveCriteria attribute is AllSecondaryIfsActive, all of the interfaces must be up for the group to be considered up. If not, then the group is considered to be down.

When one or more interfaces in the multiple link scenario is in maintenance mode, DX NetOps Spectrum will treat it as if that link does not exist, and base the status of the group on the remaining non-maintenance interfaces. The exception is if all interfaces are in maintenance mode, then the entire group is in maintenance mode.

Dialup_Link Condition Colors

The way in which the Dialup_Link model reacts to changes in the primary and secondary links depends upon the type of non-persistent connection this model represents. The following tables show the possible conditions for the Dialup_Link model representing a Dial Backup Link, Bandwidth on Demand Link, or a Primary On Demand Link.

Dial Backup Link Conditions

Primary Link	Secondary Link	Dialup_Link	Generated Events
Up	Up	Yellow	Both primary and secondary links are active.
Up	Down	Brown	Secondary link inactive.
Down	Up	Green	Secondary link active.
Down	Down	Red	Secondary link has failed to activate.
Maintenance Mode	Up	Green	Secondary link active.
Maintenance Mode	Down	Brown	Secondary link inactive.
Up	Maintenance Mode	Brown	Secondary link inactive.
Down	Maintenance Mode	Brown	Secondary link inactive.

Bandwidth On Demand Link Conditions

Primary Link	Secondary Link	Dialup_Link Condition	Generated Events
Up	Up	Green	None.
Up	Down	Brown	Secondary link is inactive.
Down	Up	Green	Secondary link is active.
Down	Down	Red	Secondary link has failed to activate.
Maintenance Mode	Up	Green	Secondary link active.
Maintenance Mode	Down	Brown	Secondary link inactive.
Up	Maintenance Mode	Brown	Secondary link inactive.
Down	Maintenance Mode	Brown	Secondary link inactive.
Maintenance Mode	Maintenance Mode	Brown	Secondary link inactive.

Primary On Demand Link Conditions

Primary Link	Dialup_Link Condition	Generated Events
Up	Green	No event is generated. Primary On Demand link is active.
Down	Brown	No event is generated. Primary On Demand link is inactive.
Up	Yellow	The maximum uptime value has been exceeded.
Maintenance Mode	Brown	No event is generated. Primary On Demand link is inactive.

There are two exceptions to these Dialup_Link Condition tables. These involve these special alarm conditions: Gray and Orange.

- A Gray condition is asserted on a Dialup_Link model when all secondary interfaces are considered unreachable.
- An Orange condition is asserted only in a multiple primary/secondary configuration when a primary link has failed but the secondary link is already active in support of another connection.

Alarms for a Dialup_Link model

The Thresholds and Watches view in a Dialup_Link model's Information tab lets you configure when alarms will be generated on the Dialup_Link model for certain conditions. To access the Thresholds and Watches view, click the Dialup_Link model, click the Information tab, and then expand the Thresholds and Watches subview.

- **Activation Grace Period (Minutes)**
  Lets you specify the time allowed, in minutes, for the secondary link to become active after a primary link failure. If this grace period expires before the secondary link is active, then a red alarm is generated. This field is only used by DBL-type link models. The value for this field can also be specified when creating a Dialup_Link model.
- **Deactivation Grace Period (Minutes)**
  Specifies the time allowed, in minutes, for an active secondary link to deactivate after the failed primary link reactivates. If the secondary link is still active after this grace period expires, then a yellow alarm is generated. This field is only used by DBL-type link models. The value for this field can also be specified when creating a Dialup_Link model.
- **Active Time Until Yellow (Hours)**
  Specifies the number of hours a backup link can be active before a yellow alarm is generated. The value for this field can also be specified when creating a Dialup_Link model.
- **Active Time Until Orange (Hours)**
  Specifies the number of hours a backup link can be active before an orange alarm is generated. The value for this field can also be specified when creating a Dialup_Link model.
- **Active Time Until Red (Hours)**
  Specifies the number of hours a backup link can be active before a red alarm is generated. The value for this field can also be specified when creating a Dialup_Link model.
- **Active Criteria**
  Specifies the active state for non-persistent connections that have more than one secondary interface, i.e. a connection that uses multiple physical connections to form one logical connection. When this multi-link type configuration is used, the Dialup_Link model will monitor all the secondary interfaces. If Active Criteria is set to Any Secondary IF Active then the dial-up link will be considered "active" if ANY of the secondary interfaces become active. If Active Criteria is set to All Secondary IFs Active then ALL the secondary interfaces must become active before the Dialup_Link model will be considered "active."

The following shows the alarms that DX NetOps Spectrum can generate on a Dialup_Link model.

> **NOTE**
> Events generated on a Dialup_Link model have an event message which contains information on the devices and interfaces that the Dialup_Link model is connected to.

Alarm Code	Alarm	Alarm Cause
0x022ffff8	Excess timer has been exceeded.	The link has been active for longer than the time specified by the Active Until Yellow, Orange or Red criteria.
0x022ffff9	Backup link is already active.	This alarm occurs when DX NetOps Spectrum attempts to activate a dialup link that is already active.
0x022ffffa	Both the primary and the secondary links are active.	Both the primary and the secondary links have been activated.
0x022ffffb	The secondary link failed to activate.	An attempt to activate the secondary link was unsuccessful.
0x022ffffc	The secondary link is inactive.	The primary link is functioning properly and the secondary link has returned to an inactive status.

0x022ffffd	The Dialup_Link model is unreachable.	This alarm is generated when all of the Dialup_Link model's neighbors are down. Neighbors include any interface model or device model to which the Dialup_Link model has a resolved connection.

Outsourcer Billing

DX NetOps Spectrum Outsourcer Billing is a powerful tool that enables service providers to produce accurate and meaningful data which can be further used as a basis for billing their customers for outsourced network services.

DX NetOps Spectrum Outsourcer Billing users should be familiar with the following:

- DX NetOps Spectrum
- Network management
- UNIX and/or Microsoft Windows
- The networks and devices you intend to bill for with DX NetOps Spectrum

Outsourcer Billing Users

Many end-customers would rather pay for managed network services as they use them, rather than buy, install, and maintain DX NetOps Spectrum themselves. DX NetOps Spectrum Outsourcer Billing helps the DX NetOps Spectrum equipped service provider bill these customers based upon the number of devices being managed or monitored by DX NetOps Spectrum in an outsourcing relationship.

Service providers who should consider using DX NetOps Spectrum Outsourcer Billing include:

- ASPs (Application Service Providers)
- CLECs (Competitive Local Exchange Carriers)
- DSPs (Data Service Providers)
- ISPs (Internet Service Providers)
- IXCs (IntereXchange Carriers)
- MSOs (Multiple Service Operators [e.g., cable, DSL, wireless, etc.])
- MSPs (Management Service Providers)
- RBOCs (Regional Bell Operating Companies)

Preliminary Information

DX NetOps Spectrum Outsourcer Billing is installed as part of the SpectroSERVER base installation.

Before you use DX NetOps Spectrum Outsourcer Billing for the first time you should gather some pertinent information about the network upon which you are utilizing Outsourcer Billing:

- The number of devices on the network.
- The types of devices on the network.
- Whether or not your customer has a distributed SpectroSERVER (DSS) environment (for example, more than one SpectroSERVER).
- Pricing schedules and volume discounts.

Such information will assist you in determining the best way to use DX NetOps Spectrum Outsourcer Billing to extract the most accurate information and eliminate billing inconsistencies.

Usage Fees

You will also need to design a usage fee schedule that meets your needs and those of your customers. You may or may not wish to incorporate volume discount pricing for your larger clients as well. This should be researched carefully to ensure an acceptable mix of value for your customers and profit for you.

Starting Outsourcer Billing

To invoke DX NetOps Spectrum Outsourcer Billing:

1. In a command prompt window, navigate to the <$SPECROOT>/SS-Tools directory.
2. Start the Billing executable using the syntax described below:

```
./Billing -landscape landscape [-detailed True|False] [-output file] [-overrideClassFile file] [-
mailQueueSize number]
[-mailTimeout seconds] [-throttle count] [-debug] [-help]
```

Parameters are described below.

- **landscape**
  The landscape handle of the default SpectroSERVER.
  Default value: 0x0
- **detailed**
  Toggles the option for a detailed report on (TRUE) or off (FALSE).
  Default value: False
- **output**
  The path to the desired output file. If no output file is specified, the output displays on the screen. If a file of the same name exists, it is overwritten.
- **overrideClassFile**
  A user-defined text file used to force a different class upon a model type.
- **mailQueueSize**
  The maximum number of pending SpectroSERVER requests.
  Default value: 1024
- **mailTimeout**
  The minimum time, in seconds, the MailService waits for a SpectroSERVER response before the request is canceled.
  Default value: 1800 (30 minutes)
- **throttle**
  The maximum number of models from which DX NetOps Spectrum Outsourcer Billing can read information simultaneously.
  Default value: 500
- **debug**
  Invokes DX NetOps Spectrum Outsourcer Billing in debug mode.
- **help**
  Displays DX NetOps Spectrum Outsourcer Billing syntax information.

WARNING
The amount of time that DX NetOps Spectrum Outsourcer Billing takes to complete a billing audit is dependent upon the numbers of devices in the network and models in the SpectroSERVER database. Audits run on large networks will take longer than those run on smaller networks.

Output

Invoking the application with no options (by typing only ./Billing at the command line) causes DX NetOps Spectrum Outsourcer Billing to read and display a report on the device models in all landscapes in the local SpectroSERVER's landscape database.

If you type an incorrect landscape handle using the -landscape option, DX NetOps Spectrum Outsourcer Billing prompts you for a valid landscape handle from a list of known SpectroSERVERs (VNMs) in the local SpectroSERVER's landscape database. Enter the number that corresponds to the landscape against which you wish to run DX NetOps Spectrum Outsourcer Billing. Pressing the Enter (or Return) key selects the default landscape.

For example, if you enter a landscape handle value of '0' the screen output would look similar to this:

```
% ./Billing -landscape 0
Invalid landscape 0x0
Please select from the following list of valid
landscapes. Enter the number (1, 2, 3, etc.)
corresponding to the VNM name and landscape handle,
and press the return key.
   1) storyville (0x8400000)
   2) cottonclub (0x8e00000)
   3) birdland (0xa600000)
Selection? [default: 1]
```

You then make your selection, which in this case was '3' for the SpectroSERVER 'birdland', you would see the following:

```
3
Please wait - working...
```

Progress Messages

DX NetOps Spectrum Outsourcer Billing provides report progress feedback in the form of informational status messages as it performs the following operations:

- Retrieves the landscape map
- Retrieves device models from the landscape
- Reads device models
- Retrieves device class information for each device
- Retrieves port counts for each device

General Output Summary

If the following syntax is issued from running DX NetOps Spectrum Outsourcer Billing in a distributed SpectroSERVER environment:

```
$ ./Billing -landscape <landscape_handle>
```

The following output will be generated:

```
Retrieving the landscape map
Retrieving device models from server birdland
Retrieving Class information for each device. Total device
count=78
Read 78 models
Retrieving port count and system information for each device
```

```
Read 78 models

Audit Summary
-------------
SpectroSERVER=birdland Port=48879 Landscape=0xa600000

Device Class      Type      Quantity
-----------------------------------------
Router             1            0
Router             2            0
Router             3            0
Switch             1            24
Switch             2            12
Switch             3            0
Hub                1            2
Hub                2            0
Hub                3            0
Class 1           n/a           117
Pingable          n/a           38
```

Detailed Output

Detailed output provides you with more granular information. It includes the summary output as described in General Output Summary as well as information about every device modeled in the SpectroSERVER's database. This information, which provides the basis for the accurate billing you require, includes:

- Device name
- Device vendor
- Device class
- Number of ports
- Device type value based on the device class and the number of ports:

Class	Type 1	Type 2	Type 3
Hub	<= 24 ports	25-120 ports	> 120 ports
Switch	<= 24 ports	25-120 ports	> 120 ports
Routers	<= 4 ports	5-12 ports	> 12 ports
Class 1	no types		
Pingable	no types		

If the following syntax is issued from running DX NetOps Spectrum Outsourcer Billing in a distributed SpectroSERVER environment:

```
$ ./Billing -landscape <landscape_handle> -detailed True
```

The following output will be generated:

```
Retrieving the landscape map
Retrieving device models from server birdland
Retrieving Class information for each device.
Total device count=78
Read 78 models
Retrieving port count and system information for each device
```

```
Read 78 models

Audit Summary
-------------
SpectroSERVER=birdland Port=48879 Landscape=0xa600000

Device Class      Type      Quantity
-------------------------------------------
Router             1            0
Router             2            0
Router             3            0
Switch             1            12
Switch             2            6
Switch             3            0
Hub                1            1
Hub                2            0
Hub                3            0
Class 1           n/a           59
Pingable          n/a           19

Advanced Operations

DX NetOps Spectrum Outsourcer Billing enables you to customize its operation to your needs using several advanced options.

Overriding Class Files for Custom Billing

There may be times when you wish to override the default device classifications. For example, you may have a need to define a brouter as either a switch or a router. Or, you may at some point need to define a completely new device classification. This is where the overrideClassFile parameter is used.

To override the default device class files

1. Create a text file containing the model type name and new class number in the following format:
   ```
   model_type_name new_class_number
   ```
   The file might look something like this:
   ```
   GnSNMPDev 5
   ```
2. Give the new file a name.
3. Invoke DX NetOps Spectrum Outsourcer Billing using the -overrideClassFile parameter with the newly created file's name as the value. For example:
   ```
   $ ./Billing -landscape <landscape_handle> -overrideClassFile newclass
   ```
   The output file is displayed on the screen and includes the new device class by name (e.g., Hub, Switch, etc.).

Adjusting the Mail Queue Size

By default DX NetOps Spectrum Outsourcer Billing can have 1024 pending SpectroSERVER requests queued at any one time. However, if your mail queue becomes full, you can configure the queue size so that more requests can be passed to DX NetOps Spectrum Outsourcer Billing using the mailQueueSize parameter.

To adjust the mail queue size when using DX NetOps Spectrum Outsourcer Billing

- Invoke DX NetOps Spectrum Outsourcer Billing using the -mailQueueSize parameter. For example:

```
$ ./Billing -landscape <landscape_handle> -mailQueueSize 2048
```

Now 2048 pending SpectroSERVER requests can be passed to DX NetOps Spectrum Outsourcer Billing.

NOTE
The value for the mailQueueSize parameter must be greater than or equal to 1. If an invalid value is entered (for example, 0 or a negative value), DX NetOps Spectrum Outsourcer Billing will terminate.

Adjusting the Mail Timeout Value

There may be instances when you wish for DX NetOps Spectrum Outsourcer Billing to wait longer than the default 1800 seconds for a response from the SpectroSERVER. For example, if in a DSS environment, a remote SpectroSERVER upon which you wish to run DX NetOps Spectrum Outsourcer Billing terminates abnormally, you may wish to increase the timeout value to compensate for the time required for that machine to come back up.

To adjust the mail timeout value when using DX NetOps Spectrum Outsourcer Billing

- Invoke DX NetOps Spectrum Outsourcer Billing using the -mailTimeout parameter. For example:

  ```
  $ ./Billing -landscape <landscape_handle> -mailTimeout 3600
  ```

  Now DX NetOps Spectrum Outsourcer Billing will wait for 3600 seconds before responding with an error message indicating a lack of response from the remote SpectroSERVER.

Adjusting the Throttle Count

There may be instances when DX NetOps Spectrum Outsourcer Billing is reading device information from some device models that have timed out, thus causing the application to appear sluggish. This can happen because by default DX NetOps Spectrum Outsourcer Billing reads information from 500 models at once. You can reduce that default number upon invoking DX NetOps Spectrum Outsourcer Billing.

To adjust the throttle count when using DX NetOps Spectrum Outsourcer Billing

- Invoke DX NetOps Spectrum Outsourcer Billing using the -throttle parameter. For example:

  ```
  $ ./Billing -landscape <landscape_handle> throttle 200
  ```

  Now DX NetOps Spectrum Outsourcer Billing will read information from just 200 models simultaneously.

  NOTE
  The value for the throttle parameter must be greater than or equal to 1. If an invalid value is entered (for example, 0 or a negative value), DX NetOps Spectrum Outsourcer Billing will terminate.

Gathering Debug Information

In the event that you require technical assistance with DX NetOps Spectrum Outsourcer Billing, you should run the application with the -debug option and capture the output to a file. This will provide the support personnel with needed low-level information for troubleshooting and analysis. For example:

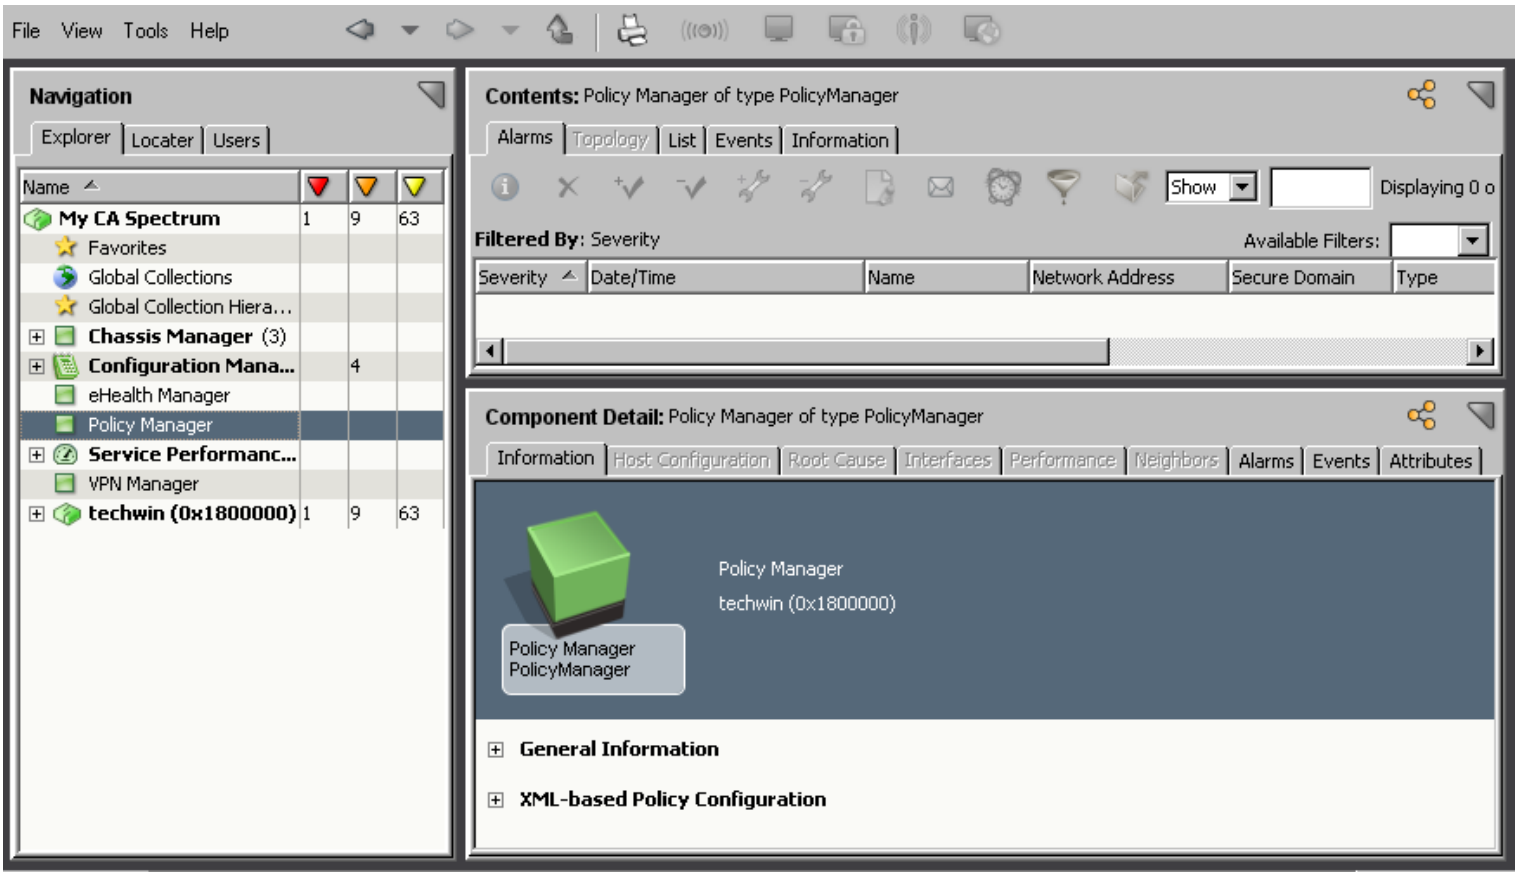
```
$ ./Billing -landscape <landscape_handle> -debug > debugfile
```

Policy Manager

DX NetOps Spectrum Policy Manager lets you apply network management policies across all models in a distributed SpectroSERVER environment. You can add, remove, or modify policy configurations while the SpectroSERVER is running and apply the changes immediately. Policy Manager automates the enforcement of management policies in DX NetOps Spectrum, eliminating the need to make manual updates as models are added or changed.

Access Policy Manager

To access Policy Manager, click Policy Manager in the Explorer tab. Policy Manager information is displayed in the Information tab in the Component Detail panel.



NOTE
All defined policies appear beneath Policy Manager in the Explorer tab and in the List tab in the Contents panel. For more information, see Viewing Policies.

The Component Detail panel contains the following subviews:

- **General Information** - The General Information subview contains general details about Policy Manager, including model class and security string.
- **XML-based Policy Configuration** - This subview provides details about maintaining legacy policies. For more information, see Legacy XML-based Policies.

Policy Manager Policies

Policies consist of DX NetOps Spectrum attribute settings that, when applied to a defined set of models, let DX NetOps Spectrum consistently implement a network management configuration. For example, you implemented a policy that defines how DX NetOps Spectrum manages alarm thresholds on all router port models. This policy is enforced on all existing router port models and is also implemented on any newly created router port models.

A policy comprises the following components:

- Policy definition
- Policy rules
- Rule settings

All policy components are configured and maintained in the OneClick Console.

> **NOTE**
> For legacy policies, you can also use XML files to configure and maintain policy definitions. For more information, see Legacy XML-based Policies.

Policy Definition

A policy is a set of prioritized policy rules. The priority handles situations in which a model resides in more than one of the global collections for the policy rules in one policy.

Policy Rules

A policy rule is a collection of rule settings and the global collections to which they apply. You can define multiple rules for one policy.

Rule Settings

Rule settings define the model attributes and attribute values that a policy maintains. Policy Manager provides predefined policy settings, including Passive Port Monitoring, Poll Unconnected Ports, Maintenance Mode, 10 Minute Polling, and Disable Redundancy. If the predefined settings do not meet your needs, you can define your own settings, using any of the available attributes. You can also include SpectroWatch settings that can activate or deactivate defined watches when a policy rule is triggered.

Creating Policies

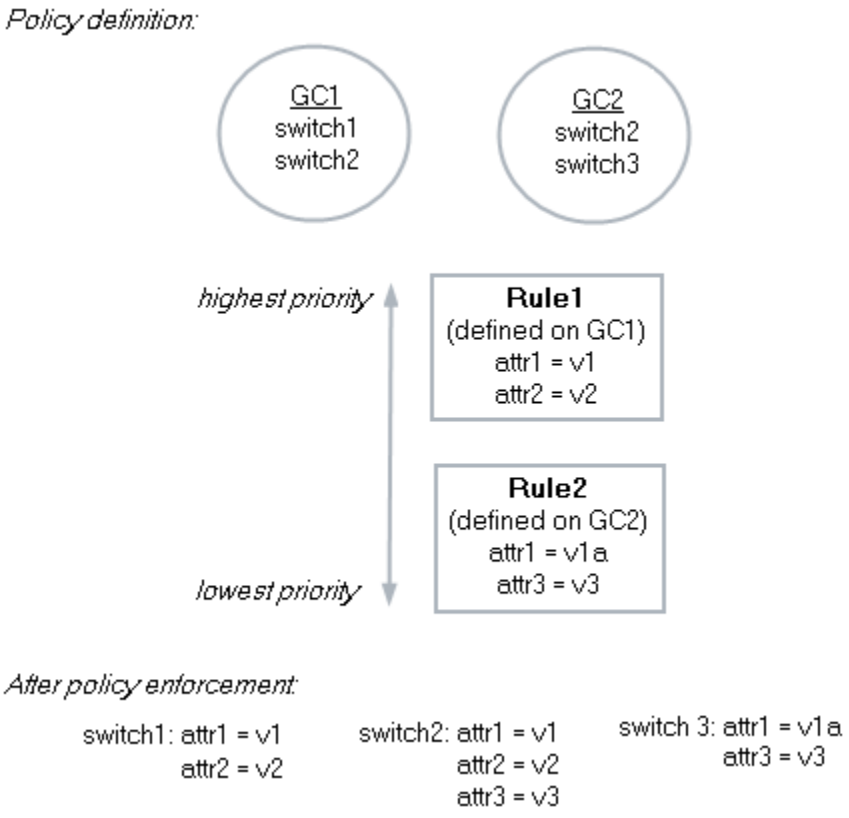
A policy consists of a policy definition, one or more policy rules, and rule settings. Policies must be enabled before they can be enforced.

> **NOTE**
> For legacy policies, use XML files to configure and maintain policy definitions. For more information, see Legacy XML-based Policies.

About Policies

A policy defines a group of related attributes for a set of policy rules. One or more rules are combined to create a policy. The settings that are applied to a model during policy enforcement can come from more than one rule. Rules are prioritized to handle situations in which a model resides in more than one of the global collections for the rules in a policy. Each rule is evaluated in prioritized order until all rules are exhausted. A model adopts the settings of the first rule whose criteria is met. If a model matches the criteria in a subsequent rule, only settings that have not yet been encountered are applied.

For example, the following diagram describes a policy that is defined on two different global collections, GC1 and GC2. Switch1 belongs to GC1 exclusively and only the settings in Rule1 are applied. Switch3 belongs to GC2 exclusively and only the settings in Rule2 are applied. Switch2 belongs to both GC1 and GC2. Because of rule priority, settings in Rule1, which includes attr1 and attr2, are applied first. Then, any settings in Rule2 that have not yet been applied to this model are applied, which is attr3 only. attr1 is ignored because it has already been applied to this model.



A policy must be enabled to be in effect. Events and alarms for the policy and affected device models track the activity and enforcement of a policy.

How to Successfully Plan Policy Definitions

When designing policies to be implemented at your site, consider the following guidelines:

- Use recommended policies. For more information, see Recommended Policy Settings.
- Use predefined settings. Typically, using templates is the best approach when setting up policies. Start with the collection of attributes in a template and then adjust the attributes and their values as needed.
- Define the policy to address a certain condition. If you identified a problem in your network, consider the attributes to monitor based on the nature of the problem.
- Develop a new policy in a test environment and then move into a production environment. For more information, see Exporting and Importing Policies.

Example: Port Fault Management Policy

Suppose you want to set up a policy for port status monitoring: you want to passively monitor all switch ports and actively monitor all router ports. From review of the section Recommended Policy Settings, you determine that the Port Fault Management Policy reflects this policy scenario. To implement this policy, you define a series of policy rules:

- Rule 1: Define a global collection specifying search criteria which identifies all switch ports. You can then use the predefined settings for passive monitoring in the Passive Port Monitoring template on all devices in this global collection. Adjust attribute values as necessary.
- Rule 2: Define a global collection specifying search criteria which identifies all router ports. Then, on all devices in the collection, use the predefined settings for port status monitoring using Live Pipes, as defined in the Live Pipes template. Adjust attribute values as necessary.

These two policy rules are combined to create the Port Fault Management Policy. The policy must then be enabled to take effect.

> **NOTE**
> The Port Fault Management Policy and other recommended policies are described in Recommended Policy Settings.

Restrictions in Policy Definitions

Consider the following restrictions when planning how to define your policies:

You cannot include the same attribute in more than one policy, regardless of whether the policy is enabled.

- Rules that apply to the same global collection cannot use the same setting target. One rule can apply to multiple global collections, but two *different* rules using the *same* setting target cannot apply to the *same* global collection.

These restrictions are in place to help prevent conflicts in your policy definitions.

Internal Attributes

Although Policy Manager is designed to modify and enforce DX NetOps Spectrum internal attributes, do not use Policy Manager to modify certain attributes.

Some attributes are used to control and customize DX NetOps Spectrum behavior and are documented for customizing. These attributes can be included in Policy Manager policies with expected results.

The values of other attributes change automatically in the DX NetOps Spectrum model (such as the Link_Condition attribute) or are intended as status only. These attributes change values as they are polled from the modeled device or in response to other attribute changes involved in computing the value. Overwriting these automatic attribute values can lead to unpredictable behavior. Do not use Policy Manager to modify these attributes.

External Attributes

Policy Manager is designed to enforce Spectrum internal attributes. You can specify external attributes (such as sysContact, sysLocation, or Firmware_version) in policies. However, the results differ from internal attributes, as follows:

- If the device is modeled with a read/write community string, the attribute value in the policy is written to the device.
- If the device is modeled with a read-only community string, the write fails.
- The SpectroSERVER has no write-lock. The external attributes can be modified through OneClick or the SpectroSERVER.
- You can modify the attribute on the device by other means, such as telnet/ssh to the device. The attribute value in the policy is enforced again the next time the policy is re-enabled.

Create a Policy in Policy Manager

You can create a policy using the OneClick Console. Define at least one rule when creating a policy. You can add more rules and settings later, as needed.

Follow these steps:

1. Click Policy Manager in the Explorer tab.
   Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of existing policies is displayed.

3. Click  .
   The Configure Policy dialog opens.
4. Type a name for this policy in the Policy Name field.
5. Create a rule for the policy:
   a. Click  .
      The Configure Rule dialog opens.
   b. Type a name for this rule in the Rule Name field.
   c. Click Browse.
      The Select Global Collections dialog appears.
   d. Select the global collections for this policy, move them to the 'Applies to' list on the left, and then click OK.

      NOTE
      You can create global collections directly from the Select Global Collections dialog using the Create button. For information about creating and maintaining global collections, see Modeling and Managing Your IT Infrastructure .
   e. Define rule settings. Rule settings define the model attributes and attribute values that a policy uses. Use one or more of the following methods:
      - 
        - Create a new, custom setting.
      - 
        - Activate/deactivate a SpectroWatch.
      - 
        - Select predefined settings from a template.
   f. Click OK
      The rule is added to the list of Associated Rules and, when selected, the settings for the rule appear in the Rule Settings window.
6. Repeat step 5 to add more rules to the policy, as needed.

   NOTE

   ■ You can copy an existing rule by clicking the Copy an Existing Rule button.
   ■ Rules that apply to the same global collection cannot use the same setting target. Change the global collection designation when copying rules.
7. After all rules are defined, use the up and down arrows on the toolbar to adjust the priority of the rules in the list: the higher the rule is in the list, the higher the priority of the rule.
   The rules are adjusted in the list and the priority values are modified accordingly.
8. (Optional) Select 'Enable Policy on Creation' to enable and enforce the policy when it is created.

   NOTE
   You can also enable the policy later. For more information, see Enabling and Disabling Policies.
9. Click OK.
   The policy is created and the Configure Policy dialog closes. The new policy appears under Policy Manager in the Explorer tab and in the List tab of the Contents panel. If you enabled the policy on creation, the policy is enforced.

Creating a Custom Rule Setting

By creating custom rule settings, you can specify your own selection of model attributes and values in a policy rule.

> **NOTE**
> Policy Manager also provides templates that include predefined settings. For more information, see Add a Predefined Rule Setting.

Follow these steps:

1. On the Configure Rule dialog, click
   
   The Configure Attribute Setting dialog opens.
2. Type a name for this rule setting in the Setting Name field.
3. Specify an attribute using *one* of the following tasks:
   – Select an attribute from the Attribute drop-down list.
   – Click the Attribute button, select an attribute from the Attribute Selector dialog, and click OK.
   The selected attribute appears in the Attribute field.
4. Enter a value in the Attribute Value field using one of the following methods. The available methods vary depending on the attribute:
   – Accept the default value.
   – Select an attribute from a drop-down list.
   – Use the Browse button.
   – Enter a value manually.
5. Click OK.
   The selected attribute and its value are added to the Rule Settings list.
6. Repeat the steps 1 through 5 to add more custom rule settings.

Add a SpectroWatch Setting

By including SpectroWatch settings in your policy, you can activate or deactivate defined watches on a per-model basis when a policy rule triggers.

Watches can be set on any attribute of a model type, including both internal and external attributes. For example, a log watch can be set on ‘contact status’ or ‘total packets.’ Also, you can set multiple watches on a single attribute. For example, two threshold watches could be set on a device’s packet rate:

- One to generate a yellow alarm when the value exceeds 10,000
- Another to generate a red alarm when the value exceeds 15,000

> **NOTE**
>
> For more information about working with SpectroWatches, see Watches .

Follow these steps:

1. On the Configure Rule dialog, click
   
   The Configure SpectroWatch Setting dialog opens.
2. Type a name for this rule setting in the Setting Name field.
3. Select a SpectroWatch Value from the drop-down list.
   – **Active**

Activate the SpectroWatch when the rule is triggered.

- **Inactive**
  Deactivate the SpectroWatch when the rule is triggered.

4. Specify a watch using *one* of the following tasks:
   - Click Model Type, select a value from the Select Model Type dialog, and click OK.
   - Select a value from the Model Type drop-down list. The model type value of 'SpectroWatch' includes watches internal to DX NetOps Spectrum.

   The list is populated with available watches.

   NOTE
   The lists can take a moment to be populated.
5. Select the SpectroWatches you want to add to this policy rule.
6. Click OK.
   The selected SpectroWatches are added to the Rule Settings list.
7. Repeat steps 1 through 6 to add more SpectroWatch settings.

Add a Predefined Rule Setting

Policy Manager provides templates that contain predefined policy settings that you can add to your policy rule. Each template contains a number of related attributes and attribute values for a particular purpose. For example, the AlarmThresholdingSettingsTemplate includes alarm-related attributes that can be used to manage alarm thresholding on certain device or port models.

NOTE

Policy Manager also allows you to specify custom settings in your rules. For more information, see Creating a Custom Rule Setting.

Follow these steps:

1. On the Configure Rule dialog, click

   The Select Template dialog opens and lists all available templates. Predefined templates have a value of 'CA' in the Type field.

   NOTE
   Templates with a value of PolicyRule in the Type field are user-defined rules that have already been created for this policy. You can use these rules as templates when assigning the same settings for different global collections in the same policy.
2. Select the template that contains the attributes you want to use in the policy rule.

   NOTE
   To see the complete template description, roll over the description field for the template.

   The attributes that make up the selected template are listed in the Rule Settings section.
3. Click OK.
   The Select Template dialog closes and the attributes that make up the template you selected appear in the Rule Settings list. Any default attribute values are shown in the Value column.
4. Modify or define attribute values. Each setting requires an attribute value before the rule can be saved.
   a. Select an attribute in the Rule Settings list and click

   The Configure Attribute Setting dialog opens.

b. Enter a value in the Attribute Value field. Depending on the attribute, you can select from a drop-down list, use a Browse button, or enter a value manually.
c. Click OK.
The Configure Attribute Setting dialog closes and the attribute value appears in the Value column for that setting.
d. Repeat step 4 to modify or define attribute values for all rule settings as necessary.

5. Repeat steps 1 through 4 to add more predefined settings.

Enable and Disable Policies

For a policy to enforce its defined network management configurations, it must be enabled. Also, to edit or delete a policy or to export policy definitions, the policy must be disabled.

NOTE
Legacy XML-based policies can only be enabled or disabled by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.

Follow these steps:

1. Expand the Policy Manager node in the Explorer tab.

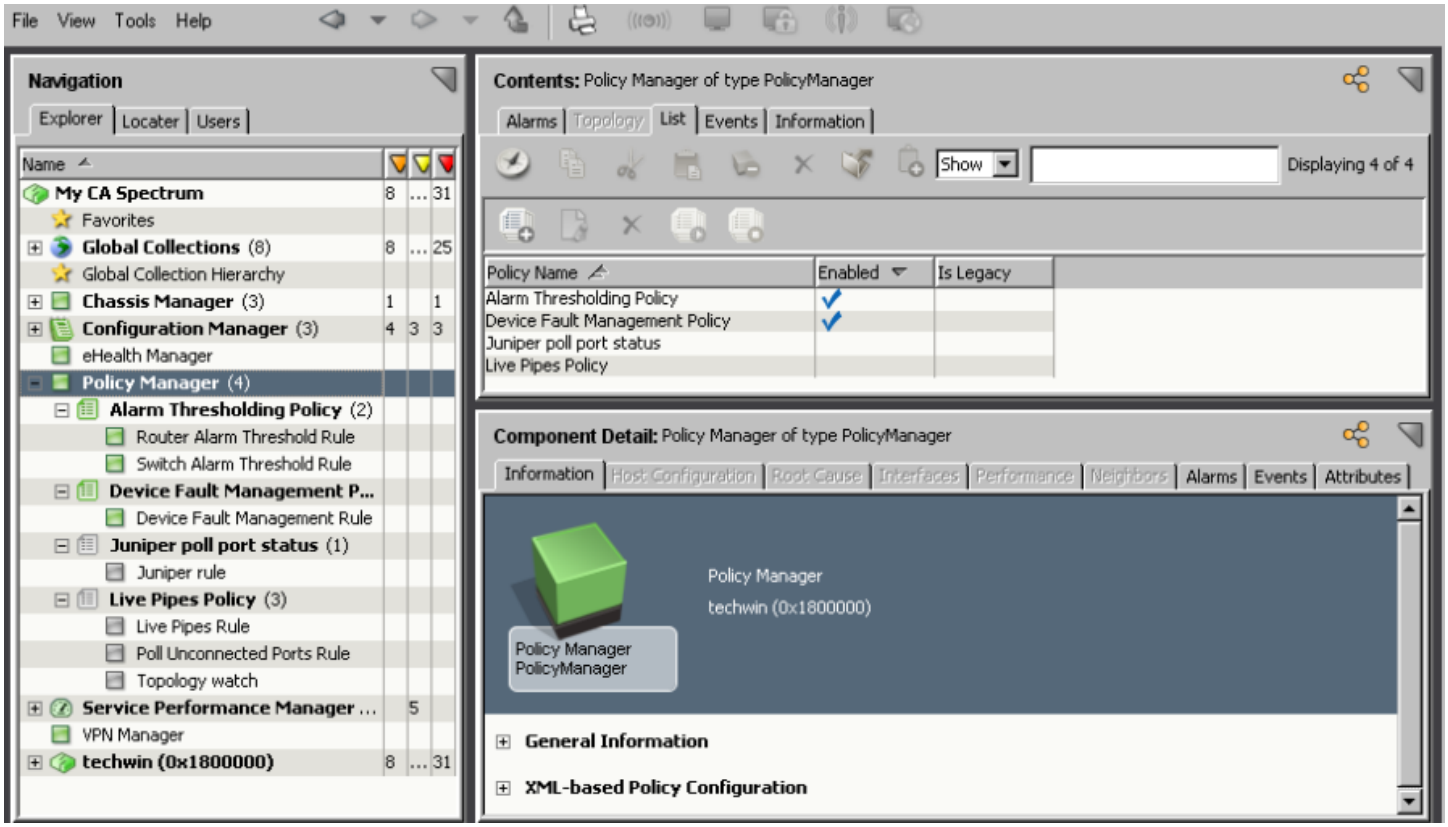
NOTE
Policies appear in the Explorer tab beneath the Policy Manager node. Enabled policies have a green icon and disabled policies have a gray icon.

2. Select the List tab in the Contents panel.
A list of available policies appears. A check in the Enabled column indicates an enabled policy.
3. Select the policies that you want to enable or disable.
4. Perform *one* of the following tasks:
– To enable the selected policy or policies,
click  .
– To disable the selected policy or policies,
Click  .
A check appears or disappears in the Enabled column accordingly.

NOTE
You can also enable or disable a policy using the Enabled field in the General Information subview for a specific policy.

Viewing Policies

Defined policies appear beneath Policy Manager in the Explorer tab and in the List tab in the Contents panel.



In the Explorer tab, the icons for enabled policies and their associated rules are green. Icons for disabled policies and rules are gray.

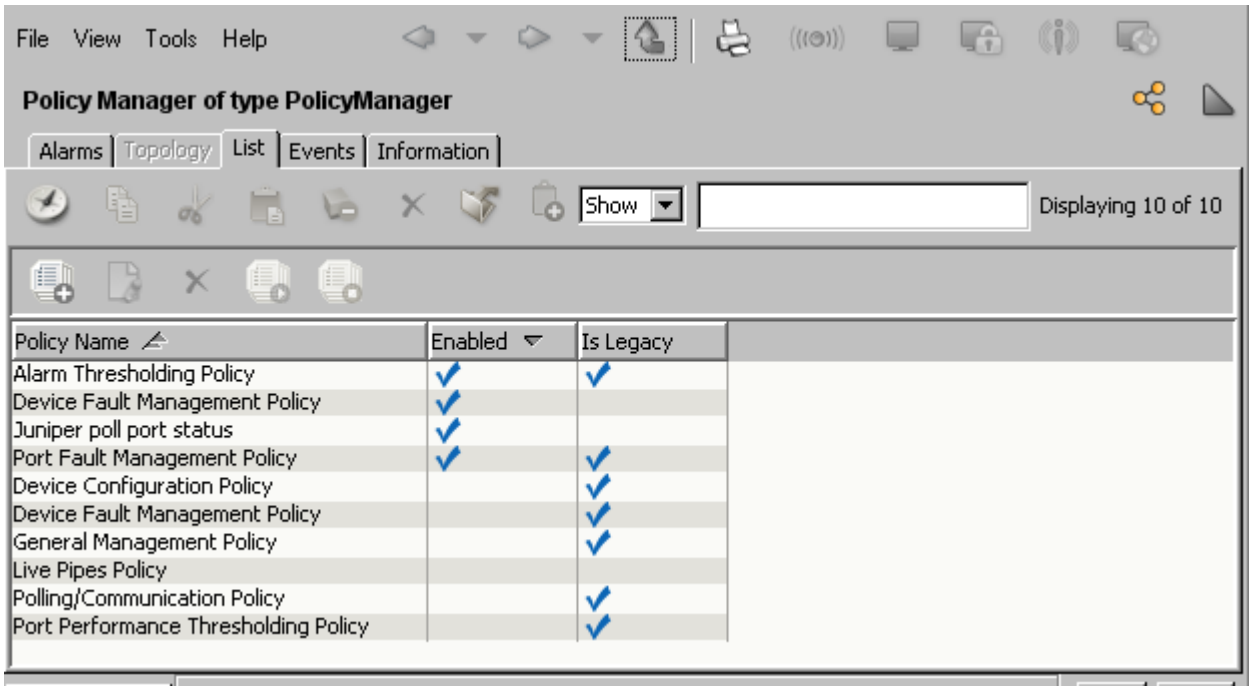
View All Policies

The following procedure describes how to view all existing policies.

Follow these steps:

1. Click Policy Manager in the Explorer tab.
   Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of existing policies is displayed. From this view, you can create policies, and you can edit, delete, enable, and disable non-legacy policies.

   NOTE
   Legacy XML-based policies can only be edited, deleted, enabled, or disabled by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.



NOTE
You can also view all policies from the Locater tab: Policy Manager, All Policies.

View Policy Information

To view the details of a specific policy, select the policy in the Explorer tab under the Policy Manager node. The Contents and Component Detail panels are updated with information about the policy.

The List tab in the Contents panel contains information about the rules for the selected policy, including priority, name, global collections, and parent policy.

The Information tab in the Component Detail panel contains the following subviews:

- **General Information**
  Contains information about the policy, including security string and whether the policy has been enabled.
- **Global Collections**
  Lists the global collections to which this policy is applied.
- **Associated Rules**
  Lists the rules for the policy.

View Policies by Global Collection

You can view policies that are applied to a particular global collection.

Follow these steps:

1. In the Explorer tab, select the global collection for which you want to view Policy Manager policies.
   Information about the global collection is displayed in the Contents panel and the Component Detail panel.
2. Expand the Policy Manager Policies subview in the Information tab of the Component Detail panel.
   A list of existing policies identifies enabled policies and legacy policies.

View Policy Rule Information

To view the details of a policy rule, select the rule in the Explorer tab. Rules are located under policies in the Policy Manager node. The Contents and Component Detail panels are updated with information about the rule.

NOTE
To view all rules, use the Locater tab: Policy Manager, All Rules.

The List tab in the Contents panel contains information about the rules for the parent policy, including priority, name, global collections, and parent policy.

The Information tab in the Component Detail panel contains the following subviews:

- **General Information**
  Contains information about the rule, including priority, global collections to which it is applied, and security string.
- **Rule Settings**
  Lists the rule settings for this policy rule.
- **Affected Models**
  Lists the models affected by this policy rule.

NOTE
The policy must be enabled for this information to exist.

Search from the Locater Tab

Policy Manager provides multiple search criteria options for finding existing policies and rules in DX NetOps Spectrum. In addition to viewing policies from the Explorer tab, you can also search for specific policies and rules in the Locater tab**.**

NOTE
For more information about OneClick searches and configuration options, see Use OneClick .

Follow these steps:

1. Perform the following steps to display all policies or rules:
   a. Expand the Policy Manager folder in the Locater tab.
   b. Double-click the All Policies or All Rules option, as appropriate, to launch the search.
   c. Specify appropriate landscape information in the "Select Landscapes to Search" dialog and click OK.
   The Results tab displays search results appear in the Contents panel.
2. Perform the following steps for a criteria-based policy or rule search:
   a. Expand the Policy Manager folder in the Locater tab.
   b. Expand the Policies By or Rules By folder, as appropriate.
   c. Select the type of criteria-based search you want to run.
   d. Click the Search button.

   NOTE
   Depending on which search you select, you are prompted to enter values in a Search dialog before the search is executed.

   The Results tab displays search results in the Contents panel.

Editing Policies

You can change a policy name, the rules for the policy, and the rule settings. The following topics describe how to perform these tasks:

NOTE

- Only users with the appropriate privileges can edit policies. For more information, see Policy Manager Privileges.
- To modify the device or port models affected by a policy, edit the global collection and not the policy. For information about creating and maintaining global collections, see Modeling and Managing Your IT Infrastructure.

Edit a Policy

The following procedure describes how to edit a policy.

NOTE

- A policy must be disabled before it can be edited. For more information, see Enabling and Disabling Policies.
- Legacy XML-based policies can only be edited by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.

Follow these steps:

1. Click Policy Manager in the Explorer tab.
   Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of policies is displayed.
3. Select the policy for editing and
   click 
   The Configure Policy dialog opens.
4. Modify the policy as needed and as described in Creating a Policy.
5. Click OK.
   The policy is updated and the Configure Policy dialog closes.
6. Enable the policy if needed.
   The updated settings are enforced.

Edit a Policy Rule

You can edit a specific policy rule and its settings without editing the entire policy. The parent policy must be disabled to edit one of its rules. The following procedure describes how to edit an existing policy rule.

- A policy must be disabled before its rules can be edited. For more information, see Enabling and Disabling Policies.
- Legacy XML-based policy rules can only be edited by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.

Follow these steps:

1. Select the rule to be modified in the Explorer tab.
   Note: You can also select the parent policy of the rule to be modified in the Explorer tab.
   Information about the selected rule and policy is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of the rules for the parent policy is displayed.
3. Select the rule for editing, and then perform one or more of the following tasks:
   – 

- Add a rule to the policy

– 

- Modify the selected rule

– 

- Copy the selected rule

The Configure Rule dialog opens.

4. Create or modify the rule as needed and as described in Creating a Policy.

   NOTE
   To modify an attribute value, click the modify the selected rule icon in the Rule Settings panel of the Configure Rule dialog.

5. Click OK.
   The rule is updated and the Configure Rule dialog closes.
6. Enable the parent policy if needed.
   The updated settings are enforced.

Editing a Rule Setting (Attribute Value)

You edit the attribute value by editing the rule itself. For more information, see Editing a Policy Rule.

Deleting Policies

The following procedure describes how to delete a policy. When you delete a policy, all rules and rule settings are also deleted.

NOTE

- A policy must be disabled before it can be deleted. For more information, see Enabling and Disabling Policies.
- Legacy XML-based policies can only be deleted by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.

Follow these steps:

1. Click Policy Manager in the Explorer tab.
   Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of policies is displayed.
3. Select the policy to be deleted and

   click 
   The Delete Policy confirmation dialog opens.
4. Click Yes.
   The policy and all its associated rules and rule settings are deleted.

Delete a Policy Rule

The following procedure describes how to delete a policy rule. When you delete a policy rule, the rule settings for that rule are also deleted.

NOTE

- The parent policy must be disabled before one of its rules can be deleted. For more information, see Enabling and Disabling Policies.
- Legacy XML-based policy rules can only be deleted by modifying and reloading the policy definition XML. For more information, see Legacy XML-based Policies.

Follow these steps:

1. Select the rule to be deleted in the Explorer tab.

   NOTE
   You can also select the parent policy of the rule to be deleted in the Explorer tab.

   Information about the selected rule and policy is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of the rules for the parent policy is displayed.
3. Select the rule to be deleted and
   click 
   The Delete Rule confirmation dialog opens.
4. Click Yes.
   The rule and its rule settings are deleted. The rule priority values are adjusted accordingly.

Managing Policies

How to Check for Policy Enforcement

After a Policy Manager policy is enabled, you can verify results of its enforcement in the following ways:

- Check for generated events and alarms. An event is generated on the model when a rule cannot be enforced, such as when an attribute value cannot be written to a device. For more information, see Events and Alarms.
- Check the Affected Models subview of the rule. All models affected by the enforcement of the rule are listed. For more information, see Viewing Policy Rule Information.

Events and Alarms

DX NetOps Spectrum generates events and alarms to inform the user of Policy Manager activity.

An event is generated for conditions such as the following examples:

- When a policy is enabled or disabled.
- When the enforcement of a rule is successful.
- When a rule cannot be enforced, such as when an attribute value cannot be written to a device.
- When legacy XML-based policies are loaded or attempted to be loaded. Errors that occur during reloading are recorded in the event.

An alarm is generated for parsing errors that occur when legacy XML-based policies are reloaded.

Export Policies

You can export and import Policy Manager policies using DX NetOps Spectrum Modeling Gateway. This capability is useful when developing policies in a test environment and then moving them into a production environment. All related Policy Manager models, policies, rules, permissions, and templates are included.

NOTE
For more information about using the Modeling Gateway, see Modeling Gateway Toolkit .

Follow these steps:

1. Choose the SpectroSERVER from which to export Policy Manager policies, namely, where all policies exist. In a distributed SpectroSERVER environment, a policy may not exist on every SpectroSERVER, depending on the global collections it is associated with.

   NOTE
   You can also make policies exist temporarily on a SpectroSERVER by making all global collections for the policies exist on the SpectroSERVER.
2. On the chosen SpectroSERVER, modify the Modeling Gateway toolkit XML file to specify what to export:
   a. Open the following file for editing:
      `<$SPECROOT>/SS-Tools/.modelinggatewayresource.xml`
   b. Locate the ExportConfiguration tag and make the following edits below the tag:
      - Set the export_policy_manager and export_global_collections values to 'true'.

        NOTE
        You cannot select specific policies or global collections to export when using the Modeling Gateway. All policies and global collections are exported.
      - To avoid more exports, set all other values to 'false'.
   c. Save and close the file.
3. Export Policy Manager policies with the Modeling Gateway command-line tool, 'modelinggateway', located in the following directories.
   – On Linux:
      `<$SPECROOT>/SS-Tools>./modelinggateway -vnm vnm_name -e export_file`
   – On Windows:
      `<$SPECROOT>/SS-Tools>modelinggateway.bat -vnm vnm_name -e export_file`
   – ***vnm_name***
   is the name of the SpectroSERVER host
   – ***export_file***
   is the output file name
   The export process begins. Messages indicate the successful export of various models. Two files are created in the *<$SPECROOT>*/SS-Tools directory:
   – *export_file*.log - contains any error information
   – *export_file*.xml - contains exported Policy Manager data
4. Review the contents of *export_file*.xml to verify that all expected policies, rules, settings, and associations are included.

Import Policies

You can use the DX NetOps Spectrum Modeling Gateway to export and import Policy Manager policies. This capability is useful when developing policies in a test environment and then moving them into a production environment. All related Policy Manager models, policies, rules, permissions, and templates are included.

NOTE
For more information about using the Modeling Gateway, see Modeling Gateway Toolkit .

Follow these steps:

1. In the OneClick Console, disable and delete any policy that exists on the SpectroSERVER that you are going to replace with an imported policy. For more information, see Enabling and Disabling Policies and Deleting a Policy.

2. Review the contents of *export_file*.xml that was generated in the export procedure. Verify that all expected policies, rules, settings, and associations to be imported are included.
3. Import Policy Manager policies with the Modeling Gateway command-line tool, 'modelinggateway', located in the following directories.
   - On Linux:
     ```
     <$SPECROOT>/SS-Tools>./modelinggateway -vnm vnm_name -i export_file.xml
     ```
   - On Windows:
     ```
     <$SPECROOT>/SS-Tools>modelinggateway.bat -vnm vnm_name -i export_file.xml
     ```
   - ***vnm_name***
     is the name of the SpectroSERVER host
   - ***export_file.xml***
     is the name of the file containing the exported policy data

   The import process begins. Messages indicate the successful import of various models.
4. Verify in the OneClick Console that all policy information was correctly imported. For more information, see Viewing Policies.
5. Enable the policies as necessary. For more information, see Enabling and Disabling Policies.

Legacy XML-based Policies

In previous DX NetOps Spectrum releases, Policy Manager policies and rules could be developed and maintained using XML files exclusively. This DX NetOps Spectrum release continues to support these legacy XML-based policies with minimal integration into the OneClick Console interface. The topics in this section are provided to assist you during your migration from legacy policies to new OneClick Console-based policies.

> **WARNING**
> Using the DX NetOps Spectrum OneClick Console is the recommended and supported method for creating and maintaining policies in Policy Manager.

Maintaining XML-based Policies

Explanations and procedures describing how to create, modify, and maintain XML-based policies are provided in full in previous releases of DX NetOps Spectrum documentation. Please refer to the documentation provided in previous releases for details on maintaining your XML until you have fully migrated to OneClick Console-based policies.

Migrate from XML-based to OneClick Console-based Policies

Although legacy XML-based Policy Manager policies are still supported, you are encouraged to migrate your policies from XML to the OneClick Console-based format. The following process is a suggested workflow for this migration. We strongly recommend that you develop new policies in a test environment.

1. Identify a policy to be converted. Begin with your most basic policy.
2. Remove the policy from the XML file in the <*$SPECROOT*>/PolicyMgmt directory, then reload the policy.
   This step stops the policy from being enforced and deletes the policy.
3. Develop the same policy using the OneClick Console user interface, enable it, and test.

1. When the policy works as expected, use the Modeling Gateway to export the policy from the test environment and import it to the production environment.

Examples for Policy Settings

Configure the Device Fault Management Policy

This example shows you how to configure the Device Fault Management Policy using the OneClick Console. The policy settings in this example are predefined.

Follow these steps:

1. Click Policy Manager in the Explorer tab.
   Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
   A list of existing policies is displayed.
3. Click 
   The Configure Policy dialog opens.
4. Type **Device Fault Management Policy** in the Policy Name field.
5. Click 
   The Configure Rule dialog opens.
6. Type **Device Fault Management Rule** in the Rule Name field.
7. Click Browse.
   The Select Global Collections dialog opens.
8. Create a global collection for the policy:
   a. Click Create.
      The Create Global Collection dialog opens.
   b. Type **All Devices** in the Name field.
   c. Click Search Options.
      The Search Options dialog opens.
   d. Click Show Advanced and click Add Existing.
      The Add Existing Search dialog opens.
   e. Expand the Devices folder, click All Devices, and click OK.
      The Add Existing Search dialog closes and the selected search criteria appears in the Expression field.
   f. Click OK.
      The Search Options dialog closes.
   g. Click OK.
      The Create Global Collection dialog closes. The All Devices global collection is created and added to the 'Applies to' list on the left.
9. Click OK.
   The Select Global Collections dialog closes and the All Devices global collection is added to this rule.
10. Specify the predefined settings for this policy:
    a. In the Rule Settings section of the Configure Rule dialog,
       click 
       The Select Template dialog opens.
    b. Select NoInvalidDLCIAlarms from the list of available templates.
       The Rule Settings list displays the policy settings that make up the No Invalid DLCI Alarms template.
    c. Click OK.
       The Select Template dialog closes and the settings are added to this rule.
    d. Select the first parameter, NoInvalidDLCIAlarms_1, and
       click 
       The Configure Attribute Setting dialog opens.

e. Set the Attribute Value to No, and click OK.
The Configure Attribute Setting dialog closes and the attribute value is defined.
f. Repeat the previous two steps for NoInvalidDLCIAlarms_2.
Values are now specified for all attributes.

11. Click OK.
The Configure Rule dialog closes and the rule is added to the policy.
12. Select 'Enable Policy on Creation' to enable and immediately enforce the policy when it is created.
13. Click OK.
The Configure Policy dialog closes. The Device Fault Management Policy is created, enabled, and appears in the policy list.

Configure the Alarm Thresholding Policy

This example shows you how to configure the Alarm Thresholding Policy for devices on your network. This example creates two alarm threshold policy settings: one that is applied to routers and one that is applied to switches.

The following attributes are used in this example:

- Value_When_Yellow (0x1000c)
- Value_When_Orange (0x1000d)
- Value_When_Red (0x1000e)
- Yellow_Threshold (0x10010)
- Orange_Threshold (0x10011)
- Red_Threshold (0x10012)

Follow these steps:

1. Click Policy Manager in the Explorer tab.
Information about Policy Manager is displayed in the Contents panel and the Component Detail panel.
2. Click the List tab in the Contents panel.
A list of existing policies is displayed.
3. Click 
The Configure Policy dialog opens.
4. Type **Alarm Thresholding Policy** in the Policy Name field.
5. Click 
The Configure Rule dialog opens.
6. Type **Router Alarm Threshold Rule** in the Rule Name field.
7. Click Browse.
The Select Global Collections dialog opens.
8. Create a global collection for the policy:
a. Click Create.
The Create Global Collection dialog opens.
b. Type **Routers** in the Name field.
c. Click Search Options.
The Search Options dialog opens.
d. Select 'Model Class (0x11ee8)' from the Attribute drop-down list.
e. Select 'Router' from the Attribute Value drop-down list.
f. Click OK.
The Search Options dialog closes.
g. Click OK.

The Create Global Collection dialog closes. The Routers global collection is created and added to the 'Applies to' list on the left.

9. Click OK.
   The Select Global Collections dialog closes and the Routers global collection is added to this rule.
10. Specify the predefined settings for this policy:
    a. In the Rule Settings section of the Configure Rule dialog,
       click 
       The Select Template dialog opens.
    b. Select AlarmThresholdingSettingsTemplate from the list of available templates.
       The Rule Settings list displays the policy settings that make up the Alarm Thresholding Settings template.
    c. Click OK.
       The Select Template dialog closes and the settings are added to this rule.
    d. Select the first parameter, AlarmThresholdingSettingsTemplate_1, and
       click 
       The Configure Attribute Setting dialog opens.
    e. Enter **2** for the Attribute Value and click OK.
       The Configure Attribute Setting dialog closes and the attribute value is defined.
    f. Repeat the previous two steps for the following settings:
       - AlarmThresholdingSettingsTemplate_2: **3**
       - AlarmThresholdingSettingsTemplate_3: **4**
       - AlarmThresholdingSettingsTemplate_4: **4**
       - AlarmThresholdingSettingsTemplate_5: **6**
       - AlarmThresholdingSettingsTemplate_6: **8**

       Values are now specified for all attributes.
11. Click OK.
    The Configure Rule dialog closes and the rule is added to the policy.
12. Click 
    The Configure Rule dialog opens.
13. Type **Switch Alarm Threshold Rule** in the Rule Name field.
14. Click Browse.
    The Select Global Collections dialog opens.
15. Create a global collection for the policy:
    a. Click Create.
       The Create Global Collection dialog opens.
    b. Type **Switches** in the Name field.
    c. Click Search Options.
       The Search Options dialog opens.
    d. Select 'Model Class (0x11ee8)' from the Attribute drop-down list.
    e. Select 'Switch' from the Attribute Value drop-down list.
    f. Click OK.
       The Search Options dialog closes.
    g. Click OK.
       The Create Global Collection dialog closes. The Switches global collection is created and added to the 'Applies to' list on the left.
16. Click OK.
    The Select Global Collections dialog closes and the Switches global collection is added to this rule.

17. Specify the predefined settings for this policy:
    a. In the Rule Settings section of the Configure Rule dialog,
    click 
    The Select Template dialog opens.
    b. Select AlarmThresholdingSettingsTemplate from the list of available templates.
    The Rule Settings list displays the policy settings that make up the Alarm Thresholding Settings template.
    c. Click OK.
    The Select Template dialog closes and the settings are added to this rule.
    d. Select the first parameter, AlarmThresholdingSettingsTemplate_1, and
    click 
    The Configure Attribute Setting dialog opens.
    e. Enter **1** for the Attribute Value and click OK.
    The Configure Attribute Setting dialog closes and the attribute value is defined.
    f. Repeat the previous two steps for the following settings:
    - AlarmThresholdingSettingsTemplate_2: **2**
    - AlarmThresholdingSettingsTemplate_3: **3**
    - AlarmThresholdingSettingsTemplate_4: **3**
    - AlarmThresholdingSettingsTemplate_5: **4**
    - AlarmThresholdingSettingsTemplate_6: **5**

    Values are now specified for all attributes.
18. Click OK.
    The Configure Rule dialog closes and the rule is added to the policy.
19. Select 'Enable Policy on Creation' to enable and immediately enforce the policy when it is created.
20. Click OK.
    The Configure Policy dialog closes. The Alarm Thresholding Policy is created, enabled, and appears in the policy list.

Recommended Policy Settings

Provided in this section are recommended policies that you can implement at your site. Each recommended policy is based on the settings in predefined settings templates. Each template configures the attributes in a different way. You select the policy setting that matches the way you want to implement your network management. You can also adjust the settings to suit your specific needs.

> **NOTE**
> Some attributes in these policy settings do not have predefined values. You can create your own settings for such attributes if necessary. If you do not want to enforce an attribute, simply remove it from the rule.

Port Fault Management Policy

The Port Fault Management Policy is used to maintain all port-level attributes related to fault management.

Policy Settings

This policy has four predefined settings templates:

- **Passive Port Monitoring**

These settings enable port status monitoring using only passive means. DX NetOps Spectrum listens for link down traps and generates alarms when needed. This method is the most efficient but least reliable means of port status monitoring. These settings are the default DX NetOps Spectrum settings.

- **Live Pipes**
  These settings enable port status monitoring using Live Pipes. DX NetOps Spectrum actively polls the status of ports in modeled connections. Colored pipes in all applications indicate the status of the connection. Trap-based monitoring is also enabled for expedited fault detection.
- **Poll Unconnected Ports**
  These settings enable port status monitoring for ports whose connectivity is not modeled in DX NetOps Spectrum. DX NetOps Spectrum actively polls the status of the port. Trap-based monitoring is also enabled for expedited fault detection.
- **Disabled Port Monitoring/No Alarms**
  These settings disable all port status monitoring methods and prevent any related alarms from being generated.

Attributes

The following attributes are used in the Port Fault Management Policy:

- **PollPortStatus**
  Attribute ID: 0x1280a
  Controls status polling of a port whose connectivity is not modeled.
- **ok_to_poll**
  Attribute ID: 0x11dd8
  Controls whether the pipe associated with this port is live. The status of the port is polled.
- **AlarmOnLinkDownTrap**
  Attribute ID: 0x11fc2
  Determines how DX NetOps Spectrum handles a Link Down trap on this particular port.
- **AssertLinkDownAlarm**
  Attribute ID: 0x12957
  Determines whether DX NetOps Spectrum generates a yellow alarm on the device model when a link-down trap is received for this port.
- **GeneratePortStatusAlarms**
  Attribute ID: 0x12a54
  Indicates whether a port status alarm is generated on this port.

Device Fault Management Policy

The Device Fault Management Policy is used to maintain all device-level attributes related to fault management.

Policy Settings

This policy has one predefined settings template:

- **No Invalid DLCI Alarms**
  These settings prevent DX NetOps Spectrum from generating red alarms on DLCI ports that have an ‘invalid’ state. Invalid DLCIs have a brown condition instead of a red condition.

Attributes

The following attributes are used in the Device Fault Management Policy:

- **PollPortStatus**
  Attribute ID: 0x12809
  Provides device-level control over the polling of port status for ports whose connectivity is not modeled.
- **support_ICMP**
  Attribute ID: 0x11d3d

Determines whether DX NetOps Spectrum attempts to contact a device using ICMP when SNMP contact is lost.

- **AlarmOnInvalidDLCIs**
  Attribute ID: 0x129ee
  Determines whether DX NetOps Spectrum generates red alarms on DCLI ports that have an 'invalid' state. When set to FALSE, invalid DLCIs have a brown condition instead of a red condition.

General Management Policy

The General Management Policy is used to maintain all device-level attributes related to general network management.

Policy Settings

This policy has two predefined settings templates:

- **Maintenance Mode**
  These settings suspend model management and put the model into Maintenance Mode. The model has a brown condition and no events or alarms are generated on the model. No SNMP requests are sent to the agent.
- **No Events Generated**
  These settings suspend event and alarm generation on the model. SNMP requests are sent to the agent.

Attributes

The following attributes are used in the General Management Policy:

- **isManaged**
  Attribute ID: 0x1295d
  Controls how DX NetOps Spectrum manages this model. When set to FALSE, DX NetOps Spectrum suspends management.
- **IsEventCreationEnabled**
  Attribute ID: 0x129f8
  Controls whether events are generated on the model. When set to FALSE, DX NetOps Spectrum stops generating events on the model, but SMNP and ICMP communication is still allowed.
- **Criticality**
  Attribute ID: 0x1290c
  Determines the relative significance of this device or port model. This value is used in determining the impact severity of a Contact Lost alarm. Any numeric value is supported.
- **DisableTrapEvents**
  Attribute ID: 0x11cd0
  Determines whether DX NetOps Spectrum escalates a trap into an event on a particular port model.
- **ContactStatusEventSwitch**
  Attribute ID: 0x11a56
  Determines whether DX NetOps Spectrum generates events when the Contact_Status of a device changes.

Polling/Communication Policy

The Polling/Communication Policy is used to maintain all device and port attributes for polling and communication with an SNMP agent.

Policy Settings

This policy has four predefined settings templates:

- **No Logging**
  Model statistics are not logged for the model.
- **1-Minute Polling**

The model is polled every 60 seconds.
- **5-Minute Polling**
  The model is polled every 300 seconds.
- **10-Minute Polling**
  The model is polled every 600 seconds.

Attributes

The following attributes are used in the Polling/Communication Policy:

- **PollingStatus**
  Attribute ID: 0x1154f
  Determines whether DX NetOps Spectrum polls the specified attributes of the model.
- **Polling Interval**
  Attribute ID: 0x10071
  Controls how often DX NetOps Spectrum polls this model.
- **Poll Log Ratio**
  Attribute ID: 0x10072
  Controls how often model statistics are logged. The actual interval is determined by multiplying the Polling_Interval by the Poll_Log_Ratio.
- **DCM Timeout (ms)**
  Attribute ID: 0x110c4
  Determines how long DX NetOps Spectrum waits to receive an SNMP response before sending a retry.
- **DCM Retry Count**
  Attribute ID: 0x110c5
  Determines the number of times that DX NetOps Spectrum attempts an SNMP get request before failing.
- **SNMP Community String**
  Attribute ID: 0x10024
  Specifies the SNMP password for communicating with an SNMP agent.
- **CommunityNameForSNMPSets**
  Attribute ID: 0x11a7f
  Specifies the SNMP password for performing an SNMP set. If this attribute is not filled in for a model, DX NetOps Spectrum uses the value of SNMP Community String.
- **Throttling**
  Attribute ID: 0x11f79
  Controls whether DX NetOps Spectrum restricts the amount of outstanding SNMP requests to a device. Throttling helps to alleviate problems involving SNMP agents that cannot handle large amounts of SNMP requests.
- **Throttle Count**
  Attribute ID: 0x11f39
  Determines how many outstanding SNMP requests are allowed when throttling is enabled for a device.
- **Agent_Port**
  Attribute ID: 0x10023
  Controls the port number for communicating with an SNMP agent.
- **Message Size**
  Attribute ID: 0x1197b
  Determines the largest packet size (in bytes) that DX NetOps Spectrum can send to an SNMP agent.

Alarm Thresholding Policy

The Alarm Thresholding Policy contains all the attributes that are related to the roll-up conditions and significance levels for models.

Policy Settings

This policy has one predefined settings template:

- **Alarm Thresholding Settings Template**
  These settings control the roll-up condition and significance level for a model.

Attributes

The following attributes are used in the Alarm Thresholding Policy:

- **Value_When_Yellow**
  Attribute ID: 0x1000c
  Specifies the significance level that the model inherits when its condition is yellow.
- **Value_When_Orange**
  Attribute ID: 0x1000d
  Specifies the significance level that the model inherits when its condition is orange.
- **Value_When_Red**
  Attribute ID: 0x1000e
  Specifies the significance level that the model inherits when its condition is red.
- **Yellow_Threshold**
  Attribute ID: 0x10010
  Specifies the threshold value that controls when the roll-up condition is yellow. The roll-up condition is yellow when its composite condition is greater than or equal to this value.
- **Orange_Threshold**
  Attribute ID: 0x10011
  Specifies the threshold value that controls when the roll-up condition is orange. The roll-up condition is orange when its composite condition is greater than or equal to this value.
- **Red_Threshold**
  Attribute ID: 0x10012
  Specifies the threshold value that controls when the roll-up condition is red. The roll-up condition is red when its composite condition is greater than or equal to this value.

Port Performance Thresholding Policy

The Port Performance Thresholding Policy contains all attributes for calculating and alarming on port performance.

Policy Settings

This policy has one predefined settings template:

- **Port Performance Thresholding Settings Template**
  These settings are used to calculate and alarm on port performance.

Attributes

The following attributes are used in the Port Performance Thresholding Policy:

- **% Utilization Threshold**
  Attribute ID: 0x1294b
  Specifies the threshold value for load on a port. When load is greater than or equal to this value, an alarm is generated.
- **% Utilization Reset**
  Attribute ID: 0x1294f
  Specifies the threshold value that controls when an alarm for load on a port is cleared. When load is less than this value, the alarm is cleared.
- **SET LEVEL IN LD**
  Attribute ID: 0x12d9f

Specifies the threshold value for receive load on a port. When receive load is greater than or equal to this value, an alarm is generated.

- **RESET LEVEL IN LD**
  Attribute ID: 0x12da0
  Specifies the threshold value that controls when an alarm for receive load on a port is cleared. When receive load is less than this value, the alarm is cleared.
- **SET LEVEL OUT LD**
  Attribute ID: 0x12da3
  Specifies the threshold value for the transmit load on a port. When the transmit load is greater than or equal to this value, an alarm is generated.
- **RESET LEVEL OUT LD**
  Attribute ID: 0x12da4
  Specifies the threshold value that controls when an alarm for transmit load on a port is cleared. When the transmit load is less than this value, the alarm is cleared.
- **SET LEVEL PR 64**
  Attribute ID: 0x12da7
  Specifies the threshold value for the packet rate on a port. When the packet rate is greater than or equal to this value, an alarm is generated.
- **RESET LEVEL PR 64**
  Attribute ID: 0x12da8
  Specifies the threshold value that controls when an alarm for the packet rate on a port is cleared. When the packet rate is less than this value, the alarm is cleared.
- **% Errors Threshold (micropercent)**
  Attribute ID: 0x1294d
  Specifies the threshold value for the error rate on a port. When the error rate is greater than or equal to this value, an alarm is generated. This attribute is in units of micropercent (1/1,000,000 of a percent). For example, 1 percent is entered as 1000000.
- **% Errors Reset (micropercent)**
  Attribute ID: 0x12951
  Specifies the threshold value that controls when an alarm for the error rate on a port is cleared. When the error rate is less than this value, the alarm is cleared. This attribute is in units of micropercent (1/1,000,000 of a percent). For example, 1 percent is entered as 1000000.
- **% Discarded Threshold (micropercent)**
  Attribute ID: 0x1294e
  Specifies the threshold value for the discard rate on a port. When the discard rate is greater than or equal to this value, an alarm is generated. This attribute is in units of micropercent (1/1,000,000 of a percent). For example, 1 percent is entered as 1000000.
- **% Discarded Reset (micropercent)**
  Attribute ID: 0x12952
  Specifies the threshold value that controls when an alarm for the discard rate on a port is cleared. When the discard rate is less than this value, the alarm is cleared. This attribute is in units of micropercent (1/1,000,000 of a percent). For example, 1 percent is entered as 1000000.

Device Configuration Policy

The Device Configuration Policy contains all attributes for how DX NetOps Spectrum automatically configures a device.

Policy Settings

This policy has one predefined settings template:

- **Disable Redundancy**

These settings control how DX NetOps Spectrum handles automatic device configuration. By default, DX NetOps Spectrum updates the model only when the primary address is accessible, even when a list of preferred redundant addresses exists.

Attributes

The following attributes are used in the Device Configuration Policy:

- **RedundancyEnabled**
  Attribute ID: 0x11d2c
  Specifies whether DX NetOps Spectrum updates the model when the primary address is not accessible and a list of redundant preferred addresses exists.
- **Rdnd_CheckGenAlarms**
  Attribute ID: 0x11dd6
  Controls whether DX NetOps Spectrum generates alarms when redundancy intelligence updates the network address.
- **If_IsAutoCnfgActive**
  Attribute ID: 0x11dd4
  Determines whether DX NetOps Spectrum automatically updates its modeling of interfaces when a change is detected on this device.
- **Create_Sub_Interfaces**
  Attribute ID: 0x11f3c
  Determines whether DX NetOps Spectrum models logical interfaces for this device.

  NOTE
  This setting applies only if this device supports RFC 1573.
- **DiscoverConnectionsAfterLinkUpEvent**
  Attribute ID: 0x11d25
  Controls whether DX NetOps Spectrum remodels the interfaces when this device sends a LINK UP or LINK DOWN trap.
- **DeviceDiscoveryAfterReconfig**
  Attribute ID: 0x11d27
  Determines whether DX NetOps Spectrum updates its knowledge of connections from device interfaces after a reconfiguration occurs.
- **IsMovable**
  Attribute ID: 0x11a80
  Controls whether DX NetOps Spectrum relocates the device model to a different topological location during the Discovery process.
- **IfModelNameOption**
  Attribute ID: 0x12a1e
  Controls the naming convention for interface models at the device level. The attribute ID is used to determine what suffix is appended to the model name for an interface model. Valid attribute IDs include:
  – 0x11f7e (ifAlias)
  – 0x1134b (ifDescr)
  – 0x11f6f (ifName)
  – 0x11348 (ifIndex)
- **Disposable_Precedence**
  Attribute ID: 0x114e2
  Determines the modeling precedence for this device. If a duplicate device is created with a higher precedence, the device model with the lower precedence is automatically destroyed.

Policy Manager Privileges

This section lists Policy Manager privileges for OneClick users.

NOTE
See OneClick Administration for more information about configuring privileges.

- **Policy Manager**
  Lets the administrator configure the Policy Manager application. Lets an operator view the Policy Manager application.
- **Explorer Add On Views/Policy Manager Hierarchy**
  Controls whether the Policy Manager node is displayed in the Navigation panel.
- **Policy Management**
  Controls access to the Policy Management privileges. Policy Management privileges are available for administrators with read/write privileges only. Deselecting the Policy Management privilege automatically deselects the following two privileges:
  - **Add/Edit/Delete Policies**
    Lets the administrator (AdministratorRW only) create, edit, and delete policies. This privilege does not let the user enable a policy.
  - **Enable/Disable Policies**
    Lets the administrator (AdministratorRW only) enable or disable a Policy Manager policy.
- **XML-based Policy Configuration/Reload Legacy Policies**
  Lets the administrator reload legacy XML-based policies.

How to Set up Policy Manager to Suppress Port Alarms

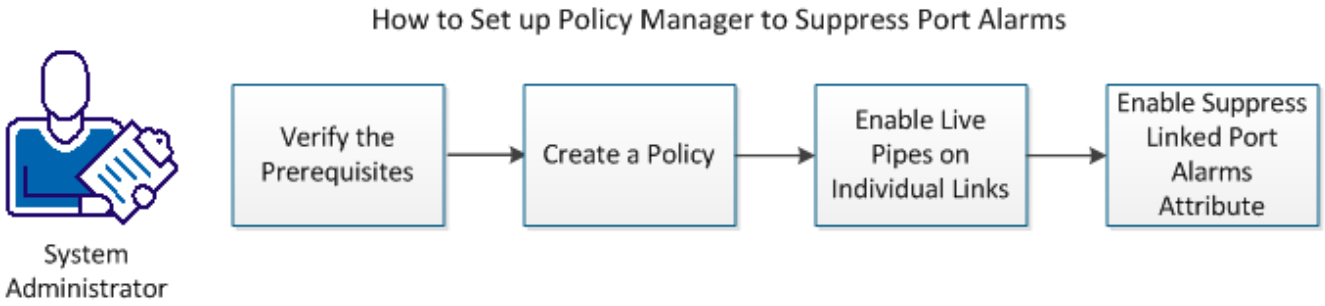
This scenario describes how a DX NetOps Spectrum administrator creates and uses a policy to suppress unwanted port alarms.

As a DX NetOps Spectrum system administrator you can suppress unwanted port alarms by creating a policy with the Live Pipes option in the Policy Manager. This policy suppresses duplicate alarms for a single problem and enables you to reduce network traffic and improve system performance.

The Live Pipes option allows you to enable port status monitoring for individual links. In the port status monitoring process, the new Live Pipes policy helps you to perform the following tasks:

- Suppress duplicate alarms on ports that have a broken connection or that are connected to a device unreachable by the SpectroSERVER.
- Suppress port alarms when the linked port model already has an alarm.

The following diagram shows how to set up Policy Manager to suppress port alarms:



Verify the Prerequisites

Before you create a policy to suppress port alarms, verify the following prerequisites:

You are logged in to the OneClick console as an administrator.

- You have the privileges and knowledge to create and enable a policy in the Policy Manager application.
- You understand the recommended policy settings and templates in the Policy Manager.

Create a Policy

Create a new policy in the OneClick console to suppress unwanted port alarms and to improve system performance by reducing network traffic.

> **NOTE**
> If you already have a policy with the Live Pipes option enabled, you can change the Suppress Linked Port Alarms attribute value to reduce port alarms.

A policy requires at least one rule. You can add more rules and settings later, as needed. All policy components are configured and maintained in the OneClick console. A policy contains the following components.

Policy DefinitionA set of prioritized policy rules. If a model resides in multiple global collections, policy rules are applied to the model based on the policy priority for a global collection.Policy RulesA collection of Rule Settings and the global collections to which the rule settings apply. You can define multiple rules for one policy.Rule SettingsDefine the model attributes and attribute values that a policy maintains.

Follow these steps:

1. Click Policy Manager in the Explorer tab of the OneClick console.
2. In the Contents panel, click the List tab, Create Policy and type a name.
   Example: SuppressPortAlarms
3. Click Create Rule and type a name.
4. Click Browse and select Global Collections for this policy.

   > **NOTE**
   > You can create global collections directly from the Select Global Collections dialog with the Create button.
5. Click Move to move the selected global collections to the Applies to list on the left, and click OK.
6. Click Predefined Settings in the Rule Settings box.
   The Select Template dialog opens.
7. Select Live Pipes from the Templates list and click OK.
   The Live Pipes settings are added to the Rule Settings.

   > **NOTE**
   > You cannot include the same attribute in more than one policy, regardless of whether the policy is enabled or not.
8. Click OK.
   The rule is added to the list of Associated Rules.
9. Select the rule and use the up and down arrows to adjust the rule priority in the list.

   > **NOTE**
   > The higher the rule is in the list, the higher the priority of the rule.

   The rules are adjusted in the list and the priority values are modified accordingly.
10. Select Enable Policy on Creation and click OK.
    The policy is created and enforced. The new policy appears in the List tab of the Contents panel.

Enable Live Pipes on Individual Links

To monitor the connection status between devices, enable Live Pipes on individual links from the Live Pipes subview. If an existing policy with the Live Pipes option is enabled for individual links, you can enable the Suppress Linked Port Alarms attribute in the Live Pipes subview to suppress unwanted port alarms.

Live Pipes for individual links are disabled by default. When an individual live pipe is enabled, the ok_to_poll attribute is set to TRUE for both ports in the link.

If Live Pipes are already enabled on individual links, continue to the next procedure.

Follow these steps:

1. Right-click the link that you want to enable as a live pipe, and select Enable Live Links.
2. Select the check box for the link to enable and click OK.
3. Click Set in the Live Pipes field and select Enabled from the drop-down list.
   The Enable Live Links dialog closes. The link that you selected is enabled as a live pipe.

Enable Suppress Linked Port Alarms Attribute

The Live Pipes subview lets you enable or disable the Suppress Linked Port Alarms attribute. Enable the attribute to suppress port alarms when the connected device is unreachable or the linked port model already has a red alarm.

Follow these steps:

1. Expand the Live Pipes subview in the Information tab of the OneClick console.
2. Select YES from the Suppress Linked Port Alarms drop-down list.
   The Suppress Linked Port Alarms attribute is enabled.

QoS Manager

DX NetOps Spectrum QoS Manager facilitates IP fault and performance management of networks that are configured for Quality of Service. QoS is deployed in IP data networks that carry traffic from services such as Voice Over IP (VoIP), order processing, and video conferences. QoS on routers lets the infrastructure serve the unique performance requirements of each service.
The QoS Manager performs the following tasks:

- Provides visibility into the health and performance of QoS traffic classes across the network.
- Automatically discovers QoS classes and policies on your network and maps them to the associated physical routers and interfaces.
- Creates models to represent each QoS policy, QoS traffic class, and QoS behavior.
- Creates traffic-class collections so you can view all identical traffic class models implemented on devices across the landscape.

QoS Manager also lets you drill down to per-class statistics such as packet drops, queue size, and pre-policy rates. You can view the individual performance statistics based on the QoS configuration type.

This section explains how to configure, discover, and manage the QoS elements in your network using DX NetOps Spectrum.

NOTE

Only Cisco devices that feature CISCO-CLASS-BASED-QOS MIB are supported.

Access the QoS Manager Interface

You can access the QoS Manager interface through the OneClick Console.
Follow these steps:

1. Launch the OneClick console from the OneClick homepage.

2. Expand the appropriate landscape in the Explorer tab and select QoS Manager.
   The QoS Manager interface appears.

   NOTE

   For information on using the OneClick Console, see Using OneClick .

Model Types

The following model types are available in the hierarchical view of the QoS Manager interface:

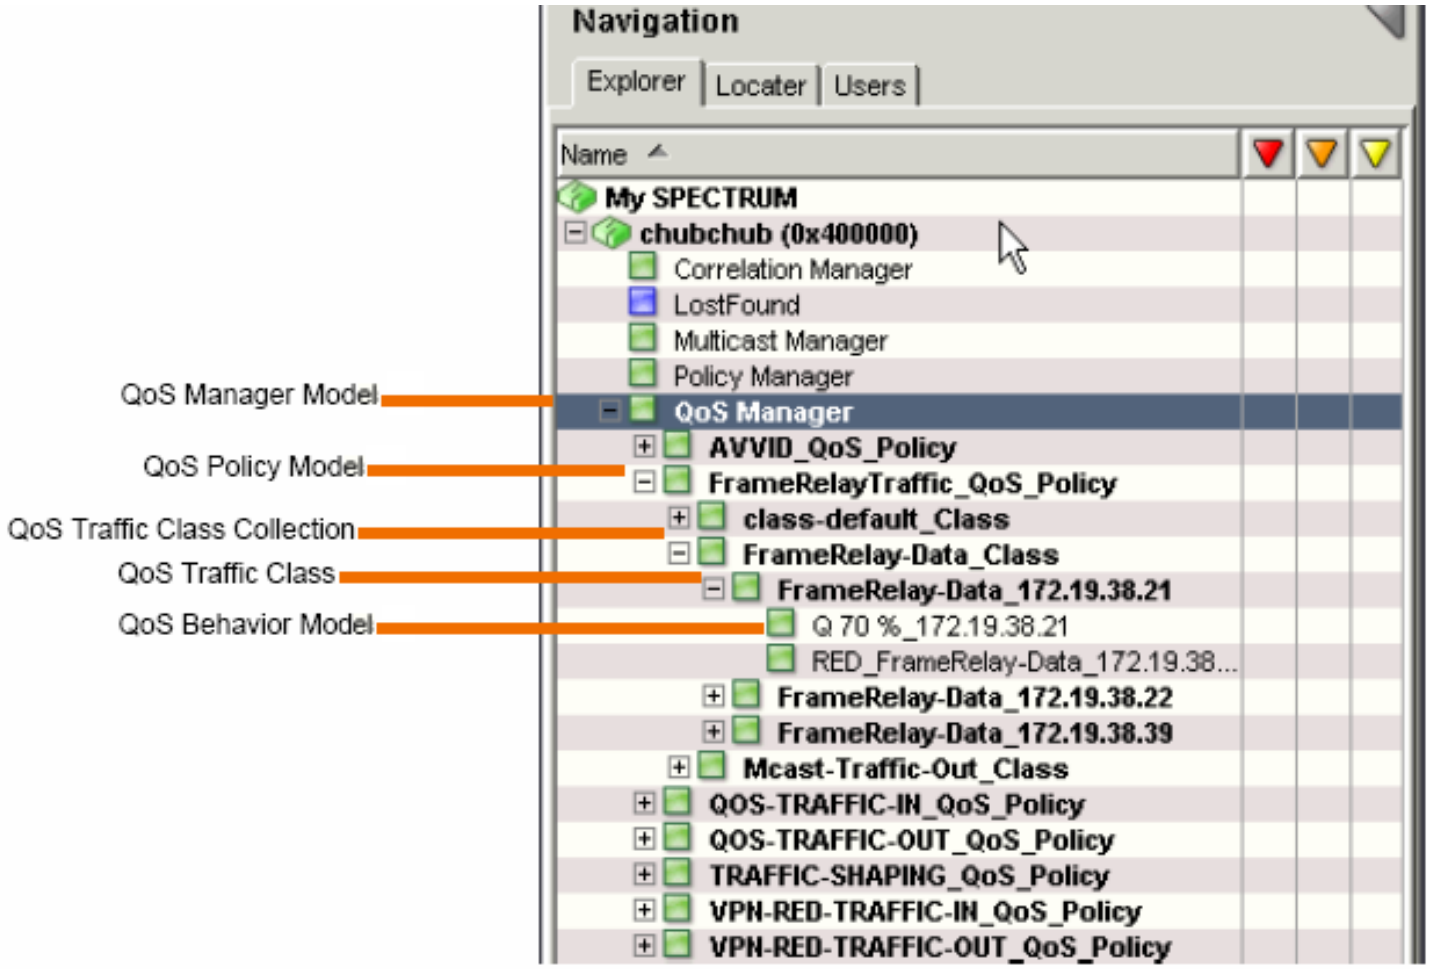
QosManager
Identifies the specific QoS Manager installation for a DX NetOps Spectrum landscape. Use this model type to configure alarm thresholds, launch QoS Discovery, and enable performance and report functionality.
Note: You need administrator privileges to use these configuration options.

QosPolicy
Defines the QoS policies that are set on your network. You can view general information, associated devices, and associated traffic classes of these models.

QosClassCollection
Lets you view all identical traffic class models across devices on your network. You can view general information, associated devices, and associated traffic classes of these models.

QosTrafficClass
Identifies the traffic classes that are defined on your network. You can view general information, associated devices, and associated behaviors of these models.

Behavior
Represents the behaviors per each hop defined on your network. There are four behavior model types: QosQueueing, QosRandomDetect, QosPolicing, and QosTrafficShaping. You can view the general information and performance statistics of these model types.
The following diagram shows the QoS Manager navigation hierarchy:



Search Options

The following search options are available on the OneClick Locater tab:

All Behaviors
Finds all QoS behaviors defined on selected landscapes.

All QoS Managers
Finds all QoS Manager models.

All QoS Policy Models
Finds all QoS policies defined on selected landscapes.

All QoS Services
Currently, this search is not enabled.

All Traffic Class Collections
Finds all Traffic Class Collection models defined on selected landscapes.

All Traffic Classes
Finds all Traffic Class models defined on selected landscapes.

Behavior By
Finds Behavior models by behavior, interface, name, or router.

QoS Policy By
Finds QoS Policy models by behavior, interface, name, or router.

Traffic Class By
Finds Traffic Class models by behavior, interface, name, or router.

NOTE
For more information on the Locater tab and performing a search, see Using OneClick.

QoS Manager Configuration

Access Configuration Parameters

The QoS Manager configuration parameters are provided in the Component Detail panel of the QoS Manager model. The Component Detail panel has three sections:

- General Information
- Configuration
- Traffic Behavior Alarm Thresholds

You should review these configuration parameters before you begin working with the QoS Manager to help ensure that the QoS Manager is set up to meet your network management needs.

NOTE
You need administrator privileges to make configuration changes.

QoS Manager Models

The following information can be accessed from the Information tab in the Component Detail panel for each QoS Manager model:

- **General Information**
  Displays the following general information about traffic class:
  - **Model Class**
    Indicates the model class for the QoS Manager model.

    NOTE
    For more information on a model type's model class, see SpectroSERVER and DX NetOps Spectrum Databases Overview..
  - **Creation Time**
    Indicates the date and time that this QoS Manager model was created.
  - **Security String**
    Indicates the security string for the QoS Manager model. If you have the required privileges, you can modify the security string by clicking Set, entering the security string into the available field, and clicking Save.
  - **Notes**
    Indicates the notes available for the QoS Manager. If you have the required privileges, you can add notes by clicking Set, entering the notes into the available field, and clicking Save.

Management Configuration

The Configuration section has the following parameters:

- **Enable Port Polling**
  Determines if the ports on a QoS-enabled device are polled.
  Default: Yes
- **Enable Performance Alarms**
  Lets you enable or disable the generation of performance alarms. Performance alarms are generated when a threshold defined in a Behavior model's Performance Component Detail has been violated.

Default: Yes

- **Enable Device Alarms**
  Enables or disables the generation of alarms on QoS-enabled devices.
  Default: Yes
- **Enable Statistic Polling**
  Enables the Performance Collection system.
  Default: No
- **Statistic Polling Interval**
  Controls how frequently statistical information is obtained for use in performance calculations. However, this polling interval will have no effect unless Enable Statistic Polling is set to Yes.
  Default: 300
- **Log Statistics to File**
  Enables you to send the performance statistics to a log file. No statistics will be captured and logged unless the Enable Statistic Polling parameter is set to Yes.
  Default: True
- **Minutes Per Log File Cycle**
  Specifies how often a new log file is created. No statistics can be logged unless the enable Statistic Polling parameter is set to Yes. The frequency at which statistics are written to the log file is defined by the Statistic Polling Interval described above.

Traffic Class Percent Dropped Thresholds

The Traffic Class Percent Dropped Thresholds section lets you define the critical threshold, major threshold, and minor threshold for violations based on percentage of packets dropped in any traffic class.

These thresholds indicate when critical, major, and minor alarms will be generated on a traffic class model. The default values are as follows:

- Five percent for a critical alarm
- Three percent for a major alarm
- One percent for a minor alarm

QoS Manager Traffic Behavior Alarm Thresholds

The Traffic Behavior Alarm Thresholds section lets you set the critical threshold, major threshold, and minor threshold for each type of traffic behavior, including policing percent dropped, queueing percent dropped, random early detect percent dropped, and traffic shaping percent dropped.

Each threshold sets percentage level of packets dropped that will cause a specific level of alarm. The default values are as follows:

- Five percent for a critical alarm
- Three percent for a major alarm
- One percent for a minor alarm

QoS Manager Discovery and Modeling

Device Discovery

DX NetOps Spectrum discovers and models the physical network infrastructure through OneClick Discovery, manual modeling, or the Modeling Gateway. Before using QoS Discovery, use one of these methods to model the physical components of your network in DX NetOps Spectrum.

NOTE

Only Cisco devices that feature CISCO-CLASS-BASED-QOS MIB are supported. For more information, see Certifications , OneClick Administration , and Modeling Gateway Toolkit.

QoS Manager requires that each QoS class have a unique name.

Reconfigure a QoS Device

If any of the QoS devices on your network were modeled before you installed QoS Manager, reconfigure them to create application models. Run the Reconfigure Model command on each of these models. Reconfiguration creates the CiscoCBQoSApp model, which supports the CISCO-CLASS-BASED-QOS MIB. This application provides necessary information to the QoS Manager.

Follow these steps:

1. Select the device model on the Contents panel.
2. Expand the Reconfiguration option on the Information tab in the Component Detail panel.
3. Click the Reconfigure Model button.
   The QoS application model is created for the device.

Run an On-Demand QoS Discovery

Use the QoS Discovery feature to discover and model the QoS policies, traffic classes, and behaviors defined on your network.

NOTE
If a QoS network element discovered and modeled by the QoS Manager is deleted from the network configuration, manually remove it from the modeled QoS hierarchy. It is not automatically removed by QoS Manager.

Follow these steps:

1. Select the QoS Manager model in the Explorer.
2. Select the Information tab in the Component Detail panel.
3. Select the Configuration option in the Component Detail panel.
4. Select the QoS Discovery option and click Run.
   The status bar indicates that the Discovery is running. Once the Discovery is complete, status returns to idle.

NOTE
Administrator privileges are required to run QoS Discovery.

Filter Traffic Class Names During Discovery

The QoS Manager lets you filter the Traffic Class during Discovery.

Follow these steps:

1. Select QoS Manager in the Explorer tab.
2. Select the Information tab in the Contents panel.
   The configuration options for QoS Manager appear.
3. Expand the QoS Discovery subview.
   The Discovery options that are available include the following settings:
   – **Traffic Class Filter Type**
   Determines if the Traffic Class in the 'Traffic Class Filter' field are included or excluded from modeling. Options include the following:

  - Exclusive
  - Inclusive
- **Traffic Class Filter**
  Lists the Traffic Classes to be included or excluded when the QoS Discovery is run. This field is used with the 'Traffic Class Filter Type' field.

  NOTE
  The Traffic Classes are not filtered and saved unless you add them in the Traffic Class Filter. Even if the Traffic Class Filter Type is inclusive and the Traffic Class Filter is empty, all Traffic Classes are discovered.

QoS Manager Model Naming Convention

During QoS Discovery, the QoS Manager assigns model names to policy, class collection, traffic class, and behavior models using the following conventions:

- **QoS Policy models**
  <*xxx*>_QosPolicy where <*xxx*> is the policy name assigned by the user who created the policy in the device's IOS Configuration.
- **Traffic Class Collection models**
  <*xxx*>_Class where <*xxx*> is the name of the traffic class assigned by the user who configured it.
- **Traffic Class models**
  <*xxx*>_QosPolicy_<yyy>_<*DeviceModelName*>, where:
  - <*xxx*> is the policy name assigned by the user who created the policy in the IOS Configuration of the device.
  - <*yyy*> is the name of the traffic class assigned by the user who configured it.
  - <*DeviceModelName*> is the device model name the user assigned to the device model using the traffic class.
- **Behavior models**
  Behavior models can be one of the following:
  - **Queuing Behavior Models**
    Q <*Bandwidth Units*> <*DeviceModelName*> where <*Bandwidth Units*> is the units of bandwidth used for queuing and <*DeviceModelName*> is the device model name the user assigned to the device model using the traffic class.
  - **RED Behavior Models**
    RED_<*ParentModelName*> where <*ParentModelName*> is the name of the parent traffic class model.
  - **Policing Behavior Models**
    Policing <Rate> <*DeviceModelName*> where <*Rate*> is the assigned policing rate and <*DeviceModelName*> is the device model name the user assigned to the device model using the traffic class.
  - **Traffic Shaping Behavior Models**
    TrafShaping <*Rate*> <*DeviceModelName*> where <*Rate*> is the assigned traffic shaping rate and <*DeviceModelName*> is the device model name the user assigned to the device model using the traffic class.

Change Policy and Class Model Names

You can change the default name that is assigned to a policy or class model.

Follow these steps:

1. Click the set link next to the model name on the Information tab.
2. Enter the new model name in the text box provided.
   The default name is changed.

Run QoS Discovery on Selected Models

You can configure the QoS Network Services Discovery from the OneClick views that display models. Then run QoS Network Services Discovery on selected models.

Follow these steps:

1. Select the models.
2. Click Tools, Utilities, Network Services Discoveries, QoS Discovery.
   The Discovery process is initiated. You can check the status in the Configuration subview.

Configuring QoS Discovery During Modeling

DX NetOps Spectrum lets you configure Network Services Discoveries, including QoS, during modeling. As a part of modeling configuration, you can specify which network service discoveries to run with the modeling process.

NOTE

For more information, see Modeling and Managing Your IT Infrastructure.

Model Types in QoS Manager

QoS Policy Models

The following information can be accessed from the Information tab in the Component Detail panel for each QoS policy model.

- **General Information**
  Displays the following general information about a QoS policy model:
  - **Condition**
    Defines the condition of the QoS policy model, which reflects the alarms that may be present on the model.
  - **Entity Condition**
    Indicates the calculated value of the model condition, which is based on the models that make up the QoS policy.
  - **Model Class**
    Specifies the model class of the QoS policy model.
  - **Policy ID**
    Indicates the policy identifier defined when the policy was created.
  - **Policy Type**
    Indicates the policy type selected when the policy was created.
  - **Security String**
    Defines the security string for this model. To change this value, click Set and enter the changes you want to make in the field provided. You must have administrator privileges to make changes to this field.
  - **Landscape**
    Defines the DX NetOps Spectrum landscape on which the policy exists.
  - **Description**
    Defines the description entered when the policy was created.
- **Associated Devices**
  Displays a table that shows all the devices that use this policy.
- **Associated Traffic Classes**
  Displays a table that shows all the traffic classes that are affiliated with this policy.

Traffic Class Collection Models

The following information can be accessed from the Information tab in the Component Detail panel for each traffic class collection model.

- **General Information**

Displays the following general information about a traffic class collection model:

- **Condition**
  Defines the condition of the traffic class collection model. This condition reflects the alarms that may be present on the model.
- **Entity Condition**
  Indicates the calculated value of the model condition, which is based on the models that make up the traffic class collection.
- **Traffic ID**
  Indicates the identifier defined when the traffic class collection was created. It uniquely identifies this traffic class collection.
- **Model Class**
  Defines the model class of the traffic class collection model.
- **Security String**
  Defines the security string for this model. To change this value, click Set and enter the changes you want to make in the field provided. You must have administrator privileges to make changes to this field.
- **Landscape**
  Defines the DX NetOps Spectrum landscape on which this traffic class collection exists.
- **Description**
  Indicates the description entered for this traffic class collection when it was defined.

- **Associated Devices**
  Displays a table that lists all of the devices that use the traffic classes contained in this traffic class collection.
- **Associated Traffic Classes**
  Displays a table that lists all of the traffic class models that make up this collection.

Traffic Class Models

The following information can be accessed from the Information tab in the Component Detail panel for each traffic class model.

- **General Information**
  Displays the following general information about a traffic class model:
  - **Condition**
    Defines the condition of the traffic class model. This condition reflects the alarms that may be present on the model.
  - **Entity Condition**
    Indicates the calculated value of the model condition, which is based on the models that make up the traffic class.
  - **Model Class**
    Defines the model class of the traffic class model.
  - **Traffic ID**
    Indicates the identifier defined when the traffic class was created. It uniquely identifies this traffic class. This is made up of the traffic class collection ID and the IP address of the interface that implements this traffic class.
  - **Security String**
    Defines the security string for this model. To change this value, click Set and enter the changes you want to make in the field provided. You must have administrator privileges to make changes to this field.
  - **Landscape**
    Defines the DX NetOps Spectrum landscape on which this traffic class exists.
  - **Match Statement**
    Defines the match statement defined for this traffic class. A match statement defines specific match criteria to identify packets for classification purposes.
  - **Description**
    Indicates the description entered when this traffic class was created.
  - **Drop Rate**

Specifies the rate of packets dropped aggregated across all interfaces supporting this traffic class.
  - **No Buffer Drops**
    Indicates the drop packet count, aggregated across all interfaces supporting this traffic class, which occurred due to a lack of SRAM buffers during output processing on this interface.
- **Associated Devices**
  Displays a table that lists all of the devices that use this traffic class.
- **Associated Behaviors**
  Displays a table that lists all of the behaviors that are applied to this traffic class.

Behavior Models

The following information can be accessed from the Information tab in the Component Detail panel for each behavior model.

- **General Information**
  Displays the following general information about a Behavior model:
  - **Condition**
    Defines the condition of the Behavior model. This condition reflects the alarms that may be present on the model.
  - **Entity Condition**
    Indicates the calculated value of the model condition, which is based on the interface models that use the behavior.
  - **Model Class**
    Indicates the model class of the Behavior model.
  - **Security String**
    Defines the security string for this model. To change this value, click Set and enter the changes you want to make in the field provided. You must have administrator privileges to make changes to this field.
  - **Behavior ID**
    Indicates the identifier defined when the behavior was defined. It uniquely identifies this behavior.
  - **Landscape**
    Defines the DX NetOps Spectrum landscape on which this behavior exists.
- **Performance**
  See Behavior Model Performance for the parameters provided in this selection.

QoS Alarms

QoS Manager generates alarms based on the configuration parameters you define. These alarms help define the status or condition of each of the modeled QoS components.

You can set a critical, major, and minor threshold for each type of behavior and traffic class model. Each threshold sets percentage level of packets dropped that will cause a specific level of alarm.

You can also enable the generation of alarms on QoS-enabled device models by setting the Enable Device Alarms parameter in the QoS Policy Manager model's Management Configuration to yes. The QoS Manager also generates alarms if there are problems logging statistical data.

The QoS Manager generates the following alarms:

- **0x4b30401**
  Defines the alarm generated on a QoS-enabled device model if one of the QoS Components exceeds a defined threshold.
- **0x4b30506**
  Defines the alarm generated on a behavior or traffic class model if the threshold set for a critical alarm is violated.
- **0x4b3050a**
  Defines the alarm generated on a behavior or traffic class model when the threshold set for a minor alarm is violated.
- **0x4b30000**

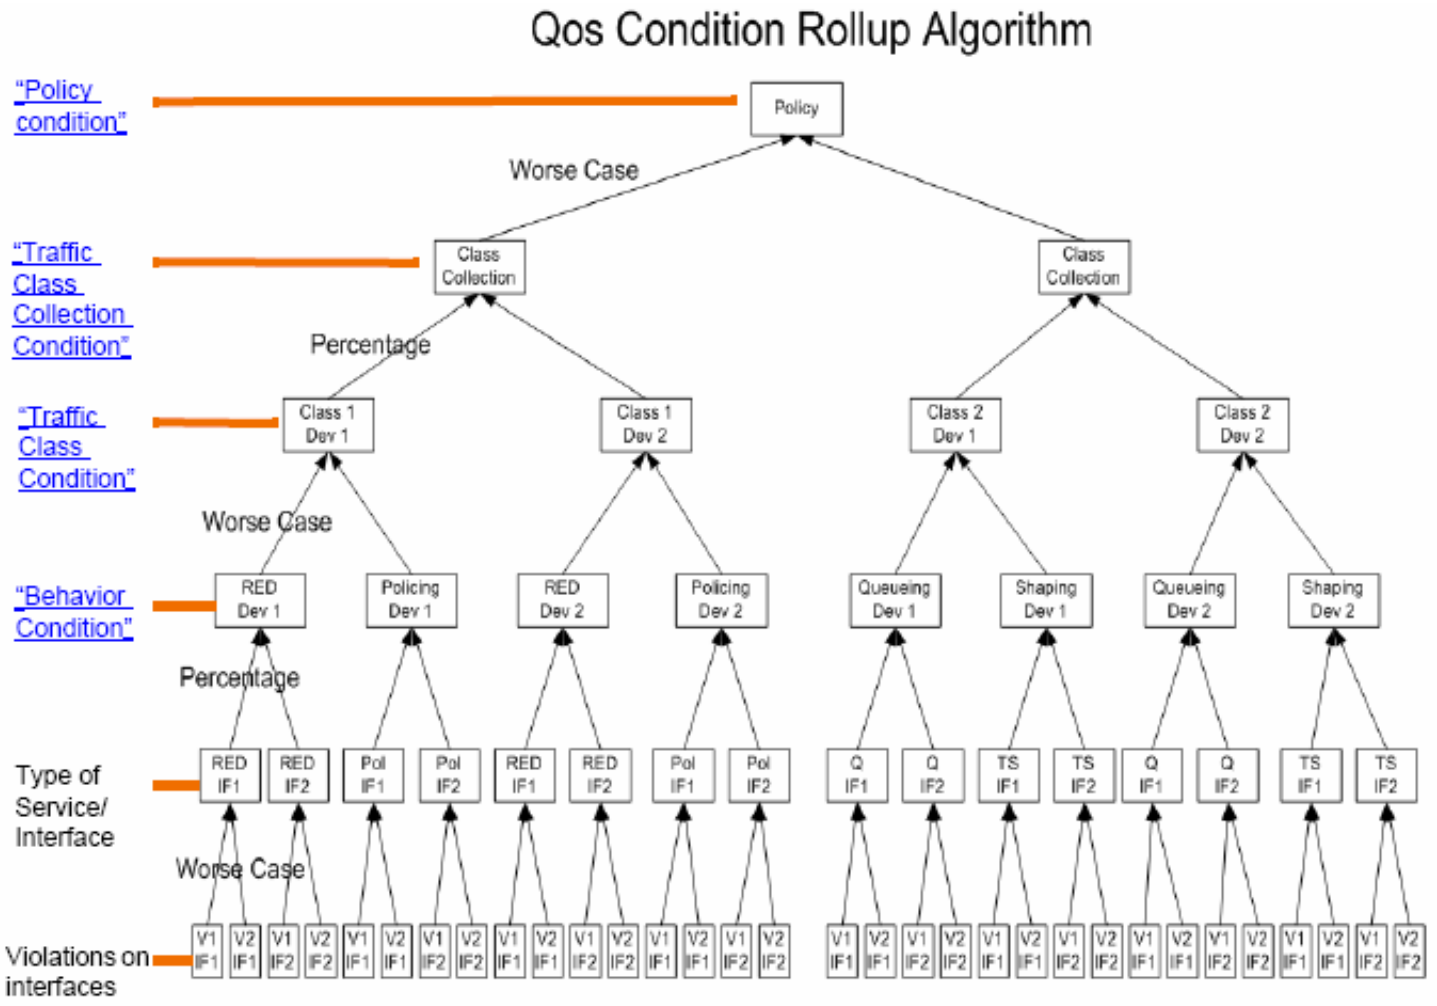
Indicates that the statistics log file could not be opened for writing. Because of this, at least one polling cycle's statistics will not be logged. This data is needed by other applications to determine the status of the network.

- **0x4b30001**
  Indicates that the statistics log file could not be closed. This may cause the statistical data to be lost and unused by other applications that may need it.

QoS Conditions

QoS Manager uses the QoS Condition Rollup algorithm to determine the entity condition of policy, traffic class collection, traffic class, and behavior models.

The following diagram illustrates the QoS Condition Rollup algorithm:



The conditions are as follows:

- **Policy**
  Is computed based on the status of the Class Collections contained in the policy. The condition of the Policy model is the worst condition found among all of the Traffic Class models monitored by the policy.
- **Traffic Class Collection**
  Is based on the status of the Traffic Class models contained in the collection. QoS Manager finds the condition that exists on the highest percentage of traffic classes contained in the collection. This predominant condition becomes the condition of the Traffic Class Collection model.

For example, if 45 percent of the traffic class models in the collection had a green condition, 10 percent had a red condition, and 20 percent had an orange condition, and 25 percent had a yellow condition, the condition of the collection would be green.

- **Traffic Class**
  Is based on the status of the Behavior models that are associated with the Traffic Class model. The condition of the traffic class model is the worst condition, or “worst case” found amongst all of the Behavior models in the traffic class.
- **Behavior**
  Is determined by the thresholds settings defined in QoS Manager traffic behavior alarm thresholds. These thresholds watch the percentage of dropped packets on a device for each specific service (queueing, random early detection, policing, or shaping) and designate what percentage level will generate a critical, major, and minor alarm condition. The percentage measurement used for these thresholds is derived from the average percentage of packets dropped for a particular service across all interfaces of the device. The percentage of packets dropped on each interface is equal to the worst percentage drop for a particular type of service on an interface.

QoS Performance

QoS Manager presents performance analysis information at both the traffic class and behavior level. In order for any of these statistics to be available, you must set the Enable Statistic Polling to Yes and set a value for the Statistic Polling Interval. These parameters can be found in the QoS Policy Manager model's Management Configuration.

View Traffic Class Performance Graphs

For each traffic class model, you can access graphed performance analysis based on Packet Drops and Pre-Policy Rate. The statistics for the graphs are derived from values in the CISCO-CLASS-BASED-QOS MIB.

To view traffic class performance graphs

1. Click the appropriate traffic class model in the OneClick Navigator.
2. Click the Performance tab in the Component Detail panel.
3. Select a graph from the drop-down list.
   The performance graph opens.

Behavior Model Performance

Performance information is available for each behavior model. The performance statistics provided depend on the type of service monitored by the behavior. These types of services are:

- queueing
- shaping
- policing
- random early detection

The statistics are derived from values in the individual service's Configuration and Statistics tables in the CISCO-CLASS-BASED-QOS MIB.

> **NOTE**
> The statistics provided for queueing (Mean Queue Depth), random early detection (Mean Queue Size), and shaping (Current Queue Size) are averages of the values gathered from each interface passing traffic for the given the service on the device. All other statistics are totals of values gathered from each interface passing traffic for the given service on the device.

Each behavior model has two ways to access performance information. The first method is to access the Information tab in the behavior model's Component Detail panel. This tab has a selection called Performance, which displays different statistics depending on the type of service the behavior model monitors. The data in this section does not refresh dynamically. To refresh the data, click the Refresh button.

This section also shows the critical, major, and minor percent violation thresholds for the behavior. These thresholds are set in the section QoS Manager traffic behavior alarm thresholds.

In addition, you can display the behavior model's performance information graphically by choosing the Performance tab in the behavior model's Component Detail panel. The graphs depend on the type of service the behavior model monitors. The data in these graphs refreshes dynamically.

Queueing Behavior Models

The following performance statistics are available on the Information tab for a queueing behavior model:

- **Configured Bandwidth**
  Indicates the configured bandwidth allocated to this traffic class.
- **Total Discarded Packets**
  Indicates the number of packets, associated with this class, that were dropped by queueing.
- **Average Queue Depth**
  Indicates the average queue depth in packets. This is an average of an average, because each value averaged by this statistic is based on the average queue depth for each interface.

The following performance graphs are available on the Performance tab for a queueing behavior model:

- **Queue Depth**
  Displays the value of the Average Queue Depth statistic over time.
- **Discard Rate**
  Displays the value of the Total Discarded Packets statistic over time.

Shaping Behavior Models

The following statistics are available in the Performance section of the Information tab for a shaping behavior model:

- **Configured Burst Size**
  Indicates the amount of traffic, in bits, in excess of the committed traffic-shaping rate that is instantaneously permitted.
- **Configured Extended Burst Size**
  Indicates the amount of traffic, in bits, in excess of the burst limit, which may be conditionally permitted.
- **Configured Traffic Shaping Rate**
  Displays the current adaptive traffic shaping rate.
- **Total Delayed Packets**
  Displays the total number of packets delayed.
- **Total Dropped Packets**
  Displays the total number of packets dropped.
- **Average Queue Size**
  Displays the traffic shaping queue depth in packets. Note that this is actually an average of an average, since each value averaged by this statistic is based on the average queue size for each interface.

The following performance graphs are available in the Performance tab for a shaping behavior model:

- **Queue Size**
  Displays the value of the Average Queue Size statistic over time.
- **Delays and Drops**
  Displays the values of the Total Delayed Packets and Total Dropped Packets statistics over time.

Policing Behavior Models

The following statistics are available in the Performance section of the Information tab for a policing behavior model:

- **Configured Burst Size**

Indicates the amount of traffic, in bytes, in excess of the committed policing rate that is permitted.

- **Configured Extended Burst Size**
  Indicates the amount of traffic, in bytes, in excess of the burst limit, which may be conditionally permitted by the policing feature. The probability that the traffic is not permitted increases as the received burst size increases.
- **Configured Policing Rate**
  Indicates the committed policing rate. This is the sustained rate permitted by policing.
- **Total Exceeded Packets**
  Indicates the number of packets treated as non-conforming by the policing service.
- **Total Violated Packets**
  Indicates the number of packets treated as violated by the policing service.

The Violated and Exceeded Packets graph is available in the Performance tab for a policing behavior model. This graph shows the values of the Total Exceeded Packets and the Total Violated Packets over time.

Random Early Detection Behavior Models

The following statistics are available in the Performance section of the Information tab for a random early detection behavior model:

- **Configured Decay Factor**
  Indicates the decay factor for the queue average calculation. The decay factor is equal to raising 2 to the power of N, where N could be up to 16. The smaller the number, the faster the decay.
- **Configured Mean Queue Size**
  Indicates the configured average queue size computed and used by the WRED algorithm.
- **Mean Queue Size**
  Indicates the average queue size computed and used by the WRED algorithm.
- **Total Random Drops**
  Indicates the number of packets dropped when the number of packets in the associated queue was greater than the minimum configured threshold and less than the maximum configured threshold.
- **Total Tail Drops**
  Indicates the number of packets dropped when the number of packets in the associated queue was greater than the maximum configured threshold.

The Mean Queue Size and Drops graph is available in the Performance tab for a random early detection behavior model. This graph shows the Mean Queue Size, Total Random Drops, and Total Tail Drops over time.

Remote Operations Suite

About Remote Operations Suite

Remote Operations Suite is the remotely deployed component of a DX NetOps Spectrum remote deployment. Remote Operations Suite is a stand-alone DX NetOps Spectrum management system that delivers all the standard DX NetOps Spectrum management capabilities. These capabilities include traditional fault-tolerant DX NetOps Spectrum management.

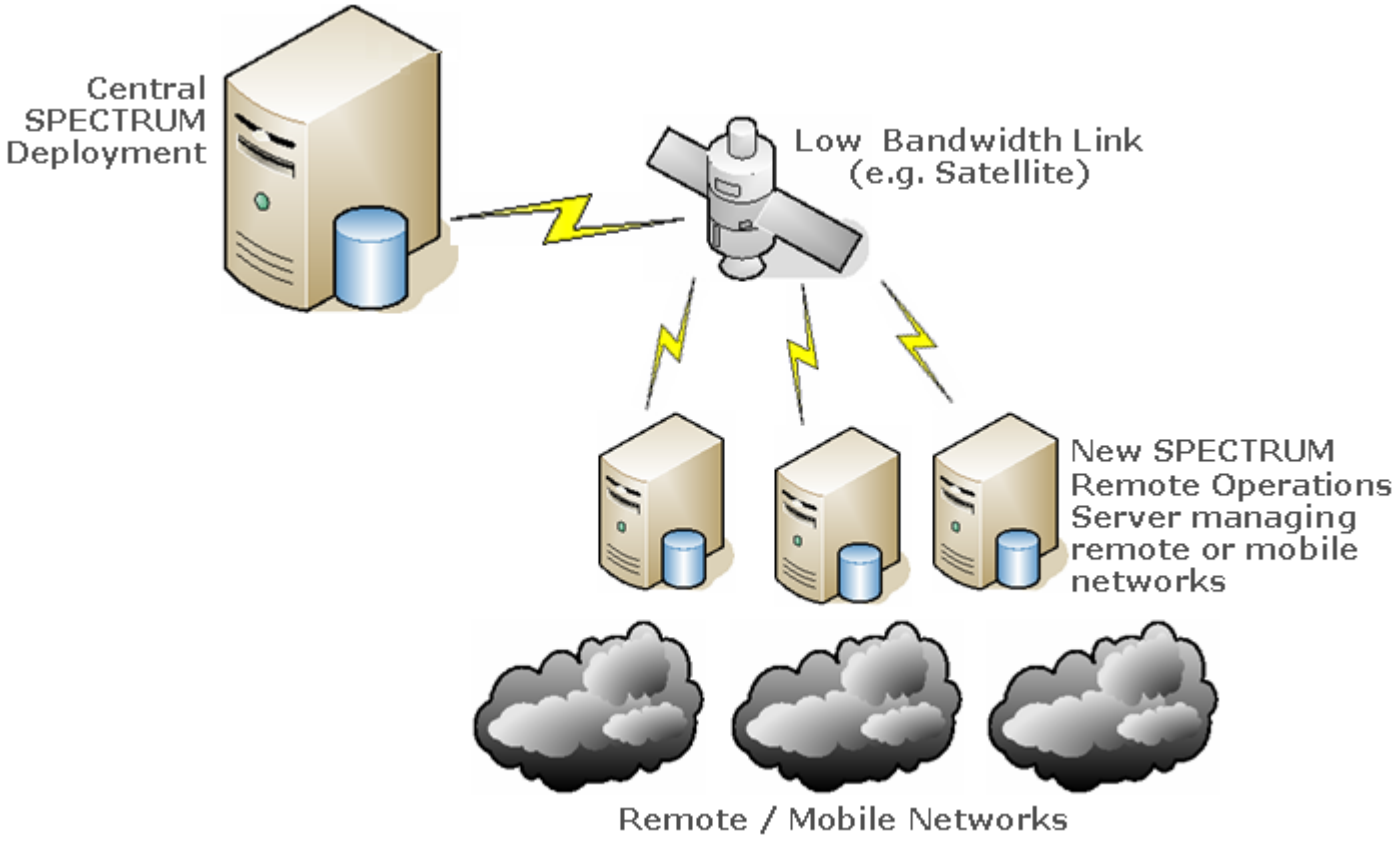
Remote Operations Suite supports operations in remote or mobile tactical environments. The remote component communicates with a designated Central SPECTRUM server to deliver real-time, or on-demand network topology. Remote Operations Suite also delivers the operational status of the managed remote site, mobile network over unreliable, or limited bandwidth communication links.

NOTE
In the environments where higher-speed communications links are more readily available, deploy the traditional DX NetOps Spectrum distributed architecture.

NOTE
Remote Operations Suite performs the following functions:

- Enables the network manager at the remote or mobile site to manage the local network infrastructure
- Delivers all the standard DX NetOps Spectrum management capabilities (for example, network discovery, root cause analysis, impact analysis, alarming/alerting)
- Connects to another DX NetOps Spectrum deployment situated in global network operations or central command to deliver real-time inventory and operational status of the remote network
- Enables an administrator to determine the information that the remote site sends to the central site to be low-impact on the limited bandwidth (and often costly) communications links

NOTE
The following architecture shows the Remote Operations Suite deployment:



NOTE
Remote Operations Suite uses the OneClick Console. For more information about OneClick, see the Using OneClick section.

Remote Operations Suite includes the following components:

- **Remote Operations Server**
  Is the remotely deployed DX NetOps Spectrum installation of a Remote Operations Suite deployment. The Remote Operations Server is a lightweight, stand-alone DX NetOps Spectrum Management system that performs traditional fault tolerant DX NetOps Spectrum management, including fault management and root cause analysis for the network

it manages. The Remote Operations Server communicates with its designated Central SPECTRUM Server through the installed Remote Operations Connector component. This architecture enables the delivery of network topology and operational alarm status over unreliable or limited bandwidth communication links.

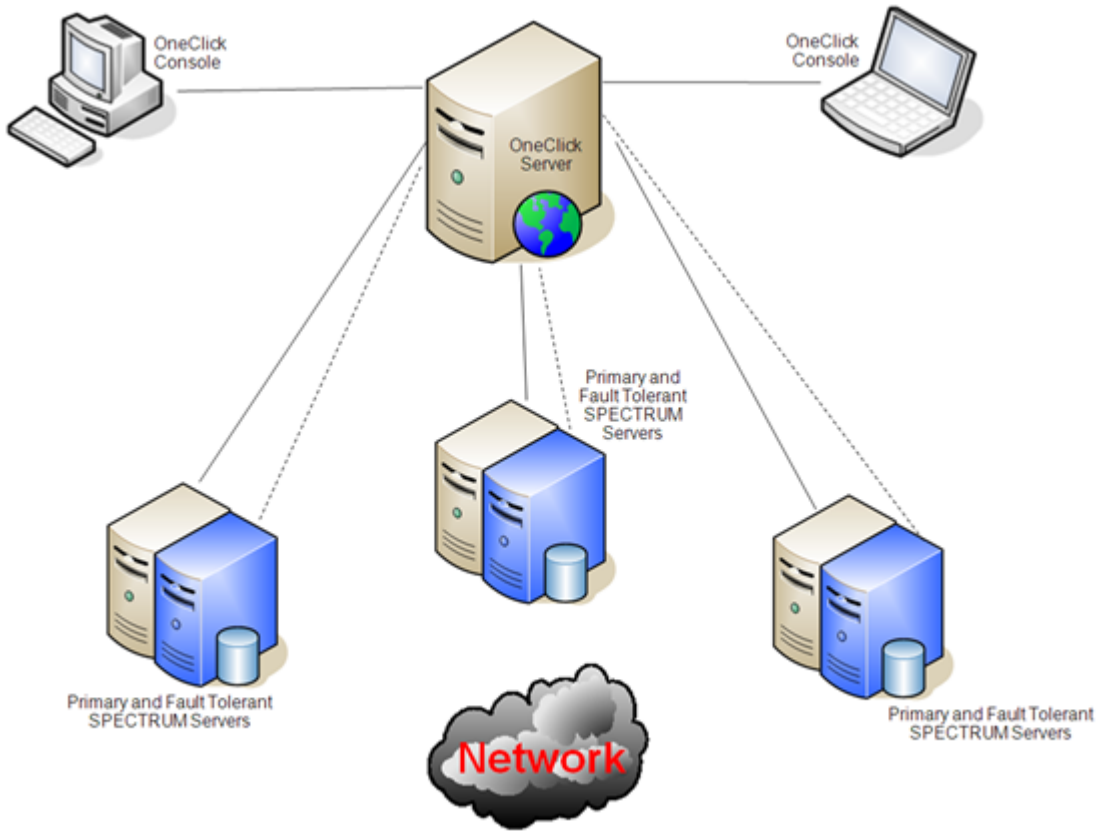
- **Central SPECTRUM Server**
  Is a separate installation of DX NetOps Spectrum that includes the Remote Operations Manager component. This component listens for new connections from Remote Operations Servers. A single Central SPECTRUM Server with the Remote Operations Manager component installed can integrate with multiple Remote Operations Servers. The integrated servers let you discover and monitor managed elements in the Universe hierarchy of the Remote Operations Server.
  The Remote Operations Manager component on the Central SPECTRUM Server communicates with the Remote Operations Connector component on all connected Remote Operations Servers. The remote server instructs connectors to forward all current topology data. Each Remote Operations Connector component receives the requested information and returns the topology data to the Remote Operations Manager component on the Central SPECTRUM Server, where the topology is modeled in the database.

Distributed Concepts in the Remote Operations Suite

The distributed capability of a Remote Operations Suite environment differs from the distributed capability of a traditional DX NetOps Spectrum environment. Remote Operations Suite has unique features to support distributed deployments.

A traditional DX NetOps Spectrum Distributed SpectroSERVER (DSS) environment deploys multiple DX NetOps Spectrum servers, which are sometimes referred to as SpectroSERVERs or landscapes. Each SpectroSERVER manages a different portion of the network. In this environment, you can see a combined or rolled-up view of the entire network using the OneClick Console as an aggregation point. OneClick provides monitoring and administration capabilities for each DX NetOps Spectrum server in the distributed environments. You can also designate primary and secondary DX NetOps Spectrum servers for the fault tolerance.

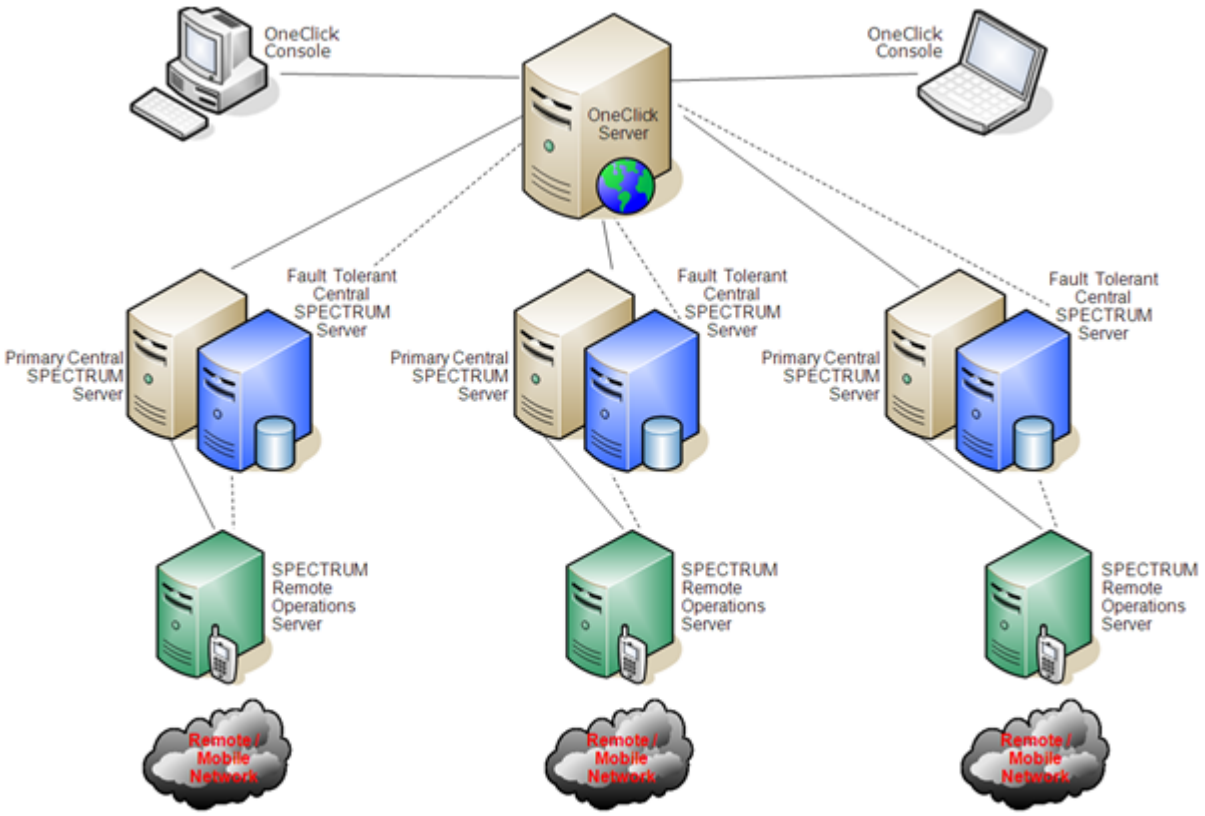
The following architecture shows a traditional DX NetOps Spectrum distributed deployment:



Remote Operations Suite also lets you deploy multiple Remote Operations Servers to manage a set of remote or mobile network devices. You can configure each Remote Operations Server to forward inventory information (for example, device and interface information) and the associated alarm data to a designated primary Central SPECTRUM Server. The primary Central SPECTRUM Server acts as the aggregation point for multiple Remote Operations Servers. Administrators at the central site have access to all of the information that has been forwarded from the Remote Operations Servers, by viewing each one on the primary Central SPECTRUM Server.

Fault tolerance features are also supported in a distributed Remote Operations configuration. You can configure each Remote Operations Server to connect to both a primary Central SPECTRUM Server and a backup Central SPECTRUM Server. All topology and alarm data is forwarded to the primary Central SPECTRUM Server. If the connection to the primary central SPECTRUM server is lost, the Remote Operations Server automatically sends a full topology and alarm update to the designated backup Central SPECTRUM Server. The Remote Operations Server then begins forwarding alarm information to the backup server. Once the connection to the primary Central SPECTRUM Server is restored, data forwarding to the backup Central SPECTRUM Server stops. The Remote Operations Server sends a full topology and alarm update to the primary Central SPECTRUM Server, and normal alarm forwarding resumes.

The following diagram shows a distributed Remote Operations deployment:



Management Visibility in a Remote Operations Environment

When a Remote Operations Server manages a network asset directly, you have access to all information that has been gathered about the device, regardless of the various methods DX NetOps Spectrum uses to collect that information. Direct management is therefore equivalent to management by a traditional DX NetOps Spectrum server. A difference appears in the available management data when the device is managed by a Remote Operations Server, but the information is viewed from a connected Central SPECTRUM Server.

When a Remote Operations Server forwards its topology to a designated Central SPECTRUM Server, the devices are represented in the Central SPECTRUM Server as “lightweight” models. Viewed locally by operators using the Remote Operations Server, the same models are "complete" models, providing complete local visibility. But the Central SPECTRUM Server only displays the essential information about these devices. You can still clearly identify the managed devices and their subcomponents. In addition, all alarms impacting the managed assets can be transferred from the Remote Operations Server to the Central SPECTRUM Server.

Less information is available from the Central SPECTRUM Server because Remote Operations Suite must operate over low-speed, unreliable connections. The communications that occur between the Remote Operations Server and the Central SPECTRUM Server are therefore optimized to conserve bandwidth.

The Remote Operations Server communicates only the information that is required to provide the Central SPECTRUM Server with a real-time view of its managed topology and operational alarm state.

Setting Up Remote Operations Suite

Install the Remote Operations Suite

Installing Remote Operations Servers resembles the procedure for installing DX NetOps Spectrum. The installers are similar. However, a few additional steps are required.

Designating a Main Location Server is required as part of the installation. Be sure to read Selecting a Main Location Server before you begin the installation.

Follow these steps:

1. Start the installation on Windows or Linux.
   The Install dialog opens.
2. Select the Install DX NetOps Spectrum option.
   The Introduction dialog opens.
3. Click Next to proceed.
   The License Agreement dialog opens.
4. Scroll through and read the license agreement, accept the agreement, and click Next.
   The Destination Host dialog opens.
5. Enter the name of the host system where you are installing DX NetOps Spectrum and click Next.
   The SRAdmin Authentication dialog opens.

   NOTE
   If the 'Unable to connect to DX NetOps Spectrum Remote Administration Daemon (SRAdmin)' dialog appears, install SRAdmin before continuing with the installation. To install SRAdmin, click Install on this dialog.
6. Enter a username and password as follows, and click Next:
   – For Linux installation, enter a username with root access. Or, you can use a sudoers file for root permissions.

     NOTE
     If you have root access when starting this installation, you are not prompted for a user name and password.
   – For a Windows installation, enter a username that has Administrator rights, and verify the domain name (if applicable).

   The Destination Location dialog opens.
7. Click Next to install DX NetOps Spectrum in the default directory. The default directory is C:\win32app\SPECTRUM on Windows and /usr/SPECTRUM on Linux.
   To install in a location other than the default directory, click Choose, select a location, and click Next.
   The installer reports that it is extracting installation information.
   The Select Destination Language dialog opens.
8. Select one of the supported languages to install in addition to English, and click Next.
   Localized CsEvFormat, CsPCause and EventTables will be installed for the selected language.
   The Select Options dialog opens.
9. Select Remote Operations Server as the Installation Type.
10. Select to install both the SpectroSERVER and OneClick from the list, and click Next.

    WARNING
    The Connector must be installed on a system with both OneClick and the SpectroSERVER installed.

    The Host Evaluation dialog opens.
11. Scroll down to verify that no warnings appear, and click Next to proceed.
    The DX NetOps Spectrum Installation Owner dialog opens.
12. Enter a username and password, and click Next. This username is used to create the initial DX NetOps Spectrum user (for the SpectroSERVER) and becomes the installation owner. For a OneClick installation, the username also determines the SpectroSERVERs to which the OneClick web server connects.
    For more information, see the Installing section.

NOTE
For first-time installations, the default DX NetOps Spectrum password for the installation owner is spectrum.

WARNING
When installing OneClick, be sure to specify a DX NetOps Spectrum username to which the administrative license is associated. This user needs access to all models in DX NetOps Spectrum (ADMIN access). We recommend that you specify the installation owner that you specified during the SpectroSERVER installations. This user must also exist on the installation host and does not have to be a Windows administrative user.

The Main Location Server dialog opens.

WARNING
Be sure to read Selecting a Main Location Server before you select a server. For more information about location servers and the Main Location Server, see the Distributed SpectroSERVER Administration section.

13. Enter a hostname for the Main Location Server and click Next. The Main Location Server should be installed on a separate server.

NOTE
DX NetOps Spectrum must be able to resolve the hostname, regardless of whether you provide a fully qualified hostname.

The Web Server Port Number dialog shows the default value.

14. (Optional) Enter a port number other than the default, and click Next.

NOTE
The default port is 80 for Windows and 8080 for Linux.

WARNING
During a typical SpectroSERVER installation, you are prompted to supply a landscape handle. The Remote Operations Server installation does not prompt for this value. Instead, the installer supplies a default value of 16. In some situations, multiple SpectroSERVERs are deployed with the Remote Operations Server. You can then change the landscape handles of selected SpectroSERVERs. For more information, see Set the Landscape Handle for the SpectroSERVER.

15. Click Next.
    The Review Settings dialog opens.
16. Scroll down to ensure all the settings are what you selected and click Next.
    The Installing DX NetOps Spectrum dialog appears. After DX NetOps Spectrum is installed, the status changes to 'Installation successful,' and the Next button is enabled.
17. Click Next.
    The Installation Complete dialog opens.
18. Click Done.
    The configuration dialog appears for a brief moment and closes.
    DX NetOps Spectrum is configured for your system.
19. Click Close on the initial Install dialog. Log out, and log back in.
    DX NetOps Spectrum is installed.
    Next, you must Configure the Remote Operations Connector.

Set the Landscape Handle for the SpectroSERVER

The Landscape Handle dialog that prompts you during DX NetOps Spectrum installation does not appear during Remote Operations Server installation. Instead, the handle setting for the SpectroSERVER defaults to 16. To use a different value for the landscape handle, you must set it. Unique landscape handles are crucial if you are configuring a distributed SpectroSERVER environment. Use the default handle setting for Multiple Remote Operations Servers if a Remote Operations Server does not report to another Remote Operations Server as its MLS.

Landscape handles can be assigned by using a utility named lh_set. For more information see the **Assign Landscape Handles** section in Setting up a Distributed SpectroSERVER Environment.

> **WARNING**
> Run the lh_set utility before you run the SpectroSERVER for the first time. Otherwise, DX NetOps Spectrum assigns a default landscape handle that is the same every time that DX NetOps Spectrum assigns it. As a result, duplicate landscape handles can be created when multiple landscapes are configured. Such landscapes can never be accessed simultaneously from the same application.

Follow these steps:

1. Navigate to the SS directory.
2. Enter the following command:
   ```
   ../SS-Tools/lh_set <landscape handle>
   ```
   You can specify the new landscape handle in either decimal or hexadecimal notation. If you use decimal notation, the lh_set utility converts your entry into a hexadecimal landscape handle.

   > **NOTE**
   > For more information, see the Installing section.

Selecting a Main Location Server

During Remote Operations Suite installation, you are prompted to select a Main Location Server. The *main location server (MLS)* is the primary SpectroSERVER used to coordinate the information and events from all other SpectroSERVERs connected in a DSS environment. Typically, a Remote Operations Server deployment does not use the same architecture as a typical DSS deployment.

In a Remote Operations Suite deployment, select the Remote Operations Server as the Main Location Server.

> **WARNING**
> Do not select the designated primary Central SPECTRUM Server as the MLS.

The Remote Operations Server OneClick points to the Remote Operations SpectroSERVER as the MLS. The interactivity to the full DX NetOps Spectrum environment comes from configuring the Remote Operations Server Connector on the server VNM model to point to a SpectroSERVER in the standard DX NetOps Spectrum environment.

If your environment uses Remote Operations Servers in a DSS deployment, select your MLS, but in such a case, the MLS should not be one of your Full Production SpectroSERVERs.

Configure the Remote Operations Server

When the installation completes and you have logged out of the server and logged back in, you are ready to enable the Remote Operations Connector component. This component links the Remote Operations Server to the Remote Operations Manager on the Central SPECTRUM Server. Configure the Remote Operations Connector with the information required to send the topology and alarm information to the Central SPECTRUM Server.

Follow these steps:

1. Log in to the OneClick server that is associated with the Remote Operations Suite deployment.
2. Launch the Spectrum Control Panel.
3. Start the SpectroSERVER process, which is equivalent to starting the Remote Operations Suite.
4. In OneClick, locate the new Remote Operations Server in the Explorer tab of the Navigation panel.
5. Expand the landscape, and expand the Universe.
6. Select the Virtual Network Manager (VNM) model.
   Information about the VNM model appears in the Component Detail panel.

We recommend configuring the Connector parameters in the following order:

a. Topology Forwarding
b. Alarm Forwarding
c. Central SPECTRUM Server - General

Configure Topology Forwarding

The Remote Operations Connector provides a representation of all modeling data in the Universe hierarchy of the associated Remote Operations Server. The Universe hierarchy includes containers, devices, ports, and applications. The Remote Operations Connector sends the topology information to the Remote Operations Manager component of the Central SPECTRUM Server. By default, the entire network topology under the Universe hierarchy is forwarded.

Configure the topology forwarding feature to selectively forward topology components. You can designate the components of the network topology that you want the Remote Operations Connector to forward to the Central SPECTRUM Server.

Follow these steps:

1. Locate the Remote Operations Connector configurations and expand the Topology Forwarding subview.
   The Topology Forwarding configuration options display.
2. Click set next to Hierarchy and select the aspects of the selected Remote Operations Server hierarchy you want to forward to the Central SPECTRUM Server:
   – Entire Universe hierarchy (including all containers)
   – Devices Only
   The selected value displays next to Hierarchy.

Click set next to Device Sub-Components and select the Remote Operations Server subcomponents to forward to the Central SPECTRUM Server:

- All Device Sub-Components (ports and applications)
- Interfaces Only
- Applications Only

NOTE
Remote Operations Connector always forwards all device models to the Central SPECTRUM Server. To forward alarms on port and application models to the Central SPECTRUM Server, configure the Remote Operations Connector to forward these models too. For example, if only device and interface models are sent to the Central SPECTRUM Server, then only device and interface alarms are forwarded. Alarms on application models are not forwarded.

The selected value appears next to Device Sub-Components.

NOTE
Do not click Update Remote Operations Topology after an initial configuration of the product. The topology data of the Remote Operations Server is sent to the Central SPECTRUM Server once you establish the initial connection.

Topology forwarding is configured.

Configure Alarm Forwarding

The Remote Operations Servers generates the alarms. The alarms are forwarded to the Remote Operations Manager component on the Central SPECTRUM Server by the Remote Operations Connector.

Configure the alarm forwarding feature to specify the severity of alarms that are forwarded to the Central SPECTRUM Server. You can also filter alarm forwarding, which is based on alarm probable cause IDs. The Remote Operations Connector only forwards alarms that are configured for sending to the Central SPECTRUM Server. Any alarm that does not match the alarm forwarding filter is not forwarded.

Follow these steps:

1. Locate the Remote Operations Connector configurations and expand the Alarm Forwarding subview.
   The Alarm Forwarding configuration options display.
2. Click the set link and select Yes, to select which alarm severities to send to the Central SPECTRUM Server. By default, the critical, major, minor, and maintenance alarm severity options are enabled.
   The value of each alarm displays next to the alarm.

   NOTE
   Suppressed, maintenance, and initial conditions on DX NetOps Spectrum models typically do not generate actual alarms. Fewer alarms improve the performance of the SpectroSERVER process during network outages. The forwarding of suppressed, maintenance, or initial alarms by the Remote Operations Server results in the generation of these alarms in the SpectroSERVER. Verify that the alarms have been generated by opening the Alarm Management subview of the VNM model. Examine the Disable Initial Alarms, Disable Suppressed Alarms, and Disable Maintenance Alarms settings. These alarm management attributes must be set to “No” to enable alarms of that severity to be forwarded by the Remote Operations Server.
3. Click Add under the Probable Cause Filter option to specify any alarm probable cause codes to forward to the Central SPECTRUM Server.
   The Add dialog appears.
4. Enter the probable cause code in the Enter PCause ID field and click OK.
   The probable cause code displays in the Probable Cause Filter list.

   NOTE
   If any probable cause codes are listed in the Probable Cause Filter list, then only alarms that match a probable cause ID in that list are forwarded to the Central SPECTRUM Server. All others are not forwarded. If the Probable Cause Filter list is empty, then no filtering of alarms that are based on probable cause code is performed.

Alarm forwarding is configured.

NOTE
For more information about alarms, see the Event Configuration section.

Configure and Connect to the Central SPECTRUM Server

Configure each Remote Operations Connector with the name of the Central SPECTRUM Server host to connect to the Central SPECTRUM Server. The Remote Operations Connector requires information about where to forward alarm and topology data.

NOTE
Alarm forwarding must be configured before you set the primary and backup Central SPECTRUM Server hostnames.

Follow these steps:

1. Locate the Remote Operations Connector configurations and expand the General subview.
   The General configuration options display.
2. Verify that the Remote Operations Server ID is correct. (The Remote Operations Server ID defaults to the local servername). If it is not correct:
   1. Select *Set*
   2. Enter the *Remote Operations Server ID*
   3. Select *Enter*.

   The Remote Operations Server ID displays next to Remote Operations Server ID.
3. (Optional) Click set next to the Backup Central SPECTRUM Server Host Name to enter the hostname of a backup Central SPECTRUM Server, and press Enter.

NOTE
This hostname must not be the fully qualified hostname.

The backup hostname displays next to the Backup Central SPECTRUM Server Host Name.

4. Click set next to the Primary Central SPECTRUM Server Host Name, enter the hostname of the primary Central SPECTRUM Server, and press Enter.

NOTE
This hostname must not be the fully qualified hostname. The server that you designate as the Primary Central SPECTRUM Server can be the MLS. For more information, see Selecting a Main Location Server. Ensure that the Remote Operations Server ID matches the Remote Operations Server local machine name.

The primary hostname displays next to the Primary Central SPECTRUM Server Host Name.

WARNING
Initial topology and alarm data are immediately sent to the Central SPECTRUM Server once the primary Central SPECTRUM Server hostname is set. Set the primary Central SPECTRUM Server hostname last.

Subsequent topology updates occur only when contact with the Central SPECTRUM Server is reestablished after a disconnect, or with an ondemand topology update.

Fault Tolerance

If primary and backup Central SPECTRUM Server host names are defined, the Remote Operations Server automatically starts forwarding topology and alarm information to the backup server if the connection to the primary server goes down. When this switchover happens, a full topology and alarm update is sent to the backup server and normal alarm forwarding begins.

NOTE
Be sure that the primary and backup Central SPECTRUM Servers are already in a fault tolerant environment before defining the host names for these servers.

Once the connection to the primary server is restored, the Remote Operations Server stops sending data to the backup server, a full topology, and alarm update is sent to the primary server, and normal alarm forwarding resumes.

NOTE
Manually clear the residual alarms. Delete any unnecessary RemoteOperationsManagedElement models that exist in the backup server after the Remote Operations Server stops forwarding data to it.

Using Remote Operations Suite

This chapter assumes that you are the administrator at your central site, using the Central SPECTRUM Server.

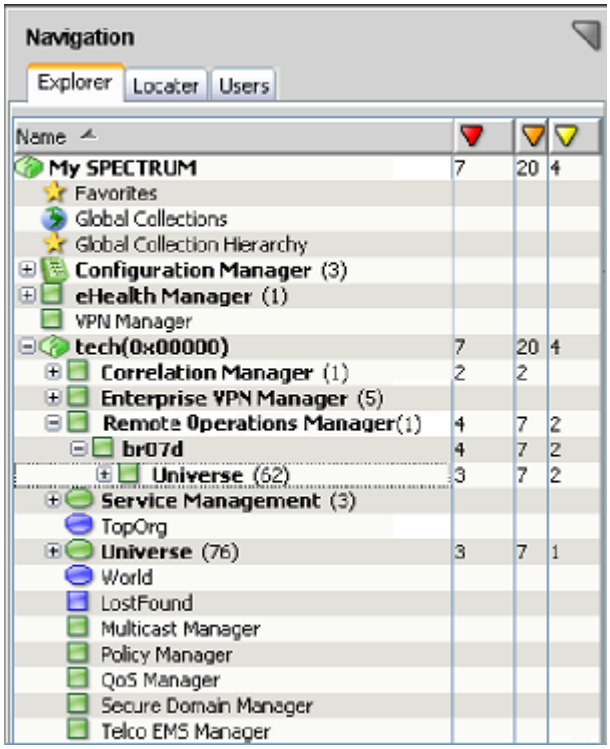
View Remote Operations Server Information

View information that is related to the connected Remote Operations Servers and subcomponents, from the Remote Operations Manager component on the Central SPECTRUM Server.

Follow these steps:

1. Expand Remote Operations Manager in the Explorer tab of the Navigation panel.
   Remote Operations Servers currently connected display.
2. Expand each Remote Operations Server to reveal its subcomponent hierarchy.

Information and alarm data associated with the selected Remote Operations Server or Remote Operations subcomponent display in the Contents and Component Detail panels.



Update Remote Operations Server Topology Data

The Remote Operations Connector does not keep the Central SPECTRUM Server up to date with topology and modeling changes that occur on the Remote Operations Server. The Remote Operations Connector forwards topology data to the Central SPECTRUM Server only when an initial connection to the Central SPECTRUM Server is made and when the connection is reestablished after a disconnect.

You can also manually update the Remote Operations Server topology data at any time, and instruct the Remote Operations Server or Remote Operations Servers, to send the topology data to the Central SPECTRUM Server.

> **NOTE**
> Each time the topology data is updated, if the *Model_Name* of any models in the Remote Operations Server has changed, the corresponding lightweight Remote Operations models are also updated. Each time the topology data is updated, the alarm status for all newly-forwarded and existing managed elements is also updated.

To update topology data for all connected Remote Operations Servers

1. Select the Remote Operations Manager in the Navigation panel.
   Information displays in the Contents panel.
2. Select the Information tab in the Component Detail panel and expand the Configuration subview.
   The Update Remote Operations Topology button is displayed.
3. Click Update Remote Operations Topology.
   The Start Remote Operations Topology Update dialog opens.
4. Click Yes to start the Remote Operations Topology Update.
   The Start Remote Operations Topology Update dialog displays if the Remote Operations topology update was successful.
5. Click OK.
   The topology data is updated for all connected Remote Operations Servers.

To update topology data for a single Remote Operations Server

1. Expand the Remote Operations Manager node in the Navigation panel.
   All connected Remote Operations Servers display.
2. Select the single Remote Operations Server for which the topology data should be updated.
   Information displays in the Contents panel.
3. Select the Information tab in the Component Detail panel and expand the Configuration subview.
   The Update Remote Operations Topology button is displayed.
4. Click Update Remote Operations Topology.
   The Start Remote Operations Topology Update dialog opens.
5. Click Yes to start the Remote Operations Topology Update.
   The Start Remote Operations Topology Update dialog displays if the Remote Operations topology update was successful.
6. Click OK.
   The topology data is updated for the selected Remote Operations Server.

   NOTE
   You can also update the topology data for a single Remote Operations Server from the computer where that Remote Operations Server resides.

To update topology data for a single Remote Operations Server on the machine where the Remote Operations Server resides

1. Select the Remote Operations Server for which the topology data should be updated in the Navigation panel.
   Information displays in the Contents panel.
2. Select the Information tab in the Component Detail panel and expand the Configuration subview.
   The Update Remote Operations Topology button is displayed.
3. Click Update Remote Operations Topology.
   The Start Remote Operations Topology Update dialog opens.
4. Click Yes to start the Remote Operations Topology Update.
   The Start Remote Operations Topology Update dialog displays if the Remote Operations topology update was successful.
5. Click OK.
   The topology data is updated for the selected Remote Operations Server.

RemoteOperationsManagedElement Model Type

The Central SPECTRUM Server can discover any or all managed network elements in the Universe hierarchy of the Remote Operations Server.

The Central SPECTRUM Server stores all of the Remote Operations-related data in the modeling database. It uses the model type RemoteOperationsManagedElement to model all network entities that are managed by a Remote Operations Server. All subcomponent relationships between two RemoteOperationsManagedElement models (for example, a "port" being a subcomponent of a "device") are modeled in the DX NetOps Spectrum database as associations, using the RemoteOperationsContains relation.

The RemoteOperationsManagedElement model type contains the following attributes:

- **RemoteOperationsServerId**
  Identifies the Remote Operations Server where the RemoteOperationsManagedElement is stored.
- **RemoteOperationsServerModelHandle**
  Identifies the RemoteOperationsManagedElement in its associated Remote Operations Server, using a unique model handle.
- **RemoteOperationsServerModelName**

Identifies the model name given to the element inside the Remote Operations Server.

- **RemoteOperationsServerModelType**
  Identifies the model type used to model the element inside the Remote Operations Server.

You can copy and paste a RemoteOperationsManagedElement model anywhere in DX NetOps Spectrum's topology views (Universe, World, or TopOrg), to arrange your network containment.

Search for Models

Search for models if you do not know the exact hierarchy where a particular model exists.

Follow these steps:

1. Select the Locater tab in the Navigation panel on the Central SPECTRUM Server and expand Remote Operations.
2. Double-click All Remote Operations Managed Elements.
   All of the models for the managed elements display in the Contents panel.
3. Double-click All Remote Operations Servers.
   All of the server models display in the Contents panel.
4. To search for managed elements that are based on the model name of the managed element or by the server name on which it resides, expand Remote Operations Managed Elements By and do the following actions:
   – Double-click Remote Operations Model Name to search by the name of the model.
   – Double-click Remote Operations Server to search by the name of the Remote Operations Server on which it resides.

   The Search dialog opens.
5. Enter the model name for the managed element, and click OK.
6. Enter the server name for the managed element, and click OK.
   The managed element displays in the Contents panel.

> **NOTE**
> Click Landscapes to specify the landscapes from which OneClick exports data in a distributed environment. Move the landscapes whose data you want to export data into Show Landscapes. Move any landscapes whose data you do not want to export into Hide Landscapes in the Landscape Filter.

Device Management

Remote Operations Suite limits the number of models that can be created in a DX NetOps Spectrum database. Specifically, the Remote Operations Server is limited to managing 100 device models. As a result the Remote Operations Server is limited to managing 100 network devices. The 100 device limit includes device models that have an IP address and are derived from the device model type. Devices that are modeled as hosts or as pingables are not included in this limit.

You can determine whether the Remote Operations Server can manage all of your device models using some simple arithmetic.

Example: 590 Devices

This example shows how the Remote Operations Server can manage 590 devices:

A customer network comprises 10 routers, 60 switches, 10 firewalls, 10 devices that DX NetOps Spectrum has automatically modeled using the Generic SNMP Device (GnSNMPDev) model type, approximately 500 servers and workstations, and many other devices DX NetOps Spectrum has modeled using the “pingable” device model type.

In this example, the models that would be included in the device limit would total only 90. The 10 routers, 60 switches, 10 firewalls, and the 10 devices that are modeled with GnSNMPDev would be included. The 500 workstations and servers and the other devices that are modeled as pingables do not affect the 100 device limit.

Fault Isolation

If the Central SPECTRUM Server loses contact with a Remote Operations Server, it generates a red alarm on the corresponding Remote Operations Server model. All RemoteOperationsManagedElement models that are associated with the disconnected Remote Operations Server model display a suppressed (gray) condition, indicating that their status is unknown.

The Central SPECTRUM Server cannot manage the RemoteOperationsManagedElement models in a suppressed state. When the Central SPECTRUM Server reestablishes contact with the Remote Operations Server, the red alarm is cleared. The state of all corresponding RemoteOperationsManagedElement models is reevaluated.

By default, the Central SPECTRUM Server waits for 30 seconds for a keepalive signal, or heartbeat, from the Remote Operations Server before generating the red alarm. You can change this default setting using the following parameter in the ".vnmrc" file of the Central SPECTRUM Server:

- **ros_heartbeat_timeout**
  Specifies the maximum number of seconds the Remote Operations Manager waits for a heartbeat from the Remote Operations Server, before a contact lost alarm is raised. This parameter must be configured on Central SPECTRUM Server.
  The heartbeat parameter has the following format:
  ros_heartbeat_timeout=# of seconds
  Default: 30 seconds

  NOTE
  When contact with a Remote Operations Server is lost, the previously existing alarms on all RemoteOperationsManagedElement models still appear in the OneClick Alarms tab.

Remote Operations Suite Alarms

When the Remote Operations Server forwards an alarm to the Central SPECTRUM Server, it includes two important pieces of information: the title of the alarm, and the actual text of the event that prompted alarm generation.

The restrictions of tactical deployments and geography can mean that the version of DX NetOps Spectrum that is installed and running on the Remote Operations Server is slightly different from the version that is running on the Central SPECTRUM Server. In such a case, the two servers do not have the same fault detection intelligence. Therefore, the Central SPECTRUM Server lacks the alarm support files. The alarm support files are required to generate the identical alarm type as was generated on the Remote Operations Server.

To ensure the Central SPECTRUM Server handles all alarm types that the Remote Operations Server sends, the Central SPECTRUM Server uses a set of Remote Operations-specific alarm types. One alarm type for each alarm severity. When an alarm is forwarded from the Remote Operations Server, the Central SPECTRUM Server generates the appropriate Remote Operations-specific alarm, which is based on the severity of the forwarded alarm.

This generic alarm is displayed in the OneClick Alarms tab like all other alarms. Instead of displaying a generic alarm title, the Alarm Details tab displays the title of the alarm that was forwarded from the Remote Operations Server. In addition, the Central SPECTRUM Server appends the actual event text that is forwarded from the Remote Operations Server to the event that generates the forwarded alarm. This event text is also displayed in the Alarm Details tab, like all other event text.

Example: Alarm Title

This example shows an alarm title from the Remote Operations Server:

```
DEVICE HAS STOPPED RESPONDING TO POLLS
```

Example: Probable Cause Text

This example shows the body of the Remote Operations critical alarm probable cause:

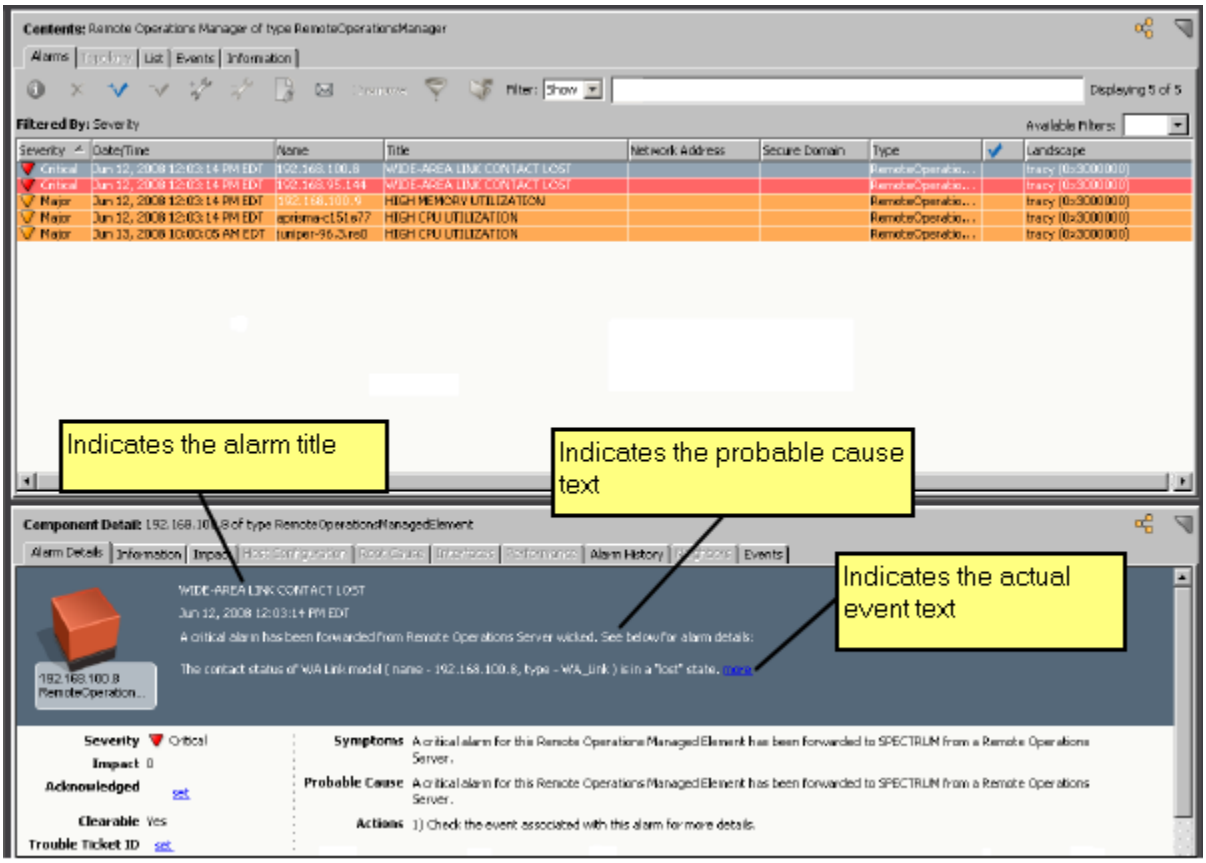
```
CRITICAL ALARM ON REMOTE OPERATIONS-MANAGED ELEMENT
SYMPTOMS:
A critical alarm for this Remote Operations-managed element has been forwarded to SPECTRUM from a SPECTRUM
 Remote Operations Server.
PROBABLE CAUSES:
A critical alarm for this Remote Operations-managed element has been forwarded to SPECTRUM from a SPECTRUM
 Remote Operations Server.
RECOMMENDED ACTIONS:
1) Check the event associated with this alarm for more details.
```

Example: Actual Event Text

In the following example, the event that is associated with the alarm displays the actual event text that was generated in the Remote Operations Server:

```
{d "%w- %d %m-, %Y - %T"} - A critical alarm has been forwarded to SPECTRUM from SPECTRUM Remote Operations
 Server TEAM_A.  See below for alarm details:
{d "%w- %d %m-, %Y - %T"} - Device Router1 of type Rtr_Cisco has stopped responding to polls and/or external
 requests.  An alarm will be generated.   (event [{e}])
(event [{e}])
```

The following image shows each part of the alarm as it appears in the OneClick Console:



NOTE
For more information about alarms, see the Event Configuration section.

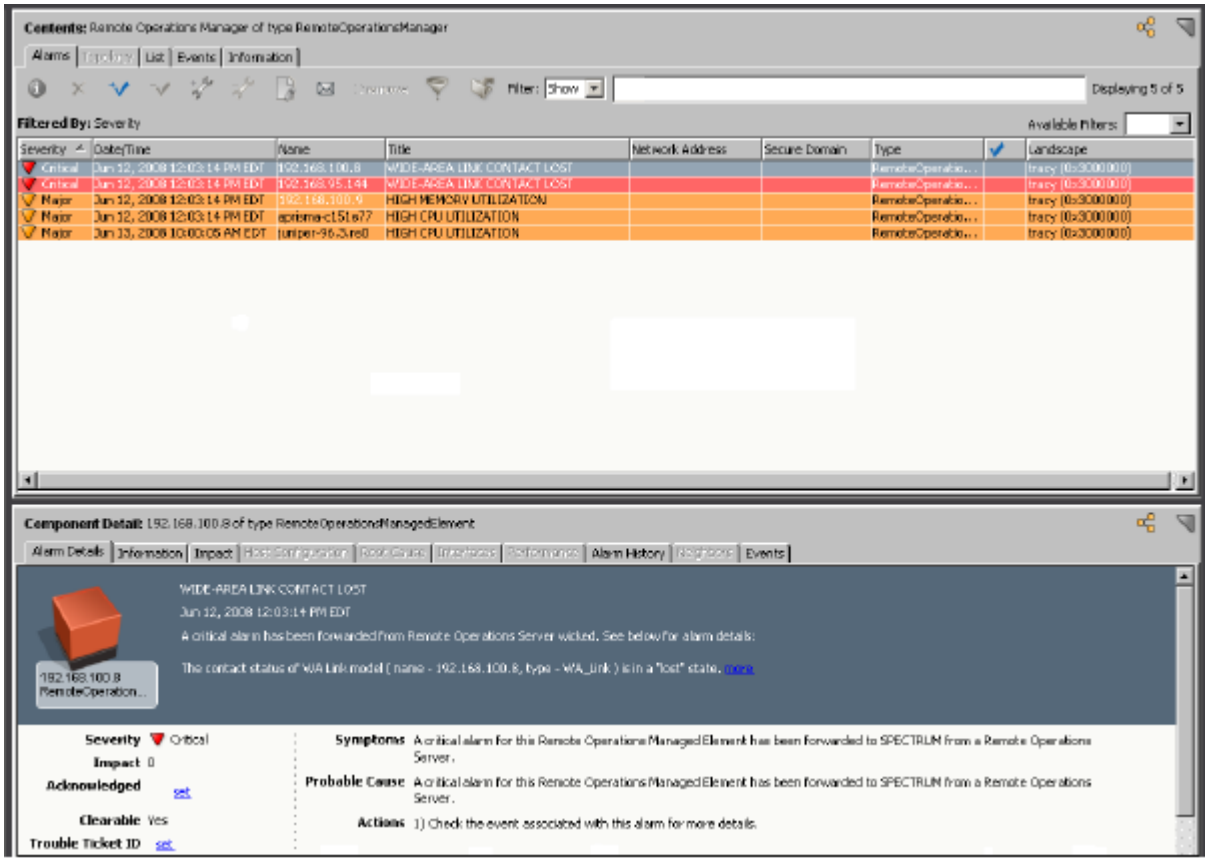
View Remote Operations-Related Alarms

You can view the Remote Operations-related alarms on all models in the Remote Operations hierarchy.

WARNING
Configure the Remote Operations Connector on each Remote Operations Server to forward alarms to the Central SPECTRUM Server. For more information about forwarding alarms to the Central SPECTRUM Server, see Configure Alarm Forwarding.

To view only the Remote Operations-related alarms on the Central SPECTRUM Server, select the Remote Operations Manager model in the Explorer tab of the Navigation panel. Click the Alarms tab in the Contents panel.

Information such as alarm symptoms and possible alarm causes displays in the Contents and Component Detail panels for all models in the Remote Operations hierarchy.



NOTE
If the topology data on the Central SPECTRUM Server is not synchronized with the topology data on the Remote Operations Server or subcomponent, the alarm data does not update. Perform an on-demand Topology synchronization to ensure that your topology and alarm data is current. For more information about synchronizing alarm data, see Update Remote Operations Server Topology Data.

Remote Operations Forwarding Events

When an alarm is forwarded to the Central SPECTRUM Server for processing, a Remote Operations Forwarding Event is generated on the corresponding lightweight Remote Operations model (RemoteOperationsManagedElement). The Remote Operations Forwarding Event contains the following varbinds:

- **RemoteOperationsServerId**
  Identifies the Remote Operations Server where the RemoteOperationsManagedElement is stored.
- **RemoteOperationsServerModelHandle**
  Identifies the RemoteOperationsManagedElement in its associated Remote Operations Server, using a unique model handle.
- **RemoteOperationsServerEventCode**
  Identifies the standardized DX NetOps Spectrum event/alarm code for the event.
- **RemoteOperationsServerEventSeverity**
  Identifies the severity of the event/alarm. Possible values include critical, major, minor, maintenance, suppressed, initial, and message.
- **RemoteOperationsServerEventType**
  Identifies the type of event. Possible values include message, alarm_set, and alarm_cleared.
- **RemoteOperationsServerEventCommentData**
  Displays a textual description of the event that caused an alarm to be generated or cleared.
- **RemoteOperationsServerEventTitle**
  Identifies the textual title (abstract) of the alarm.

> **NOTE**
> DX NetOps Spectrum does not log the Remote Operations Forwarding Event. DX NetOps Spectrum applies event rules to the Remote Operations Forwarding Event that determine the type of alarm or message event that is generated and logged. These event rules are stored in the following file: <*$SPECROOT*>/SS/CsVendor/Spectrum_ROS/EventDisp.

Remote Operations Alarming Events

A Remote Operations Forwarding Event is mapped to the Remote Operations Alarming Event by the event rules if the value of the RemoteOperationsServerEventType varbind is equal to "alarm_set". The following types of Remote Operations Alarming Events are defined:

- Remote Operations Critical Alarm Event
- Remote Operations Major Alarm Event
- Remote Operations Minor Alarm Event
- Remote Operations Maintenance Alarm Event
- Remote Operations Suppressed Alarm Event
- Remote Operations Initial Alarm Event

The value of the RemoteOperationsServerEventSeverity varbind determines which Remote Operations Alarming Event is generated. DX NetOps Spectrum logs the event. The event is used to generate the appropriate alarm. All varbind values in the Remote Operations Forwarding Event are copied to the new event.

Remote Operations Clearing Events

A Remote Operations Forwarding Event is mapped to the Remote Operations Clearing Event by the event rules if the value of the RemoteOperationsServerEventType varbind is equal to "alarm_cleared". This event clears any existing alarm on a model that has the same RemoteOperationsServerEventCode and RemoteOperationsServerEventSeverity values. All varbind values in the Remote Operations Forwarding Event are copied to the new event.

> **NOTE**
> When clearing events, the RemoteOperationsServerEventCode that is sent is not the actual event code that was generated in the Remote Operations Server. Rather, the code for the event that generated the original alarm is sent.

Remote Operations Message Events

A Remote Operations Forwarding Event is mapped to the Remote Operations Message Event by the event rules if the RemoteOperationsServerEventType varbind is equal to "message". This event is for informational purposes only and is not used to generate an alarm. However, this event is logged to DX NetOps Spectrum. All varbind values in the Remote Operations Forwarding Event are copied to the new event.

To create your own event and alarm types, modify the EventDisp file, which is located in <*$SPECROOT*>/SS/CsVendor/Spectrum_ROS.

Secure Domain Manager (SDM)

DX NetOps Spectrum Secure Domain Manager

Secure Domain Manager is a DX NetOps Spectrum network management solution that allows users to manage devices in secure networks. You can manage devices without deploying a local SpectroSERVER. Secure Domain Manager lets you manage your secure domains by securely tunneling SNMP and ICMP traffic through a secure connection. Only a single port is opened on the firewall, which allows the extended manageability without impacting security policies in place. This solution is transparent to end-users and client applications, eliminating the need to perform more administrative tasks.

Challenges to Managing Highly Secure Networks

Data networks are more secure than ever nowadays. The challenges that are involved in managing devices and applications in secure networks are correspondingly greater. These challenges include:

- Managing network elements in overlapping (or private) IP domains (NAT environments)
- Managing network elements behind firewalls that are configured to block SNMP and ICMP traffic
- Managing network elements across insecure network domains

The Secure Domain Manager product provides a unique solution to these management challenges.

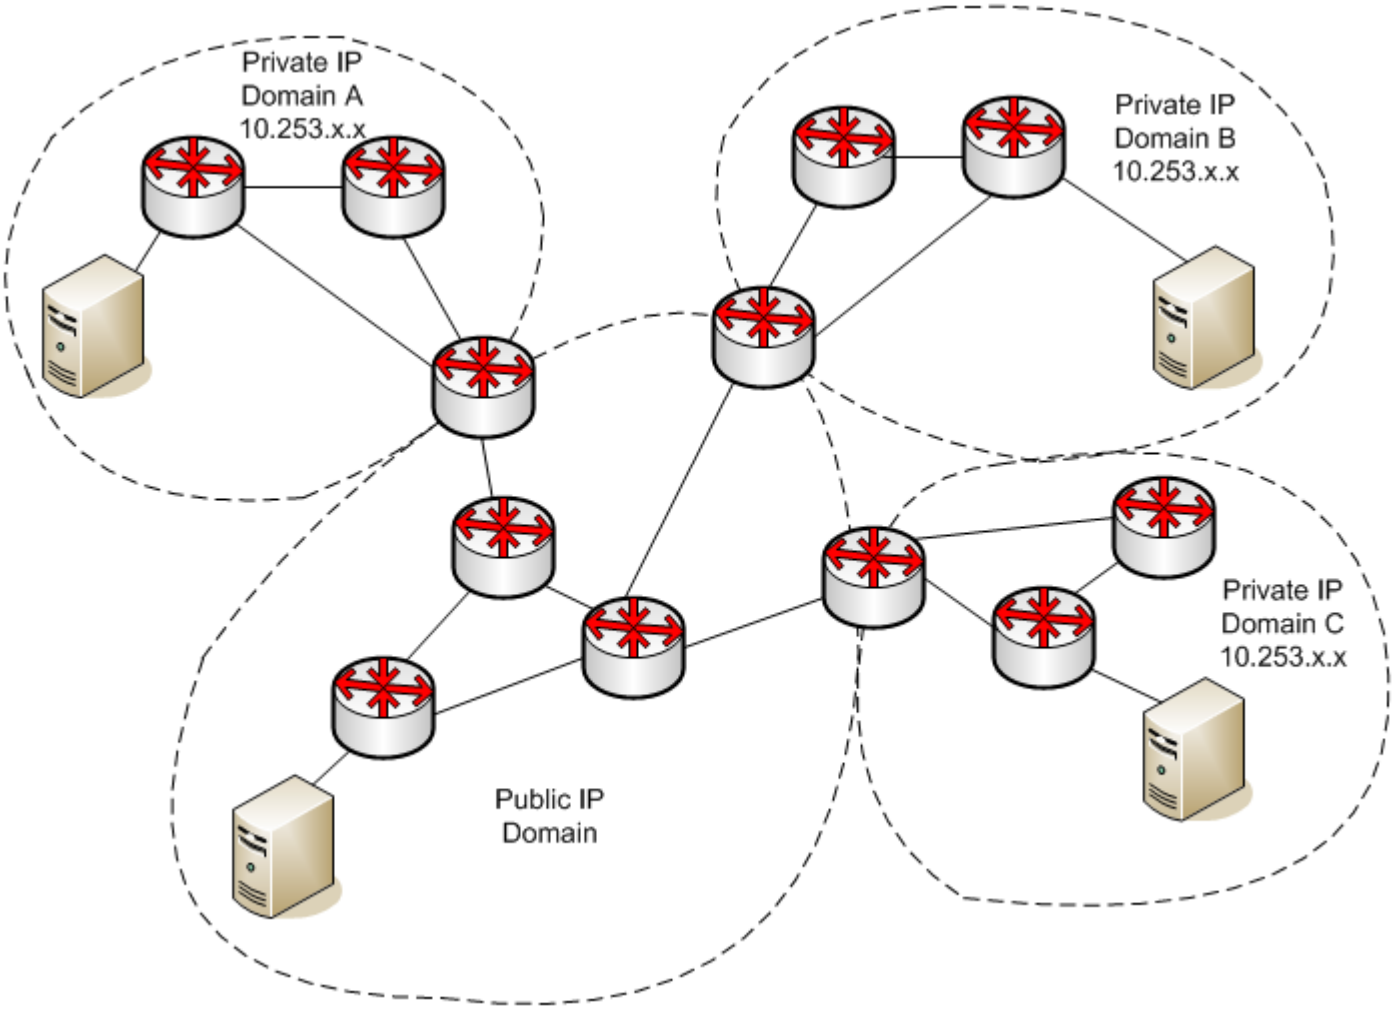
Benefits of Secure Domain Manager

The Secure Domain Manager solution enhances the existing management capabilities included with DX NetOps Spectrum in the following ways:

- Lets DX NetOps Spectrum communicate with all SNMP-compliant devices: SNMPv1, SNMPv2, and SNMPv3.
- Lets DX NetOps Spectrum communicate with devices located behind firewalls that block SNMP and ICMP traffic.
- Simplifies firewall configuration. A single "hole" is opened for traffic passing between two well-known hosts on a well-known port.
- Lets DX NetOps Spectrum pass SNMP and ICMP traffic securely through insecure networks.
- Lets DX NetOps Spectrum manage devices in overlapping IP domains (NAT environments) using a single SpectroSERVER.
- Provides enhanced Discovery capabilities to discover and model devices in secure environments, one IP address space at a time.

Overlapping IP Domains

The following diagram shows a NAT network that contains a public IP domain and three private IP domains that contain the same IP subnets.



Domains can represent the managed network of a company, a newly acquired division of a large enterprise, or a managed wireless hot spot in an airport terminal.

The following types of DX NetOps Spectrum customers face the overlapping IP challenge:

- **Managed service providers (MSPs)**
  MSPs use DX NetOps Spectrum to manage the networks of other organizations. The customers that MSPs manage invariably use IP ranges typically used for private IPs, 10.x.x.x or 172.16.x.x, for example. Therefore, the MSP must address the challenge of managing duplicate or overlapping IP addresses. In the past, this challenge was addressed by dedicating a DX NetOps Spectrum management server (the SpectroSERVER) to each customer that was using the same IP address space.
  This posed two issues. The first involved cost. A dedicated management server was necessary for each customer, regardless of the size of the managed environment and the number of overlapping IP addresses it used. The second issue involved administration. The MSP was burdened with maintaining more management systems. MSPs required less expensive and efficient alternatives to dedicated management systems, especially when the number of elements with overlapping IP addresses was small and did not warrant the expense of a dedicated management server.
- **Hotspot (Wi-Fi) access providers**
  Hotspot access providers provide Wi-Fi access in locations such as airport terminals, airport lounges, hotel rooms, and coffee shops. For each location, the same private IP address space is issued. This approach simplifies configuration, installation, and administration. A provider may have hundreds or thousands of hotspots. To deploy a new hotspot

quickly, each set of equipment that establishes the hotspot in a property is configured identically, including the IP address space. Once the hotspot is up and running, the challenge becomes managing it proactively to sustain an optimal level of service.

- **Enterprise managers**
  In an organization merger or acquisition scenario, an enterprise management staff must typically combine two entirely different and separately constructed IP networks, in many instances resulting in multiple overlapping IP addresses. In this scenario, the new IT organization must now deal with managing the combined network, especially the management of a network with the same IP address spaces. One solution to this challenge is to reassign IPs to every IP entity so there is no duplication of IP addresses. That solution involves a huge undertaking that presents many challenges.

Secure Domain Manager lets these customers overcome the challenge of managing overlapping IP domains in the following ways:

- Allows MSPs to deploy only a single, lightweight agent process on a host machine in each customer's remote network, thus removing the need to deploy and administer a full DX NetOps Spectrum installation.
- Allows the Hotspot access providers and large enterprises keep the overlapping private IP domains intact and manage the networks by using a lightweight agent process.

Firewalls Blocking SNMP and ICMP Traffic

Firewalls provide the security crucial to many network environments. Some challenges exist in managing a network behind a firewall. First, network administrators often configure firewalls to block SNMP and ICMP traffic, which provide the visibility into their network infrastructure, to unauthorized sources. Second, the configuration that is required to manage network elements through a highly secure firewall is complicated. Because, all the hosts and ports that are involved are identified and opened on the firewall to enable full management capabilities.

Secure Domain Manager allows network managers to overcome the challenge of managing networks through secure firewalls in the following ways:

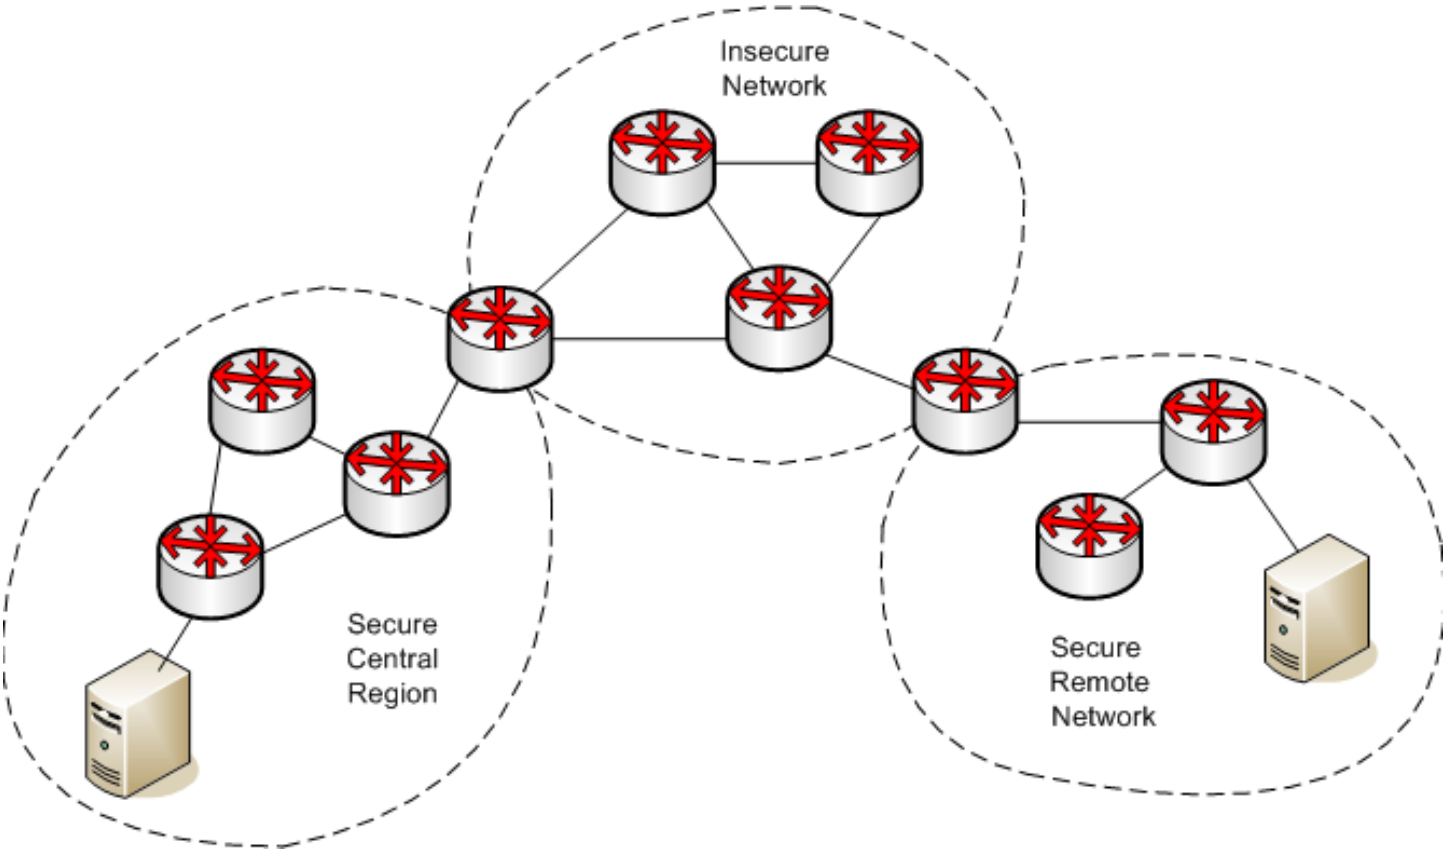
- Encoding UDP-based SNMP and the ICMP packets into a TCP/IP based protocol to overcome the restriction of the firewall on SNMP and ICMP traffic.
- Simplifying the configuration of the firewall by opening a single port that allows SNMP and ICMP traffic to flow between two well-defined hosts, on a well-defined port.

SNMP Traffic Passing Across Insecure Networks

SNMPv1 and SNMPv2 are insecure protocols: their data is not encrypted and can be viewed using a protocol analyzer. Therefore, it is undesirable to send this traffic across insecure networks. Allowing the SNMP traffic to cross insecure networks to reach a network you want to manage becomes challenging.

The following diagram shows a network management system on the host computer in the "Secure Central Region" that manages devices in a "Secure Remote Network." Management traffic must flow through the "Insecure Network" region. Network managers want to avoid exposing the data inside insecure protocol packets such as SNMPv1 and SNMPv2 in this portion of the network.

SNMP Across an Insecure Network



Secure Domain Manager lets network managers encrypt all management traffic that passes between the SpectroSERVER host and the host in the remote managed network. This solution securely passes insecure SNMP traffic across insecure networks. Data security is maintained when the traffic traverses the intermediate insecure networks.

How Secure Domain Manager Works

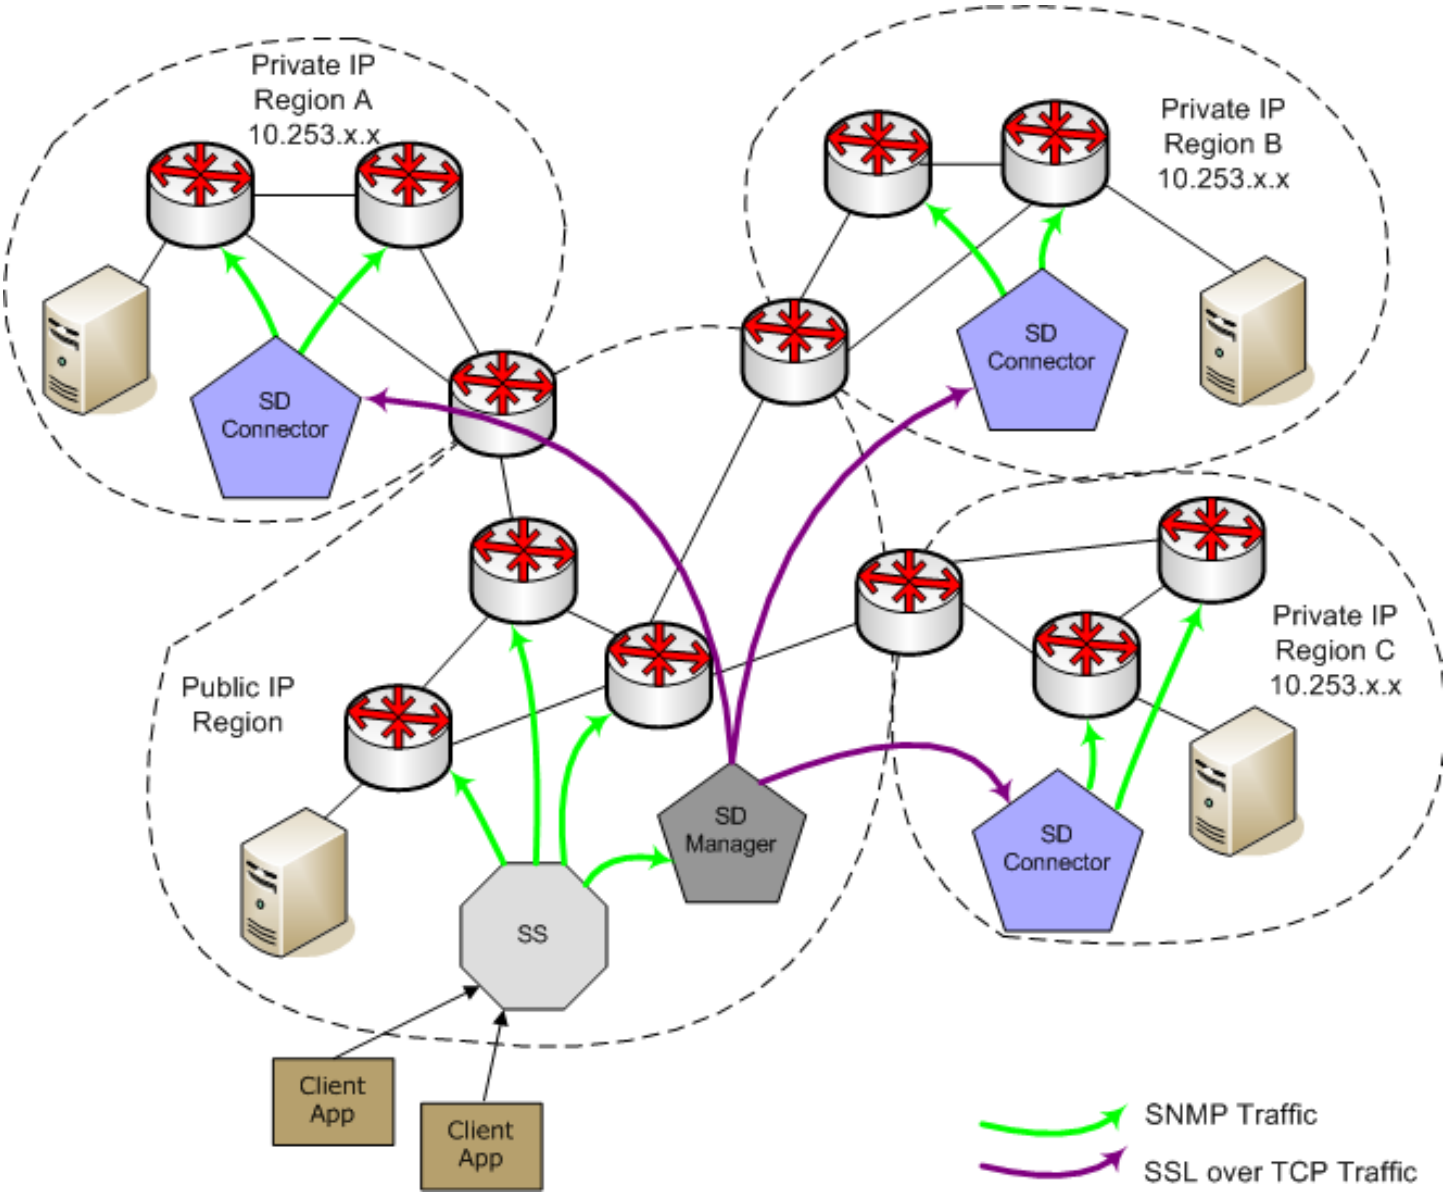
Secure Domain Manager supports SNMPv1, SNMPv2, and SNMPv3 communication. It consists of two different processes, SDManager (SDM) and SDConnector (SDC):

- **SDManager**
  SDManager is a server messaging library that is loaded by the SpectroSERVER.
- **SDConnector**
  SDConnector is a remote process responsible for communicating with the SDManager on the SpectroSERVER. It runs on a host machine that is located in a remote private network and it is capable of forwarding SNMP and ICMP messages on behalf of the SpectroSERVER (which would ordinarily be deployed in the private IP region) so that it can manage devices in the private network. SDConnector is configured using a configuration file (sdc.config) which can contain both primary and backup SpectroSERVER information. It is a part of the Secure Domain Manager solution.

The following diagram shows how these processes are deployed in a secure network environment.

> **NOTE**
>
> We recommend that you have a one to one mapping between SDC and SDM. In case of multiple SDMs connected to a single SDC, the SDC forwards traps to all the connected SDMs.

NAT Network Environment Using Secure Domain Manager



NOTE
Devices that are located in the same region as the SpectroSERVER are managed using SNMP, but without using Secure Domain Manager.

When the SpectroSERVER located in the public IP region must communicate with a device that is located in a remote secure region, the SpectroSERVER sends the request to the SDManager. The SDManager converts the SNMP data into a proprietary format and sends the data to the SDConnector located in the same region as the device. If the SDManager and SDConnector have been configured to run with SSL, the data is encrypted and sent through a secure tunnel to the SDConnector using SSL over TCP. When the SDConnector receives the data, it converts the data back to SNMP and sends a request to the appropriate device.

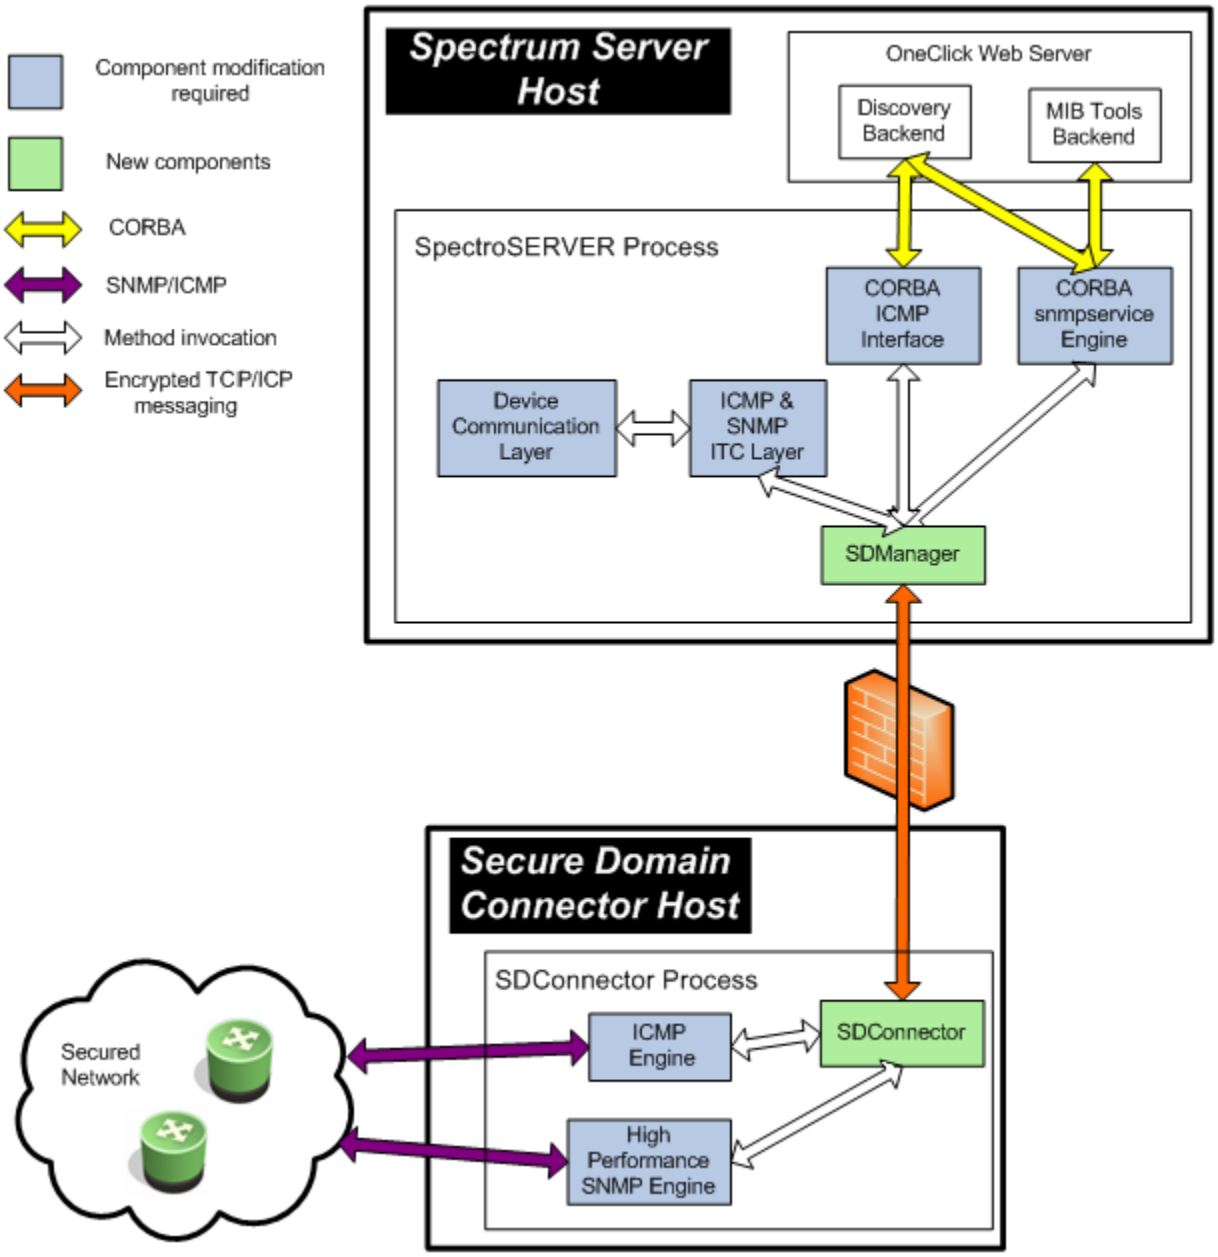
If the firewalls are deployed, it works the same way. The Network administrators must create a "hole" in each firewall that is dedicated to two well-known hosts. Devices that are located in regions that traverse more than one firewall are also manageable using this solution. To enable this communication, open a port on each firewall. The port must be a well-known port, which lets a pair of well-known hosts in adjacent regions to communicate using TCP.

When deploying Secure Domain Manager to manage overlapping IP domains, each SDConnector host machine must have a unique public IP address. The host must be able to communicate with all devices with which the SDConnector must communicate, including the SpectroSERVER host machine and all devices within the single private IP domain it manages. A likely candidate for this SDConnector host would be a machine behind the NAT that has a unique IP address that is statically assigned to it from the NAT. The SpectroSERVER uses the unique IP address of the SDConnector host machine as the additional discriminator to uniquely identify multiple devices that have the same private IP address.

NOTE
Certain DX NetOps Spectrum products such as Network Configuration Manager (NCM) and IP services management applications (including Multicast Manager and Enterprise VPN Manager) cannot manage overlapping IP addresses. However, you can still use Secure Domain Manager with these applications if you model their devices on the SDConnector rather than on the SpectroSERVER. Such configurations can have multiple SDConnectors deployed for each SpectroSERVER as long as the SDConnectors are not managing devices that are configured with overlapping IP addresses. Using this approach, you can still model devices on the local SpectroSERVER too, but only if they have not been configured with IP addresses that overlap with the IP addresses configured on the devices being managed through the SDConnectors.

Secure Domain Manager Architecture

The following diagram illustrates how the Secure Domain Manager operates:



Benefits of Secure Domain Manager

The Secure Domain Manager solution enhances the existing management capabilities included with DX NetOps Spectrum in the following ways:

- Lets DX NetOps Spectrum communicate with all SNMP-compliant devices: SNMPv1, SNMPv2, and SNMPv3.
- Lets DX NetOps Spectrum communicate with devices located behind firewalls that block SNMP and ICMP traffic.
- Simplifies firewall configuration. A single "hole" is opened for traffic passing between two well-known hosts on a well-known port.
- Lets DX NetOps Spectrum pass SNMP and ICMP traffic securely through insecure networks.
- Lets DX NetOps Spectrum manage devices in overlapping IP domains (NAT environments) using a single SpectroSERVER.
- Provides enhanced Discovery capabilities to discover and model devices in secure environments, one IP address space at a time.

Installing and Configuring Secure Domain Manager Processes

This section describes how to install and configure the Secure Domain Manager solution, a process that involves installing and configuring the SDConnector and SDManager.

How to Set Up Secure Domain Manager Processes

Setting up Secure Domain Manager involves installing and configuring Secure Domain Manager processes and then setting them up on the SpectroSERVER using OneClick.

Install and Configure Processes

Installing and configuring Secure Domain Manager processes requires the following steps:

1. Install the SDConnector process on a designated host.

   NOTE
   SDManager is installed when you install the core DX NetOps Spectrum product; however, it is only active if it is included in the bundle your company purchased.

   NOTE

   Information! During the install of the Secure Domain Manager, Microsoft Visual C++ 2013 Redistributable Update is also installed automatically as it is a required program to run SDConnector.
2. (Optional) Create and deploy SSL certificates for SSL encryption.
3. Set parameters in the configuration file for the SDConnector on the SDConnector host.
4. Set parameters in the configuration file for the SDManager on the SpectroSERVER.

Set Up Secure Domain Manager on SpectroSERVER

After you have installed and configured the SDConnector and SDManager processes, set up Secure Domain Manager on the SpectroSERVER host using OneClick. This setup involves the following steps:

1. Import the SDManager configuration file.
2. Model an SDConnector host.
3. Model the devices in secure domains that you want to manage.

Hardware Recommendations

Follow these recommendations to achieve an optimal Secure Domain Manager performance:

- To maintain an optimal SpectroSERVER modeling capacity, the SpectroSERVER/SDManager installation computer must have two CPUs: one dedicated to the SpectroSERVER and the other dedicated to servicing SDManager

functions. If SDManager and SpectroSERVER are required to share a single processor to manage network elements, SpectroSERVER modeling capacity reduces by 40%.

- We recommend that you have a host computer that is dedicated solely to running each SDConnector process you deploy. The SDConnector installation system requirements are the same as those for SpectroSERVER-only installations. Except for the special requirements of multiple disk configuration.

  NOTE
  For more information about installation requirements, see the Installing DX NetOps Spectrum section.
- An SDConnector has only one SDManager connected to it. Two SDManagers from fault-tolerant SpectroSERVERs can be connected to a single SDConnector, if that is a requirement for your setup. See Setting Up Processes in a Fault-Tolerant Environment for more information.

About SDConnector CPU and Memory Usage

The SDConnector uses half the CPU capacity that the SpectroSERVER uses to manage devices. If the SpectroSERVER computer uses 50 percent total CPU and all devices are managed using SDManager, the SDConnector uses approximately 25 percent of CPU capacity, on an equally powerful system. The major difference is that the SDConnector does not use much memory. If it is devoted as an SDConnector only, 512 MB of RAM suffices, although more RAM would be better.

Install the SDConnector Process

Before using Secure Domain Manager capabilities to manage devices and applications in secure networks with DX NetOps Spectrum, install a single SDConnector process on a host computer in the secure network. You must be an administrative user on your Windows system, or the root user on Linux systems when you install the SDConnector. To configure multiple SDC processes on a single server, refer to Configure Multiple SDC (Secure Domain Connector) processes on a single host computer.

NOTE
As a best practice before upgrading the SDConnector process on any platform, stop and if required kill the process. Stopping or killing the process ensures that the process runs properly after an upgrade.

To install SDConnector

1. On the nonSpectroSERVER host machine where you want to run SDConnector, launch the appropriate DX NetOps Spectrum installer for the platform.

   NOTE
   Only the SDConnector for the same operating environment as your SpectroSERVER is available for installation. If you have to install SDConnectors for other operating environments, contact CA Support. For information about launching the installer, see the Install DX NetOps Spectrum section.

   The Install dialog opens.
2. Select 'Install CA Secure Domain Connector.'
   The Introduction dialog opens.
3. Click Next to proceed.
   The License Agreement dialog opens.
4. Scroll through and read the license agreement, accept the agreement, and click Next.
   The Destination Location dialog opens.
5. Click Next to install the SDConnector in the default directory. The default directory is C:\Program Files\CA \SDMConnector on Windows and /usr/SDMConnector on Linux.
   To install the SDConnector in a location other than the default folder, click Choose, select a folder, and click Next. The Choose button only appears for a local installation (not for a nonlocal, remote installation).

NOTE
You cannot install the SDConnector into a directory that contains a space in the name.The Pre-Installation Summary dialog opens.

6. Click Install.
   The Installing SPECTRUM_SDM_Connector dialog opens. After the SDConnector is installed, the status changes to Install Complete and the Done button is enabled.
7. Click Done.
   The dialog closes.
8. Click Close on the initial Install dialog.
   SDConnector is installed on this host computer. The SDConnector is installed as a service, and starts automatically every time your system is restarted.

NOTE
You can also check the installation log located in the directory where SDConnector was installed to verify that the installation completed successfully.

Configure Multiple SDC (Secure Domain Connector) processes on a Single Server

Prerequisites for installing Secure Domain Connector (SDC)

- System requirements for SpectroSERVER and OneClick server
- Hardware recommendations for Secure Domain Manager (SDM) -Secure Domain Connector (SDC)

Configure multiple SDCs in a single machine (For Linux):

Follow these steps:

1. Extract the SDC_Install_<platform>.tgz file installed from the SpectroSERVER-side installation.
2. Stop Secure Domain Connector Service if already running on the linux server chosen for this setup.
3. Copy the extracted sdmc directory to SDConnector machine.
4. As `root` user, install SDC by running 'install.bin'.
5. Go to /opt/CA and make copies of the entire SDMConnector folder.

NOTE

Copy the SDMConnector folder as many times as the number of instances of SDMconnectors you would like to have.

6. Go to each SDC home (default /opt/CA/SDMConnector/) and change directory to bin.
7. Edit the sdc.rc file as below for each instance of SDMConnector:

```
icmp_listen_ip= <IP address for the instance>

snmp_comm_ip= <IP address for the instance>

snmp_comm_port= <Port for communication>

snmp_trap_ip= <IP address for the instance>
```

```
snmp_trap_port= <Port for SNMP traps>

snmp_trap_port_enabled= yes

snmp_trap_max_time_to_live_sec= 120

max_snmp_traps_per_sec= 300

snmpv3_default_auth_protocol= md5

snmpv3_default_priv_protocol= des

snmpv3_engine_id= <Leave this property blank>
```

8. Edit the **sdc.config** file, as follows:

```
-accept <IP address for the SDM>

-bind <IP address for the SDC instance>
```

9. Start each instance of SDMConnector using the command "./SdmConnectorService.exe --start".
10. Navigate to *<SPECROOT>*/SDM directory on the SpectroSERVER host machine and using a text editor, edit the **sdm.config** file to add a remoteconnect entry for each instance of SDMConnector as below:

```
-remoteconnect <IP address for the instance 1> -remoteconnect <IP address for the
 instance 2>
```

11. Import the SDM configuration from Oneclick.

You now have as many Secure Domain Connectors as you have configured on this server. All the SDC instances are bound to the SDM whose IP you have configured.

Configure multiple SDCs in a single machine (For Windows):

Follow these steps:

1. Extract the ***install.exe*** file from the SpectroSERVER-side installation (**Build Folder\sdmc\nt**) or use the **setupnt.exe > Install Secure Domain Connector**.
2. Stop the Secure Domain Connector Service (Navigate to services.msc on the Windows server and stop the service. (If the service is already running on the Windows server chosen for this setup).
3. Copy the extracted sdmc directory (**SDMConnector** folder) to SDConnector machine ***C:\Program Files\CA*** .
4. Navigate to **C:\Program Files\CA** and make copies of the entire SDMConnector folder.

NOTE

Copy the SDMConnector folder as many times as the number of instances of SDM connectors you would like to have.

5. Go to each SDC home (***C:\Program Files\CA\SDMConnector***) and change directory to ***C:\Program Files\CA\SDMConnector\bin*** .
6. In the same directory, edit the **sdc.rc** file for each instance of SDMConnector, as follows:

```
icmp_listen_ip= <IP address for the instance>

snmp_comm_ip= <IP address for the instance>

snmp_comm_port= <Port for communication>

snmp_trap_ip= <IP address for the instance>

snmp_trap_port= <Port for SNMP traps>

snmp_trap_port_enabled= yes

snmp_trap_max_time_to_live_sec= 120

max_snmp_traps_per_sec= 300

snmpv3_default_auth_protocol= md5

snmpv3_default_priv_protocol= des

snmpv3_engine_id= <Leave this property blank>

internal_name= <The name you specify here will be displayed in the Spectrum OneClick
 View>

display_name= <The name you specify here will be SDC connector/service name in the
 server you have installed>
```

7. Navigate to ***C:\Program Files\CA\SDMConnector\bin*** and install SDC using the **SdmConnectorService.exe --install.**
8. Edit the **sdc.config** file as follows:

```
-accept <IP address for the SDM>

-bind <IP address for the SDC instance>
```

9. Start each instance of SDMConnector by performing one of the following:
   – Use the command "./SdmConnectorService.exe --start"/
   – Double-click the SdmConnectorService.exe.
10. Navigate to the Spectroserver machine **<C:\win32app\Spectrum\SDM>**, edit the **sdm.config** file to add a remoteconnect entry for each instance of SDMConnector as specified below:

```
-remoteconnect <IP address for the instance 1> -remoteconnect <IP address for the
 instance 2>
```

11. Import the SDM configuration from Oneclick.
    You now have as many Secure Domain Connectors as you have configured on this server. All the SDC instances are bound to the SDM whose IP you have configured.

SDC TrapX Support

Introduction

TrapX is a Simple Network Management Protocol (SNMP) management application that receives and filters SNMP trap messages and forwards them to other management applications on other hosts and ports. With DX NetOps Spectrum TrapX, you can forward the traps to other management stations. 10.3.2 supports the new TrapX feature, that filters and forwards v1, v2, v3 traps to different products. The Secure Domain Connector (SDC) behaves as the TrapX, filters out v1, v2 and v3 traps, and pushes the filtered traps to the mentioned destination, converting the v2 to v1 and v3 to v1 translations.

DX NetOps Spectrum TrapX feature simplifies trap configuration and management and lets users focus on Information Technology (IT) resources on more strategic activities. CA TrapX is especially useful in environments where multiple management applications must receive trap messages from a diverse set of SNMP-capable devices that can issue messages to only a limited number of SNMP managers. Users can leverage TrapX for the following purposes:

- Filtering traps
- Forwarding traps to other trap receivers
- Forwarding traps to element managers
- Forwarding traps through TCP connections
- Extending fault tolerance for management software

Previously legacy TrapX did not support filtering or translating of v3 traps, but with the 10.3.2 release, the SDC TrapX supports filtering, translating and forwarding of v3 traps. This release also supports the v2 traps with 64-bit counters being translated to v1, which was a limitation with the legacy TrapX feature.

Considerations

Review the following considerations:

- From 10.4.2, you can convert an SDC setup into an SDC-TrapX setup by adding the trapX.config file. You can then add actions in it based on your requirements. You do not need to uninstall the existing environment. Note that the underlying approach has not been changed. For example, users can use their setup either as SDC or SDC-TrapX. They cannot use a combination of both. Similar to previous releases, users need to add -trapx -remoconnect <sdc ip> at SDM to process v3 traps for SDC-TrapX.

  NOTE

  - The trapX.config file should not be empty. It should have filters. The reason is that if it is empty (that is, no filters are added), then it will act as SDC and not SDC-TrapX.
  - If you have an SDC TrapX setup, you cannot convert that setup into an SDC setup by removing the trapX.config file because the NCM services will not be retrieved in this case.
  - You cannot convert an SDC High Availability (HA) setup to SDC TrapX HA setup by adding the trapx.config file. This functionality is not supported currently.
- To listen to the traps on the TCP SNMP port, you need to add the following line to the trapX.config file:
  `listen_for_tcp_traps on`
  An example is as follows:
  ```
  listen_for_tcp_traps on 161
  listen_for_tcp_traps off 161
  ```
  NOTE
  From 10.4.2, it is disabled (off) by default.
- Previously, multiple v3 profiles with the same username and unmanaged traps with that username were not processed by SpectroSERVER. With this release, multiple v3 profiles with the same username and unmanaged v3 traps with that username are processed by SpectroSERVER if the exact v3 local profile is present.
- If SDC is installed as TrapX then it does not function as a regular SDC, and does not model any device on a particular SDC-TrapX.

Supported Operating System

The SDC TrapX supports the following operating systems:

NOTE
DX NetOps Spectrum 10.4.2 has not been validated on Windows Server 2012. However, Broadcom will support any DX NetOps Spectrum product issues, if found. We reserve the right to have you upgrade to Windows Server 2016 (or later) if deemed necessary.

- Microsoft Windows Server 2012 R2 Standard Edition on a 64-bit processor
- Microsoft Windows Server 2016 Standard Edition on a 64-bit processor
- Microsoft Windows Server 2019 on a 64-bit processor
- Red Hat Enterprise Linux 7.x on a 64-bit processor
- Red Hat Enterprise Linux 8.0/8.1 on a 64-bit processor

Traps Management in DX NetOps Spectrum SDC TrapX

The following illustration shows how the DX NetOps Spectrum SDC TrapX can filter and forward traps to various devices.

Enabling SDC Support for TrapX

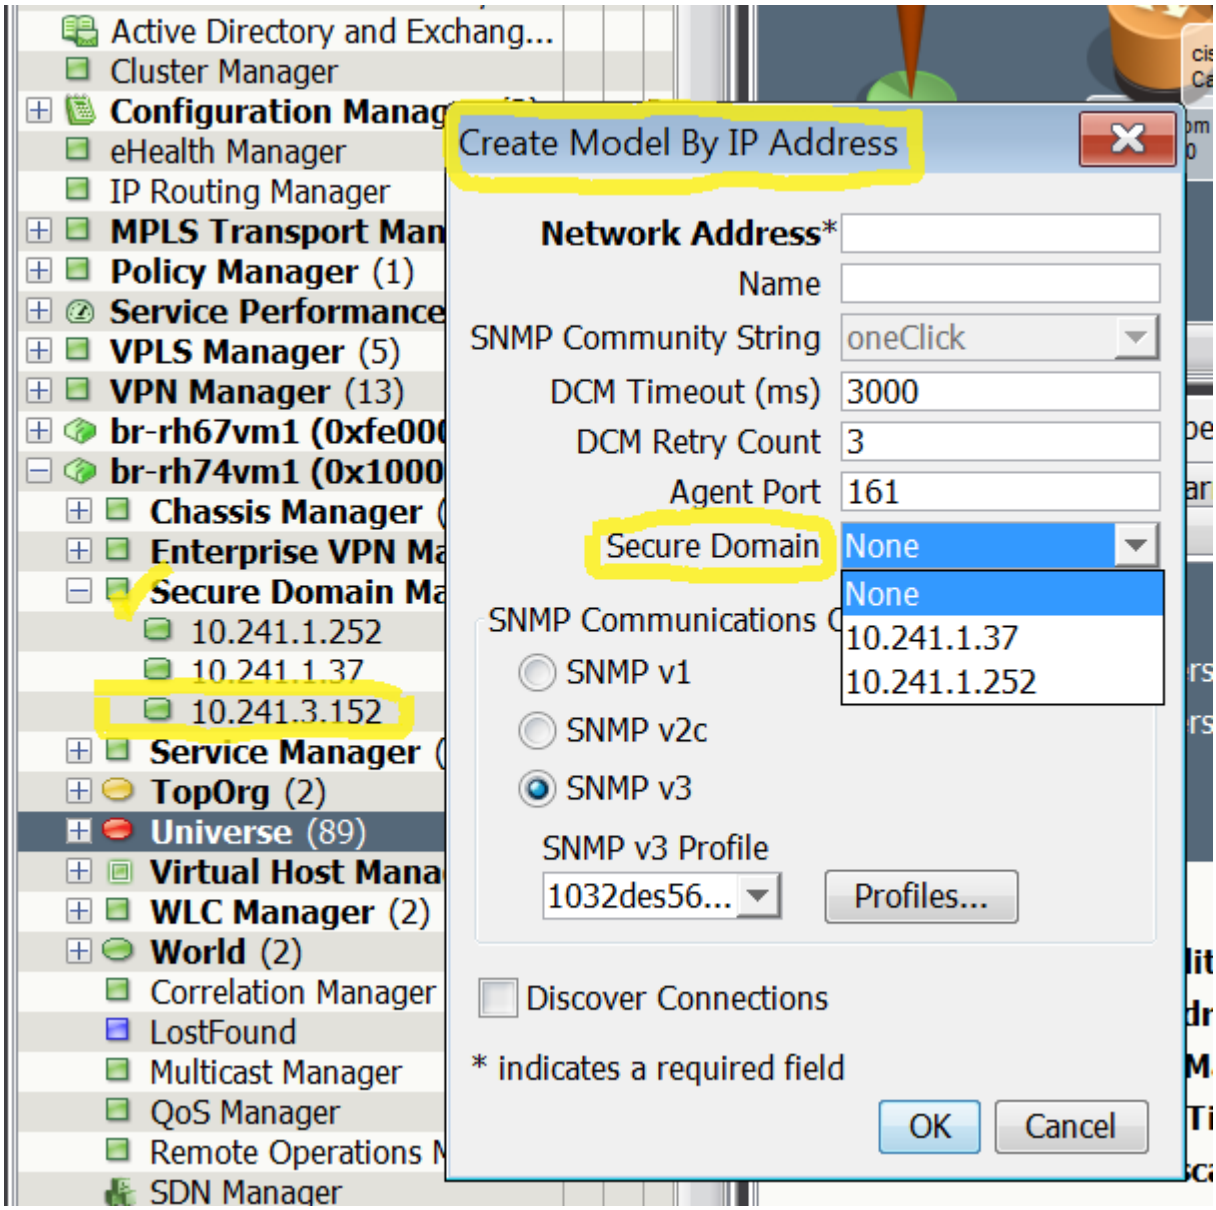
To convert the SDC feature into a TrapX capability, enable the TrapX checkbox during the Secure Domain Connector installation as shown here:

NOTE

Upgrading from SDC/TrapX, which is already installed, to TrapX/SDC through silent installation fails, and returns an error message in the "InstallationError.log" file under the SDMConnector/bin folder. For more information on the workaround, refer to the KB article on the CA support site.

Expected Behavior

- All v3 profiles created under the SDC domain during the SNMPv3 profile creation, are pushed to SDC for traps to be processed.
- If SDC is installed as TrapX then the same SDC cannot be used for managing devices (includes polling) under the Secure Domain. It is recommended to have a dedicated VM/physical box to deploy SDC TrapX.
- SDC profiles created under the Secure Domain Manager (SDM) are not modeled under the Model By IP, Discovery Console and the MIB Tools. For example, **10.241.3.152** is a SDC TrapX, listed under the 'Secure Domain Manager', as shown in the screenshot below, but **10.241.3.152** does not get modeled under the 'Secure Domain' list in the 'Model By IP Address' window.



SpectroSERVER and SDC TrapX Support on the Same Computer

Users can install SDC TrapX on a SpectroSERVER computer provided SDC TrapX and SpectroSERVER versions are the same.

NOTE

In this scenario, the SNMP communication port must be changed on SpectroSERVER and SDC. Both SpectroSERVER and SDC will be listening on 162.

For SpectroSERVER, change the value of the snmp_comm_port parameter in the $SPECROOT\SS\bin.vnmrc file.

For SDC, change the value of the snmp_comm_port parameter in the /opt/CA/SDMConnector/bin/sdc.rc file.

Configure Filters

To configure filters:

- Create the trapX.config file.
- Add the filters in the configuration file. For filter expressions for TrapX use the following format:

```
filter DateTime SrcIP Agent TrapType SpecificType Enterprise Action [Option]
```

Filter Name/Type	Description	Filter Value
DateTime (Optional)	A regular expression indicating the date and time that the trap was received by SDC TrapX.	For example, Fri May 11 09:23:34 EDT 2001. **Note**: This value does not necessarily indicate the time that the trap was sent by the device.
SrcIP (Optional)	An IP address-based regular expression that SDC TrapX uses to match the source IP, as in the IP packet header. The IP address from which the trap was received is not always equivalent to the agent IP address in the Trap PDU. The regular expression indicates that any IP address causes a match. You can specify a host name instead of an IP address for this field.	
AgentIP (Optional)	An IP address-based regular expression that SDC TrapX uses to match the IP address of the managed object that generated the trap (as in the Agent IP Address field in the Trap PDU). The IP address from which the trap was received is not always equivalent to the agent IP address in the Trap PDU. The regular expression indicates that any IP address causes a match. You can specify a host name instead of an IP address for this field. **Note**: Ensure that you add a backslash character (\) before any period (.) components that appear within the IP address. The period (.) is a special character in regular expression syntax.	
TrapType (Optional)	An integer-based regular expression that SDC TrapX compares to the Trap PDU's TrapType field.	Following are the Valid SNMP TrapType values: ■ coldStart(0) ■ warmStart(1) ■ linkDown(2) ■ linkUp(3) ■ authenticationFailure(4) ■ egpNeighborloss(5) ■ enterpriseSpecific(6)
SpecificType (Optional)	An integer-based regular expression that SDC TrapX compares to the Trap PDU's SpecificType field. Any integer is a valid value for this field.	
Enterprise (Optional)	An OID-based regular expression that SDC TrapX compares to the Trap PDU's enterprise field. **Note**: Ensure that you add a backslash character (\) before any period (.) components that appear within the OID. The period (.) is a special character in regular expression syntax.	

Action (Optional)	Action (Optional) A keyword that indicates the action that SDC TrapX performs, they include:
	• **file:** Logs the Trap PDU to a file specified by the Option field. SDC TrapX creates the file if it does not exist. This option is applicable only for SNMPv1 traps SNMPv2 traps, when performing SNMPv2c to SNMPv1 trap translation.
	• **forward:** Forwards the Trap PDU through UDP to a host specified by the Option field. Use this option if the trap receiver does not support TCP or if the TCP connection is broken.
	• **break:** This action causes no action to be taken for a given trap. No further filter processing is done on the current Trap PDU, and does not evaluate any remaining filters for the current Trap. Any option to this action is ignored.
	• **Tcp:** Forwards traps through a TCP connection without buffering the traps. This action drops the traps if SDC TrapX cannot connect to the remote trap receiver.
	• **Tcpbuff:** Forwards traps through a TCP connection. This action saves traps until SDC TrapX is able to connect to the remote trap receiver (or until the timeout limit is reached). Number of traps that are buffered depends on the queue size that is specified in the filter.
	Note: If you are using the tcp or tcpbuff actions and you receive the error message, “SDC TrapX: tcp forw detected a broken socket to: [port],” the TCP connection is broken or invalid. Use the forward action (which forwards traps through UDP).
	• **blind:** Forwards traps without parsing or decoding them first. This feature is useful for forwarding malformed traps or unsupported SNMP versions. It enables filtering only on the source IP address.
	• **exec:** This action executes a program or a script. The path to the script should be an absolute path, and the entire path and arguments must be enclosed in single quotes. For example: **exec '/path/to/script [arg1 [arg2...]] '**
	`exec '/tmp/trapScript.pl 0 123 4321'`
	`exec 'c:\temp\trapScript.pl 0 123 4321'`
	To run a script, give an absolute path of executable as well, for example:
	`filter * * * * * * exec 'C:\\win32app\\Spectrum\ \bin\\perl.exe C:\\abc.pl'`
	• **nat:** This action translates the agent-addr field in the trap to another IP address.
	Note: This action only does the address conversion. No forwarding is implied by this action. Therefore, place this rule before any forwarding rules that the nat action should be in effect. For example: **nat new-agent-addr** or **nat 1.2.3.4**
	• **tunnelfwd:** This action lets you forward traps through the SDC-SS tunnel. This action works only in that environment where SDC and SS are connected. For example, the -remoteconnect <sdc ip> option in sdm.config and the -accept <ss ip > option in sdc.config.
	An example of the tunnelfwd action is as follows:
	`filter * * * * * * tunnelfwd`
	Another example is as follows. This example can filter traps that are modeled on SDC:
	`filter * 1\.74\.24\.139 * * * * tunnelfwd` SDC TrapX will forward traps to all the connected SpectroSERVERs.	

NOTE

Restart the SDC services if you have modified the trapX.config file (for example, filters or global parameters).

NOTE

The TrapX feature from SDM supports the -remoteconnect parameter and from SDC supports the -accept parameter.

Enable Translation

You can globally enable translation of SNMP v2c traps to SNMPv1 traps by adding the translate_v2c_traps option to the trapX.config file. Follow these steps:

1. Add **translate_v2c_traps** in a trapX.config file.
2. If the device sends v2c traps without the snmpTrapAddress, enable the following option:
   agentaddr_is_srcaddr_translated_v1
   This option makes the v2c trap agent address the same as the source address. This option is used when the v2c to v1 translation and v3 to v1 translation is enabled. If this translation is not enabled, this option cannot be used.

To enable translation of SNMPv3 traps to SNMPv1 traps add translate_v3_traps:1:test to the conf. file. For example:

```
filter * * * * * * forward  138.42.86.54 translate_v3_traps:1:xyz
```

Here option 1 is to enable transition, it coverts v3 traps to v1 with the community string if this option not provided it will it take public.

Sample Filters

This section includes sample filters that you can add to the trapX.config file. To add the filters:

Ensure that you have first created the trapX.config file. You can use these examples to help design filters suitable for your environment. In these examples, asterisks (*) indicate placeholders for fields for which you do not want to filter on a specific value.

- **Match Trap PDUs from a Local Host:** These examples match all Trap PDUs from the local host, and effectively drop and suspend filter processing for them.
  ```
  filter * * 127\.0\.0\.1 * * * break
  filter * * ::1 * * * break
  ```

  NOTE

  By default, SDC trapX listens for traps on UDP port 162 and on TCP port 161 (if listening is enabled on the TCP port). You can configure these ports by changing the "snmp_trap_port=" value in the sdc.rc file for UDP and the trapX.config file for TCP.

- **Match Authentication Failure Traps:** This example matches all authenticationFailure (4) traps and forwards them to the system named concord at UDP port 162 (the default).
  ```
  filter * * * 4 * * forward concord
  ```
- **Match Private-Enterprise Traps:** This example matches all private-enterprise traps of SpecificType 3 through 8 and forwards them to the system named concord at UDP port 191.
  ```
  filter * * * 6 [3-8] * forward concord:191
  ```
- **Match Traps by Enterprise OID**: This example matches all traps that contain the enterprise OID 1.3.6.1.4.1.546.1.1 and forwards them to the system named ottoman at UDP port 162 (the default).
  ```
  filter * * * * * 1\.3\.6\.1\.4\.1\.546\.1\.1 forward ottoman
  ```

  NOTE

  A backslash character (\) appears before each period character (.) so that the period character is read correctly as part of the enterprise ID and not as a regular expression wildcard operation.

- **Match Traps by Date:** This example matches all traps that SDC TrapX received on Friday and forwards them to the system named ottoman.
```
filter "Fri" * * * * * forward ottoman
```
- **Match Traps by Source IP Address:** These examples match all traps that originated from the source IPv4 address 199.250.183.215 and forwards them to the system named ottoman.
```
filter * 199\.250\.183\.215 * * * * forward ottoman
filter * fe80::a00:20ff:fe8c:af7e * * * * forward ottoman
```
- **Match Traps by Agent IP Address:** These examples match all traps that were sent by a managed object with an IPv4 address of 199.250.183.215 and forwards them to the system named ottoman.
```
filter * * 199\.250\.183\.215 * * * forward ottoman
 filter * * fe80::a00:20ff:fe8c:af7e * * * forward ottoman
```
- **agentaddr_is_srcaddr_translated_v1:** This command works with translate_v2c_traps and translate_v3_traps, when translate_v2c_traps or translate_v3_traps are turned on, this makes the v2c trap or v3 trap agent address as the source address. By default it is commented out.

Varbind Filtering

The 10.4.1 release supports the SDC TrapX varbind filtering. This filtering supports the following operations that you can use with a combination of **AND** and **OR** statements:

- Equals
- NotEquals
- StartsWith
- EndsWith
- Contains
- NotContains

Some examples are as follows:

- **AND example:** In the following example, if all the operations are mentioned inside AND[] and if they are matched, then traps get processed:
```
filter * * * * * 1.3.6.1.6.3.1.1.5   forward 10.241.3.151 translate_v3_traps:0:public
"AND[1.3.6.1.2.1.2.2.1.2.1:Equals:FastEthernet0/0,1.3.6.1.4.1.9.2.2.1.1.20.1:EndsWith:p,1.3.6
```
- **OR example:** In the following example, if either one of the operations is inside OR[] and if it matches, then traps get processed:
```
filter * * * * * 1.3.6.1.6.3.1.1.5   forward 10.241.3.151 translate_v3_traps:0:public
"OR[1.3.6.1.2.1.2.2.1.2.1:Equals:FastEthernet0/0,1.3.6.1.4.1.9.2.2.1.1.20.1:EndsWith:p,1.3.6.
```
- **file example:** The following is a file example:
```
filter * * * * * 1.3.6.1.6.3.1.1.5  file /opt/CA/SDMConnector/bin/trapX.txt
 "AND[1.3.6.1.4.1.9.2.2.1.1.20.1:Equals:Link Down Trap]" 10
filter * * * * * *  file /opt/CA/SDMConnector/bin/trapX1.txt * 10
```
(10 represent file size; it is optional.)
- **break statement:** If you want to forward all the traps without filtering except a few traps with varbind filters, then you can review the following example. In this example, all the traps are forwarded to the destination 10.241.3.151 except traps 1.3.6.1.6.3.1.1.5 and 1.3.6.1.4.1.9.9.187.
1.3.6.1.6.3.1.1.5 traps are forwarded to the destination 10.241.3.151 when the varbind filter criteria matches and then the break statement does not execute further filters. This ensures that traps of these types are not forwarded to the destination again if the varbind filter criteria is a success or failure.

1.3.6.1.4.1.9.9.187 traps are forwarded to the destination 10.241.3.151 when the varbind filter criteria matches and then the break statement does not execute further filters. This ensures that traps of these types are not forwarded to the destination again if the varbind filter criteria is a success or failure.

```
filter * * * * * 1.3.6.1.6.3.1.1.5 forward 10.241.3.151 translate_v3_traps:0:public
"AND[1.3.6.1.6.3.1.1.4.1.0:Equals:1.3.6.1.6.3.1.1.5.3]"
filter * * * * * 1.3.6.1.6.3.1.1.5 break
filter * * * * * 1.3.6.1.4.1.9.9.187 forward 10.241.3.151 translate_v3_traps:1:public
"AND[1.3.6.1.6.3.1.1.4.1.0:Equals:1.3.6.1.4.1.9.9.187.0.2]"
filter * * * * * 1.3.6.1.4.1.9.9.187 break
```

- **tcp buff:** The following is a tcp buff example:

```
filter * * * * * 1.3.6.1.4.1.9.9.276.0.1.0.1 tcpbuff  10.241.3.151:5058
 translate_v3_traps:0:public 60 300 AND["1.3.6.1.2.1.2.2.1.7.436240384:equals:1"]
```

- **tcp forward:** The following is a tcp forward example:

```
filter * * * * * 1.3.6.1.4 tcp  138.42.246.37:1771  translate_v3_traps:0:public 300
 AND["1.3.6.1.2.1.2.2.1.1:Contains:10]"
```

Forward Traps through TCP Connections

TrapX can forward traps through TCP connections when you specify the host name (or IP address), port, and a connection timeout value. TrapX provides two actions for forwarding traps through TCP: tcp and tcpbuff. When you specify the tcp action for trap filtering in the TrapX file, TrapX does not buffer the traps. In that case, if the trap receiver is unavailable, TrapX drops the traps. When you specify the tcpbuff action, TrapX can queue the traps and then send them when the trap receiver restarts, providing better management of TCP connections than the tcp action provides. You can forward traps through TCP with or without buffering. To buffer the traps (save them if the trap receiver is unavailable), use the tcpbuff action. To filter traps without buffering them, use the tcp action. For example:

NOTE

Forwarding traps through TCP does not provide security, privacy, or authentication. It simply enhances the reliability of the trap reception. Listen_for_tcp_traps on 1771 and forward the traps on the TCP port in trapX.config file. For example, filter * * * * * * tcp 10.241.3.151:1771 translate_v3_traps 300

- **Filter Traps through TCP with buffering**: This example forwards traps through a TCP connection to a system with a hostname of violet on port 5058 with a buffer size equivalent to 60 traps and a timeout value of 300 seconds.

```
filter * * * * * *  tcpbuff  violet:5058  translate_v3_traps 60 300
```

  CA SDC TrapX buffer traps in a buffer that can hold a maximum of 60 traps for 300 seconds before dropping them.
- **Filter Traps through TCP without buffering**: This example forwards traps without buffering through a TCP connection to a system with a hostname of electrode on port 162 with a timeout value of 30 seconds.

```
filter * * * * * * tcp electrode:162 30
```

- **Forward Traps through UDP Connections:** This example forwards traps through a UDP connection to a system with a hostname of orange on port 5058. You can forward traps through UDP when the trap receiver does not support TCP.

```
filter * * * * * * forward orange:5058
```

- **Forward Traps Blindly** This example forwards traps to a system with a hostname of lemon on port 5058 without parsing or decoding. You can blindly forward traps without parsing or decoding.

```
filter * * * * * * blind lemon:5058
```

SDC TrapX Limitations

The limitations with this feature include:

- The multi-nic and SDC TrapX High Availability (HA) are not supported with this release.
- Installing SDC Trapx on an SDC computer is not supported.
- The filters that not supported with this release are listed as follows:

Filter Name	Value	Description
overloaded_header	overloaded_header	This flag overloads 16-byte agent IP address into SNMPv1 trap PDU, while translating v2c traps to v1. This flag is effective only when the translate_v2c_traps flag is on.
so_rcvbuf <buffer-size-in-bytes>	so_rcvbuf 128000	This command sets the size of the socket receive buffer. This applies to both the UDP and TCP listening sockets. The default is 128000 bytes.
tcp_receive_timeout <timeout-in-seconds>	tcp_receive_timeout 5	This command defines the timeout for recv() operations on the TCP listen socket, in seconds. Essentially, this keeps TrapEXPLODER from being indefinitely blocked by a rogue TCP connection. A value of 0 disables the timeout, allowing TCP recv() operations to block indefinitely. This option only has an effect if listen_for_tcp_traps is set to 'on'. The default is 5 seconds.
'aview' action	aview /opt/aview/var/traps aview c:\aview\var\traps	This action writes out traps in the aview format. This action does not work, if the Trap Exploder is running on an eHealth® machine with a Fault Manager license present.
'eh' action	eh 1.2.3.4:666 666 30	This action is used with CA eHealth® 5.0 to forward traps to the eHealth trap receiver. This action is deprecated with CA eHealth® 5.5 and higher.

Installation Files

Be aware of the following directories and files that are created during the installation process.

On the SpectroSERVER

The DX NetOps Spectrum installation process installs the following Secure Domain Manager directories and files in the <*$SPECROOT*>/SDM directory on the SpectroSERVER:

- **cert**
  This directory is the repository for the SSL certificates you create for the SDManager.
- **Logs**
  This directory contains output logs that are generated when you import a configuration file to the SpectroSERVER. Detail of the work that is performed. The work includes any errors that occur, are contained in the log file.
- **README**
  This file provides details on how to configure Secure Domain Manager on the SpectroSERVER host.

On the SDConnector Host

The SDConnector installation process installs the following directories and files in the SDMConnector directory on the SDConnector host:

- **bin**
  This folder contains the following items for working with the SDConnector:
  - **cert**
    This directory is the repository for the SSL certificates you create for the SDConnector.
  - **README**
    This file provides details on how to configure the SDConnector process on the SDConnector host.
  - **SdmConnectorService[.exe]**
    The executable file for the SDConnector.

Change Permissions (.ssh\config) on SDC Cygwin

In 10.4.2, Cygwin 3.1 with Perl modules is shipped with SDC on Windows. These modules are required for executing scripts to perform NCM operations on SDC-managed devices. On Linux, it must be installed manually.

> **NOTE**
> For more information about scripts, see the Perl Modules section in Network Configuration Manager Extension Utility. For more information about NCM operations on SDC-modeled devices, see NCM Enablement in Secure Domain.

You must change the permissions under .ssh\config from SYSTEM to Administrator on the SDC Cygwin to perform the configurations.

1. Open the command prompt.
2. Navigate to the "$SDCINSTALL$NT_TOOLS/SDCRE" directory.
   For example, "cd C:\Program Files\CA\SDMConnector\NT-TOOLS\SDCRE"
3. Execute `sdc.bat uninstall` .
   This command changes the permissions to Administrator.
4. Open and perform the required changes to the configuration ("$SDCINSTALL$\NT-TOOLS\SDCRE\home\SYSTEM \.ssh\config").
   For example, C:\Program Files\CA\SDMConnector\NT-TOOLS\SDCRE\home\SYSTEM\.ssh\config
5. Execute `sdc.bat install` .
   This command changes the permissions back to SYSTEM.

Working with Certificates

Certificates are loaded by default for both SDManager and SDConnector. This lets you use the SSL encryption to secure ICMP and SNMP (SNMPv1, SNMPv2c, and SNMPv3) data that is transmitted between SDManager and SDConnector hosts across nonsecured networks. If you do not want to use the SSL encryption for any SDManager-SDConnector connections in your network environment, include the nonsecure option in the configuration files for SDManager and SDConnectors. For more information about how to use the nosecure optionsee Configure SDConnector Process Settings.

Create Certificates

Secure Domain Manager uses digital certificates to ensure the security. The default certificates are provided with your DX NetOps Spectrum installation and site-specific certificates can be created using the CertGen tool.

Default Certificates

If you want to use the default certificates, do not perform any actions. All default files reside in the <*$SPECROOT*>/SDM/cert directory and include the following files:

- **SDMCA.pem**
  Certificate authority. Distribute this file to any computer that uses Secure Domain Manager or Secure Domain Connector in any capacity and can be treated as a trusted CA file.
- **SDMCAKey.pem**
  Private key of CA. It can be used to issue certificates but should not necessarily be distributed to any machines.
- **SDMCert.p12**
  Application certificate that is signed by SDMCA.pem. This is the certificate file that is used between SDManager and SDConnector. It should be carefully distributed to computers that deserve trust and used to assert the identity of those computers.
- **CertGen[.exe]**
  Program that is used to generate the site-specific certificate authority, key file, and certificate file. Run CertGen -h to review all certificate options available.
- **openssl[.exe]**
  OpenSSL open source implementation of the SSL protocol.

Site-Specific Certificates

If you want to create site-specific certificates, move the default certificate files (*.pem and *.p12) to another location on the hard drive. Perform the following procedures to create and deploy the custom certificates.

Create Site-Specific Certificates

Create site-specific certificates for better security. Create these certificates on a single computer that only qualified personnel can access. This computer can be the SDManager host.

> **WARNING**
> You must have administrator or root privileges to create the SSL certificates for Secure Domain Manager.

Follow these steps:

1. Run the following command to create a certificate authority certificate and the private key for the certificate authority certificate:
   ```
   CertGen -t ca -c US
   ```
   You only have to perform this step once to create the necessary certificate authority certificate for your organization. The following files are created:
   a. SDMCA.pem
   b. SDMCAKey.pem

   > **NOTE**
   > The default certificate authority and key file that come with Secure Domain Manager are read-only files. If you receive a permission error, check your user privileges or move SDMCA.pem and SDMCAKey.pem to another location and run the command again.
2. Run the following command to create a certificate for the SDManager:
   ```
   CertGen -t cert -c <Country Code>
   ```
   The SDMCert.01.p12 file is created.
3. (Optional) For the added security, use the -p option to generate the certificate with a password as follows:
   ```
   CertGen -t cert -p <password> -c <Country Code>
   ```
   Enter the password in the sdc.config file and sdm.config file.
4. Rename SDMCert.01.p12 to SDMCert.p12.

The new site-specific certificate is ready for use.

Deploy Site-Specific Certificates

After you create your certificate files, perform the following tasks:

- Deploy the certificate files on the SDManager hosts and on the SDConnector hosts.
- Restart the SpectroSERVER on the SDManager hosts and the SDConnector process on the SDC hosts.

To deploy certificates, copy the SDMCA.pem file that you created to the <*$SPECROOT*>/SDM/cert directory on the SDManager host computer and to the cert directory under the SDConnector installation on the SDConnector hosts that will connect to the SDManager host. Administrator, or root should own the SDMCert.p12 file.

WARNING
Retain the SDMCAKey.pem file on the computer where you plan to create more certificates. Restrict the file to authorized personnel only. This computer can be the SDManager host computer but is not a requirement.

After the certificates have been deployed, restart both the SpectroSERVER on the SDManager hosts and the SDConnector process on the SDC hosts. For information on restarting the SDConnector Process, see Start, Stop, and Restart the SDConnector Process on Windows or Start, Stop, and Restart the SDConnector Process on Linux.

Configure SDConnector Process Settings

This section describes the configuration options you can set in the SDConnector configuration file (sdc.config). This configuration file is read at startup and the options specified are applied at that time. Only one line of options is accepted in the sdc.config. The following is a sample line from an sdc.config file. It specifies that the SDConnector will accept connections from SDManager (192.168.0.2):

```
-accept 192.168.0.2
```

To configure SDConnector settings

1. Create (or open, if it already exists) a file named 'sdc.config' in the SDMConnector\bin directory on the SDConnector host machine using a text editor.
2. Add and specify details for the following options on one line in the file, according to your particular requirements:
   - **-accept remote_ipaddr:[local_port]**
     Accepts a connection from an SDManager running on a host at address <*ip*> at local port number < *port*>. Connections must originate from the IP address specified; otherwise, connection attempts are disregarded.
     If this option is specified, the SDManager that connects to this SDConnector must have the -remoteconnect option that specifies this SDConnector <*ip*> in its configuration file (sdm.config). Also, if this option is specified you cannot connect (-connect) to that SDManager.
   - **-buffersize <*size*>**
     Specifies the size of the send and receive socket buffer sizes in bytes.
     Default: 262,144 (256k, which should be sufficient in most deployments)
   - **-certdir <*dir*>**
     Specifies the directory for SSL certificates (application certificate, private key, and the certificate authority certificate) if they are not located in the default directory (/cert).
     If the -nosecure option is specified, certificates are not accessed.
   - **-certpassword <passwd>**
     Provides the certificate password. If you are using the default certificates that ship with Secure Domain Manager, then -certpassword need not be supplied. Otherwise, supply the certificate password using this option. If the password contains spaces, it must be enclosed in quotation marks ("). DX NetOps Spectrum assumes that the password for the application certificate will be encrypted.

NOTE
If you use -certpassword, it must be the first option declared in the config file.

- **-connect remote_ipaddr:[remote_port]**
  Connects to the SDManager running on a host at IP address <*ip*> and port <*port*>. If <*port*> is not specified, 6844 is assumed.
  If this option is specified, the SDManager to which this SDConnector connects must have the -remoteaccept option that specifies this SDConnector's IP address in its configuration file (sdm.config).
  If this option is specified, this SDConnector cannot accept (-accept) connections from or listen (-listen) for connections from the specified SDManager (sdm.config).
- **-keepalive <*n*>**
  Changes the default internal timeout (in seconds) when the SDManager or SDConnector sends out a small message to verify the network connection is still alive. If either the SDManager or an SDConnector does not hear from the other within three times the value of <*n*>, the connection is terminated.
  Default: 10 seconds
- **-listen [port]**
  By default, the SDConnector listens at port 6844 for connection requests from any SDManagers. However, if any -connect or -accept options are specified, then the SDConnector no longer listens by default.
  A port specified in a -listen option trumps a port specified in an -accept option. That is, if a port is specified in a -listen option, there will be no verification done of the source IP address for that port.
  Note: -listen and -listen6 are mutually exclusive.
- **-listen6 [local_port]**
  Accept connections from any IPv6 SDManager on the given port.

  NOTE
  -listen and -listen6 are mutually exclusive.
- **-loglevel fatal|error|warning|info|debug**
  Specifies the types of messages to log.
  Default: warning (includes error and fatal as well)
- **-maxlogsize <*n*>**
  Sets the maximum sdmLog.log size in megabytes.
  Default: 5M
  Minimum: 1M
- **-nosecure**
  Disables Secure Socket Layers (SSL) security, which is enabled by default. If the -nosecure option is used before any -connect or -accept entries, SSL is disabled for all connections. Otherwise, you can specify the -nosecure option after each -connect or -accept entry and it will pertain just to that entry.
  If SSL security is requested, the data stream is encrypted, and mutual cryptographic authentication is enforced. If either the SDManager or the SDConnector requests security, then security is mandatory on that connection.
- **-trappoll <*n*>**
  Forward traps to the SDManager every <*n*> seconds.
  Default: 15 seconds
- **-withfips**
  Specifies to run with FIPS mode. FIPS mode is off by default.

  NOTE
  If an empty sdc.config is created, SDConnector listens for connections from any SDManager on port 6844; the SDManager initiates the connection.

3. Save and exit the file.
   The SDConnector is configured.

   NOTE
   You must restart the SDConnector process every time you make updates to the sdc.config file.

Configure SDManager Process Settings

The SDManager configuration file (sdm.config) specifies the operational settings for the SDManager process. By default, the SDManager process is disabled. The SDManager process will not work until you create the sdm.config file and configure it according to your needs. After you configure the sdm.config file for the first time, or any time you revise its settings, you must import it into DX NetOps Spectrum to put SDManager settings into effect on the SpectroSERVER. For more information, see Import the SDManager Configuration File. You can configure the sdm.config either before or after the SpectroSERVER is started.

Only one line of options is accepted in the sdm.config. The following is a sample line of options for an sdm.config. It is specifying the connections (-remoteconnect) to two SDConnectors (172.24.148.196 and 172.19.32.199):

```
-remoteconnect 172.24.148.196 -remoteconnect 172.19.32.199
```

NOTE
If you use the -nosecure option to launch one or more of the SDConnector processes, you must specify the same -nosecure option for the corresponding -remoteconnect/-remoteaccept entry in the SDManager options, or simply specify -nosecure before all -remoteconnect/-remoteaccept entries to disable SSL for all connections.

To configure SDManager settings

1. Create (or open, if it already exists) a file named 'sdm.config' in the <*SPECROOT*>\SDM directory on the SpectroSERVER host machine using a text editor.
2. Add and specify details for the following options on one line in the file, according to your particular requirements:
   - **-apiclientport [port]**
     Sets the port to listen for API client connections. This parameter applies to the stand-alone SDManager process only.
   - **-buffersize <*size*>**
     Specifies the size of the send and receive socket buffer sizes in bytes.
     Default: 262,144 (256k, which should be sufficient in most deployments)
   - **-certdir <*dir*>**
     Specifies the directory for SSL certificates (application certificate, private key, and the certificate authority certificate) if they are not located in the default directory (/cert).
     If the -nosecure option is specified, certificates are not accessed.
   - **-certpassword <passwd>**
     Provides the certificate password. If you are using the default certificates that ship with Secure Domain Manager, then -certpassword need not be supplied. Otherwise, supply the certificate password using this option. If the password contains spaces, it must be enclosed in quotation marks ("). DX NetOps Spectrum assumes that the password for the application certificate will be encrypted.

     NOTE
     If you use -certpassword, it must be the first option declared in the config file.
   - **-clientServiceThreads <*n*>**
     Sets the number of threads per client that will process requests. This parameter applies to the stand-alone SDManager process only.
   - **-keepalive <*n*>**
     Changes the default internal timeout (in seconds) when the SDManager or SDConnector sends out a small message to verify the network connection is still alive.
     Default: 10 seconds
     If either the SDManager or an SDConnector does not hear from the other within three times the value of <*n*>, the connection is terminated.
   - **-loglevel fatal|error|warning|info|debug**
     Specifies the types of messages to log.

Default: warning (includes error and fatal as well)

- **-maxapiconnections <*n*>**
  Sets the maximum number of API client connections to <*n*>. This parameter applies to the stand-alone SDManager process only.
- **-maxlogsize <*n*>**
  Sets the maximum sdmLog.log size in megabytes.
  Default: 5M
  Minimum: 1M
- **-nosecure**
  Disables the Secure Socket Layers (SSL) functionality, which is enabled by default. If the -nosecure option is used before any -remoteconnect or -remoteaccept entries, SSL is disabled for all connections. Otherwise, you can specify the -nosecure option after each -remoteconnect or -remoteaccept entry and it will pertain just to that entry. If SSL security is requested, the data stream is encrypted, and mutual cryptographic authentication is enforced. If either the SDManager or the SDConnector requests security, then security is mandatory on that connection.
- **-remoteaccept remote_ipaddr[:local_port]**
  Accepts a connection from an SDConnector running on a host at address <*ip*> at local port number < *port*>. You must specify the SDConnector's public IP address.
  If this option is specified, the SDConnector that connects to this SDManager must have the -connect option that specifies this SDManager's IP address in its configuration file (sdc.config). Also, if this option is specified, you cannot connect (-remoteconnect) to the SDConnector (sdc.config).
- **-remotebackup (-remb) remote_ipaddr[:remote_port]**
  Specifies the backup SDConnector in a fault-tolerant Secure Domain Manager setup using the SDConnector's public IP address. For more information, See Setting Up Processes in a Fault-Tolerant Environment.
- **-remoteconnect remote_ipaddr[:remote_port]**
  Connects to the SDConnector running on a host at IP address <*ip*> and < *port*>. If < *port*> is not specified, 6844 is assumed. You must specify the SDConnector's public IP address.
  If this option is specified, the SDConnector to which this SDManager connects must have the -accept option that specifies this SDManager or the -listen option in its configuration file (sdc.config). Also, if this option is specified you cannot accept connections (-remoteaccept) from the specified SDConnector in this configuration file.
- **-withfips**
  Specifies to run with FIPS mode. FIPS mode is off by default. If changing the configuration from FIPS mode to non-FIPS, or vice versa, you must restart the application.

NOTE
If the sdm.config file is empty, the SDManager process is disabled.

3. Save and close the sdm.config file.
   The SDManager is configured.

Start, Stop, and Restart the SDConnector Process on Windows

Use the Services manager to start, stop, or restart the SDConnector process. The SDConnector process is listed under the name 'Secure Domain Connector.'

Start, Stop, and Restart the SDConnector Process on Linux

To start the SDConnector process, log in as root, open a command line console, and enter the following commands:
In 10.4.2, run the following command:

```
$ cd /etc/init.d
$ ./sdmconnector start
```

In 10.4.2.1, run the following command:

```
systemctl start sdmconnector
```

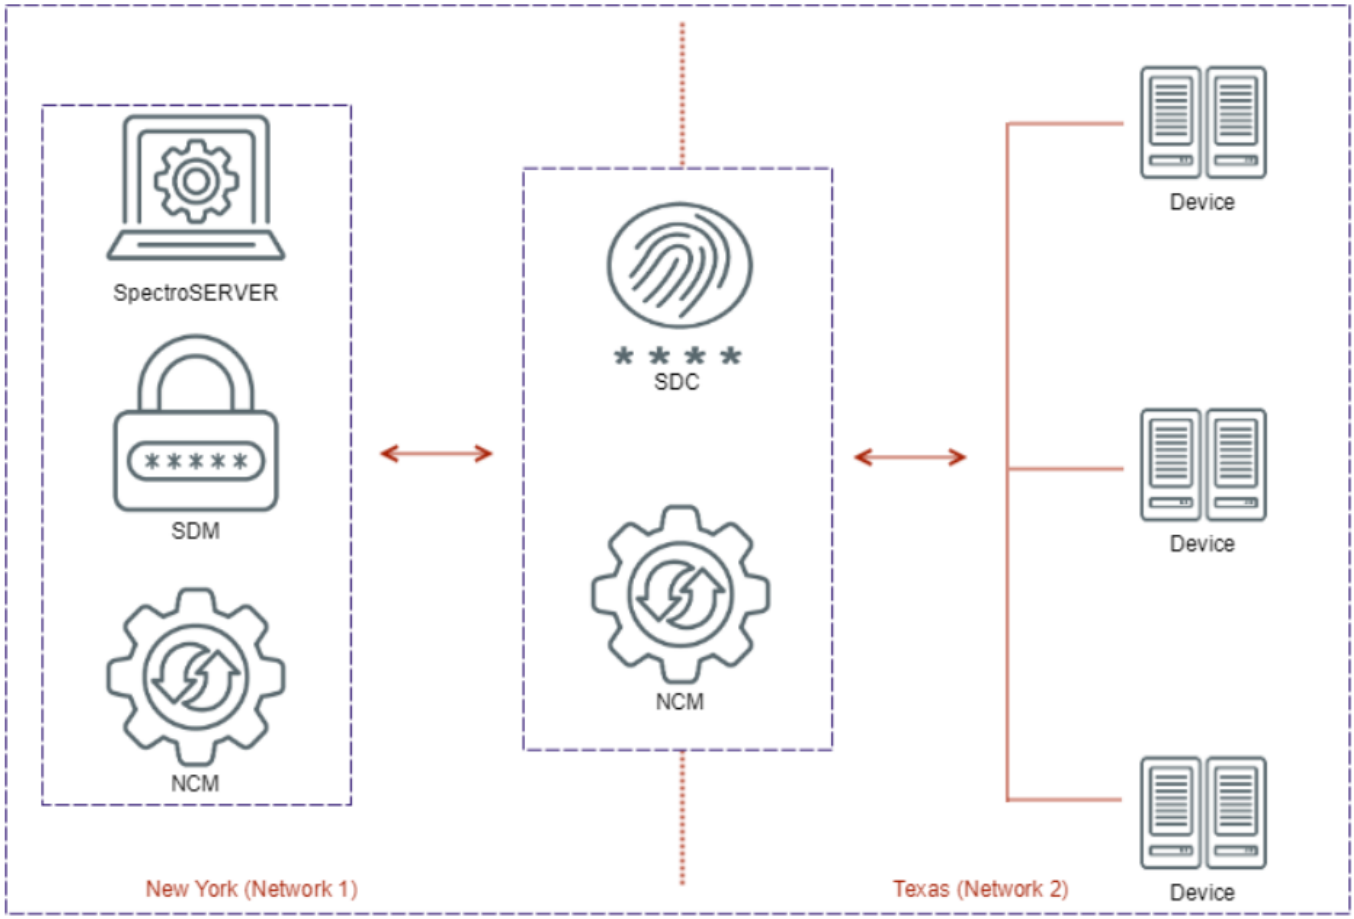
To stop the SDConnector process, issue the **./sdmconnector stop** command.

To restart the SDConnector process, issue the **./sdmconnector restart** command.

NCM Enablement in Secure Domain

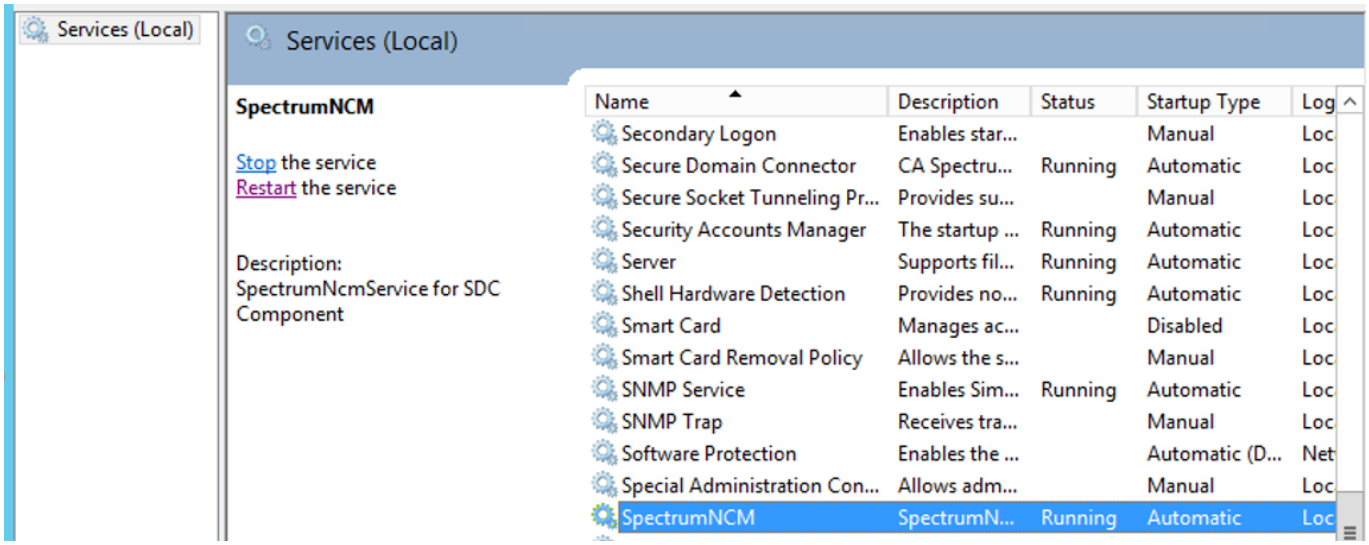
DX NetOps Spectrum supports Network Configuration Manager (NCM) operations (for example, load, sync, capture configurations) on the Secure Domain Connector (SDC)-managed models; that is, devices under a private network.

The following diagram shows the high-level representation:



When you install SDC, NCM is automatically installed as part of SDC; it is installed as a service.

- **Windows:** On Windows SDC, the SpectrumNCM service is installed for NCM. The following screenshot shows the service:



Note that the Secure Domain Connector service is also available.

NOTE
In 10.4.2, Cygwin with Perl modules is shipped with SDC on Windows. These modules are required for executing NCM scripts to perform NCM operations on SDC-managed devices. All the operations (such as capturing or writing a startup configuration, capturing or uploading a running configuration, uploading device firmware, reloading a device, and canceling the reload operation on a device) are supported. You can configure scripts within NCM for each of these operations and execute them on the SDC-managed devices. For more information about the NCM scripts, see the Perl Modules section in the Network Configuration Manager Extension Utility article.

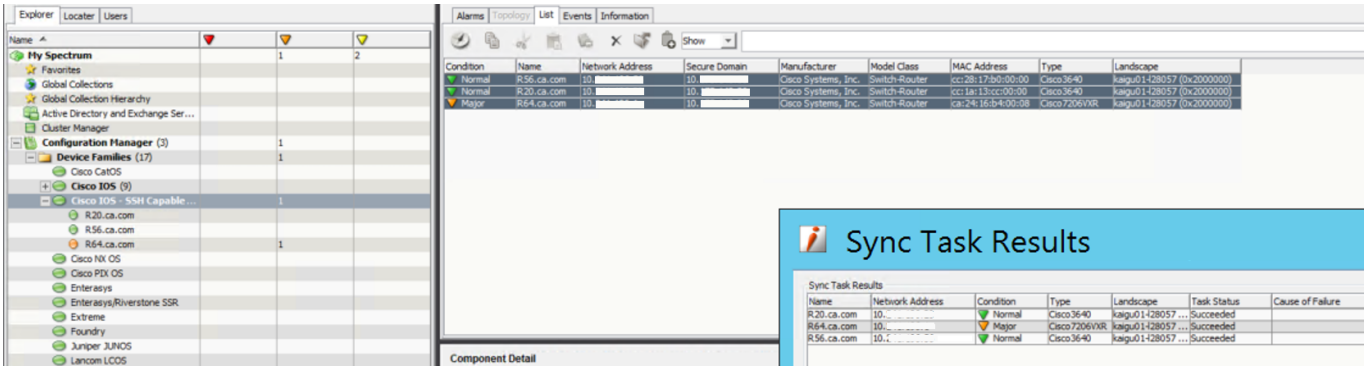
- **Linux:** On Linux SDC, use the following command to find out the SDC and NCM services:
  In 10.4.2, run the following command:
  ```
  [root@host ~]# /etc/init.d/sdmconnector status
  ```
  In 10.4.2.1, run the following command:
  ```
  [root@host ~]# systemctl status sradmin
  SdmConnectorService (pid 16467) is running...
  NCM Service is running pid - 16480
  [root@host ~]#
  ```

  NOTE
  In an upgraded 10.4.1 (or later) environment (for example, upgraded from 10.3.2 SS and SDC to 10.4.1), devices that have been modeled through SDC before the upgrade do not move on their own to the SSH-capable family. However, when the Reevaluate NCM Device Family action is performed, they move to the SSH-capable device family as expected.

SDC–NCM Support on Devices in Existing Device Family

Cisco devices that are modeled through SDC support SSH/SCP as a primary communication mode from the “Cisco IOS – SSH Capable” device family.

The following screenshot shows the required information:



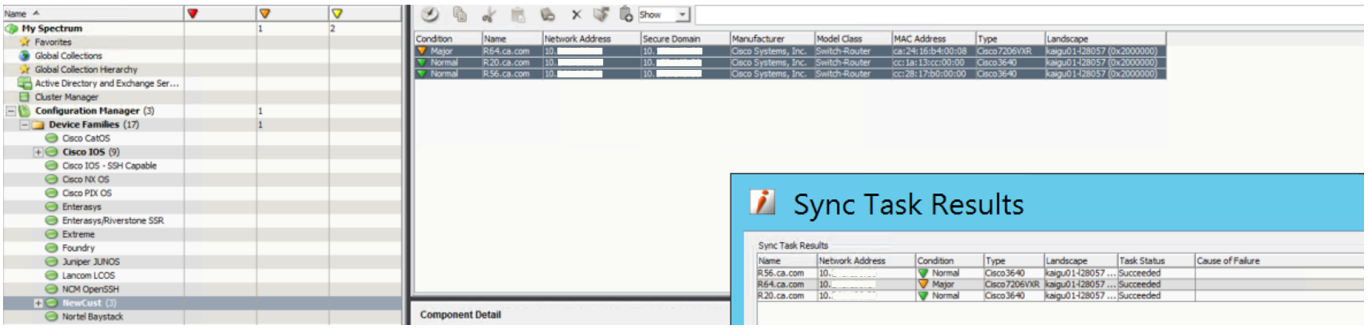
NOTE
In 10.4.2, you can use Perl scripts to execute the NCM operations on the devices modeled through SDC. For more information about how to use Perl scripts to perform various NCM operations, see Network Configuration Manager Extension Utility. In 10.4.1, such script operations were not supported on SDC-modeled devices.

NCM Self-Certification Supporting SDC–NCM

As part of NCM self-certification, it supports SSH as the only supported communication mode. In case of a new device family for NCM self-certification:

- Create a new device family.
- Add the new device modeled into it.
- Add the supported running, startup, and load commands from the newly created device family.

The following screenshot shows the required information:



Scenario: How to Sync Startup Configuration with Running Configuration

For a custom device family, you can use a Perl script to sync the startup configuration with the running configuration. For more information about using the script, see Network Configuration Manager Extension Utility.

Additionally, you can also use appropriate commands to sync the startup configuration with the running configuration. For example, in case of a Cisco device, the "write" command performs this job. Now, suppose you want to sync after you perform an upload task, there are two ways in which you can do this:

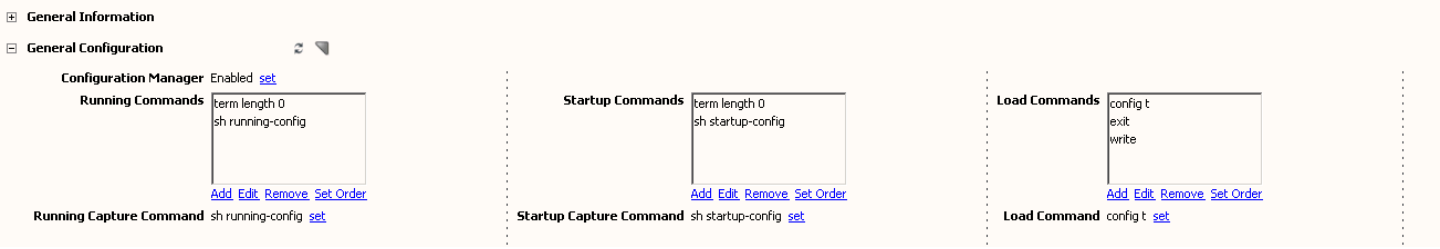
Using Command List

For the device family, navigate to **Information** tab **-> General Configuration**. Under "**Load Commands**", give the following command list:

```
config t
exit
write
```

This ensures that every time you do any upload task, the startup configuration is synced with the running configuration.

The following screenshot shows the required information:



Using Task

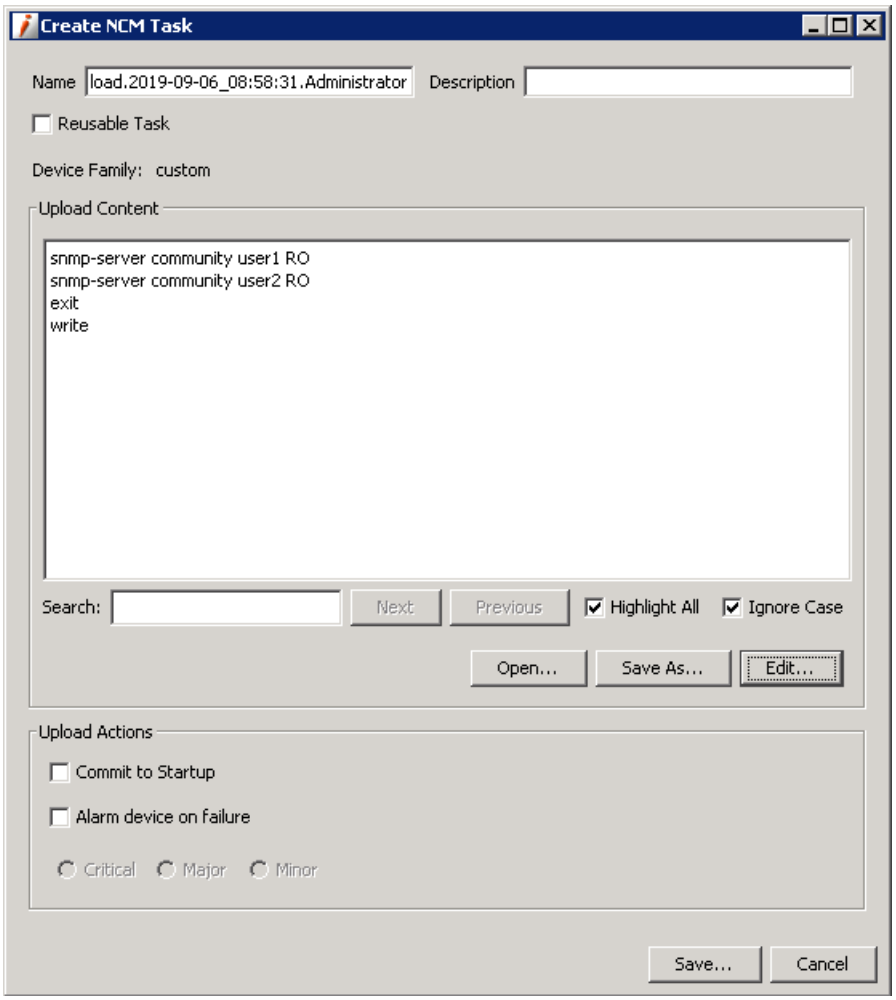
When you create an upload task, you add the following lines at the end of the upload content:

> **NOTE**
> Verify that the config t command is already added to the Load Commands list.

```
exit
write
```

This ensures that every time you run that upload task, the startup configuration is synced with the running configuration.

The following screenshot shows the required information:



NOTE
Commit to Startup is not applicable for self-certification, because it is taken care of by the proper sequence of the commands that users enter to perform the sync task. It is not done by enabling this option.

Configure the Secure Domain Time-out

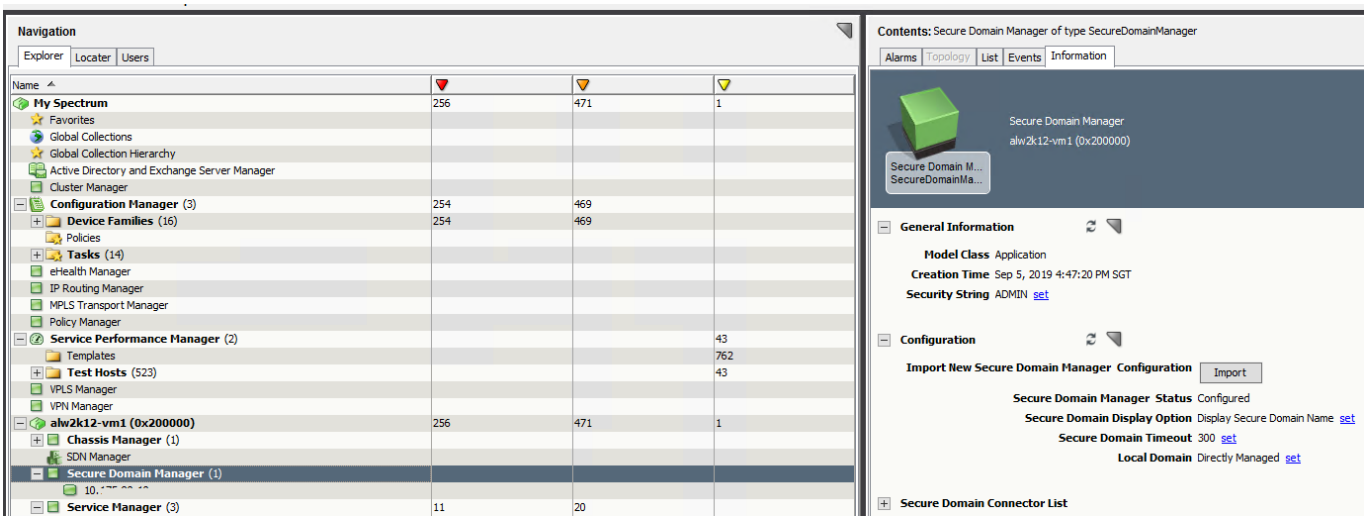
You can now configure the secure domain time-out setting based on your requirements. By default, the value is set to 300 seconds. You can specify any value between 60 seconds to 7200 seconds.

Follow these steps:

1. In the **Explorer** tab, navigate to **Secure Domain Manager**.
2. Click the **Information** tab in the right pane.
3. Expand the **Configuration** section.
4. Locate the **Secure Domain Timeout** option.
5. Click **set** and enter the required value.

You have successfully configured the time-out value.

The following screenshot shows the **Secure Domain Timeout** option:



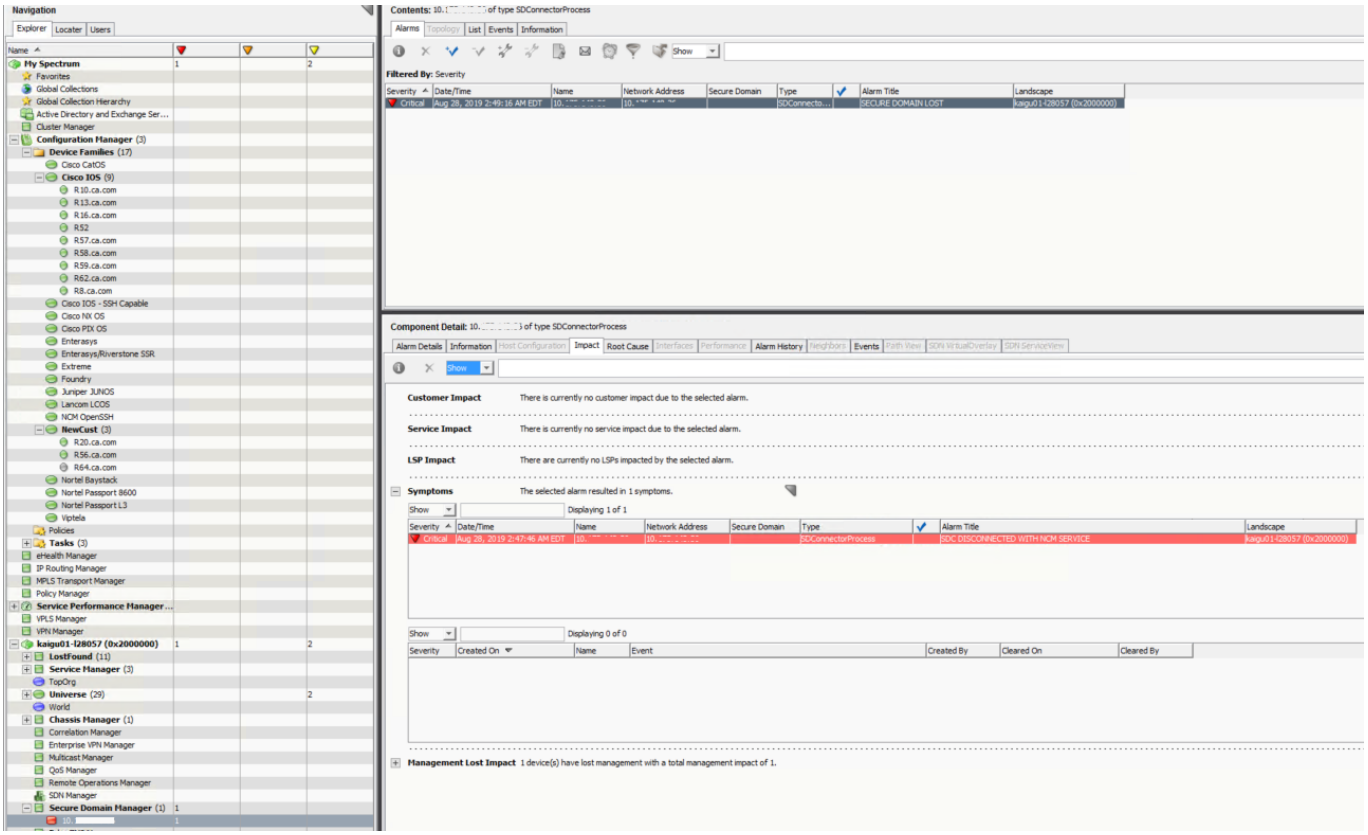
Scenario: NCM Down on SDC

If NCM is down on SDC, it creates a critical alarm on NCM down. In the case of the SDC service being down, it raises two critical alarms, where SDC down is the root cause and NCM down is the symptom.

Furthermore, if SDC is configured in a Fault-Tolerant (FT) environment, then the behavior is as follows:

- When NCM is down on the primary SDC, NCM on the secondary SDC starts working. But it will raise a major alarm on the DX NetOps Spectrum side stating that on the primary SDC, NCM is down and it has switched to the secondary SDC.
- If both NCMs are down, a critical alarm is raised.

The following screenshot shows the root cause as SDC and the symptom as NCM:



Telnet/FTP Support for SDC-Modeled Devices

In this release, for device families that support Telnet/FTP as a communication mode for SDC-modeled devices, you can perform the following NCM tasks on such devices:

- Capture
- Upload
- Sync
- Save to Startup

To use this functionality, you must provide the appropriate information in the **FTP Configuration** section.

NOTE

- This functionality is not supported on the SDC High Availability (HA) computers.
- Shared FTP and device-level FTP details are not supported.
- FTP server location must be in the same SDC system.
- Each SDC device must have its specific FTP server details.
- FTP server details must be provided in SDC.

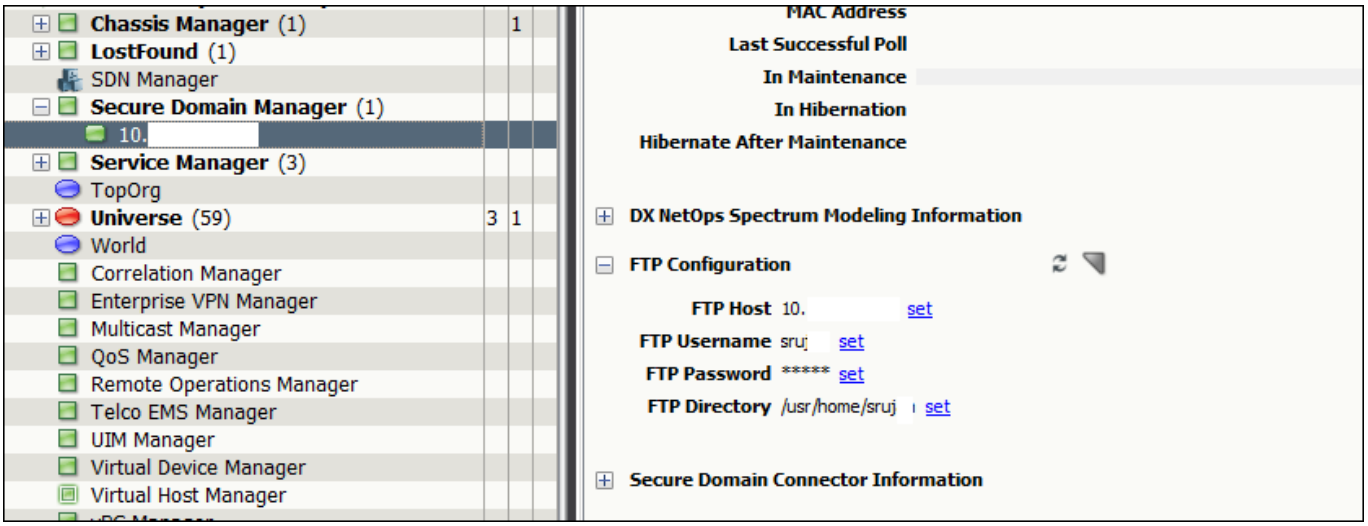
Follow these steps:

1. Navigate to **Secure Domain Manager** in the **Explorer** tab.
2. Select the required IP address under **Secure Domain Manager**.
3. Click the **Information** tab in the **Contents** pane.
4. Expand the **FTP Configuration** subview.
5. Provide information in the following fields; click set against each field, provide the value, and save it:

- **FTP Host**
  Specifies the FTP host IP address.
- **FTP Username**
  Specifies the FTP user name required to access the FTP host.
- **FTP Password**
  Specifies the password associated with the FTP user name.
- **FTP Directory**
  Specifies the FTP directory location.

6. Review the information.

You have successfully enabled the Telnet/FTP support for SDC-modeled devices. The following screenshot shows the required information:

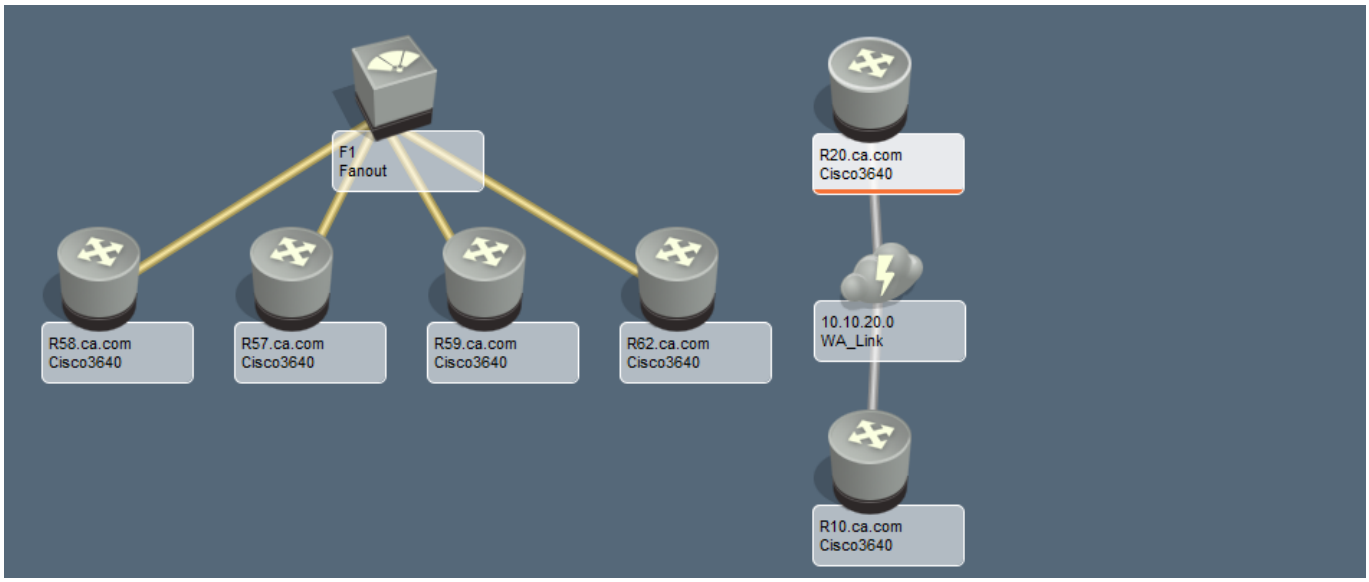


SDC Fault Isolation

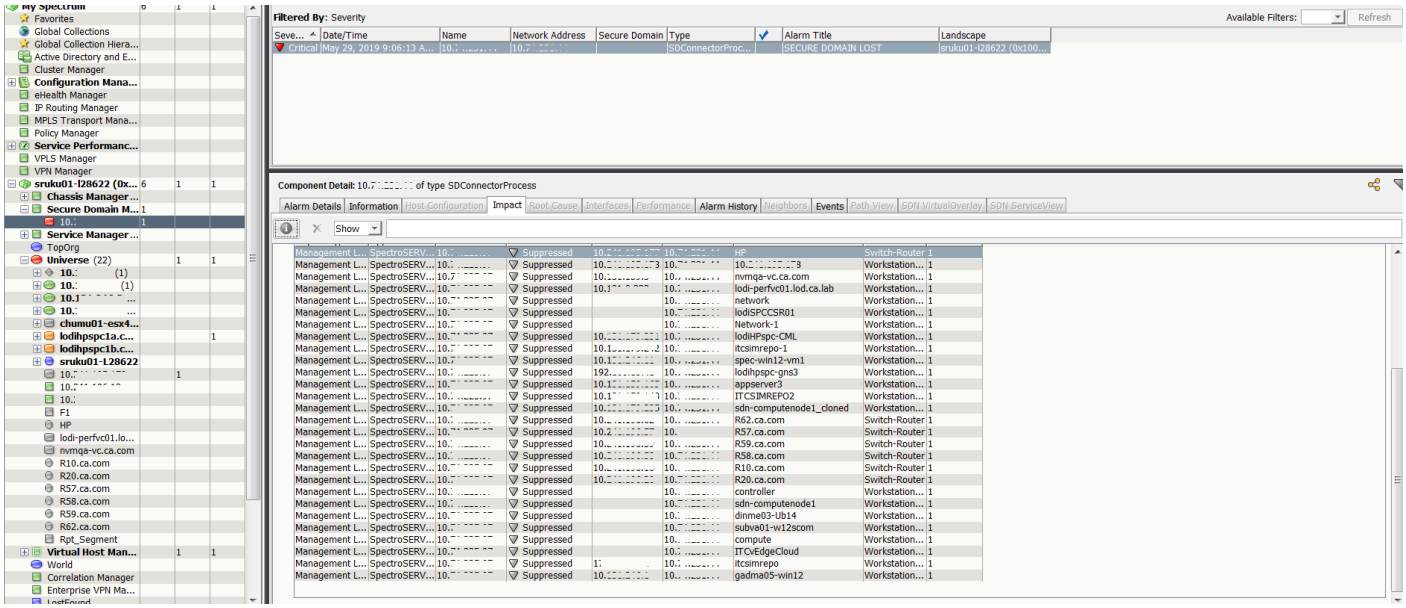
Secure Domain Connector (SDC) is used for managing devices. When SDC gets down, all the devices managed by SDC become unreachable. Previously, such devices would start generating individual alarms. Now, this behavior has changed in the 10.4.1 release. In this release, when SDC goes down, all devices modeled under SDC are suppressed and show the root cause as *SDC down*. Therefore, all related individual alarms are suppressed and users see only one alarm with the root cause as *SDC down*. It also helps users to efficiently manage devices and alarms.

The following information describes the behavior when SDC goes down.

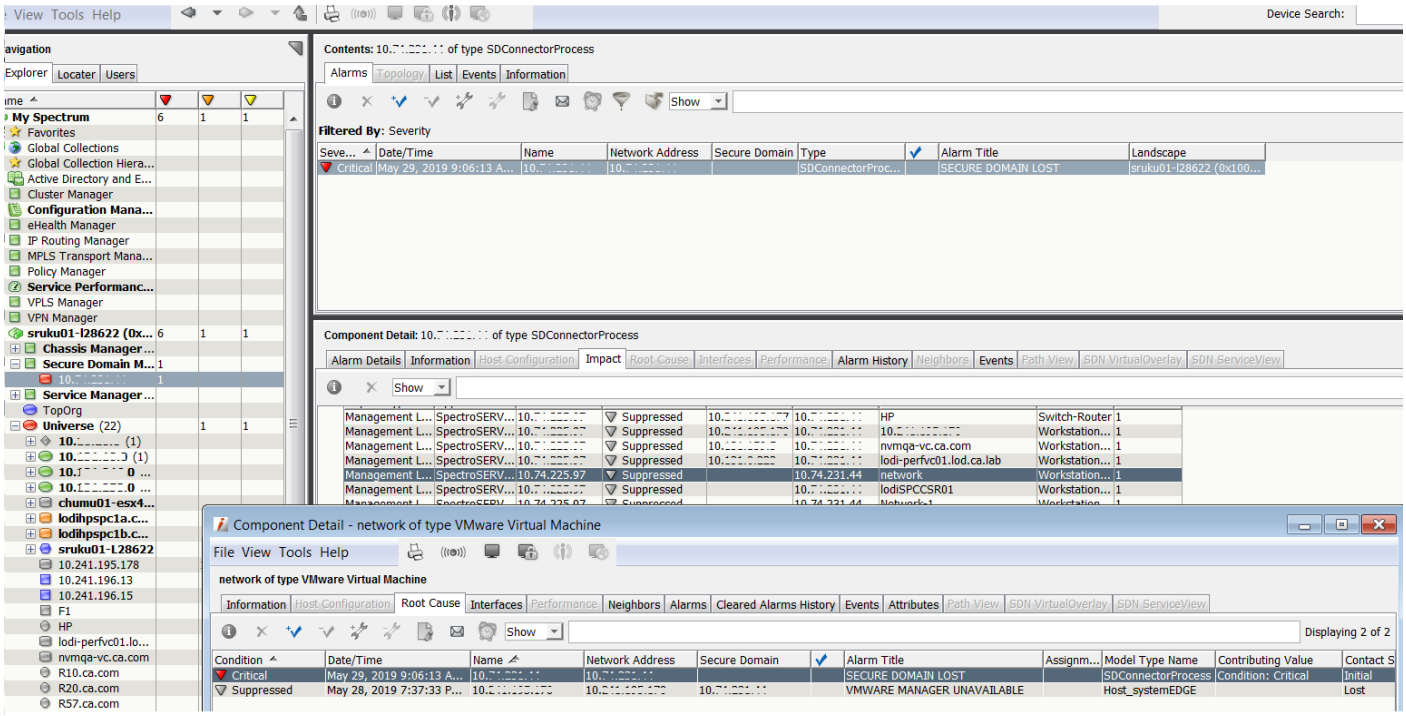
1. When SDC goes down, the SDC-modeled devices are suppressed. The following screenshot shows the required information:



In the SDC LOST alarm impact list, you can find a list of SDC-modeled devices that show the root cause as SDC down. The following screenshot shows the impact list:



The following screenshot shows the root cause:



2. If chassis down alarms are available on an SDC-managed device and SDC goes down, then those alarms on that device are also suppressed. However, when SDC comes up, SpectroSERVER again generates those alarms if the device is down.

   NOTE

   - If SDC-managed devices are in the maintenance mode and SDC goes down, then such devices are suppressed and are not shown in the impact list. And, if the device is removed from the maintenance mode, then it is shown in the impact list.
   - If a suppressed device is put in the maintenance mode and SDC goes down, then this device is not shown in the impact list.
   - Trap based alarms are not suppressed.
   - Alarms generated on System Resources (RFC 2790) on monitored processes and file systems are not suppressed.
   - It is not recommended to put virtual entities like Fanout and WA segment in maintenance mode.

Working with Secure Domain Manager

This chapter describes how to import the SDManager configuration file (sdm.config) into DX NetOps Spectrum and model SDConnector hosts and devices in secure domains. This chapter also describes OneClick tools that are use to locate Secure Domain Manager components. These components are used to ping devices in a secure domain. Ping the devices to view device MIBs, and to view information about the SDManager and SDConnector models.

Import the SDManager Configuration File

Import the sdm.config file into DX NetOps Spectrum before you can begin using OneClick with the Secure Domain Manager product and whenever you want to update the SDManager configuration. See Configure SDManager Process Settings for information about setting sdm.config parameters.

NOTE
You can import the SDManager configuration file before or after you create models for SDConnector hosts. If, however, you import an sdm.config file before you create models for SDConnector hosts, DX NetOps Spectrum automatically models the hosts as SDConnectorProcess model types. See Model SDConnector Hosts for more information about modeling options, including how to model SDConnectors as Pingable and Host_Device model types.

To import the SDManager configuration file

1. Click Secure Domain Manager in the Navigation panel in the OneClick Console.
2. Click the Information tab in the Component Detail panel and expand the Configuration subview.
3. Click Import.
   The Import Secure Domain Manager Configuration confirmation dialog opens.
4. Click Yes to confirm that you want to import the SDManager configuration file (sdm.config).
   The Import Secure Domain Manager Configuration dialog indicates whether the import started successfully. The dialog also provides information to check the output log to determine whether the import worked. The import log file in the SDM/Logs directory provides the troubleshooting information. This information is used to fix errors after an unsuccessful import.
5. Click OK.
   If the configuration file has been imported correctly, the Secure Domain Manager Status field displays "Configured." If an sdm.config file which contains no arguments to define how connections between SDManager and SDConnectors are established is imported, SDManager is disabled and the Secure Domain Manager Status field displays "Not Configured."

   NOTE
   If the sdm.config file is edited while the SpectroSERVER is not running, the SpectroSERVER automatically imports the new sdm.config file when it is started. You can verify whether the import was successful by checking the latest log file.

Model SDConnector Hosts

NOTE

When upgrading to 10.3.1 from 10.3 (directly) or 10.2.x (indirectly), if there were any alarms on the devices managed through Secure Domain Connector (SDC), those alarms will not be correlated to SDC lost alarm and only the newly generated alarms will be correlated, post upgrade.

Model SDConnector Host

Use the Model by Type option in the OneClick Topology view to model an SDConnector host computer as one of the three following model types:

- **SDConnectorProcess**
  The SDConnectorProcess model type is the default model type for SDConnectors. This model type does not allow you to manage the device status, but it does allow you to see the host computer that is represented in the OneClick Secure Domain Manager model hierarchy and provides access to the views discussed in SDConnector Model Information View.

  NOTE
  Use meaningful names for SDConnector host models that clearly identify the hosts. The model names appear in the Secure Domain Manager views in OneClick.
- **Host_Device**

Use the Host_Device model type if the host computer is running an SNMP agent.

- **Pingable**
  Use the Pingable model type if the host computer only supports ICMP.

If you use either the Host_Device or Pingable model type, you can monitor the status of the host computer. See SDConnector Modeling and DX NetOps Spectrum Fault Isolation for information about leveraging the DX NetOps Spectrum fault isolation capabilities by modeling SDConnector hosts as Host_Device or Pingable models.

Secure Domain Connector Status

In 10.2.2, you can ascertain the status of the SDC Host, if you have modeled the SDC host by any of the following methods:

- By importing from sdm.config
- By modeling SDC host as Host_Device model type
- By modeling SDC host as Pingable model type

As soon as the connection with the SDC host is lost, an alarm stating "Lost contact with SDC" is generated on whichever model type is used to model the SDC host. The alarm is asserted based on the attribute value returned for the following attributes which have been added to the SDC Host model:

SDConnectorStatus (0x12ad7) - Attribute value 0= Lost connection, and attribute value 1 = Established connection

SDConnectorStatusUpdateInterval (0x13381) - Default value = 30 seconds; Polls the SDC host model for connection status at an interval of 30 seconds.

SDConnector Modeling Considerations

By default, DX NetOps Spectrum automatically models an SDConnector host computer as an SDConnectorProcess model type if you have not created models for the computer before you initially import the SDManager configuration file.

If you prefer to model hosts as Pingables, or Host_Devices, model the hosts as your preferred type before the import. Alternately, destroy the SDConnectorProcess models after the import. Then, model the hosts as Pingables, or Host_Devices.

> **NOTE**
> If you use the Model By IP option to create a model representing the SDConnector host without first destroying the existing SDConnectorProcess model, DX NetOps Spectrum copies and pastes the SDConnectorProcess model into the topology view from which the Model By IP option was invoked.

Destroying the SDConnector host model in OneClick does not prevent the DX NetOps Spectrum from using the actual SDConnector for the device communication. The SDConnector can only be destroyed by reimporting the SDManager configuration (after editing the sdm.config file to remove the SDConnector).

If you accidentally destroy an SDConnectorProcess model, DX NetOps Spectrum recreates the model the next time you import the SDManager configuration file. If you destroy a Pingable or Host_Device model, DX NetOps Spectrum creates an SDConnectorProcess model the next time you import the SDManager configuration file. If you want to restore your Pingable or Host_Device model, explicitly recreate the model and then import the configuration file.

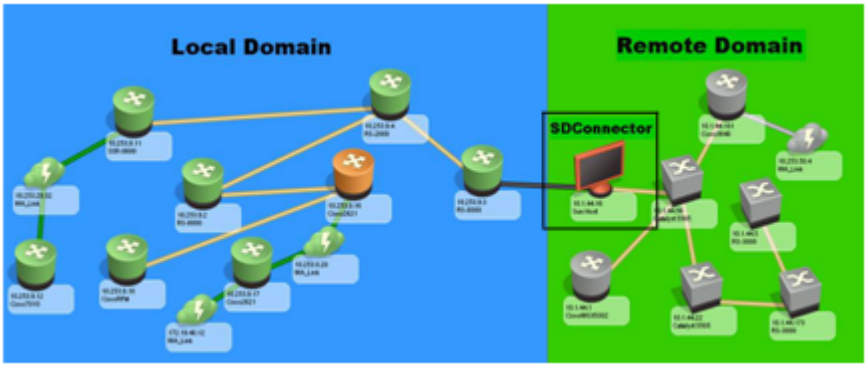
SDConnector Modeling and Fault Isolation

As described in Model SDConnector Hosts, when you model SDConnectors, you can choose one of the following model types:

- SDConnectorProcess
- Host_Device
- Pingable

We recommend modeling the SDConnector host as a Host_Device or Pingable model type. These model types let DX NetOps Spectrum fault isolation work correctly when a remote SDConnector process goes down, or loses its connection. DX NetOps Spectrum isolates the cause of an outage to the SDConnector host model, virtually eliminating unresolved fault alarms.

The SDConnector host is usually connected to a switch on the edge of a network. However, logically, it is the bridge between the public domain and secure domain regions. Model it accordingly. Place the SDConnector host model between the two models for the devices that are routing traffic between the public domain and secure domain regions. The following diagram illustrates this connection, showing the SDConnector as a Host_Device model.



Model Devices in Secure Network Domains

After you model an SDConnector host, model the network devices that you want to manage in the secure domain where the SDConnector host is located. Model the network devices one at a time using the OneClick Create Model By IP option, or Discovery. You can place the models anywhere in the Topology view. After you have successfully created models, DX NetOps Spectrum can communicate with them using the SDConnector process.

Create Model by IP

Use the OneClick Create Model By IP option to model each device in a secure domain.

> **NOTE**
> For more information about modeling in OneClick, see the Modeling and Managing Your IT Infrastructure section.

To model a device in a secure domain using the Model by IP option

1. Click the Model by IP option in the Topology view.
   The 'Create Model by IP Address' dialog opens.
2. Type the network address of the device you want to model in the Network Address field.
3. From the Secure Domain drop-down list, select the IP address of the host running the SDConnector. You also have the choice to select the name that has been configured for the SDConnector host in the secure domain where the device you are modeling is located.

   > **NOTE**
   > You can provide a secure domain name for the SDConnector host by changing the host model name in OneClick. See SDManager Model Information View for information about enabling the secure domain name as a selection option.
4. Select the SNMP version compatible with the device you want to manage in the SNMP Communications Options section.
5. Click OK.

NOTE

When you use the Modeling Gateway with devices located in a Secure Domain, you need to add the attribute details of the secure domain to the import to allow the Modeling Gateway to find models in question and discover the secure domain. Normally, devices can be found with just the device IP.

Example: (Device ip_dnsname="x.x.x.x" secdomain_ipname="y.y.y.y")"

OneClick Discovery

Use OneClick Discovery to discover and model all devices in a secure domain with an SDConnector host. Keep in mind the following points while discovering devices with overlapping IP addresses:

- Only one SDConnector can be used for each Discovery.
- Although you can use Layer 2 mapping, its effectiveness is dependent upon the accuracy of the Source Address and the Spanning Tree tables.
- The Protocol Options settings:
  - Do not use Layer 3 Autodiscovery mapping. Deselect IP Address Tables and IP Route Tables in the Protocol Options dialog.
  - Do not use Proprietary Discovery Protocols in Cisco, or the Nortel environments because they use IP addresses to convey neighbor relationships. Deselect Proprietary Discovery Tables in the Protocol Options dialog.
  - Do not use the Pingable mapping. Deselect ARP tables for Pingables in the Protocol Options dialog.

Discover Devices Using an SDConnector Host

Follow these steps:

1. Click Tools, Utilities, Discovery Console from the main menu.
   The Discovery Console opens.
2. Complete the Discovery configuration for the secure domain from which you want to model devices.

   NOTE
   For more information about configuring Discovery, see the Modeling and Managing Your IT Infrastructure section.
3. Click Advanced Options in the Configuration tab.
   The Advanced Options dialog opens.
4. In the Discovery Options section, from the Secure Domain drop-down list, select the IP address of the host running the SDConnector in this secure domain or the name that is specified for the secure domain.

   NOTE
   You can provide a secure domain name for the SDConnector host by changing the host model name in OneClick. See SDManager Model Information View for information about enabling the secure domain name to be a selection option.
5. Click OK.
   The Advanced Options dialog closes and your changes are saved.
6. Click Discover in the Discovery Console.
   The Discovery that you configured runs. After Discovery, view all the devices that are listed in the Secure Domain Connector Device Table of its corresponding SDConnector host icon.

   NOTE
   If you have already modeled the host machine running a remote SDConnector process using the SDConnectorProcess model and you perform a Discovery on the network region where the host exists, Discovery may create an additional model of the host using the Host_Device, or the Pingable model. Delete

this duplicate model once it has been created or you can filter this model out of the Discovery result that is set before it is created.About Maintaining Device Secure Domain Membership

About Maintaining Device Secure Domain Membership

In a NAT environment, multiple SDConnectors are used to manage the same IP ranges. When the duplicate IP ranges exist, DX NetOps Spectrum cannot determine the SDConnector that must manage each device. So, specify this information.

When discovering or modeling new devices in DX NetOps Spectrum, you can set the secure domain using the OneClick Model by IP view or OneClick Discovery. To update the secure domain for an existing device model, use the OneClick Attribute Editor to edit the Secure Domain Address attribute. This automatically updates the Secure Domain Name. When a new SDManager configuration file (sdm.config) is imported into DX NetOps Spectrum, any existing devices that were assigned to an old secure domain will still be assigned to it. Red alarms will likely be generated on these models.

Create Model by IP

Use the OneClick Create Model By IP option to model each device in a secure domain.

NOTE
For more information about modeling in OneClick, see the Modeling and Managing Your IT Infrastructure section.

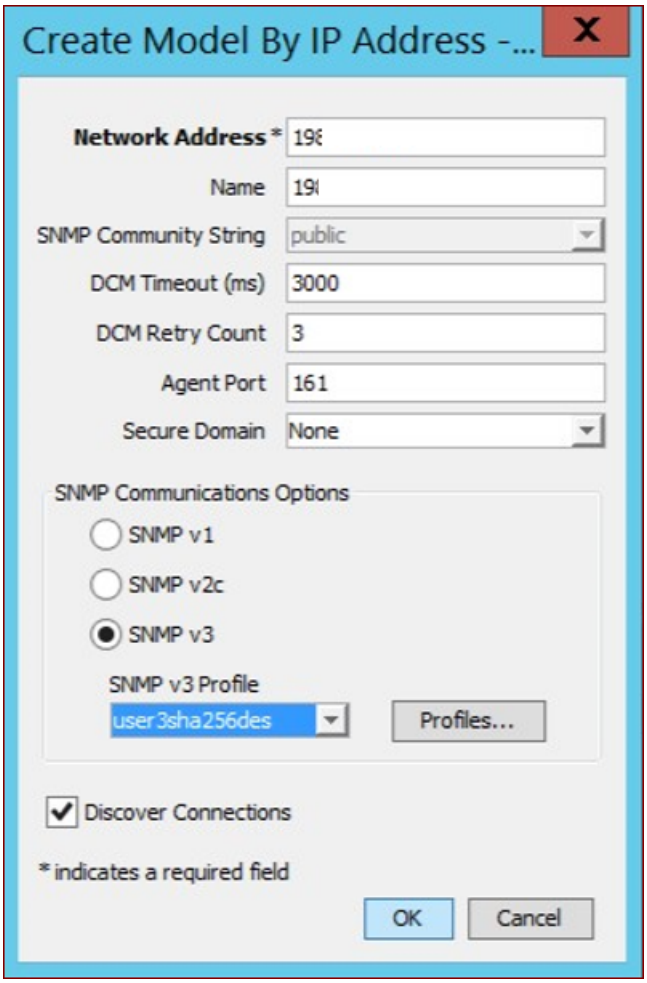
To model a device in a secure domain using the Model by IP option

1. Click the Model by IP option in the Topology view.
   The 'Create Model by IP Address' dialog opens.
2. Type the network address of the device you want to model in the Network Address field.
3. From the Secure Domain drop-down list, select the IP address of the host running the SDConnector. You also have the choice to select the name that has been configured for the SDConnector host in the secure domain where the device you are modeling is located.

   NOTE
   You can provide a secure domain name for the SDConnector host by changing the host model name in OneClick. See SDManager Model Information View for information about enabling the secure domain name as a selection option.
4. Select the SNMP version compatible with the device you want to manage in the SNMP Communications Options section. The SNMP v3 Profile drop-down is enabled only when you select the SNMP v3 option.

   NOTE
   In 10.4.2, the SNMPv3 profile creation supports SHA-256 and SHA-512 as authentication protocols. Therefore, you can now select those profiles, too.
5. Click OK.

The following screenshot shows the required information:



OneClick Discovery

Use OneClick Discovery to discover and model all devices in a secure domain with an SDConnector host. Keep in mind the following points while discovering devices with overlapping IP addresses:

- Only one SDConnector can be used for each Discovery.
- Although you can use Layer 2 mapping, its effectiveness is dependent upon the accuracy of the Source Address and the Spanning Tree tables.
- The Protocol Options settings:
  - Do not use Layer 3 Autodiscovery mapping. Deselect IP Address Tables and IP Route Tables in the Protocol Options dialog.
  - Do not use Proprietary Discovery Protocols in Cisco, or the Nortel environments because they use IP addresses to convey neighbor relationships. Deselect Proprietary Discovery Tables in the Protocol Options dialog.
  - Do not use the Pingable mapping. Deselect ARP tables for Pingables in the Protocol Options dialog.

Discover Devices Using an SDConnector Host

Follow these steps:

1. Click Tools, Utilities, Discovery Console from the main menu.
   The Discovery Console opens.

2. Complete the Discovery configuration for the secure domain from which you want to model devices.

   NOTE
   For more information about configuring Discovery, see the Modeling and Managing Your IT Infrastructure section.
3. Click Advanced Options in the Configuration tab.
   The Advanced Options dialog opens.
4. In the Discovery Options section, from the Secure Domain drop-down list, select the IP address of the host running the SDConnector in this secure domain or the name that is specified for the secure domain.

   NOTE
   You can provide a secure domain name for the SDConnector host by changing the host model name in OneClick. See SDManager Model Information View for information about enabling the secure domain name to be a selection option.
5. Click OK.
   The Advanced Options dialog closes and your changes are saved.
6. Click Discover in the Discovery Console.
   The Discovery that you configured runs. After Discovery, view all the devices that are listed in the Secure Domain Connector Device Table of its corresponding SDConnector host icon.

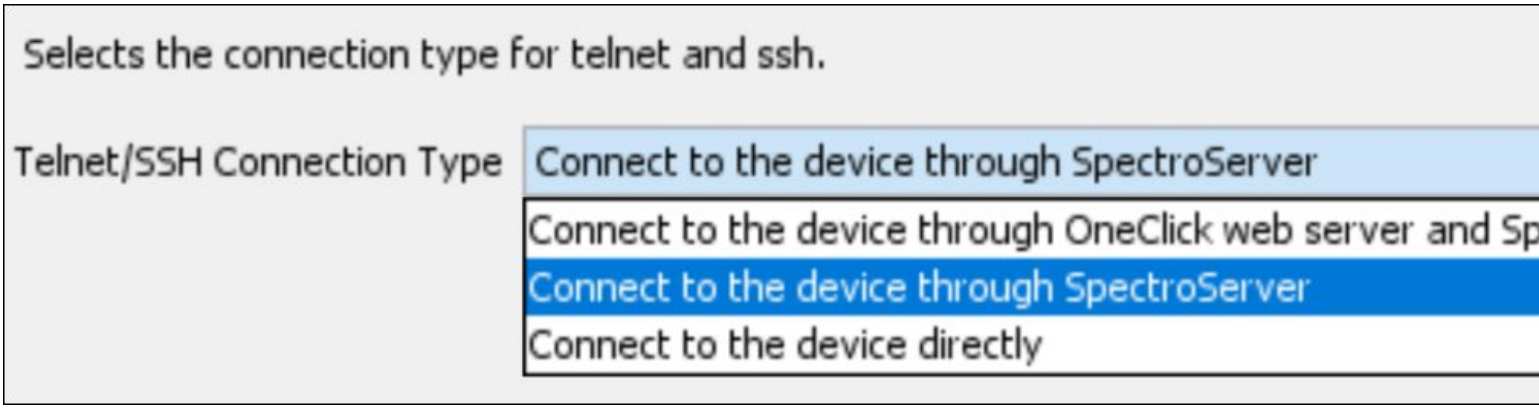
   NOTE
   If you have already modeled the host machine running a remote SDConnector process using the SDConnectorProcess model and you perform a Discovery on the network region where the host exists, Discovery may create an additional model of the host using the Host_Device, or the Pingable model. Delete this duplicate model once it has been created or you can filter this model out of the Discovery result that is set before it is created.

Telnet/SSH Connection Type

From 10.4.2.1, you can communicate from OneCLick console to devices managed through SDC using the telnet and SSH. Select **View, Preferences, Topology Tab, Telnet/SSH connection Type** to access the option.

Specifies the connection type that must be used to access the device from the OC Console for telnet and SSH. Select one of the following options:

- Connect to the device through OneClick web server and SpectroServer (**Default**)
  The communication goes from the OneClick Console workstation to the OC Tomcat server and is then routed to the SpectroSERVER and then to SDC machine which then accesses the remote device.
- Connect to the device through SpectroServer
  This connection method works when the OneClick console workstation is capable to connect to the SDC machine.
- Connect to the device directly
  Access the device from the OneClick console workstation directly.



About Maintaining Device Secure Domain Membership

In a NAT environment, multiple SDConnectors are used to manage the same IP ranges. When the duplicate IP ranges exist, DX NetOps Spectrum cannot determine the SDConnector that must manage each device. So, specify this information.

When discovering or modeling new devices in DX NetOps Spectrum, you can set the secure domain using the OneClick Model by IP view or OneClick Discovery. To update the secure domain for an existing device model, use the OneClick Attribute Editor to edit the Secure Domain Address attribute. This automatically updates the Secure Domain Name. When a new SDManager configuration file (sdm.config) is imported into DX NetOps Spectrum, any existing devices that were assigned to an old secure domain will still be assigned to it. Red alarms will likely be generated on these models.

Access Secure Domain Manager Searches

OneClick includes various predefined Secure Domain Manager search options.

To access Secure Domain Manager search options, expand the Secure Domain Manager folder in the Locater tab in the OneClick Console.

The predefined Secure Domain Manager searches available to you are displayed.

Check Device Accessibility in a Secure Domain

Determine whether the devices are accessible by using the OneClick Ping menu option to ping devices that are located in a secure domain.

> **NOTE**
> A successful ping does not display the number of bytes returned by the pinged device in a secure domain.

To check the device accessibility in a secure domain, right-click the device for which you want to assess accessibility in the OneClick Console and click Ping.

The Ping dialog opens, listing the results of the ping request. For example:

```
Secure reply from 10.254.1.5: icmp_seq=4. time =140. ms
```

If this device was not in a secure domain, the result would appear as follows:

```
64 bytes from 10.254.1.5: icmp_seq=4. time =140. ms
```

View a Device MIB in a Secure Domain

View a device MIB in a secure domain with MIB Tools. First, specify the SDConnector for the secure domain where the device is located. The following procedure describes how to specify an SDConnector.

> **NOTE**
> For more information about using MIB Tools, see the Certifications section.

Follow these steps:

1. Select the device that you want to investigate with MIB Tools.
2. Right-click the device and select Utilities, MIB Tools.
   MIB Tools open. The Contact Criteria is prepopulated with the selected SNMP contact information of the device. MIB Tools attempts to contact the device.
   If MIB Tools *cannot* contact the device an error message appears and the Contact Status indicator turns red.
   If MIB Tools *can* contact the device, the Contact Status indicator turns green.
   A status dialog also appears which shows the progress of retrieving and loading the MIB Tools database.

3. Click Advanced Options in the Contact Criteria section.
   The MIB Tools: Advanced Options dialog appears.
4. Select the applicable secure domain from the Secure Domain drop-down list.
5. Click OK.
   The Advanced Options dialog closes and your changes are saved.
6. Click Contact in the Contact Criteria section and verify that MIB Tools can contact the device successfully.
7. Close MIB Tools.
   MIB Tools closes and you have specified the SDConnector for the device.

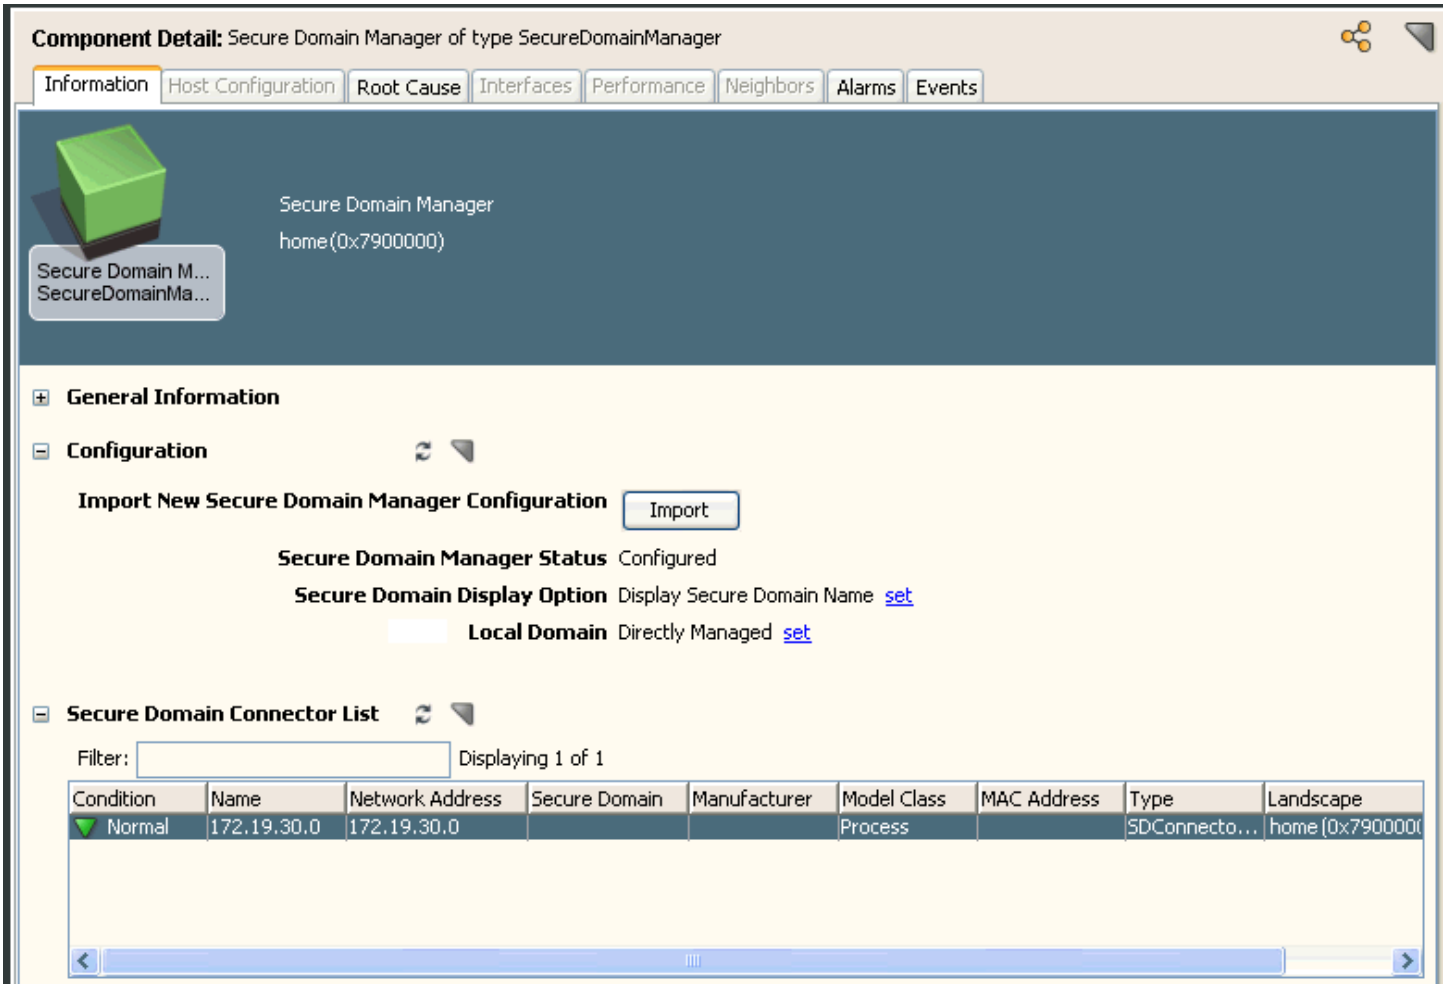
SDManager Model Information View

The Information tab in the Component Detail panel provides information about and configuration controls for the selected SDManager model in the following sections:

- **General Information**
  The General Information section provides standard information about the Secure Domain Manager model such as its model class and security string.
- **Configuration**
  The Configuration section includes the following content:
  - **Import**
    Imports the SDManager configuration file (sdm.config) into DX NetOps Spectrum.
  - **Secure Domain Manager Status**
    Indicates the configuration status of the SDManager as follows:
    - **Configured:** Indicates that the file has been successfully imported.
    - **Not Configured:** Indicates either that a custom or edited sdm.config file has never been imported, an sdm.config file with no arguments has been imported, or an sdm.config file that contains errors has been imported.
  - **Secure Domain Display Option**
    Specifies whether DX NetOps Spectrum displays the name that is used to identify the SDConnector host (and its domain) or the SDConnector host IP address. You can choose either "Display Secure Domain Name" or "Display Secure Domain Address" from the drop-down list. This determines which the type of SDConnector identifier is used throughout all OneClick views.
  - **Local Domain**
    Specifies the text that appears in the Secure Domain column for locally managed models (models that are not included in a secure domain).
    Default: Directly Managed

    NOTE
    The Secure Domain column appears in OneClick list views only when Secure Domain Manager is installed.
- **Secure Domain Connector List**
  Displays all the host machines currently running SDConnector processes in remote network regions.

The following image shows an example of the Component Detail panel for a selected SDManager model:



SDConnector Model Information View

The Information tab that is located in the Component Detail panel provides information about the selected SDConnector. The General Information and the SPECTRUM Modeling Information categories provide standard information about the SDConnector model. There is also a Secure Domain Connector section that includes the following subsection:

Secure Domain Connector Device Table
The Secure Domain Connector Device Table lists all the devices that are managed by the selected SDConnector. It also lets you print, export, and filter the list of devices. You can click the Name hyperlink of a device in this list to navigate directly to that device in the Topology view.

Setting Up Processes in a Fault-Tolerant Environment

This chapter describes how to set up SDConnectors to connect to SDManagers on primary and backup SpectroSERVERs in a fault-tolerant SpectroSERVER environment. This chapter also describes how to set up primary and backup SDConnectors.

Set Up SDManager in a Fault-Tolerant SpectroSERVER Environment

In a fault-tolerant SpectroSERVER environment, install the SDManager on both the primary SpectroSERVER and the backup SpectroSERVER. Each SDConnector that communicates with this SDManager is configured to connect to the primary and backup SpectroSERVERS. If the primary SpectroSERVER fails, the backup SpectroSERVER takes over communications with each SDConnector.

Follow these steps:

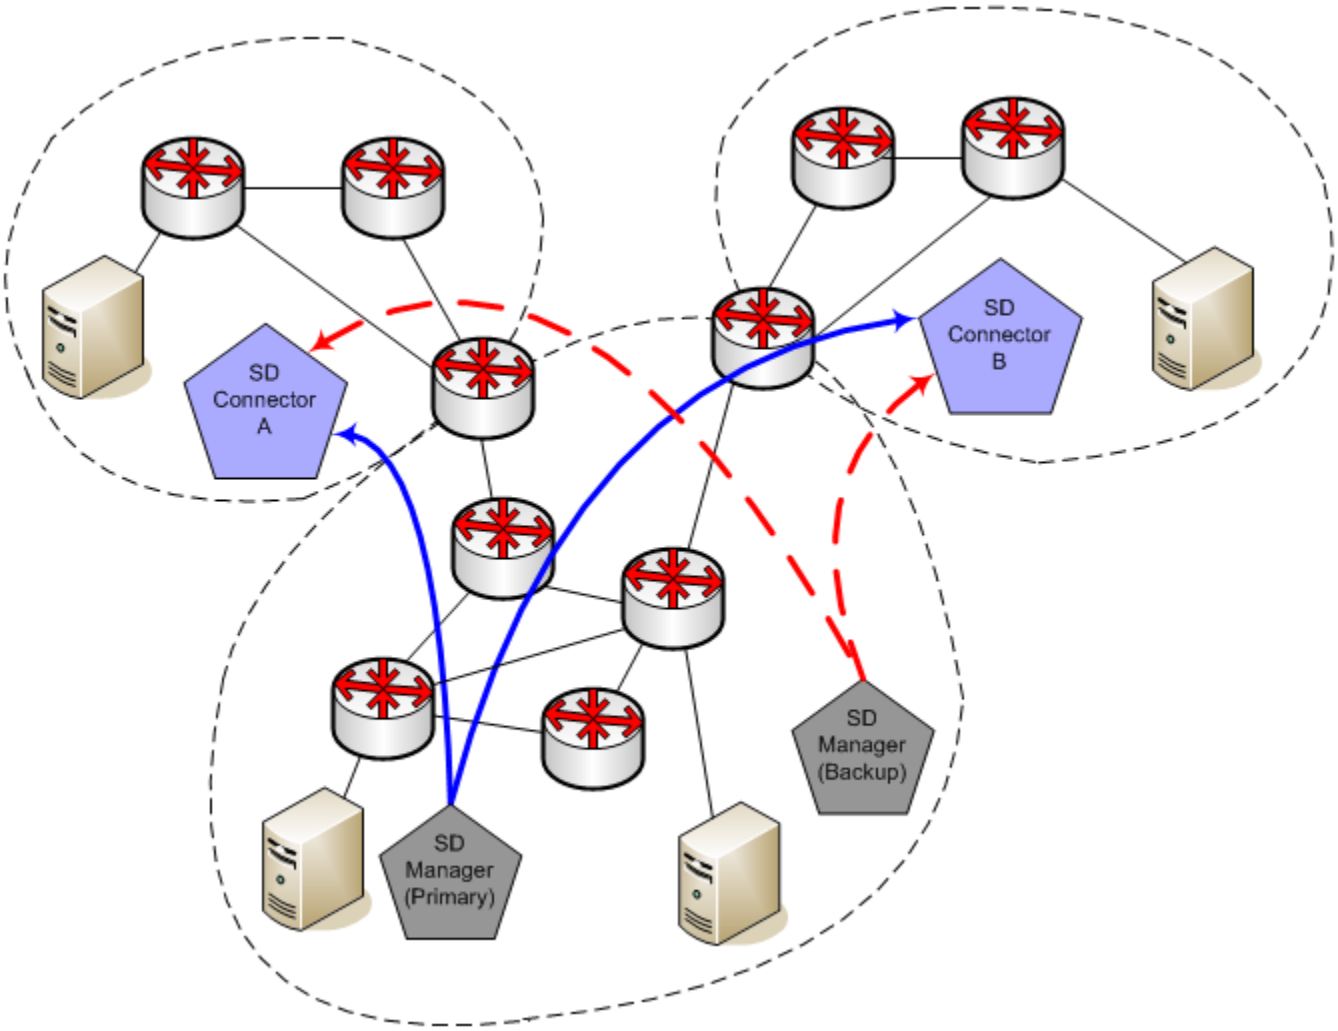
1. Deploy an SDConnector on each secure domain that you want to manage.

   NOTE
   See Installing and Configuring Secure Domain Manager Processes for detailed instructions about how to deploy SDConnectors.
2. Configure each SDConnector to accept connections from both the primary SpectroSERVER and the backup SpectroSERVER. For example, 172.24.1.2 and 172.24.3.4 respectively:

   ```
   -accept 172.24.1.2 -accept 172.24.3.4
   ```

Fault-Tolerant SpectroSERVERs (SDManagers)

The following diagram shows how two SDConnectors can be connected to both a primary SDManager and a backup SDManager:



Configuration setting for both SDManagers in the sdm.config:

```
-remoteconnect <IP of SDConnector A> -remoteconnect <IP of SDConnector B>
```

Configuration setting for both SDConnectors in the sdc.config:

```
-accept <IP of primary SDManager> -accept <IP of backup SDManager>
```

Set Up Fault-Tolerant SDConnectors

Secure Domain Manager supports the Backup functionality on a per-SDConnector basis. A backup SDConnector must be able to manage all the devices the primary SDConnector does, not merely a subset of them.

When you import a backup configuration into DX NetOps Spectrum, the backup SDConnector is not automatically modeled. If the primary SDConnector goes down, the backup functionality takes over *transparently*. There is no visible indication that the primary SDConnector is down. Also, because backups are not modeled they do not appear in the OneClick Console Model by IP or Discovery Configuration views or in MIB Tools.

Follow these steps:

1. Deploy both a primary and a backup SDConnector for each remote domain that you want to manage.

NOTE
See Installing and Configuring Secure Domain Manager Processes for detailed instructions about how to deploy SDConnectors.

2. Configure the SDManager to connect to the primary and backup SDConnectors by modifying the sdm.config file as shown in the following example:

```
-remoteconnect <IP of primary SDC> -remotebackup <IP of backup SDC>
```

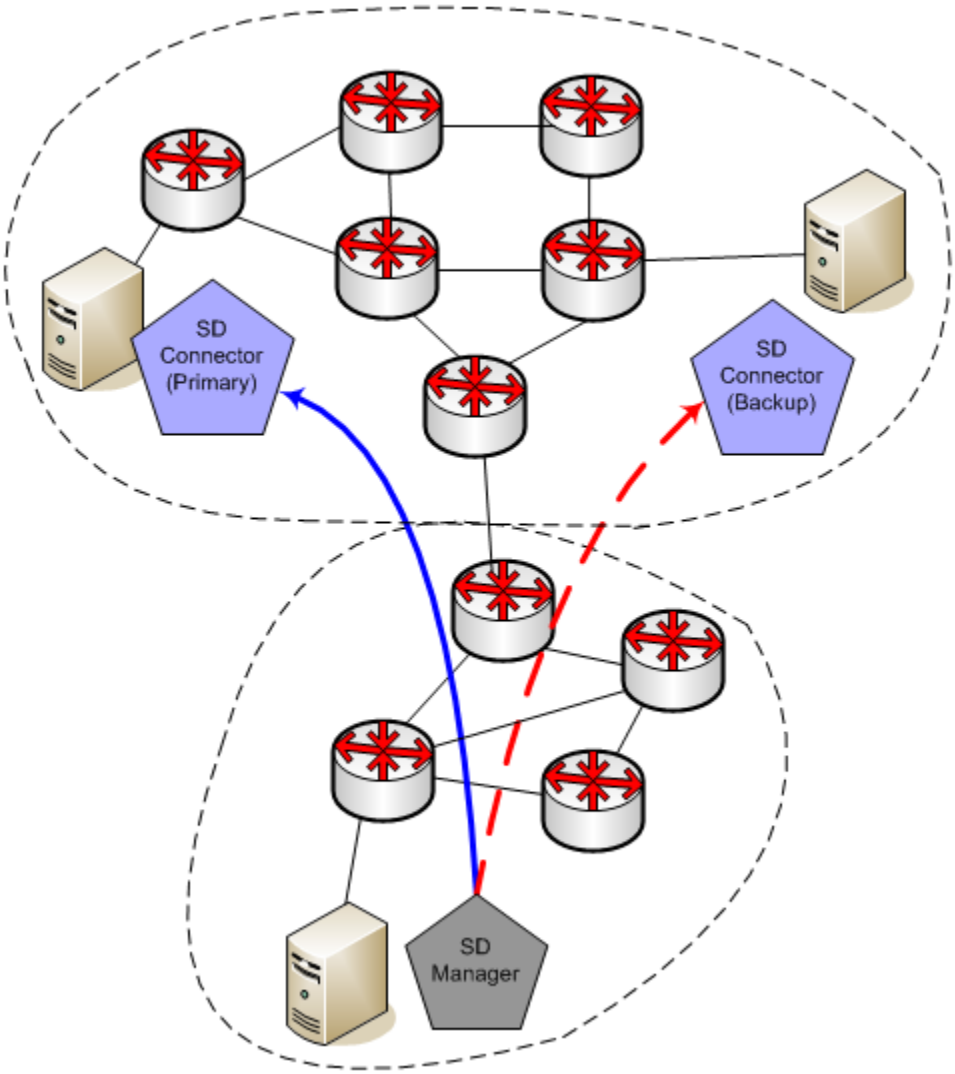
NOTE
Both primary and secondary SDCs always use different IP addresses in the sdm.config file. An example is as follows:

```
-remoteconnect 10.10.10.10 -remotebackup 20.20.20.20
```

Fault-Tolerant SDConnectors

Setting up Fault-Tolerant Secure Domain Connectors

The following diagram depicts two SDConnectors connected to a single SDManager:



Configuration setting for the SDManager in the sdm.config:

```
-remoteconnect <IP of primary SDConnector> -remotebackup <IP of backup SDConnector>
```

Configuration setting for both SDConnectors in the sdc.config:

```
-accept <IP of SDManager>
```

Secure Domain Connector (SDC) Status

From 10.2.2, you can view the status of Secure Domain Connectors (including FT/ Primary and Backup SDConnector). When the connection with SDC is lost or the SDC goes down, appropriate alarms are generated in DX NetOps Spectrum.

The SecureDomainStatus (**0x12ad7**) attribute has the following states indicating the status of the Secure Domain:

- **SecureDomainStatus** attribute Value = **1; Status:** Established
- **SecureDomainStatus** attribute Value = **2; Status:** Established, Primary SDC down
  Event: Secure Domain Connector established to secondary, but primary is down.
  Alarm Title: SECURE DOMAIN SWITCHED TO BACKUP
- **SecureDomainStatus attribute Value = 3; Status:** Established, Secondary/ Backup SDC down
  Event: Secure Domain connector established to primary, but secondary is down;
  Alarm Title: SECURE DOMAIN BACKUP IS DOWN
- **SecureDomainStatus attribute value = 4; Status: Lost**
  Event: Secure Domain connector connection lost;
  Alarm Title: SECURE DOMAIN LOST

Troubleshooting Secure Domain Manager

This section describes some potential Secure Domain Manager problems and their solutions.

Error Messages

This section provides information about Secure Domain Manager error messages. SDManager errors appear in the SDManager.out file; SDConnector errors appear on the terminal display.

Certificate Not Valid Error

Valid on Linux and Windows

Symptom:

The following SDConnector error message appears when a mismatch is found in certificates or security settings:

```
SdmEtpkiConnectEndpoint run() invalid socket security. No connection attempts will be made to the host.
Please verify that certificates and security configurations are correct.
```

Solution:

Verify that machines on which SSL is deployed have matching certificates.

Certificate or Key Error

Valid on Linux and Windows

Symptom:

The following error message appears in sdmLog.log file when a mismatch is found in a certificate or key across connector host and SpectroSERVER host:

```
SdmEtpkiConnectEndpoint run() ssock_handshake error.
```

Solution:

This error indicates a problem with the certificate/key used for SDM/SDC communication. If you are using certificates that are generated with earlier versions of Spectrum or using custom certificates, then you must regenerate the certificates using CertGen utility. If you are using your own custom certificates (not generated using CertGen), then you must ensure that the key size is minimum 1024-bits. The key of less than 1024-bit size does not work with Spectrum 9.4.3. Refer to Create Site-Specific Certificates and Deploy Site-Specific Certificates sections for the steps that are required to create and deploy the custom Site-Specific Certificates.

Port Conflicts

SDConnector Requires a Custom SNMP Trap Port

Valid on Linux and Windows

If there exists a need to change the trap port that the SDConnector listens for the SNMP traps on, configure a custom listening port.

> **NOTE**
> In the following procedure, port 951 is used as an example of a new custom listening port.

Follow these steps:

1. Configure SDConnector to listen for traps on a custom port by modifying the sdc.rc file as follows:
   ```
   snmp_trap_port = 951
   ```
2. Restart SDConnector process by rebooting the computer.
   The SDConnector now listens traps on port 951.

Installation Issues

When on some Windows installations the SDConnector service is not installed. Or, when it is installed, but not started. Then, manually install SDConnector service on Windows.

Follow these steps:

1. From a command prompt, navigate to the following folder:
   ```
   <SDC Install directory>/bin
   ```
2. Run the following command:
   ```
   SdmConnectorService.exe --install
   ```
3. Start the service from the Services window or run the following command:
   ```
   SdmConnectorService.exe --start
   ```

Service Performance Manager

Service Performance Manager Concepts

Service Performance Manager (SPM) lets you create, run, and manage performance tests that are supported by third-party products. The products from various vendors that DX NetOps Spectrum manages perform their own testing to address multiple network management requirements. The following goals are examples of the types of testing that are supported:

- Testing IT service delivery standards -- You can simulate transactions, such as HTTP transactions, login validations, or file transfers to establish delivery benchmarks. You can then measure service delivery to consumers and develop realistic service-level agreements.
- Capacity planning -- Run tests to determine whether service demands by consumers are underutilizing or exceeding current IT infrastructure capacity.
- Proactive fault management -- You can pinpoint service delivery degradation trends before they impact service consumers.

The topics in this section describe the Service Performance Manager components that let you configure and run performance tests.

Test Hosts

A *test host* is a model of a device or software agent that supports one or more performance tests for IT services. DX NetOps Spectrum creates a test host model of type RTM_TestHost during model discovery for each device that Service Performance Manager supports.

Some examples of test host devices and agents are a Cisco router, a Sun Workstation running iAgent, and a SpectroSERVER.

> **WARNING**
> Supported devices and agents must be modeled with read/write community strings to run Service Performance Manager tests. Attempts to run tests on test hosts (except for SpectroSERVERs) that are not modeled with a read/write community string cause an alarm on the test host model.

Configure the Application Model

You can configure the community string of the application model that Service Performance Manager uses. For example, you want to create the device model with a read-only community string. In such a case, you can configure the community string of the Service Performance Manager application model.

> **NOTE**
> Performance Agents and MIBs list tests that are supported by the performance agents and the associated DX NetOps Spectrum application model type. For more information, see Performance Agents and MIBs.

Follow these steps:

1. Click the Locater tab.
2. Expand the Application Models folder.
3. Double-click the By Device IP Address field, and enter the device IP address.
4. Filter and select the appropriate application model.
   For example, for Cisco IP SLA supporting hosts, enter CiscoRTTMonApp.
5. Click the Attributes tab.
6. Filter for the Community_Name.
7. Select Community_Name/0x10024 and select the right arrow.
   The attribute appears in the right panel.
8. Double-click to select and change the value.
   The community string of the application model is now configured.

Tests

A performance or response-time test is an IT service operation that returns a result. Retrieving a web page, downloading a file, and establishing a TCP connection are all examples of common service operations. A single test returns a result that can help you troubleshoot a performance issue. A group of tests return aggregate results that can help you evaluate service viability over a particular timeframe. You can also derive baseline standards that you can factor into infrastructure decision-making.

Service Performance Manager lets you create tests (model type RTM_Test) for your test hosts and discover tests that are configured on managed devices. You can schedule tests and also run them on demand. You can specify test thresholds and can incorporate tests into service management and service-level agreements.

Supported performance tests fall into the following three categories:

- Network response-time tests: Basic network response-time tests.
- Network service response-time tests: Measure the response times of essential network services.
- Network application response-time tests: Measure the response times of essential network applications.

Network Response Time Tests

Network response time tests are the most basic type of network response time tests. The following network response time tests are supported:

- **ICMP Ping**
  Tests the ICMP Echo Request messages from the test host to the destination address. If the test host and the source addresses are not same, then another ICMP Echo Request is issued from the test host to the source address. The resulting ICMP Echo Reply messages are used to determine the round-trip time between the source address and the destination address. A second metric, packet loss, is included in the results. When a series of ICMP Echo requests are made, which is typical of these tests, a coarse measure of packet loss is possible.
- **Jitter**
  Tests latency and losses between two endpoints. This test is designed to measure the quality of the network for applications that cannot tolerate loss or latency (such as VoIP).
- **Traceroute**
  Tests round-trip ICMP Echo from the host address to each layer with three hops in the discovered path.

Network Service Response Time Tests

Network service response time tests measure the response time of essential network services. The following network service response time tests are supported:

- **DHCP**
  Identifies the Dynamic Host Configuration Protocol IP address assignment.
- **DNS (Domain Name Service)**
  Translates the domain name to IP address.

Network Application Response Time Tests

Network application response time tests measure the response time of essential network applications. The following network application response time tests are supported:

- **Custom**
  Custom script execution.
- **FTP**

Indicates the File Transfer Protocol transaction time.

- **HTTP/HTTPS**
  Indicates the Hyper Text Transfer Protocol transaction time.
- **POP3**
  Indicates the Post Office Protocol transaction time.
- **SMTP**
  Indicates the Simple Mail Transfer Protocol transaction time.
- **SQL Query**
  Indicates the SQL query response time.
- **TCP**
  Indicates the Transmission Control Protocol connection time.
- **UDP Echo**
  Indicates the User Datagram Protocol transmissions echo round-trip delay.

Test Templates

Test templates contain the parameters for a particular type of test. You can selectively apply templates to multiple test host models. Or you can automatically apply templates to test host models that are added to the Global Collection models. DX NetOps Spectrum monitors Global Collection content and automatically creates the test that the template specifies on test hosts that are added to the Global Collection. Regardless of how a test template is applied to test hosts, the result is the same: the test that the template defines is created on the test hosts.

Event Alarms

Service Performance Manager generates various events representing significant occurrences that are related to response time testing. Some of these events produce alarms that notify you when a user-actionable event has occurred. For more information, see Event Codes.

You can also configure Service Performance Manager to generate an alarm whenever the duration of a response time test exceeds a predetermined threshold. Such alarms can be isolated to a specific link or path. For more information, see Specify Alarm Thresholds for a Test and Alarms and Events.

Performance Agents and MIBs

The following table lists performance agents and MIBs that are supported by Service Performance Manager. The tests that are supported for each agent or MIB are also given.

Agent/MIB	DX NetOps Spectrum Application Model Type	Tests
RFC2925	RFC2925App	ICMP Ping, Traceroute **Note:** You must verify with the vendor whether a particular device supports the RFC2925 MIB.
Cisco IOS IP SLAs Agent (Cisco IOS IP SLAs Agent is supported on Cisco routers running IOS 12.0 or greater.) **Note:** For full-mesh measurements between hubs, Cisco recommends using shadow routers that are dedicated for IOS IP SLAs. For more information, see the Cisco IOS IP SLAs documentation.	CiscoRTTMonApp	DHCP, DNS, FTP, HTTP, ICMP Ping, Jitter, TCP, UDP, ICMP_JITTER You can discover tests configured on Cisco agents with the SPM Test Discovery feature. For more information, see Discover Tests in the Network.

CA CA eHealth SystemEDGE Service Availability agent	Emp_SvRsp_App	Custom, DNS, FTP, HTTP, HTTPS, ICMP Ping, POP3, SMTP, SQL Query, TCP You can discover tests configured on SystemEDGE agents with the SPM Test Discovery feature. Tests for SystemEDGE agents are discovered in read-only mode only. For more information, see Discover Tests in the Network. **Note:** SystemEdge agents require the CA eHealth Service Availability module to run performance tests.
Network Harmoni SLAplus Agent OEM Vendors: Agilent Technologies, InfoVista, Peregrine Systems, Ericsson, Opticom, RedPoint, HP, Micromuse, Response Networks	HrmniSvcRspApp	DNS, HTTP, ICMP Ping
iAgent	SRISvcMonApp	DNS, FTP, HTTP, ICMP Ping, POP3
JUNOS Real Time Performance Monitor	JnprRFC2925ExtApp	ICMP Ping, Jitter, Traceroute
Other Support		
Cisco Ping MIB	CiscoPingApp	ICMP Ping
Wellfleet Ping MIB	WFPingApp	ICMP Ping

NOTE
It is only the current Cisco routers that support the RTTMON MIB. Older, pre-11.2 deployments support only the Cisco Ping MIB. Service Performance Manager does not support the Nortel Contivity Ping MIB (CONTIVITY-INFO-V1-MIB).

Service Performance Manager Features

Service Performance Manager supports multiple vendor and agent performance tests solutions and multiple implementation features.

Multiple Ways to Create Tests

You have the following options for creating tests with Service Performance Manager:

- Create a test from scratch.
- Create a version from a copy of another test.
- Use SPM Discovery to locate tests that are configured on test hosts.
- Apply test templates to Global Collection containers. When a test host is added to the container, a test with the settings in the template is created on the test host.

Test Scheduling

SPM offers scheduling capabilities to automate your performance testing. You can use preconfigured schedules that are provided by OneClick or you can create your own custom schedules. Scheduling tests lets you implement performance testing during peak and off-peak hours. You can then compare the results from each period and determine realistic performance standards.

For example, you want to schedule a test to run at a specific interval continually, such as 24 hours a day, 7 days a week. Or you can schedule tests to run during or after intervals when the infrastructure is in high demand. In either case, you can create test schedules that meet your requirements.

Automated Test Creation with Test Templates

Test templates let you create test configurations and apply them to multiple test hosts. Test templates leverage Global Collection container capabilities. By applying a template to a Global Collection container, you can automate the test creation process. The test that the template specifies is created for any test host that you add to the container that supports the test. Modifications to test parameters are also simple to perform. When you change template parameters, those changes extend to the parameters for all tests that are created from the template.

Single-Point Test Management

Service Performance Manager provides complete access and control over your test components on multiple landscapes from a single landscape. You can create, configure, locate, and manage tests from a single OneClick Console.

Service Performance Manager Tests and Service Level Agreement Management

Performance testing is indispensable for establishing IT service-obligation benchmarks and monitoring service performance. SPM response time test results provide a more accurate measure of service performance and viability than a notification that reports whether a service is up or down. Service consumers often consider service delivery speed the determining factor in whether a service meets their requirements.

For example, a service consumer considers a 20-second wait for a web page to load because it takes 5 seconds on average to retrieve and load a page. Such a consumer can assume that the sluggish web service is unavailable, even though it is accessible.

Service Performance Manager lets you specify response time thresholds to measure service performance in terms of latency. These thresholds support service-level agreements that ensure a specified response time and meet the requirements of the consumer. You can create and manage services and service-level agreements in DX NetOps Spectrum. For more information, see the Service Manager section.

User Roles

User access to SPM functionality depends on the rights that are granted to the user account. A DX NetOps Spectrum administrator can configure user roles and rights in OneClick. For more information, see the OneClick Administration section.

- **Service Performance Manager for Operators**
  When you are logged in to Service Performance Manager as an operator, you can view information for tests and test hosts and can run existing response time tests. As an operator, you cannot create, delete, edit, or copy any tests. Operators cannot change the state of a test on any test hosts.
- **Service Performance Manager for Administrators**
  When you are logged in to Service Performance Manager as an administrator, you have full access to all functionality, including creating, editing, deleting, and discovering tests.

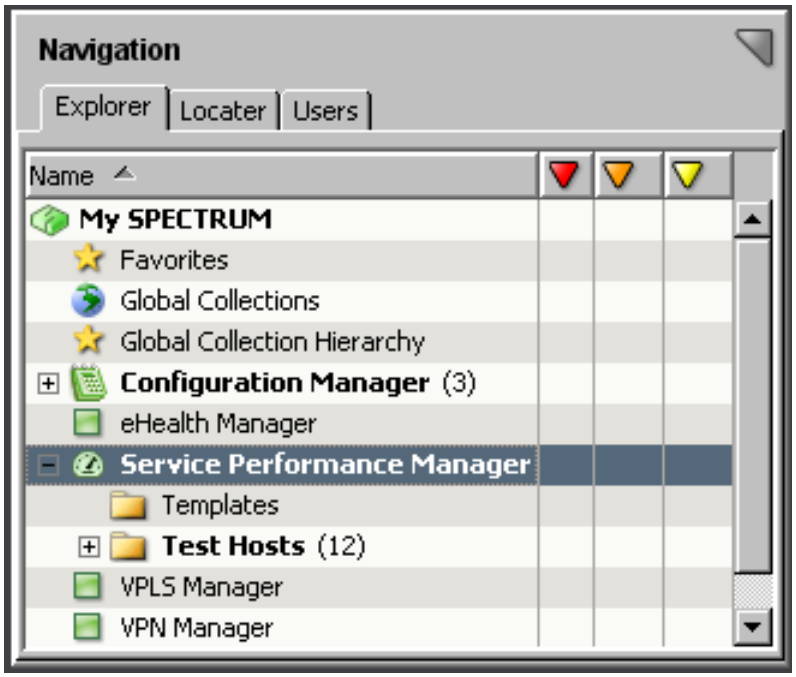
Access Service Performance Manager

This section describes the procedure to access Service Performance Manager components and the basic tasks that you can perform from the OneClick Console. This section provides information about configuring security for tests and test hosts.

You can access Service Performance Manager from the OneClick Console.

Follow these steps:

1. From the Explorer tab, select Service Performance Manager.
   The following image shows the navigation to access Service Performance Manager.



2. To display views, expand the Service Performance Manager node.
   The Templates and Test Hosts views appear.

Basic Tasks Overview

Once you have accessed Service Performance Manager in the OneClick Console Locater, perform the following basic tasks to work with its components:

- Locate a specific test component or group of components (tests, test hosts, test templates). For more information, see Finding Components.
- Create and edit tests, configure test parameters, schedule tests, specify test thresholds, manually run tests, and discover tests on test hosts. For more information, see Working with Performance Tests.
- Create and manage test templates and apply them to test hosts or to Global Collection containers that include test hosts. For more information, see Working with Test Templates.
- Create, run, and edit tests from the Command Line Interface. For more information, see Creating and Managing RTM Tests with the Command Line Interface (CLI).
- Generate reports on tests with Spectrum Report Manager and use the available result data. For more information, see Generating Reports on Test Data.

About Test Host and Test Security

A security string within the respective component controls security for test and test host models. You can use the security string to restrict access to test and test host models to authorized personnel only.

The security string originates from the device model. The test host model inherits the security string from the relevant device model. The test model later inherits the security string from the test host model.

Consider the following points when using test templates:

- When using test templates to create tests, the security string that is specified in the template is not propagated to the test model. The test model inherits its security string from the test host.
- When applying test templates to Global Containers, tests are created for the test hosts where you are authorized.

> **NOTE**
> You must have privileges to invoke detailed views of DX NetOps Spectrum models in OneClick Console and to modify security string settings for models. You can also set up DX NetOps Spectrum model security. For more information, see the OneClick Administration section.

Verify the following procedures to set or modify a security string for a test host or test:

- Secure a Test Host
- Secure a Test
- Overwrite a Security String

Secure a Test Host

You can secure a test host by specifying a security string for it.

Follow these steps:

1. In the Contents panel on the Information tab, expand Test Host Details for the test host that you want to secure.
2. Click set for the Security String parameter, and specify the security string.
   Permission to access the test host is now granted only to privileged users defined by the security string entered.

> **NOTE**
> All tests that are associated with a secured test host automatically inherit the host security string. You can override or remove a security string at a test level (or test host level). For more information, see Overwrite a Security String.

Secure a Test

You can secure a test by specifying a security string for it.

Follow these steps:

1. In the Component Detail panel on the Information tab, expand Test Details, General for the test to secure.
2. Click set for the Security String parameter.
3. Specify the security string.
   Permission to access the test is now granted only to the privileged users defined by the security string.

Override a Security String

You can override security strings for test hosts or tests (if necessary).

Follow these steps:

1. Access the Security String parameter for the component whose security string you want to override. For more information, see Secure a Test Host or Secure a Test.
2. Click set for the Security String parameter.
3. Edit or remove the security string.
   The security string is modified.

Finding Components

Service Performance Manager provides multiple options to find existing tests, test hosts, and test templates in DX NetOps Spectrum. For more information about search features, see the OneClick Administration section.

All Test Component Searches

This search category lets you search for all test hosts, tests, and test templates that are modeled in DX NetOps Spectrum. Using generated search results, you can select an item, view information about it, and can perform any operation that it supports.

Follow these steps:

1. Expand Service Performance Manager in the Explorer tab.
   The Templates and Test Hosts folders appear.
2. Expand the Templates folder.
   A list of all templates in the DSS environment is displayed.

   NOTE
   If you select the Templates folder, the list of templates also appears in the List tab of the Contents panel.
3. To display all test hosts, expand a test host.
   All test models under that host are displayed.

   NOTE
   If you select the Test Hosts folder, the list of test hosts also appears in the List tab of the Contents panel.
4. To display all tests, expand SPM folder in the Locater tab.
5. Double-click the All Tests option to launch the search.
6. Specify appropriate landscape information in the "Select Landscapes to Search" dialog and click OK.
   Search results appear in the Results tab of the Contents panel.

Criteria-Based Test Host Searches

You can search for test hosts that are modeled in DX NetOps Spectrum that meet the criteria you specify. This section describes the procedure to perform criteria-based test host searches and the supported criteria for test host searches.

How to Perform Criteria-Based Test Host Searches

You can perform a criteria-based search for test hosts.

Follow these steps:

1. Click the Locater tab in the Navigation panel.
2. Expand the SPM folder.
3. Expand the Tests Hosts By folder.
4. Select the type of criteria-based test host search to run.
5. Click the Search button.

NOTE
Depending on the search that you select, you can enter values (typically IP addresses) in a Search dialog before the search is executed.

Search results appear in the Results tab in the OneClick Contents panel. You can select an item that a search returned, view information about it, and can perform any operation that it supports.

Supported Criteria for Test Host Searches

You can perform a criteria-based test host searches based on the supported criteria for test host searches. Verify the following supported criteria for test host searches:

- **IP Address**
  Finds the test host with the Network Address or tests hosts that are associated with the address you specify in the Search dialog.

  NOTE
  The Search dialog does not support searching on partial IPs (for example, 10.253).
- **State**
  Finds test hosts in the following states:
  - **Active**
    Test hosts that have been activated.
  - **Contact Lost**
    Test hosts that have stopped responding to polls.
  - **Inactive**
    Test hosts that have not been activated or have been deactivated.
  - **Maintenance**
    Test hosts that are in maintenance mode.
- Test Discovery Support
  - **Supported**
    Finds test hosts that support test discovery.
  - **Unsupported**
    Finds the test host that does not support test discovery.
- **Test Type Support**
  Finds test hosts that support a particular test type.

Criteria-Based Test Searches

You can search for tests that are modeled in DX NetOps Spectrum and that meet criteria you specify by using the Tests By option. This section describes the procedure to perform criteria-based search for a test and the supported criteria for test searches.

Perform Criteria-Based Test Searches

You can perform a criteria-based search for a test.

Follow these steps:

1. Click the Locater tab in the Navigation panel.
2. Expand the SPM folder.
3. Expand the Tests By folder.
4. Select the type of criteria-based test search to run.
5. Click the Search button.

NOTE
Depending on the search that you select, you are prompted for additional values (such as IP addresses) before the search is executed.

Search results appear in the Results tab in the OneClick Contents panel. You can select an item that a search returned, view information about it, and can perform any operation that it supports.

Supported Criteria for Test Searches

You can perform a criteria-based test search. Verify the following supported criteria for test searches:

- **Configuration Parameters**
  Find tests that meet the following criteria as specified in the Search dialog:
  - Destination Address
  - Destination Address and Port Number
  - Source Address
  - Source Address and Destination Address
  - Source Address, Destination Address, and Port Number

  You can enter partial address strings (for example, 138.42) for the Source Address and Destination addresses. Searches with the destination port set to 0 return tests for which destination port is not applicable.
- **Discovery State**
  Find tests that meet the following criteria that are related to SPM Discovery:
  - **Discovery Read-Only**
    Tests that are discovered in Read-Only mode through SPM Discovery.
  - **Discovery Read/Write**
    Tests that are discovered in Read/Write mode through SPM Discovery.
  - **Other**
    Tests that were created by VPN Manager, other IP service applications, or the Command Line Interface.
  - **RTM Domain**
    Tests that were created using the user interface (and not through SPM Discovery).
  - **Stale Different Type**
    Tests that were discovered by Service Performance Manager with a corresponding test on the device of a different test type.
  - **Stale Entry Not Present**
    Tests that were discovered by Service Performance Manager that no longer have a corresponding test on the device. For more information, see Discover Tests in the Network.
- **Name**
  Find a test that is based on the Test Name you specify in the Search dialog.
- **Scheduled**
  Find all scheduled tests.
- **Status**
  Find a test using one of the following test status options:

  - Bad Community String
  - Bad Configuration
  - Device Disabled
  - Ready To Run
  - Running
  - Scheduled
  - Stopped
  - Timeout
  - User Disabled
- **Threshold Exceeded**
  See a list of all of the tests exceeding their thresholds.
- **Type**
  Find all tests of a particular type.

Working with Performance Tests

This section describes what tests are available and how to create them in your environment. Using DX NetOps Spectrum Command Line Interface, you can create and manage response time tests. For more information, see Creating and Managing RTM Tests with Command Line Interface (CLI).

Supported Test Types

This section includes information about specific test types that you can review before you create or can run the tests:

Custom Tests

Custom tests give you the flexibility to specify a custom script to run for the test. This test allows you to verify that the important services or other tasks are working efficiently.

> **NOTE**
> Custom tests are only for SystemEDGE hosts.

DHCP Tests

DHCP tests measure the round-trip time (latency) required to get an IP address. The DHCP server must be on the same subnet as the test host performing the DHCP test. To configure the test host to work with your DHCP server IP address, see the documentation for the device. For DHCP tests to work on a router, one of the neighboring routers must be a DHCP agent or relay. For more information, see the documentation for your device.

> **NOTE**
> DHCP test latency result values can exceed the timeout value for tests that are run on Cisco router test hosts. These values result from a known issue with Cisco IOS 12.2(2)T.

DNS Tests

DNS tests measure DNS lookup time. DNS-based host name-to-address translation must be enabled on the test host device performing the DNS test. You can verify whether DNS lookup is enabled and can enable it. For more information, see the documentation for the device.

DNS test results include the following metrics:

- Latency
- Packet Loss

FTP Tests

FTP tests measure the round-trip time to transfer a file.

FTP test results include the following metrics:

- Latency
- Packet Loss

> **NOTE**
> FTP tests that are run on Cisco test hosts using the RTTMON MIB require the username, password, and filename. However, FTP tests that are run on CA eHealth SystemEDGE Service Availability test hosts require a username and password.

HTTP Tests

HTTP tests measure the round-trip time to get a web page.

HTTP test results include the following metrics:

- Latency
- HTTP DNS Resolution Time
- HTTP TCP Connection Time
- HTTP Download Time

Considerations

- HTTP tests that are performed from Harmoni and iAgent test hosts generate only latency results.
- An HTTP test can fail on some Cisco systems using HTTP 1.1. For more information, see Firmware Issues.
- The HTTP version configuration setting is only available for HTTP tests that are run from Cisco test hosts. The Proxy URL setting is only available for HTTP tests that are run from Cisco and CA eHealth SystemEDGE Service Availability test hosts. For more information, see Configure Advanced Parameters.
- Service Performance Manager HTTP tests that require authentication are not supported on Cisco test hosts.

HTTPS Tests

HTTPS tests measure the round-trip time to get a web page over an encrypted Secure Sockets Layer (SSL) or Transport Layer Security (TLS) connection. An HTTPS test measures the same metrics as an HTTP test.

ICMP (Ping) Tests

ICMP (Ping) tests measure round-trip time from a source to a destination address.

ICMP test results include the following metrics:

- Latency
- Packet Loss

> **NOTE**
> Cisco, Juniper and Alcatel test hosts support Virtual Routing and Forwarding (VRF) Ping tests.

Considerations

- When using the Cisco IOS IP SLAs Agent, you can configure the ICMP Echo operation payload size by setting the request size. The router adds 36 bytes to the size specified. For example, if the request size is 28 bytes, the actual ICMP Packet size is 64 bytes (of IP packet). For more information, see the *Cisco IOS IP SLAs Agent Documentation*.
- The Harmoni agent does not support the configuration of sample count or packet size for ICMP Ping tests.

Jitter Tests

Jitter tests measure both latency and loss between a test host and a voice-enabled endpoint. However, they add a finer measure of the statistical behavior of a sequence of requests. The Mean Opinion Scoring (MOS) is also available from Cisco test hosts. The MOS provides a numerical measure of the quality of human speech at the receiver. Jitter test results include the following metrics, depending on the test host:

- Destination to Source Packet Loss
- Jitter Busies
- Jitter Egress
- Jitter Ingress
- Jitter Positive Destination to Source
- Jitter Positive Source to Destination
- Jitter Negative Destination to Source
- Jitter Negative Source to Destination
- Late Arrival Packet
- Latency
- Mean Opinion Score
- Missing in Action Packet
- Packet Loss
- Source to Destination Packet Loss

Jitter tests can be configured to target a destination port that is listening for Jitter traffic. For example, many Cisco devices running IOS IP SLAs use Port 16386. Failure to configure the port can result in test timeouts. Set the Destination Port parameter in the General options for Jitter tests. For more information, see Configure General Parameters.

POP3 Tests

POP3 tests measure POP3 response (transaction) time.

POP3 test results include the following metrics:

- Latency
- Packet Loss

SMTP Tests

SMTP Tests measures SMTP mail server response (transaction) time.

SMTP test results include the following metrics:

- Latency
- Packet Loss

SQL Query Tests

SQL Query tests confirm that SQL database servers are available by processing short queries that you specify.

NOTE
SQL Query tests are for SystemEDGE hosts only.

TCP Tests

TCP tests measure the time that is required to create a TCP connection.

TCP Connection test results include the following metrics:

- Latency
- Packet Loss

Trace Route Tests

Trace route discovers the layer three hops between the source and destination addresses. These tests also return a round-trip ICMP Echo measurement from the host address to each hop in the path.

Trace route test results include the following metrics:

- Latency
- Packet Loss
- For each hop, IP address and round-trip time

NOTE
Cisco, Juniper and Alcatel test hosts support Virtual Routing and Forwarding (VRF) trace route tests.

UDP Echo Tests

UDP Echo measures round-trip delay.

UDP Echo tests return Latency and Packet Loss results.

UDP tests must be configured to target a destination port that is listening for UDP traffic. For example, many Cisco devices running IOS IP SLAs use port 1967 and UNIX systems use port 7. Failure to configure the port can result in timeouts for UDP tests. Set the Destination Port parameter in the General options for UDP tests. For more information, see Configure General Parameters.

ICMP_JITTER

ICMP_JITTER tests measure end-to-end performance metrics like latency, round-trip time, jitter (inter-packet delay variance), and packet loss between a Cisco device (source) and any other IP device (destination).

ICMP_JITTER test results include the following metrics, depending on the test host:

- Latency
- Packet Loss
- Late Arrival Packet
- Jitter Busies
- Jitter Positive Source to Destination
- Jitter Positive Destination to Source
- Jitter Negative Source to Destination
- Jitter Negative Destination to Source
- Packet out of Sequence SD (Source to Destination)
- Packet out of Sequence DS (Destination to Source)
- Packet out of Sequence BOTH (SD and DS)
- Packet Skipped

Create Tests

You can create a performance test from scratch, or you can use an existing test as a starting point.

You can create tests on hosts that have not been activated. But you must activate test hosts before running the tests. For more information, see Activate and Deactivate Test Hosts.

You can also discover preconfigured tests on test hosts using SPM Discovery. Discovery models tests that have been created on test hosts using a method other than Service Performance Manager, such as the command line. For more information, see Discover Tests in the Network.

Create a Test

You can create a test of any type that the test host supports.

Follow these steps:

1. Expand Service Performance Manager in the Explorer tab.
   The Templates and Test Hosts folders appear.
2. Expand the Test Hosts folder.
   A list of all test hosts in the DSS environment is displayed.

   NOTE
   Expand a test host to see all test models that exist for that host.
3. Right-click the test host for which you want to create the test.
4. Select New Test and then select a test type.
   The New Test dialog opens. This dialog lets you configure test parameters.
5. Configure test settings and click OK.
   The new test is saved. Information about the new test appears on the Information tab in the Component Detail panel for the test host in the Test List table.

Create a Different Version of an Existing Test

You can create a test by saving a unique version of an existing test. The test can include the same settings, but a different name. You can save the new test to the base test host or to a different test host.

NOTE
You cannot copy tests between domains that are running different versions of DX NetOps Spectrum.

Follow these steps:

1. Expand Service Performance Manager in the Explorer tab.
   The Templates and Test Hosts folders appear.
2. Expand the Test Hosts folder.
   A list of all test hosts in the DSS environment is displayed. You can see a plus sign (+) for test hosts with existing test models.
3. Expand the test host whose test model you want to copy.
   A list of tests that are defined for that test is displayed.
4. Right-click the test, and select Copy Test.
   The Copy Test dialog opens, which lets you configure test parameters for the new test.

   NOTE
   Copied tests are disabled by default, and "_COPY" is appended to the test name.
5. (Optional) Rename the test.
6. Modify test settings, and click OK.
   The new test is saved. Information about the test appears on the Information tab in the Component Detail panel for the test host in the Test List table.

Discover Tests in the Network

SPM Test Discovery lets you discover and model performance tests that are configured on test hosts but not configured with Service Performance Manager.

Considerations

- Administrator role privileges are required to use SPM Test Discovery.
- Use a device that SPM Test Discovery supports.

When you run a test Discovery, you are prompted to select the Discovery mode. The following two Discovery modes determine how the tests are created in Service Performance Manager:

- Read-Only Discovery Mode
- Read/Write Discovery Mode

Read-Only Discovery Mode

When you discover tests in read-only mode, you cannot edit test configurations after the tests are modeled in DX NetOps Spectrum. Because, you do not have SNMP *set* privileges to tests. Test Discovery takes schedule information from the tests that are configured on the device and reads test results at the appropriate interval.

Considerations

- Administrator access to read-only tests is similar to that of the Operator role, but it includes full access to Threshold parameters. For more information, see Specify Alarm Thresholds for a Test.
- Read-only tests cannot be run manually; they must be scheduled.
- Sample Count is always 1.
- You can copy read-only tests to create tests that can be modified in Service Performance Manager.
- You can verify that data from read-only tests is available for response time reports, which you can generate with Spectrum Report Manager. Confirm that the test is in the Active state at the time of the read-only Discovery. You can also verify that the Events service indication in OneClick shows the Up status.

Read/Write Discovery Mode

When you discover tests in read/write mode, you can edit test configurations after the tests are modeled in DX NetOps Spectrum. SNMP *set* privileges to the tests are required. You can handle tests on these test hosts exactly like tests that are created manually in Service Performance Manager. Therefore, you can run tests on demand and can stop and edit. For more information, see Configure Tests.

Considerations

- If the test is activated on the device, the Schedule State field for the Schedule parameter field is set to Enabled.
- Sample Count is set to 1

Set the Test Name for Cisco IP SLA Tests

When discovering Cisco IP SLA tests in DX NetOps Spectrum for Cisco routers, the Tag value of the Cisco IP SLA test can be used as the test name in Service Performance Manager. Select a setting to enable this feature.

> **NOTE**
> This option is available for Cisco routers and for tests that were discovered using SPM Test Discovery only.

Follow these steps:

1. Select Service Performance Manager in the Explorer tab.
   Information about Service Performance Manager appears in the Information tab of the Contents panel.
2. Expand the General Information subview.
3. Modify the following field:
   Use Tag Field as Test Name for Cisco Test Host Discovery
   Specifies whether the Tag value is used as the test name during SPM Test Discovery.

   > **NOTE**
   > For tests created in DX NetOps Spectrum, this setting has no effect.

Run Discovery

You can run test Discovery on a single test host.

Follow these steps:

1. In the Explorer tab in the Navigation panel, under Test Hosts, right-click the test host where you want to run Discovery.
2. Select Discover Tests from the right-click menu.
   If the selected test host supports both Read-Only and Read/Write Discovery modes, the Discover Tests: Select Discovery Mode dialog opens.
   The Discover Tests option is not available in the menu if the host does not support Discovery.
3. Select the appropriate option for the test discovery mode you want to run: Read-Only or Read/Write.
   When Discovery completes, the Discover Tests Complete dialog indicates how many tests were created or updated.

You can also locate multiple test hosts that support test discovery and run test discovery on multiple hosts.

Follow these steps:

1. In the Locater tab in the Navigation panel, expand the SPM folder.
2. Run the Test Hosts By, Test Discovery Support, Supported search to locate Discovery-compatible test hosts.
   The Contents panel lists test hosts that support test Discovery.
3. Select one or more test hosts where you want to discover tests, and click the Discover Tests icon.

   > **NOTE**
   > The Discover Tests icon is disabled if a selected test host is not active, or if contact with the host is not established. For more information, see Activate and Deactivate Test Hosts.

   If the selected test host supports both Read-Only and Read/Write discovery modes, the Discover Tests: Select Discovery Mode dialog opens.

4. Select the appropriate option for the test Discovery mode you want to run: Read-Only or Read/Write.
   When Discovery completes, the Discover Tests Complete dialog indicates how many tests were created or updated.

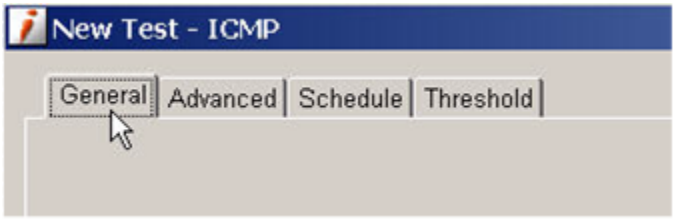
SPM Test Discovery Event Codes

The Events tab in the Component Detail panel provides results from the Discovery on the test host. The following list summarizes SPM Test Discovery event codes and descriptions:

- **SPM Test No Longer On Device Event (0x04560059)**
  Occurs when SPM Test Discovery fails to match an existing SPM Read-Only test to a table entry on the device, this event and a corresponding yellow alarm is generated on the test model.
- **SPM Test No Longer Running On Device Event (0x0456005a)**
  Occurs when SPM reads the test results and detects that the numberOfPktsSent object on the device has not increased. The operational state on the device is also read and found to be InActive. This event is generated, and the following actions occur:
  – No data is processed.
  – Schedule state on the SPM test is set to Disabled, and no more data is read.
- **SPM Duplicate Result Event (0x0456005b)**
  Occurs when SPM reads the test results and detects that the numberOfPktsSent object on the device has not increased. The operational state on the device is also read and found to be Active. This event is generated, and the following actions occur:
  – No data is processed.
  – Schedule state on the SPM test remains Enabled; therefore data is processed from the next scheduled test.
- **SPM Test Discovery Completion Event (0x0456005c)**
  Generated after an SPM Test Discovery has run. Indicates the mode (Read-Only or Read/Write) in which the Discovery was run. Can contain any of the following error output:
  – No Errors
  – No SPM Tests Were Discovered
  – Test type is invalid
  – Test name is null
  – Test timeout is 0
  – Test frequency is 0
  – Test packet size is 0
  – Test sample count is 0
  – Test port number is invalid
  – Test IP Address is invalid
  – Test URL is invalid
  – Test host name is invalid
  – Test user name is invalid
  – Test password is invalid
  – Test filename is invalid
- **SPM Test Type Mismatch Event (0x0456005d)**
  Occurs when SPM Test Discovery matches an SPM Read-Only test to a table entry on the device that is of the wrong test type. Generates this event and a corresponding yellow alarm on the test model.
- **SPM Stale Test Clear Event (0x0456005e)**
  Clears 0x4560059 or 0x456005d if subsequent SPM Test Discovery clears the condition.

Configure Tests

Whenever you issue a create, copy, or edit test command, Service Performance Manager displays a test configuration dialog. You can specify test parameters, set up a test schedule, and specify test thresholds. The following image shows example test configuration categories:



The configuration options depend on the type of test. Some of the options that are discussed in the following procedure do not apply to all types of test.

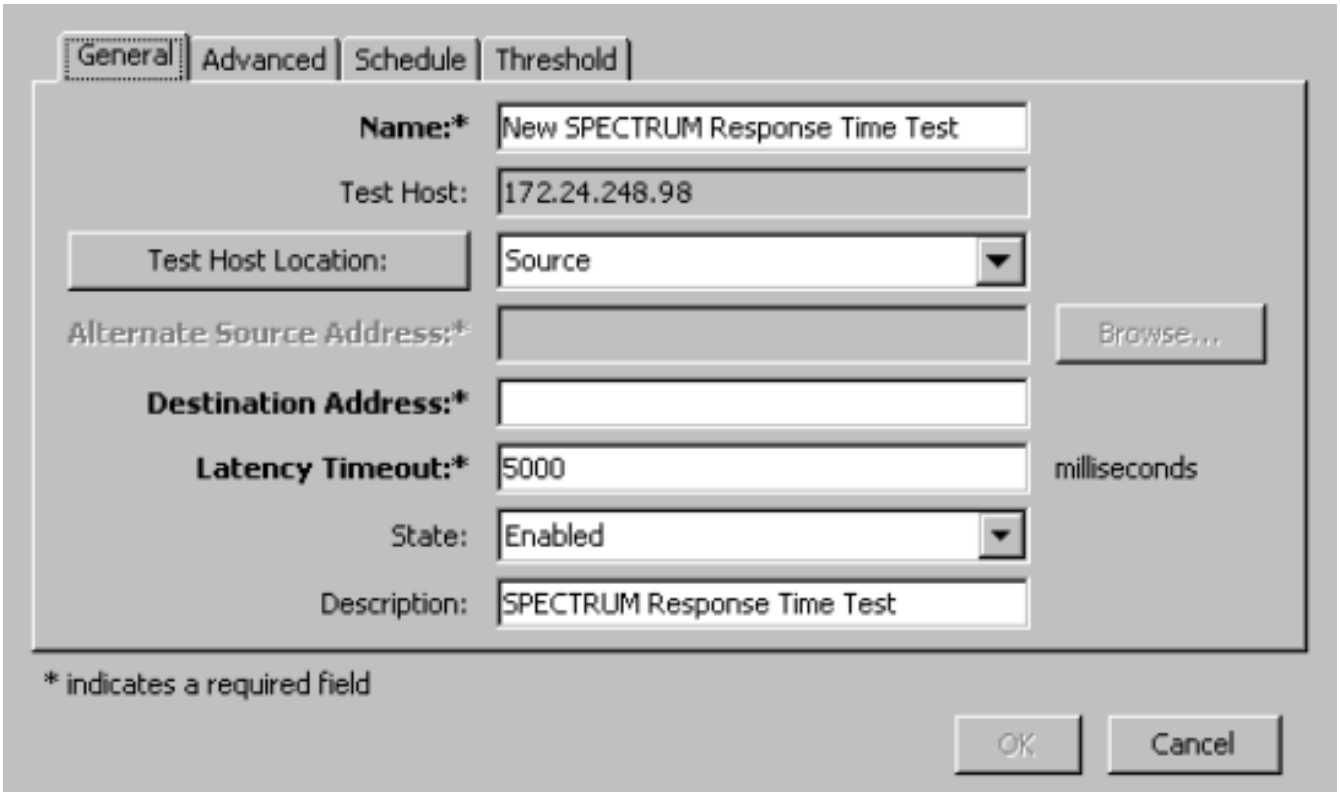
Follow these steps:

1. Enter values for the test in the parameter categories for your particular test.
   For example, test scheduling is disabled by default. If you are not interested in scheduling test runs, ignore the scheduling parameters. The same applies to the test thresholds.
2. Click OK in each parameter category to save your settings.

   NOTE
   The OK button is disabled if you do not enter required values.

Configure General Parameters

The General tab lets you configure required parameters for a test. The following image shows an example configuration dialog for an ICMP (Ping) test.



Standard General Parameters

The following general parameters are available for all performance tests that Service Performance Manager supports:

- **Name**
  Specifies the test name.
  Default: New SPECTRUM Response Time Test
- **Test Host**
  Indicates the IP address of the test host for the test.
- **Latency Timeout**
  Specifies the number of milliseconds for the response. If no response is received before this timeout occurs, DX NetOps Spectrum generates a timeout event. Any response that arrives after this timeout is ignored. Set the timeout higher than the threshold setting.
  Default: 5000 milliseconds

  NOTE
  The Harmoni agent does not support latency timeout configuration.
- **State**
  Enables and disables the test.
  Default: Enabled
- **Description**
  Specifies test annotations.
  Default: SPECTRUM Response Time Test

General Parameters for Specific Test Types

The following parameters may be included under the General tab, depending on the type of test:

- **Alternate Source Address**
  Specifies the IPv4 address or hostname of the test source location when it is not the test host. For example, specifies a mid-path location and extended path location for ICMP Ping test scenarios.

  NOTE
  IPv6 addresses are not supported.
- **Codec Type**
  Specifies the VOIP codec (audio compression/decompression) type to test: G.711 U-law, G.711 A-law and G.729A.

  NOTE
  You can set a voice quality threshold value (100 - 500) for the selected codec with the Mean Opinion Score parameter under the Threshold tab.
- **Connect String**
  Provides the string of commands that are used to connect to the database. For example,
  `jdbc:mysql://172.22.246.43/mysql?user=root&password=root`
- **Database Name**
  Specifies the name of the database.
- **Database Type**
  Specifies the type of database to test. Correct drivers must be installed on the SystemEDGE server.
- **Destination Address**
  Specifies the destination address for the test except those of type DHCP, DNS, HTTP. You can enter an IPv4 address or a host name.

  NOTE
  IPv6 addresses are not supported.
- **Destination DNS Server**
  Specifies the destination address of the DNS server for DNS tests. You can enter an IP address or a host name.
- **Destination Port**
  Specifies the port number where the service is running. For Mean Opinion Score (MOS) support in Jitter tests, the destination port can be an even-numbered port in the range 16384 through 32766 or 49152 through 65534.
- **Destination URL**
  Specifies the URL used in HTTP and HTTPS tests.
- **File Name**
  Specifies the file path that is used for the FTP test.
- **Lookup Name**
  Specifies the IP address, host name, or fully qualified domain name (FQDN) of the host in DNS tests.

  NOTE
  Some agents, such as iAgent, require the use of an FQDN rather than a host name.
- **Operation Type**
  Specifies the type of FTP operation to test.
  - **Login**
    This test logs in using the specified user name and password and then logs out.
  - **Get**
    This test logs in and reads the remote file that is specified in the File Name field (but does not perform a write operation), then logs out.
  - **Put**
    This test logs in and writes the local file that is specified in the File Name field out to the FTP server, then logs out. If the remote directory does not have write permissions, the test fails.

  Default: Login
  Note: Operation Type is available for FTP tests for SystemEDGE hosts only.
- **Password**

Specifies the password for FTP, HTTP, HTTPS, or POP3 test authentication. For SQL Query, this password is used for database access.

- **Query String**
  Specifies the query statement to execute.
- **Script Path**
  Specifies the name and location of a valid script.
- **SQL Database Server**
  Indicates the host name or IP address of the SQL database server.
- **SQL Driver**
  Specifies the name of the SQL driver. For example,
  `com.mysql.jdbc.Driver`
- **Test Host Location**
  Specifies the location of the test host on the path between the source and destination for ICMP Ping tests.
  Default: Source

  NOTE
  See About the Test Host Location Parameter for more information.
- **User Name**
  Specifies the user name for FTP, HTTP, HTTPS, or POP3 test authentication. For SMTP, you can use this email address to test. For SQL Query, this is the user name for database access.
- **Voice Test**
  Specifies whether to test voice quality for Jitter tests.

About the Test Host Location Parameter

Test host location refers to the path between the source and destination of a response time test. The location is critical to response time measurement.

Test host locations:

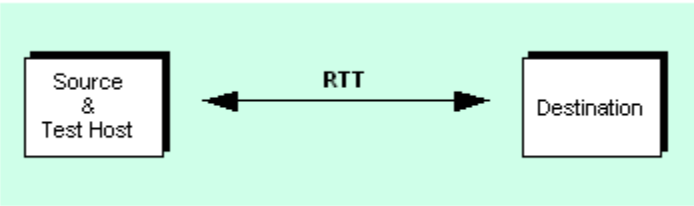
- **Source:** the test host is the source of the test.
- **Mid path:** the test host is located between the source and destination points.
- **Extended path:** test host is not located between the source and destination points.

NOTE
Only ICMP Ping tests support mid path or extended path tests.

Mid path and Extended path tests are useful only when the source or destination address is not a test host. In both of these test types, you can configure test host location.

Source Location

In the most common response time test scenario, the source, or starting point, of the test is also a test host, as shown in the following diagram:



In this case, the test host generates a transaction directly with the destination and measures the RTT.

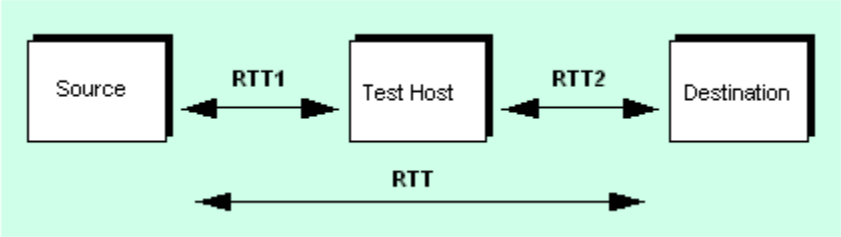
When the source of a test is a test host, response time measurements are the most direct and accurate. For this reason, you can set up tests with a test host as the source whenever possible.

Mid Path Location

In a mid path test configuration, a test host lies on the path between the source and destination points for which RTT is being measured. The source of the test is not capable of being a test host, so it cannot initiate or perform any response time measurements. Use the following calculation to measure the response time for a mid path test:

Response time for a mid path test = (response time (RTT1) from test host to the source) + (response time (RTT2) from test host to the destination)

This value is a relative value which approximates actual RTT. The following image is an example of a mid path test configuration:

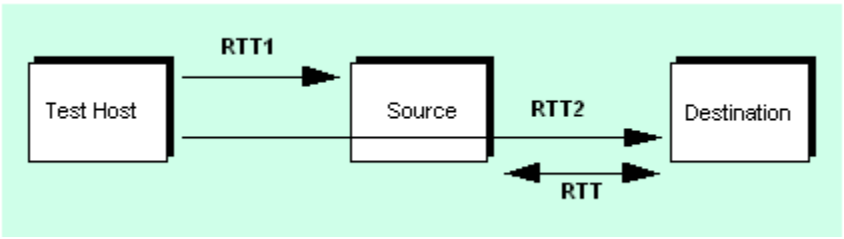


Extended Path Location

In an extended path test configuration, the source of the test is not capable of being a test host. In addition, no test host is located between the source and destination as in the Mid Path Location scenario. However, the source lies directly in the path between a test host and the destination. In this case, use the following calculation to measure the response time:

Response time = (response time (RTT2) from the test host to the destination) -- (response time (RTT1) from the test host to the source)

This value is a relative value which approximates actual RTT. The following image is an example of an extended path test configuration:



Configure Advanced Parameters

The Advanced tab lets you configure additional parameters for a given test type. Each test type has its own specific parameters.

Verify the following Advanced Parameters for all test types:

- **Alternate Packet Address**
  Specifies an alternate source IP address instead of using the default network address of the device that is discovered in DX NetOps Spectrum.

  NOTE
  The Alternate Packet Address field is available for all Cisco test hosts that support IOS IP SLAs Agent.
- **Alternate Packet Port**
  Specifies an alternate packet port instead of using the default packet port of the device that is discovered in DX NetOps Spectrum.

NOTE
The Alternate Packet Port field is available for all Cisco test hosts that support IOS IP SLAs Agent.

- **Delete Messages**
  Specifies whether to delete the messages that were downloaded during the test or to leave the messages on the test system.
  Default: False
  Note: Delete Messages is available for POP3 tests for SystemEDGE hosts only.
- **Download Content**
  Specifies whether to download all images, frames, scripts, and applets with the core HTML code from the website or URL.
  Default: False
  Note: Download Content is available for HTTP and HTTPS tests for SystemEDGE hosts only.
- **Download Type**
  Specifies whether the first or all messages are downloaded for POP3 tests.
  - **First**
    This option downloads only the first message for this user account.
  - **All**
    This option downloads all messages for this user account.

  Default: First
  Note: Download Type is available for POP3 tests for SystemEDGE hosts only.
- **Fail On Content Error**
  Specifies whether any errors encountered while downloading images, frames, scripts, and applets cause the test to fail.
  Default: False
  Note: Fail On Content Error is available for HTTP and HTTPS tests for SystemEDGE hosts only.
- **Filter Timeout Data**
  Specifies whether the Performance tab the OneClick Component Detail panel displays all data or a subset of data minus timeouts.
  Default: True
- **Frame Depth**
  The number of levels the test should traverse when downloading nested frames. The HTTP and HTTPS tests download all frames, images, external scripts, and applets during the page download. The measurement reflects the user experience when downloading a web page.
  Default: 3
  Note: Frame Depth is available for HTTP and HTTPS for SystemEDGE hosts only.
- **HTTP Version**
  Specifies the HTTP version (1.0 and 1.1) for HTTP tests.
  Default: 1.1
- **Mail Body Size**
  Specifies the size (in bytes) of the test message to send.
  Default: 1000
  Note: Mail Body Size is available for SMTP tests for SystemEDGE hosts only.
- **Minimum Matches**
  The minimum number of times the search expression must be found. If the search expression is not found at least as many times as you specify in this field, the test fails.
  Default: 1
  Note: Minimum Matches are available for HTTP and HTTPS tests for SystemEDGE hosts only.
- **Outgoing User Name**
  Specifies the outgoing user name for SMTP authentication for SystemEDGE hosts.
- **Outgoing Password**

Specifies the password for the outgoing user name for SMTP authentication for SystemEDGE hosts.

- **Packet Size**
  Specifies the value (in octets) that limits the size of the packets that are used in the test.

  NOTE
  The Harmoni agent does not support packet size configuration.
- **Proxy Password**
  Specifies the password for the Proxy User Name. The password is encrypted in the DX NetOps Spectrum database.
  Note: Proxy Password is available for HTTP tests for Cisco routers and HTTP and HTTPS tests for SystemEDGE hosts only.
- **Proxy Server**
  Specifies the host name (the name or IP address) of the proxy server to use if the system from which you are testing does not have direct Internet access.
  Note: Proxy Server is available for HTTP and HTTPS tests for SystemEDGE hosts only.
- **Proxy URL**
  Specifies the proxy URL for HTTP tests. For more information, see HTTP Tests.
- **Proxy User Name**
  Specifies a valid user name to be authenticated on the specified proxy server.
  Note: Proxy User Name is available for HTTP tests for Cisco routers and HTTP and HTTPS tests for SystemEDGE hosts only.
- **Sample Count**
  Specifies the number of times a test is performed during a test run.
  Default: 5
  - For Cisco IP SLA tests, the agent supports a sample count of '1' only for all tests other than Jitter tests. For more information, see Considerations for CA eHealth and Cisco IP SLA Tests.
  - RTTMON may occasionally perform more than the specified sample count repetitions for a Service Performance Manager test.
  - The Harmoni agent does not support the configuration of sample count.
- **Text Match**
  Specifies a regular expression or text string that you want to match on the pages you test.
  Note: Text Match is available for HTTP and HTTPS tests for SystemEDGE hosts only.
- **Type of Service**
  Specifies the Type of Service (TOS) parameter for test packets that are sent by the test host. For example, create a response time test with the TOS parameter that VOIP uses and test the performance of the network in routing the packets.
  The Type of Service octet in an IP datagram header enables packets with different TOS values to be routed differently.
- **Use SSL**
  Specifies whether to enable Secure Sockets Layer security in case the SMTP server requires SSL authentication.
  Default: False
  Note: Use SSL is supported for SMTP tests for SystemEDGE hosts only.
- **VRF Name**
  Specifies the VPN routing instance for the test (Ping and Traceroute for Cisco and Juniper test hosts).

Schedule a Test

The Schedule tab lets you schedule a test. Depending on which test you are configuring, you may or may not have access to the following Schedule parameters.

- **Schedule State**
  Enables and disables a test schedule.
  Default: Disabled
- **Schedule Time Interval**

Specifies the interval between scheduled test runs.
Default: 900 seconds

- **Schedule**
  Specifies one of the predefined schedules available from the drop-down list. For more information, see Create a Schedule.
  Default: 24/7

  NOTE
  Time zones for Schedule are local to the SpectroSERVER where the test host running the scheduled test is modeled.

- **Threshold Violation Interval**
  Specifies an alternate test interval that can be used during a threshold violation period. Decreasing the interval during a period of high latency can provide more precise data.
  Default: 300 seconds

  NOTE
  If the Threshold Violation Interval is exceeded, the test does not resume until the Threshold Violation Interval is reached, a lower or higher value than the scheduled time interval.

  WARNING
  Setting this value too low can create additional traffic and load on the router during a period of high latency to make the situation worse.

Create a Schedule

NOTE
You can create test schedules if the predefined schedules do not meet your particular requirements. The schedules that you create are not test-specific; they are available for all tests. For more information about creating schedules, see the Using OneClick section.

NOTE
If you create a schedule with Recurrence set to None, the test runs once on the start date. Then the schedule reverts to the default schedule, and the new schedule is disabled.

Follow these steps:

1. Click Create in the Schedule tab.
   The Create Schedule dialog opens.
2. Configure schedule settings, and click OK.
   The new schedule appears in the Schedule drop-down list.

Specify Alarm Thresholds for a Test

The Threshold tab lets you configure alarm thresholds to monitor response time measurements on a specific link or path. Threshold parameters vary among tests. When a threshold value is exceeded, DX NetOps Spectrum generates an event, an alarm, or both, based on the settings you specify.

Threshold parameters depend on the type of test. The following list describes Threshold parameter options:

- **Active Thresholds Schedule**
  Specifies one of the predefined schedules during which thresholds are in effect and which is available from the list. You can use this feature to measure tests against thresholds only during certain times of the day. For more information, see Create a Schedule.
  Default: 24/7

NOTE
Time zones for schedules are local to the SpectroSERVER where the test host running the scheduled test is modeled.

- **Threshold Events Asserted On**
  Specifies the model from the list where events are asserted.
- **Calculate the threshold On (From 10.4.2.1)**
  Specifies the criteria to calculate the threshold. You can specify the **minimum**, **average**, or **maximum** as threshold limit for Cisco devices and **average** for non-Cisco devices. The threshold calculation is applicable only for **time-related** test results. To see the alarms for threshold values, set Minor Alarm, Major Alarm, Critical Alarm values.

  NOTE

  - If Minor Alarm, Major Alarm, Critical Alarm values are 0 and only event value is set in latency, then only the result event is generated.
  - If Minor Alarm, Major Alarm, Critical Alarm values are set, the result event is generated and a new event generate alarm if set threshold values are breached.
- **Threshold Types**
  Identifies threshold settings for the threshold types that are related to a test.
- **Status**
  Enables and disables each threshold type for a test.
- **Event**
  Specifies a response time threshold value (greater than 0) that, if exceeded, generates an event.
  Depending on the threshold type, you can use one of the following standards to specify a threshold value:
  – A time interval in milliseconds (ms)
  – A percentage (%) of packet errors encountered
- **Minor Alarm**
  Specifies a response time threshold value (greater than 0) that, if exceeded, generates a minor alarm.
  Depending on the threshold type, you can use one of the following standards to specify a threshold value:
  – A time interval in milliseconds (ms)
  – A percentage (%) of packet errors that were encountered
- **Major Alarm**
  Specifies a response time threshold value (greater than 0) that, if exceeded, generates a major alarm.
  Depending on the threshold type, you can use one of the following standards to specify a threshold value:
  – A time interval in milliseconds (ms)
  – A percentage (%) of packet errors encountered
- **Critical Alarm**
  Specifies a response time threshold value (greater than 0) that, if exceeded, generates a critical alarm.
  Depending on the threshold type, you can use one of the following standards to specify a threshold value::
  – A time interval in milliseconds (ms)
  – A percentage (%) of packet errors encountered
- **Threshold Cycles**
  Specifies a value (greater than 0) for the number of consecutive test cycles that violate the threshold before DX NetOps Spectrum generates an event or alarm.
- **Clear Threshold**
  Specifies a response time threshold value (greater than 0) tha,t if not exceeded, clears an event or alarm. Depending on the threshold type, you can use one of the following standards to specify a threshold value:
  – A time interval in milliseconds (ms)
  – A percentage (%) of packet errors encountered
- **Clear Cycles**
  Specifies a value (greater than 0) for the number of consecutive test cycles that comply with a threshold before DX NetOps Spectrum clears an event or alarm.

Establish Baseline Data to Determine Valid Thresholds

The threshold values to use for a test are often too high or too low. You can establish baseline response times that you can then use to determine appropriate thresholds.

Use the following procedure to determine valid thresholds for a test.

Follow these steps:

1. Schedule multiple test runs over the interval to which you want to apply thresholds to tests.
2. Analyze test result data to determine realistic performance thresholds. For more information, see Viewing Service Performance Manager Information.
3. Configure test thresholds that are based on the results of your analysis.

Considerations for CA eHealth and Cisco IP SLA Tests

Service Performance Manager test scheduling is handled by the respective agent. The other management applications, such as CA eHealth, can discover the tests while providing an administrator a single point for RTM test configuration.

Cisco IP SLA tests only support a sample count of '1' for all test types other than Jitter. If a sample count other than 1 is used when configuring the test in Service Performance Manager, DX NetOps Spectrum schedules the test instead of the agent. This results in CA eHealth (and other management applications) not being able to discover the test, because CA eHealth only discovers tests that are scheduled by the agent.

The following test types describe the results that can be expected, if you specify a Sample Count value while configuring a test for a Cisco IP SLA agent:

- For all non-Jitter test types:
  - If Sample Count > 1, DX NetOps Spectrum schedules the test and CA eHealth (and other management applications) fails to discover the test.
  - If Sample Count == 1, DX NetOps Spectrum uses the agent to schedule the test and CA eHealth (and other management applications) discovers the test.
- For Jitter tests, DX NetOps Spectrum uses the agent regardless of the sample count and CA eHealth (and other management applications) discovers the test.

The Sample Count value is specified on the Advanced tab when configuring a test. For more information, see Configure Advanced Parameters.

Run Tests on an On-Demand Basis

You can run tests manually on an on-demand basis if the following criteria are met:

- The test is not scheduled or is scheduled and the schedule is disabled.
- The test is enabled.
- The test host for the test is activated. See Activate and Deactivate Test Hosts for more information.

Typically you manually run tests for diagnostic purposes. For example, you can run an HTTP test to determine a web server response to requests, or you can run a Jitter test to determine the quality of VoIP transmission.

Follow these steps:

1. In the Explorer tab under Service Performance Manager, expand the Test Hosts folder.
   Available test hosts appear.
2. Select the test host.
   Available tests appear in the Test List table on the Information tab of the Contents panel.
3. Select the test(s) you want to run and click the Run Test icon.
   Information about the test is updated in the Test List table.

NOTE
If the test information is not updated, click the Refresh icon.

Test result information is available in the Component Detail panel.

NOTE
To display the Component Detail panel from the Test List table, click the Information icon.

Activate and Deactivate Test Hosts

All test hosts are modeled in DX NetOps Spectrum in the active state. Tests can be configured on a test host in either the active or inactive state. However, tests can only be run on active test hosts.

NOTE
If the device model that is associated with a test host is in maintenance mode, an error is displayed and the test host is not activated. When the device model is taken out of maintenance mode, the test host is activated (if it was active when the device model went into maintenance mode).

Follow these steps:

1. In the Explorer tab under Service Performance Manager, expand the Test Hosts folder.
   The test hosts appear in the Contents panel on the List tab. The State field indicates whether test hosts are Active or Inactive.
2. In the Contents panel on the List tab, select the inactive test host(s) you want to activate, right-click the selection, and select Activate Test Host.
   The test host is activated.
3. To deactivate a test host, select the active test host(s) you want to deactivate, right-click the selection, and select Deactivate Test Host.

   NOTE
   Any scheduled tests stop running until the test host is reactivated.The test host is deactivated.

Manage Tests

If you have the required privileges to the test, you can edit parameter settings and can delete any test. The administrative-user and read/write privileges are required to make modifications.

WARNING
Editing and deleting tests or test templates should be performed with caution by qualified personnel. This guidance especially applies in cases when, for example, Service Performance Manager performance test results are monitored by SLAs (service level agreements) that are modeled in DX NetOps Spectrum or when tests are run for infrastructure performance analysis.

Edit a Test

You can edit all test parameter settings as required.

When you edit a test, the test stops and restarts after all changes have been completed. As a result, the test schedule can be disrupted. For example, if a test has a 60-minute interval between scheduled runs and it is edited 58 minutes after the last scheduled run, it runs for 1 hour and 58 minutes after it is restarted.

Follow these steps:

1. Locate a test to edit. In the Explorer tab under Service Performance Manager, expand the Templates or Test Hosts folders.
2. Expand templates or test hosts.

Available tests appear.
3. Right-click the test to edit, and select Edit Test.
4. Modify test parameters as required. For more information about configuration options, see Configure Service Performance Manager Tests.

Delete a Test

When you delete a test, you remove it permanently from DX NetOps Spectrum.

> **NOTE**
>
> If a Test is discovered in Read/Write mode, and if an admin deletes it, it is removed from Spectrum and also from the Test Host.

Follow these steps:

1. Access the Explorer tab under Service Performance Manager.
2. Locate a test to delete by expanding the Templates or Test Hosts folders, and then templates or test hosts. Available tests appear.
3. Right-click the test to delete, and select Delete.
   The Confirm Delete dialog opens.
4. Click Yes.
   The test is deleted.

Working with Test Templates

This section describes the procedure to create and manage Test Templates.

About Test Templates

A test template is a test configuration that you can apply to multiple test hosts in a single step to create tests on the test hosts. You configure and edit test templates the same way you do with tests. Where they are different is in their scope of application. When you create a test, you create it on a single test host. When you create a test template, however, you can apply it to multiple tests hosts in the following ways:

- Selectively apply a template to multiple test hosts that support the test that is specified by the template.
- Apply a template to any number of test hosts that support the tests that are specified by the templates and that are added to a Global Collection container.

Verify the following primary advantages of using a test template:

- You can implement automated bulk performance testing.
- All modifications to test template parameters are automatically applied to the tests on each test host to which the template is applied. For example, changing a threshold value in a template changes that threshold value for all tests that are derived from it.
- A test template allows you to specify that a test is either a test host or a destination type. A test host type specifies a variable test host but a constant destination. A destination type specifies a constant test host but variable destinations.

Create Test Templates

You can create performance test templates using either of the following methods:

- Create a test template from scratch
- Save a different version of an existing test template

You can use any method to create a test template. For more information, see Configure Service Performance Manager Tests. You can also configure the following template-specific parameters:

- **Template Type**
  Specifies Test Host or Destination. A test host type specifies a variable test host with a constant destination. A destination type specifies a constant test host with variable destinations. (The Destination configuration is not available for DHCP and HTTP test templates.)
- **Global Collections**
  (Optional) Specifies one or more Global Collection containers. OneClick automatically applies the test that is specified by the template to all test hosts that you add to the container if they support the test.

Create a New Test Template

You can create a test template from scratch. Use this method to create a test template if no other templates have been created.

Follow these steps:

1. In the Explorer tab under Service Performance Manager, right-click Templates, select Create Test Template, and select a test type.
   The Create Test Template dialog provides test template parameters. You can specify the Template type and one or more Global Collection containers to which to apply the template.
2. Configure test template settings, and click OK.
   The new template is saved and appears in the Templates folder.
3. For information about the new test template, select the new template.
   Information appears in the Information tab in the Contents panel.

Create a Different Version of an Existing Test Template

You can create a test template from a copy of another template.

> **NOTE**
> You cannot copy test templates between domains where different versions of DX NetOps Spectrum are running.

Follow these steps:

1. In the Explorer tab under Service Performance Manager, expand the Templates folder.
   The test templates appear.

   > **NOTE**
   > If no templates appear, create a test template.
2. Right-click the test template to copy, and select Copy Test Template.
   The Copy Test Template dialog lets you select settings for the new template.

   > **NOTE**
   > The test templates that you copy are disabled by default, and "_COPY" is appended to the test name. You can rename the template.
3. Modify test template settings, and click OK.
   The new template is saved and appears in the Templates folder.
4. (Optional) Select the new template.
   Information appears in the Information tab in the Contents panel.

Apply a Test Template to Test Hosts

You can selectively apply a test template to a group of test hosts that support the template test type. You also have the option to automate the process by placing test hosts in a Global Collection container and applying a test template to the container. Apply a test template to a Global Collection container so that tests are automatically created for all test hosts that support the test type as they are added to the container. For more information, see the Modeling and Managing Your IT Infrastructure section.

Selectively Apply a Test Template to One or More Test Hosts

You can manually apply a test template to a selection of test hosts. You can precisely specify only those test hosts for which you want to create tests.

Follow these steps:

1. In the Explorer tab under Service Performance Manager, select the Templates folder.
   The test templates appear in the Contents panel on the List tab.

   NOTE
   If no templates appear, create a template. For more information, see Create a New Test Template.
2. In the Contents panel on the List tab, select the template(s) to apply.
3. Right-click the selection, and select Apply Test Template.
   The Select Test Host dialog lists test hosts that support the template test type.
4. Select one or more test hosts to which to apply the test template, and click OK.
   OneClick creates the test for the selected test hosts. The tests that were created from the template appear beneath the template in the Explorer tab.

   NOTE
   The List tab in the Contents panel also lists tests that were created from a test host template type when the template is selected.

   Two naming formats are supported for tests that were created from test templates. The test names can indicate the test target IP address, or they can indicate the test target model name. The target can be the test host or a particular device, depending on the template type.
   Use the following default format:

   ```
   Template Name_IP Address
   ```

   – **Template Name**
     Specifies the name of the template that you applied to a test host.
   – **IP Address**
     Specifies the IP address for the test target.

   You can use the SPM Template Naming option from the OneClick Administration Pages to change the naming convention to the following format:

   ```
   Template Name_Model Name
   ```

   – **Template Name**
     Specifies the name of the template that you applied to a test host.
   – **Model Name**
     Specifies the model name for the test target.

   The SPM Template Naming setting does not change the naming format for tests that have already been created from a template.

Apply a Test Template to a Global Collection Container

Applying test templates to Global Collection containers lets you automate the process of creating tests of different types for multiple test hosts. For example, assume a Global Collection container includes a group of test hosts that only

supports ICMP Ping tests, a group that only supports HTTP tests, and a group that supports both. Assume also that numerous test hosts that belong to each group are sometimes added to the container.

In this case, two different test templates can be applied to the container to create the tests for the test hosts that are included in it. One template specifies an ICMP Ping test and the other specifies an HTTP test. ICMP Ping tests are created for the test hosts that support ICMP Ping tests, and HTTP tests are created for the test hosts that support HTTP tests.

This example understates the potential complexity of a “real-life” performance testing implementation. However, it does illustrate the ease with which you can use test templates to set up tests on multiple test hosts. This method is an alternative to setting them up individually. For a more information, see Example Implementation Scenario.

Follow these steps:

1. In the Create Test Template, Copy Test Template, or Edit Test Template dialog, click the Browse button next to the Global Collection parameter.
   The Select Collections dialog opens.
2. Select the Global Collections to which to apply the template, and click OK. If you prefer to create a Global Collection for your test hosts, take the following steps:
   a. Click Create.
   b. Select settings for the new Global Collection.
   c. Proceed with the selection process.

Example Implementation Scenario

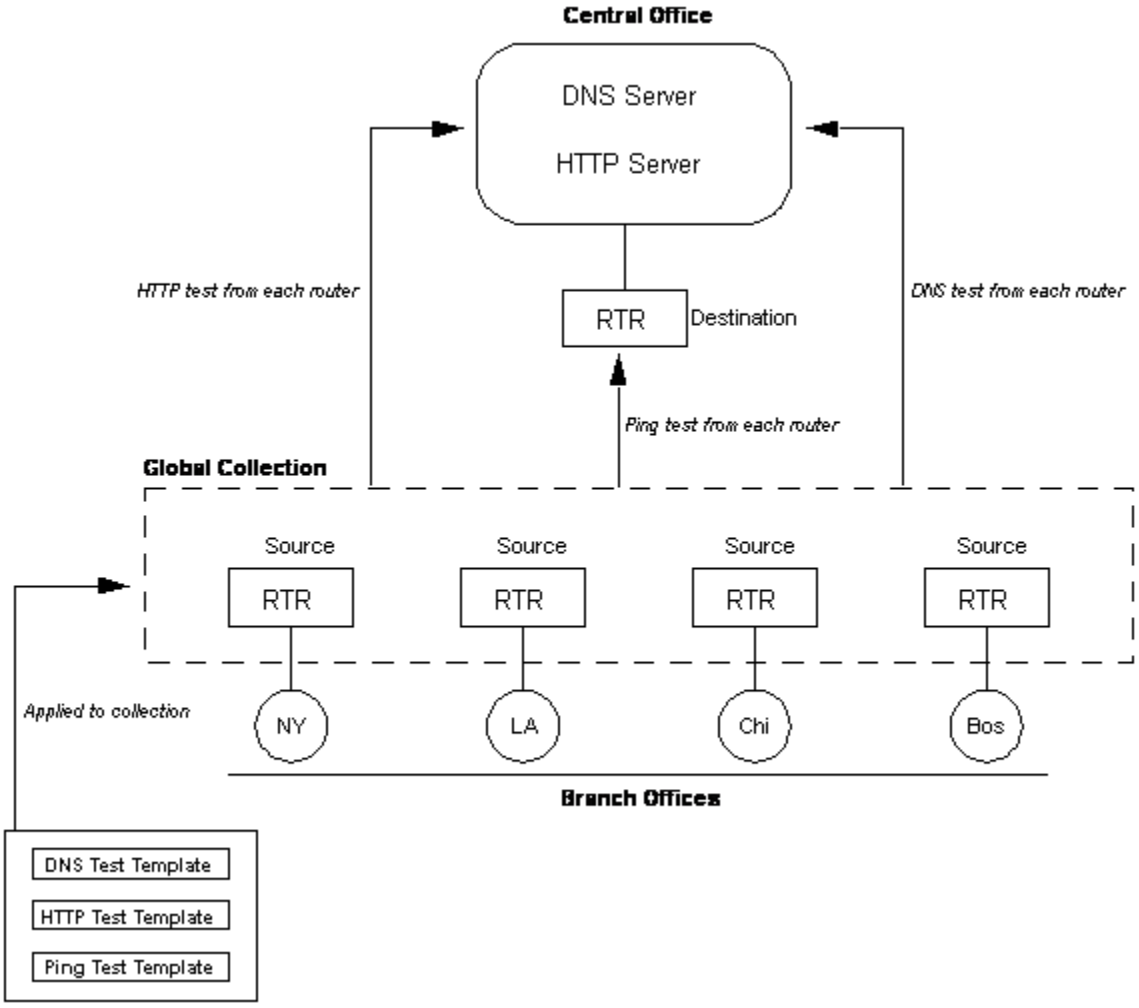
This section illustrates how test templates can be applied to a Global Collection to implement automated bulk performance testing between a central office location and branch office locations.

Scenario

- The central location of an organization provides domain name lookup and web services to numerous remote branch locations that connect to the central location on an intermittent basis.
- You can confirm that remote connections to the central location are maintained and the remote branch locations have continuous access to DNS and HTTP services that are provided by the central location.
- To determine whether service delivery from the main location to the remote locations remains viable, run Ping, DNS, and HTTP tests from remote location edge routers (that support the tests) on a regularly scheduled basis whenever they are brought online (connect to the central location edge router).
- Create a Global Collection that is configured to include all edge router models for remote locations as they are brought online.
- Three test templates are applied to a Global Container:
  – An ICMP Ping test template that is configured to create a Ping test on remote-location edge routers that tests connectivity to the central-location router.
  – A DNS test template that is configured to create a DNS lookup test on remote-location edge routers that tests DNS lookup time from the DNS server at the central location.
  – An HTTP test template that is configured to create an HTTP download test on remote-location edge routers that tests the round-trip time to download a web page from the HTTP server at the central location.

Test Template Scenario

The following image illustrates the example scenario.



About Destination Template Types

Test templates can use the Test Host or the Destination template. A Test Host template specifies a variable test host with a constant destination. A Destination template specifies a constant test host with variable destinations.

When applying a Destination test template to Global Collections, DX NetOps Spectrum populates the Destination Address from the type of model to which the test template is applied. Both port and device models are supported as destinations. These models must exist in or must be added to the target Global Collection for the test template to be applied.

- **Device models**
  When a Destination template is applied to a device model, the network address of the device is used as the Destination Address.
- **Port models**
  When a Destination template is applied to a port model, the IP address of the port is used as the Destination Address.

The Destination Address can be modified after the test is created.

Manage Test Templates

When you edit a template, all the tests that are created from the template are updated with the modified settings. When you remove the association between a template and a Global Collection or delete a template, all tests that are created from the template are deleted.

> **WARNING**
> Editing and deleting tests or test templates should be performed with caution by qualified personnel. This guidance especially applies in cases when, for example, Service Performance Manager performance test results are monitored by SLAs (service level agreements) that are modeled in DX NetOps Spectrum or when tests are run for infrastructure performance analysis.

Edit a Test Template

You can edit all test template parameter settings as required. The changes apply to all tests that you created with the template. You can also remove the association between a template and a Global Collection when you edit a template.

Note: You can remove the association between a template and a Global Collection. Delete the value of the Global Collections parameter in the Edit Test Template dialog. When you remove the association, all tests on the test hosts in the collection are deleted.

Follow these steps:

1. In the Explorer tab under Service Performance Manager, expand the Templates folder.
   The test templates appear.

   > **NOTE**
   > If no templates appear, create a template. For more information, see Create a New Test Template.
2. Right-click the test template that you want to edit and select Edit Test Template.
   The Edit Test Template dialog opens.
3. Modify the template settings and click OK.
   The changes are applied to the template and to all tests that are created from it.

Delete a Test Template

When you delete a template, you also delete all tests that are created from that template.

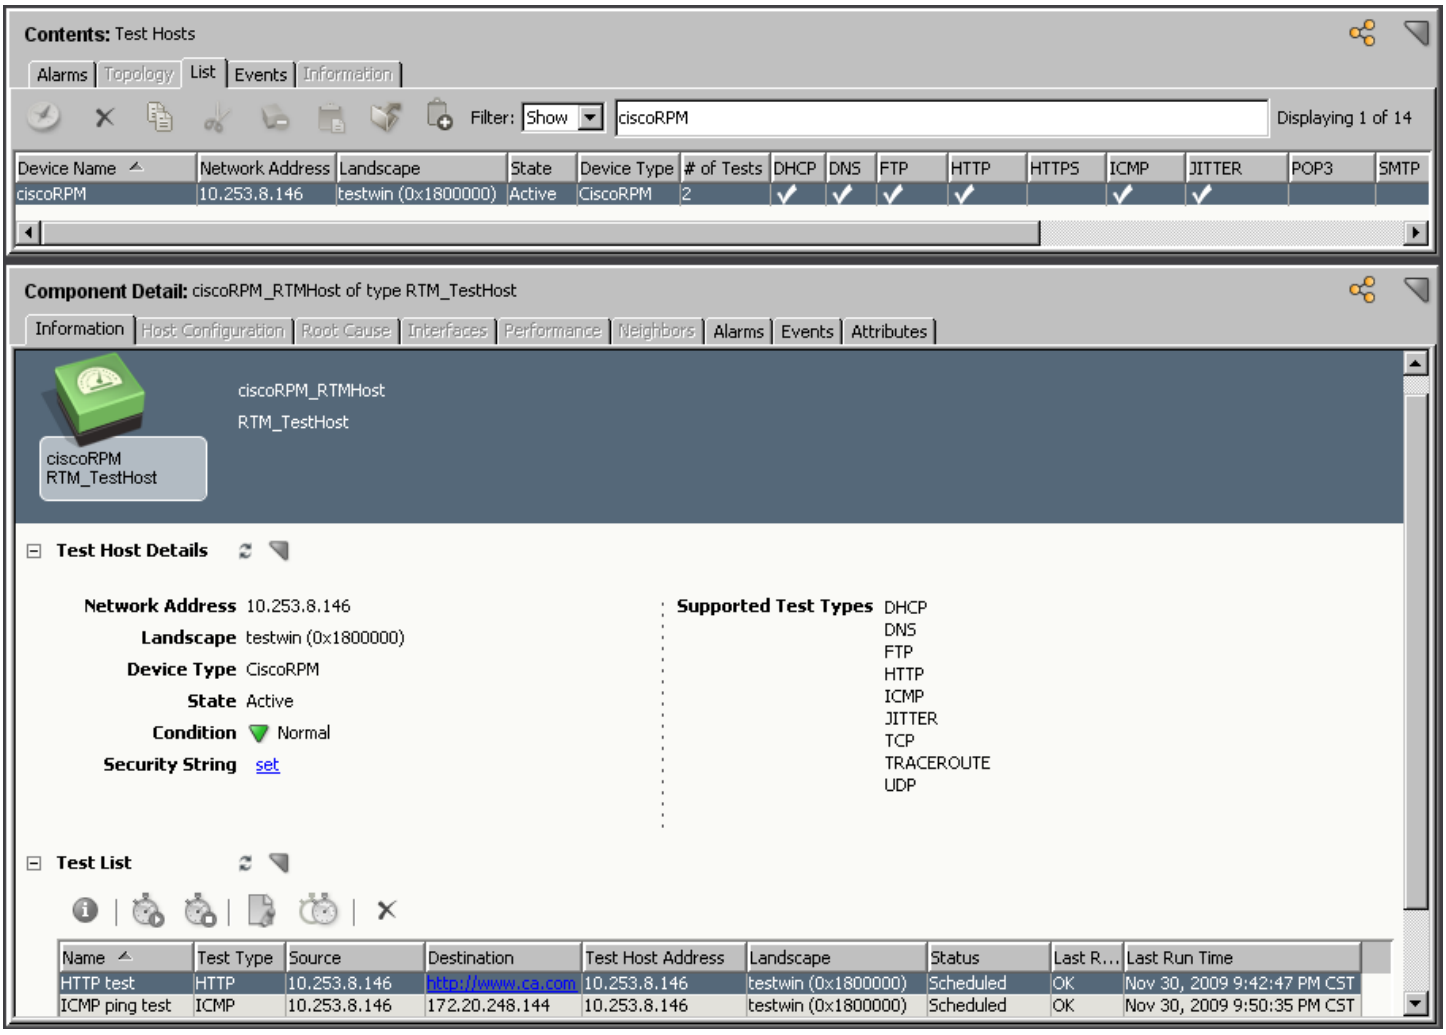
Follow these steps:

1. In the Explorer tab under Service Performance Manager, expand the Templates folder.
   The test templates appear.
2. Right-click the test template that you want to delete and select Delete.
   A confirmation dialog opens.
3. Click Yes.
   The test template is deleted.

Test Host Information

The OneClick Console displays summary and detailed information about test hosts that are modeled in DX NetOps Spectrum and lets you perform operations on tests for test hosts. OneClick provides views of test hosts, test templates, tests, and test results. You can also see detailed information about events and alarms for Service Performance Manager components.

The following image shows an example view of a test host:



Click Refresh in a OneClick view to see current information. You can refresh and customize views and dock and undock panels. You can set up table column preferences to display only the information types that you want to view. For more information, see the Using OneClick section.

The Contents panel displays information about the selected test host model, the landscape where it is modeled, its state (Active or Inactive), and the test types that it supports. From the Contents panel, you can create tests for the test host, discover tests for the test host, and activate and deactivate the test host.

Test Host Information in the Component Detail View

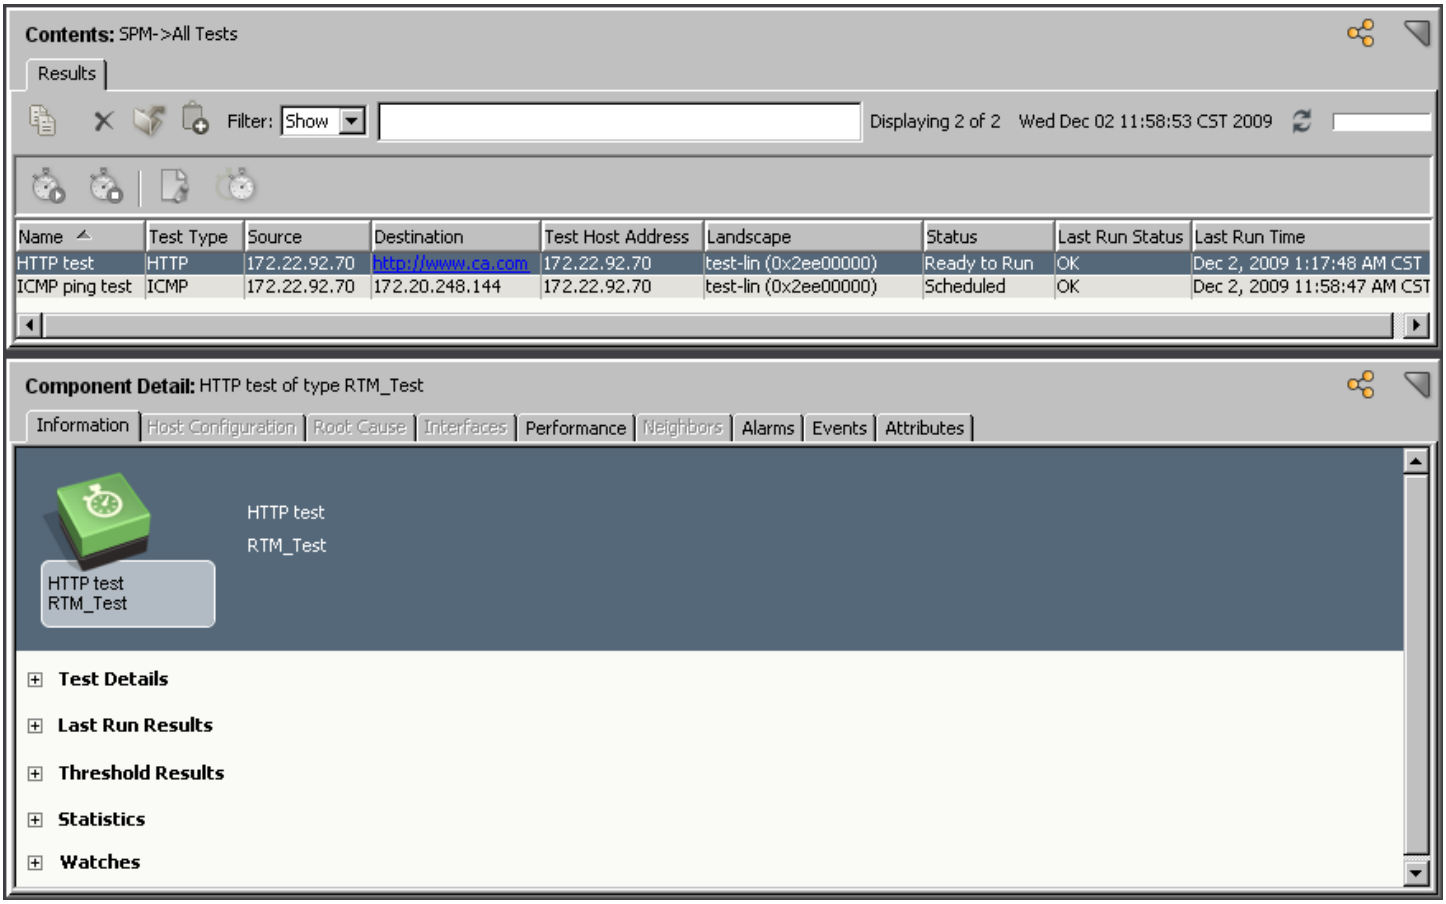
The Component Detail panel provides detailed information about a selected test host. The Information tab of the Component Detail panel includes two categories of information about the test host:

- **Test Host Details**
  Provides detailed information about the test host and lets you set the test host model security string.
- **Test List**
  Displays information about tests for the selected test host. It also lets you run tests, stop tests, manage tests, and invoke the Component Detail view for tests.

  NOTE
  For information about accessing information about alarms and events for Service Performance Manager components, see Alarms and Events.

Test Information

OneClick Console displays summary and detailed information about tests that are modeled in DX NetOps Spectrum and lets you perform operations on tests. The following image shows an example view.



The Contents panel table displays information about the selected test model, the landscape where it is modeled, the IP addresses of the test source, test destination, and test host for the test. It also provides additional information, such as the tests that are scheduled, running, or stopped, the last time the test was run, and the resulting status of the test (did or did not violate a threshold). Command icons for running, stopping, and managing tests are provided too.

Test Information in the Component Detail Panel

The Information tab in the Component Detail panel provides detailed information about a selected test:

- **Test Details**
  Provides information about test configuration settings, including scheduling and test threshold settings.
- **Last Run Results**
  Provides information about the most recent test run, including test results such as latency and packet loss values. Reported metrics vary depending on test host and test type.
- **Threshold Results**
  Provides information about threshold violations (event, minor, major, critical) resulting from the test. Threshold types vary depending on test host and test type.

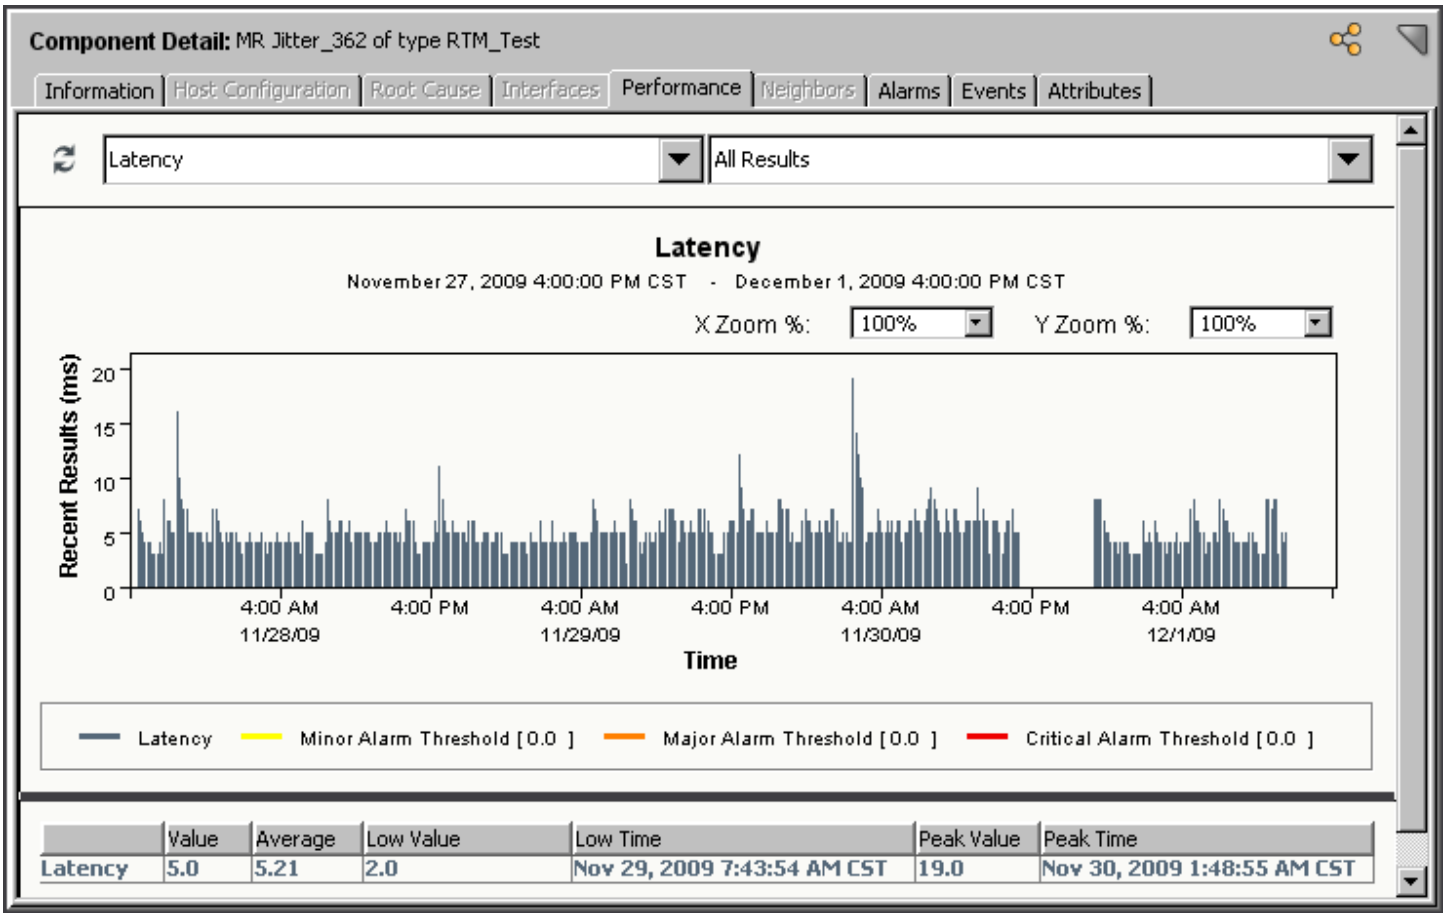
  NOTE
  Regarding the sample count and the % of Threshold values, RTTMON can perform more than the repetitions that are specified for a test. Service Performance Manager includes this count in the results and calculates

the average, maximum, and minimum results for latency and packet loss. Therefore, the value for percentage of packet loss can be other than a multiple of (1 / sample count) * 100.For example: If you set sample count to 5, typically the percentage of packet loss is a value of 0%, 20%, 40%, ...100%. If the agent performs more than 5 repetitions, you can see 0%, 16.66%, 33.33%, ...100%.

- **Statistics**
  Provides statistical test result information for tests that are run for SystemEDGE test hosts.
  Note: This section appears for tests that are created for SystemEDGE test hosts only.
- **Watches**
  Provides information about any watches that have been defined on the test model.

Test Performance Information in the Component Detail Panel

The Performance tab in the Component Detail panel shows graphical representations of test results. The following image shows an example test performance graph.



NOTE
The Archive Manager for the test landscape must be running for Service Performance Manager to display performance test results.

Specify the Interval

You can specify the following time intervals for which you want to display performance results:

- 1 hour
- 3 hours
- 6 hours
- 12 hours
- 1 Day
- 1 Week
- 4 Weeks
- All Results

> **NOTE**
> The All Results option retrieves all result data that is stored in the DX NetOps Spectrum Distributed Data Manager (DDM) database, up to a maximum of 365 days. By default, the DDM stores up to 45 days of data. See the Database Management section for more information.
>
> **WARNING**
> Retrieving large numbers of events can affect performance.

To specify the interval, select an interval from the list.

View Test Data

You can view data from a selected data point in a graph.

To view test data, position your mouse pointer over the end of a data point line in the graph. A descriptive label (including date, time, and value) is displayed for that data point.

You can also view additional test data (averages, high and low values) in tabular form under the graph.

Adjust an Axis

You can adjust the dimensions of the X and Y axes as necessary to meet your viewing requirements. For example, you can adjust the X axis to display latency outliers that are not visible from the default view.

To adjust the dimension of an axis, select a zoom percentage from the list for the X or Y axis, or supply a value.

> **NOTE**
> 100% is the minimum allowable zoom percentage.

Timeout Data Setting Affects a Performance Graph

When you configure a test, you can specify that data generated as a result of a test timeout is filtered out of test results. This setting is enabled by default. Timeouts and test failures can cause gaps in the graph. When timeout filtering is enabled, you cannot discern these gaps. Examples of test failures include lost contact to device, device in maintenance mode, or device failure.

A setting of False, however, causes the following effects:

- Skewed performance graph auto-scaling: Timeout values can so greatly exceed the response time values that exact response times on the performance graph can be difficult to discern.
- Skewed average calculation: Timeout values can so greatly exceed response times that average calculations are inaccurate.
- Skewed data from data export: Timeout values can be prevalent in the exported data. As a result, depending on your post-processing mechanisms, results can be undesirable.

Alarms and Events

You can view alarms for Service Performance Manager components from multiple points in the OneClick Console. Use the Explorer tab to view events and alarms for Service Performance Manager components.

Follow these steps:

1. Select Service Performance Manager in the Explorer tab and click the Alarms tab in the Contents panel.
   All alarms related to Service Performance Manager events appear in the Alarms tab.
2. Select an alarm in the Contents panel.
   The Alarm Details and Events tabs in the Component Detail panel display detailed information for the selected alarm.

You can also view events and alarms for Service Performance Manager components from the Locater tab.

Follow these steps:

1. List the components whose event and alarm information you want to view. For more information, see Finding Components.
2. In the Contents panel, select a component.
3. In the Component Detail panel, click the Alarms or Events tab to view information.

Service Performance Manager Result Data

You can export Service Performance Manager result data that is compiled over an extended period using the SPM result logger. SPM result logger output files include a model handle, timestamp, and a list of test-specific results per line. Once logging is enabled, Service Performance Manager produces text files with result data in SSLogger format. All result files are created and saved in an output directory that you create. New log files are created after an interval that you specify. For information about configuring data export parameters, see the OneClick Administration section.

Data Logging Event Codes

The following table lists Service Performance Manager data logging event codes:

Event Code	Event	Contains Statistics For...
0x04560000	SPM Result Event	Latency and packet loss (DHCP tests, which do not contain data for packet loss, are not included.)
0x0456002e	SPM Result Event (HTTP)	HTTP response time, DNS resolution time,TCP connect time, and HTTP download time
0x04560010	SPM Result Event (Jitter)	Jitter response time, Jitter source to destination time, Jitter destination to source time, Jitter MIA, Jitter late arrival, and Jitter busies
0x0456003e	SPM Result Event (Traceroute)	Latency

Result Events

For SPM result events, the preceding data is followed by statistical data particular to the RTM_Test. The event code dictates which of the statistics are relevant.

> **NOTE**
> Irrelevant statistics for a given test type (for example, Jitter statistics for a ping test) are reported as 0.

The remaining 12 reported statistics in a logged event correspond to, in order:

- Latency
- Packet loss
- HTTP response time
- DNS resolution time
- TCP connect time
- HTTP download time
- Jitter response time
- Jitter source to destination time
- Jitter destination to source time
- Jitter MIA
- Jitter late arrival
- Jitter busies

Data Export Sample

The following sample illustrates the structure of logged Service Performance Manager test result data:

```
0x830201d,6PM-7AM_6.6.0.2,1054176719,0x4560000,1,0.0,0,0,0,0,0,0.0,0.0,0.0,0.0,0.0

```

Test Modification Event

Service Performance Manager test modification events (event code 0x0456000a) contain the following statistical data, in addition to the common data described in Data Logging Event Codes:

- Test name
- Destination address
- Packet size
- Source address
- Test interval
- Sample count

Using the Command Line Interface (CLI) to Manage Tests

This section describes the procedure to use the Command Line Interface.

CLI Response-Time Testing

Response time tests are represented in DX NetOps Spectrum as models of model type RTM_Test. You can use the DX NetOps Spectrum Command Line Interface (CLI) to create, run, and edit response time tests and get test results as an alternative method to using the user interface in OneClick. For more information, see Working with Performance Tests. You can issue test management commands from the CLI command line, or you can embed CLI commands in scripts, which you can run on an ad hoc or scheduled basis.

Important! Before you attempt to create and manage tests with the CLI, understand Service Performance Manager concepts, CLI commands and command syntax, and DX NetOps Spectrum modeling concepts.

Create Tests in CLI

You can create any of the response time test models that DX NetOps Spectrum supports using the CLI create command. For more information, see Required Parameters for Creating Tests.

The following example script shows how to create a regularly scheduled Ping test. It enables a latency threshold, a latency value that, if exceeded, triggers a minor alarm, and a latency value that, if not exceeded, triggers an alarm clear.

```
#!/bin/ksh
cd $SPECROOT/vnmsh
connect
./create model mth=0x4560000 \
attr=0x1006e,val="Ping_Test_1" \ # Test Name
attr=0x4560005,val=0 \ # Test Type is ICMP_Ping
attr=0x45600f1,val=10.253.9.8 \ # TestHost address
attr=0x456001f,val=10.253.9.12 \ # Destination IP
attr=0x4560022,val=1 \ # Schedule is enabled
attr=0x4560014,val=600 \ # Test interval is 10 minutes
attr=0x4560035,val=1 \ # Latency Threshold is enabled
attr=0x456009b,val=100 \ # Latency Minor Threshold Set value
attr=0x4560017,val=100 \ # Latency Threshold Clear value
attr=0x4560027,val=2 # Clear Cycles
```

The following example script shows how to create an HTTP test. Note the formatting that is required for URL values.

```
#!/bin/ksh
cd $SPECROOT/vnmsh
connect
./create model mth=0x4560000 \
attr=0x1006e,val="Http_Test_1" \ # Test Name
attr=0x4560005,val=5 \ # Test Type is HTTP
attr=0x45600f1,val=10.253.9.8 \ # TestHost address
attr=0x456000f,val="http:\/\/www.ca.com\/about.htm" # Destination URL
attr=0x456008d,val="http:\/\/proxyServer" # Proxy URL
attr=0x4560022,val=1 \ # Schedule is enabled
```

Discover Tests in CLI

You can use the CLI update command to run SPM Test Discovery to discover and model performance tests that have been configured on test hosts but not with Service Performance Manager. Specify the discover tests action code (0x4560007) and the test host model handle. The following example script shows how to run SPM Test Discovery for a single test host.

NOTE
For more test action codes, see Test Action Codes.

```
#!/bin/ksh
# this will discover tests for the test host with the given model handle.
cd $SPECROOT/vnsmh
connect
./update action=0x4560007 mh=<testhostMH>
```

Run Tests in the CLI

You can run a response-time test using the CLI update command. Specify the run test action code (0x4560009) and the test model handle. For more information, see Test Action Codes.

The following example script shows how to run a single test. You can run multiple tests by specifying multiple tests in the script.

```
#!/bin/ksh
# this will run a test with the given model handle.
cd $SPECROOT/vnsmh
connect
./update action=0x4560009 mh=testMH
```

Edit Tests in the CLI

You can edit a response time test using an update command in the CLI. Change the values of test parameters by specifying new parameter values and issuing an update test action code (0x4560008).

The following example script shows how to modify a test schedule interval and test timeout values.

```
#!/bin/ksh

# change the schedule interval from 15 minutes to 30 minutes (1800 seconds)
# change the test timeout from 5000 ms to 1000 ms
# have the test not filter its timeout data

cd $SPECROOT/vnmsh
connect
./update mh=<testMH> attr=0x4560014,val=1800
./update mh=<testMH> attr=0x4560025,val=1000
./update mh=<testMH> attr=0x45600d6,val=FALSE
./update action=0x4560008 mh=$i
```

Get Test Results in CLI

You can get various test status indications and test results using the CLI show command. This command also returns the parameters with the values that you want.

The following example script shows how to get test status and test results. For more information, see Test Status and Test Results Parameters.

```
#!/bin/ksh
# obtain the latestResult status and latency/packet loss values for a given test
cd $SPECROOT/vnmsh
connect
./show attributes -e attr=0x4560004 attr=0x4560015 attr=0x456007d mh=<testMH>
```

Test Parameters Used in the CLI

The topics in this section list and describe parameters for creating and scheduling tests and setting test thresholds. You can configure RTM_Test model parameters using the user interface in OneClick. For more information, see Configure Tests.

Parameters for Creating Tests

Required Parameters

For All Test Types

The following parameters are required for all response time tests:

- **Model_Name (0x1006e)**
  Specifies the name of the test. Only one test per host can exist with the same name. Duplicate test names are appended with "_COPY".
- **Test_Type (0x4560005)**
  Specifies the type of test to create. Once a test is created, this value cannot be changed. If it is changed, it is reset when the update takes place.
  a. 0 = ICMP
  b. 1 = UDP
  c. 2 = Trace Route
  d. 3 = TCP
  e. 4 = DNS
  f. 5 = HTTP
  g. 6 = POP3
  h. 7 = DHCP
  i. 8 = FTP
  j. 9 = SMTP
  k. 10 = Jitter
  l. 13 = Custom
  m. 14 = SQL Query
  Default: None
- **Test_Host_Address (0x45600f1)**
  Specifies the IP address of a test host. This address must match the network address of the associated device model. Once a test is created, this value cannot be changed. If the value changes, it is reset when the update takes place.

For Specific Test Types

The following parameters are required when creating certain response time tests, depending on the test type:

- **Connect_String (0x456010a)**

Specifies a string of commands to connect to the database. This parameter is required for some SQL Query tests, depending on database type.
Example:

```
jdbc:mysql://172.22.246.43/mysql?user=root&password=root
```

- **Database_Name (0x4560108)**
  Specifies the name of the database. This parameter is required for some SQL Query tests, depending on the database type.
- **Database_Type (0x456010b)**
  Specifies the type of database to test. This parameter is required for SQL Query tests. Correct drivers must be installed on the CA eHealth SystemEDGE computer.
  a. 0 = Oracle
  b. 1 = Microsoft SQL
  c. 2 = Other
- **Dest_File_Name (0x456000d)**
  Specifies the destination filename. This parameter is required for FTP tests.
- **Dest_Host_Name (0x456000a)**
  Specifies the destination test hostname. For DNS tests, it is the lookup name; for FTP and POP3 tests, it is the address where the transaction is performed. For Custom tests, it is the name and location of a valid script.
- **Dest_IP_Address (0x456001f)**
  Specifies the destination IP address. This parameter is used for DNS, ICMP, Jitter, SMTP, TCP, Trace Route, and UDP tests.
- **Dest_Password (0x456000e)**

  WARNING
  The Dest_Password parameter is used for FTP, HTTP, HTTPS, POP3, SMTP, and SQL Query tests. You cannot use the CLI or the REST API for this parameter, as this password value is encrypted in the DX NetOps Spectrum database. Use the OneClick console to enter this value.
- **Dest_Port_Number (0x4560011)**
  Specifies the port number where the service is running for FTP, Jitter, POP3, SMTP, TCP, and UDP tests. For Mean Opinion Score (MOS) support in Jitter tests, the destination port must be an even-numbered port in the range 16384 - 32766 or 49152 - 65534.
  Note: Dest_Port_Number is supported for FTP, POP3, and SMTP tests only for CA eHealth SystemEDGE hosts.
- **Dest_URL (0x456000f)**
  Specifies the destination URL required for HTTP tests. Enclose the URL between double quotes (“ ”), and use escape slashes (\) before forward slashes (/). See Create Tests in CLI for a format example.
- **Dest_User_Name (0x456000b)**
  Specifies the destination user name, which is required for FTP and POP3 tests and optional for HTTP and HTTPS tests. For SMTP tests, this required parameter is the email address that you want to test. For SQL Query tests, this required parameter is the username for database access.
- **Query_String (0x456010c)**
  Specifies the query statement to execute. This parameter is required for SQL Query tests.
- **SQL_Driver (0x4560109)**
  Specifies the name of the SQL driver, which is required for some SQL Query tests, depending on the database type.
  Example:

```
com.mysql.jcbc.Driver
```

Optional Parameters

You can use optional parameters to specify various optional test parameters.

NOTE
Configure Advanced Parameters describes how to specify these parameters using the Service Performance Manager user interface in OneClick.

- **CodecType (0x45600e7)**
  Specifies the type of codec that is used by the router to perform audio compression and decompression. This parameter is important for calculating the Mean Option Score (MOS).
  a. 0 = None
  b. 1 = G.711 U-law
  c. 2 = G.711 A-law
  d. 3 = G.729A
  Default: 0
- **DeleteMessages (0x45600f5)**
  Specifies whether to delete the messages that were downloaded during the test or to leave the messages on the test system.
  Default: False
  Note: DeleteMessages is supported for POP3 tests for CA eHealth SystemEDGE hosts only.
- **DownloadContent (0x45600fd)**
  Specifies whether to download all images, frames, scripts, and applets, with the core HTML code from the website or URL.
  Default: False
  Note: DownloadContent is supported for HTTP and HTTPS tests for CA eHealth SystemEDGE hosts only.
- **DownloadType (0x45600f4)**
  Specifies whether the first or all messages are downloaded for POP3 tests.
  a. 1 = Download only the first message for this user account.
  b. 2 = Download all messages for this user account.
  Default: 1
  Note: DownloadType is supported for POP3 tests for CA eHealth SystemEDGE hosts only.
- **EchoAdminSourceAddress (0x45600b0)**
  Specifies the IP address or hostname of the test when it is not the test host. For more information, see About the Test Host Location Parameter.

  NOTE
  EchoAdminSourceAddress is supported for Cisco hosts only.
- **EchoAdminSourcePort (0x45600b1)**
  Specifies the port number that is used by the tested application (Jitter, TCP, UDP only).
  Limits: Must be less than 65536
  Note: EchoAdminSourcePort is supported for Cisco hosts only.
- **FailOnContentError (0x45600fe)**
  Specifies whether any errors that are encountered while downloading images, frames, scripts, and applets cause the test to fail.
  Default: False
  Note: FailOnContentError is supported for HTTP and HTTPS tests for CA eHealth SystemEDGE hosts only.
- **FILTER_TIMEOUT_DATA (0x45600d6)**
  Specifies whether the RTM_Test generates result events for timeouts.
  Default: True
- **FrameDepth (0x45600fa)**
  Specifies the number of levels the test should traverse when downloading nested frames. The HTTP and HTTPS tests download all frames, images, external scripts, and applets during the page download. The measurement reflects your experience when downloading a web page.
  Default: 3

Note: FrameDepth is supported for HTTP and HTTPS for CA eHealth SystemEDGE hosts only.

- **MailBodySize (0x45600f6)**
  Specifies the size (in bytes) of the test message to send.
  Default: 1000
  Note: MailBodySize is supported for SMTP tests for CA eHealth SystemEDGE hosts only.
- **MinMatches (0x45600fc)**
  Specifies the minimum number of times that the search expression can be found. The test fails if the search expression is not found for the specified number of times.
  Default: 1
  Note: MinMatches is supported for HTTP and HTTPS tests for CA eHealth SystemEDGE hosts only.
- **OperationType (0x45600f3)**
  Specifies the type of FTP operation to test.
  a. 1 = Login
  b. 2 = Get
  c. 3 = Put
  Default: 1
  Note: OperationType is supported for FTP tests for CA eHealth SystemEDGE hosts only.
- **OtherUserName (0x45600f8)**
  Specifies a username. For SMTP tests for CA eHealth SystemEDGE hosts, this is the outgoing username for SMTP authentication. For HTTP tests for Cisco routers and HTTP and HTTPS tests for CA eHealth SystemEDGE hosts, it is a valid username to be authenticated on the specified proxy server.
- **OtherPassword (0x45600f9)**

  WARNING
  The OtherPassword parameter is used for the Outgoing Password value for SMTP tests for CA eHealth SystemEDGE hosts. It is also used for the Proxy Password value for HTTP and HTTPS tests for Cisco routers and CA eHealth SystemEDGE hosts. Because this password value is encrypted in the DX NetOps Spectrum database, you cannot use CLI for this parameter. Use the OneClick Console to enter this value.
- **Packet_Size (0x4560067)**
  Specifies the value (expressed in octets) that limits the size of the packets that are used in the test.
  Default: 64
- **Proxy_URL (0x456008d)**
  Specifies a proxy URL or server.
  For Proxy URL, enclose the URL between double quotes (“ ”), and use escape slashes (\ ) before forward slashes (/).
  See Create Tests in CLI for a format example using a URL.
  For Proxy Server (for SystemEDGE hosts only), use the format <*server*>[:*port*].
  Note: Proxy_URL is supported for HTTP and HTTPS tests only.
- **Sample_Count (0x4560068)**
  Specifies the number of times during a test run that the test is performed.
  Default: 5
- **Source_IP_Address (0x45600f2)**
  Specifies the source IP address.

  NOTE
  Source_IP_Address is supported for Mid_Path/Extended_Path Ping tests only.
- **State (0x4560003)**
  Specifies the test state:
  a. 1 = Enabled
  b. 2 = Disabled
  Default: 1
- **Test_Host_Position (0x4560030)**
  Specifies test host location.

a. 0 = End point
b. 1 = Mid path
c. 2 = Extended path
Default: 0

- **TextMatch (0x45600fb)**
  Specifies a regular expression or text string to match on the pages you test.
  Note: TextMatch is supported for HTTP and HTTPS tests for CA eHealth SystemEDGE hosts only.
- **Thresh_Model (0x4560024)**
  Specifies the test entity where threshold events are asserted.
  a. 0 = Test
  b. 1 = Source
  c. 2 = Destination
  d. 3 = Host
  Default: 0
- **THRESH_SCHED_MH (0x4560090)**
  Specifies the Model Handle of a Schedule model. This parameter is used with the ThreshSchedule_Type parameter. Not specifying a value results in a 7x24 schedule.
- **ThreshSchedule_Type (0x4560090)**
  Specifies preconfigured threshold schedules for periods during which you want to see Service Performance Manager threshold alarms. Not specifying a value results in a 7x24 schedule.
  a. 0 = 7x24
  b. 1 = 7A-6P
  c. 2 = 6P-7A
  d. 3 = MF 8A-8P
  e. 4 = MF 6A-11P
  Default: 0
- **TypeOfService (0x4560099)**
  Specifies the Type of Service (TOS) octet in an IP datagram header that enables packets with different TOS values to be routed differently.
  Limits: Must be less than 256
  Default: 0
- **UseSSL (0x45600f7)**
  Specifies whether to enable Secure Sockets Layer security in case the SMTP server requires SSL authentication.
  Default: False
  Note: UseSSL is supported for SMTP tests for CA eHealth SystemEDGE hosts only.

Required Parameters for Scheduling Tests

Use these parameters to specify test timeout and test schedule management values.

> **NOTE**
> Schedule a Test explains the procedure to configure test schedule parameters using the Service Performance Manager user interface in OneClick.

- **ACTIVE_SCHED_MH (0x456008f)**
  Specifies the model handle of a test schedule model. Use this parameter as an alternative to TestSchedule_Type. Not specifying a value results in a 7x24 schedule.
- **Schedule_State (0x4560000)**
  Specifies whether the test schedule is in effect.
  a. 0 = Disables
  b. 1 = Enabled

Default: 0

- **Sched_Frequency (0x4560014)**
  Specifies the interval in seconds between scheduled test runs.
  Default: 5000
- **Test_Timeout (0x4560025)**
  Specifies the number of milliseconds before a test connection to an unresponsive test host times out.
  Default: 5000
- **TestSchedule_Type (0x456008b)**
  Specifies preconfigured test schedules. Use this parameter as an alternative to ACTIVE_SCHED_MH. Not specifying a value results in a 7x24 schedule.
  a. 0 = 7x24
  b. 1 = 7A-6P
  c. 2 = 6P-7A
  d. 3 = MF 8A-8P
  e. 4 = MF 6A-11P
  Default: 5
- **Thresh_Frequency (0x456001a)**
  Specifies an interval in seconds after which a test runs while in a threshold condition.
  Default: 300

Threshold Type Parameters

You can specify threshold management parameters for all test types. Thresholds are expressed either in terms of response, or transaction time, or packet error or loss, depending on the type of test for which the threshold is specified.

Latency Threshold Parameters

Latency_Thresh_State (0x4560035)

Specifies whether the latency threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Latency_MinorSetValue (0x456009b)

Specifies the latency threshold period in milliseconds that must be exceeded before a minor alarm is generated.

Default: 500

Latency_MajorSetValue (0x456009c)

Specifies the latency threshold period in milliseconds that must be exceeded before a major alarm is generated.

Default: None

Latency_CriticalSetValue (0x456009d)

Specifies the latency threshold period in milliseconds that must be exceeded before a critical alarm is generated.

Default: None

Thresh_Set_Value (0x4560016)

Specifies the latency threshold period in milliseconds that must be exceeded before an event is generated.

Default: None

Thresh_Clear_Value (0x4560017)

Specifies the latency threshold period in milliseconds the test must not exceed before an event is cleared.

Default: 500

Thresh_Set_Delay (0x4560026)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Thresh_Clear_Delay (0x4560027)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Packet Loss Threshold Parameters

PL_Thresh_State (0x4560034)

Specifies whether the packet loss threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

PacketLoss_MinorSetValue (0x456009e)

Specifies the packet lost percentage that must be exceeded before a minor alarm is generated.

Default: 20percent

PacketLoss_MajorSetValue (0x456009f)

Specifies the packet lost percentage that must be exceeded before a major alarm is generated.

Default: None

PacketLoss_CriticalSetValue (0x45600a0)

Specifies the packet lost percentage that must be exceeded before a critical alarm is generated.

Default: None

PL_Set_Value (0x456002c)

Specifies the packet lost percentage that must be exceeded before an event is generated.

Default: None

PL_Clear_Value (0x456002e)

Specifies the packet lost percentage that must not be exceeded before a minor alarm is generated.

Default: 20percent

PL_Set_Delay (0x456002d)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

PL_Clear_Delay (0x456002f)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

HTTP DNS Threshold Parameters

Statistic_1_Thresh_State (0x4560036)

Specifies whether the HTTP DNS threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_1_MinorSetValue (0x45600a1)

Specifies the resolution time threshold period in milliseconds that must be exceeded before a minor alarm is generated.

Default: 500

Statistic_1_MajorSetValue (0x45600a2)

Specifies the resolution time threshold period in milliseconds that must be exceeded before a major alarm is generated.

Default: None

Statistic_1_CriticalSetValue (0x45600a3)

Specifies the resolution time threshold period in milliseconds that must be exceeded before a critical alarm is generated.

Default: None

Statistic_1_Set_Value (0x4560039)

Specifies the resolution time threshold period in milliseconds that must be exceeded before an event is generated.

Default: None

Statistic_1_Clear_Value (0x456003a)

Specifies the resolution time threshold the test must not exceed before an event is cleared.

Default: 500

Statistic_1_Set_Delay (0x456003b)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_1_Clear_Delay (0x456003c)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

HTTP TCP Threshold Parameters

Statistic_2_Thresh_State (0x456003e)

Specifies whether the HTTP TCP threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_2_MinorSetValue (0x45600a4)

Specifies the connection time threshold period in milliseconds that must be exceeded before a minor alarm is generated.

Default: 500

Statistic_2_MajorSetValue (0x45600a5)

Specifies the connection time threshold period in milliseconds that must be exceeded before a major alarm is generated.

Default: None

Statistic_2_CriticalSetValue (0x45600a6)

Specifies the connection time threshold period in milliseconds that must be exceeded before a critical alarm is generated.

Default: None

Statistic_2_Set_Value (0x4560041)

Specifies the connection time threshold period in milliseconds that must be exceeded before an event is generated.

Default: None

Statistic_2_Clear_Value (0x4560042)

Specifies the connection time threshold that must not exceed before an event is cleared.

Default: 500

Statistic_2_Set_Delay (0x4560043)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_2_Clear_Delay (0x4560044)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

HTTP Download Threshold Parameters

Statistic_3_Thresh_State (0x4560046)

Specifies whether the HTTP download threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: None

Statistic_3_MinorSetValue (0x45600a7)

Specifies the download time threshold period in milliseconds that must be exceeded before a minor alarm is generated.

Default: 500

Statistic_3_MajorSetValue (0x45600a8)

Specifies the download time threshold period in milliseconds that must be exceeded before a major alarm is generated.

Default: None

Statistic_3_CriticalSetValue (0x45600a9)

Specifies the download time threshold period in milliseconds that must be exceeded before a critical alarm is generated.

Default: None

Statistic_3_Set_Value (0x4560049)

Specifies the download time threshold period in milliseconds that must be exceeded before an event is generated.

Default: None

Statistic_3_Clear_Value (0x456004a)

Specifies the download time latency threshold the test must not exceed before an event is cleared.

Default: 500

Statistic_3_Set_Delay (0x456004b)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_3_Clear_Delay (0x456004c)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Source to Destination Packet Loss Threshold

Statistic_1_Thresh_State (0x4560036)

Specifies whether the Jitter source to destination packet loss threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_1_MinorSetValue (0x45600a1)

Specifies the percentage of packets that must be lost before a minor alarm is generated.

Default: 20percent

Statistic_1_MajorSetValue (0x45600a2)

Specifies the percentage of packets that must be lost before a major alarm is generated.

Default: None

Statistic_1_CriticalSetValue (0x45600a3)

Specifies the percentage of packets that must be lost before a critical alarm is generated.

Default: None

Statistic_1_Set_Value (0x4560039)

Specifies the percentage of packets that must be lost before an event is generated.

Default: None

Statistic_1_Clear_Value (0x456003a)

Specifies the percentage of packets lost that cannot be exceeded before an event or alarm is cleared.

Default: 20percent

Statistic_1_Set_Delay (0x456003b)

Specifies the number of consecutive cycles the test must run in violation of a threshold before an event or alarm is generated.

Default: 1

Statistic_1_Clear_Delay (0x456003c)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Destination to Source Packet Loss Threshold

Statistic_2_Thresh_State (0x456003e)

Specifies whether the Jitter destination to source packet loss threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_2_MinorSetValue (0x45600a4)

Specifies the packet lost percentage that must be exceeded before a minor alarm is generated.

Default: 20percent

Statistic_2_MajorSetValue (0x45600a5)

Specifies the packet lost percentage that must be exceeded before a major alarm is generated.

Default: None

Statistic_2_CriticalSetValue (0x45600a6)

Specifies the packet lost percentage that must be exceeded before a critical alarm is generated.

Default: None

Statistic_2_Set_Value (0x4560041)

Specifies the packet lost percentage that must be exceeded before an event is generated.

Default: None

Statistic_2_Clear_Value (0x4560042)

Specifies the packet lost percentage that must not be exceeded before a minor alarm is generated.

Default: 20percent

Statistic_2_Set_Delay (0x4560043)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_2_Clear_Delay (0x4560044)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter MIA Threshold Parameters

Statistic_3_Thresh_State (0x4560046)

Specifies whether the Jitter MIA threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_3_MinorSetValue (0x45600a7)

Specifies the percentage of missing in action packets that must be exceeded before a minor alarm is generated.

Default: 20percent

Statistic_3_MajorSetValue (0x45600a8)

Specifies the percentage of missing in action packets that must be exceeded before a major alarm is generated.

Default: None

Statistic_3_CriticalSetValue (0x45600a9)

Specifies the percentage of missing in action packets that must be exceeded before a critical alarm is generated.

Default: None

Statistic_3_Set_Value (0x4560049)

Specifies the percentage of missing in action packets that must be exceeded before an event is generated.

Default: None

Statistic_3_Clear_Value (0x456004a)

Specifies the percentage of missing in action packets that must not be exceeded before an event or alarm is cleared.

Default: 20percent

Statistic_3_Set_Delay (0x456004b)

Specifies the number of consecutive cycles the test must exceed the threshold before an event or alarm is generated.

Default: 1

Statistic_3_Clear_Delay (0x456004c)

Specifies the number of consecutive cycles the test must not exceed the threshold before an event or alarm is generated.

Default: 1

Jitter Late Arrival Threshold Parameters

Statistic_4_Thresh_State (0x456004e)

Specifies whether the Jitter late arrival threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_4_MinorSetValue (0x45600aa)

Specifies the percentage of late packets that must be exceeded before a minor alarm is generated.

Default: None

Statistic_4_MajorSetValue (0x45600ab)

Specifies the percentage of late packets that must be exceeded before a major alarm is generated.

Default: 20percent

Statistic_4_CriticalSetValue (0x45600ac)

Specifies the percentage of late packets that must be exceeded before a critical alarm is generated.

Default: None

Statistic_4_Set_Value (0x4560051)

Specifies the percentage of late packets that must be exceeded before an event is generated.

Default: None

Statistic_4_Clear_Value (0x4560052)

Specifies the percentage of late packets that must not be exceeded before an event or alarm is cleared.

Default: None

Statistic_4_Set_Delay (0x4560053)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 20percent

Statistic_4_Clear_Delay (0x4560054)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Busies Threshold Parameters

Statistic_5_Thresh_State (0x4560056)

Specifies whether the Jitter busies threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_5_MinorSetValue (0x45600ad)

Specifies the percentage of busy failures that must be exceeded before a minor alarm is generated.

Default: 20

Statistic_5_MajorSetValue (0x45600ae)

Specifies the percentage of busy failures that must be exceeded before a major alarm is generated.

Default: None

Statistic_5_CriticalSetValue (0x45600af)

Specifies the percentage of busy failures that must be exceeded before a critical alarm is generated.

Default: None

Statistic_5_Set_Value (0x4560059)

Specifies the percentage of busy failures that must be exceeded before an event is generated.

Default: None

Statistic_5_Clear_Value (0x456005a)

Specifies the percentage of busy failures that must not be exceeded before an event is generated.

Default: 20

Statistic_5_Set_Delay (0x456005b)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_5_Clear_Delay (0x456005c)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Positive Source to Destination Threshold Parameters

Statistic_6_Thresh_State (0x45600ba)

Specifies whether the Jitter positive source to destination threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_6_MinorSetValue (0x45600b4)

Specifies the percentage of positive Jitter that must be exceeded before a minor alarm is generated.

Default: 25

Statistic_6_MajorSetValue (0x45600b5)

Specifies the percentage of positive Jitter that must be exceeded before a major alarm is generated.

Default: None

Statistic_6_CriticalSetValue (0x45600b6)

Specifies the percentage of positive Jitter that must be exceeded before a critical alarm is generated.

Default: None

Statistic_6_Set_Value (0x45600b3)

Specifies the percentage of positive Jitter that must be exceeded before an event is generated.

Default: None

Statistic_6_Clear_Value (0x45600b7)

Specifies the percentage of positive Jitter that must not be exceeded before an event is generated.

Default: 25

Statistic_6_Set_Delay (0x45600b8)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_6_Clear_Delay (0x45600b9)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Positive Destination to Source Threshold Parameters

Statistic_7_Thresh_State (0x45600ce)

Specifies whether the Jitter positive destination to source threshold is enabled or disabled for a test.

0 = Disabled

1 = Enabled

Default: 0

Statistic_7_MinorSetValue (0x45600bd)

Specifies the percentage of positive Jitter that must be exceeded before a minor alarm is generated.

Default: 25

Statistic_7_MajorSetValue (0x45600be)

Specifies the percentage of positive Jitter that must be exceeded before a major alarm is generated.

Default: None

Statistic_7_CriticalSetValue (0x45600bf)

Specifies the percentage of positive Jitter that must be exceeded before a critical alarm is generated.

Default: None

Statistic_7_Set_Value (0x45600bc)

Specifies the percentage of positive Jitter that must be exceeded before an event is generated.

Default: None

Statistic_7_Clear_Value (0x45600c0)

Specifies the percentage of positive Jitter that must not be exceeded before an event is generated.

Default: 25

Statistic_7_Set_Delay (0x45600c1)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_7_Clear_Delay (0x45600c2)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 25

Jitter Negative Source to Destination Threshold Parameters

Statistic_8_Thresh_State (0x45600cc)

Specifies whether the Jitter negative source to destination threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

Statistic_8_MinorSetValue (0x45600c5)

Specifies the percentage of negative Jitter that must be exceeded before a minor alarm is generated.

Default: 25

Statistic_8_MajorSetValue (0x45600c6)

Specifies the percentage of negative Jitter that must be exceeded before a major alarm is generated.

Default: None

Statistic_8_CriticalSetValue (0x45600c7)

Specifies the percentage of negative Jitter that must be exceeded before a critical alarm is generated.

Default: None

Statistic_8_Set_Value (0x45600c5)

Specifies the percentage of negative Jitter that must be exceeded before an event is generated.

Default: None

Statistic_8_Clear_Value (0x45600c9)

Specifies the percentage of negative Jitter that must not be exceeded before an event is generated.

Default: 25

Statistic_8_Set_Delay (0x45600ca)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_8_Clear_Delay (0x45600cb)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Jitter Negative Destination to Source Threshold Parameters

Statistic_9_Thresh_State (0x45600d5)

Specifies whether the Jitter negative destination to source threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: None

Statistic_9_MinorSetValue (0x45600cf)

Specifies the percentage of negative Jitter that must be exceeded before a minor alarm is generated.

Default: 25

Statistic_9_MajorSetValue (0x45600d0)

Specifies the percentage of negative Jitter that must be exceeded before a major alarm is generated.

Default: None

Statistic_9_CriticalSetValue (0x45600d1)

Specifies the percentage of negative Jitter that must be exceeded before a critical alarm is generated.

Default: None

Statistic_9_Set_Value (0x45600ce)

Specifies the percentage of negative Jitter that must be exceeded before an event is generated.

Default: None

Statistic_9_Clear_Value (0x45600d2)

Specifies the percentage of negative Jitter that must not be exceeded before an event is generated.

Default: 25

Statistic_9_Set_Delay (0x45600d3)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

Statistic_9_Clear_Delay (0x45600d4)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Packet out of Sequence SD Threshold Parameters

POOS_SD_ThreshState (0x4560119)

Specifies whether the Packets out of Sequence SD threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

POOS_SD_MinorSetValue (0x4560113)

Specifies the percentage of Packets out of Sequence SD that must be exceeded before a minor alarm is generated.

Default: 25

POOS_SD_MajorSetValue (0x4560114)

Specifies the percentage of Packets out of Sequence SD that must be exceeded before a major alarm is generated.

Default: None

POOS_SD_CriticalSetValue (0x4560115)

Specifies the percentage of Packets out of Sequence SD that must be exceeded before a critical alarm is generated.

Default: None

POOS_SD_SetValue (0x4560112)

Specifies the percentage of Packets out of Sequence SD that must be exceeded before an event is generated.

Default: None

POOS_SD_ClearValue (0x4560116)

Specifies the percentage of Packets out of Sequence SD that must not be exceeded before an event or alarm is cleared.

Default: 25

POOS_SD_SetDelay (0x4560117)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

POOS_SD_ClearDelay (0x4560118)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Packet out of Sequence DS Threshold Parameters

POOS_DS_ThreshState (0x4560124)

Specifies whether the Packets out of Sequence DS threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

POOS_DS_MinorSetValue (0x456011e)

Specifies the percentage of Packets out of Sequence DS that must be exceeded before a minor alarm is generated.

Default: 25

POOS_DS_MajorSetValue (0x456011f)

Specifies the percentage of Packets out of Sequence DS that must be exceeded before a major alarm is generated.

Default: None

POOS_DS_CriticalSetValue (0x4560120)

Specifies the percentage of Packets out of Sequence DS that must be exceeded before a critical alarm is generated.

Default: None

POOS_DS_SetValue (0x456011d)

Specifies the percentage of Packets out of Sequence DS that must be exceeded before an event is generated.

Default: None

POOS_DS_ClearValue (0x4560121)

Specifies the percentage of Packets out of Sequence DS that must not be exceeded before an event or alarm is cleared.

Default: 25

POOS_DS_SetDelay (0x4560122)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

POOS_DS_ClearDelay (0x4560123)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Packet out of Sequence BOTH Threshold Parameters

POOS_BOTH_ThreshState (0x456012f)

Specifies whether the Packets out of Sequence BOTH threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

POOS_BOTH_MinorSetValue (0x4560129)

Specifies the percentage of Packets out of Sequence BOTH that must be exceeded before a minor alarm is generated.

Default: 25

POOS_BOTH_MajorSetValue (0x456012a)

Specifies the percentage of Packets out of Sequence BOTH that must be exceeded before a major alarm is generated.

Default: None

POOS_BOTH_CriticalSetValue (0x456012b)

Specifies the percentage of Packets out of Sequence BOTH that must be exceeded before a critical alarm is generated.

Default: None

POOS_BOTH_SetValue (0x4560128)

Specifies the percentage of Packets out of Sequence BOTH that must be exceeded before an event is generated.

Default: None

POOS_BOTH_ClearValue (0x456012c)

Specifies the percentage of Packets out of Sequence BOTH that must not be exceeded before an event or alarm is cleared.

Default: 25

POOS_BOTH_SetDelay (0x456012d)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

POOS_BOTH_ClearDelay (0x456012e)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Packet Skipped Threshold Parameters

PSKIPPED_ThreshState (0x456013a)

Specifies whether the Packets Skipped threshold is enabled or disabled for a test.

1. 0 = Disabled
2. 1 = Enabled

Default: 0

PSKIPPED_MinorSetValue (0x4560134)

Specifies the percentage of Packets Skipped that must be exceeded before a minor alarm is generated.

Default: 25

PSKIPPED_MajorSetValue (0x4560135)

Specifies the percentage of Packets Skipped that must be exceeded before a major alarm is generated.

Default: None

PSKIPPED_CriticalSetValue (0x4560136)

Specifies the percentage of Packets Skipped that must be exceeded before a critical alarm is generated.

Default: None

PSKIPPED_SetValue (0x4560133)

Specifies the percentage of Packets Skipped that must be exceeded before an event is generated.

Default: None

PSKIPPED_ClearValue (0x4560137)

Specifies the percentage of Packets Skipped that must not be exceeded before an event or alarm is cleared.

Default: 25

PSKIPPED_SetDelay (0x4560138)

Specifies the number of consecutive cycles the test must run in violation of the threshold before an event or alarm is generated.

Default: 1

PSKIPPED_ClearDelay (0x4560139)

Specifies the number of consecutive cycles the test must run without exceeding the threshold before an event or alarm is cleared.

Default: 1

Test Action Codes

Use action codes with the CLI update command to discover tests, save changes to tests, run tests, and control timeout debugging information.

- **Discover tests (0x4560007)**
  Specifies to run SPM Test Discovery to discover and model performance tests that are configured on test hosts and not with Service Performance Manager. Use this action code with the RTM_TestHost model.
- **Update test (0x4560008)**
  Specifies to update test after making attribute changes.
- **Run test (0x4560009)**
  Specifies to run the test.
- **Update and Run test (0x456000a)**
  Specifies to run a combination of the Update and Run actions.
- **Include Timeout Debugging Information (0x456000e)**
  Specifies to include diagnostic information with SPM Timeout Event description.
- **Turn Off Timeout Debugging Information (0x456000f)**
  Specifies not to include diagnostic information with SPM Timeout Event description.

Test Status and Test Results Parameters

SPM LatestStatus (0x4560004) Attribute Values

You can use the latest status attribute with the CLI show command to get status information for the most recently run test.

- **1 = Ok**
  Test ran successfully.
- **2 = Threshold**
  Test result has exceeded its Set Value.
- **3 = Timeout**
  Test timed out.
- **4 = Failed**
  Test failed to create a response time test table entry due to configuration issue.
- **5 = Initial**
  Test has never run.
- **6 = Bad_comm**
  Test failed to create a response time test table entry because of an invalid community string.
- **7 = Running**
  Test is running.
- **8 = Stopped**
  Test has stopped running.
- **9 = Threshold_minor**
  Test result has exceeded its Minor Set Value.
- **10 = Threshold_major**

Test result has exceeded its Major Value.
- **11 = Threshold_critical**
  Test result has exceeded its Critical Value.

Test Results

Use the CLI show command to get results for a particular test.

- **Result_Timestamp (0x456005e)**
  The time test last completed.
- **Latest_Result (0x4560015)**
  Average Response Time (scalar).
- **TRACEROUTE_Result (0x4560075)**
  TraceRoute Result. List of IP Address Latency Result pairs.
- **PL_Result (0x456007d)**
  % Packet Loss.
- **DNS_Latest_Result (0x4560037)**
  Average HTTP DNS Lookup Time (scalar).
- **TCP_Latest_Result (0x456003f)**
  Average HTTP TCP Connection Time (scalar).
- **DL_Latest_Result (0x4560047)**
  Average HTTP Page Download Time (scalar).
- **JPLSD_Latest_Result (0x456007e)**
  % Jitter Packets Loss between Source and Destination.
- **JPLDS_Latest_Result (0x456007f)**
  % Jitter Packets Loss between Destination and Source.
- **JBUS_Latest_Result (0x4560080)**
  % Jitter Packets Busy.
- **JMIA_Latest_Result (0x4560081)**
  % Jitter Packets Missing in Action.
- **JLATE_Latest_Result (0x4560082)**
  % Jitter Packets Arriving Late.
- **PosJitterSD_LatestResult (0x45600b2)**
  Average Positive Jitter between Source and Destination.
- **PosJitterDS_LatestResult (0x45600bb)**
  Average Positive Jitter between Destination and Source.
- **NegJitterSD_LatestResult (0x45600c4)**
  Average Negative Jitter between Source and Destination.
- **NegJitterDS_LatestResult (0x45600cd)**
  Average Negative Jitter between Destination and Source.
- **MOS_Latest_Result (0x45600e5)**
  Mean Opinion Score Value (0 - 500). It provides a numerical measure of the quality of human speech at the destination end of the circuit.

Troubleshooting Service Performance Manager

This chapter identifies error messages that may be generated during Service Performance Manager operations and describes corrective action where feasible. Other maintenance and optional configuration issues are also addressed.

Firmware Issues

Certain router firmware revisions can exhibit instability. CA follows published interfaces to the SNMP agents, and rely on the device vendors to fully support these interfaces. Before deploying Service Performance Manager, it is advisable that users review device and firmware documentation from the vendor and apply any updates as appropriate.

Cisco IOS

When managing Jitter tests on Cisco IP SLA hosts, certain Cisco IOS versions do not allow codec type changes once the test has been run.

Cisco IOS 12.0(9)

Cisco IOS 12.0(9) has an issue that causes the router to reload upon the first SNMP SET performed to validate that the MIB is writable.

Cisco IOS 12.0(9) has an issue that causes the router to reload upon an SNMP Get of the supported test types table, which occurs during model activation.

Cisco IOS 12.0(7)T2

Cisco IOS 12.0(7)T2 has an issue which causes the test that is described in Traceroute Tests to fail. The problem is that the device does not report hop data correctly in the result tables of the CISCO-RTTMON-MIB, which causes Service Performance Manager to put erroneous data in the result event for average response time. To address this issue, upgrade your firmware to Cisco IOS 12.1(17).

Cisco IOS below 12.2

Cisco IOS below 12.2 has an issue which causes HTTP version 1.1 tests to fail with a “Request Timed Out” error message. Upgrading to Cisco IOS 12.2 or later versions will fix this issue.

Workaround: Changing the HTTP version from 1.1 to 1.0 may correct the timeout error message. See Configure Advanced Parameters for more information.

Cisco IOS 12.2(2)T

Cisco IOS 12.2(2)T has an issue that causes the router to intermittently report incorrect operation error codes such as DHCP response time tests that have timed out are reported as OK. If you encounter this issue during a run of a DHCP test, Service Performance Manager can report a latency value for the DHCP test, greater than the timeout value set for the test. To address this issue, Cisco recommends upgrading your firmware to Cisco IOS 12.2(15)T2.

Cisco IOS 12.2(11)T

Cisco devices running IOS firmware 12.2(11)T and higher correctly function as test hosts in Service Performance Manager. Previously, configured tests would not operate correctly due to changes in the RTTMon MIB.

Cisco IOS 12.3(4)

When running Service Performance Manager tests, a router running Cisco IOS version 12.3(10a) that is configured for SAA/RTR may crash because of a memory leak in the SAA/RTR process. This issue has been resolved in IOS version 12.3 (11) TO4.

Cisco IOS 12.3(5) and below

In Cisco IOS 12.3(5) and lower versions, changing the packet size on a Jitter Tests can cause the IOS to crash and reboot the router. This issue is addressed in Cisco IOS 12.3(5.013).

Cisco IOS 12.2(18)SXF3 and 12.2(18)SXF4

Cisco Routers running IOS 12.2(18)SXF3 with version 12.2(18)SXF4 can crash, when Service Performance Manager tests are run. Because of Cisco bug CSCin62031, the router can crash. Routers running these IOS versions cannot be modeled as test hosts capable of running Cisco IPSLA. To prevent these routers from being modeled as test hosts capable of running Cisco IPSLA, add the following commands to the router configuration before modeling:

```
snmp-server view NoRTTMON internet included
snmp-server view NoRTTMON ciscoRttMonMIB excluded
snmp-server community TEST view NoRTTMON RO
```

If these configuration commands are added after modeling, any attempt to run Service Performance Manager tests fails and do not let the router to crash.

Juniper (all JUNOS devices)

On a Juniper host device, running a response time test with a name longer than 32 characters returns an error. If you see such an error, recreate the test with a shorter name. When test templates are used, be aware that the model name or IP address is appended onto the template name. Be sure to leave enough characters when using templates so that the final, full test name reaches or falls below the 32 character limit.

Riverstone RS-8000 FW 9.0.0.4

Response time tests that are run from Riverstone RS-8000 (firmware 9.0.0.4) test host devices can return Bad Configuration errors. If you see these errors, verify that no two tests (configured for the Riverstone test host) have names with the same character length. If necessary, rename any such tests. For more information, see Configure General Parameters.

Timeout Errors

In most cases, lack of access is the cause of timeout errors during Service Performance Manager tests. For example, when Network Address Translation (NAT) is enabled, it can deny access to networks that are not in the list of networks to translate. Thus response time tests for HTTP or ICMP echo from an unlisted range of IPs would result in timeouts.

The solution in this case is to add the test network to the NAT list and rerun the tests. Other tests, such as DNS, DHCP, and UDP require the test host device to be properly configured for the service to be tested.

Timeout errors can also be caused by setting the latency timeout parameter to an invalid value. Valid values for test timeouts can vary from one test type to another, and from one device to another. For example, the CISCO-RTTMON-MIB provides the following guideline in describing its timeout value:

```
To prevent unwanted closure of connections, be sure to set this value to a realistic connection timeout.
```

You can verify the following common solutions for timeout errors:

- Verify that you have SNMP read/write access on the test host device.
- Verify that you have access from the test host device to the service being tested (such as ICMP, HTTP).
- Verify that you have set reasonable values for a test timeout.

NOTE
HTTP tests using certain Cisco Routers that run HTTP version 1.1 can fail with a Request Timed Out error. For more information, see Firmware Issues.

ICMP Ping Tests and Extreme Summit Test Host Devices

Ping tests that are run from Extreme Summit test host devices can result in timeouts. When you execute a ping from certain Extreme Summit devices, the RFC2925 branch of their MIB agents incorrectly reports a response time of 0. Service Performance Manager interprets this issue as a timeout, when in fact the device has replied to the ping. The current workaround is to use a different device as a test host.

Traceroute Tests and iAgent Test Hosts

Service Performance Manager always reports a timeout when traceroute tests are run on an iAgent test host. This issue is resolved by iAgent version 16.2.

Add Debugging Information to a Timeout Event

When attempting to determine the cause of a timeout event, you can collect diagnostic information for use by CA Support. Use the Command Line Interface to send an action to a test model so that it includes debugging information with the timeout event.

Using a CLI command, you can add debugging information to a timeout event and also disable debugging.

Follow these steps:

1. Open the Command Line Interface and enter the following command:
   ```
   update action=0x456000e mh=<RTM_Test Model_Handle>
   ```
   where *RTM_Test Model_Handle* is the Model_Handle attribute for the test model.
2. Add the following information to the SPM Timeout Event description:
   ```
   Additional Info: id xxxxx error: yy
   ```
   The information is added to the SPM Timeout Event description.
3. To disable debugging, use the following command:
   ```
   update action=0x456000f mh=<RTM_Test Model_Handle>
   ```
   where *RTM_Test Model_Handle* is the Model_Handle attribute for the test model.
   Debugging is disabled.

NOTE
For more information, see the Command Line Interface section.

Scheduling Tests in Geographically Distributed Environments

In a geographically distributed environment, the following network components can potentially be in different time zones:

- SpectroSERVERs
- OneClick consoles
- Web servers
- Test host devices

Test scheduling in Service Performance Manager is based on the time zone of the SpectroSERVER where the test host is modeled. Test results are based on the time zone of the OneClick console. To address the time discrepancy, select the 24/7 option when scheduling.

SpectroSERVER Crashed while Deleting the RTM_Hosts

Symptom:

When RTM_Hosts are deleted from Service Performance Manager, SpectroSERVER crashes.

Solution:

RTM Test Hosts are automatically created when a device is modeled and it supports the RTTMON application You must not delete these models. These models lets you know the device that supports the RTTMON application.

Delayed SpectroSERVER Activation Resulting from External Reads

For agents that support performance test types through MIB objects, DX NetOps Spectrum must perform external reads of these MIB objects at SpectroSERVER activation time to obtain the list of supported test types. This action can delay the SpectroSERVER activation time. You can configure the spm_wait_activate parameter in the .vnmrc file to delay the external reads until the SpectroSERVER is activated.

Set the default value of spm_wait_activate from No to Yes to prevent Service Performance Manager from performing external reads until the SpectroSERVER is activated.

> **NOTE**
> The agent test host remains inactive until the SpectroSERVER is activated.

Event Codes

This section describes the Event Code descriptions.

About SPM Timeout Event

Service Performance Manager determines when it is appropriate to generate an SPM Timeout Event and its associated alarm:

- SPM Timeout Event and its related alarm are suppressed, if the destination IP of the test represents a DX NetOps Spectrum device model that does not have ICMP contact. The alarm appears as a symptom of the DEVICE HAS STOPPED RESPONDING TO POLLS alarm of the DX NetOps Spectrum device model.
- SPM Timeout Event and its related alarm are not generated, if the test host does not have SNMP contact at the time that the RTM results are read for a given Service Performance Manager test.

Event Code Descriptions

The following table lists Service Performance Manager events by event code, event name, the model types that event can be asserted on, the alarm that is generated or cleared (if any), and the alarm severity.

Event Code	Event Name	Model Type Asserted On	Alarm Generated or Cleared	Alarm Severity
0x04560000	SPM Result Event	RTM_Test	None	N/A
0x04560001	SPM Timeout Event. For more information, see About SPM Timeout Event.	RTM_Test	0x04560001	Yellow
0x04560002	SPM Test Host Configuration Failed Event	RTM_Test	0x04560002	Yellow
0x04560003	SPM Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560004	SPM Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560003	Yellow
0x04560005	SPM Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560003	Orange
0x04560006	SPM Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560003	Red
0x04560007	SPM Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x04560003	N/A
0x04560008	SPM Test Creation Event	RTM_Test	None	N/A
0x0456000a	SPM Test Modification Event	RTM_Test	None	N/A
0x0456000b	SPM Packet Loss Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x0456000c	SPM Packet Loss Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456000b	Yellow
0x0456000d	SPM Packet Loss Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456000b	Orange
0x0456000e	SPM Packet Loss Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456000b	Red
0x0456000f	SPM Packet Loss Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x0456000b	N/A
0x04560010	SPM Result Event (Jitter)	RTM_Test	None	N/A

0x04560011	SPM Jitter Packet Loss Source to Destination Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560012	SPM Jitter Packet Loss Source to Destination Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560011	Yellow
0x04560013	SPM Jitter Packet Loss Source to Destination Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560011	Orange
0x04560014	SPM Jitter Packet Loss Source to Destination Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560011	Red
0x04560015	SPM Jitter Packet Loss Source to Destination Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x04560011	N/A
0x04560016	SPM Jitter Packet Loss Destination to Source Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560017	SPM Jitter Packet Loss Destination to Source Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560016	Yellow
0x04560018	SPM Jitter Packet Loss Destination to Source Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560016	Orange
0x04560019	SPM Jitter Packet Loss Destination to Source Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560016	Red
0x0456001a	SPM Jitter Packet Loss Destination to Source Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x04560016	N/A
0x0456001b	SPM Jitter Packet MIA Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x0456001c	SPM Jitter Packet MIA Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456001b	Yellow
0x0456001d	SPM Jitter Packet MIA Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456001b	Orange
0x0456001e	SPM Jitter Packet MIA Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456001b	Red
0x0456001f	SPM Jitter Packet MIA Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x0456001b	N/A
0x04560020	SPM Jitter Packet Late Arrival Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560021	SPM Jitter Packet Late Arrival Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560020	Yellow

0x04560022	SPM Jitter Packet Late Arrival Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560020	Orange
0x04560023	SPM Jitter Packet Late Arrival Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560020	Red
0x04560024	SPM Jitter Packet Late Arrival Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x04560020	N/A
0x04560025	SPM Jitter Busies Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560026	SPM Jitter Busies Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560025	Yellow
0x04560027	SPM Jitter Busies Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560025	Orange
0x04560028	SPM Jitter Busies Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x04560025	Red
0x04560029	SPM Jitter Busies Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x04560025	N/A
0x0456002a	SPM Test Pause (Test Host Down) Event	RTM_Test	None	N/A
0x0456002b	SPM Test Restart (Test Host Recontacted) Event	RTM_Test	None	N/A
0x0456002c	SPM Test Entering Management Mode Event	RTM_Test	None	N/A
0x0456002d	SPM Test Exiting Management Mode Event	RTM_Test	None	N/A
0x0456002e	SPM Result Event (HTTP)	RTM_Test	None	N/A
0x0456002f	SPM HTTP DNS Resolution Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A
0x04560030	SPM HTTP DNS Resolution Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456002f	Yellow
0x04560031	SPM HTTP DNS Resolution Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456002f	Orange
0x04560032	SPM HTTP DNS Resolution Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	0x0456002f	Red
0x04560033	SPM HTTP DNS Resolution Threshold Cleared Event	RTM_Test, RTM_TestHost, Source, or Destination	Clears 0x0456002f	N/A

0x04560034	SPM HTTP TCP Connect Threshold Exceeded Event	RTM_Test, RTM_TestHost, Source, or Destination	None	N/A

Standards-Based Protocol Reference

This section describes the standard protocols that DX NetOps Spectrum supports. When a device is modeled in OneClick, DX NetOps Spectrum automatically creates child application models for the standards supported by that device. Information about the standards is available in various OneClick subviews. From OneClick, you can view standard MIB information through model attributes, create attribute watches, and edit attribute values.

The standards that are described in this section are organized according to their functionality.

Bridging

This section describes the bridging standards applications that DX NetOps Spectrum supports. Bridging applications include models such as Spanning Tree and PPP Bridging.

Bridges are generally more flexible and intelligent than repeaters because they interconnect separate LAN or WAN data links and they learn the addresses of nodes that can be reached over each data link. Traffic can then be relayed selectively across each bridge. The bridging function operates in the MAC (Media Access Control) sublayer and is transparent to layers above the MAC sublayer.

Bridges can interconnect networks using different transmission techniques or MAC methods. A bridge can connect a LAN data link to a WAN telecommunications operation. Multiple bridges can be used to interconnect a series of networks. A pair of bridges with a telecommunications entity located between them can interconnect two different LAN locations.

Individual LAN data links that are interconnected by a bridge are considered to be a single subnetwork. Subnetwork station addresses must be unique and must use the same station address format. An Extended LAN is actually a LAN subnetwork constructed of bridges and is different from a single physical LAN. Operating layers above the MAC sublayer view, the Extended LAN acts as if it were a single LAN data link.

A bridge can implement a frame-filtering mechanism, or filtering bridge, to receive all frames that are transmitted over each attached data link. Based on each frame's destination address, the bridge determines if each frame can be transmitted across the bridge to any other attached data links. A bridge can therefore isolate network traffic generated on a LAN data link from other LAN data links in the Extended LAN. Broadcast traffic generated on one LAN is transmitted across a bridge to other data links to which it is attached; traffic generated by any station is received by all stations on the Extended LAN.

PPP Bridging

PPP (Point-to-Point Protocol) is used for managing the bridge network control protocol on subnetwork interfaces using the family of Point-to-Point protocols.

- RFC 1474
  - **Name:** PPP Bridge
  - **Model Type Name:** PPP_Bridge_App
  - **Name:** PPP_Bridge
  - **Model Type Name:** PPP_BdgApp1474

QBridge

QBridge, or IEEE 802.1Q, defines VLAN tagging, used to allow multiple bridged networks to transparently share the same physical network link without leakage of information between networks.

- RFC 2674
  - **Name:** Q Bridge
  - **Model Type Name:** qbridge_app_05

Source Routing

The Source Routing application contains utilization statistics derived from source routing. This information may be present in bridging token ring packets, and may affect a specific token ring interface. The Source Routing data is collected from the source routing information potentially present in any token ring packet. This information can be present in a transparent bridging or a mixed bridging environment, and can only be valid in a pure source route bridging environment.

- RFC 1525
  - **Name:** Source Routing
  - **Model Type Name:** rfc1525App

Spanning Tree Bridges

A spanning tree bridge learns appropriate routes from frames and verifies that all bridges are using the same network topology. Spanning tree bridges are used to form tree structures in which any two stations on an extended LAN are connected by one active path. A spanning tree bridge is transparent to ordinary stations on the interconnected LANs. To create and maintain the spanning tree, each bridge periodically multicasts Hello packets to all other bridges on the extended LAN. These packets are used to calculate the spanning tree and to verify that all bridges are using the same topology. Redundant links are not used. If a bridge or link failure occurs, the Hello packet transmissions allow the bridges to quickly calculate a new spanning tree.

- RFC 1493
  - **Name:** Spanning Tree
  - **Model Type Name:** Span_Tree_App

Static Bridging

Static bridging deals with destination-address filtering, letting you create an entry that stays in the static routing table without aging out or being removed if a device is powered off.

The Static Group, one of the five groups within the Bridge MIB, contains objects that describe the entity's state with respect to destination address filtering. If destination address filtering is not supported, this group is not implemented. This group is applicable to any type of bridge that performs destination address filtering.

- RFC 1493
  - **Name:** Static
  - **Model Type Name:** Static_App

Transparent Bridges

Transparent bridges operate in a manner that is transparent to network hosts. A transparent bridge learns the network's topology by analyzing the source address of incoming frames from all attached networks. From this process, it builds a table, which it then uses as a basis for traffic forwarding. When a frame is received on one of the bridge's interfaces, the bridge looks up the frame's destination address in its internal table. If the table contains an association between the destination address and any of the bridge's ports, aside from the one on which the frame was received, the frame is forwarded out to the indicated port. If no association is found, the frame is sent to all ports except the inbound port. Broadcasts and multicasts are also flooded in this way.

- RFC 1493
  - **Name:** Transparent
  - **Model Type Name:** Transparnt_App

Broadband

This section describes the broadband standards applications that DX NetOps Spectrum supports.

ADSL

ADSL (Asymmetric Digital Subscriber Line) is a continuously available connection over an existing phone line.

- RFC 2662
  - **Name:** ADSLLineApp
  - **Model Type Name:** ADSLLineApp

DOCSIS

DOCSIS (Data Over Cable Service Interface Specifications) is an international standard that defines the communications and operation support interface requirements for a data over cable system. It permits the addition of high-speed data transfer to an existing Cable TV system.

- Draft DOCS-BPI-MIB
  - **Name:** DOCSISBPIApp
  - **Model Type Name:** DOCSISBPIApp
- Draft DOCS-BPI2-MIB
  - **Name:** DOCSISBPI2App
  - **Model Type Name:** DOCSISBPI2App
- RFC 2669
  - **Name:** DOCSISCblDvApp
  - **Model Type Name:** DOCSISCblDvApp
- RFC 2670
  - **Name:** DOCSISIFApp
  - **Model Type Name:** DOCSISIFApp
- Draft DOCS-QOS-MIB
  - **Name:** DOCSISQOSApp
  - **Model Type Name:** DOCSISQOSApp

Device and System Identity

This section describes the device and system identity standards applications that DX NetOps Spectrum supports.

Entity

RFC 2737, Entity MIB, provides insight into logical and physical entities managed by an SNMP agent.

- RFC 2737
  - **Name:** EntityMIBApp
  - **Model Type Name:** RFC2737App

Host Resources

DX NetOps Spectrum supports the following Host Resources standards applications:

- RFC 2790
  - **Name:** Host Resources
  - **Model Type Name:** rfc2790App
- RFC 1514
  - **Name:** Host Resources
  - **Model Type Name:** rfc1514App

System Application

The system application RFC provides objects for fault, configuration, and performance management of applications from a systems perspective.

- RFC 2287
  - **Name:** SystemLvlApp
  - **Model Type Name:** RFC2287App

IP Protocols and Services

The section describes the standards DX NetOps Spectrum supports for application models associated with IP protocols and services.

DHCP

DHCP (Dynamic Host Configuration Protocol) is a computer networking protocol used by devices (DHCP clients) to obtain configuration information for operation in an Internet Protocol network.

- RFC 2131
  - **Name:** dhcpApp
  - **Model Type Name:** dhcpApp

ICMP

ICMP (Internet Control Message Protocol) uses IP datagrams and is typically generated in response to errors in IP datagrams or for diagnostic or routing purposes.

- RFC 792
  - **Name:** ICMP
  - **Model Type Name:** ICMP_App

    NOTE
    If the firmware on your device supports both the draft and the RFC version of the 2933 MIB, only the RFC2933App is modeled.

IGMP

IGMP (Internet Group Management Protocol) provides support for managing the membership of IP multicast groups. IGMP is used by IP hosts and adjacent multicast routers to establish multicast group memberships.

- Draft RFC 2933

  - **Name:** IGMP Draft
  - **Model Type Name:** Draft2933App
- RFC 2933
  - **Name:** IGMP
  - **Model Type Name:** RFC2933App

IP

IP (Internet Protocol) is commonly used as a delivery service. IP is a connectionless service responsible for moving datagrams from one device to another. As a delivery agent, IP watches to verify that the datagrams are within shipping regulations. To deliver datagrams, IP deals with two issues: addressing and fragmentation.

- RFC 1354
  - **Name:** IP
  - **Model Type Name:** IP1_App

IPM

The IP Multicast Routing (IPM) standard is used for managing IP Multicast Routing for IPv4, independent of the specific multicast routing protocol in use.

- RFC 2932
  - **Name:** IPMRouteStd
  - **Model Type Name:** RFC2932App

IP Tunnel

IP Tunnel MIB describes managed objects used for managing tunnels of any type over IPv4 networks.

- RFC 2667
  - **Name:** IPTunnel
  - **Model Type Name:** RFC2667App

MPLS

MPLS (Multi-Protocol Label Switching) is a standards-approved technology for speeding up network traffic flow and making it easier to manage.

- MplsVpn Draft 3
  - **Name:** MplsVpnApp
  - **Model Type Name:** MplsVpnApp
- MplsVpn Draft 4
  - **Name:** MplsVpnD4App
  - **Model Type Name:** MplsVpnD4App

MSDP

MSDP (Multicast Source Discovery Protocol) is a standard that describes a mechanism to connect multiple IPv4 protocol independent multicast sparse-mode (PIM) domains together.

- IETF Draft 3
  - **Name:** Msdp_D3_App
  - **Model Type Name:** Msdp_D3_App
- IETF Draft 7

  - **Name:** Msdp_D7_App
  - **Model Type Name:** Msdp_D7_App

PIM

PIM (Protocol Independent Multicast) describes objects used for managing the PIM protocol for IPv4, which is applicable to IPv4 routers that implement PIM.

- RFC 2934
  - **Name:** PIM-MIB
  - **Model Type Name:** rfc2934App

SNMP

SNMP is the standard protocol used to monitor IP gateways and the networks to which they attach.

- RFC 1213
  - **Name:** MIB-I
  - **Model Type Name:** SNMP1_Agent
- RFC 1213
  - **Name:** MIB-II
  - **Model Type Name:** SNMP2_Agent
- RFC 4293
  - **Name:** SNMP2_v6_Agent
  - **Model Type Name:** SNMP2_v6_Agent
- RFC 2271, RFC 3411
  - **Name:** SNMP Management Frameworks
  - **Model Type Name:** RFC2271App
- RFC 3413
  - **Name:** SNMP Applications
  - **Model Type Name:** RFC3413App
- RFC 3584
  - **Name:** SNMP Coexistence
  - **Model Type Name:** RFC3584App
- RFC 3415
  - **Name:** View-based Access Control Model
  - **Model Type Name:** RFC3415App
- RFC 1213
  - **Name:** System
  - **Model Type Name:** System1_App

TCP

TCP (Transmission Control Protocol) refers to the connection-oriented transport (communications) protocol used in the Internet suite.

- RFC 2012
  - **Name:** TCP
  - **Model Type Name:** TCP1_App

UDP

UDP (User Datagram Protocol) is part of the transport layer of the OSI model and uses the services of IP to deliver data.

- RFC 2013
- – **Name:** UDP
  – **Model Type Name:** UDP1_App

LWAPP

LWAPP (Lightweight Access Point Protocol) is a Cisco proprietary protocol defining how Wireless Termination Points communicate with Access Controllers. Wireless Termination Points and Access Controllers may communicate either by means of Layer 2 protocols or by means of a routed IP network.

- RFC 5412
  – • **Name:** LWAPP
    • **Model Type Name:** Cisco_LWAPP_App

CAPWAP

The CAPWAP (Controlling And Provisioning of Wireless Access Points) protocol is a generic protocol defining AC and WTP control and data plane communication via a CAPWAP protocol transport mechanism. CAPWAP Control messages, and optionally CAPWAP Data messages, are secured using Datagram Transport Layer Security (DTLS) [RFC4347].

- RFC 5415
  – • **Name:** CAPWAP
    • **Model Type Name:** CapwapApp

LAN

This section describes the following LAN standards applications that DX NetOps Spectrum supports:

Character Stream

The Character Stream application standard provides objects for the management of character stream devices, specifically to interface ports that carry a character stream, whether physical or virtual, serial or parallel, synchronous or asynchronous.

- RFC 1316
  – **Name:** Character Stream
  – **Model Type Name:** RFC1316App

Ethernet

The Ethernet standard provides objects for managing ethernet, such as media.

- RFC 1284
  – **Name:** Ethernet IF App
  – **Model Type Name:** EthernetIfApp

FDDI

FDDI (Fiber Distributed Data Interface) provides speed and reliability to a LAN and is often used as a backbone technology as well as a means of connecting high-speed computers in a local area. DX NetOps Spectrum supports the following FDDI applications:

- RFC 1512
  - **Name:** FDDI
  - **Model Type Name:** rfc1512App
  - **Name:** SMT_1
  - **Model Type Name:** GenFDDISmt_II
  - **Name:** MAC_1.1
  - **Model Type Name:** GenFDDIMac_I
  - **Model Type Name:** GenFDDIMac_II

Link Aggregation

Link aggregation is supported through the IEEE8023-LAG-MIB, developed by IEEE for managing 802.3ad. LACP (Link Aggregation Control Protocol) dynamically detects the links that can be aggregated into a Link Aggregation Group (LAG) and aggregates when links are available.

- 802.3ad
  - **Name:** LinkAggregation
  - **Model Type Name:** 802dot3adApp

    NOTE
    You can verify LACP_IF_Port for link aggregation interface information. For more information, see Manage Link Aggregation.

    .

Power Over Ethernet

Power over Ethernet (POE) provides objects that allow management of power ethernet power sourcing equipment.

- RFC 3621
  - **Name:** Power Ethernet
  - **Model Type Name:** RFC3621App

  For devices that support POE, their corresponding device model's POE interfaces can be identified through the POE column in the Interfaces table. You can disable the POE interface identification by changing the value of the ‘EnablePOEMapping’ attribute on the selected device model.

  NOTE
  For more information about setting attribute values, see Modeling and Managing Your IT Infrastructure .

RS-232

RS-232 is one of several common data terminal equipment (DTE) or data circuit-terminating equipment (DCE) interface standards. There are three RS-232 applications:

- RFC 1317

  - **Name:** RS-232
  - **Model Type Name:** RFC1317App
  - **Name:** RS-232 sync
  - **Model Type Name:** RFC1317sync
  - **Name:** RS-232 async
  - **Model Type Name:** RFC1317async

Token Ring

The standard for the Token Ring protocol is IEEE 802.5. FDDI also uses a Token Ring protocol.

- RFC 1231
  - **Name:** Token Rng IF App
  - **Model Type Name:** TokenRingIfApp

Wireless LAN

802.11 is a family of IEEE standards for wireless local area networks (WLANs).

- 802.11
  - **Name:** WirelessLAN
  - **Model Type Name:** 802dot11App

Performance

This section describes the standards DX NetOps Spectrum supports for the following performance-related application models:

RMON

The RMON (Remote Network Monitoring) MIB is based on RFC1757 (Ethernet) and RFC1513 (Token Ring). It is divided into the following groups:

- Statistics
- History
- Alarm
- Host
- HostTopN
- Matrix
- Filter
- Packet Capture
- Event
- Token Ring

Each group defines a set of objects to be monitored. In addition, each group stores data and statistics collected by the agent on the device, which may have multiple network interfaces.

The RMONApp model accesses and presents RMON data from all network interfaces supported by a device. DX NetOps Spectrum supports the following RMON application models:

- RFC 1757, RFC 1513

  - **Name:** RMON
  - **Model Type Name:** RMONApp
- RFC 1757
  - **Name:** E Probe
  - **Model Type Name:** RMONEthProbe
- RFC 1513
  - **Name:** T R Probe
  - **Model Type Name:** RMONTRProbe

Traceroute/Lookup

The Traceroute/Lookup standard defines objects for performing remote ping, traceroute, and lookup operations at a remote host.

- RFC 2925
  - **Name:** RFC2925App
  - **Model Type Name:** RFC2925App

Routing

This section describes the following routing standards applications that DX NetOps Spectrum supports:

BGP4

BGP (Border Gateway Protocol) is the core routing protocol of the Internet.

- RFC 1269
  - **Name:** BGP4
  - **Model Type Name:** BGP4_App

IP Routing

The IP routing applications contain information used by DX NetOps Spectrum to resolve the interconnections of devices through the network at the IP level (Layer 3).

- RFC 1213, RFC 2096, RFC 1354
  - **Name:** IP Routing
  - **Model Type Name:** IPRtrApp
  - **Name:** IP Routing
  - **Model Type Name:** IP2RtrApp

IS-IS Routing

The Intermediate System to Intermediate System (IS-IS) routing protocol is used to build routing tables for IP networks.

- RFC 4444
  - **Name**: IS-IS Routing
  - **Model Type Name**: RFC4444App

OSPF

The OSPF (Open Shortest Path First) protocol is a hierarchical interior gateway protocol (IGP) for routing.

- RFC 1253
  - **Name:** OSPF
  - **Model Type Name:** OSPF2RtrApp

Repeater

The Repeater standard provides support for objects used to manage IEEE 802.3 repeaters, sometimes referred to as hubs.

- RFC 1516
  - **Name:** SNMP-Repeater
  - **Model Type Name:** rfc1516App

RIP2

RIP2 (Routing Information Protocol 2) is a distance-vector routing protocol.

- RFC 1724
  - **Name:** RIP2
  - **Model Type Name:** RFC1724App

VRRP

The VRRP (Virtual Router Redundancy Protocol) application allows several routers on a multi-access link to use the same virtual IP address. One router is elected as the master with the other routers acting as backups. This allows host systems to be configured (manually or using DHCP) with a single default gateway rather than running an active routing protocol. This protocol also supports the ability to load-share traffic when both routers are up.

- RFC 2338
  - **Name:** VRRP
  - **Model Type Name:** VRRPApp

SAN

This section describes the SAN (Storage Area Network) standards applications that DX NetOps Spectrum supports.

Fibre Channel

Fibre Channel is a gigabit-speed network technology. It is the standard connection type for SAN in enterprise storage.

- Draft FC MGMT-MIB
  - **Name:** FcMgmt
  - **Model Type Name:** DraftFcMgmtApp
- Draft RFC 2837
  - **Name:** FcFabricElement
  - **Model Type Name:** Draft2837App
- RFC 2837
  - **Name:** FcFabricElement
  - **Model Type Name:** RFC2837App

The DX NetOps Spectrum DraftFcMgmtApp application model type supports versions 3.0 and 4.0 of the Fibre Channel Management Framework Integration MIB, which was developed by the Fibre Alliance in order to provide an integrated management environment for an enterprise class storage network. If a device that supports this MIB is modeled with DX NetOps Spectrum, a DraftFcMgmtApp model is created for that device.

Security-Based Protocols

Port-Based Network Access Control

The IEEE 802.1x standard is designed to enhance the security of wireless local area networks (WLANs). It provides an authentication framework for wireless LANs, allowing a user to be authenticated by a central authority.

- 802.1x
  - **Name:** PortNetAccControl
  - **Model Type Name:** 802dot1xApp

RADIUS

DX NetOps Spectrum supports the following RADIUS (Remote Authentication Dial-In User Service) standards applications:

- RFC 2618
  - **Name:** RADIUS Authentication Client
  - **Model Type Name:** RFC2618App
- RFC 2620
  - **Name:** RADIUS Accounting Client
  - **Model Type Name:** RFC2620App

User-Based Security Model

This standard provides a description of the User-based Security Model (USM) for SNMP. It defines the elements of procedure for providing SNMP message-level security and provides objects for remotely monitoring and managing the configuration parameters for this security model.

- RFC 3414
  - **Name:** User-based Security Model
  - **Model Type Name:** RFC3414App

WAN

Wide Area Network (WAN) data link technology is used to implement point-to-point connections between devices. This section describes the foloowing WAN standards applications that DX NetOps Spectrum supports:

ATM

The ATM (Asynchronous Transfer Mode) Client application allows you to monitor virtual channel links and change channel statistics.

- RFC 1695
  - **Name:** ATM_Client
  - **Model Type Name:** ATMClientApp
  - **Name:** ATM_Switch
  - **Model Type Name:** ATMSwitchApp

DS1

DS1 is a high-speed baseband transmission link.

- RFC 1406

  - **Name:** DS1
  - **Model Type Name:** DS1App1406
  - **Model Type Name:** DS1_1406App
- RFC 1232
  - **Name:** DS1
  - **Model Type Name:** RFC1232App

Frame Relay

Frame relay is a packet-based interface standard that has been optimized for the transport of protocol-oriented data. The frame relay interface specification provides a signaling and data transfer mechanism. Frame relay's ability to statistically multiplex means that paths or virtual circuits are defined throughout the network, but no bandwidth is allocated to the paths until data needs to be transmitted. Frame relay provides multiple logical connections within a single physical connection.

RFC 1315 is the MIB for Frame Relay DTEs (Data Terminal Equipment).

- RFC 1315
  - **Name:** Frame Relay
  - **Model Type Name:** FR_1315App
  - **Name:** Frame Relay
  - **Model Type Name:** rfc1315App

    NOTE
    The FR_1315App replaces the rfc1315App when Frame Relay Manager is installed.

RFC 2115 is the MIB for Frame Relay DTEs using SMIv2.

- RFC 2115
  - **Name:** FrameRelayApp
  - **Model Type Name:** rfc2115App

PNNI

PNNI (Private Network-to-Network Interface) is a suite of network protocols that can be used to discover an ATM network topology, create a database of topology information, and route calls over the discovered topology.

- PNNI-MIB
  - **Name:** PNNI_App
  - **Model Type Name:** PNNI_App

PPP

The PPP (Point-to-Point Protocol) application provides a method for transmitting datagrams over serial point-to-point links.

- Draft IETF-PPP-MIB
  - **Name:** PPP
  - **Model Type Name:** PPPLinkApp

SONET

SONET (Synchronous Optical Network) applications let you manage SONET/SDH (Synchronous Digital Hierarchy) interfaces. The following SONET standards are supported by DX NetOps Spectrum:

- RFC 1595

  - **Name:** SONET
  - **Model Type Name:** rfc1595App
- RFC 2558
  - **Name:** SONET
  - **Model Type Name:** rfc2558App

Accessing Standard Protocol Information in OneClick

This section describes how to access standards-based application information in OneClick. You can access application models and the information related to them from the Information tab of the device or by using the search functionality in the Locater tab.

Access Standards-Based Information Using the Information Tab

Depending on the device, you have modeled, you might have various OneClick subviews available to you from the Information tab in the Component Detail panel. From these subviews, you can view application model information.

To access standards-based information from a specific device model

1. Select the device from which you want to view RFC information.
2. In the Component Details panel, in the Information tab, expand the subview containing the information that you want to review.

   NOTE
   Various subviews are available depending on what MIB standards the device supported when it was modeled.

Locater Search

You can use the search functionality in the Locater tab to find application models and to subsequently view application model information. Search results appear in the Results tab of the Contents panel. Detailed information for application models that are selected in the results list appears in the Component Detail panel.

Search for Application Models

If you are not sure which device to access for the application models you want to view, you can use the search functionality of the Locater tab to list every application model that was created and to which you have access rights.

NOTE
If you are operating a Distributed SpectroSERVER (DSS) environment, some searches require you to select which landscapes to include in your search from the 'Select Landscapes to Search' dialog.

To access application models using Locater search

1. Click the Locater tab in the Navigation panel.
2. In the Locater tab, in the Name column, click 'Application Models' to expand it, and then do one of the following:
   - Double-click 'All Application Models.'
   - Click 'All Application Models,' and then click the 'Create a new search' button.
3. Enter any additional information if prompted, depending on the type of search you are running, and click OK.

   NOTE
   If additional input is not required, the search runs immediately and the search results appear in the Results tab of the Contents panel.
4. To narrow your search, enter further criteria in the Filter box at the top of the results list in the Results tab.

For example, if you were looking for the Repeater application, you could enter **1516** in the Filter box, which would find the Repeater model by its Model Type Name, 'rfc1516App.' Alternatively, you could enter **repeater** in the Filter box, which would find the Repeater model by its Name, '<*device_name*>_SNMP-Repeater.'
The Results tab refreshes to show only those models that match the criteria in the Filter box.

5. In the Results tab list, select the application model you want more information about.
The Component Detail view displays details about the selected application model.
6. Click any of the available tabs in the Component Detail view to review information specific to the selected application model.

NOTE
For more information about using Locater search functionality, see Using OneClick.

Manage Link Aggregation

IEEE 802.3ad-based link aggregation lets you aggregate two or more links together to form Link Aggregation Groups (LAGs), such that a MAC client considers LAG as a single link. DX NetOps Spectrum supports LACP (Link Aggregation Control Protocol) with the following features:

- Locater Search
- Spotlight View
- Threshold Alarm

LACP OneClick View

The LACP Port Aggregation table contains Link Aggregation Control configuration information of every Aggregation Port associated with a device.

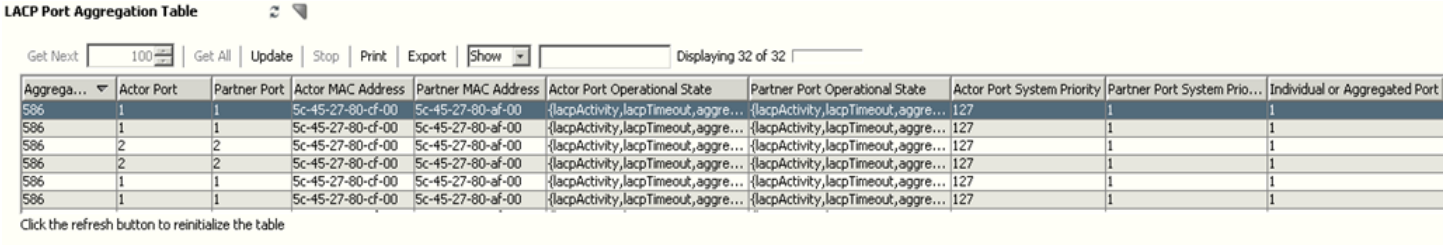
The following attributes are available in the LACP Port Aggregation Table:

- **Aggregator ID**
Indicates the ID number as the base port number or lowest number of an aggregator. Each aggregator must have an ID number. For example, an aggregator with ports 12, 16, and 17 must be assigned the ID number 12 because that is the base port number.
- **Actor Port**
Indicates a port number that is assigned to the port by the actor, encoded as an unsigned integer.
- **Partner Port**
Indicates a port number that is associated with the link assigned to the port by the partner, encoded as an unsigned integer.
- **Actor MAC Address**
Defines the value of the system ID for the system that contains the Aggregation Port.
Default: Six-digit MAC address.
- **Partner MAC Address**
Represents the current value of the Aggregation Port protocol.
Default: Six-digit MAC address.
- **Actor Port Operational State**
Indicates the operational values of Actor_State, transmitted by the actor in the Link Aggregation Control Protocol Data Units (LACPDU).
- **Partner Port Operational State**
Indicates a string of 8 bits, corresponding to the current values of Actor_State in the most recently received LACPDU transmitted by the protocol Partner. In the absence of an active protocol partner, this value might reflect the manually configured aAggPortPartnerAdminState value.
- **Actor Port System Priority**
Defines the priority value that is associated with the Actor System ID.

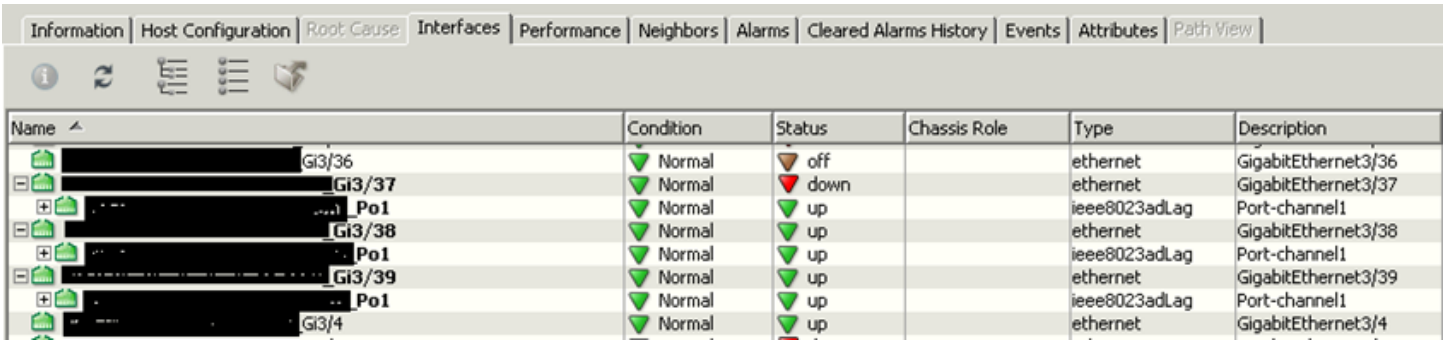
Default: Two-digit MAC address.

- **Partner Port System Priority**
  Indicates the current administrative value of the port priority for the protocol partner.
- **Individual or Aggregated Port**
  Represents a Boolean value of the Aggregation Port. This value indicates whether the Aggregation Port can Aggregate (TRUE) or can only operate as an Individual link (FALSE).

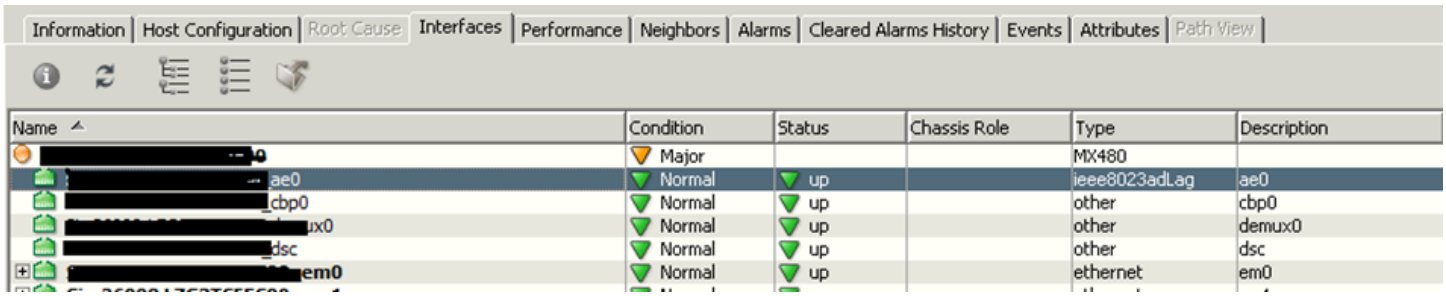
The following image displays the LACP Port Aggregation Table that is available in OneClick:



The port channel aggregation is displayed in the Interfaces tab of OneClick. The port channel is displayed as a sub-interface of aggregated Ethernet interfaces in the Interface tab. The LACP configured port channels are of type ieee8023adLag.
The following image displays the Interfaces tab of a device configured for LACP.



In case of VLAN tagging enabled on top of LACP configuration, the port channel is displayed separately and not as a sub-interface of aggregated Ethernet interfaces in the Interface tab of OneClick.
The following image displays the Interface tab in case of VLAN tagging enabled:



LACP Locater Search

You can use the search functionality in the Locater tab to find the devices that are configured with LACP and the application models that are associated with LACP. Search results appear in the Results tab of the Contents panel. Detailed information for application models that are selected in the results list appears in the Component Detail panel. Access LACP Locater search from the Locater tab of the Navigation

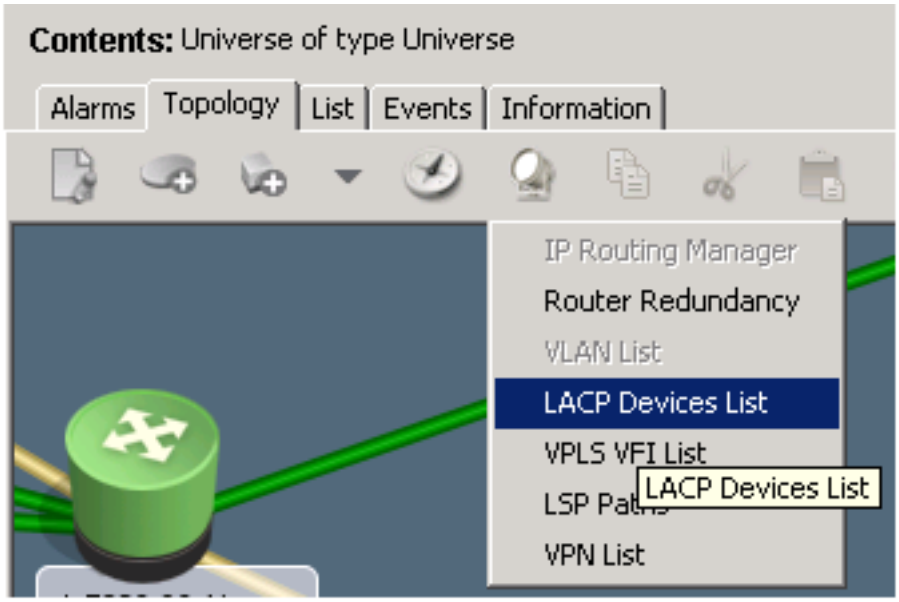
Follow these steps:

1. Open the OneClick Console.
2. From the Navigation Panel, Click the Locater tab.
   The Search Options window opens.
3. Select Devices, Supports Application, and LACP.
   The LACP Locater Search results are displayed in Contents panel.

Spotlight View

You can use the Spotlight feature in OneClick to view the devices that are configured with LACP on your network.

The following image displays the LACP Devices List option that is available in Spotlight View:



You can spotlight the listed items if they have been enabled and configured on your network. You can click the Spotlight View button that is available on the Topology toolbar and can select the LACP Devices List option to display the LACP configured devices.

LACP Threshold Computation

Spectrum generates various LACP threshold violation alarms on the LACP port channel model, such as critical, major, and minor. All the physical interfaces that are aggregated to the logical port of LACP participate in threshold calculation. You can use this threshold alarm to know the usage of the physical interfaces in an aggregate group of LACP.

The LACP threshold is calculated based on the IfOperStatus of the aggregated interfaces. To access IfOperStatus, you must have the admin link (based on external attribute, ifAdminStatus) status as UP.

```
down/totallinks
```

The following scenarios are considered during the threshold comparisons:

- If the LACP_IF_Port attributes are set to a value other than 0 but not greater than 100, the following attributes are used during the threshold comparisons:

  - LACP_Critical_Threshold = 0x2202c0
  - LACP_Major_Threshold = 0x2202bf
  - LACP_Minor_Threshold = 0x2202be
- If the LACP_IF_Port attributes are set to 0 or less than 0 or greater than 100, the following VNM attributes values are used during the threshold comparisons:
  - Critical_Threshold = 0x0001321e
  - Major_Threshold = 0x0001321d
  - Minor_Threshold = 0x0001321c
- If all the LACP port level attributes are set to 0 and the VNM LACP threshold attributes are set to greater than 100, no threshold is calculated.

Condition Correlation of LACP ports

Starting from the 10.2.2 release, the LACP threshold violation alarms functionality is enhanced to avoid multiple independent alarms (on port and port channel) for bad links. With this enhancement, the alarms generated on the ports that are part of an LACP aggregation are correlated and suppressed. Only the LACP threshold violation alarms are generated on the port channels and the alarms generated on the ports are suppressed and shown as symptoms.

Troubleshooting

Symptom
The LACP Port Aggregation Table does not contain Link Aggregation Control configuration information of every Aggregation Port associated with a device.

Solution

1. Verify the values in the dot3adAggPortAggregateOrIndividual table in IEEE8023-LAG-MIB. This indicates whether a port is attached to an LACP channel. If the port is attached to an LACP channel, the value can be TRUE, otherwise the value can be FALSE.
2. Verify the values in the dot3adAggPortAttachedAggID table in IEEE8023-LAG-MIB. Spectrum uses this table to get the aggregated port details.

Symptom
For Cisco devices, the LACP port channel type is displayed wrongly. It is displayed as propVirtual instead of ieee8023adLag in Interfaces tab of OneClick.
SolutionConfigure the 'IsLACP_PropVirtual=true in. vnmrc' file, then delete and rediscover the devices. If there are multiple devices, use the LACP migration script.

Symptom The Lacp_HASPART associations are not created correctly for LACP configured port channels. **Solution** Verify whether LACP is correctly configured on the device and whether the values are correct in the dot3adAggPortAttachedAggID table in IEEE8023-LAG-MIB. Spectrum uses this table to get the aggregated port details.

Symptom The LACP threshold violation alarms are not getting generated correctly. **Solution** Verify whether the Lacp_HASPART associations are correctly created for LACP configured port channels. There should be Lacp_HASPART association that are created between:

i) the device (left model handle) and port channel (right model handle).
ii) the port channel (left model handle) and the aggregated physical interfaces (right model handle).

Symptom The link information tab is not displaying all the links correctly. **Solution** Verify whether the CDP/LLDP is configured correctly for the device. For example, following are the OIDs Spectrum checks in case of Juniper devices in which LLDP is configured.

1.0.8802.1.1.2.1.3.7.1.2 (lldpLocPortIdSubtype)
1.0.8802.1.1.2.1.3.7.1.3 (lldpLocPortId)

1.0.8802.1.1.2.1.3.7.1.4 (lldpLocPortDesc)

Diagnostics/Logs

In case, the above troubleshooting did not help to resolve the problem, enable the following logging.

1. Enable the LACP logging on SpectroSERVER by adding the configuration lacp_debug=true in the .vnmrc file. This change requires a SpectroSERVER restart.
   After enabling the above logging, reproduce the issue and collect the VNM.out file.
2. Take an attributes dump of the LACP application model associated with the problematic device. To find the associated LACP application model, click Locater Search -> Application Models -> By Device Name. After listing the application models associated with the device, filter the list by 802dot3adApp.

Reconfigure LACP-Enabled Interface Models

When you upgrade 9.3 to 10.0, the LACP modeling requires deletion and rediscovery of the affected models. To eliminate the problem of manually deleting and re-discovering the effected models, run the RecreateLACPModels.pl script, which migrates the LACP configured devices without any problem.

Click to download the RecreateLACPModels.pl script attached to this page.

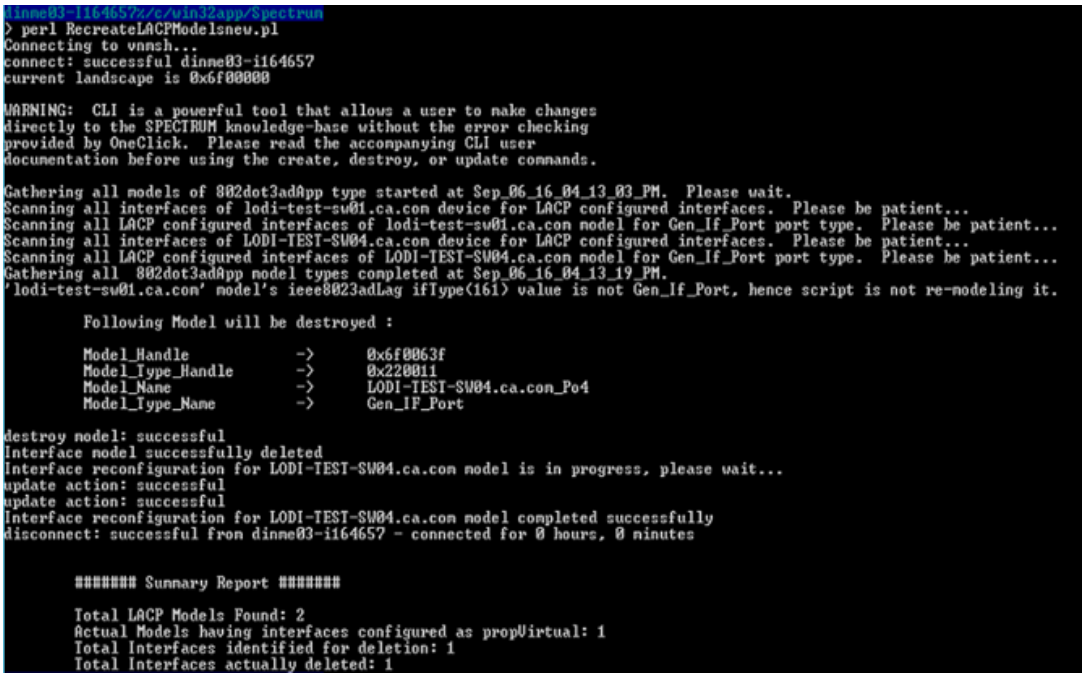
Use the script to:

1) Identify the LACP configured devices by reading the LACP mib (IEEE8023-LAG-MIB).
2) Delete the LACP configured interfaces/port channels and model them correctly.

After the migration, follow these steps to run the script:

1. Copy the downloaded script to $SPECROOT
2. Set the IsLACP_PropVirtual=true in the vnmrc file, which is located at $SPECROOT\SS
3. To Run the script manually, connect to the bash prompt where the SpectroSERVER installed
4. Go to the $SPECROOT Directory (cd /c/win32app/Spectrum)
5. Run the script (RecreateLACPModels.pl) using the Perl

For your reference, following is a sample output of the RecreateLACPModels.pl command.



RFC Reference

The following is a list of all RFCs that are supported by DX NetOps Spectrum. RFC support is typically provided in the form of application models, which allows it to be dynamically applied to any device model in DX NetOps Spectrum that is identified as supporting the particular RFC, including GnSNMPDev.

RFC Number	RFC Name	RFC Description
RFC1286	RFC1286-MIB	Definitions of Managed Objects for Bridges.
RFC1493	BRIDGE-MIB	Definitions of Managed Objects for Bridges.
RFC1474	PPP-BRIDGE-NCP-MIB	Definitions of Managed Objects for Bridges.
RFC2674	Q-BRIDGE-MIB	Management Information Base for Network Management of TCP/IP-based Internets: MIB-II.
RFC1525	SOURCE-ROUTING-MIB	Definitions of Managed Objects for Source Routing Bridges.
RFC1289	RFC1289-phivMIB	DECnet Phase IV MIB Extensions.
RFC1559	DECNET-PHIV-MIB	DECnet Phase IV MIB Extensions.
RFC2662	ADSL-LINE-MIB	Definitions of Managed Objects for the ADSL Lines.
RFC2669	DOCS-CABLE-DEVICE-MIB	DOCSIS Cable Device MIB Cable Device Management Information Base for DOCSIS Compliant Cable Modems and Cable Modem Termination Systems.
RFC2670	DOCS-IF-MIB	Radio Frequency (RF) Interface Management Information Base for MCNS/ DOCSIS Compliant RF Interfaces.

RFC2737	ENTITY-MIB	The MIB module for representing multiple logical entities supported by a single SNMP agent.
RFC1514	HOST-RESOURCES-MIB	Host Resources MIB.
RFC2790	HOST-RESOURCES-MIB	Host Resources MIB.
RFC1565	APPLICATION-MIB	Network Services Monitoring MIB.
RFC2248	NETWORK-SERVICES-MIB	Network Services Monitoring MIB.
RFC2788	NETWORK-SERVICES-MIB	Network Services Monitoring MIB.
RFC1566	MTA-MIB	Mail Monitoring MIB.
RFC2249	MTA-MIB	Mail Monitoring MIB.
RFC2789	MTA-MIB	Mail Monitoring MIB.
RFC1567	DSA-MIB	X.500 Directory Monitoring MIB.
RFC2605	DSA-MIB	X.500 Directory Monitoring MIB.
RFC1628	UPS-MIB	UPS Management Information Base.
RFC2287	SYSAPPL-MIB	Definitions of System-Level Managed Objects for Applications. The MIB module defines management objects that model applications as collections of executables and files installed and executing on a host system. The MIB presents a system-level view of applications; objects in this MIB are limited to those attributes that can typically be obtained from the system itself without adding special instrumentation to the applications.
RFC792		Internet Control Message Protocol (ICMP).
RFC2933	IGMP-STD-MIB	The MIB module for IGMP Management.
RFC1158	RFC1158-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC1213	RFC1213-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC1354	RFC1354-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2011	IP-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2012	TCP-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2013	UDP-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2096	IP-FORWARD-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.

RFC4293	IP-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2465	IPV6-TC	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC2452	IPV6-TCP-MIB	Management Information Base for Network Management of TCP/IP-based internets: MIB-II.
RFC1573	IANAifType-MIB	The MIB module which defines the IANAifType textual convention, and thus the enumerated values of the ifType object defined in MIB-II's ifTable.
RFC1907	SNMPv2-MIB	The MIB module for SNMPv2 entities.
RFC2233	IF-MIB	The MIB module to describe generic objects for network interface sub-layers. This MIB is an updated version of the MIB-II ifTable, and incorporates the extensions defined in RFC1229.
RFC2863	IF-MIB	The MIB module to describe generic objects for network interface sub-layers. This MIB is an updated version of the MIB-II ifTable, and incorporates the extensions defined in RFC1229.
RFC2213	INTEGRATED-SERVICES-MIB	The MIB module to describe the Integrated Services Protocol.
RFC2932	IPMROUTE-STD-MIB	The MIB module for management of IP Multicast routing, but independent of the specific multicast routing protocol in use.
RFC2667	TUNNEL-MIB	The MIB module for management of IP Tunnels, independent of the specific encapsulation scheme in use.
RFC2934	PIM-MIB	The MIB module for management of PIM routers.
RFC2271	SNMP-FRAMEWORK-MIB	An Architecture for Describing SNMP Management Frameworks.
RFC3411	SNMP-FRAMEWORK-MIB	An Architecture for Describing SNMP Management Frameworks.
RFC3413	SNMP-TARGET-MIB	Defines five types of SNMP applications that make use of an SNMP engine as described in STD 62, RFC3411.
RFC3584	SNMP-COMMUNITY-MIB	Describes the coexistence between Version 1, Version 2, and Version 3 of the Internet-Standard Network Management Framework.
RFC3415	SNMP-VIEW-VASED-ACM-MIB	View-Based Access Control Model (VACM) for the Simple Network Management Protocol.
RFC1316	RFC1316-MIB	Definitions of Managed Objects for Character Stream Devices using SMIv2.

RFC1658	CHARACTER-MIB	Definitions of Managed Objects for Character Stream Devices using SMIv2.
RFC1284	RFC1284-MIB	Definitions of Managed Objects for the Ethernet-like Interface Types.
RFC1398	RFC1398-MIB	Definitions of Managed Objects for the Ethernet-like Interface Types.
RFC1623	EtherLike-MIB	Definitions of Managed Objects for the Ethernet-like Interface Types.

VPLS Manager Solution

This section provides concepts, processes, and procedures for installing and configuring VPLS Manager. It also describes how to discover and model the VPLS environment, and how to monitor the performance of the VFIs and Sites.

Getting Started with VPLS

About VPLS Manager

VPLS Manager is a DX NetOps Spectrum add-on application that provides management tools to service providers deploying VPLS technology in their environment. Service providers who offer Layer 2 MPLS VPN service to their customers can benefit from using VPLS Manager to monitor their environment. In combination with the MPLS VPN Manager application, VPLS Manager provides seamless management of both Layer 3 (BGP) and Layer 2 MPLS VPNs within the same navigation and viewing framework. The primary benefits of the product are the discovery, modeling, and monitoring of Layer 2 networks, services, and resources. As an integrated application of the DX NetOps Spectrum product family, VPLS Manager benefits from the DX NetOps Spectrum ability to manage the entire network.

NOTE
For more information about the MPLS VPN Manager application, see MPLS VPN Manager .

Fault management is a key capability provided by VPLS Manager. VPLS Manager constantly monitors the resources used to provide VPLS to customers and intelligently computes the condition of the VPLS environment. For example, VPLS Manager monitors the devices, interfaces, configurations, and circuits with which the VPLS service is implemented. Monitoring is accomplished through polling and intelligent trap handling.

Another key capability is performance management of your VPLS environment. Performance management is accomplished by monitoring the traffic on VPLS-enabled interfaces and displaying them in real time.

VPLS Manager is designed to be a distributed SpectroSERVER (DSS) enabled application. This design provides the application significant scalability and capacity, supporting management of the largest networking environments.

Who Should Use VPLS Manager

VPLS Manager is designed for service providers who are running a VPLS core environment and must monitor their client network traffic for performance and accuracy within this network. VPLS Manager supports service provider environments that use Juniper equipment in their MPLS core and edge networks.

MIBs and Devices Supported by VPLS Manager

VPLS Manager manages Virtual Private LAN Service (VPLS) as described in the draft "RFC 4761 VPLS using BGP for Auto-Discovery and Signaling." These MIBs provide access to the configuration information for Layer 2 VPNs configured on PE router interfaces.

VPLS Manager supports the following tables in the Juniper Enterprise VPN MIB:

- Table of Configured VPNs (jnxVpnTable)
- Table of VPN Interfaces (jnxVpnIfTable)

VPLS Manager functionality is supported by Juniper on JunOS 6.1 or later.

System Requirements

VPLS Manager is an add-on application that works within DX NetOps Spectrum. In addition to a running SpectroSERVER installation, VPLS Manager requires the following:

- SNMP access to all PE devices in the VPLS service.
- Juniper VPN MIB implemented and populated on your MPLS hardware for Juniper.

  NOTE

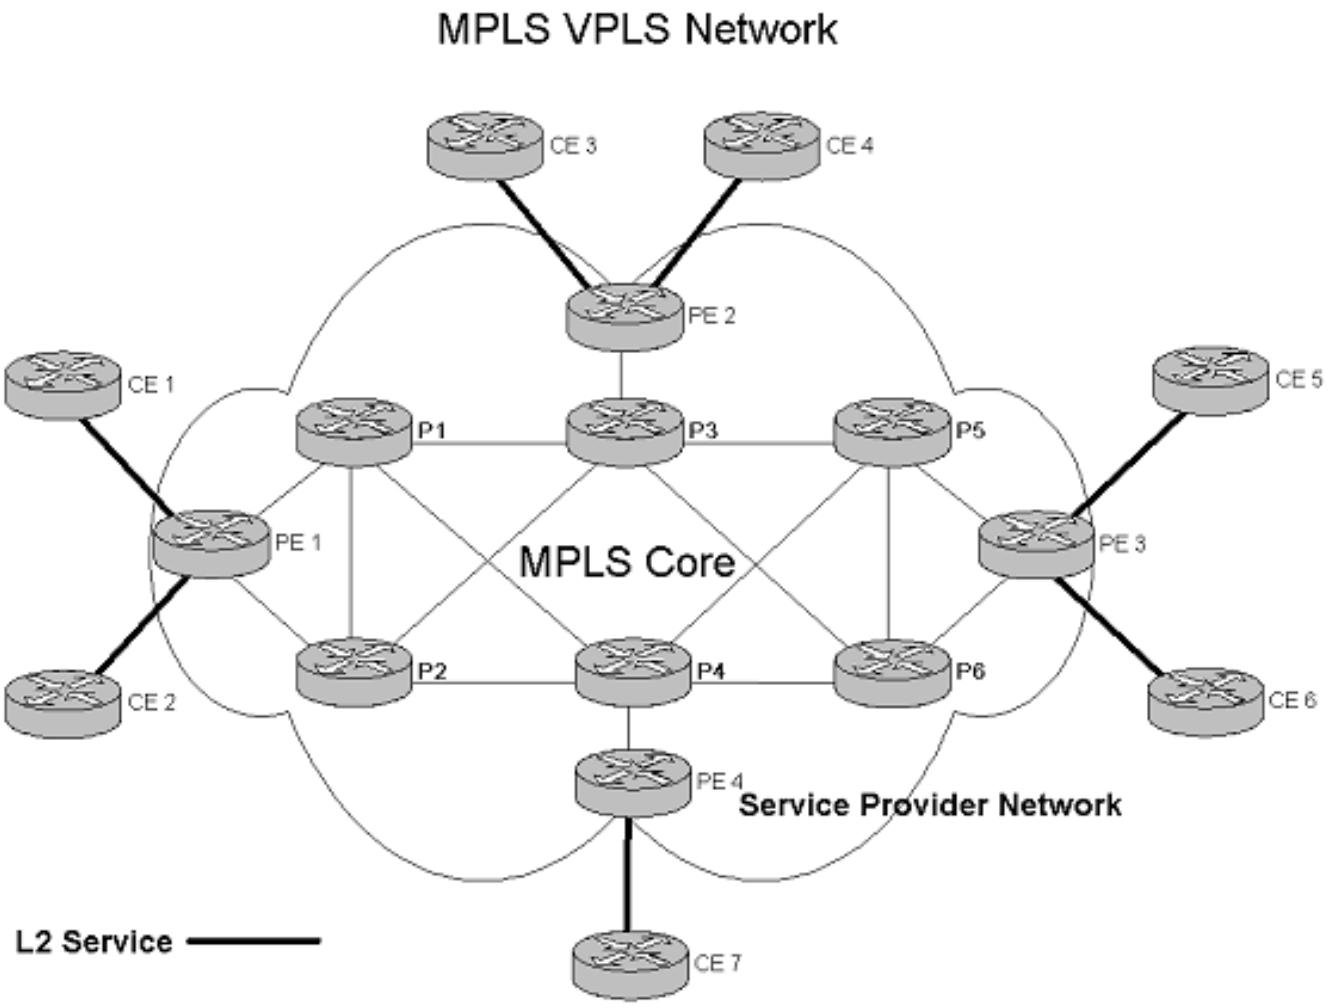
  DX NetOps Spectrum comes with all required MIBs.
- Management module for Juniper routers.

  NOTE

  The device models in this module have the necessary application models needed for discovery of your VPLS environment.

How VPLS Manager Works

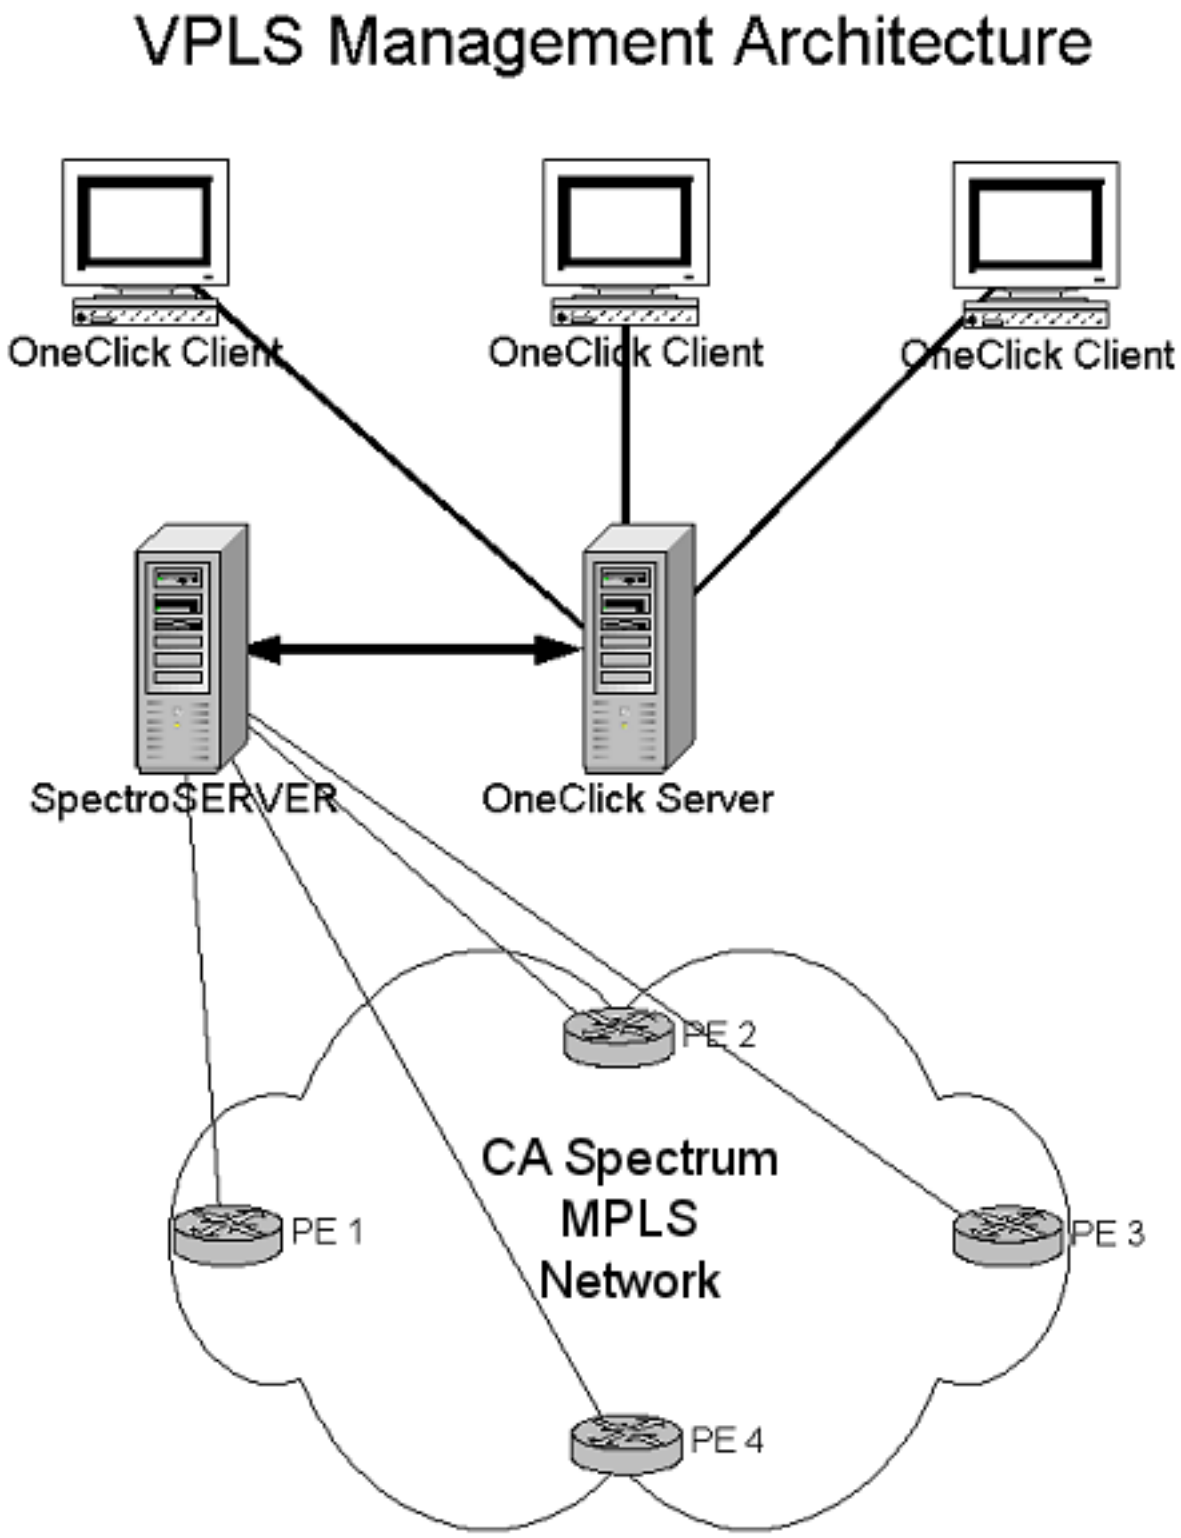
As a service provider, your goal is to use your MPLS VPLS core network to transport data packets from one part of your customer's network to another. For example, your MPLS network may transfer data packets from your customer's New York office to their London office. In this situation, your customer cannot model and monitor their network traffic through your MPLS VPLS network, and you, as a service provider, typically cannot model and monitor the client networks in New York or London. The following diagram shows that in this scenario the only interface between the customer network and your MPLS VPLS network is the relationship between their Customer Edge (CE) routers and your Provider Edge (PE) routers:



As shown by the architectural diagram, the major components of this environment are the following entities:

- Provider’s core MPLS network (P routers)
- Provider’s edge routers (PE routers)
- Customer edge routers (CE routers)

VPLS Manager focuses on the information provided by the PE routers and does not utilize nor provide any information on what exists in the MPLS core. As shown in the following deployment diagram, the management of the customer edge equipment is not part of VPLS Manager:



VPLS Management Architecture
OneClick Client
OneClick Client
OneClick Client
SpectroSERVER
OneClick Server
PE 2
CA Spectrum
MPLS
Network
PE 1
PE 3
PE 4

As shown in the diagrams above, VPLS Manager monitors your MPLS VPLS network environment as follows:

1. The PE routers use Layer 2 services to gather information from the CE routers, including the discovery of configuration and performance information from the supported MIBs. In addition, traps are supported where they are available.
2. The SpectroSERVER communicates with your PE routers when executing Discovery, modeling, polling, and fault management operations. All database operations with respect to modeling are handled by the SpectroSERVER.
3. The OneClick server periodically polls the SpectroSERVER database for management information, then displays this information in the OneClick clients.

VPLS Manager

Install VPLS Manager

VPLS Manager is included in your DX NetOps Spectrum extraction key. When you install DX NetOps Spectrum, the VPLS Manager components are automatically installed and available for use. For best results, you can adjust the configuration settings appropriately after installation is complete.

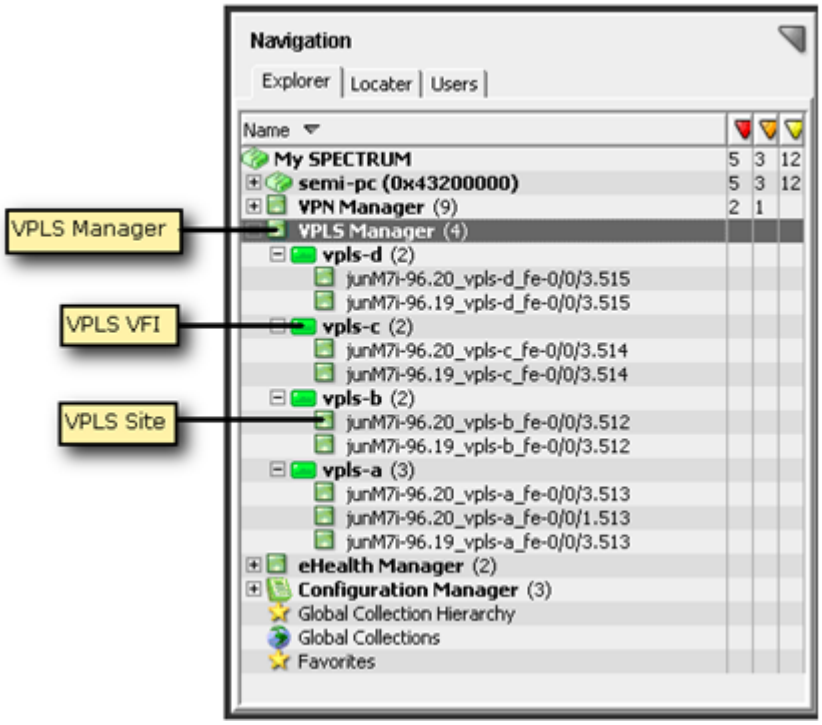
To install VPLS Manager properly, the administrator must install DX NetOps Spectrum.

For existing DX NetOps Spectrum installations, perform an in-place installation to help ensure the VPLS Manager components are installed. In a fault tolerant environment, VPLS Manager must be installed on each SpectroSERVER to be fault tolerant.

> **NOTE**
> Perform this procedure on all SpectroSERVERs in a distributed environment for which you want to use VPLS Manager. For specific installation instructions, see *the* Installation *section*.

Accessing VPLS Manager

You can access VPLS Manager from the Explorer tab of the Navigation panel. Expanding the VPLS Manager node displays all VFIs managed by the VPN Manager. Expanding each VFI displays the VPLS sites contained in the VPLS environment. The following is an example of the VPLS Manager hierarchy in the Navigation panel.



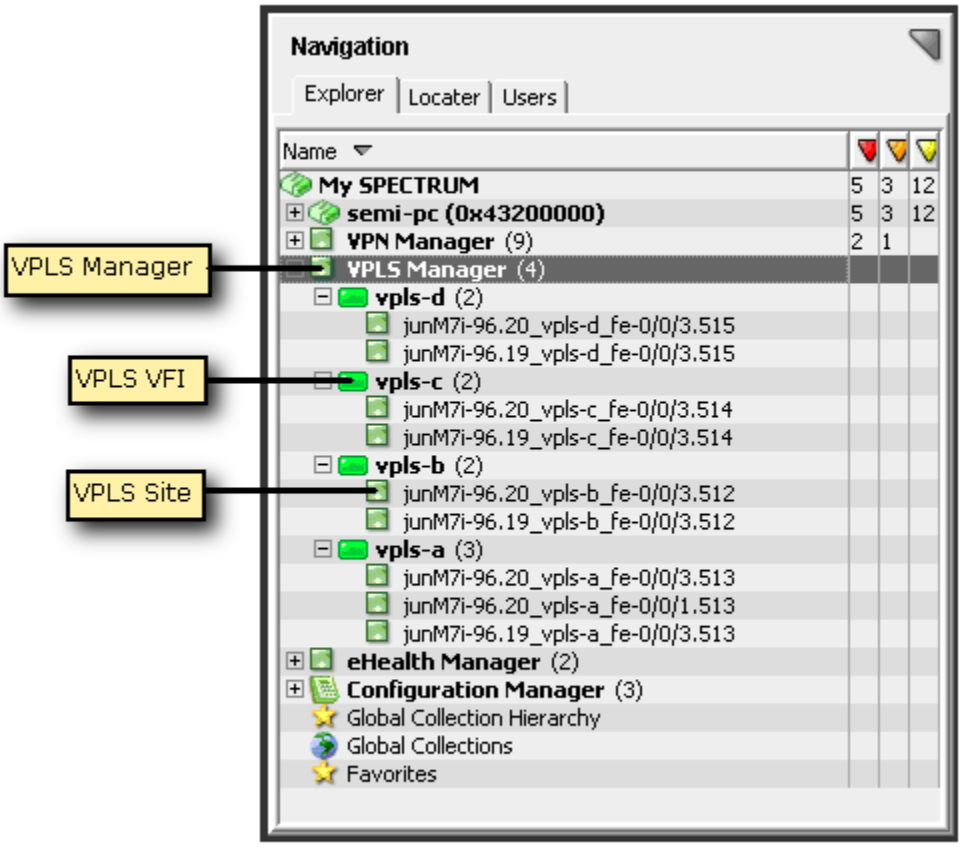
The Contents panel displays the Alarm list for the modeled element that you have selected in the Navigation panel. The Component Detail panel displays the Alarm details for the Alarm selected in the Alarm list shown in the Contents panel. If the Alarm list is empty, the Component Detail panel displays the Information view for the modeled element selected in the Navigation panel.

Viewing VPLS Manager Data

This section describes where to find VPLS Manager data in DX NetOps Spectrum, the model types, and additional options for viewing the available data. The content in this section is intended for all VPLS Manager users.

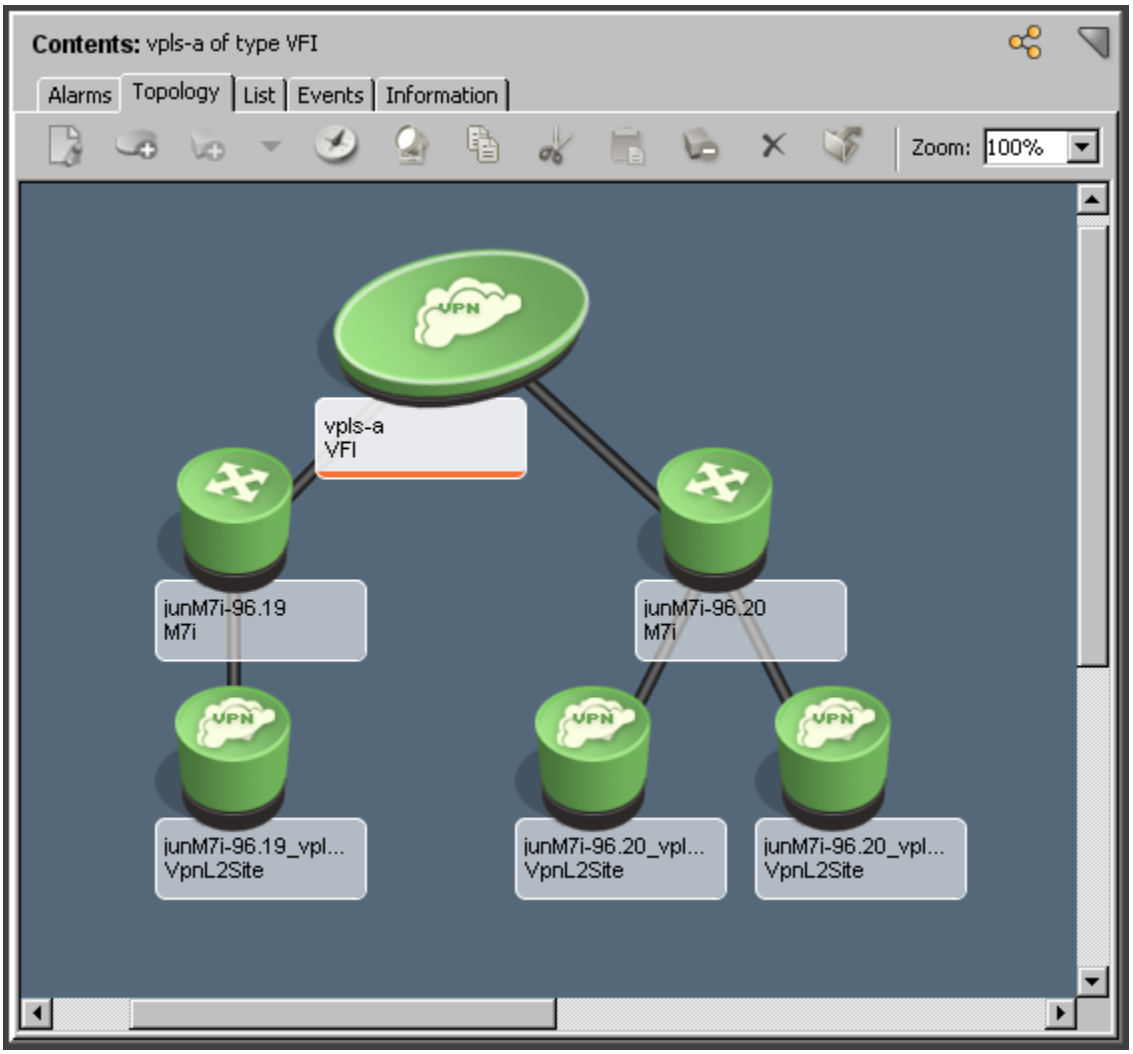
Navigation

OneClick is the main tool for interacting with VPLS Manager models. Using OneClick, you can configure the application, as well as view and search model information. All VPLS Manager navigation is contained within the VPLS Manager hierarchy in the Navigation panel, as shown in the following example:



Topology

VPLS Manager contains a topology view that shows how your VPLS entities are connected to other devices in your network environment. For example, the following topology view shows a VPLS environment with the VFI model (vpls-a) connected to two PE routers (junM7i-96.19 and junM7i-96.20). Then, these PE routers are connected to the VFI Site models, as shown:



VPLS Manager Model Types

During VPLS Discovery, several DX NetOps Spectrum models are created to represent different aspects of the MPLS/BGP VPN MIB in VPLS Manager. DX NetOps Spectrum uses these models to build your VPLS environment topology and reflect the current status of each entity in that environment.

The VPLS Manager topology includes the following model types:

- **VPLS Manager**
  Represents the VPLS Manager application. By default, DX NetOps Spectrum creates this model when the application is installed with DX NetOps Spectrum. This model cannot be destroyed. This application model must be present for VPLS Discovery to successfully discover MPLS-VPLS information.
  Model Type: VplsManager
- **VFI**
  Represents each unique VPLS VFI. A *Virtual Forwarding Instance (VFI)* is a logical collection of VPLS Sites that are part of the same virtual packet forwarding instance. These VPLS Sites share a common Layer 2 forwarding database, much the same way that Layer 3 devices may share a common routing table. The Model Class attribute for the VFI model is set to Transport Service.

Model Type: VFI

- **VPLS Site**
  Represents each unique VPLS Site modeled during VPLS Discovery. A *VPLS Site* represents the service delivered to a customer over an interface in your VPLS environment. DX NetOps Spectrum creates a VPLS Site model on the same SpectroSERVER on which its associated PE router is modeled. The Model Class attribute for the VPLS Site model is set to Transport Service. VPLS Manager assumes that each VPLS Site is connected to a given PE by a single interface. By default, DX NetOps Spectrum does not create VpnL2Site models for loopback and tunnel interfaces.
  Model Type: VpnL2Site

VPLS Site Model Names

DX NetOps Spectrum generates unique names for VPLS Site models during VPLS Discovery. The naming convention is as follows:

```
RouterName_VFI_IfName
```

To help ensure the name is unique, the naming convention is based on the following three parts:

- *RouterName* -- The PE router associated with the VPLS Site
- *VFI* -- The associated VFI
- *IfName* -- The IfName of the interface to which the VPLS Site is connected

View Associated VPLS Sites

For an individual VFI model, you can view a list of associated VPLS Sites. Using the list, you can quickly see the condition of related VPLS Sites that can affect the performance of the selected VFI.

To view a list of associated VPLS Sites

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Select the VFI model
   Details about the selected model display in the Contents panel.
3. Click the Information tab.
4. Expand the Associated Sites subview.
   A table lists all of the VPLS Site models associated with the selected VFI model.

View Associated PE Routers

For an individual VFI or VPLS Site model, you can view a list of associated PE routers. Using the list, you can quickly see the condition of all related routers that can affect the performance of the selected model.

To view a list of associated PE routers

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Select the VFI or VPLS Site model.
   Details about the selected model display in the Contents panel.
3. Click the Information tab.
4. Expand the Associated Edge Routers subview.
   A table lists all of the PE routers associated with the model selected in step 2.

Spotlighting VFIs

The spotlighting feature in OneClick lets you isolate and visualize model relationships within your network that are not readily visible from the Topology view. For example, the Topology view does not visually distinguish VFIs and VPLS Sites, making it more difficult to picture these relationships within the context of your network. With spotlighting, these model relationships are accentuated, showing you where they appear in the network topology.

Using the spotlighting feature, you can select a VFI to view in the Topology view. Viewing VFI information from this view can help you more easily understand which devices are related to the selected VFI. From this view, you can also see if any alarming devices are impacting the performance of the VFI.

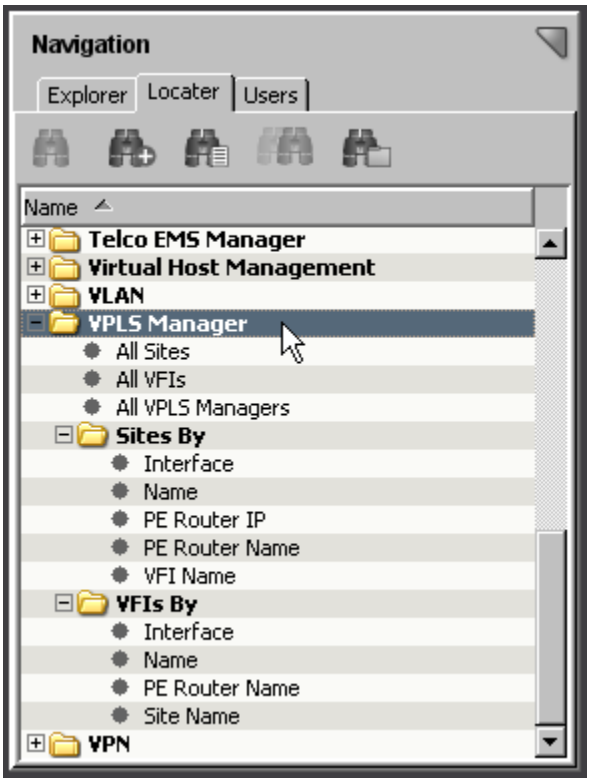
> **NOTE**
> For more information about how to use spotlighting, see Using OneClick.

VPLS Manager Searches

Using the search feature can help you find details about your VPLS environment that help you monitor the performance. Searches can locate specific components of your MPLS-VPLS core, such as locating VPLS Sites by PE router IP or all VFIs within a specific landscape. These types of searches can help you investigate information related to a specific customer, because you can use details associated with your customer SLAs in your searches, such as specific device or site name.

VPLS searches support cross-server device modeling. You can specify one or more, or all SpectroSERVERs to search for a particular VPLS Manager model, sets of VFIs, or VPLS Sites that are managed by a specific SpectroSERVER. You can use the search results to access a number of views that present management, performance, and configuration information.

The search options are grouped under the VPLS Manager folder, as shown:



For example, if you know the IP address or name of a specific PE router, you can search for all VPLS Sites that use it. Using the list of VPLS Sites affected by the router can be useful when performing scheduled maintenance. You can change your VPLS Sites to use a different router, or be sure to place the VPLS Site model in maintenance mode to avoid unnecessary alarms in DX NetOps Spectrum. Also, you can give prior notice to any customers affected by those VPLS Sites.

NOTE
For more information about Locater searches, see Using OneClick .

Discovery and Modeling (VPLS)

Before you can use VPLS Manager to manage your VPLS network, you must run VPLS Discovery. VPLS Discovery discovers each VFI and VPLS Site currently configured on devices modeled in DX NetOps Spectrum. Before running VPLS Discovery, you can configure the VPLS Discovery options to achieve the best results for your environment.

Discovery Prerequisites

For VPLS Discovery to complete successfully, devices must meet the following prerequisites:

- VPLS devices must support the correct MPLS-VPLS MIBs.
- DX NetOps Spectrum discovers and models the physical network infrastructure via Discovery, manual modeling, or the Modeling Gateway. Before using the VPLS Discovery functionality, you must first model the physical components of your network in DX NetOps Spectrum using one of these methods.

  NOTE
  For instructions about using these mechanisms to model your network, see the Modeling and Managing Your IT Infrastructure and the Modeling Gateway Toolkit .
- The devices must have MPLS-VPLS properly configured.

Configure VPLS Manager for Discovery

Before you run VPLS Discovery, you can configure the VPLS Discovery options. Making these selections helps ensure that DX NetOps Spectrum finds and manages only the VPLS devices you want to monitor.

To configure VPLS Manager for VPLS Discovery

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration, VPLS Discovery subview and make your selections from the following configuration options:
   - **Enable Dynamic Discovery**
     Determines whether to start the VPLS Discovery automatically when a new PE router is modeled. Starting VPLS Discovery automatically helps to keep the VPLS information current when new devices are added to the network.

     NOTE
     As the VPLS Manager application is running, VPLS sites may be created or destroyed when certain traps are received.

     Default: No
   - **VFI Name Filter Type**
     Determines if the VFI names in the 'Global VFI Name Filter' field are included or excluded from modeling. This feature can save unnecessary resources by limiting the number of VPLS sites that require monitoring. Options include the following:

- Exclusive
- Inclusive

– **Global VFI Name Filter**
Lists the VFI names to be included or excluded from modeling. This field is used together with the 'VFI Name Filter Type' field.

VPLS Discovery options are configured.

Discover and Model Your VPLS Environment

To view and monitor your VPLS environment in DX NetOps Spectrum, you must model your VPLS devices. Running VPLS Discovery is the most comprehensive method of modeling your VPLS environment, but it also requires the greatest amount of system resources. To accommodate your modeling needs, you can choose from the following options when discovering and modeling the VPLS devices in your environment:

- Run a full VPLS Discovery
- Run VPLS Discovery on selected models only
- How to Update the New VPLS VFI Interface
- Filter the full VPLS Discovery results
- Configure DX NetOps Spectrum modeling to include VPLS Discovery

Run VPLS Discovery

To discover and model your entire VPLS environment, you can run a VPLS Discovery. Before you run an on-demand VPLS Discovery, be sure that you meet the prerequisites and that you configured your VPLS Discovery options.

Follow these steps:

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration, VPLS Discovery subview.
4. Click Run in the Discovery Status field.
   A dialog opens to request the landscapes on which you want to run VPLS Discovery.
5. Select the landscapes and click OK.
   VPLS Discovery runs. When complete, the VPLS Discovery Status field lists the status. Also, a tooltip on this field lists the number of discovered VPLS devices (single SpectroSERVER) or servers (distributed SpectroSERVER).

Run VPLS Discovery on Selected Models

In the available OneClick views for VPLS Manager, you can select a set of models and can run VPLS Discovery for those models only. This ability can help you minimize the DX NetOps Spectrum resources required when troubleshooting or verifying changes to the status of only specific devices.

To run VPLS Discovery on selected models

1. Select the models in OneClick.
2. Click Tools, Utilities, Network Services Discoveries, VPLS Discovery.
   The VPLS Discovery process is initiated for the selected models only. You can check the status in the Configuration, VPLS Discovery subview.

How to Update the New VPLS VFI Interface

When a new VPLS enabled device is added in your VPLS environment, you model it in your OneClick landscape. If you run the VPLS discovery, the new device is created as a child of the configured VPLS VFI under the VPLS Manager in

the Navigation pane. But the new interface is not updated in the Interfaces tab in the Component Detail pane for the new device under the VPN VFI. Manually update the new interface.

Follow these steps:

1. In the Navigation pane, select VPLS Manager.
2. In the Contents pane, select List.
   A list of all the VPLS VFIs is displayed.
3. Delete the configured VPLS VFI.
4. In the Component Detail pane, select Information and run the VPLS Discovery.
   The VPLS VFI model that was deleted is created with the same number of child devices.
5. Select Interfaces, and verify that the new interface is added.

The new interface is updated for the configured VPN VFI.

Filter VPLS Discovery Results

If you do not want to monitor all VFIs, you can apply a filter that includes or excludes selected VFIs from discovery and modeling. This feature can help save resources by reducing the number of VFIs DX NetOps Spectrum polls.

To filter VPLS Discovery results

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration, VPLS Discovery subview.
   VPLS Discovery options display.
4. Click Set in the VFI Name Filter Type field and select one of the following options:
   – Exclusive
   – Inclusive
5. Click Add in the Global VFI Name Filter field.
   The Add dialog opens, prompting you to enter the VFI name.
6. Enter the VFI name and click OK.
   The VFI name is added to the Global VFI Name Filter list. Depending on the VFI Name Filter Type that you select, VPLS Discovery is filtered to include or exclude the listed VFIs.

Configure DX NetOps Spectrum Modeling to Include VPLS Discovery

DX NetOps Spectrum lets you configure modeling to include network services discoveries, such as VPLS Discovery. As a part of modeling configuration, you can specify which network service discoveries to run with the DX NetOps Spectrum modeling process.

NOTE
For more information, see the Modeling and Managing Your IT Infrastructure *section.*

Configuring VPLS Manager

This section describes how to configure VPLS Manager options. These are tasks that are typically performed by the VPLS Manager administrator.

VPLS Manager Model Configuration

After VPLS Discovery, you must configure VPLS Manager so that it manages your VPLS environment appropriately. The VPLS Manager application offers configuration options for VPLS Manager models, the individual VFI models,

and for VPLS Site models. In addition to the typical configuration options for DX NetOps Spectrum models, the VPLS Manager model lets you specify parameters for all the VFIs managed by the selected VPLS Manager model. Using these configuration options, you can optimize how DX NetOps Spectrum monitors your VPLS environment. Configuration options include the following:

- Port polling
- Traps for creating and deleting models

NOTE
By default, both options are enabled.

Configure Port Polling

With traps, the polling mechanism is used to determine the health of the resources that make up your VPLS environment. Although enabled by default, you can disable polling to reduce network traffic. However, disabling polling causes the loss of significant functionality in VPLS Manager. Port polling must be enabled to update the condition of VPN Site models.

NOTE
Only an administrator performs this task.

To configure port polling in your VPLS environment

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration, Management Configuration subview.
   VPLS Manager configuration options display.
4. Click the 'set' link in the Enable Port Polling field.
   The value for the selected option becomes editable.
5. Select the desired value for the field and click Save.
   VPLS Manager is configured to poll devices in your VPLS environment according to your selection.

Configure Traps to Create and Delete Models (VPLS)

If your VPLS devices are properly configured to send traps to the SpectroSERVER host, you can use this trap data to create or delete VFI and VPLS Site models automatically. Traps that are sent from the devices in your VPLS environment can ensure that devices in your VPLS environment are not unmanaged. Likewise, traps can also help to keep the information in DX NetOps Spectrum accurate by eliminating VPLS devices that no longer exist.

Some environments do not support the use of traps, and you can choose to disable them. However, we recommend that you enable traps when possible, because traps (with polling) provide the best response to network faults and outages.

NOTE
Only an administrator performs this task.

To configure traps to create and delete VPLS device models automatically

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Click the Information tab in the Contents panel.
3. Expand the Configuration, Management Configuration subview.
   VPLS Manager configuration options display.
4. Click the 'set' link in the following fields, as needed:
   - **Create on Trap**
     Creates a VFI or VPLS Site when the mplsVrfIfUp/ mplsL3VpnVrfUp or jnxVpnIfUp trap is received and the device model already exists.

Default: Yes

- **Delete on Trap**
  Deletes an existing VFI or VPLS Site model when the mplsVrfIfDown/ mplsL3VpnVrfDown or jnxVpnIfDown is received and the device no longer exists in DX NetOps Spectrum.
  Default: Yes

The value for the selected option becomes editable.

5. Select the desired value for the field and click Save.
   The traps are configured to create or delete devices in your VPLS environment according to your selection.

VFI Model Configuration

After VPLS Discovery, you must configure VPLS Manager so that it manages your VPLS environment appropriately. The VPLS Manager application offers configuration options for VPLS Manager models, the individual VFI models, and for VPLS Site models. In addition to the typical configuration options for DX NetOps Spectrum models, the VFI model lets you specify parameters for the selected VFI and the VPLS Sites it manages. Using these configuration options, you can optimize how DX NetOps Spectrum monitors your VPLS environment. Configuration options include the following:

- Impact thresholds
- Alarms for VFIs or VPLS Sites

Set Impact Thresholds

The path of network traffic across your VPLS environment depends on which VPLS Sites are available for use. Network traffic can move most efficiently when all VPLS Sites for a VFI are available to your customers. Therefore, monitoring the performance of your VFIs can help ensure you provide your customers the correct level of service. To monitor the performance, you can set impact thresholds that trigger alarms when a percentage of the VPLS Sites for a VFI are no longer available.

To set impact thresholds for your VFIs

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Select a VFI in the Navigation panel.
   Details for the selected VFI display in the Contents panel.
3. Click the Information tab in the Contents panel.
4. Expand the Configuration Information subview.
   VFI configuration options display.
5. Click the 'set' link in the following fields, as needed:
   - **Critical Threshold %**
     Specifies the percentage of down (unreachable) VPLS Sites that cause DX NetOps Spectrum to generate a critical alarm for the model.
     Default: 15
     Limits: 0-100
     Note: A value of zero causes DX NetOps Spectrum to always generate a critical alarm when any VPLS Site becomes unreachable.
   - **Major Threshold %**
     Specifies the percentage of down (unreachable) VPLS Sites that cause DX NetOps Spectrum to generate a major alarm for the model.
     Default: 10
     Limits: 0-100
     Note: A value of zero causes DX NetOps Spectrum to always generate a major alarm when any VPLS Site becomes unreachable.
   - **Minor Threshold %**

Specifies the percentage of down (unreachable) VPLS Sites that cause DX NetOps Spectrum to generate a minor alarm for the model.
Default: 5
Limits: 0-100
Note: A value of zero causes DX NetOps Spectrum to always generate a minor alarm when any VPLS Site becomes unreachable.

The value for the selected option becomes editable.

6. Enter the desired value for the field and click Save.
   The impact thresholds are configured to generate alarms when the threshold values for the selected VFI are breached.

Enable or Disable Alarms

To alert you to problems within your VPLS environment, DX NetOps Spectrum can generate alarms for VFIs or VPLS Sites. For example, an event is triggered when contact is lost to one of these models. When alarms are enabled, DX NetOps Spectrum generates a corresponding alarm. Although both alarm types are enabled by default, you can disable these alarms for non-critical devices to reduce the number of unnecessary alarms.

To enable or disable alarms

1. Open VPLS Manager in the Navigation panel.
   The main details page for VPLS Manager opens in the Contents panel.
2. Select a VFI in the Navigation panel.
   Details for the selected VFI display in the Contents panel.
3. Click the Information tab in the Contents panel.
4. Expand the Configuration Information subview.
   VFI configuration options display.
5. Click the 'set' link in the following fields, as needed:
   - **Enable VFI Alarms**
     Determines whether DX NetOps Spectrum generates a VFI alarm when the condition of the VFI model changes. When this option is enabled and traps are properly configured, a contact lost event triggers an alarm that is asserted against the VFI model. When this option is disabled, a contact lost event causes the VFI model to turn red, but no alarm is created.
     Default: Yes
   - **Enable Site Alarms**
     Determines whether DX NetOps Spectrum generates a VPLS Site alarm when the condition of a VPLS Site managed by the selected VFI changes to critical. When this option is enabled, DX NetOps Spectrum generates an alarm. However, DX NetOps Spectrum does not generate an alarm when this option is disabled.
     Default: Yes

   The value for the selected option becomes editable.
6. Select the desired value for the field.
   The alarms for the selected VFI model are configured according to your selection.

Distributed SpectroSERVER Configuration

In a DSS environment, you can model your PE routers from any SpectroSERVER. DX NetOps Spectrum creates an L2Site model on the same SpectroSERVER on which its associated PE router is modeled. However, DX NetOps Spectrum creates all VFI models on the main location server (MLS). All the discovered VFIs appear in the VPLS Manager area of the OneClick console. The local SpectroSERVERs must have a connection to the MLS to support this distributed configuration.

WARNING
To create a distributed VPLS Manager environment, all VFI models must reside on the SpectroSERVER that is on the MLS. When you change the MLS, the VFI and VpnL2Site models become invalid and are deleted by each SpectroSERVER in the DSS environment. To change the MLS properly, see the procedure for designating a new MLS. For more information, see the Distributed SpectroSERVER Administration section.

Distributed SpectroSERVER Considerations

Review the following considerations before configuring a Distributed SpectroSERVER:

- When the same PE router is modeled on multiple landscapes, multiple site models are created. The site models have the same name (unless the device models are named differently) but reside on different landscapes. If an outage occurs, you can see multiple similar alarms because multiple sites are experiencing an outage.
- If you do not want to receive alarms on one set of the site models, use proxy models. Otherwise, DX NetOps Spectrum raises alarms on each site model.
- If you model the same device in multiple landscapes, name the device differently. Using different device names lets you easily differentiate the similar alarms in multiple landscapes.

Applying Global Configurations

In a DSS environment, you can apply configuration settings globally using the VPLS Manager model on the MLS. By default, the configuration options you set on the main VPLS Manager model are applied to the VPLS Managers on remote SpectroSERVERs. Setting a configuration option globally provides an efficient method for setting your preferences across all SpectroSERVERs.

If needed, you can override a global configuration on a remote VPLS Manager. For example, if you have a lab environment that is managed by a separate SpectroSERVER, you can turn off VFI alarms generated by the devices managed on that SpectroSERVER. Turning these off helps eliminate unnecessary alarms.

NOTE
Use caution when making overrides. Whenever possible, update the model information about the MLS as a best practice and use local overrides for any changes required on a specific SpectroSERVER.

Override a Global Configuration

By default, the configuration options you set on the main VPLS Manager model are applied to the VPLS Managers on remote SpectroSERVERs in a DSS environment. However, you can override these settings on a remote VPLS Manager. For example, if you have a lab environment that is managed by a separate SpectroSERVER, you can eliminate unnecessary alarms by turning off VFI alarms generated by the devices managed on that SpectroSERVER.

Follow these steps:

1. Search for the VPLS Manager you want to configure.
   The VPLS Manager model appears in your search results in the Contents panel.
2. Select the VPLS Manager model.
3. Click the Information tab in the Component Details panel.
4. Expand the Configuration, Management Configuration subview.
5. Click the 'set' link for the configuration option to override.
   The Local Override Panel displays. The Global value reflects the value set on the MLS VPLS Manager model.
6. Enter a value that is different from the global value, uncheck the 'Use global value' checkbox, and click Save.
   Your changes are saved, and the new configuration settings override the global settings for the selected VPLS Manager model.

NOTE
When a local override is being used, the Management Configuration subview displays an asterisk appended to the non-global attribute value.

Managing Models, Traps, and Alarms

This section describes the concepts and procedures for managing models, traps, and alarms generated for VPLS Manager devices.

VPLS Manager Alarms

To alert you to problems within your monitored networks, DX NetOps Spectrum generates alarms. When monitoring your VPLS environment, your VPLS Manager models display an alarm state for the following conditions:

- Site Down
- VFI Condition (Initial, Good, Minor, Major, Critical)

Trap Support

NOTE

Alcatel traps are not supported by the VPLS Manager for this release.

The following table lists the Juniper traps supported by VPLS Manager. Receipt of either a jnxVpnIfUp trap or a jnxVpnIfDown trap typically results in a change of the VFI model condition. Events are created based on changes in condition.

NOTE
Each device must be configured to send SNMP traps to the DX NetOps Spectrum Virtual Network Machine (VNM).

Trap	Result of Receiving Trap
jnxVpnIfUp	If the VFI model already exists, a change in status is reported. Otherwise, a new VFI model is created.
jnxVpnIfDown	If both the VFI model and the VPLS Site on the device sending this trap exist, a change in status is reported. Otherwise, the VFI model is deleted.
jnxVpnPwUp	If no other related outages are present, the status of the VPLS Site is upgraded to good.
jnxVpnPwDown	If the VPLS Site is no longer provisioned in the device, the VPLS Site is deleted.

VPLS Site Model Deletion

When you no longer need to monitor a VPLS Site, you can manually select the VPLS Site model and delete it. VPLS Site models are also deleted in the following situations:

- When you delete a VFI model, DX NetOps Spectrum automatically deletes all VPLS Site models associated with this VFI model.
- When you delete a PE router model, DX NetOps Spectrum deletes all of the associated VPLS Site models. When the last VPLS Site is deleted, DX NetOps Spectrum also deletes the VFI model associated with those VPLS Site models.
- If a PE router model sends a jnxVpnIfDown SNMP trap and the same VRF entry has been removed from the device's VRF Table, DX NetOps Spectrum deletes the VPLS Site model.

Monitoring Status and Performance

This section explains the information you need to monitor the performance of your VPLS environment and check your adherence to customer SLAs using VPLS Manager. This section is intended for general VPLS Manager operators.

Monitoring Performance and SLAs

For an ISP, continuity of service is crucial for each customer, which is why client SLAs are often established. Although all service outages are not avoidable, the customer relies on the ISP to keep the outages to a minimum, adhering to the terms agreed upon in their SLA.

Monitoring a VPLS environment for adherence to customer SLAs can be difficult. VPLS Manager makes this task easier by monitoring the performance of the VPLS devices and providing a way to view the relationship of those devices to your PE routers. By knowing which customers are impacted by a specific VFI, you can monitor SLAs when monitoring VPLS environment performance in one of the following ways:

- **Analyze the condition of your VFIs** -- Using fault monitoring, VPLS Manager continually updates you about the latest condition of your VPLS devices. These conditions can trigger traps and alarms. All alarms generated from the VPLS environment can provide insight into performance glitches.
- **Search for a customer's VFIs to monitor their health** -- Using search, you can locate the VFIs or VPLS Sites used by a specific customer. After locating these device models, you can check their current condition or performance details to help ensure they meet your established SLA.
- **View real-time performance details** -- For any VFI or VPLS Site model, you can view an on-demand performance report.
- **Run reports** -- VPLS Manager provides various reports to help you monitor the health of your VPLS environment, such as event or availability reports.

Some of these monitoring tasks are proactive (such as searching for specific VFIs) and some are the result of an alarm triggered by a device in your VPLS environment.

Although SLA information is not maintained in VPLS Manager, you can use the information you have about your SLAs, such as the name of a VFI used by a client, to determine which customers are impacted by an alarm involving a VPLS device.

How the Condition of VPLS Devices is Calculated

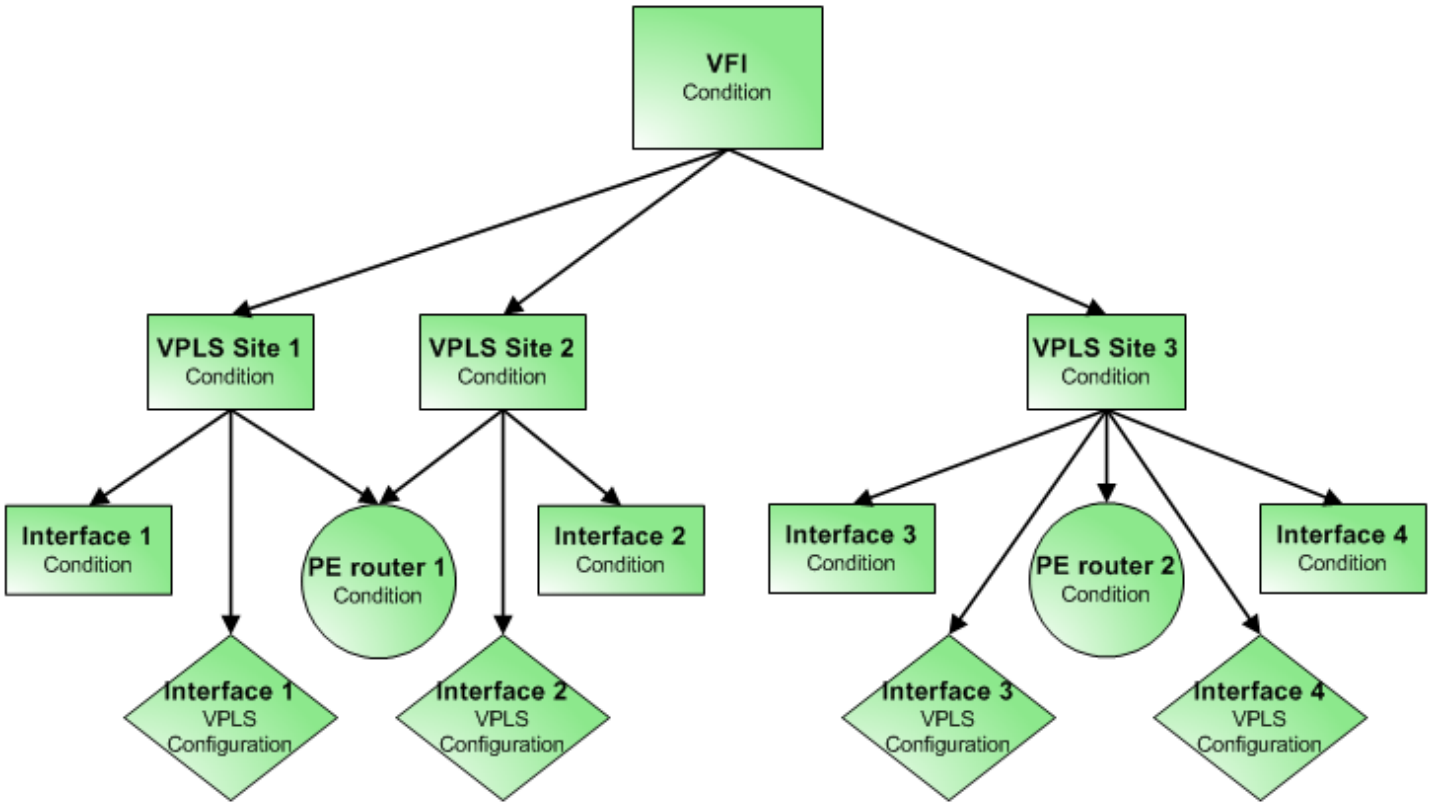
The overall condition of a VFI is of critical importance to providers of VPLS services. Knowing the condition of a VFI can help ensure that you meet your customer SLAs or determine when performance tuning in your VPLS environment is needed.

DX NetOps Spectrum constantly monitors the status of the resources used to provide the VPLS service. The goal of VPLS Manager is to determine the health of the VPLS service by understanding its relationship to physical and logical network entities. VPLS Manager calculates VFI condition based on analysis of the VFI's aggregate VPLS Site conditions.

The process for calculating VFI condition is as follows:

1. The PE routers, interfaces, and interface VPLS configurations are polled at a user-defined interval.
2. When one of these monitored resources experiences an outage, this condition is reflected in the health of the VPLS Site model. Specifically, VPLS Site condition is computed, based on these factors:
   - Contact status of the PE router
   - Condition of the VPLS-enabled interface (IPLS)
   - Configuration of the VPLS-enabled interface
   - Value of mplsVpnVrfOperStatus
   - Value of ifOperStatus for the physical interface
   - Receipt of a jnxVpnIfUp, jnxVpnPwUp, jnxVpnIfDown, or jnxVpnPwDown trap
3. The status of all VPLS Sites is then rolled up into the health of the VFI.

The following diagram demonstrates how condition is calculated for VPLS Sites and rolled up to the VFI models:



For example, DX NetOps Spectrum calculates the condition of VPLS Site 1 as a combination of the Interface 1 condition, PE router 1 condition, and the VPLS configuration of Interface 1. For VPLS Site 3, the condition is affected by two interfaces Interface 3 and Interface 4. Therefore, the condition of VPLS Site 3 is a combination of the PE router 2 condition and the condition and VPLS configuration of the two interfaces.

The condition of the VFI model is determined by the condition of all of the L2VpnSites contained in the VFI. The following list explains how each condition of a VFI is determined:

- **Initial**
  No L2VpnSites are modeled or all VPLS Site models are “Initial.” The percentage of VPLS Sites that are “Initial” is greater than the Minor threshold.
- **Maintenance**
  All the L2VpnSite models are in maintenance mode.
- **Minor**
  The percentage of L2VpnSites down (Site Rollup condition) is greater than the Minor threshold and less than the Major threshold.
- **Major**
  The percentage of L2VpnSites down is greater than the Major threshold and less than the Critical threshold.
- **Critical**
  The percentage of L2VpnSites down is greater than the Critical threshold.
- **Good**
  The percentage of L2VpnSites down is less than the Minor threshold.

You can set threshold values for each VFI model that control whether the VPLS Manager model generates VFI condition alarms.

View Real-Time Performance Data

To measure the performance of your VPLS environment, you must analyze the devices and interfaces used by the VFIs. Their status helps to determine the overall health of your VPLS environment and to decide if you must make changes to improve the performance. Real-time performance monitoring is accomplished by on-demand polling of VPLS-enabled interfaces. The following interface statistics are polled:

- Bytes In Rate
- Bytes Out Rate

To view real-time performance data for a VPLS device

1. Search for the VPLS device you want to monitor.
   The VPLS device model appears in your search results in the Contents panel.
2. Select the VPLS device model.
   Details about the selected model appear in the Component Details panel.
3. Click the Performance tab in the Component Details panel.
4. Select one of the following on-demand reports from the drop-down field:
   – Total Traffic
   – Component Traffic In
   – Component Traffic Out

   NOTE
   Performance data for a selected VFI is an aggregation of the performance data of the component VPLS Sites in a VFI.

   Performance data for the selected report is displayed in the real-time graph. Although DX NetOps Spectrum does not store this data, the graph is updated every 10 seconds to reflect the current performance information.

Reports

Reports provide information that helps you and your customers make informed decisions about your IT assets. Viewing a report lets you analyze specific areas of your VPLS environment to determine if changes are necessary to improve performance.

VPLS Manager uses Spectrum Report Manager to generate reports. Using Spectrum Report Manager you can create the following types of reports:

- Asset reports
- Availability reports

NOTE
For more information about report options and procedures to generate these reports using Spectrum Report Manager, see Report Manager.

Asset Reports

Asset reports generate information about the inventory of assets in the IT infrastructure, including information about VPLS environment assets. Asset reports can help you determine the health of your VPLS environment by focusing on the status of a model's condition over time.

The asset reports available for VPLS Manager include the following:

- **Site Health History** -- A tabular report showing the status of a single VPLS Site during a specified time period
- **Site Health Percentage** -- A pie chart for a single VPLS Site showing all statuses reported and the percentage of time spent in each status during a specified time period
- **VFI Health History** -- A tabular report showing the condition of a single VFI during a specified time period
- **VFI Health Summary** -- A pie chart for a single VFI showing all conditions reported and the percentage of time spent in each condition during a specified time period

Availability Reports

Availability reports provide historical information about up time and down time for assets in the IT infrastructure. Availability reports can help you determine the health of your VPLS environment by highlighting which VFIs and VPLS Sites performed the best and worst over time.

> **WARNING**
> The availability reports cannot function properly when duplicate site or VFI names are modeled in DX NetOps Spectrum. To help ensure these reports work correctly, be sure you provide unique names for all site and VFI models.

The availability reports available for VPLS Manager include the following:

- **Top N Most Available Sites** -- A tabular report of best performing VPLS Sites in respect to up-time accumulated during a specified time period
- **Top N Least Available Sites** -- A tabular report of the worst performing VPLS Sites in respect to up-time accumulated during a specified time period
- **Top N Most Available VFIs** -- A tabular report of the best performing VFIs in respect to up-time accumulated during a specified time period
- **Top N Least Available VFIs** -- A tabular report of the worst performing VFIs in respect to up-time accumulated during a specified time period

Watches

This section contains information about how to work with Watches.

Working With Watches

A *watch* is a mechanism for adding thresholds for model attributes. Watches let you monitor network elements, such as routers, with a high level of detail. They also provide current data that can be used with other DX NetOps Spectrum tools in network analysis.

Watch administration comprises two main components: an intelligent circuit in the SpectroSERVER that performs monitoring functions, and a OneClick administration interface. Watch administration is available under the Thresholds And Watches view on the Information tab for a model.

You can dynamically apply watches on any type of attribute and can monitor attributes against thresholds to generate events and alarms. You can also copy the properties of a watch to another watch. You can thus retain the first watch information while adding new information to the second watch.

You can set watches on the internal and external attributes of any model type. You can also set multiple watches for an attribute. For example, you can set two packet rate threshold watches on a device. One threshold generates a yellow alarm when the value exceeds 10,000, and another threshold generates a red alarm for values above 15,000.

NOTE
We recommend familiarizing yourself with DX NetOps Spectrum administration before setting up watches. For more information, see Database Management, OneClick Administrator , and Performance Administration. Familiarity with the OneClick interface is also helpful.

The watch feature lets you perform the following tasks:

- Dynamically apply watches on any type of attribute.
- Monitor attributes against thresholds and generate events and alarms.
- Execute scripts when watches are violated or when they are reset.
- Generate reports about watches.

NOTE
Watches that you create in one release of DX NetOps Spectrum can be migrated to later releases.

Thresholds And Watches Subview

You can create, configure, and administer watches in OneClick. View and configure watches from a table in the Thresholds And Watches subview.

NOTE
You can access the Thresholds and Watches subview from the Information tab for a model.

The Watches table displays information for each watch defined on that model. The Watch Status column displays the watch condition with color codes as follows:

- **Gray**
  Indicates that the watch is inactive. The watch is not currently running because it has not been activated.
- **Blue**
  Indicates the initial state of the watch. The watch is activated but has yet to run for the first time.
- **Green**
  Indicates that the watch is active and running without any violation.
- **Yellow**
  Indicates that the watch threshold is violated.
- **Red**
  Indicates that the watch failed to evaluate. The text explains the reason.

The toolbar buttons let you do the following:

- Activate
- Deactivate
- Create
- Edit
- Copy
- Delete
- Display watch information
- Print watch information
- Export the Watches table

Create and Edit a Watch

You can create watches to monitor selected attributes of network models.

Follow these steps:

1. Click the Information tab for a model, and expand the Thresholds And Watches subview.
2. Expand the Watches subview.
   The Watches table appears.
3. On the toolbar in the Watches subview, click Create a new watch 
   The Create Watch dialog opens.

   NOTE
   The Expression tab is selected by default.
4. Enter a name for the new watch and select a data type from the Data Type list.

   NOTE
   This data type is the watch destination attribute. The watch expression must evaluate to this data type.
5. Build the expression for the watch by combining operators, functions, and model type attributes:
   - Click a button to the left of the expression area to insert an operator or function into the watch expression at the cursor.
   - Click the Attributes button and select the required attribute to insert an attribute.

     NOTE
     Set the PollingStatus attribute to True to activate a watch.
6. Click the Properties tab and specify the following settings:
   - **Active By Default**
     Specifies whether the watch is active by default for all models that inherit the watch. If this option is not set, activate the watch manually for the desired models.

     WARNING
     Setting Active By Default for a polled watch can adversely affect SpectroSERVER performance.
   - **Evaluate On Demand**
     Evaluates the watch expression only when the watch attribute is read.
   - **Evaluate On Change**
     Evaluates the watch expression if any attribute in the watch expression changes. The attributes must have either the Memory or Database flag set.
   - **Evaluate By Polling**
     Evaluates the watch after each poll interval.
   - **Poll Interval**
     Specifies the polling frequency in seconds. This field is enabled only if you select Evaluate By Polling.

     NOTE
     A watch does not become active if the poll interval is set to 0.
   - **Create watch on model type *model type***
     Specifies the model type where the watch is created. Click Browse to select a different parent model type.

     NOTE
     The watch is created on the model type of the selected model by default. However, you can select a different parent model type for the watch to let other derived model types inherit the watch.
   - **Make Inheritable**
     Makes the watch available for models of all model types that are derived from the selected model type.
7. Click the Threshold tab and select the Attach a Threshold check box if you want to attach a threshold value to the watch.
   The Comparison, Notification, and Script options are enabled.

8. Specify the following Comparison options. The Comparison options specify the threshold settings that specify the boundaries or limits to regulate watch notifications:
   - **Threshold violated if value**
     Specifies the operator for threshold violations. For example, select "greater than". The threshold is considered violated if the sample returns a value that exceeds the value in the threshold attribute. For the threshold violation value, specify a constant or click Attributes to select an attribute.
   - **Threshold reset if value**
     Determines when a threshold status of Violated is reset to Normal. For each subsequent sample after a threshold violation, this reset value is compared to the watch expression using the comparison primitive in the opposite direction. That is, if the comparison primitive is >= (greater than or equal to), the status is reset to Normal as soon as a sample returns a value that falls below this reset value. The reset value is not applicable when the Threshold Comparison is set to == or != because the watch is considered violated if the value is either greater than or less than the watch expression, irrespective of the direction. In such a situation, this option is disabled; otherwise, this entry is mandatory. For the threshold reset value, specify a constant or click the Attributes button to select an attribute.
9. Specify the following Notification options. The Notification options let you specify the type of notification that is sent when the threshold is violated.
   - **No Notification**
     Prevents notification generation when a threshold is violated.
   - **Generate Event(s)**
     Specifies the events to be generated by the DX NetOps Spectrum event management system when the watch is violated or reset. Selecting this option enables fields for event codes as follows:
     - when threshold is violated -- Specifies the event that is generated when the threshold is violated.
     - when threshold is reset -- Specifies the event that is generated when the threshold is reset.
     - when deactivated/all instances are reset -- Specifies the event that is generated when all instances of this watch are reset or when a violated watch is deactivated.

     You can further configure these events to generate or clear alarms and to participate in Event Rules and Procedures. Events are not required for all fields; events are only generated for those fields that contain valid event codes.
   - **Generate Alarm**
     Specifies an alarm to be generated directly if the watch threshold is violated. A generic event (0x480004) is also generated and associated with the alarm. If the watch resets and the alarm is cleared, a generic reset event (0x480005) is generated. Selecting this option enables the following fields:
     - Severity -- Specifies the alarm severity as Minor, Major, or Critical.
     - Description -- Specifies the alarm cause description. A generic description is provided by default. The Browse button lets you select a different cause description or create a new one. Newly created descriptions are stored on the OneClick server in the directory $INSTALL/custom/Events/CsPCause. If you have multiple OneClick servers, copy the files manually.
     - User clearable -- When set, lets you manually clear the watch alarm.
     - Reset watch upon user clearing alarm -- Resets the watch if the alarm is manually cleared even if the watch has not reached its reset value. The alarm can be generated again on a subsequent violation. This option is only available if User Clearable is selected.
10. Specify the following Script options. The Script options let you specify a script to execute if the watch threshold is violated or cleared.
    - **Execute a Script when threshold**
      Enables script execution. Select the threshold condition that triggers script execution.
    - **Execute for each instance**
      If enabled and the watch expression contains list attributes, the script is executed for each instance that meets the threshold condition.
    - **Script File**

Specifies the script file on the SpectroSERVER to execute. If no directory path is specified, the default directory, <*$SPECROOT*>/SS-Tools/SwScript, is used. You can change the default directory by setting sw_script_path in the file <*$SPECROOT*>/SS/.watchrc.

NOTE
Scripts are executed by the user who starts the SpectroSERVER. Therefore, that user requires the privileges to access and execute the scripts. If a permission problem is detected during watch creation or modification, an error message appears. An event is generated if privileges are changed later and the problem is detected in an attempt to execute the script.

11. Click the Landscapes button to specify the destination landscapes for the watch. In the OneClick environment, you can distribute watches to multiple landscapes in a distributed server environment. New watches are created in all landscapes by default.
    A dialog opens with a list of landscapes.
12. Move the landscapes in which you do not want to create the watch to the right.

    NOTE
    If a landscape is not available when the watch is created, you can add the watch to that landscape later. Use the Edit Watch dialog and click Landscapes.
13. Click OK.
    The watch is created.

Create and Edit an Alarm Cause Description

You can create and edit cause descriptions for alarms that are generated for threshold violations. A notification of a threshold violation is delivered through the DX NetOps Spectrum event and alarm facilities. These features support notification delivery by telephone, pager, or by email using an external script interface.

Follow these steps:

1. Select a watch and
   click edit 
   The watch opens in the Edit Watch dialog.
2. Select the Threshold tab, and select Generate Alarm.
   The alarm options are displayed.
3. Click Browse.
   The Select Alarm Cause Code dialog opens. The alarm details appear at the bottom.
4. To create a new alarm cause,
   click create 
   Or, to edit it, select one from the list and click
   edit 

   A dialog opens to let you create or edit the alarm cause.

   NOTE
   The Cause Code field is read-only.
5. Enter information in the fields as required, and click OK.
   The alarm cause description is created or modified.

Copy an Alarm

Use the Copy feature to create multiple alarm cause descriptions that differ only minimally from each other.

Follow these steps:

1. Select a watch in the Watches table and
   click Edit 
   The watch opens in the Edit Watch dialog.
2. Select Generate Alarm on the Threshold tab and click Browse.
   The Select Alarm Cause Code dialog opens.
3. Select an alarm cause description from the list and
   click Copy 
   The Copy Alarm Cause dialog opens.
4. Enter the cause code.
5. (Optional) Edit other alarm properties.
6. Click OK.
   The new alarm cause description is created.

Edit a Watch

You can edit a watch to change its expression, properties, and thresholds.

Follow these steps:

1. Click the Information tab for a model, and expand the Thresholds And Watches subview.
2. Expand the Watches subview.
3. Select the watch in the Watches table and
   click Edit 
   The watch opens in the Edit Watch dialog.
4. Change the watch expression, properties, and thresholds as required, and click OK.

   NOTE
   For more information about the watch expression, properties, and thresholds, see the Create and Edit a Watch section.

   The watch is edited.

Copy a Watch

Use the Copy feature to create multiple watches that differ only minimally from each other.

Follow these steps:

1. Select a watch in the Watches table, and click Copy
   Watch 
   The watch opens.
2. Enter a name for the new watch, change any other information as needed, and click OK.
   The watch is copied and a new watch is created.

Delete a Watch

You can delete a watch if you no longer require the associated threshold monitoring.

Follow these steps:

1. Select the watch in the Watches table and
   click Delete 
   If the watch exists in multiple landscapes, a dialog opens. The left side displays the landscapes where the watch exists and from which it will be deleted.
2. (Optional) To preserve the watch on a landscape, move that landscape to the right.
3. Click OK.
   The watch is deleted from the landscapes that are listed on the left.

Display Watch Information

You can display watch information to see a report about the watch. You can also print and export the information to a text file or HTML file.

Follow these steps:

1. Select a watch in the Watches table and
   click information 
   The Watch Report dialog displays the watch information.
2. (Optional) Click Print to print the watch information.
3. (Optional) Click Export to save the information to a text or HTML file.
   The watch is printed or exported.

Generate a Report on Multiple Watches

You can generate a report about multiple watches from the OneClick Administration page.

Follow these steps:

1. Open the OneClick home page in a browser, and click the Administration tab.
   The Administration Pages opens.
2. Click the Watch Reports link.
   The Generate Watch Report dialog opens. The Select Landscape list and the Select Model Type(s) list are displayed.
3. Select the landscape and model types for which you want to generate a report, and click Generate Report.
   The report is generated.

Inheritable Watch Edits

When you edit an inheritable watch, the watch definition on the selected model type is modified by default. You can select a different parent model type for the watch. Use the Browse button in the Model Type section of the Properties tab.

If a watch definition is modified for a model type that was derived from the watch's originating model type, the changes only take effect for models of that type and its derived types. The model type where the watch originated is not changed.

For example, a watch is originally created on Gen_IF_Port and is inheritable. Serial_IF_Port is derived from Gen_IF_Port, so Serial_IF_Port models inherit the watch. If the watch definition is modified on the Gen_IF_Port model type, the changes are propagated to Serial_IF_Port models. However, if the watch definition is modified on Serial_IF_Port, the new version overrides the definition on Gen_IF_Port. Only Serial_IF_Port models are affected, while Gen_IF_Port models retain the original watch definition. As a result of the inheritance rules, you can redefine or override inheritable watches differently for derived model types.

Manage and Configure Events

Events

To illustrate DX NetOps Spectrum advanced event processing, consider the following scenario. For testing purposes, you want to temporarily allow a high child count. You want to generate an alarm only if the high child count condition persists for more than one minute, and to clear any such alarms when the watch is reset. Using an EventPair Event Rule, DX NetOps Spectrum can perform the following tasks:

- Generate an initial event when the ChildLimit watch is violated.
- Suppress the alarm unless that initial event is *not* followed by a reset event within 60 seconds.
- Generate another event when all instances of this watch are either reset or deactivated.

> **NOTE**
> For more information about event rules and creating events, see Event Configuration.

Configure Events

The following procedure is an example of event configuration. Building from the example in the previous topic, the first event is "Initial child count too high" (0xffffffff), and the second event is "Reset" (0xfffffffe). If the child count threshold is violated and is not reset within 60 seconds, a "Child count too high" alarm (event/alarm 0xfffffffd) is generated.

Follow these steps:

1. Select Utilities, Event Configuration from the Tools menu.
   The Event Configuration page appears with the Navigation, Contents, and Details panels.
2. Click
   
   (Create Event) in the Navigation panel.
   The Create Event dialog appears, with Event Code populated with a default value.
3. (Optional) Edit the event code and enter an event message and click OK.
   The event is created and its details appear in the Contents and Details panels on the right.
4. Create and save the initial Child count too high event (0xffffffff).
   This event triggers the EventPair rule that conditionally generates an alarm and a Reset event (0xfffffffe). The watch uses the Reset event to evaluate the persistence of the child count condition and to clear any alarms that the EventPair rule generates when the watch is reset.
5. Create and save an event "0xfffffffd" and a corresponding alarm that is used to generate a notification if the child count is persistently high.
6. Create and save an Event Pair rule for the initial "Child count too high" event (0xffffffff) that generates the "0xfffffffd" event and alarm if the Reset event (0xfffffffe) is not received within 60 seconds.

   > **WARNING**
   > If the SpectroSERVER is updated while an event is being processed using an Event Rule, the processing is not completed. All event rules that are processing when this functionality is invoked are flushed.
7. Click File, Save All.
   The new events are saved.
8. Open a watch for editing.
9. On the Threshold tab, select Generate Event(s) under Notification.
   The event code fields appear.
10. Enter the initial "Child count too high" event (0xffffffff) that you previously created in the 'when threshold is violated' field.
11. Enter the alarm-clearing "Reset" event (0xfffffffe) that you previously created in the 'when threshold is reset' field, and click OK.
    The event is associated with the watch.

If the LAN_802_3 container contains 5 or more models, the initial "Child count too high" event is generated, and the event rule is evaluated. An alarm is generated only if the reset event is not received within 60 seconds of the initial event. If the watch is reset, any "Child count too high" alarms that the watch generates are cleared.

The EventDisp entries (if needed) for this example are as follows:

```
# make sure child count too high (0xffffffff) is
# reset (0xfffffffe) within 60 seconds
# otherwise generate alarming event (0xfffffffd)0xffffffff E 50 R Aprisma.EventPair, 0xfffffffe, 0xfffffffd,
 60
# generate an alarm on persistent child count too high0xfffffffd E 50 A 1,0xfffffffd
# if child count drops below threshold, clear any existing alarms0xfffffffe E 50 C 0xfffffffd
```

Event Codes

Event codes are generated in the DX NetOps Spectrum Event Log for each event.

NOTE
An event is not generated for watch creation.

The following list contains event codes and their descriptions:

- **0x0048000a**
  Watch could not be activated for a model
- **0x00480000**
  Modification of a watch
- **0x00480001**
  Destruction of a watch
- **0x00480002**
  Activation of a watch
- **0x00480003**
  Deactivation of a watch
- **0x00480004**
  Violation of a watch threshold
- **0x00480005**
  Resetting of threshold status for a watch (with variable reset value)
- **0x00480006**
  Violation of an instance of a watch
- **0x00480007**
  Resetting of threshold status for an instance of a watch (with variable reset value)
- **0x00480010**
  Bad probable cause message
- **0x00480012**
  Logging interval conflict
- **0x00480013**
  Error executing a script (for threshold watches only)
- **0x00480014**
  Resetting a watch threshold for a model, with reason

Event Format Files

You can use the existing event format files Event00480004 and Event00480005 (located in <*$SPECROOT*>/SG-Support/CsEvFormat) as templates to create your own watch-related event format files.

NOTE
For more information, see Event Configuration.

Event Variables

The events for watch threshold violation (0x00480004) and reset (0x00480005) have variable bindings. This applies both to watches that generate alarms directly and watches that generate events. The clear event has a single variable binding, ID #2, containing the watch name.

The following table shows the binding variables and their contents:

Variable Binding ID	Contents
2	Watch name
4	Threshold reference value
5	Threshold reset value (only for reset events)
6	Comparison string value
7	Calculated watch value
8	Instance object identifier (OID) if the watch has instances, otherwise empty
9	Internal; strings to complete the respective event message
10	Internal; strings to complete the respective event message
11	Internal; strings to complete the respective event message

Watch Expressions

A watch expression defines what is monitored by the watch. The watch expression can be as simple as the name of an attribute or as complex as a formula. A watch expression includes attributes and constant values that are related to each other through mathematical symbols and Boolean operators, which are referred to as primitives.

Expressions are evaluated proceeding from left to right in the following order of precedence for primitives:

Precedence	Primitives
1	.# .
2	( )
3	DELTA ( ) COUNTER_DELTA ( )
4	!
5	| &
6	* /
7	+ -
8	= = != >= <= < >

Primitives

Primitives are typically used in expressions that have a left side and a right side. For example, in A+B, + is the primitive defining the relationship between the left side, A, and the right side, B. Parentheses are used to indicate the order of evaluation for expressions with multiple components.

The available primitives are as follows:

- +
- -
- *
- /
- ==
- !=
- >
- <
- >=
- <=
- ! (not)
- & (and)
- ,
- |
- (
-)
- TRUE
- FALSE
- TIME
- DELTA
- MIN
- MAX
- INTEGER
- REAL
- UNSIGNED
- COUNTER_DELTA
- UNSIGNED64

You can group primitives by function and applicability. You can apply the following primitives only between text strings or in numerical expressions:

- = = equal to
- >= greater than or equal to
- <= less than or equal to
- != not equal to
- > greater than
- < less than

NOTE
These primitives do not support the attribute types Object ID, IP Addr, and Boolean.

You can apply the following primitives only for numerical expressions:

- + addition
- - subtraction
- * multiplication
- / division

These primitives do not support the attribute types Text String, Object ID, IP Addr, and Boolean. Supported types are evaluated in the following order:

- Real
- Time Ticks, Date, Gauge, Counter
- Enumeration Integer

If elements are from two different levels, they are evaluated as belonging to the higher level. For example, 5 + 5 is evaluated as an integer, while 5 + 5.1 is evaluated as a real.

> **NOTE**
> DX NetOps Spectrum model types use the attribute type Counter to store unsigned long integers. If you use the unsigned primitive illegally in an expression, for example, "Text String + UNSIGNED(5)", the resulting error message is of type Counter.

You can apply the following primitives only to Boolean expressions:

- ! logical not
- & and
- | or

The following primitives are composed of words instead of symbols:

- **TIME**
  Represents the current time as the number of seconds since January 1, 1970, 00:00 Greenwich Mean Time.
- **DELTA**
  Calculates the change of an attribute over the intervals of the sampling frequency. For example, a watch on an integer attribute named int1 at 30-second intervals might produce DELTA values as follows:

Interval	Values
0	100, 0
30	1000 900
60	1000 0
90	-1000 -2000
120	2000 3000

The DELTA primitive supports the following attribute types:

- Integer
- Enumeration
- Real
- Short
- Time Ticks
- Date
- Gauge
- Counter

In cases where the value is never expected to go down (such as with Time Ticks and Counter), use COUNTER_DELTA.

You can instance attributes in DELTA expressions as follows:

- DELTA (If_In_Octets.2)
- DELTA (If_Out_Octets.#)
- DELTA (TIME) is also supported

> **NOTE**
> DELTA (TIME) is the difference between now and the last evaluation of the watch; it is useful only for calculations involving internal attributes. To generate a rate calculation involving external attributes, use the

device's time, for example, DELTA (XfIDELTA (Sys_Up_Time), where Sys_Up_Time is the time counter on the device.

- **COUNTER_DELTA**
  Calculates the change of an attribute whose value is assumed to be an increasing unsigned integer. The value may be reset to zero, but the result of this primitive is always a positive unsigned integer. Negative attribute values are treated as large unsigned values.
  The COUNTER_DELTA primitive supports the same attribute types as DELTA, and you can also instance attributes within COUNTER_DELTA expressions as described for DELTA. COUNTER_DELTA (TIME) is also supported.
- **ATTR**
  Indicates that the hexadecimal number in parentheses following the primitive is an attribute identifier. This primitive lets an attribute to be uniquely identified when duplicate names exist as shown in the following examples:
  ATTR (<*attr_id*>)
  ATTR (<*attr_id*>).<*instance id*>
  ATTR (<*attr_id*>).#
  The <*attr_id*> value is “0x” or “0X” followed by between one and eight hexadecimal numerals.
- **TRUE**
  Defines the Boolean constant True.
- **FALSE**
  Defines the Boolean constant False.
- **MAX**
  Identifies the larger of two expressions separated by a comma and enclosed by parentheses, for example, (attribute x +1, attribute y-5). The expressions may consist of any combination of operands, attributes, or primitives that results in a numeric value (non-text, string, octet, bool).
- **MIN**
  Identifies the smaller of two expressions separated by a comma within parentheses, for example, (attribute x+1, attribute y-5). The expressions may consist of a combination of operands, attributes, or primitives that results in a numeric value (non-text, string, octet, bool).

You can use the following primitives (not shown on the pop-up selector menu) to indicate the instances of a list attribute that are monitored by a watch.

- **.**
  Indicates that the following entry identifies a specific instance of a list attribute.
  For example, If_In_Octets.2 specifies the second instance of the attribute If_In_Octets. In the case of an IP address table, the identifier might be an entire address instead of a single digit.
  A watch fails if the specified instance of an attribute does not exist even for one of the models for which the watch is activated. In cases where the instance exists for some models but not for others, the watch succeeds for those models where it is present and fails for others.
- **.#**
  Indicates that the current Instance Specifier value shown in the Watch Detail View determines which instances are monitored.
  For example, if the Instance Specifier value is ALL, the expression If_In_Octets.# applies the watch to all instances of the If_In_Octets attribute. However, if the Instance Specifier value is RANGE (1-3), only instances 1, 2, and 3 are monitored.
  In cases where a range of instances is specified, the watch fails even if one of the instances in the range is not present for one of the models. Conversely, the watch is successful for any model where all of the instances in the range are present.

Data Types

The following table shows the data type values that you can assign to the various attribute types.

Note: Although DX NetOps Spectrum does not support watches of attributes with the data type OCTET STRING, you can watch such attributes using the TEXT STRING data type.

Expression Result Type	Acceptable Destination Attribute Types
BOOLEAN	Any Numeric Type
TEXT STRING	Text String
INTEGER	Integer, Enumeration, Real
ENUMERATION	Integer, Enumeration, Real
REAL	Integer, Enumeration, Real
DATE	Real, Date, Time Ticks, Counter, Gauge, Counter64
TIME TICKS	Real, Date, Time Ticks, Counter, Gauge, Counter64
COUNTER	Real, Date, Time Ticks, Counter, Gauge, Counter64
GAUGE	Real, Date, Time Ticks, Counter, Gauge, Counter64
OBJECT Id	OBJECT Id
IP ADDRESS	IP ADDR
COUNTER64	COUNTER64, Real

For example, given an integer attribute named Int1, the expression Int1 = 50.5 (requires a cast) is allowed, while Int1 = “a string” is not allowed.

The rules are most flexible for assigning values to Boolean and Text String attributes. Any expression can be evaluated to a 0 and 1 and can be written to a Boolean attribute. For example, given Bool1 as a Boolean attribute, the expression Bool1 = 500 * 50 + 450 assigns TRUE to Bool1. The expression Bool1 = (500 * 50 + 450) * 0 assigns FALSE to Bool1. Similarly, any expression can be evaluated to a text string. Given a Text String attribute named str1, the expression str1 = 500 + 50 assigns the string “550” to str1.

> **NOTE**
> The Text String attribute type accepts text strings in quotation marks, and arithmetic expressions that are not contained in quotation marks, such as 500 + 50, which results in a string of “550.”

Constants

Like attribute values and operators, you can enter constants directly into the expression field. You can enter the following types of constants in expression formulas:

- UnsignedInteger, represented by a sequence of one or more digits with a positive value.
- Real, represented by a sequence of zero or more digits followed by a dot, followed by a sequence of one or more digits. For example, .7 or 1.7 or 23.24 (but not 7).
- Signed Integer, represented by a sequence of one or more digits with either a positive or negative value.
- Text String, represented by any sequence of characters that are enclosed by double quotation marks. For example, "a string" or "5.25" or " ".

Casting Operators

Casting forces one data type into another. When you perform casting, you risk losing some portion of the value being cast. Casting is unnecessary when the range of the source data type fits into the range of the destination data type.

For example, you can assign an integer to a real number without casting because -1.79769 e+308 **<=** -2,147,483,648 and 2,147,483,647 **<=** 1.79769 e+308. However, you must use casting when assigning an integer to a counter because the ranges do not overlap.

Casting works correctly for the overlapping ranges of the involved data types. For example, casting the integer 5 to a counter behaves as expected. But negative numbers do not fit inside of the range of Counter. As a result, casting -5 to a Counter produces the unsigned (positive) result of 4,294,967,291 because of the way computers represent numbers. Conversely, casting a counter value larger than 2,147,483,647 into an integer produces a negative number.

You can use the following operators to cast the result of an expression in parentheses to a selected data type.

Operator	Result of Casting
UNSIGNED	Normally, 27 is treated as a signed integer; however, “UNSIGNED (27)” is interpreted as the unsigned integer 27. If a negative number appears in the expression following this operator, it is interpreted as unsigned. Example: UNSIGNED (-5) is interpreted as 5. The number, -5 is UNSIGNED with a value of: 4294967291.
INTEGER	Any real number in the expression following this operator is rounded up or down to the nearest integer. Examples: INTEGER (2.4) is interpreted as 2 and INTEGER (2.6) is interpreted as 3.
REAL	Example: REAL (3) is interpreted as 3.0.

Data Type of a Literal Number

A numeric literal in a watch expression is compared against a series of ranges to determine its data type. The Type column in the table below is the actual data type of the numeric literal, which is directly interchangeable with the other types that are listed in that column cell.

The following table shows how the data type of a literal number is determined:

Minimum	Maximum	Type
-2,147,483,648	2,147,483,647	Integer, Boolean*, Enumeration
0	4,294,967,295	Counter, Date**, Gauge, TimeTicks
0	18,446,744,073,709,551,615	Counter64
-1.79769 e+308	1.79769 e+308	Real

* You can also use the constants TRUE and FALSE for Boolean data types. Any non-zero value is equivalent to TRUE.

**The number of seconds from Jan 1, 1970 00:00:00 UTC(0).

Attributes And Instance Identifiers

The attributes that you enter in watch expression formulas must always begin with a letter and consist of a combination of letters, digits and underscore characters (_). Enclose attributes with names identical to primitives (TRUE, FALSE, TIME, DELTA, COUNTER_DELTA) in single quotes. You can also specify attributes by attribute ID using the ATTR primitive.

A watch expression can consist of a single attribute. To create a multi-attribute expression, select an operator from the button palette, then select another attribute and so on.

If a list attribute is specified in the expression, you must include instance information. To specify an instance, append a '.' followed by the instance ID number (for example, **ifInOctets.2**). Or append '.#' (for example, ifInOctets.#), and select either All or Range in the Instance field. For Range, specify the low and high IDs in the From and To fields. List attributes are indicated with "[]" in the Type column in the Attribute Selector dialog.

In addition to the attributes that you enter as part of watch expressions, you can also dynamically create the attributes that are required to store watch information and destination attributes.

Instance Identifiers

You can use instance identifiers to specify a particular object when you are using list attributes in a watch expression formula.

List attributes require instance IDs to fully identify an object. You can specify a specific instance, a range of instances, or all the possible instances of an attribute in a watch expression. When an OID is built, it uses up to two different sub-OIDs: the standard SpectroSERVER OID mechanism or the Watch Instance Specifier. The SpectroSERVER creates an OID from the OID prefix and the OID reference (optional). When you specify an instance for the watch expression on the Expression page, it is appended to the OID as follows:

```
OID = OID prefix + OID reference + Watch instance
```

If you use the Instance Specifier to specify a range, a result for each instance in the range is computed. If the range specified is larger than the actual instances, results are only computed for the actual instances. That is, if you specify a range of 1-10, and there are only 3 instances, only 3 results are computed.

For example, you want to set a watch on If_In_Octets for a router. You supply a range of 1-3 as the Instance Specifier. Because the OID prefix that the DX NetOps Spectrum database uses for If_In_Octets is 1.3.6.1.2.1.2.2.1.10, the following OIDs are assigned:

- OID = 1.3.6.1.2.1.2.2.1.10 + .1
- OID = 1.3.6.1.2.1.2.2.1.10 + .2
- OID = 1.3.6.1.2.1.2.2.1.10 + .3

If you use ALL as the Instance Specifier, all of the instances for the If_In_Octets object are dynamically determined. You can also specify an instance in the watch expression, or you can mix specific instances of an object with RANGE or ALL Instance Specifiers. Using the Instance _of primitive (“.”) to specify an instance of an object overrides the Instance Specifier for that object.

For example, in the following formula, the Instance_of primitive (followed by a value) is used to specify instance number 3 of the If_In_Errors object, and the .# primitive indicates that the current Instance Specifier should be used for the If_In_Octets object.

```
If_In_Errors.3 / If_In_Octets.#
```

Assume that the current Instance Specifier is ALL, and both If_In_Errors and If_In_Octets are list attributes with the OIDs 1.3.6.1.2.1.2.2.1.14 and 1.3.6.1.2.1.2.2.1.10 respectively. The division operation for each instance would be performed, using the following OIDs:

```
If_In_Errors OID = 1.3.6.1.2.1.2.2.1.14 + .3
If_In_Octets OID = 1.3.6.1.2.1.2.2.1.10 + .1
If_In_Errors OID = 1.3.6.1.2.1.2.2.1.14 + .3
If_In_Octets OID = 1.3.6.1.2.1.2.2.1.10 + .2
If_In_Errors OID = 1.3.6.1.2.1.2.2.1.14 + .3
If_In_Octets OID = 1.3.6.1.2.1.2.2.1.10 + .n
```

Notice how the Instance_of primitive overrides the Instance Specifier for the If_In_Errors attribute OID. Instead of each attribute using each possible instance as a result of selecting ALL, the Instance_of primitive allows specification of a particular instance. However, the Instance Specifier still determines the number of instances of a particular watch.

The INSTANCE_ID of the model and the Instance Specifier is applied to each list attribute in the watch expression. If the watch expression contains attributes that use different instances, an error is returned when you attempt to add the watch.

For example, if you enter one formula that contains an attribute that uses board number as an instance and another formula that uses board port as an instance, an error is returned.

Watch Definition Attributes

When you create a watch for a model, an attribute is created to store the watch details. The attribute has a computer-generated name. It is created using the active database Developer ID (registered or default) in the Watch Definition group under the model type to which the model belongs.

Watch Destination Attributes

When you create a watch for a model, a destination attribute is also created with the same name and data type as the watch. This attribute resembles any other model type attribute. When it is read, the watch expression is automatically evaluated. The result of the evaluation is the result of the read operation.

Threshold Reference and Reset Compatibility

For threshold watches, the threshold and reset expressions must be of a type that is compatible with the watch expression.

The following table shows the result types and the corresponding acceptable types:

Result Type	Acceptable Types
BOOLEAN	Boolean
TEXT STRING	Text String
INTEGER	Integer, Enumeration, Real
ENUMERATION	Integer, Enumeration, Real
REAL	Real
DATE	Real, Date, Time Ticks, Counter, Gauge, Counter64
TIME TICKS	Real, Date, Time Ticks, Counter, Gauge, Counter64
COUNTER	Real, Date, Time Ticks, Counter, Gauge, Counter64
GAUGE	Real, Date, Time Ticks, Counter, Gauge, Counter64
OBJECT Id	OBJECT Id
IP ADDRESS	IP_ADDR
COUNTER64	Counter64, Real

Alarm Script and Watch Type Examples

You can refer the alarm script and watch type examples that are available in this section.

Alarm Script Example

The following sample is an example of a UNIX script file that you can create as a notification. You can designate scripts for execution whenever an alarm is set or cleared in conjunction with a threshold watch. This example script is named *sw_alrm_script* and is included in the SS-Tools/SwScript directory when you install DX NetOps Spectrum.

```
#!/bin/sh
############################################################
This is an example script that can used by users to perform important tasks upon threshold violation of a
 watch (Watch Status is #VIOLATED) or when an already violated watch becomes normal (Watch Status #is NORMAL).
#
```

```
# In each of the above cases, the user-specified script is executed (specified during watch creation) and
 provides twenty arguments. The arguments in ascending order are:
#
# 1) DATE   - The date on which the watch was violated.
# 2) TIME        - The time at which the watch was violated.
# 3) MTYPE_NAME     - The model type of the watch.
# 4) MODEL_HANDLE   - The modelhandle of the model.
# 5) MODEL_NAME     - The model of the watch.
# 6) INSTANCE       - The instance (port, board, etc) for which the watch is either violated or reset.
# 7) ALARM_ID      - The ID of the alarm.
# 8) CONDITION     - The CONDITION of the alarm.
# 9) CAUSE_CODE    - The cause code of the alarm.
# 10) REPAIR_PERSON   - The repair person assigned to troubleshoot.
# 11) ALARM_STATUS  - The status of the alarm.
# 12) SCRIPT_TYPE  - This is set to "VIOLATED" if the script is getting executed upon violation and it is set
 to # "NORMAL" if the script is getting executed upon reset.
# 13) WATCH_NAME  -  The name of the watch for which the script is executed.
# 14) WATCH_CREATOR  - The name of the creator of the watch.
# 15) WATCH_SRC  - The formula for the watch expression.
# 16) WATCH_SRC_VAL  - The value of the watch expression formula.
# 17) WATCH_REF  - The formula for threshold reference.
# 18) WATCH_REF_VAL  - The value of the threshold reference.
# 19) WATCH_RES  - The formula for threshold reset.
# 20) WATCH_RES_VAL  - The value of the threshold reset.
################################################################
## Save the argument values into variables that could be used later.
## Remember that DATE is the first argument and WATCH_RES_VAL is the last argument.
# IMPORTANT NOTE:
## Pay particular attention to the variable, "SCRIPT_TYPE". If the watch has a violated status, SCRIPT_TYPE
 is set to "VIOLATED". If a watch has normal status, SCRIPT_TYPE is set to "NORMAL". You can be use this to
 decide what to do when the watch is violated and when it is normal.

Watch Type Examples

First Watch Scenario

The following parameters establish a watch on Hub_CSI_IRBM. This watch checks the total number of frames transmitted and collisions received every 60 seconds. It generates a minor alarm with the message "Too many collisions" if the threshold value of one million is exceeded. The Threshold Reset Value indicates that the threshold status is reset from Violated to Normal (and the alarm is cleared) when the total number of collisions falls to 500,000.

You can create watches for this scenario as follows:

1. Create an inactive watch of type Counter and name it HubColls_v. Assign the total number of collisions of 1000000 in the expression.
2. Create an inactive watch of type Counter and name it HubColls_r. Assign the total number of collisions of 500000 in the expression.

3. Create an active watch of type Counter and name it HubColls and assign it values as shown in the following watch examples.

Examples: Watches

The first watch consists of the following parameters:

- Name: HubColls_v
- Data Type: Counter
- Expression:
  - Expression: 1000000
- Instance: None
- Properties
  - Default Activation: Inactive
- Threshold: None

The second watch consists of the following parameters:

- Name: HubColls_r
- Data Type: Counter
- Expression:
  - Expression: 500000
- Instance: None
- Properties
  - Default Activation: Inactive
- Threshold: None

The third watch consists of the following parameters:

- Name: HubColls
- Data Type: Counter
- Expression
  - Expression: Hub_Trans_Coll+Hub_Rec_Colls
- Instance: None
- Properties
  - Default Activation: Active
  - Evaluated: By Polling
  - Poll Interval: 00:01:00
- Threshold
  - Attach a Threshold (checked) Threshold Violated if value: > HubColls_v (create a counter watch named HubColls_v Inactive, expression is 1000000.)
  - Threshold reset if value: HubColls_r (create Counter watch named HubColls_r Inactive, expression is 500000.)
  - The attributes, HubColls_v and HubColls_r must be created before the creation of the HubColls watch.
  - Generate Alarm (checked) Severity: Minor Alarm Desc: CollsExceeded (Create a new alarm named CollsExceeded with the message "Too Many Colls".)

Second Watch Scenario

A network administrator wants to monitor the level of disk utilization on a server, but wants to exclude CD-ROM drives from monitoring. CD-ROM drives typically show 0% utilization if no CD is present, but they show close to 100% utilization if a full CD is in the drive. However, such information is not useful to the administrator.

To check disk utilization, the administrator wants to use RFC2790App, which returns device types as OIDs. Each OID maps to a different device type. Any expression that must check against a storage type in this MIB must use its OID for comparison. (You can compare strings to OIDs).

The following table shows RFC2790App Device Type/OID Mapping.

Device Type	OID
hrStorage	1.3.6.1.2.1.25.2
hrStorageTypes	1.3.6.1.2.1.25.2.1
hrStorageOther	1.3.6.1.2.1.25.2.1.1
hrStorageRam	1.3.6.1.2.1.25.2.1.2
hrStorageVirtualMemory	1.3.6.1.2.1.25.2.1.3
hrStorageFixedDisk	1.3.6.1.2.1.25.2.1.4
hrStorageRemovableDisk	1.3.6.1.2.1.25.2.1.5
hrStorageFloppyDisk	1.3.6.1.2.1.25.2.1.6
hrStorageCompactDisk	1.3.6.1.2.1.25.2.1.7
hrStorageRamDisk	1.3.6.1.2.1.25.2.1.8
hrStorageFlashMemory	1.3.6.1.2.1.25.2.1.9
hrStorageNetworkDisk	1.3.6.1.2.1.25.2.1.10

The administrator must create two new watches on the RFC2790App model. The first watch sets up a Boolean value that is used in the second watch to exclude CD-ROM drives (OID 1.3.6.1.2.1.25.2.1.7) from monitoring. The second watch monitors the disk utilization (expressed as a percentage) of other types of storage devices on the host. In this example, an alarm is sent if utilization exceeds 90%.

Examples: Watches

The first watch consists of the following parameters:

- Name: isNotCDROM
- Data Type: Boolean
- Expression: Expression: hrStorageType.# != 1.3.6.1.2.1.25.2.1.7
- Instance: All
- Properties
  - Default Activation: Active
  - Evaluate: On Demand
- Threshold: None

The second watch consists of the following parameters:

- Name: PctDiskUsed
- Data Type: Real
- Expression
  - Expression: REAL(hrStorageUsed.#)/REAL(hrStorageSize.#) * 100 * REAL(isNotCDROM.#)
  - Instance: All
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 30 seconds
- Threshold

  - Threshold violated if value >= <*set to the acceptable level of disk utilization*>
- Alarm
  - Alarm Severity: Minor
  - Alarm Description: DiskUtilAlarm
  - Alarm is user clearable
  - Watch is not reset upon user clearing of alarm.
- Script: None

Evaluate-On-Change Watches

The following watches are examples of evaluate-on-change (EoC) watches. These watches determine when a view was edited. As a result, the administrator can run a search that shows exactly when LANs were edited and when new models were added to them. Both attributes are evaluated on change, and neither attribute is likely to change frequently.

Examples: Evaluate-on-Change Watches

The first watch consists of the following parameters:

- Name: Child_Count_Watch
- Data Type: Integer
- Expression
  - Expression: Child_Count
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By EoC
  - Poll Interval: None
- Threshold: None

The second watch consists of the following parameters:

- Name: Edit_Count
- Data Type: Integer
- Expression
  - Expression: EDIT_COUNT
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By EoC
- Threshold: None

Polled Threshold Watches

In the following example, a Polled Threshold watch is created to generate a minor alarm each time the number of children in a LAN_802_3 exceeds 5. The watch clears the alarm when the count of children falls below 5.

First, create the attribute watch ChildLimit_v (an arbitrary name) and give it an expression of "5". Creating a watch depicts the creation of this watch in detail. Then create a polled threshold watch named Child_Limit.

Examples: Polled Threshold Watches

The first watch consists of the following parameters:

- Name: ChildLimit_v
- Data Type: Counter
- Expression: 5
- Properties: None
- Threshold: None

The second watch consists of the following parameters:

- Name: ChildLimit
- Data Type: Integer
- Expression
  - Expression: Child_Count
- Instance: None
- Properties
  - Default Activation: Active
  - Evaluated: By Polling
  - Poll Interval: 00:01:00
- Threshold
  - Attach a Threshold (checked)
  - Threshold Violated if value: > ChildLimit_v
  - Threshold reset if value: <= ChildLimit_v
  - Generate Alarm (checked)
  - Severity: Minor
  - Alarm Description: ExceedChildLimit (Create a new alarm named ExceedChildLimit with the message "Only 5 children allowed.")

First On-Demand Watch Scenario

On-Demand watches are evaluated whenever information is requested from them.

The following examples of simple On-Demand watches work with a polled Threshold watch that generates an alarm when a Cisco router (model type: Rtr_CiscoIGS) starts running out of memory. The attribute, freeMem, is less than 1500 and clears when it exceeds 2500.

Examples: Simple On-Demand Watches Working With a Polled Threshold Watch

The first watch consists of the following parameters:

- Name: MemLow
- Data Type: Integer
- Expression
  - Expression: 1500
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluated: On Demand
- Threshold: None

The second watch consists of the following parameters:

- Name: MemHigh
- Data Type: Integer
- Expression

  - Expression: 2500
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluated: On Demand
- Threshold: None

The third watch consists of the following parameters:

- Name: Mem_Good
- Data Type: Integer
- Expression
  - Expression: freeMem
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 1 minute
- Threshold
  - Threshold violated if value: <= MemLow
  - Threshold reset if value: > MemHigh
- Alarm
  - Alarm Severity: Major
  - Alarm Description: Rtr+Memory
- Script: None

Second On-Demand Watch Scenario

On-Demand watches are evaluated whenever information is requested from them.

The following watches are designed to show the network administrator colored alarm conditions as the performance of a Cisco router (model type: Rtr_ Cisco) progressively degrades. A minor alarm has a value of 50 -59; a major alarm has a value of 60 - 69, and the value of a critical alarm exceeds 70.

Examples: On-Demand Watches

The first watch consists of the following parameters:

- Name: True_Ref
- Data Type: Boolean
- Expression
  - Expression: 1
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluate: On Demand
- Threshold: None

The second watch consists of the following parameters:

- Name: Minor_Busy
- Data Type: Boolean
- Expression

  - Expression: ((busyPer >= 50) & (busyPer <60))
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 1 minute
- Threshold
  - Threshold violated if value: > True_Ref
  - Threshold reset if value: <= True_Ref
- Alarm:
  - Alarm Severity: Minor
  - Alarm Description: RtrBusy1
  - Script: None

The third watch consists of the following parameters:

- Name: Major_Busy
- Data Type: Boolean
- Expression
  - Expression: ((busyPer >= 60) & (busyPer < 70))
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 1 minute
- Threshold
  - Threshold: Threshold violated if value: == True_Ref
  - Threshold reset if value: != True_Ref
- Alarm
  - Alarm Severity: Major
  - Alarm Description: RtrBusy 2
  - Script: None

The fourth watch consists of the following parameters:

- Name: Critical_Busy
- Data Type: Boolean
- Expression
  - Expression: (busyPer >= 70)
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 60
- Threshold
  - Threshold violated if value: == True_Ref.
  - Threshold reset if value: ! = True_Ref.
- Alarm:

  - Alarm Severity: Critical
  - Alarm Description: RtrBusy3
  - Script: None

Third On-Demand Watch Scenario

On-Demand watches are evaluated whenever information is requested from them.

For this scenario, a network administrator wants to see an alarm anytime a Frame Relay link fails, causing the dial-backup lines to activate. The dial backup is ISDN Interface Type 21 (the basic ISDN service). The following watches verify whether traffic is received on any ISDN port. If traffic is flowing, a minor alarm is placed on the Cisco router (model type: Rtr_Cisco).

Examples: On-Demand Watches

The first watch consists of the following parameters:

- Name: True_Ref
- Data Type: Boolean
- Expression
  - Expression: 1
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluate: On Demand
- Threshold: None

The second watch consists of the following parameters:

- Name: ISDN_Backup
- Data Type: Boolean
- Expression
  - Expression: ((COUNTER_DELTA (ifInOctets.#) > 0) & (ifType.# == 21))
  - Instance: All
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 1 minute
- Threshold
  - Threshold violated if value: == True_Ref
  - Threshold reset if value: != True_Ref
- Alarm:
  - Alarm Severity: Minor
  - Alarm Description: Backup_Active
- Script: None

Fourth On-Demand Watch Scenario

On-Demand watches are evaluated whenever information is requested from them.

For this scenario, the watch monitors the ifOutOctets value on ISDN interface models to see whether it increases or is non-zero. This value indicates whether the interface is active. You can modify the polling, logging, alarm severity, and alarm text to suit your requirements. The second watch uses a true or false (1/0) indicator: 1 indicates that the interface is sending ifOutOctets, and 0 indicates that the interface is not sending.

Examples: On-Demand Watches

The first watch consists of the following parameters:

- Name: isISDN
- Data Type: Boolean
- Expression
  - Expression: (X_ifType == 21)
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: On Demand
  - Inheritable: False
- Threshold
  - Threshold: None

The second watch consists of the following parameters:

- Name: ISDN_Up
- Data Type: Integer
- Expression
  - Expression: MAX(0, MIN(1, INTEGER(((COUNTER_DELTA (X_OutOctets) * INTEGER(isISDN)) > 0))))
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 0+00:05:00
  - Inheritable: False
- Threshold:
  - Threshold violated if value == 1
  - Threshold reset if value != 1
- Alarm
  - Alarm Severity: Minor
  - Alarm Description: ErrorTholdAlarm
  - Alarm is user clearable
  - Watch is not reset upon user clearing of alarm.
- Script: None

First Usability and Testing Watch Scenario

The example watches that are described here are used for usability and testing.

For this scenario, you create two watches, one to create an attribute named WatchLoad_v with an expression value of .75, and a second watch to use the CPULoadRate attribute. In the following example, you create an Alarm Description named WatchLoad_Alarm that says, for example, “The CPU load has exceeded 75%.”

Examples: Usability and Testing Watches

The first watch consists of the following parameters:

- Name: WatchLoad_v
- Data Type: Real
- Expression

  - Expression: .75
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluate: On Demand
- Threshold: None

The second watch consists of the following parameters:

- Name: CPU_Load
- Data Type: Real
- Expression
  - Expression: CPULoadRate
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 1 minute
- Threshold
  - Threshold violated if value: > WatchLoad_v
  - Threshold reset if value: < = WatchLoad_v
- Alarm
  - Alarm Severity: Minor
  - Alarm Description: WatchLoad_Alarm
  - Script: None

Second Usability and Testing Watch Scenario

The example watches that are described here are used for usability and testing.

In this example, you create an EoC watch that generates a minor alarm when Composite Condition attribute of a container model exceeds 4. You first create a reference attribute named conditionCheck_ref and use that attribute in a watch named ConditionCheck. Then use the Alarm Description dialog box to create an Alarm Description named “ConditionCheckAlarm” (or another appropriate string).

The reference attribute has the following parameters:

- Name: ConditionCheck_ref
- Data Type: Integer
- Expression
  - Expression: 4
  - Instance: None
- Properties: None
- Threshold: None

Example: Usability and Testing Watch

The watch consists of the following parameters:

- Name: ConditionCheck
- Data Type: Integer
- Expression

  - Expression: Composite_Condition
  - Instance: None
- Properties
  - Default Activation: Active
  - Evaluate: EoC
- Threshold
  - Threshold violated if value: > ConditionCheck_ref
  - Threshold reset if value: <= ConditionCheck_ref
- Alarm:
  - Alarm Severity: Minor
  - Alarm Description: ConditionCheckAlarm
- Script: None

Third Usability and Testing Watch Scenario

The example watches that are described here are used for usability and testing.

In this example, if the load value falls below 10% for longer than 90 minutes, you create an alarm. To configure this watch, change the watch expression to use your desired external attributes, and set the threshold to the number of consecutive polls equal to the desired time duration, divided by the polling interval.

Examples: Usability and Testing Watches

The first watch consists of the following parameters:

- Name: Watch_Load_Under_10_Pct
- Data Type: Integer
- Expression
  - Expression: MAX (0, MIN (1, (<Load under 10% test expression here>)))
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluation: On demand
- Threshold: None

The second watch consists of the following parameters:

- Name: Watch_TimeTicker_LoadUnder10Pct
- Data Type: Integer
- Expression
  - Expression: (Watch_TimeTicker_LoadUnder10Pct + 1) * Watch_Load_Under_10_Pct
  - Instance: None
- Properties
  - Default Activation: Inactive
  - Evaluation: On demand
- Threshold: *The desired number of consecutive polls*

Fourth Usability and Testing Watch Scenario

The example watches that are described here are used for usability and testing.

The first watch monitors the CPU for a sustained referenced usage value (80% in this example).

The second watch triggers an alarm if the CPU usage remains at a certain level (80%) for a sustained period of time. This watch calculates this time period using the threshold value (3), multiplied by the polling interval (5 minutes). Therefore, this watch violates the threshold and triggers an alarm if the CPU usage exceeds 80% for 15 minutes. You can adjust these values to suit your requirements.

Examples: Usability and Testing Watches

The first watch consists of the following parameters:

- Name: CPU_Duration_Over_80
- Data Type: Integer
- Expression
  - Expression: MAX(0, MIN(1, INTEGER((INTEGER(cpqHoCpuUtilMin.#) >= 80))))
  - Instance: All
- Properties
  - Default Activation: Active
  - Evaluate: On Demand
  - Inheritable: False
- Threshold: None

The second watch consists of the following parameters:

- Name: CPU_Time_Duration
- Data Type: Integer
- Expression
  - Expression: ((CPU_Time_Duration.# + 1) * CPU_Duration_Over_80.#)
  - Instance: All
- Properties
  - Default Activation: Active
  - Evaluate: By Polling
  - Poll Interval: 0 + 00:05:00
  - Inheritable:False
- Threshold
  - Threshold violated if value >= 3
  - Threshold reset if value < 3
- Alarm
  - Alarm Severity: Minor
  - Alarm Description: ErrorTholdAlarm
  - Alarm is user clearable
  - Watch is not reset upon user clearing of alarm.
  - Script: None

WLC Manager

Overview

The WLC Manager lets you discover, model, and monitor Wireless LAN controller (WLC) module components, regardless of the device it is present in, allows you to centrally manage and configure a number of access points (APs) in a simplified manner within the network environment. WLC Manager provides AP (Wireless Access Point) Names and Device discovery and modeling, AP connectivity status, SNMP trap handling, monitoring of WLC conditions, and performs calculation of and alarming on AP conditions.

WLC Manager discovers all the Access Points (AP) associated with a particular WLC Controller. If the intermediate L2 and L3 devices are discovered connections are automatically made. DX NetOps Spectrum creates AP models representing each unique Access Point. These AP models can then be polled for their current operational status (Up or Down).

In addition, WLC Manager supports CAPWAP and CISCO LWAPP (Lightweight Access Point Protocol), a protocol that can control multiple WiFi Wireless Access Points at once. This helps reduce the amount of time that is spent on configuring, monitoring, or troubleshooting a large network. The system also allows network administrators to closely analyze the network. This system is installed in a central server that gathers data from RF devices from different brands and settings. The server can command a selected group of devices to apply given settings simultaneously.

This enables you to monitor the status of the paths between the sites in each of the modeled APs. You can configure threshold alarms to alert you when path changes exceed the configured tolerance.

NOTE

- Do not delete a WLC device, while it is still being modeled. We recommend that you wait until the WLC model is activated and the modeling is completed, before you delete the WLC, so that all the AP models created (associated with the WLC you want to delete) are also deleted.
- If you delete a WLC device before all its associated Access Points (AP) model creation is complete, all the sub-modules or models may not be deleted and can be found in the Lost/Found Container.

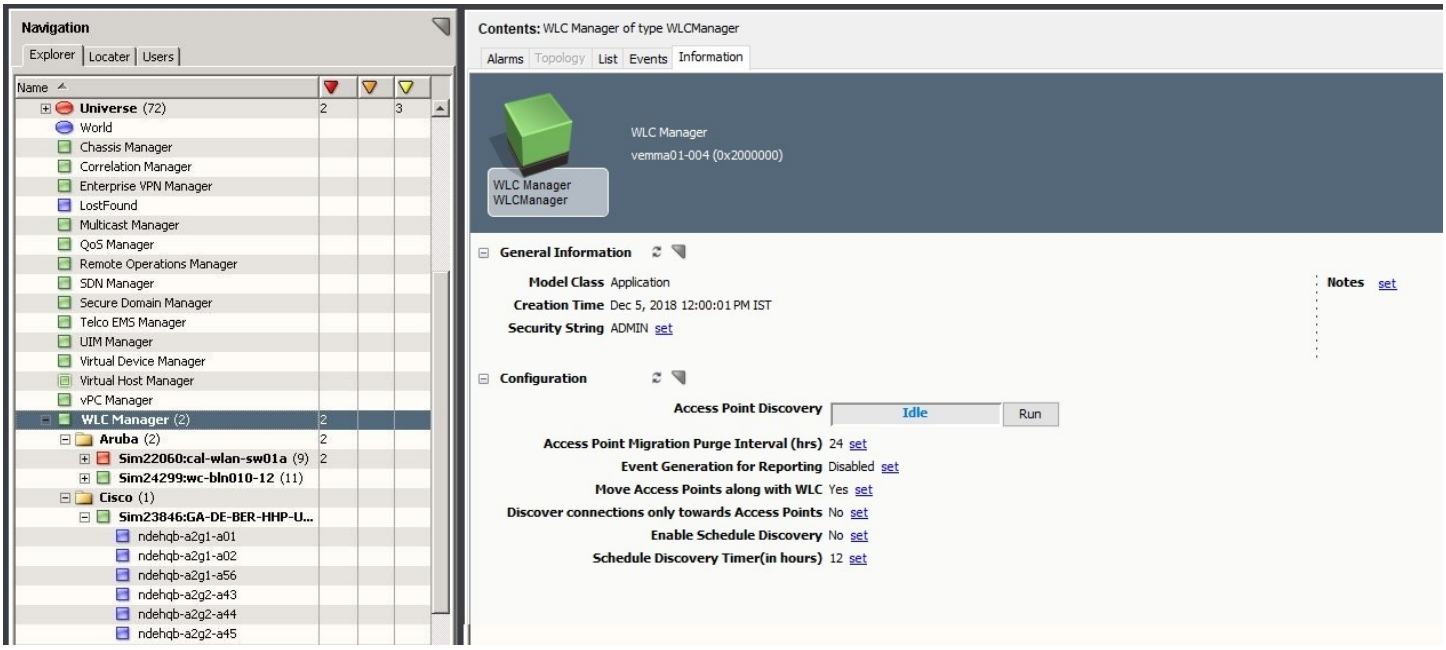
NOTE

- DHCP IP changes are now supported for APs; duplicate models were being created as dynamic IPs were created when WLC/ AP down/ reboot happened.
- Now models are created on unique MAC ID thus negating the possibility of duplicate models.
- AP name changes are now supported and the updated AP name will reflect after the next polling cycle of the WLC.

WARNING

From 10.2, you can no longer manually discover and model APs by model type (AP-Pingable in earlier releases). Navigate to the **WLC Controller > Information Tab > Configuration sub-view and Run AccessPoint discovery.**
If you are upgrading to 10.2, all existing AP-Pingable models will be modeled as AccessPoint models after the upgrade.

To view the WLC Manager in the OneClick Console Topology view, select WLC Manager from the Explorer Hierarchy



WLC Manager provides searches that let you quickly find a particular AP or all APs. Search results contain a list of the current Wireless Access Points that are configured within the environment and their status.
You can drill into a single AP to see the current list of Wireless interfaces participating within that AP and the status of the Access Point(s).

Moving Access Points (APs) with WLC

From 10.2.2, the WLC Manager includes the option to move access points (APs) with the WLC. When the WLC is moved to any other container, all the APs attached to it are moved to that respective WLC container. This feature automates the movement of APs across various containers. By default, this value is set to **Yes.** If you want to retain the APs attached in the WLC container, then set this value to **No**, then access points (APs) remain in the same container, although the WLC is moved to a different container.

Wireless Reports

From r10.2, DX NetOps Spectrum lets you generate reports for events that are raised on Wireless APs, by enabling the Event Generation for Reporting option, at the WLC Manager level.

NOTE

The default value for the **Event Generation for Reporting** field is **Disabled.**

To enable these Wireless reports, from the OneClick console> Explorer Hierarchy, navigate to the **WLC Manager** > **Information Tab** > **Event Generation for Reporting** field and select **Enabled** from the corresponding drop down option.

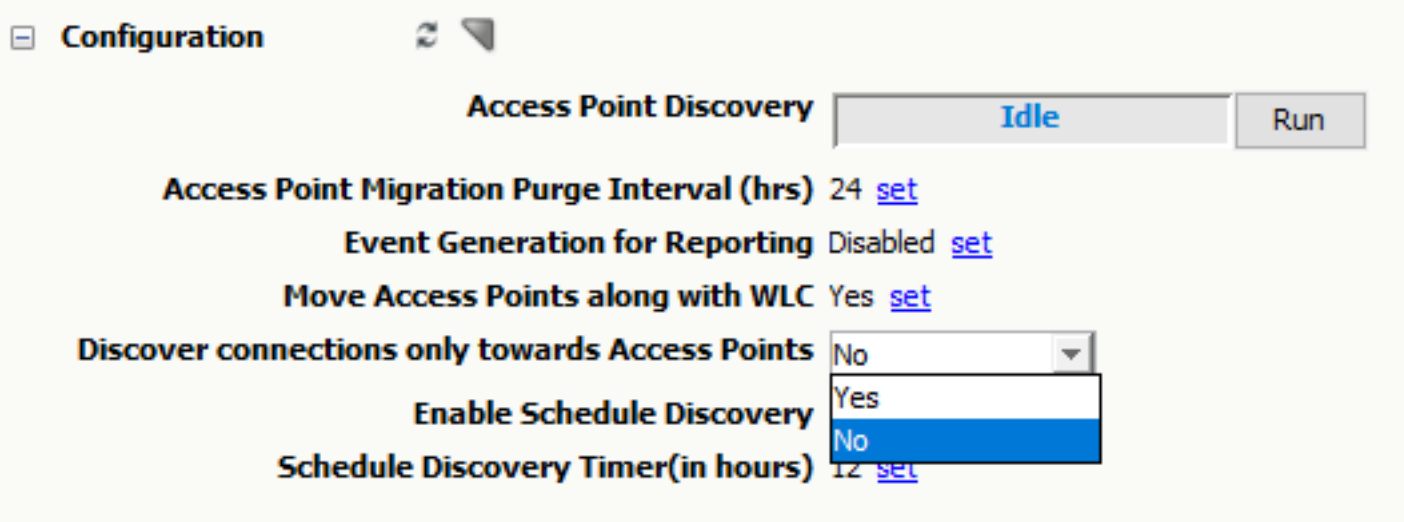
Once you set this to **Enabled,** the events that are raised on the selected WLC Controller, are registered in the SRM DB, parsed and the event information is saved in the MySQL database named 'reporting' which Report Manager uses to store data. This database contains all the tables that are required to store the data that is used by SRM application to generate reports. At startup, the Report Manager retrieves the data from the primary Archive Manager for each SpectroSERVER through OneClick and stores the data in the SRM databases.

NOTE

For more information about the Wireless Reports, refer to the **wirelessaps** table in the reporting Database.

Discover Connections Only toward Access Points

In the 10.3 and earlier releases, when the Access Point Discovery is run, the WLC Manager discover connections on all the subnet switches corresponding to the access points (APs). From 10.3.1, the WLC Manager includes an option to discover connections only toward the access points (APs) from their right upstream switches, which skips creation of other neighboring connections for the subnet switches. This feature uses MAC address (SAT Table) or IP address (CDP Table) of the Access Point to discover a connection toward its upstream switch.



By default, this value is set to No (in releases prior to 10.4.2). If you want to see the connections only toward access points, then set this value to **Yes**.

> **NOTE**
> In 10.4.2, this option is enabled by default; that is, the parameter value is already set to Yes. In previous releases, the option was not enabled by default.

Raise Access Point-Related Alarms Only on Associated Access Points

In 10.4.1, if any applicable alarm is raised on an access point (AP), then the alarm is asserted to that AP. Similarly, if any alarm is raised on a WLC controller, then the alarm is asserted to the WLC controller. This functionality helps in the proper organization of the alarms based on the associated AP or WLC controller, allowing you to manage your devices more efficiently. Previously, all alarms were getting asserted to the WLC controller irrespective of the fact where the alarm had been raised: AP or WLC controller.

> **NOTE**
> If the required AP is not accessible for asserting the alarm, then the related AP alarm is asserted to the associated WLC controller.

Access Point (AP) Attributes

The details in the **Access Point > Information Tab** is populated with relevant values, only when SNMP APs make the association with its WLC. (The values are actually exposed from the WLC MIBs)

> **NOTE**
>
> By default, the information displayed in **Access Point > Information Tab** is not exposed by SNMP APs. This is because, Standalone/Autonomous **Access Points** (i.e APs not associated to any WLC), do not have this information in its MIBs, and this information is available only from associated WLCs.

To view the details / values in the *Access Point > Information Tab*:

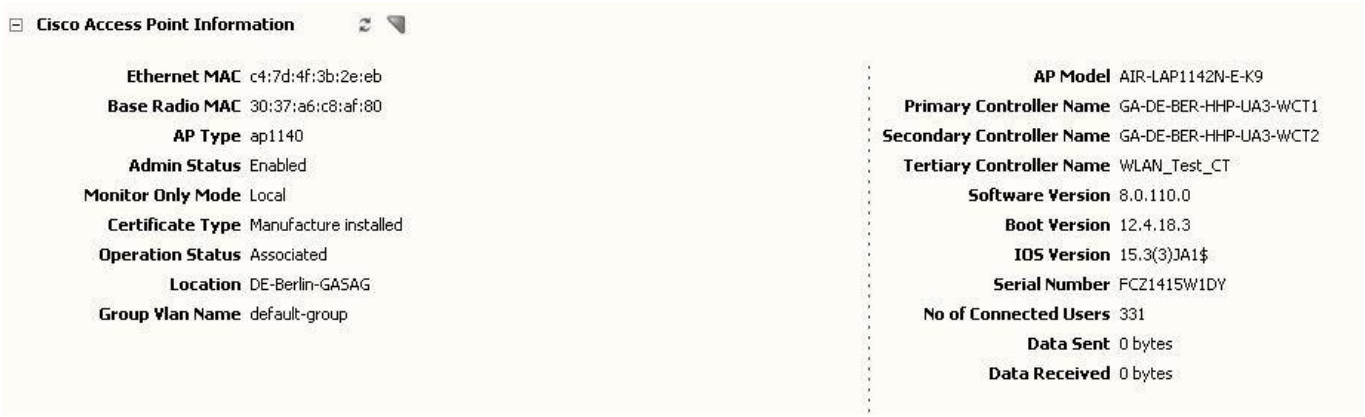
- Model the parent **Wireless Controller** device, by enabling Access Point Discovery, using the **Create Wireless Access Points** option.

NOTE

For the **Access Point Information** sub view to populate, a minimum of one polling cycle is required.

Cisco Access Point Information

The following attributes are displayed when you navigate to **Access Point > Information Tab** > **Access Point Information** sub view for an identified and modeled AP, under the **WLC Manager** nodes.



Access Point Information sub view displays the following information:

- Ethernet MAC
- Base Radio MAC
- AP Type
- Admin Status
- Monitor Only Mode
- Certificate Type
- Operation Status
- AP Model
- Location
- Group Vlan Name
- Primary Controller Name
- Secondary Controller Name
- Tertiary Controller Name
- Software Version
- Boot Version
- IOS Version
- Serial Number
- No of connected Users
- Data Sent
- Data Received

Aruba Access Point Information

The following attributes are displayed when you navigate to **Access Point > Information Tab** > **Aruba Access Point Information** sub view for an identified and modeled AP, under the **WLC Manager** > **Aruba** nodes.

The Aruba Access Point Information sub view displays the following information:

- MAC Address
- IP Address
- Name
- Group Name
- Up Time
- AP Type
- IP Sec Mode
- Location
- AP Model
- Operation Status
- Active Controller IP Address
- Standby Controller IP Address
- Access Point Connected as
- Software Version
- Serial Number
- No of Connected Clients
- Data Sent
- Data Received

Access Point Migration

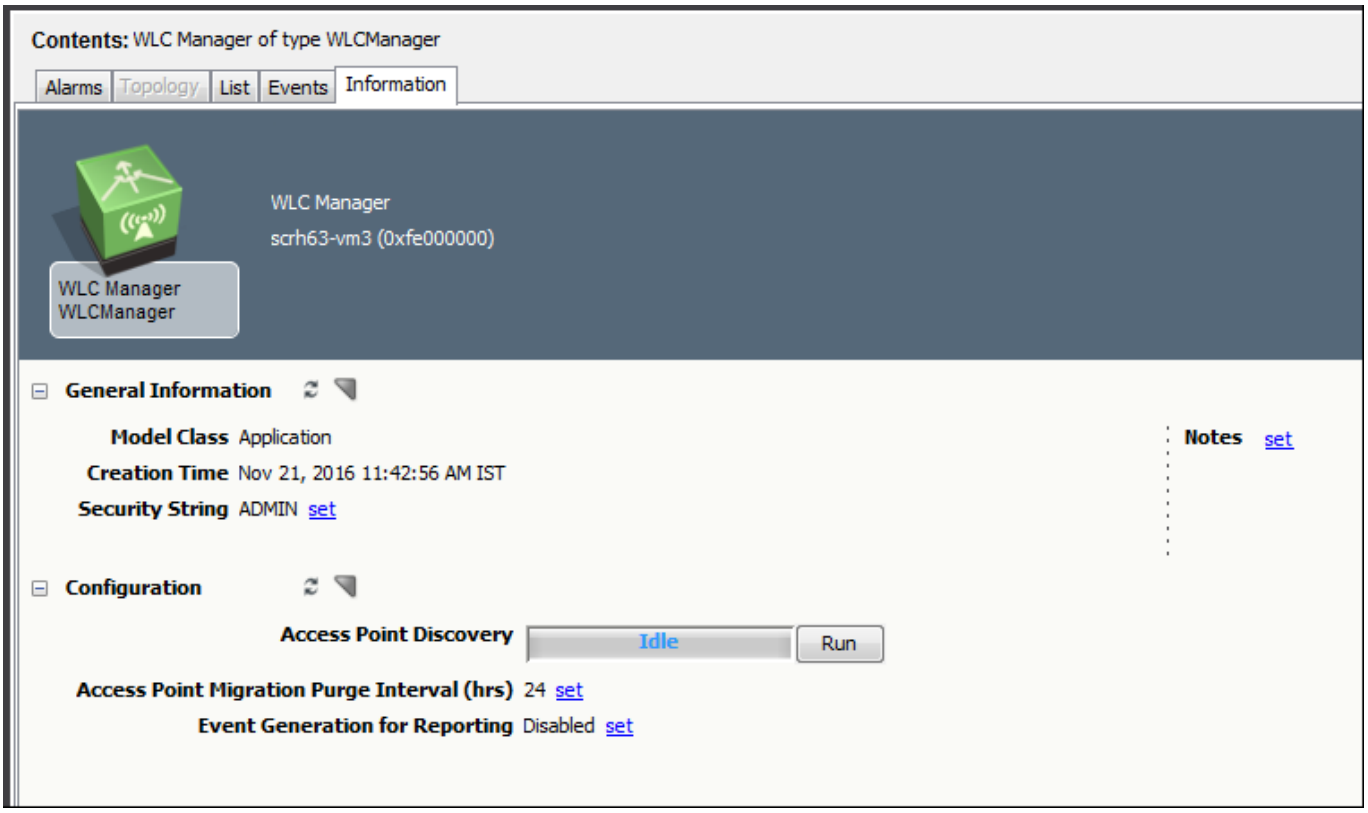
DX NetOps Spectrum identifies the mobility/migration of Access Points across WLCs. In DX NetOps Spectrum when you remove an AP physically from one WLC and connect to another WLC, the Access Point model will be moved from the previous WLC's (source WLC) hierarchy, to the WLC you have subsequently connected to (Destination WLC). This happens during the next polling cycle, of the destination WLC.
On successful migration, an AP migration event (**Attribute ID: 0x6760001**) will be raised on the Destination WLC.

NOTE

AP model is not deleted and recreated during migration (unless you explicitly do so), but same existing AP model is updated with its parent WLC relation.

The **Access Point Migration Purge Interval (hrs)** value is set to 24 (hrs), by default.

You can configure the same from **WLC Manager** > **Information Tab** > Configuration:



NOTE

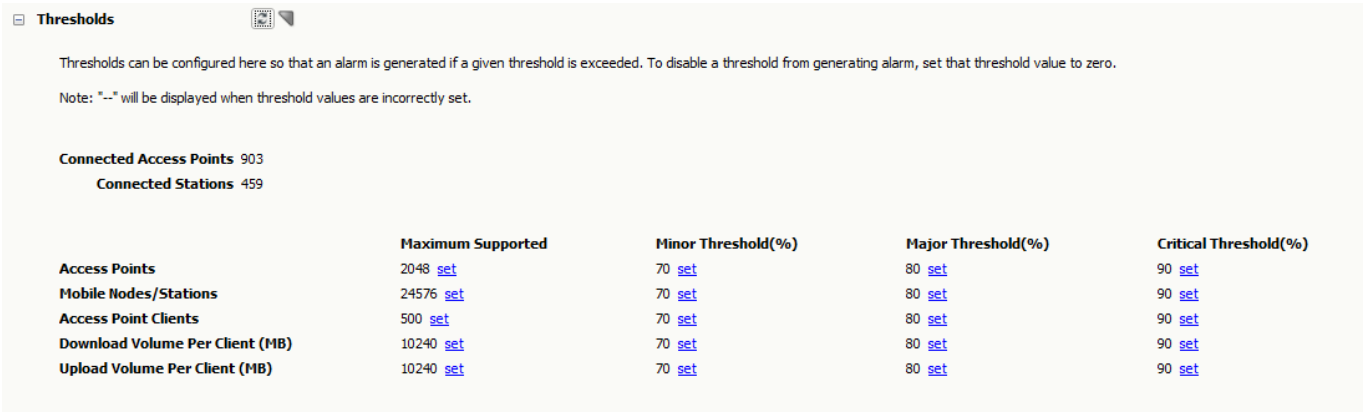
If Access Point is physically removed from one WLC and is not to attached/migrated to any other WLC within Purge interval, then AP Migration event will not be raised.

Configuring WLC related Thresholds

You can configure minor, major and critical thresholds from the **OneClick Explorer View** > **Wireless Device/ Controller level** > **Information Tab**> **Cisco Light Weight Access Point Protocol/ Aruba Controller Information** > **Thresholds** to generate alarms related to WLC/ AP/ Clients.
Please refer to the list below to view where the corresponding alarms are asserted.

NOTE

Threshold violation alarms will not work if the devices are modeled using snmp v1. It is recommended to model them using snmp v2 or v3.



Thresholds

Thresholds can be configured here so that an alarm is generated if a given threshold is exceeded. To disable a threshold from generating alarm, set that threshold value to zero.

Note: "--" will be displayed when threshold values are incorrectly set.

Connected Access Points 903
Connected Stations 459

	Maximum Supported	Minor Threshold(%)	Major Threshold(%)	Critical Threshold(%)
Access Points	2048 set	70 set	80 set	90 set
Mobile Nodes/Stations	24576 set	70 set	80 set	90 set
Access Point Clients	500 set	70 set	80 set	90 set
Download Volume Per Client (MB)	10240 set	70 set	80 set	90 set
Upload Volume Per Client (MB)	10240 set	70 set	80 set	90 set

Access Points

- Number of Access Points supported by current WLC device
- Max supported is defined in device configuration (WLC MIBs)

Alarm(s) are asserted on WLC

Mobile Nodes/Clients

- Number of Clients supported by current WLC device
- Max supported is defined in device configuration (WLC MIBs)

Alarm(s)are asserted on WLC

Access Point Users

- Number of Users supported by each AP (applicable for all APs under current WLC device)
- Max supported is configurable by the user (Default Value: 500)

Alarm(s) are asserted on AP

Download Volume Per Client

- Download data used per Client (applicable for all clients under current WLC device)
- Max supported is configurable by the user (Default value: 10240 MB)

Alarm(s) are asserted on AP, under which Client is latched

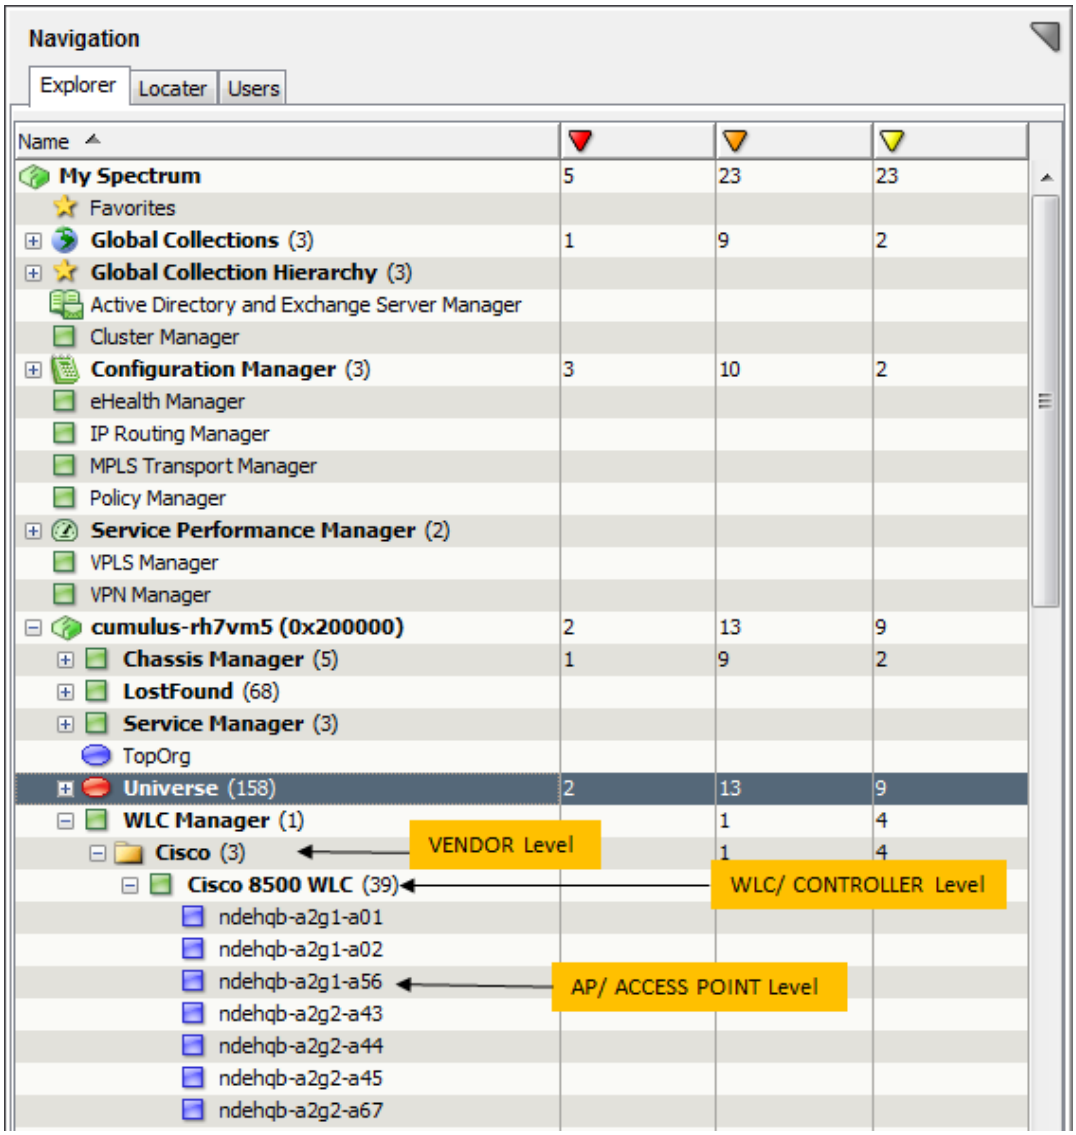
Upload Volume Per Client

- Upload data used per Client (applicable for all clients under current WLC device)
- Max supported is configurable by the user (Default value: 10240 MB)

Alarm(s) are asserted on AP, under which Client is latched

Explorer Hierarchy for WLC Manager

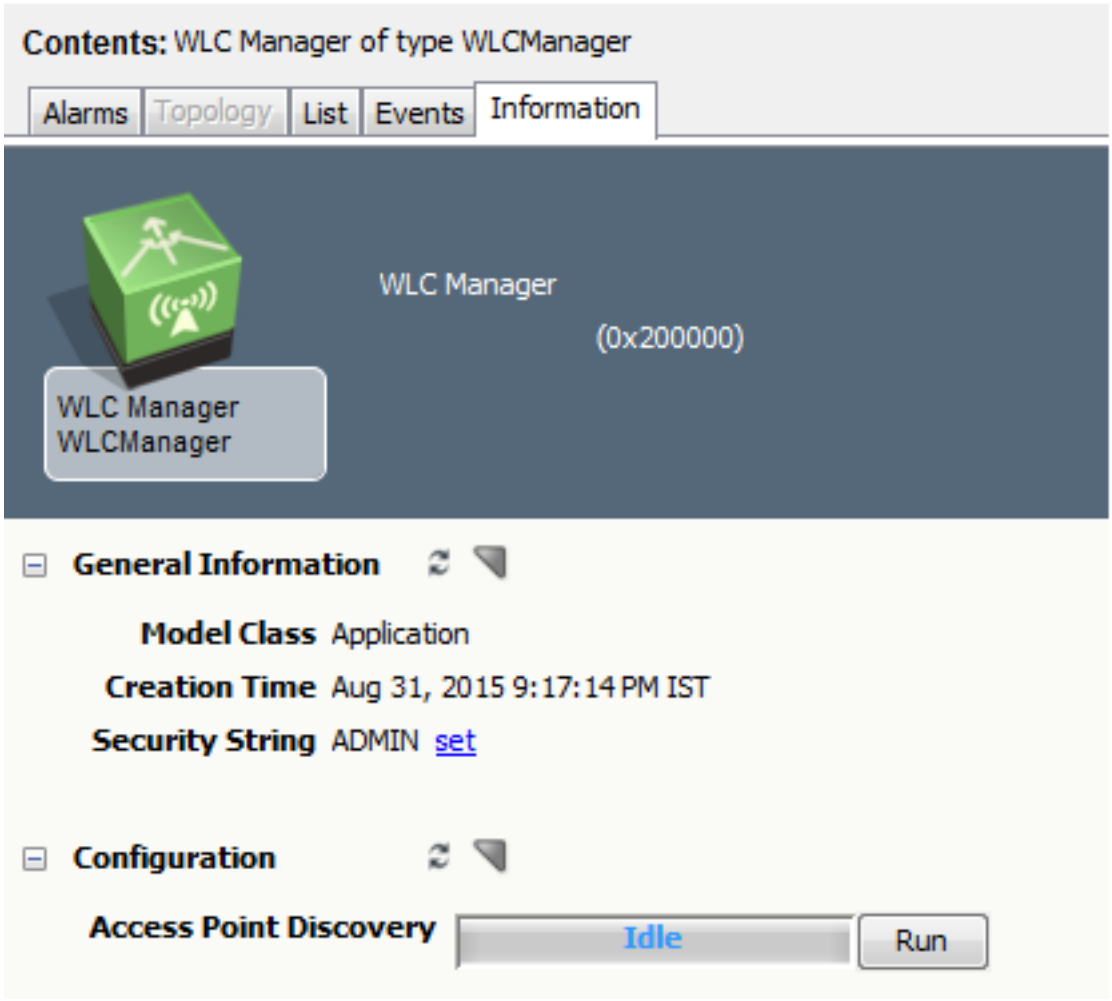
When the WLC devices are discovered, models will be created under **WLC Manager** under it's corresponding Vendor's folder, as indicated in the figure below. All access points will be created under their corresponding WLC Device(s) in the WLC Manager Hierarchy, as displayed in the **Explorer View> Landscape> WLC Manager > Navigation Hierarchy**.



In case you have not enabled the **"Create Wireless Access Points"** option in the **Discovery Console** > **Modeling Options** during initial discovery or used the **Create model by IP** option, Access Points **(APs)** will not be discovered.

To model APs from the WLC Manager (shown below) without performing the procedures mentioned above, do the following:

1. Navigate to **Explorer View > WLC Manager > Information Tab > Configuration** sub-view **> Access Point Discovery:** and then click **Run.**All access points **(APs)** will be created under their corresponding **WLC Device** (s).



WARNING

If you performs one of the following actions, affected WLC devices need to be remodeled (manually) in Spectrum:

- Delete/Remove operation at vendor level under **WLC Manager**
- Remove operation at WLC / Controller level under **WLC Manager** > **Vendor Level**

NOTE

Cisco Wireless controller devices that were modeled prior to 10.1 will automatically associated under '**WLC Manager**' after upgrade.

If the modeled CISCO WLC device is down during the upgrade, Spectrum will not recognize device's vendor after upgrade. This device model will be kept under WLC Manager > **Other** vendor folder.

To discover & associate Access Points run "**Access Points Discovery**" from **Explorer View > WLC Manager > Information Tab > Configuration**. See image above for reference

Explorer Hierarchy for Aruba Controller

When the Aruba WLC devices are discovered, models will be created under **WLC Manager** under it's corresponding Vendor's folder, as indicated in the figure below. All the access points are created under their corresponding WLC Device(s) in the WLC Manager Hierarchy, as displayed in the **Explorer View> Landscape> WLC Manager > Navigation Hierarchy**. Since, Aruba WLC architecture follows a Master – Local design, the hierarchy is a little different from the Cisco WLC and AP hierarchy.

Access Point Switchover

Switchover driven by Access Points

In this scenario, there is no direct communication between primary or secondary WLCs. But switchover of traffic is driven by Access Points.
Access Points are manually configured (via Management Console/GUI), with Primary and Secondary WLC information. AP automatically switches to the secondary controller if the primary is not responding.

When Primary WLC goes down, AP will stop receiving a ‘keep-alive’ request from it.
By recognizing the loss of this request, AP starts sending a join request to secondary WLC IP (which is already configured), and establishes the connection. Once primary is up, AP again reverts its connection toward primary WLC IP.

This is the simplest failover configuration and the process may cause interruption of wireless service to the user.

NOTE

The WLCs are not HA aware and no heartbeat happens between WLC’s. However, an AP will always be up and running under any one of the WLCs.

AP-SSO: Access Point Stateful Switchover (Cisco WLC High Availability)

The Cisco SSO technology helps mitigate and improve user experience by reducing the downtime faced by the user by utilizing a secondary standby controller connected to the primary controller throughthe HA link over a dedicated redundancy port. In this case, when the primary controller goes down the AP can move over to the secondary controller instantly, this means the client devices will not experience any SSID downtime. The Cisco SSO technology also transfers the security keys of all the client devices connected through the AP, to the standby controller, so that the client can re-authenticate seamlessly.

NOTE

Cisco WLC High Availability.supports 1:1 (Active:Standby-Hot) stateful switchover of access points (AP SSO).

Before HA is configured, both the controllers will have their physical IPs and management IPs separately. Once HA is established, both the controllers will share common management IP (which is of primary) and primary acts like active, and secondary in Standby-Hot mode.

NOTE

There will be a heartbeat between WLCs and automatically if one WLC goes down the other will be active.

CA Spectrum 10.2 leverages the Cisco SSO technology where the two controllers are always in sync with a duplicate copy of the AP information.

As per Cisco's design, only active WLC is enabled with SNMP. In AP SSO, when the currently active controller (Primary) goes down, the standby controller (Secondary) becomes active and SNMP enabled.

When active WLC is modeled in DX NetOps Spectrum, standby WLC will be automatically modeled as Pingable (since SNMP is disabled on standby, as per Cisco design).
If secondary WLC is already down, at this time an alarm will be raised on the primary model, to indicate that the secondary WLC is down.

When the primary controller goes down the secondary controller becomes active, and its model will be upgraded from pingable to SNMP.
The SNMP community string, auto-placement and enable/disable of AP discovery, secure domain information, etc, for secondary WLC model, is referenced from the primary WLC model.

NOTE

Secondary WLC would be remodeled as an SNMP device model (that is, with a new model handle) replaces the earlier (pingable model) with an SNMP model.

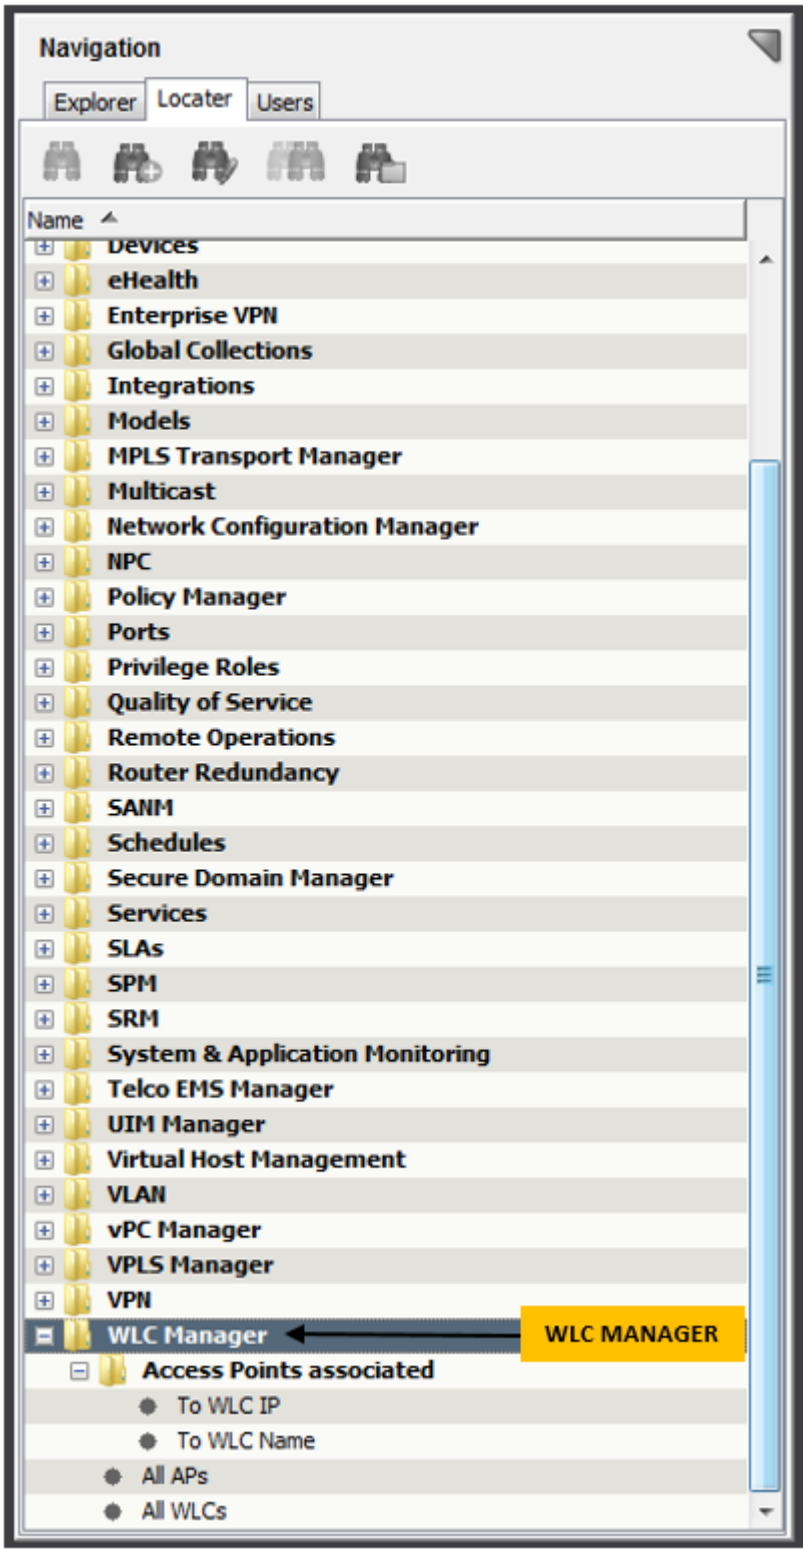
The Secondary (standby) controller will be upgraded to SNMP (active) based on two conditions:

- Primary controller contact status is down
- The secondary controller (pingable model) receives (Lost Peer, Moving to Active-No-Peer State) trap.

WARNING
Due to a limitation in the Cisco SSO technology, SNMP is enabled only on the Active WLC. Hence, Management Agent Lost alarm is generated only on the secondary WLC when the switchover happens from secondary to primary WLC.

Locater Search for Wireless Controller and Access Points

You can use pre-configured searches to locate entities in the DX NetOps Spectrum database that are related to Wireless technologies quickly. The searches are grouped under the **WLC Manager** folder in the **Locater** tab of the **Navigation** panel, as shown below:



The following searches are specific to Wireless models:

WLC Manager

Locates all devices that are modeled in the DX NetOps Spectrum database that have been identified as serving the specified role in one of the following searches:

- **Access Points associated**
  - **To WLC IP -** This search will return all Access Points associated with the specified WLC IP address.
  - **To WLC Name -** This search will return the Access Points associated with all WLCs whose model name matches the specified text.
- **All APs** - This search will return all access points modeled under the specified landscape(s).
- **All WLCs** - This search will return all the WLC devices under the specified landscape(s).

NOTE

Only those users with the appropriate privileges can access **WLC Manager** searches. For more information, see the OneClick Administration section.

Follow these steps, to view Access Points associated to WLC IP/ WLC Name:

1. Navigate to **Locater** tab, **WLC Manager**, Access Points associated to and select one of the following:
   - **TO WLC IP**
   - **TO WLC NAME**
2. Specify the WLC IP Address/ WLC Name in the relevant dialog box.
3. Do one of the following:
   - Click **Landscapes** button to filter the landscapes you wish to search against.
   - Click **List** button to import or enter values against which you wish to search.
4. Click **OK.**
   The results matching your query is displayed.

Schedule Discover Jobs for WLC Manager

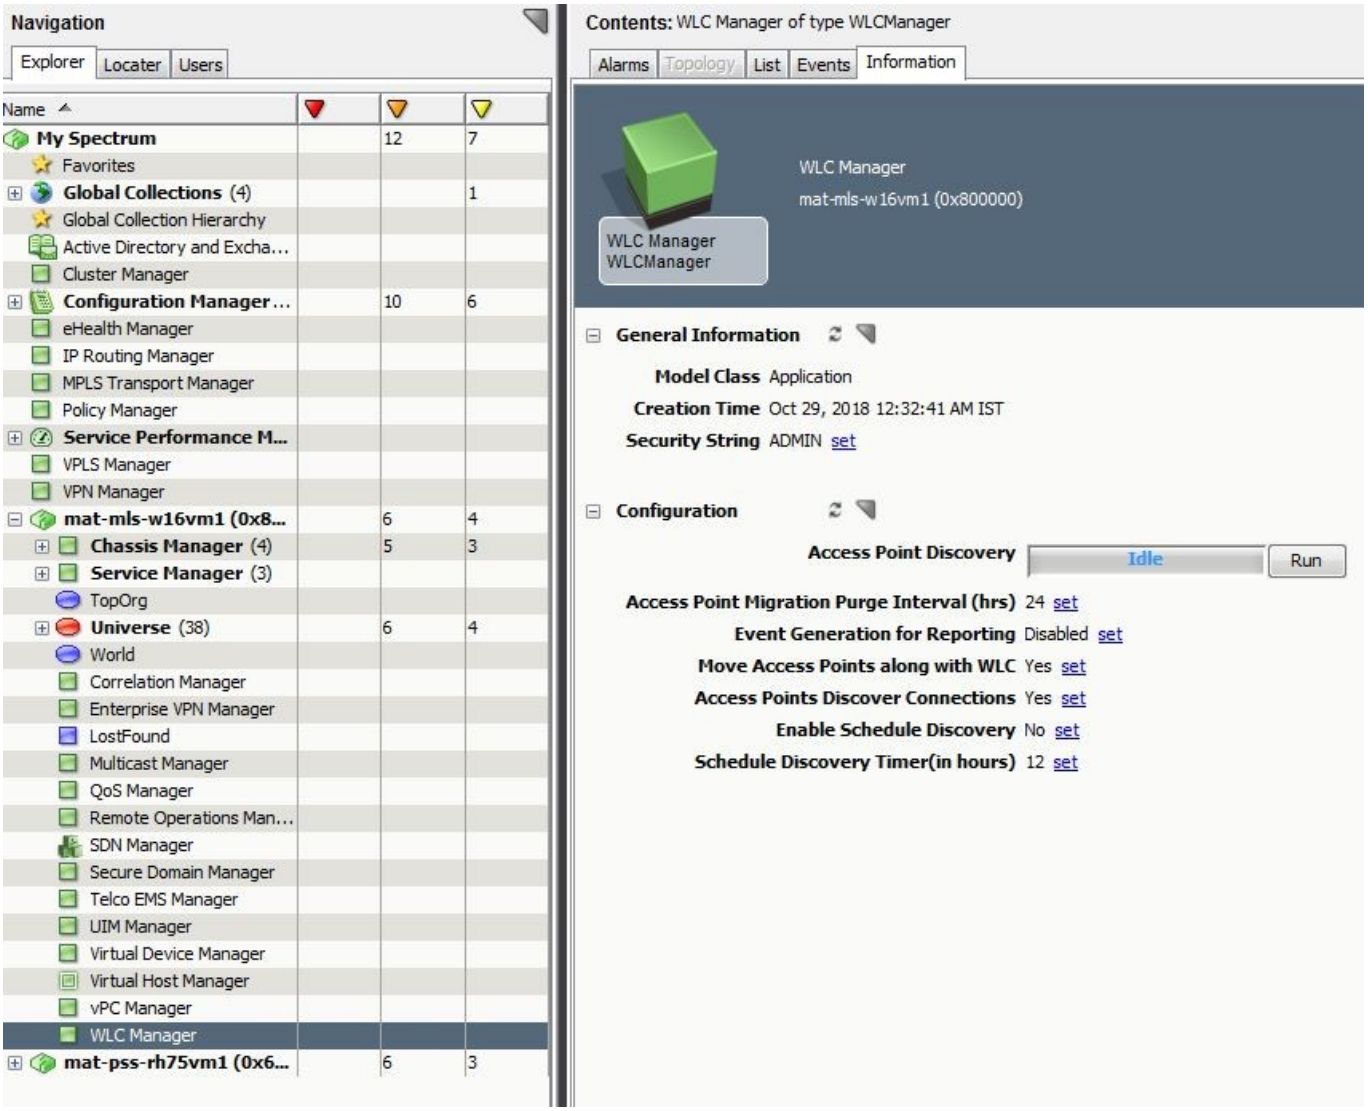
Scheduling discovery jobs for WLC AP addresses performance issues with the continuous discovery requests which are triggered from WLC APs. With an increase in the capacity that is the number of models, performance issues are prevalent, and scheduling discovery jobs can prove to be beneficial in managing large customer environments. This interim solution is introduced in Spectrum 10.3.1, to schedule time (default of 12 hours) and queue up all the discovery jobs to run them post schedule expiry time.

Users can now **set** the '**Enable Schedule Discovery**' feature to '**Yes**' to enable scheduling of discovery jobs, then **set** the '**Schedule Discovery Timer**' (in hours) to the time they want, for queuing up all the discovery jobs. Users can specify any given time (in hours) between 1 hour and 24 hours *only*. If a user does not specify a time, then by default the 'Timer' is set to 12 hours.

NOTE

If the schedule discovery option is enabled on an active server, that goes down and does not come up back until the scheduled discovery time, then the scheduled discovery does not run on the backup server.

Following is a screenshot of the WLC Manager Configuration Settings Tab:



Spotlighting Wireless Devices

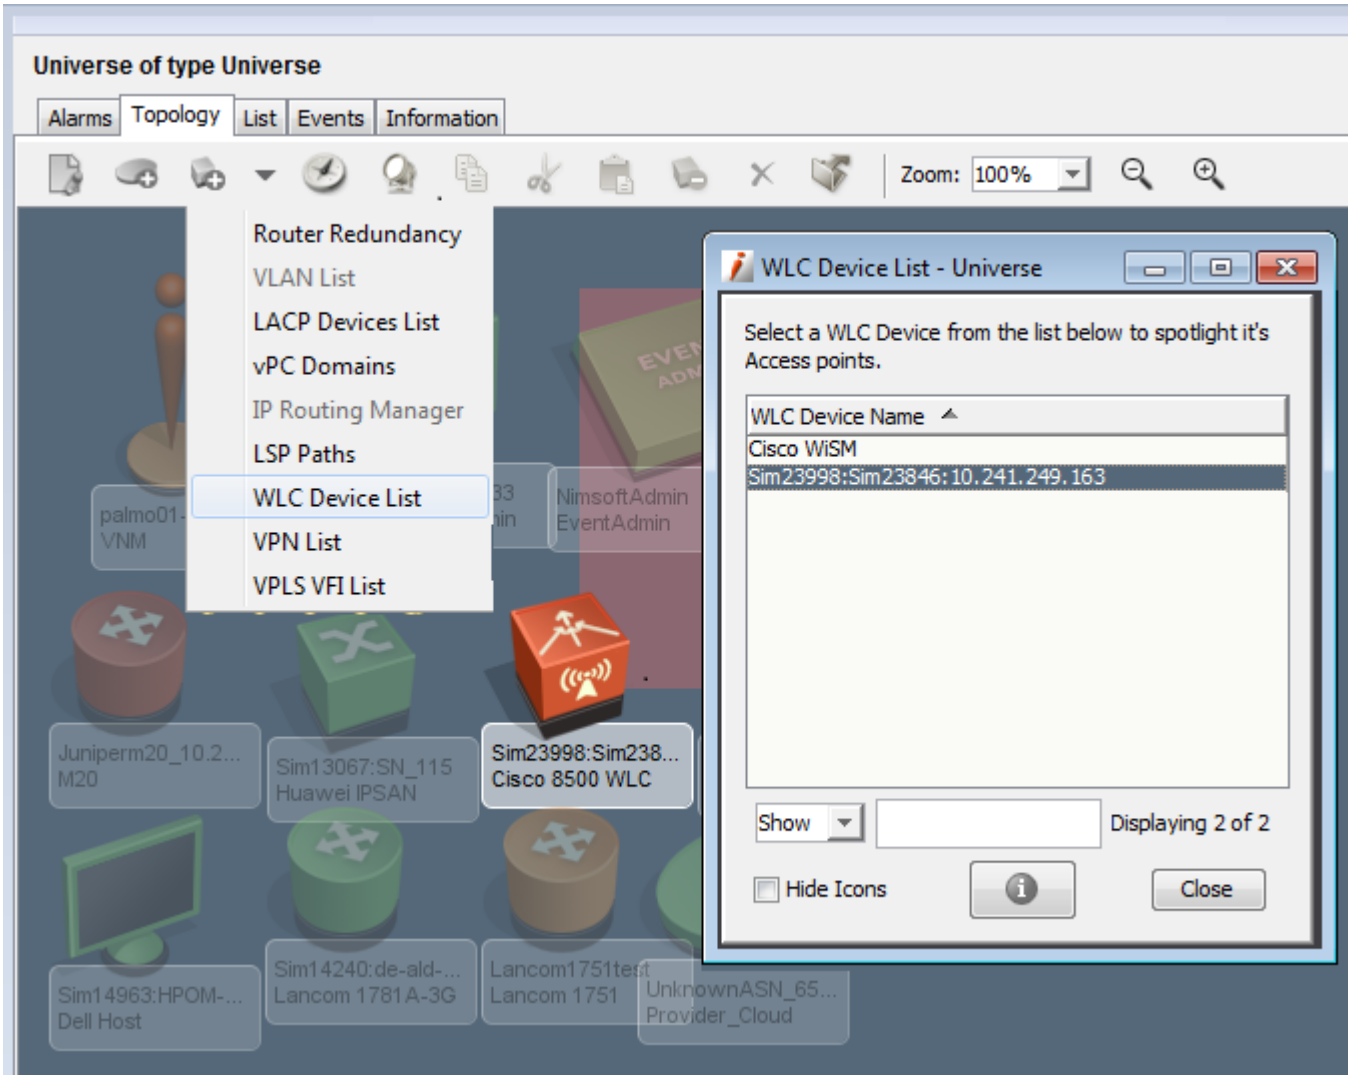
Spotlighting Wireless Devices in the Topology view helps you determine relationships between WLC Devices and Access Points on your network. Use the OneClick Spotlight feature to see all Access Points related to a WLC (Wireless Controller) in the Topology view.

NOTE
When spotlighting in the Topology views, you can select only single WLC device.

To spotlight Wireless Devices:

1. Open **OneClick.**
2. Expand the desired landscape on the **Explorer** tab and select **Universe**.
   Details about the selected **Universe** appear in the **Contents** panel.
3. Click the **Topology** tab.
   The topology of the Universe is displayed.

4. Click  **(S**
View) and select **WLC Device List** from the list of options.
The **WLC Device List** dialog opens.
5. Select a **WLC Device** from the list of options..

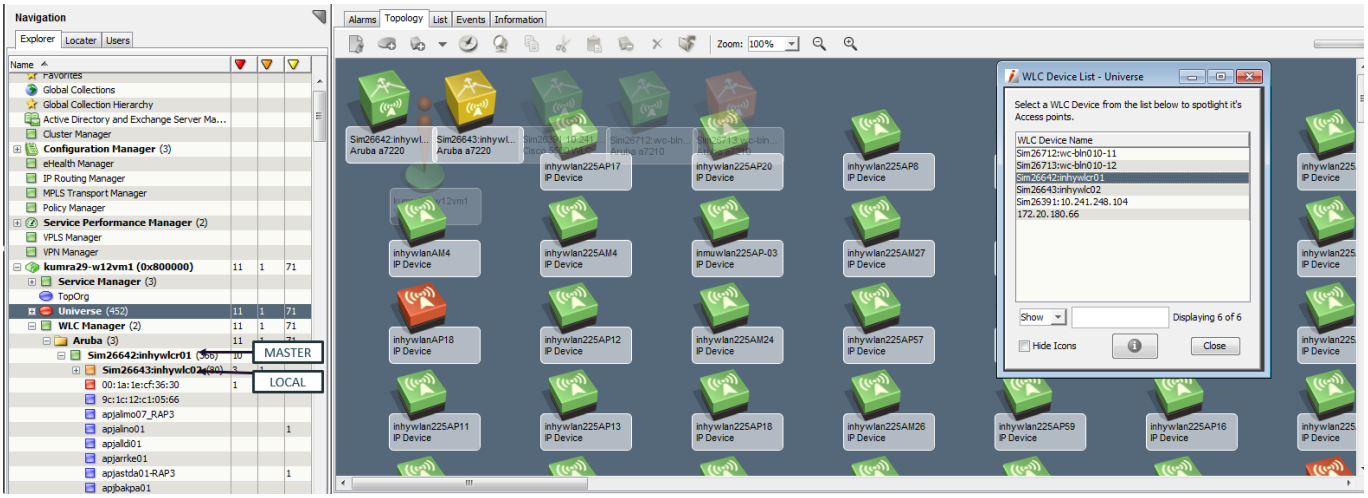


DX NetOps Spectrum spotlights the WLC device selected from the list and its corresponding APs (Access Points) by dimming all other models/devices in the topology.

Spotlighting Aruba Wireless Devices

Since an Aruba network uses a master/local architecture, if you select a Master controller from the WLC Device List, it's local controller(s) and the APs associated with the Master controller(s) are also highlighted.

As you can see in the following setup, the master controller is selected for spotlighting from the WLC Device List. The master controller and and it's associated AP along with it's local controller are also highlighted.



NOTE

You can use the **Hide Icons** option in the **WLC Device List** dialog to view only the selected WLC device and its APs.

NOTE

To view information about the selected WLC Device from the list, click the View the **Component Detail** icon on the **WLC Device List** dialog.

Support for Aruba WLC and Fault Tolerance

In a large campus WLAN that has separate network services and aggregation layers, APs and AMs should never terminate on the master controller. APs and AMs should terminate only on the local controller. Aruba Mobility Controllers are deployed in clusters that consist of a master and one or more local controllers to solve this management scalability issue. This design is the recommended model when two or more controllers exist in the same network.

Large scale deployments generally involve more than two controllers. When you have more than a single pair of controllers, change control and network consistency can become an issue. In an Aruba network that uses a master/local design, configuration is performed only on the master and it is pushed down to the locals. Local controllers reside at the aggregation layer of the Aruba overlay architecture. They handle AP termination, user authentication, and policy enforcement. When you configure any local controller, you must know the IP address of the master and the pre-shared key (PSK) that was used to encrypt communication between the controllers. The control channel between all Aruba controllers is protected by an IP Security (IPsec) connection.

NOTE

Note: The controllers have a preconfigured key at first boot. Change this key after the first boot so that the operation of the master/local cluster is secure.

For more details on the functions and responsibilities of master and local mobility controllers in Aruba architecture, see the Aruba Mobility Controllers and Deployment Models Validated Reference Design.

Fault Tolerance in Aruba WLC

Large network would have a master/backup master pair and a lot of local controllers that point to them. If the master controller has a problem, the backup master would step in, and you would still have an appliance that has read-write capability in your network without any interruption.

If you have a master/local, but no backup master, you would lose the ability to make global changes to your network. Your network would however, still be able to run.

With this configuration, if the master becomes unreachable or unavailable and no standby master has been configured, the network continues to operate as expected, except for certain operations. You cannot perform configuration, RF visualization, or location services until connection to the master controller is restored. The master controller is needed to perform configuration and reporting, but it is not a single point of failure in the network.

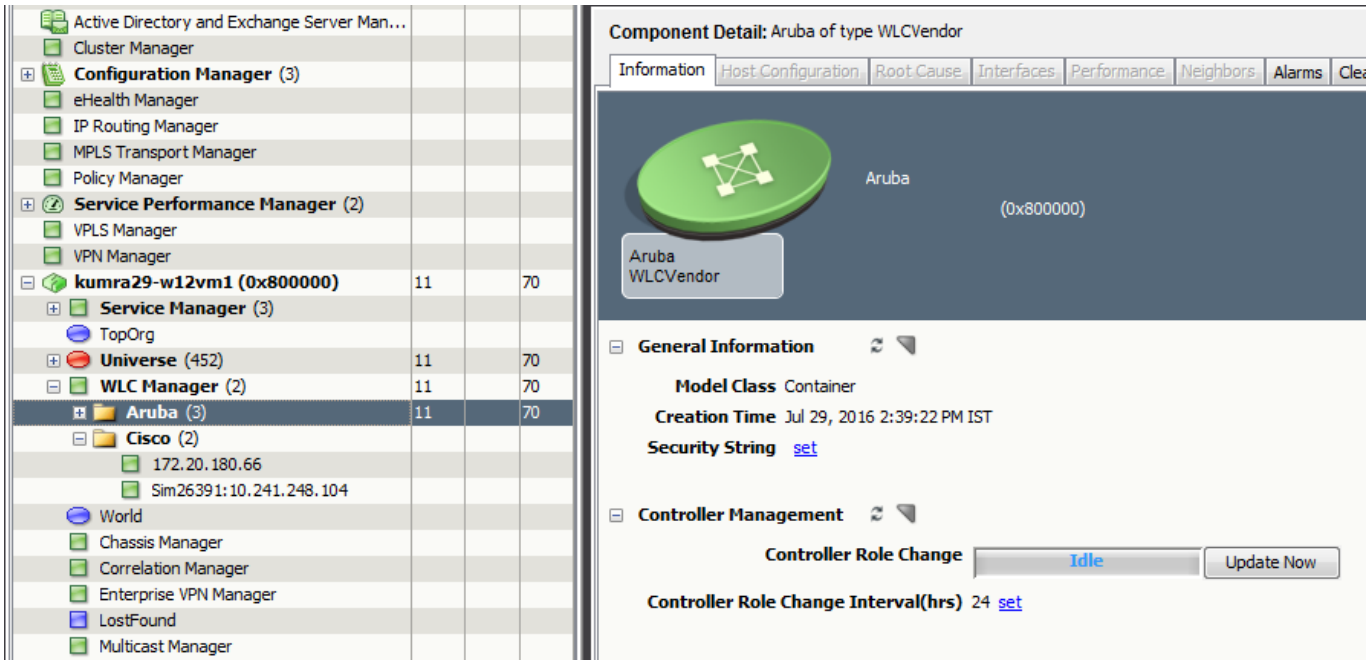
The master is where all configuration changes are made. The local connects to the master and gets the majority of its configuration from it. Selecting "Standalone" during the startup wizard just allows you to avoid configuring credentials for a local to connect to it. A "Standalone" controller is essentially a master. All controllers, whether Master or Local, can terminate access points.A backup master is a master controller that you cannot terminate access points on. It's sole responsibility is to back up the only read-write appliance you have in your network. A master does a lot of the database processing, so in larger environments, you don't want access points to terminate at all.

Controller Management

DX NetOps Spectrum allows you automatically detect the Role change (Master to Backup, Master to Local , Local to Master, etc all combinations).

This supports the ' ***wlsxNSwitchRoleChange'*** trap and poll based Association changes in WLC Manager Topology. AP's should automatically moved based on the role change(s) occurred between Master and Local controllers, after every device polling interval.You should be able to see the role changes for the configured **Role Change Interval Period**, which is 24 hours by default.However, the next scheduled polling interval is user configurable.

1. Select the **Aruba** vendor folder in the OneClick Explorer, navigate to the **Component detail: Aruba of type WLCVendor** and select the **Information** tab.
2. Expand **Controller Management**.



3. Use the **Update Now** button, for the following scenarios:
   - View changes made at Controller level to roles (master and local) and the resultant change in hierarchy
   - If Traps are disabled so switchover (role change) information and hierarchy mapping is not reflecting or happening
   - You have made changes to the hierarchy and wants the changes to reflect before the next scheduled polling interval.

4. Click **set** and configure your desired Controller Role Change Interval in hours.

Certifying and supporting virtual systems within Check Point Firewall

Overview

10.2 certifies and enables discovery and modeling of virtual systems present in the Checkpoint Point Firewall.

Each Checkpoint Firewall has a Primary context and multiple Virtual contexts, which can be treated as separate Firewalls. The primary and virtual contexts share the same IP address, but maintain their own set of interfaces and routing tables. With SNMPv2, you cannot discover and model virtual systems, only the root context information can be fetched.

WARNING

If you want to monitor virtual systems within a CheckPoint Firewall you need to have the Firewall configured with SNMPv3.

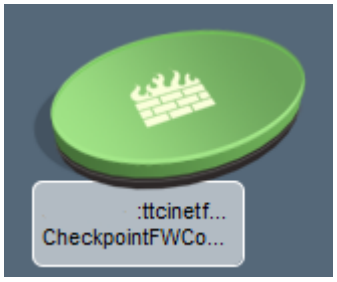
A separate container is created when DX NetOps Spectrum discovers a Check Point firewall device that has virtual systems. Using the context name to discover the virtual systems of the Checkpoint Firewall, DX NetOps Spectrum communicates with each virtual systems and fetches the corresponding interface information and other VPN, VSX, and connectivity related information.

NOTE

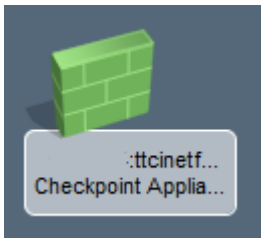
Please ensure that you enable the **802.3 Fanout** check box during discovery of upstream switches and Check Point Firewall.

Topology View

The following icons represent the virtual entities associated with Check Point virtual Firewall after they are modeled in DX NetOps Spectrum:



Represents the container for Check Point Firewall that has virtual systems.

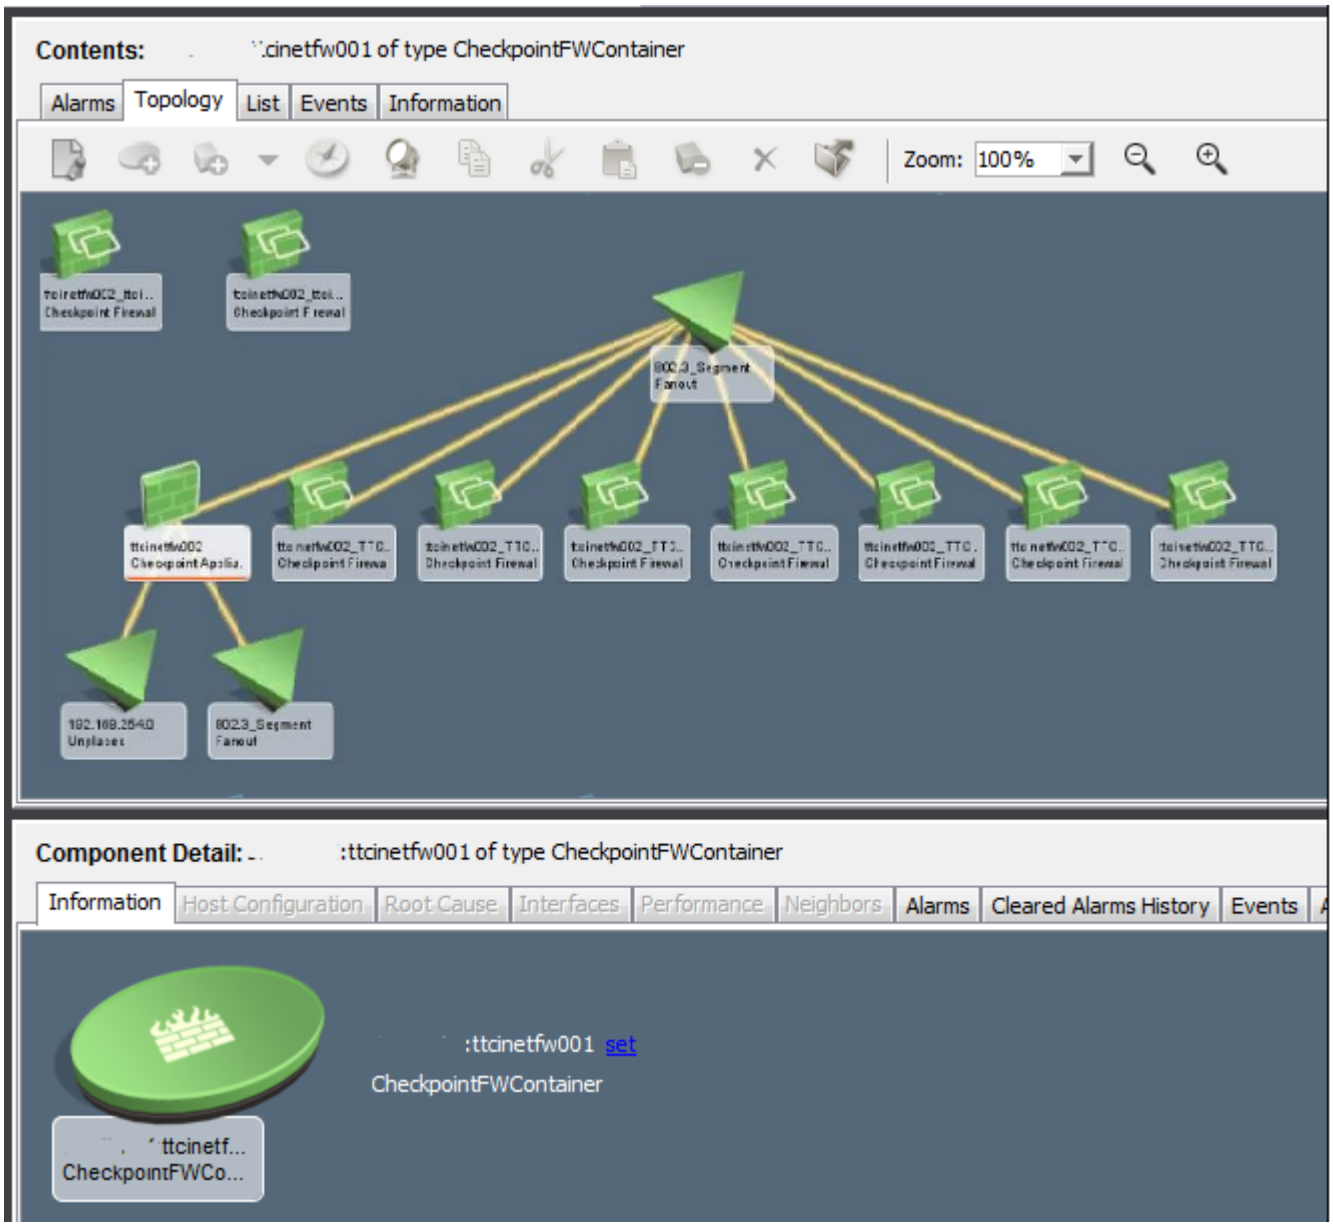


Represents the models with Root context

Represents the models with Virtual context

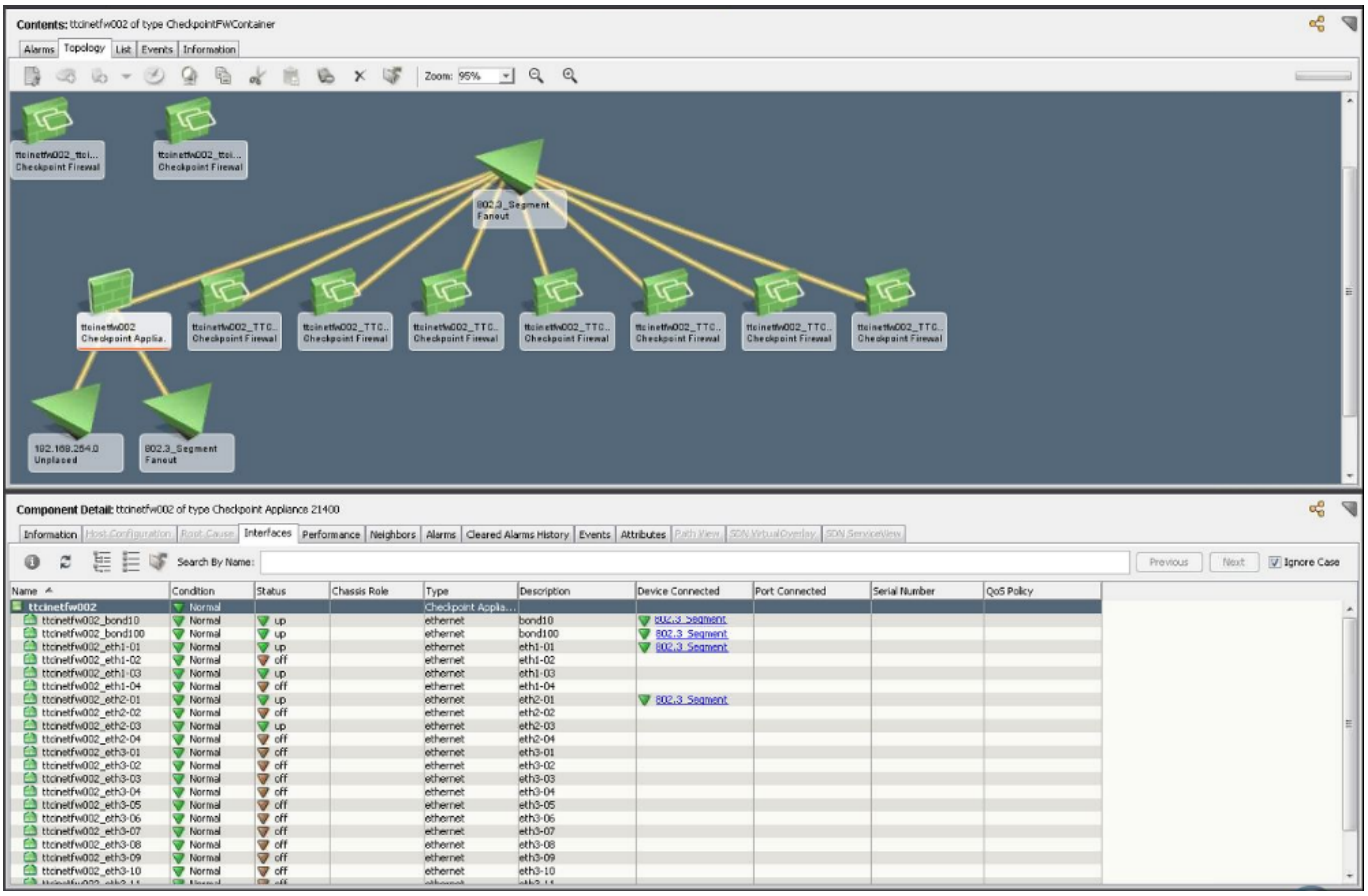
To view the models (related to Check Point Firewall) in its relevant context, follow these steps:

In the OneClick Console, **Explorer View**, navigate to the **Check Point Firewall container** > Check Point appliance/ root context, and select the **Topology** tab.
The Topology view displays all the systems in its root/ virtual context:



Interface Tab and connections between Neighbors and virtual systems

You can drill down and view the information corresponding to the interfaces and devices connected to the virtual systems within the Check Point firewall root context. This enables you to view neighboring virtual systems as individual devices and their connection details. You can view all the independent interfaces connected to a virtual system in a root context.

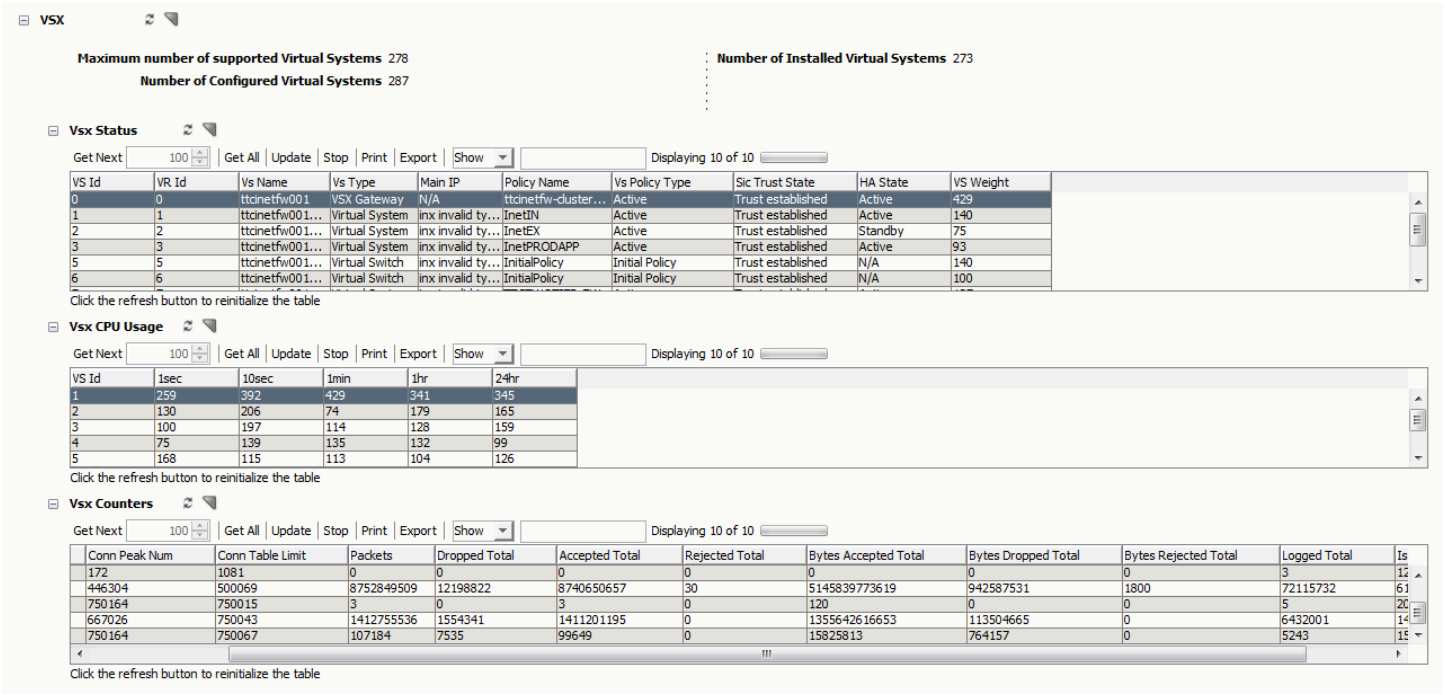


Information Tab details

The following fields of information are displayed under **Information Tab > CheckPoint Firewall** for Check Point Firewall root context models:

- **CheckPoint Firewall**
- **VPN**
- **Management**
- **VSX**

The following fields of information are displayed under the VSX node in the Information Tab:



- **ASG**

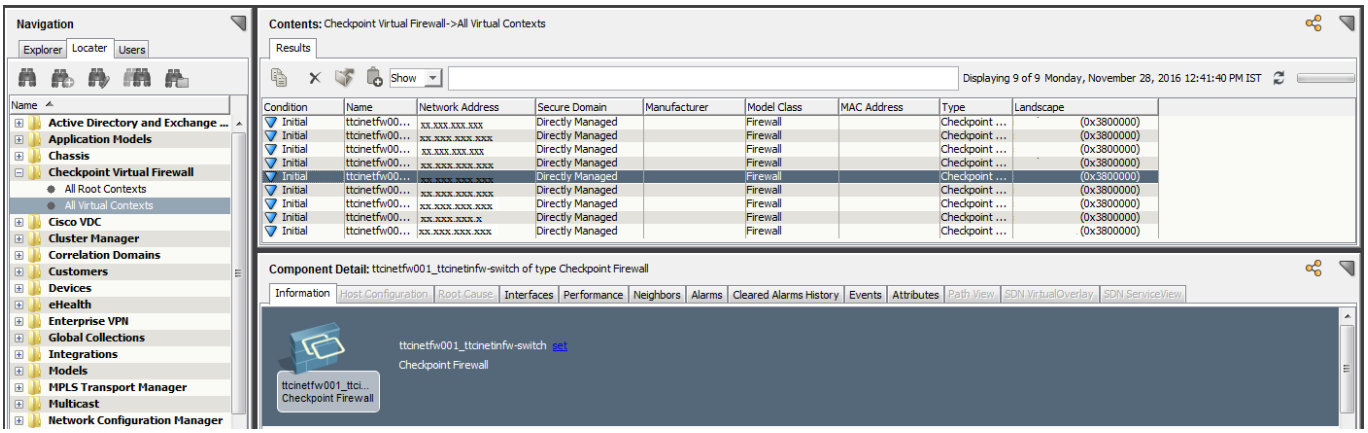
Alarm Correlation

After modeling of the virtual systems is complete, DX NetOps Spectrum monitors the virtual entities normally as it monitors independent switch / physical chassis devices. As a result, when any number of virtual systems within a Check Point firewall device go down, corresponding number of alarms are generated on DX NetOps Spectrum.

However, if the Check Point Firewall device is down and assuming that the virtual systems are functioning independently as per functionality, all virtual entities will go down and raise separate alarms. However, if all the virtual systems along with root context are down, using it's correlation domain capabilities, DX NetOps Spectrum suppresses alarms on all the virtual systems and generates a single alarm on the Checkpoint Firewall Container.

Locater Search for Check Point Virtual Firewall

You can use pre-configured searches to locate Check Point Virtual Firewall context entities related to Check Point Virtual Firewall devices, in the DX NetOps Spectrum database quickly. The searches are grouped under the **CheckPoint Virtual Firewall** folder in the **Locater** tab of the **Navigation** panel, as shown below:



The following searches are specific to Check Point Virtual Firewall models:

CheckPoint Virtual Firewall
Locates all devices that are modeled in the DX NetOps Spectrum database that have been identified as serving the specified role in one of the following searches:

- **All Root Contexts:** This search will return all models with Root context.
- **All Virtual Contexts**: This search will return all models with virtual context.

Follow these steps, to view appliances/ virtual devices associated to Check Point Virtual Firewall:

1. Navigate to **Locater** tab, **CheckPoint Virtual Firewall**, and select one of the following:
   – All Root Contexts:
   – All Virtual Contexts:
2. Select the landscapes you wish to search against, in the Select Landscapes to Search dialog box.
3. Click OK.
   The results matching your query is displayed in the Contents pane.

Troubleshooting for Checkpoint Virtual Context

Problem: Checkpoint virtual contexts stay blue initially.

Solution: Enable the virtual context to poll.

1. Create an SNMPv3 user.
2. Enable the VS mode.
3. Start the SNMP agent.

Use the following sample commands:

```
> add snmp usm user admin security-level authNoPriv auth-pass-phrase abcd1234
> set snmp mode vs
> set snmp agent on
```

The contexts are modeled and are green now.

Enhanced VRF support for Cisco Nexus devices

Starting from 10.2.1, VRF support for Cisco Nexus devices is enhanced. DX NetOps Spectrum now displays the list of VRF available on the devices along with the IP Routing and IP Address table for each VRF. You can now select the specific VRF you want from the VRFs available on the router/device and view the IP Routing/ IP Address table corresponding to the selected VRF.

Virtual Routing and Forwarding technology that allows multiple instances of a routing table to coexist on the same router at the same time. There can be multiple VRFs on the same router. Prior to this release the Interface tab would not populate the IP Addresses of non-default VRFs. Even if the device had multiple VRFs, only the instances belonging to the default VRF would display the IP Addresses. From this release we are polling the IP Address Table, per VRF, mapping the IP Address table and populating data in the **Interfaces** tab > **IP Address** column.

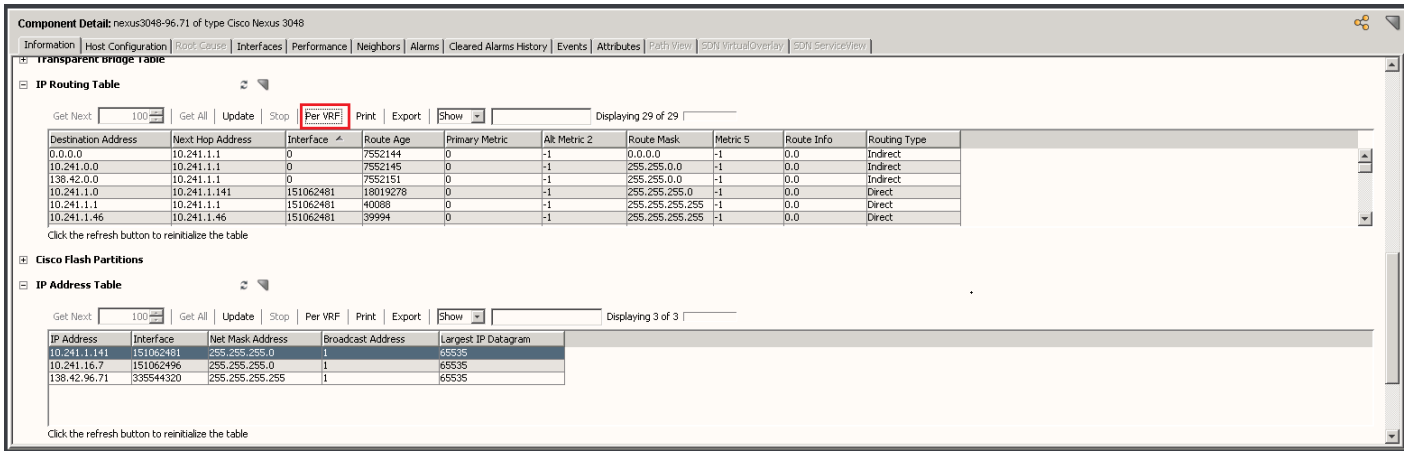
DX NetOps Spectrum now displays the list of VRFs available on the router/devices and the routing table for each VRF. You can select the VRF by clicking the Per VRF button and view the corresponding/associated routing table.

WARNING

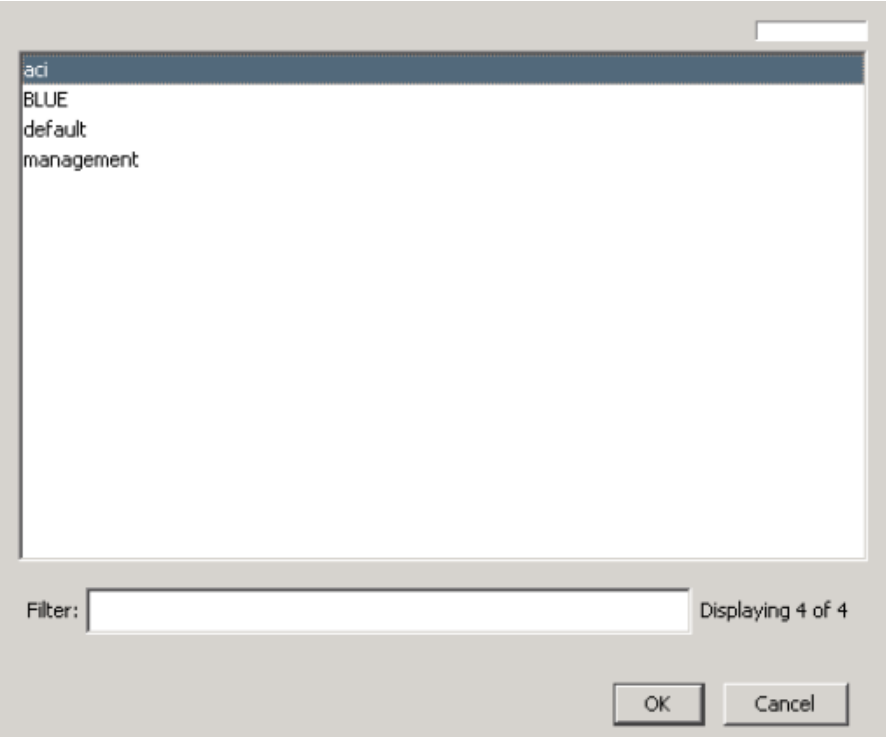
Prerequisite! You have to create/configure the VRF context in the device on the SNMP side, i.e. context mapping needs to be performed as a prerequisite to be able to get the VRF-IP Routing Table.

To view the IP Routing table for a specific VRF, follow these steps:

1. In the OneClick > **Explorer** View, navigate to **Virtual Device Manager** > Cisco Nexus device (which has VDC/VRF) > **Information** tab.
2. Select one of the following:
   - **IP Routing Table**
   - **IP Address Table**



3. Click **Per VRF**.
   The **Select VRF** dialog box displays the list of VRFs available on the router/ Cisco Nexus device.



4. Select the **VRF** you wish to view the IP Routing/ IP Address table data, and click **OK**.
   The IP Routing/ IP Address table now displays the data specific to the VRF you have selected.

   WARNING

   If there are multiple routes for the same destination in Cisco Nexus device, the IP Routing Table in the Information Tab, does not list all the routes, as the MIB used (IPRoutingTable) populates only one next hop address. This is applicable for default or any other VRF.

Alcatel Device Management

Alcatel PSS Series

The Photonic Service Switch (PSS) is a technology used for optical networking which converts a single wavelength of light into a virtual network. It is comprised of optmized platforms with various deployment environments for networking, interconnecting data centers positioned at network junction points to multi-layer, efficiently scaling large metro and multiservice optical networks. As part of service assurance and managing underlying IT infrastructure DX NetOps Spectrum leverages common software, hardware, management and control to offer seamless operations across the network through the Photonic Service Switch (PSS) technology.

The various technologies involving in tracking, encoding and supporting, administrating and maintenance of an integrated optmized wavelength include:

- OTN switching
- Wavelength routing
- Embedded multi-layer capability
- Integrated packet transport
- Transport software-defined networking (T-SDN)

Alcatel Photonic Services Switch (PSS) Deployment Topology

Dense wavelength division multiplexing (DWDM) is a technology that offers data from various sources together on an optical fiber, with each signal carried at the same time on its own separate light wavelength. Using DWDM, up to 80 (and theoretically more) separate wavelengths or channels of data can be multiplexed into a light stream transmitted on a single optical fiber. Dense Wavelength Division Multiplexing (DWDM) is the only technology that allows full network flexibility and adaptability at speeds of 100G and beyond, quick service turnup to meet changing bandwidth needs, and a ultra-low latency connectivity. DWDM offers reliable transport-grade of protocol-independent data.

This is an illustration of the PSS Deployment Topology

Managing Systems

This section contains information about how to use ADES Manager, Cluster Manager, and Virtual Host Manager.

Active Directory and Exchange Server Manager

The DX NetOps Spectrum Active Directory and Exchange Server Manager (ADES Manager) feature models and monitors your Microsoft Active Directory and Microsoft Exchange Server environments. ADES Manager provides an enterprise-wide view of your Active Directory and Exchange Server environments, showing topology as well as the logical relationships between servers. ADES Manager also provides visibility into key Active Directory and Exchange Server metrics. Finally, ADES Manager helps you pinpoint and effectively troubleshoot problems by applying unique fault isolation techniques to your Active Directory and Exchange Server environments.

ADES Manager is intended for DX NetOps Spectrum administrators who want to monitor Active Directory and Exchange Server hosts.

ADES Manager Features

DX NetOps Spectrum ADES Manager features include:

- Automated device discovery and modeling. ADES Manager automatically creates models and connections for all managed Active Directory and Exchange Server hosts.
- A distributed solution that can handle scaling. Domain management can be distributed across multiple SpectroSERVERs.
- Identification of Active Directory and Exchange Server hosts in the topology.
- Hierarchical representation of Active Directory and Exchange Server environments.
- Dedicated ADES Manager views that provide visibility into data specific to Active Directory and Exchange Server environments.
- Enhanced fault management. ADES Manager recognizes and suppresses symptomatic alarms and aids fault isolation with proxy management.
- Locater searches specific to Active Directory and Exchange Server.

System Requirements

ADES Manager works within DX NetOps Spectrum when all required components are configured properly. ADES Manager requires the following components:

- A dedicated host machine with:
  - CA SystemEDGE 5.x or later
  - Active Directory and Exchange Server AIM (ADES AIM) r12.7 with latest PTFs, or later

WARNING
The ADES AIM must be the only AIM installed on the CA SystemEDGE host. The CA SystemEDGE host itself cannot be a host in your Active Directory and Exchange Server environment.

NOTE
For CA SystemEDGE host and ADES AIM requirements, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Supported Technologies

DX NetOps Spectrum Active Directory and Exchange Server Manager supports the following product versions and technologies:

Active Directory for Windows Server 2012 and Windows 2016

- Active Directory Domain Services (AD DS) Server Role

Exchange Server 2007, 2010

- Hub Transport Server Rol
- Mailbox Server Role

Active Directory Overview

Active Directory is a directory service that provides administrators the ability to discover and manage network resources throughout the organization. Using Active Directory, you can efficiently manage directory-enabled objects (such as users, computers, groups, printers, and applications) from one secure, centralized location. DX NetOps Spectrum ADES Manager helps you to manage and monitor your Active Directory environment so that you can increase the availability of your network resources.

An Active Directory implementation can vary in size. You can have a few objects to millions of objects. Active Directory enables administrators to manage centrally enterprise-wide network information from a repository that is globally replicated. Once the information has been added to Active Directory, it is available throughout the entire enterprise.

Active Directory uses server roles to assign different functions to different servers, and a single server can fulfill several roles at once. The following server roles are available for Active Directory:

- **Active Directory Certificate Services (AD CS)**
  Allows you to create, distribute, and manage customized public key certificates.
- **Active Directory Domain Services (AD DS)**
  Stores directory data for all objects in your network and manages the communication between users and domains, including authentication requests and directory searches.
- **Active Directory Federation Services (AD FS)**
  Provides secure identity technologies that are used to authenticate users for access to resources.
- **Active Directory Lightweight Directory Services (AD LDS)**
  Provides support for directory-enabled applications without the restrictions of AD DS.
- **Active Directory Rights Management Services (AD RMS)**
  Protects your digital information from unauthorized use by identifying the rights that a user has to a file.

> **WARNING**
> DX NetOps Spectrum ADES Manager supports the AD DS server role only. The following section provides more information on this role.

Active Directory Domain Services (AD DS)

Active Directory Domain Services provide the central location of the directory. The directory stores configuration information, authentication requests, and other information about all the objects in your network. The basic internal structure of the Active Directory is a hierarchical arrangement of objects.

The following components of the Active Directory structure are used in DX NetOps Spectrum ADES Manager:

- **Forest**
  An Active Directory container structure that contains a collection of Active Directory objects, their attributes, and attribute syntax. A forest is at the highest level of the logical structure. A forest is a collection of domain trees sharing a common global catalog, directory configuration, directory, schema, and logical structure.
- **Domain**
  An Active Directory container structure that contains a collection of objects that share a common set of policies, name, and security database. A domain is at the lowest level of the logical structure of an entire network. The domain name identifies the domain.
- **Domain Controller**
  A host that is running AD DS. Typically multiple domain controllers host Active Directory within a domain. You can manage your network resources from any domain controller within your domain.

Exchange Server Overview

Exchange Server is a back-end product that provides messaging services (such as email, calendar, and contacts) to its end users. With email and messaging as business-critical tools, your Exchange Server implementation must be able to support a highly available messaging environment. DX NetOps Spectrum ADES Manager helps you to manage and monitor your Exchange Server environment so that you can achieve increased levels of reliability.

Exchange Server provides the underlying infrastructure to support a messaging system, which includes the following components:

- The database to store email data
- The transport infrastructure to move the data from one place to another
- Access points to access email data from a number of different clients

Exchange Server uses server roles to assign these different functions to servers throughout the enterprise, and you choose which roles each server supports. You can install only the roles you need, and you can split server functions across multiple servers. You can also install more than one role on a single machine.

The following server roles are available in Exchange Server:

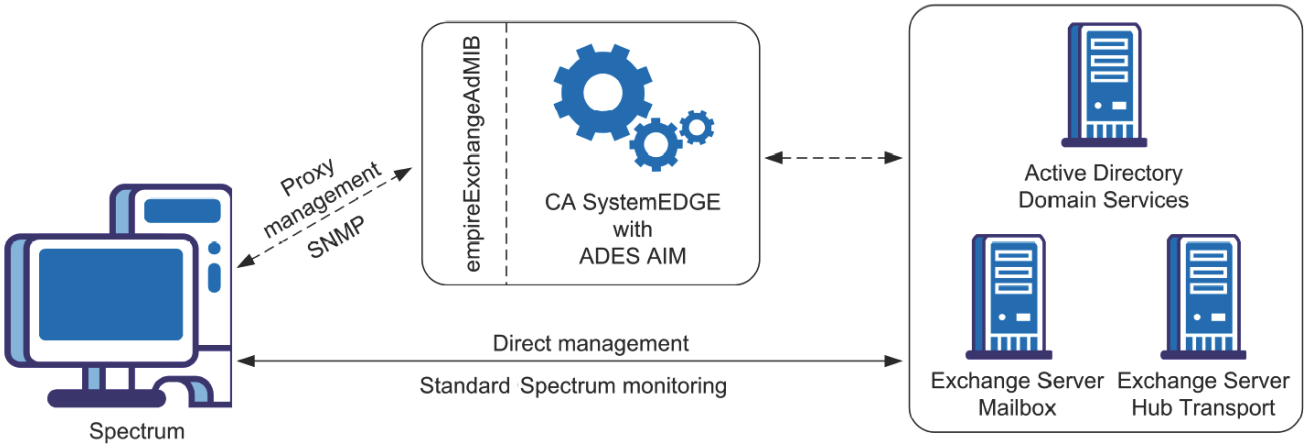
- **Mailbox**
  Provides email storage (including user mailboxes), advanced scheduling services, and supports public folders. Continuous replication technology provides a reliable failover mechanism in the event of failure. In Exchange 2007, continuous replication failover is at the server level. With Exchange 2010 and the introduction of database availability groups (DAGs), failover is at the database level.
- **Client Access**
  Handles how users connect to Exchange by supporting functions such as Outlook, POP3, and web services such as calendar sharing.
- **Hub Transport**
  Handles email flow and routing. All messages are delivered through this role, regardless of whether they are being delivered locally or remotely.
- **Unified Messaging**
  Integrates your phone system with your email, handling automated call routing and directing voicemails to the appropriate user mailbox.
- **Edge Transport**
  Supports antispam and antivirus functions for inbound and outbound messaging.

  WARNING
  DX NetOps Spectrum ADES Manager supports the Mailbox Server and Hub Transport Server roles only.

Solution Architecture

ADES Manager monitors your Active Directory and Exchange Server environments seamlessly within your network, while providing data that is specific to the supported server roles. DX NetOps Spectrum gathers information about your Active Directory and Exchange Server hosts using two different methods. As with other DX NetOps Spectrum-managed devices, ADES Manager uses standard DX NetOps Spectrum monitoring. In addition, ADES Manager also retrieves specialized information from an alternate (proxy) manager, a SystemEDGE Application Insight Module (AIM). Specifically, ADES Manager uses the Active Directory and Exchange Server AIM (ADES AIM).

An AIM is a specialized extension of the SystemEDGE agent and resides on its own host. This host is referred to as the Active Directory and Exchange Server Host Manager (ADES Host Manager). The ADES AIM obtains data from Active Directory and Exchange Server hosts that is specific to the Active Directory and Exchange Server role technologies. This data is then written to a CA-developed MIB (empireExchangeAdMIB). DX NetOps Spectrum then accesses the data from the MIB using SNMP requests. This solution allows other SNMP clients, such as CA eHealth, to utilize the ADES AIM. Each ADES AIM can support multiple domains, and ADES Manager can support multiple AIMs either within a single SpectroSERVER or distributed across multiple SpectroSERVERs.



NOTE
For more information about the ADES AIM, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Planning Your ADES Manager Implementation

The purpose of ADES Manager is to monitor your Active Directory and Exchange Server environments. ADES Manager is highly scalable and can monitor hundreds of servers using multiple AIMs and distributed SpectroSERVERs. You can configure your ADES Manager implementation differently for performance, geographical, and logical purposes. Understanding the various configuration and management options provides for a more efficient ADES Manager implementation.

Environment Management Considerations

During the setup of ADES Manager, you specify how to organize the management of your environments. With a small environment, you can have one ADES AIM managing all your hosts in one domain in one location on one SpectroSERVER. In a complex environment, you can have multiple ADES AIMs to manage different host subsets from multiple domains in different locations across multiple SpectroSERVER landscapes.

Although organizational specifications can be changed at any time, knowing the available configuration management options allows for a better initial set up.

Consider the following points when setting up your ADES Manager environment:

- A single ADES AIM can manage hosts from one or more domains.
- One or more ADES AIMs can manage a single domain.
- Domain management can be distributed across multiple SpectroSERVERs using multiple ADES AIMs. Multiple ADES AIMs can also be supported within a single landscape.
- Manage a host by one ADES AIM only. If a host fulfills multiple roles, manage all the roles by the same ADES AIM.

When deciding how to distribute host management, consider the number and location of hosts in your environment. The number of hosts an ADES AIM manages and the geographic proximity of the AIM to the monitored environment can affect performance. For the best performance, size and balance management of the environment appropriately.

NOTE
Domain-level management is controlled on the ADES AIM and not in DX NetOps Spectrum. For information on domain specification, load balancing, and sizing guidelines, see the CA Virtual Assurance for Infrastructure Managers Administration section.

Host Modeling

As with other network elements supported in DX NetOps Spectrum, you discover and model your Active Directory and Exchange Server hosts to monitor them. ADES Manager uses different types of discovery when modeling your ADES environment:

- Discovery by the ADES AIM (ADES AIM Discovery)
- Discovery within DX NetOps Spectrum (ADES Manager Discovery)

ADES Manager relies on the ADES AIM to discover and provide information about available Active Directory and Exchange Server hosts in the specified domains. ADES Manager then uses this information to model each host individually in DX NetOps Spectrum.

> **NOTE**
> Information that is used for the ADES Manager feature is gathered primarily from the ADES AIM. More information is also gathered directly from the hosts.

The following topics provide more details about the modeling process.

> **NOTE**
> Procedures for discovering and modeling your environment are provided in Discovery and Modeling ADES Environment.

What is Modeled

ADES AIM Discovery finds any host in the specified domain or domains that supports any of the supported roles. These hosts are made available for management in DX NetOps Spectrum. Supported server roles include Active Directory Domain Services, Exchange Server Hub Transport, and Exchange Server Mailbox. If a machine only has unsupported roles, the machine is not included in the list of available hosts and the machine is not modeled. Of the available hosts, not all are necessarily modeled in DX NetOps Spectrum. Only those hosts that are designated by the DX NetOps Spectrum administrator for DX NetOps Spectrum ADES Manager to manage are discovered and modeled in DX NetOps Spectrum.

> **NOTE**
> You can specify in the ADES AIM to monitor Active Directory only, Exchange Server only, or both technologies. When monitoring a single technology, only those hosts having a supported role in that technology are included as available hosts. You can also specify in the ADES AIM to manage automatically all newly available hosts. In this case, all newly available hosts having any of the supported roles are modeled automatically in DX NetOps Spectrum. Functionality that the AIM provides is described more in Understanding ADES AIM Technology.

Models that are created during ADES Manager Discovery are placed in the topology in an ADES Managed Hosts container specific to the ADES AIM. These models are also visible in the Active Directory and Exchange Server Manager hierarchy. If a host that has already been modeled in your DX NetOps Spectrum-managed network before ADES Manager Discovery, it is not modeled again. Also, the original model is not moved in the topology during ADES Manager Discovery. Although the model is not reflected in the ADES Managed Hosts container in the topology view automatically, it does appear in the ADES Manager hierarchy. In certain cases, you can move the host model into the ADES Managed Hosts container manually.

> **NOTE**
> Active Directory and Exchange Server host models can also be moved out of the ADES Managed Hosts container. This container is not limited to Active Directory and Exchange Server hosts. Other devices can be moved into the container when the administrator considers the inclusion to be logical. If the container is destroyed, all models in the container (except for models in a global collection) are moved to the Lost and Found (LostFound). Any models that are moved manually into the container and are not necessarily Active Directory or Exchange Server hosts are also moved.

Modeling Methods

Hosts in the Active Directory and Exchange Server environment are modeled as SNMP-managed elements when possible. SNMP-capable modeling supports enriched device monitoring that can provide added value to your ADES Manager solution. If an SNMP agent is not installed on the host, it is modeled as an ICMP (Pingable) device.

Model Naming

When modeling Active Directory and Exchange Server hosts, the model name that DX NetOps Spectrum assigns depends on the type of modeling used, as follows:

- For SNMP modeling, DX NetOps Spectrum automatically attempts to supply a name for the model using standard DX NetOps Spectrum naming conventions. Automatic naming is controlled at the SpectroSERVER level as indicated by the Model Naming Order field on the SpectroSERVER Control view for the VNM model.
- For ICMP (Pingable) modeling (when not a virtual device), DX NetOps Spectrum uses the hostname that the ADES AIM provides.

  WARNING
  For ICMP (Pingable) modeling, model names that Virtual Host Manager sets take precedence over ADES Manager.

The administrator can modify the name of an Active Directory or Exchange Server host model at any time. As with other managed network elements, DX NetOps Spectrum automatically updates the model name using established naming rules, which can replace the user-defined value. To retain a user-defined value, lock the model name.

NOTE
You can modify and lock the model name using the following model attributes: Model_Name (0x1006e) and Lock_Model_Name (0x12a52).

IP and MAC Address Determination

When modeling Active Directory and Exchange Server hosts, the IP and MAC addresses that DX NetOps Spectrum assigns depends on the type of modeling used:

- For SNMP modeling, DX NetOps Spectrum automatically attempts to determine the addresses by querying the resident SNMP agent.
- For ICMP (Pingable) modeling (when not a virtual device), DX NetOps Spectrum uses the addresses that the ADES AIM provides.

  WARNING
  For ICMP (Pingable) modeling, addresses that Virtual Host Manager sets take precedence over ADES Manager.

If neither SNMP modeling or Virtual Host Manager can supply a valid IP or MAC address, the ADES AIM value is used.

Host Management and Multiple ADES AIMs

Manage an Active Directory or Exchange Server host by a single ADES AIM. If, inadvertently, multiple ADES AIMs manage a host, expect the following behavior:

- If the managing ADES Host Managers are in a single landscape, duplicate models are not created for the Active Directory or Exchange Server host. ADES Manager recognizes when another ADES AIM is managing a host and issues an alarm on the Active Directory or Exchange Server host.
- If the managing ADES Host Managers exist across multiple landscapes, duplicate models exist.

  WARNING
  Managing a single host by multiple ADES AIMs can introduce performance issues. For more information, see the CA Virtual Assurance for Infrastructure Managers Administration section.

Hosts Managed by Multiple DX NetOps Spectrum AIM Solutions

When managing a host model by multiple DX NetOps Spectrum AIM solutions, defined ranked order of management applies, as follows:

1. Virtual Host Manager
2. Cluster Manager
3. Other technologies (such as ADES Manager)

When a host with a SystemEDGE agent is already modeled in DX NetOps Spectrum, ADES Manager recognizes the model and a duplicate model is not created. Instead, ADES Manager pulls the existing model into its own management, abiding by and applying the rules for each solution using the ranked order.

For example, when both the Virtual Host Manager and ADES Manager are managing a host, model parameters that Virtual Host Manager assigns are used. Examples of these parameters include the model name, IP address, and MAC address.

When a solution no longer manages a device, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.

This defined order of management also affects how models appear in the Universe topology.

> **NOTE**
> For more information, see the Virtual Host Manager section and the Cluster Manager section.

Supporting Changes to Your Active Directory and Exchange Server Environments

After the initial modeling of your Active Directory and Exchange Server environments in DX NetOps Spectrum, changes to the environment are not automatically detected. ADES AIM discovery must be started manually to recognize and model any subsequent changes.

The ADES AIM performs its discovery of the Active Directory and Exchange Server environments when the AIM starts up. Then, DX NetOps Spectrum models the environment accordingly. After the initial ADES AIM Discovery, start an ADES AIM discovery manually for the ADES AIM to recognize any changes in the environment. DX NetOps Spectrum then automatically reflects these changes in its modeled environment.

Because of the potentially large size of the Active Directory and Exchange Server environments, dynamic updates would be expensive to maintain. The manual start process also allows the administrator to address many environment changes at the same time in a controlled time frame.

> **NOTE**
> For information about updating your modeled ADES environment, see Updating ADES Environment.

Understanding ADES AIM Technology

ADES Manager uses the ADES AIM for discovery, modeling, and monitoring of your Active Directory and Exchange Server environments. This section describes functionality that the ADES AIM controls and provides. Review these topics before setting up your ADES Manager implementation.

After the initial setup, configurations can be modified. Some settings can only be changed directly in the ADES AIM, while others can be changed from within DX NetOps Spectrum.

> **NOTE**
> This section describes features of the ADES AIM at a high level. For detailed information, see theVirtual Host Manager section.

Discovery Options for the ADES AIM

This section describes the ADES AIM Discovery options. These options are defined in the ADES AIM and control what hosts in your Active Directory and Exchange Server environments are discovered. These options also control how the discovered hosts are initially managed. The main settings on the ADES AIM are:

- **Domain name**
  Controls what domains to monitor.
- **Management entity**
  Controls what technologies to monitor: Active Directory, Exchange Server, or both. This setting is specified on a per-domain basis.
- **Management mode**
  Controls how discovered hosts are initially monitored: domain-based or host-based. This setting is specified on a per-domain basis.

The following explanation describes how these settings work together and how DX NetOps Spectrum ADES Manager uses them.

When you install and configure an ADES AIM, you provide the names of one or more domains to manage. You also specify by domain whether to manage Active Directory hosts, Exchange Server hosts, or both.

Using the specified domain names, the ADES AIM queries the Global Catalogs to retrieve all Active Directory and/or Exchange Server hosts (based on your setting). The ADES AIM then identifies the roles that are configured on each server. The ADES AIM uses the respective roles of each host to determine whether the host qualifies for inclusion as an available host.

For each domain, you also specify whether the ADES AIM initially manages (domain-based management) or does not manage (host-based management) newly discovered hosts. Domain-based management identifies and automatically manages all new hosts that serve the requested technology within the domain. Host-based management identifies but does not manage all new hosts by default. Domain-based management is typically used with domains that are small enough for a single AIM to manage. Host-based management is typically used with domains that are large enough to be managed by multiple ADES AIMs.

> **NOTE**
> Using host-based management, you specify manually within DX NetOps Spectrum which hosts to manage. See Specify Hosts to Manage by ADES Manager.

Polling by the ADES AIM

The ADES AIM polling interval indicates how often the ADES AIM queries the managed hosts for information. The default value is 300 seconds with a minimum value of 30 seconds. The interval must be a multiple of 30 seconds.

The ADES AIM polling interval can be modified from within DX NetOps Spectrum. For more information, see Updating ADES AIM Configuration Options.

> **WARNING**
> DX NetOps Spectrum uses its own polling interval to control how often to poll the ADES AIM. For more information on polling intervals that ADES Manager uses, see Controlling Polling Intervals to Update ADES Data.

Installing ADES Manager Components

ADES Manager is included in all DX NetOps Spectrum extraction keys. When you install DX NetOps Spectrum, the ADES Manager components are automatically installed and available for use. However, ADES Manager is operable only after you also install and configure the SystemEDGE agent and ADES AIM. To manage your environment properly, DX NetOps Spectrum must be able to contact the SystemEDGE agent, which has the ADES AIM loaded. The AIM must be able to communicate with your Active Directory and Exchange Server hosts.

To install ADES Manager properly, the administrator must complete these tasks:

- Install the SystemEDGE agent and load and configure the ADES AIM, specifying the domain or domains for monitoring. Note the following requirements:
  - The SystemEDGE agent and ADES AIM must be installed on a Windows host that meets the following conditions:
    - The Windows host Is a member server in one of the domains to be monitored, with a trust relationship to the remaining domains.
    - The Windows host does not have any Active Directory or Exchange Server roles.

      WARNING
      Do not install the SystemEDGE agent and ADES AIM on a host that ADES Manager is going to manage.
  - The ADES AIM must be the only AIM installed on the SystemEDGE host.
  - The ADES AIM can monitor the domain using various configurations. The ADES AIM can be configured to monitor Active Directory hosts, Exchange Server hosts, or both. The ADES can also be configured to use either domain-based or host-based management mode.

    NOTE
    For more information about ADES AIM functionality at a high level, see Understanding ADES AIM Technology. For details about installing the CA SystemEDGE agent and ADES AIM, see the *CA Virtual Assurance for Infrastructure Managers Installation section* and *CA Virtual Assurance for Infrastructure Managers Administration section*, respectively.
- Install DX NetOps Spectrum with ADES Manager included.

  WARNING
  Do not install the SpectroSERVER on a machine that ADES Manager is going to manage.

  NOTE
  For specific installation instructions, see the Fresh Install section.

You can now discover and model your Active Directory and Exchange Server environment in DX NetOps Spectrum. See Discovery and Modeling ADES Environment.

Discovery and Modeling ADES Environment

After you have installed the necessary components, discover and model any hosts that ADES Manager is going to manage. The following types of discovery are used:

- Discovery on the ADES AIM (ADES AIM Discovery)
- Standard DX NetOps Spectrum Discovery
- Discovery within DX NetOps Spectrum of Active Directory and Exchange Server hosts to be managed (ADES Manager Discovery)

ADES Manager relies on the ADES AIM discovery to collect information about available Active Directory and Exchange Server hosts in the specified domains. Then, through ADES Manager Discovery, ADES Manager uses this information to model each Active Directory or Exchange Server host individually. Models are placed in the hierarchy and in ADES Managed Hosts containers in the topology. Using standard DX NetOps Spectrum logic, connections are established between the hosts and the upstream devices that are modeled during standard DX NetOps Spectrum Discovery.

Discover and Model Your Active Directory and Exchange Server Environment

The following steps are necessary to discover and model your Active Directory and Exchange Server environments:

1. Run a standard Discovery to model the ADES Host Manager and connecting devices.
2. If necessary, upgrade the CA SystemEDGE model.

3. Specify hosts to manage by ADES Manager.
4. Let ADES Manager Discovery run.

ADES AIM Discovery

ADES AIM Discovery occurs automatically when you set up the ADES AIM on the ADES Host Manager. The following explanation describes the ADES AIM Discovery process and is provided for reference only. No action is required.

ADES AIM Discovery works as follows:

1. After successful installation, the ADES AIM queries the Global Catalogs to retrieve all Active Directory and/or Exchange Server hosts for the configured domains. The ADES AIM also identifies the roles that are configured on each host. Hosts that have one or more supported roles are made available for management by DX NetOps Spectrum ADES Manager. The management entity setting is used to include only those hosts having a supported role for the configured technology (Active Directory, Exchange Server, or both).
2. Using the specified management mode, the ADES AIM sets all hosts as managed (domain-based management) or not managed (host-based management) by default.
3. The ADES AIM immediately begins polling all hosts that are set as managed to gather information about their respective server role function.
4. After the initial discovery, ADES AIM Discovery must be started manually to detect any subsequent changes to the environment. For more information, see Updating Your Managed Environment.

NOTE
The ADES AIM stores a list of available hosts and their managed settings. On a restart of the ADES AIM, this host list is read in. Any host that still resides in the Active Directory and Exchange Server environment retains its previous managed setting.

Run Discovery to Model the ADES Host Manager and Connecting Devices

NOTE
After you have set up the ADES Host Manager and ADES AIM Discovery has started, model the ADES Host Manager and any connecting devices. You can use standard DX NetOps Spectrum Discovery to:

- Model the ADES Host Manager, which must be modeled with a read/write community string.
- Model the necessary upstream routers and switches of your Active Directory and Exchange Server environments. Modeling of connecting devices allows connections from the Active Directory and Exchange Server hosts to be established later.

WARNING
Do not specify Active Directory and Exchange Server hosts to be modeled. Active Directory and Exchange Server hosts are discovered and modeled automatically during ADES Manager Discovery.

NOTE
An administrator performs this procedure.

Follow these steps:

1. Open the Discovery console.

NOTE
Prepare by gathering the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port.

2. In the Navigation panel, click the **Creates a new configuration** icon  .
   The Configuration dialog opens.
3. Specify a name and location for the new configuration, and then click **OK**.
   The Configuration dialog closes.
4. Enter individual IP addresses or the beginning and ending IP addresses in the IP/Host Name Boundary List fields, and then click **Add**.

   NOTE
   Verify that the range of IP addresses includes all ADES Host Managers and the interconnecting switches and routers.
5. Configure SNMP Information.

   WARNING
   You must model the ADES Host Manager with a read/write community string. If you are modeling the ADES Host Manager in this Discovery, verify that its community string is placed appropriately in the ordered list. Alternatively, you can change the community string for the ADES Host Manager to its read/write value after the discovery.
6. Configure your Modeling Options as follows:
   a. Select **Discover and automatically model to Spectrum**.
   b. Click **Modeling Options**.
      The Modeling Configuration dialog opens.
   c. Click **Protocol Options**.
      The Protocol Options dialog opens.
   d. Select **ARP Tables for Pingables**, and then click **OK**.
      The Protocol Options dialog closes.
   e. Click **OK** to close the Modeling Configuration dialog.
7. (Optional) Click **Advanced Options** in the Advanced Options group, add any nonstandard SNMP ports, and then click **OK**.
   The Advanced Options dialog closes.
8. Enter any additional values that are needed in the Discovery console for modeling your connecting devices and ADES Host Managers, and then click **Discover**.
   Models are created and added to your network topology in DX NetOps Spectrum for the following entities:
   – Active Directory and Exchange Server Host Manager (ADES Host Manager).

     NOTE
     If the Discovery process did not assign the read/write community string to this model, update this setting manually. Use the Modeling Information subview for the model.
   – The upstream switches and routers that connect the hosts in your Active Directory and Exchange Server environment to your network.

   When these models exist in DX NetOps Spectrum, ADES Manager Discovery can begin.

   NOTE
   Instead of using standard DX NetOps Spectrum Discovery, you can manually model your ADES Host Manager by IP address or hostname. If you do, model the upstream devices first (because modeling the ADES Host Manager automatically triggers an ADES Manager Discovery). Modeling in the proper order allows the correct creation of connections in the topology between your hosts and the remainder of your network. For more information, see the Modeling and Managing Your IT Infrastructure section.

Upgrade the SystemEDGE Host Model (If Necessary)

If the SystemEDGE host model was created before loading the ADES AIM on the agent, the existing model is not compatible with ADES Manager. Upgrade the SystemEDGE host (Host_systemEDGE) model so that ADES Manager can access the ADES AIM capabilities in SystemEDGE.

To upgrade the SystemEDGE host model, right-click the model and select Reconfiguration, Reconfigure Model.

The SystemEDGE host model is upgraded to support the ADES AIM.

> **NOTE**
> You can also send a reconfigure model action to the SystemEDGE agent using CLI. For instructions on how to send a reconfigure model action to the SystemEDGE agent, see the Modeling and Managing Your IT Infrastructure section.

Specify Hosts to Manage by ADES AIM

Hosts must be set as "managed" to be modeled in DX NetOps Spectrum. When using domain-based management, all hosts are set initially to be managed; with host-based management, all hosts are set initially not to be managed. Use the Universal Host Table (UHT) view in DX NetOps Spectrum for specifying hosts to manage, as described in this section.

Using host-based management, you can distribute the management of hosts in a domain across multiple ADES AIMs for load balancing. The UHT contains all available hosts in all domains for which the ADES AIM is configured and lets you specify hosts for management. Manage a host by a single ADES AIM only.

> **WARNING**
> Managing a single host by multiple ADES AIMs can introduce performance issues. For more information, see the *CA Virtual Assurance for Infrastructure Managers Administration Guide*.

> **NOTE**
> These settings can also be set using MIB Tools or another MIB browser. However, it is recommended that you use the UHT view that is provided in DX NetOps Spectrum.

When a host is set to be managed, it appears in the Managed Host Table (MHT) view in DX NetOps Spectrum. The MHT contains the subset of UHT hosts for which the ADES AIM is polling for Active Directory and Exchange Server metrics. The MHT resides in the ADES AIM. ADES Manager uses the MHT as its basis for creating, deleting, or updating Active Directory and Exchange Server host models.

> **NOTE**
> Only those users with the appropriate privileges can modify host management. For more information, see the OneClick Administration section.

Follow these steps:

1. Select the ADES Host Manager model. The model has a device type of 'Active Directory and Exchange Server Host Manager.'

   > **NOTE**
   > The host must have been modeled with a read/write community string.

   The Component Detail panel displays information for the selected ADES Host Manager.
2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management, Host Management, Universal Host Table subview.
   The Universal Host Table lists all hosts that are available for management by this ADES AIM. The table also indicates the server roles that are defined for each host.
3. Select one or more hosts in the table. Click Manage or Do Not Manage to specify whether this ADES AIM is going to manage the hosts.

NOTE
When working with many hosts, undock the Universal Host Table subview to enable expansion of the table view. You can also use shift-click and control-click to control your host selection, as follows:

- To select a consecutive group of hosts, click the first host, press and hold down the Shift key, and then click the last host.
- To select nonconsecutive hosts, press and hold down the Ctrl key, and then click each host that you want to select.

A checkmark is displayed in the Managed column for any host that this ADES AIM manages. Each managed host exists in the MHT, as displayed by the Managed Host Table view.

NOTE
For information about moving a host from the management of one ADES AIM to another, see Modifying ADES Manager Host Management and Models.

NOTE

For SystemEDGE to populate CPU related OIDs with data, run the following command from the command prompt to reload the Windows performance counters and restart SystemEDGE.

```
lodctr /r
```

Specify Hosts to Manage by ADES AIM

Hosts must be set as "managed" to be modeled in DX NetOps Spectrum. When using domain-based management, all hosts are set initially to be managed; with host-based management, all hosts are set initially not to be managed. Use the Universal Host Table (UHT) view in DX NetOps Spectrum for specifying hosts to manage, as described in this section.

Using host-based management, you can distribute the management of hosts in a domain across multiple ADES AIMs for load balancing. The UHT contains all available hosts in all domains for which the ADES AIM is configured and lets you specify hosts for management. Manage a host by a single ADES AIM only.

NOTE

Managing a single host by multiple ADES AIMs can introduce performance issues. For more information, see the *CA Virtual Assurance for Infrastructure* Managers documentation.

NOTE

These settings can also be set using MIB Tools or another MIB browser. However, it is recommended that you use the UHT view that is provided in DX NetOps Spectrum.

When a host is set to be managed, it appears in the Managed Host Table (MHT) view in DX NetOps Spectrum. The MHT contains the subset of UHT hosts for which the ADES AIM is polling for Active Directory and Exchange Server metrics. The MHT resides in the ADES AIM. ADES Manager uses the MHT as its basis for creating, deleting, or updating Active Directory and Exchange Server host models.

NOTE

Only those users with the appropriate privileges can modify host management. For more information, see the OneClick Administration section.

1. Select the ADES Host Manager model. The model has a device type of 'Active Directory and Exchange Server Host Manag**er.'**

   NOTE
   The host must have been modeled with a read/write community string.

The Component Detail panel displays information for the selected ADES Host Manager.

2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management, Host Management, Universal Host Table subview.
   The Universal Host Table lists all hosts that are available for management by this ADES AIM. The table also indicates the server roles that are defined for each host.
3. Select one or more hosts in the table. Click Manage or Do Not Manage to specify whether this ADES AIM is going to manage the hosts.

   NOTE
   When working with many hosts, undock the Universal Host Table subview to enable expansion of the table view. You can also use shift-click and control-click to control your host selection, as follows:

   - To select a consecutive group of hosts, click the first host, press and hold down the Shift key, and then click the last host.
   - To select nonconsecutive hosts, press and hold down the Ctrl key, and then click each host that you want to select.

   A checkmark is displayed in the Managed column for any host that this ADES AIM manages. Each managed host exists in the MHT, as displayed by the Managed Host Table view.

NOTE
For information about moving a host from the management of one ADES AIM to another, see Modifying ADES Manager Host Management and Models.

ADES Manager Discovery

ADES Manager Discovery is the modeling within DX NetOps Spectrum of any required ADES Manager components. These components include any managed Active Directory and Exchange Server hosts. Modeling the ADES Host Manager automatically triggers an ADES Manager Discovery.

After the ADES Host Manager is modeled initially, anytime you modify a host in the Universal Host Table subview, ADES Manager Discovery runs automatically. ADES Manager Discovery also runs automatically whenever an ADES AIM Discovery runs and effects changes in the Managed Host Table.

The following description explains the entire ADES Manager Discovery process and is provided for reference. No action is required.

ADES Manager Discovery works as follows:

1. After DX NetOps Spectrum models a CA SystemEDGE host and detects the presence of the ADES AIM, the following actions occur:
   a. When the ADES AIM is detected, the device type of the CA SystemEDGE host changes to 'Active Directory and Exchange Server Host Manager'.
   b. An application model that can run ADES AIM Discovery is created.
   c. An ADES Managed Hosts container is created to contain any new Active Directory or Exchange Server host models for this ADES AIM.
2. When communication between DX NetOps Spectrum and the ADES AIM is established, the host-modeling process begins automatically. ADES Manager uses information from the MHT in the ADES AIM to determine which hosts to model. For each host to be modeled, if a model does not exist, a new host model is created. If an SNMP agent exists on the host, an SNMP-capable host model is created. Otherwise, an ICMP (Pingable) model is created.
3. New Active Directory or Exchange Server host models appear in the Active Directory and Exchange Server Manager hierarchy in the Explorer view. New host models are also placed into the ADES Managed Hosts container for the ADES AIM in the topology view. Connections to any upstream devices are made.

WARNING
If a host is already modeled in your DX NetOps Spectrum-managed network before ADES Manager discovery, it is not modeled again. Also, the original model is not moved in the topology. However, it is still included in the Active Directory and Exchange Server Manager hierarchy.

NOTE
You can also manually control whether a host is managed using the Universal Host Table. Modifying the UHT adds or deletes the host in the Managed Host Table, which triggers the modeling process. An ADES AIM Discovery can also add or remove host models from the MHT, which also triggers the modeling process.

How to Model Your Environment When Using Multiple AIM Solutions

Depending on your environment, you can use ADES Manager along with other DX NetOps Spectrum AIM solutions simultaneously to manage your network entities. Some configurations, such as the following examples, require using multiple solutions to manage your environment completely:

- An Active Directory or Exchange Server host runs on a virtual machine.
- The ADES AIM runs on a virtual machine.
- An Active Directory or Exchange Server host is a cluster node.

Each of DX NetOps Spectrum AIM solutions provide information that is specific to the technology it supports. For example:

- Virtual Host Manager provides details that are specific to virtual technologies.
- Cluster Manager provides details that are specific to cluster technologies.
- ADES Manager provides details that are specific to the supported Active Directory and Exchange Server roles.

The combination of these features provides a complete monitoring solution. To set up your implementation of multiple AIM solutions effectively, the following approach is recommended.

WARNING
When using multiple AIMs, only a single AIM can be installed on a given SystemEDGE host.

Follow these steps:

1. Configure the AutoDiscovery settings on the VNM model.
2. Configure the Virtual Host Manager settings that are related to your virtual technology.
3. Set up Virtual Host Manager by modeling the virtual technology manager and all virtual technology components.
4. Set up Cluster Manager by modeling the cluster technology manager and all cluster components.
5. Set up ADES Manager by modeling the ADES Host Manager and all Active Directory and Exchange Server hosts.

NOTE
For more information, see the Virtual Host Manager section and Cluster Manager section.

How to Model Your ADES Environment When Using Multiple AIM Solutions

Depending on your environment, you can use ADES Manager along with other DX NetOps Spectrum AIM solutions simultaneously to manage your network entities. Some configurations, such as the following examples, require using multiple solutions to manage your environment completely:

- An Active Directory or Exchange Server host runs on a virtual machine.
- The ADES AIM runs on a virtual machine.
- An Active Directory or Exchange Server host is a cluster node.

Each of the DX NetOps Spectrum AIM solutions provide information that is specific to the technology it supports. For example:

- Virtual Host Manager provides details that are specific to virtual technologies.
- Cluster Manager provides details that are specific to cluster technologies.
- ADES Manager provides details that are specific to the supported Active Directory and Exchange Server roles.

The combination of these features provides a complete monitoring solution. To set up your implementation of multiple AIM solutions effectively, the following approach is recommended.

> **WARNING**
> When using multiple AIMs, only a single AIM can be installed on a given SystemEDGE host.

Follow these steps:

1. Configure the AutoDiscovery settings on the VNM model.
2. Configure the Virtual Host Manager settings that are related to your virtual technology.
3. Set up Virtual Host Manager by modeling the virtual technology manager and all virtual technology components.
4. Set up Cluster Manager by modeling the cluster technology manager and all cluster components.
5. Set up ADES Manager by modeling the ADES Host Manager and all Active Directory and Exchange Server hosts.

> **NOTE**
> For more information, see the Virtual Host Manager section and the Cluster Manager section.

Models Created for ADES Manager

ADES Manager provides several models to represent the components of your Active Directory and Exchange Server environments. Understanding the following basic models can help you to understand better Discovery and how the models relate to one another.

- Active Directory and Exchange Server Host Manager (ADES Host Manager)

Model Type: Host_systemEDGE
Represents the host that contains the ADES AIM. The ADES AIM monitors the Active Directory and Exchange Server hosts in your environment. Successful creation of this model indicates that all requisite intelligence to support ADES Manager has been installed on the ADES Host Manager. This model has a device type of Active Directory and Exchange Server Host Manager.

- <*ADES_Host_Manager_name*> Managed Hosts

Model Type: ADESHostContainer
Initially contains newly created host models that the named ADES AIM manages. You can add or remove models from the container, but you cannot destroy the container itself. When possible, this container model is created alongside the ADES Host Manager model. If a managed host has already been modeled elsewhere in your DX NetOps Spectrum-managed network, it is not modeled again. Also, the existing model is not moved into this container. This behavior applies to a host that another ADES AIM manages. When multiple ADES AIMs manage a host in one landscape, the host model does not appear in multiple ADES Managed Hosts containers. Instead, the host appears in the ADES Managed Hosts container for the first AIM to model it.

NOTE

- If the ADES Host Manager is a virtual machine, the container is placed in the same topology as the Virtual Host Manager physical host container.
- Active Directory and Exchange Server hosts that are virtual machines and managed by Virtual Host Manager are not placed into the ADES Managed Hosts container.

- Active Directory and Exchange Server Host

Represents an Active Directory or Exchange Server host.

NOTE
When multiple ADES AIMs resides in different SpectroSERVERs of a multi landscape environment manage a single host, duplicate models exist. For more information, see Duplicate Models Created After Discovery.

For information about changing your modeled environment, including modifying host management by ADES AIM or deleting ADES Manager models, see Maintaining Your ADES Environment.

Viewing Your Active Directory and Exchange Server Environments

The purpose of ADES Manager is to provide visibility into your Active Directory and Exchange Server environments. This visibility allows you to identify easily the function or role each host plays as well as the logical relationships between the players. Most importantly, when a problem occurs in your environment you can pinpoint its cause.

ADES Manager provides several methods for viewing your Active Directory and Exchange Server environments, as follows:

- The Active Directory and Exchange Server Manager hierarchy in the Explorer tab of the Navigation panel shows the logical relationships between entities. Examples of hierarchy nodes include forests, domains, and roles.
- A graphical topology view helps you group like-managed Active Directory and Exchange Server hosts together as well as visualize the connections between the hosts.
- Customized Information views in the Component Detail panel provide details that are specific to Active Directory and Exchange Server technologies.
- Customized searches provide a quick way to find hosts by using Active Directory and Exchange Server metrics.
- Customized icons for individual models provide status and model type information at a glance and are integrated throughout the ADES Manager feature.

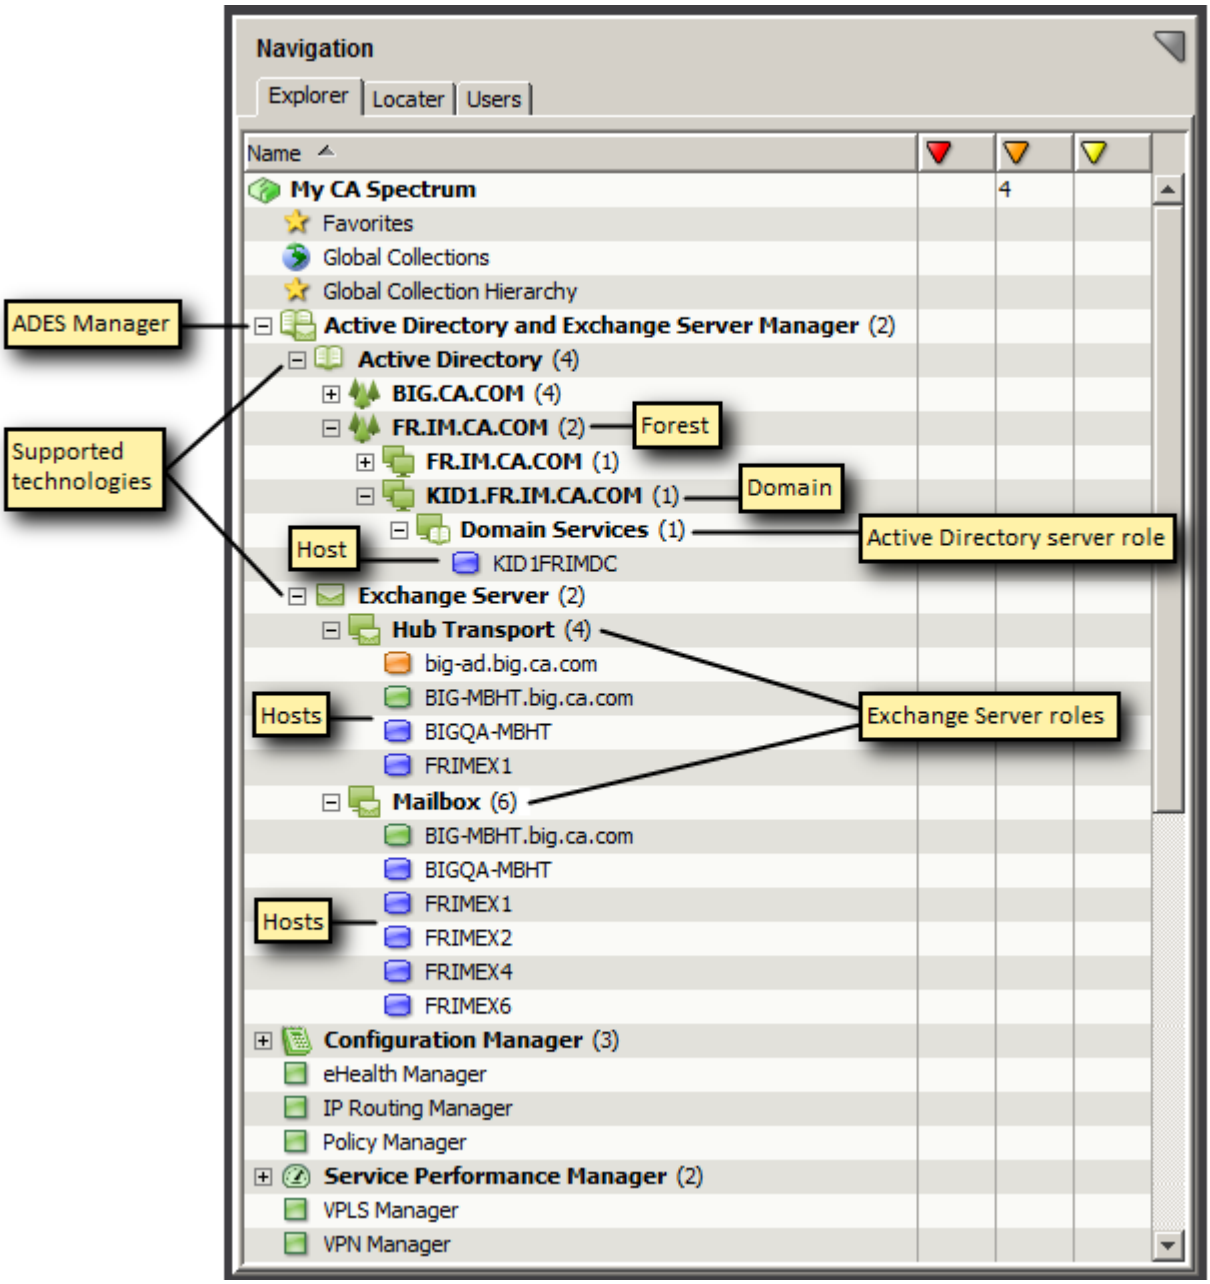
Understanding each of these methods helps you easily monitor your Active Directory and Exchange Server environments. Efficient monitoring then lets you troubleshoot issues and optimize performance more effectively.

Explorer View

On the Explorer tab of the Navigation panel, the Active Directory and Exchange Server Manager node provides a hierarchical tree structure. This format helps you visualize the logical organization of your managed Active Directory and Exchange Server environments. Distinctive icons distinguish the technologies, forests, domains, hosts, and roles that are used in your managed environment.

Using this information, you can see how the hosts are logically arranged as well as which functions or roles each host in your environment supports.

The following image is an example of the ADES Manager hierarchy:



The following nodes form the hierarchy:

- Active Directory and Exchange Server

  Manager
  Active Directory and Exchange Server Manager is the root node for the Active Directory and Exchange Server environments that are currently managed. ADES Manager is a distributed manager that handles multiple landscapes. For this reason, the node appears above the landscape level.
  Expanding the Active Directory and Exchange Server Manager node displays the technologies that are supported, as follows.

NOTE
Only technology, forest, domain, or role nodes that contain at least one managed host in their subhierarchy are displayed.

Topology View

The models for your managed Active Directory and Exchange Server environment are organized and integrated into the Universe topology view. These models include the ADES Host Manager (SystemEDGE host) and the Active Directory and Exchange Server host models. This graphical representation helps you visualize the structure of your managed environment, including connections between managed hosts and other elements of your network.

The host models that are created during ADES Manager Discovery are placed in an ADES Managed Hosts container specific to the ADES AIM. When possible, this container model is created alongside the corresponding ADES Host Manager model.

NOTE
The ADES Host Manager can be a virtual machine. If so, the ADES Managed Hosts container is created in the same topology as the Virtual Host Manager physical host container.

If a managed host has already been modeled in your DX NetOps Spectrum-managed network before ADES Manager Discovery, it is not modeled again. And, the original model is not moved into the ADES Managed Hosts container during ADES Manager Discovery. This behavior applies to a host that another ADES AIM within the same landscape is managing. When multiple ADES AIMs manage a host in one landscape, the host model does not appear in multiple ADES Managed Host containers. Instead, the host appears in the ADES Managed Hosts container for the first AIM to model it.

The following rules apply to the ADES Managed Hosts containers:

- You can move Active Directory and Exchange Server host models out of the ADES Managed Hosts container. Additionally, this container is not limited to Active Directory and Exchange Server hosts. In certain cases, you can move other host models into the ADES Managed Hosts container manually if the administrator considers the inclusion to be logical.
- You cannot destroy an ADES Managed Hosts container directly. The ADES Managed Hosts container is destroyed only when an ADES Host Manager model is deleted. When the container is destroyed, all models in the container are moved to the Lost and Found (LostFound). This action includes any models that are moved manually into the contains and are not necessarily Active Directory or Exchange Server hosts

  NOTE
  An exception is when a host model is in a global collection; in this case, the model remains in the global collection.

  WARNING
  The contents of an ADES Managed Hosts container are not necessarily a comprehensive reflection of all hosts that the corresponding ADES AIM manages. If a host is already modeled in the landscape, the host is not modeled again. And, the existing model is not moved into the ADES Managed Hosts container.

Placement of Models

The placement of host models in the topology during discovery occurs as follows:

- If ADES Manager discovery creates the model, the model is placed in an ADES Managed Hosts container.
- If the Active Directory and Exchange Server host is a virtual machine that Virtual Host Manager manages, the model remains in the physical host container. The host model does not appear in the ADES Managed Hosts container.

WARNING
A virtual machine cannot be moved from its physical host container. An Active Directory or Exchange Server host that is a virtual machine is not reflected in the ADES Managed Hosts container.

- If the model exists and is for a physical machine that another AIM solution manages, the model is not moved from its current container. The model is not represented in the ADES Managed Hosts container. An example of another AIM solution is Cluster Manager.
- If the model exists and no other AIM solution manages the model, the model is moved to the ADES Managed Hosts container.

Information Subviews

Customized views in the Component Detail panel provide detailed information about the components in your Active Directory and Exchange Server environments. You can view information specific to your managed Active Directory and Exchange Server environments by ADES Host Manager (ADES AIM) Subviews and Individual Host.

ADES Host Manager (ADES AIM) Subviews

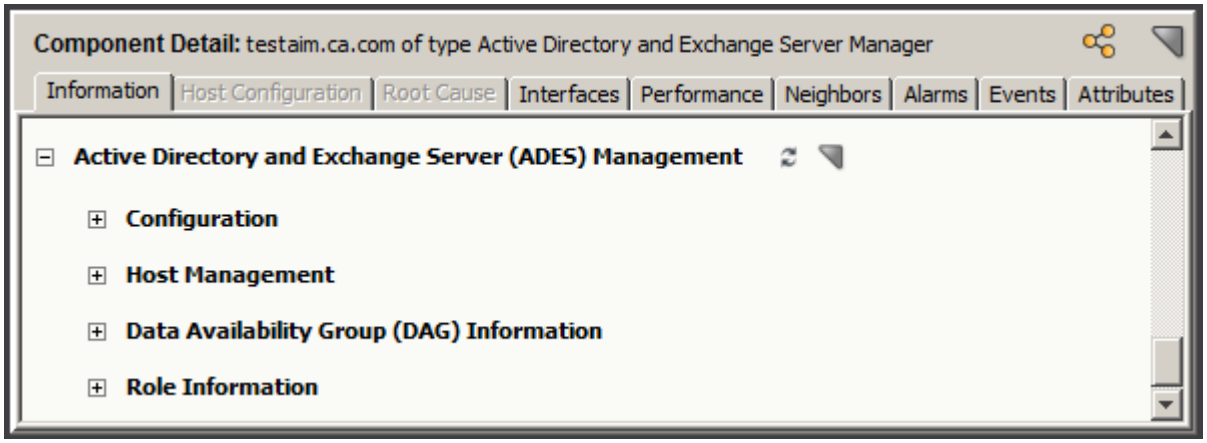
Using views that are provided at the ADES Host Manager (ADES AIM) level, you can view the following information:

- Information specific to the ADES Host Manager such as agent version, polling interval, and ADES AIM Discovery status. You can also control certain options in the ADES AIM from these views, including polling interval and initiation of an ADES AIM Discovery.
- Information about hosts that are available for management and that the ADES AIM is actually managing. You can also control which hosts to manage by the ADES AIM.
- Consolidated information about all hosts in your Active Directory and Exchange Server environments that this single ADES AIM is managing. Views at the ADES AIM level combine information from all hosts that the AIM is managing. For example, you can see collectively all hosts that serve a supported role or a list of domain controllers. From this perspective, you can also see a list of all mailbox databases that reside on hosts that an ADES AIM is managing.

The following procedure describes how to view information for an ADES Host Manager (ADES AIM).

Follow these steps:

1. Select the ADES Host Manager model. The model has a device type of 'Active Directory and Exchange Server Host Manager.'
   The Component Detail panel displays information for the selected ADES Host Manager.
2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management subview.
   The expanded subview appears, as follows:



Active Directory and Exchange Server (ADES) Management Subviews - ADES Host Manager (ADES AIM)

The following subviews are available at the ADES Host Manager (ADES AIM) level.

> **NOTE**
> When viewing host information using the ADES Host Manager subviews, the Host Name that appears reflects the name as provided by the ADES AIM. This value can differ from the model name that DX NetOps Spectrum chose and which appears in the hierarchy and topology views. For more information on how DX NetOps Spectrum assigns model names for ADES Manager, see Model Naming.

- **Configuration**
  Provides information specific to the ADES Host Manager, including:
  - Agent identification, version, and status details.
  - ADES AIM polling interval and Windows Event settings. This view also lets you modify these settings, as described in Updating ADES AIM Configuration Options.
  - Date and time when the ADES AIM inventory was last updated.
  - Date and time when the last ADES AIM Discovery was performed. This view also lets you initiate a new ADES AIM Discovery, as described in Updating Your Managed Environment.
- **Host Management**
  Provides information about available hosts and whether this ADES AIM is managing them currently.
  - **Universal Host Table**
    Lists all hosts that are available for management by this ADES AIM and the server roles that are defined for each host. This table also lets you control which hosts are managed.
    For more information about the Universal Host Table, see Specify Hosts to Manage by ADES AIM.
  - **Managed Host Table**
    Lists all hosts that this ADES AIM is managing. The read-only Managed Host Table also provides AIM-specific polling and status information for each host.

    > **NOTE**
    > The Universal Host Table lists all hosts that this AIM *can* manage. The Managed Host Table lists those hosts that this AIM is *actually* managing.

    For more information about the Managed Host Table, see Specify Hosts to Manage by ADES AIM.
- **Data Availability Group (DAG) Information**
  Provides read-only information about the DAGs that any of the Mailbox hosts that this ADES AIM is managing are members of. Various subviews are provided, each presenting DAG-related information from a different perspective, including:
  - General DAG configuration details such as originating and witness server information, compression and encryption that are being used, and other replication details.
  - Database information including active or passive copy status, issued error messages, latest snapshots, and other backup details.
  - Organizational information for DAG hosts and networks.
- **Role Information**
  Provides read-only information specific to each of the supported server roles. For the Domain Services role, all domain controllers are included in the views whether managed or not. For other roles, only hosts that this ADES AIM is managing are included.

  > **NOTE**
  > A subview table contains data only when at least one host satisfying the stated criteria exists. Otherwise, the table is empty.

Individual Host Subviews

You can view information for individual hosts in your managed Active Directory and Exchange Server environments. Views for individual hosts provide information that is specific to all the server roles that the host provides. Examples include real-time LDAP activity metrics for Active Directory hosts or DAG information for Mailbox hosts.

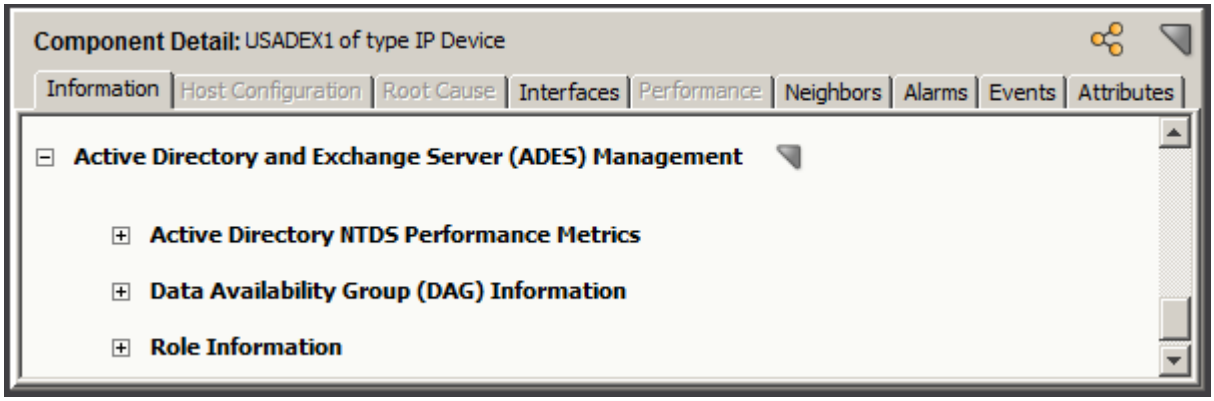
The following procedure describes how to view information for an individual host that ADES Manager is monitoring.

Follow these steps:

1. Select the model for a host that ADES Manager is managing. The model exists under the Active Directory and Exchange Server Manager hierarchy in the Explorer tab of the Navigation panel.

   NOTE
   You can also select the host using any of the standard DX NetOps Spectrum methods. These methods include from a list (for example, in the Contents panel, List tab) or in the topology.

   The Component Detail panel displays information for the selected Active Directory or Exchange Server host model.
2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management subview.
   The expanded subview appears, as follows:



Active Directory and Exchange Server (ADES) Management Subviews - Individual Hosts

The following subviews are available for individual hosts.

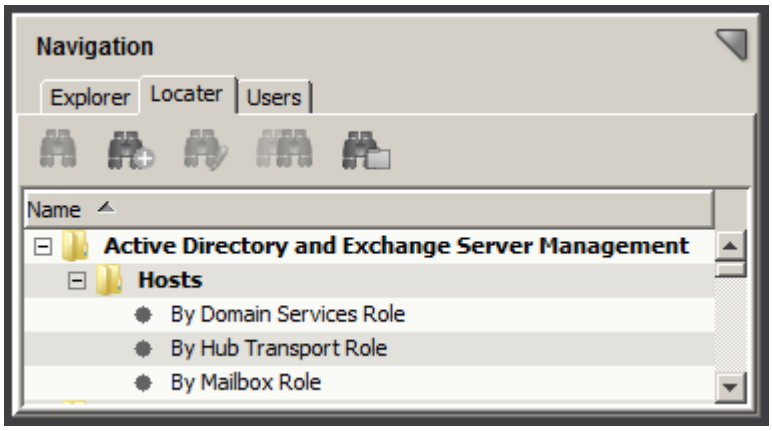
NOTE
When viewing host information using the individual host subviews, the referenced host names that appear reflect the names as provided by the ADES AIM. These values can differ from the model names DX NetOps Spectrum chose and which appear in the hierarchy and topology views. For more information on how DX NetOps Spectrum assigns model names for ADES Manager, see Model Naming.

- **Active Directory NTDS Performance Metrics**
  (For Domain Services hosts) Provides performance data on activities such as LDAP operations, object updates and replication, and authentication requests.
- **Data Availability Group (DAG) Information**
  (For Mailbox hosts) Provides read-only information about the DAG that the selected Mailbox host is a member of. Information includes active or passive status, data center activation mode, and other DAG-related details.
- **Role Information**
  Provides read-only information specific to each of the supported server roles, as follows.

  NOTE
  A subview table contains data only when the host supports the respective role.

Locater Searches

You can use preconfigured searches to locate entities in the DX NetOps Spectrum database that is related to the Active Directory and Exchange Server technologies quickly. The searches are grouped under the Active Directory and Exchange Server Management folder in the Locater tab of the Navigation panel, as shown:



The following searches are specific to Active Directory and Exchange Server technologies:

- **Hosts**
  Locates all hosts that are modeled in the DX NetOps Spectrum database that have been identified as serving the specified role in one of the following searches:
  – By Domain Services Role
  – By Hub Transport Role
  – By Mailbox Role

  NOTE
  Only those users with the appropriate privileges can access Active Directory and Exchange Server Management searches. For more information, see the OneClick Administration section.

Event Reports

To help you monitor your Active Directory and Exchange Server environments, you can create event reports. Event reports gather the information that helps you make informed decisions about your Active Directory and Exchange Server environment entities. Using the correct event filters, you can base these reports on any of the various events that are generated for your managed environment in DX NetOps Spectrum.

To report on ADES Manager events, the `ADES-events-filter.xml` event filter file is included with Report Manager:

NOTE
You can use the event codes of the .xml file, to generate event reports in Spectrum Report Manager. For more information, see the Report Manager section. You can also generate reports using the predefined event filter files. For more information, see the Install Report Manager section.Spectrum Report Manager

Maintaining Your ADES Environment

This section discusses the ways in which you can maintain your ADES Environments.

Controlling Polling Intervals to Update ADES Data

Polling intervals control how often information is obtained from managed devices. To keep data for your managed Active Directory and Exchange Server environments current, DX NetOps Spectrum ADES Manager uses polling intervals set on the following components:

- **ADES AIM**

The ADES AIM polling interval indicates how often the ADES AIM queries the managed hosts for information. The ADES AIM polling interval exists in the ADES AIM but can be modified from within DX NetOps Spectrum. The default value is 300 seconds with a minimum value of 30 seconds. The interval must be a multiple of 30 seconds. For information on how to update the ADES AIM polling interval from within DX NetOps Spectrum, see Updating ADES AIM Configuration Options.

- **ADES Host Manager model**
  The polling interval on the ADES Host Manager model determines how often DX NetOps Spectrum polls the ADES AIM. The default value is 300 seconds with a minimum value of 30 seconds. This setting is available on the DX NetOps Spectrum Modeling Information view for the Active Directory and Exchange Server Host Manager (Host_systemEDGE) model.

Updating ADES AIM Configuration Options

ADES Manager uses the ADES AIM for discovery, modeling, and monitoring of your Active Directory and Exchange Server environments. The ADES AIM provides and controls certain functionality exclusively. Some ADES AIM settings can only be changed directly in the AIM (such as what domains are managed). Other settings can be changed from within DX NetOps Spectrum (such as the ADES AIM polling interval). This section describes how to change certain ADES AIM settings from within DX NetOps Spectrum.

NOTE
For detailed information about all ADES AIM parameters, see the CA Virtual Assurance for Infrastructure Managers section.

Follow these steps:

1. Select the ADES Host Manager model that supports the ADES AIM. The model has a device type of 'Active Directory and Exchange Server Host Manager.'
   The Component Detail panel displays information for the selected ADES Host Manager.
2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management, Configuration subview.
   The expanded Configuration subview appears.
3. Update ADES AIM polling and Windows Event parameters as appropriate.

Modifying ADES Manager Host Management and Models

When changing your modeled environment, consider the following points:

- When multiple ADES AIMs manage a host in one landscape, the host model does not appear in multiple ADES Managed Hosts containers. Instead, the host appears in the ADES Managed Hosts container for the first AIM that modeled it only. If the first ADES AIM no longer manages the host, the host remains in its original container even though another ADES AIM is managing it. To move the host to the ADES Managed Hosts container for another ADES AIM (or another location in the topology), manually move the model.

  NOTE
  Use cut-and-paste to move a model manually.
- When an ADES AIM no longer manages a host, the host is moved from the ADES Managed Hosts container to the Lost and Found (LostFound). The following cases are exceptions:
  - Another ADES AIM is managing the host.
  - The host is in a global collection.
- When the IP or MAC address for a host model that ADES Manager manages is modified, connections to any connecting devices are automatically updated.

Deleting ADES Manager Models

Consider the following regarding deleting models in your DX NetOps Spectrum modeled environment:

- When ADES Manager no longer manages a host, the host model is removed from the ADES Managed Hosts container.

  NOTE
  Host models that are removed from ADES Manager management are moved to the Lost and Found (LostFound). An exception is when a host is in a global collection, in which case, the model remains in the global collection.
- You can delete host models from your DX NetOps Spectrum modeled environment; however, you cannot manually delete forests, domains, and roles. ADES Manager Discovery automatically deletes these models when they are no longer needed.
- If you delete a host model that an ADES AIM is managing, a new host model is created on the next ADES Manager Discovery. Any customizations made to the original model are lost.
- Hosts that both Virtual Host Manager and ADES Manager manage adhere to all the standard modeling behaviors of virtual machines. These models cannot be deleted from the topology.
- When an ADES Host Manager model is deleted, the corresponding ADES Managed Hosts container is destroyed. All models in the container (except for models in a global collection) are moved to the Lost and Found (LostFound). Any models that are moved manually into the container and are not necessarily Active Directory or Exchange Server hosts are also moved.
- The ADES Manager hierarchy synchronizes after the Lost and Found (LostFound) is emptied.

Deleting Models When Using Multiple AIM Solutions

If you use ADES Manager along with other DX NetOps Spectrum AIM solutions, consider the following points when deleting models in your environment:

- If you plan to no longer manage the host models using Virtual Host Manager, configure Virtual Host Manager delete settings to retain models. Otherwise, Virtual Host Manager deletes the host model initially, losing any history or customization. ADES Manager then recreates the host model during the next ADES Manager Discovery.

  NOTE
  The Virtual Host Manager setting to retain models when the technology manager is deleted applies to SNMP-enabled device models only. For ICMP (Pingable) models, Virtual Host Manager deletes the model, and then ADES Manager recreates the model.
- When Virtual Host Manager unmanages a host and the model is retained, ADES Manager automatically pulls the model into its management.
- If another solution no longer manages a host, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.
- When a higher ranking AIM solution no longer manages a host, the host model is removed from the respective solution containers. (Examples of higher ranking solutions are Virtual Host Manager or Cluster Manager.) If ADES Manager continues to manage the host, the model does not appear in the ADES Managed Hosts container automatically. To move the model into the ADES Managed Hosts container, cut and paste the model from the Lost and Found (or global collection, if applicable).

Updating Your Managed Environment

After the initial, automatic modeling of the Active Directory and Exchange Server environments, initiate ADES AIM Discovery manually to update DX NetOps Spectrum with any subsequent changes. Due to the potentially large size of the Active Directory and Exchange Server environments, dynamic updates would be expensive for the ADES AIM to

maintain. After ADES AIM Discovery completes, ADES Manager Discovery begins automatically, modeling changes in the environment as detected by the ADES AIM.

Discovery Process for Updating Your Modeled Environment

Discovery for ADES Manager consists of two phases:

1. Discovery by the ADES AIM identifies changes to your Active Directory and Exchange Server environment as reflected in the Global Catalogs. These hosts are made available for management in the ADES AIM.
2. Discovery by ADES Manager. This process uses the environment information that the ADES AIM gathers and the settings that the ADES AIM defines to update the DX NetOps Spectrum modeled environment. For a new host detected in a Global Catalog, the ADES AIM determines if the host is available to manage. This determination is based on the management entity for the domain. If the host can be managed, the ADES AIM then examines the management mode for its domain. Based on the management mode, the following behavior occurs:
   - In domain-based management, the host is set automatically to be managed. DX NetOps Spectrum models and begins monitoring the new host automatically.
   - In host-based management, the host is set automatically not to be managed. Specify explicitly to manage the host using the Universal Host Table so that DX NetOps Spectrum models and begins monitoring the new host.

     NOTE
     The determination of whether a host is managed or not managed applies to *newly detected* hosts only. A host that was previously detected in a Global Catalog and identified by the ADES AIM as available to manage retains its previous managed setting.

The next section describes how to update your DX NetOps Spectrum modeled environment.

How to Update Your Modeled Environment

The following steps describe how to update your modeled environment, which begins with initiating an ADES AIM Discovery.

NOTE
Only those users with the appropriate privileges can initiate ADES AIM Discovery. For more information, see the OneClick Administration section.

Follow these steps:

1. Select the ADES Host Manager model that supports the ADES AIM. The model has a device type of 'Active Directory and Exchange Server Host Manager.'
   The Component Detail panel displays information for the selected ADES Host Manager.
2. In the Information tab in the Component Detail panel, expand the Active Directory and Exchange Server (ADES) Management, Configuration subview.
   The expanded Configuration subview appears and displays information about when the last ADES AIM Discovery was run.
   - **Last Agent Inventory Update**
     Indicates the last time that an ADES AIM Discovery was performed or the last time a change was made to the ADES AIM inventory. The ADES AIM inventory is used for DX NetOps Spectrum modeling. Editing host management in the Universal Host Table is a direct way to alter the ADES AIM inventory.
   - **Last ADES AIM Discovery of Hosts**
     Indicates the last time that an ADES AIM Discovery was performed.
3. Click Run.

   WARNING
   Running an ADES AIM Discovery can require significant system resources on the ADES Host Manager.

The ADES AIM Discovery begins. Any change that is detected in your Active Directory and Exchange Server environment causes the following actions:

- Updates the forest, domain, and host information in the ADES AIM inventory.
- Updates the 'Last Agent Inventory Update' and 'Last ADES AIM Discovery of Hosts' timestamp values.
- Triggers an ADES Manager Discovery in DX NetOps Spectrum so that your modeled environment reflects any changes.

NOTE
If you are using host-based management and new hosts are introduced, manually specify to manage the hosts. See Specify Hosts to Manage by ADES AIM.

Alarms and Fault Management

Knowing about certain activities, such as a DAG failover, can minimize potential problems in your Active Directory and Exchange Server environment. To alert you, DX NetOps Spectrum generates alarms and uses advanced fault management techniques to isolate the root cause.

Problems with a single device can cause several other devices in your network to generate events. Deciding which devices are the root cause of an alarm can be challenging. For example, when you lose contact with the ADES Host Manager (the proxy manager), you also lose proxy communication with the hosts that it manages. As a result, alarms are generated for the ADES Host Manager and each of its managed hosts. Sifting through potentially hundreds of simultaneously produced alarms manually to pinpoint the problem could be a tedious and error-prone process. Using fault isolation techniques, ADES Manager significantly simplifies the troubleshooting process by automatically correlating these alarms to identify a single root cause. As a result, you can identify and correct the problem more quickly.

ADES Manager evaluates which devices are issuing alarms and the type of events that devices generate. DX NetOps Spectrum uses all available information to correlate the alarms to the appropriate root cause, only alarming on the isolated faulty device. ADES Manager relies on the combination of standard DX NetOps Spectrum monitoring, proxy management, and traps to create meaningful events and alarms.

ADES Manager Alarms

To alert you to problems within your monitored Active Directory and Exchange Server environments, ADES Manager generates alarms for the following conditions:

- Active Directory or Exchange Server proxy communication lost, which indicates that updated Active Directory or Exchange Server metrics can no longer be obtained.
- ADES Host Manager (ADES AIM) down or communication lost

Traps

DX NetOps Spectrum supports many of the traps that the ADES AIM generates. Trap activity generates an event in DX NetOps Spectrum and is reported initially on the ADES Host Manager model. Some events are then forwarded to a corresponding entity type (that is, the "destination" entity), depending on the type of trap.

The following table provides the traps and destination entity type and indicates whether the trap generates an alarm by default.

Trap Name	Trap OID	Alarm?	Destination Entity
exchAdForestAddedTrap	1.3.6.1.4.1.546.1.1.0.166100	No	ADES Host Manager

exchAdForestRemovedTrap	1.3.6.1.4.1.546.1.1.0.166101	No	ADES Host Manager
exchAdDomainAddedTrap	1.3.6.1.4.1.546.1.1.0.166102	No	ADES Host Manager
exchAdDomainRemovedTrap	1.3.6.1.4.1.546.1.1.0.166103	No	ADES Host Manager
exchAdManagedHostAddedTrap	1.3.6.1.4.1.546.1.1.0.166104	No	ADES Host Manager
exchAdManagedHostRemovedTrap	1.3.6.1.4.1.546.1.1.0.166105	No	ADES Host Manager
exchAdManagedHostPollStatusChangedTrap	1.3.6.1.4.1.546.1.1.0.166106	No*	ADES Host Manager
exchAdDomainControllerAddedTrap	1.3.6.1.4.1.546.1.1.0.166107	No	ADES Host Manager
exchAdDomainControllerRemovedTrap	1.3.6.1.4.1.546.1.1.0.166108	No	ADES Host Manager
exchAdDagAddedTrap	1.3.6.1.4.1.546.1.1.0.166109	No	ADES Host Manager
exchAdDagRemovedTrap	1.3.6.1.4.1.546.1.1.0.166110	No	ADES Host Manager
exchAdHostAddedToDagTrap	1.3.6.1.4.1.546.1.1.0.166111	No	ADES Host Manager
exchAdHostRemovedFromDagTrap	1.3.6.1.4.1.546.1.1.0.166112	No	ADES Host Manager
exchAdDagFailOverTrap	1.3.6.1.4.1.546.1.1.0.166117	Yes	ADES Host

* The polling intelligence handles the alarm generation.

NOTE
For more information on ADES AIM traps, use MIB Tools to view the empireExchangeAdMIB MIB. For more information, see the Modeling and Managing Your IT Infrastructure section.

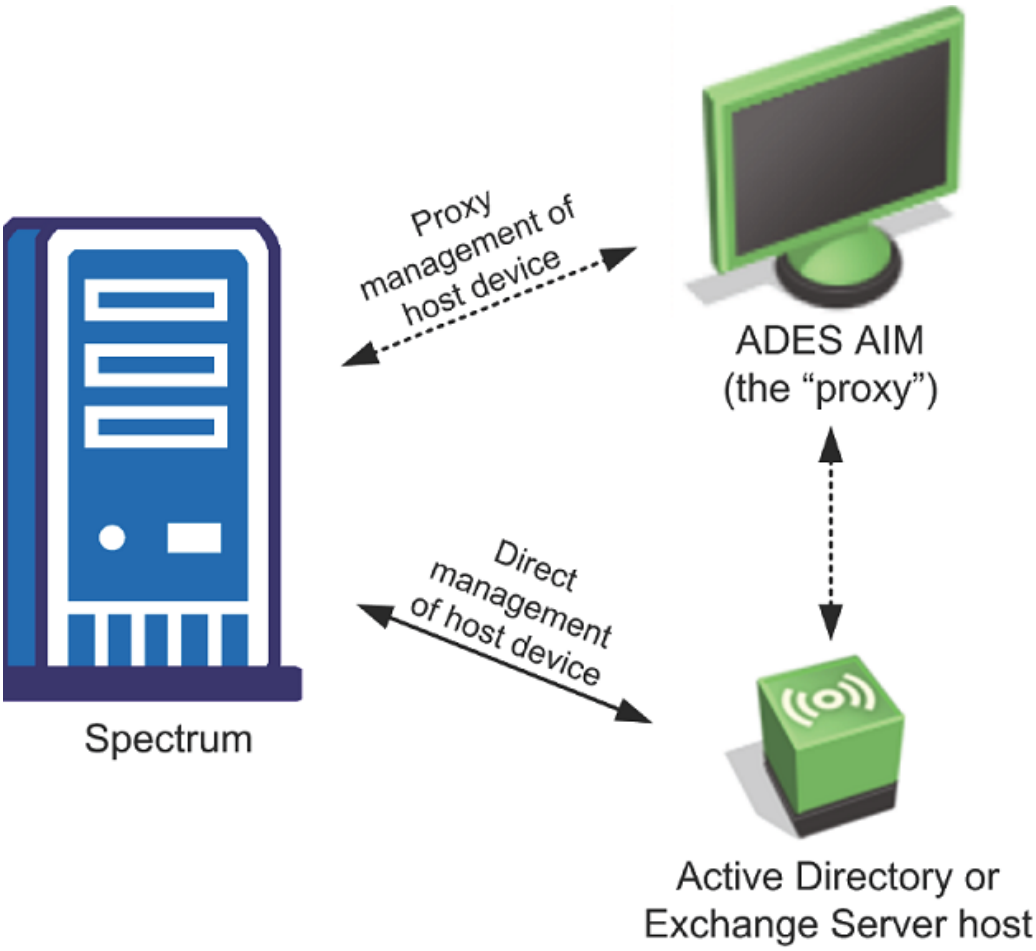
Proxy Management

Hosts that the ADES AIM manages provide a unique management opportunity. They provide DX NetOps Spectrum an alternate management perspective in addition to standard device monitoring methods.

Proxy management is the management of a device by way of an alternate source (such as the AIM) rather than from the device itself. The ADES AIM serves as a "proxy" from which DX NetOps Spectrum gathers information specific to the Active Directory and Exchange Server technologies.

Using standard monitoring, DX NetOps Spectrum gathers information directly from a device. Using proxy management, DX NetOps Spectrum also simultaneously gathers Active Directory and Exchange Server metrics for your managed hosts from the ADES AIM. These metrics include information that is specific to each server role, which cannot be obtained through standard monitoring.

NOTE
The ADES AIM is not a Proxy Model as defined by DX NetOps Spectrum Modeling Information. For information about models that are designated as a Proxy Model, see the Modeling and Managing Your IT Infrastructure section.



Standard DX NetOps Spectrum fault management handles this dual management in two ways:

- **Proxy management alarms.** By using the ADES AIM for management, proxy-related alarms can be generated. These alarms are unique because they alert you when the acquisition of Active Directory or Exchange Server metrics through the proxy is affected, not the state of the device or direct (SNMP) management. Knowing when contact through the proxy is lost is important because you could be missing important server role information about your environment. Proxy management alarms are of major severity and are not clearable by the user.
  - **Proxy unavailable** - When DX NetOps Spectrum cannot communicate with the ADES AIM, a proxy unavailable alarm is generated on the ADES Host Manager model.
    The following text is used for the proxy unavailable alarm:
    ```
    ACTIVE DIRECTORY AND EXCHANGE SERVER MANAGER UNAVAILABLE
    ```
  - **Proxy lost** - When DX NetOps Spectrum cannot obtain information about the managed host by way of the proxy, then a proxy lost alarm is generated. For example, when DX NetOps Spectrum cannot communicate with the ADES Host Manager model, DX NetOps Spectrum generates a proxy unavailable alarm. DX NetOps Spectrum also generates a proxy lost alarm for each of the hosts that the ADES Host Manager manages. As another example, DX NetOps Spectrum also generates a proxy lost alarm when the ADES AIM cannot successfully communicate with a managed host.
  - The following text is used for the proxy lost alarm:
    ```
    ACTIVE DIRECTORY AND EXCHANGE SERVER HOST PROXY LOST
    ```
    A proxy lost alarm is generated only for hosts that ADES Manager manages. If the host is removed from management by the proxy, the respective proxy management alarms are cleared. If more than one ADES AIM

manages a host, multiple proxy lost alarms are generated for the managed host, one per ADES Host Manager model.

NOTE
Manage a host by a single ADES AIM only.

- **Enhanced contact lost alarms.** DX NetOps Spectrum alarms that indicate loss of contact with the ADES Host Manager contain added correlation of ADES Manager proxy management alarms. These proxy management alarms indicate loss of Active Directory and Exchange Server metrics acquisition.
  The following text is used for the contact lost alarm:
  ```
  DEVICE HAS STOPPED RESPONDING TO POLLS
  ```

Alarm Correlation

Using standard DX NetOps Spectrum fault management and proxy information, ADES Manager automatically correlates the alarms to identify a single root cause. Proxy unavailable alarms on an ADES Host Manager model are correlated to any of the following alarms on the model:

- Contact lost
- Maintenance
- Hibernation
- Management lost

Also, the proxy lost alarms, which are generated upon creation of a proxy unavailable alarm, are correlated to the proxy unavailable alarm.

NOTE
You can find out more about alarms that are correlated or symptomatic by using the Impact tab for the alarm.

The scenarios in the next section provide details about generated alarms, what they indicate, and how they are correlated.

ADES Manager Fault Management Scenarios

The following scenarios describe how ADES Manager attempts to determine the root cause in different fault management situations.

Scenario: Contact between DX NetOps Spectrum and ADES AIM is lost

When DX NetOps Spectrum cannot communicate with ADES AIM, DX NetOps Spectrum loses information about the Active Directory and Exchange Server environment the AIM manages. To isolate the problem, ADES Manager determines the root cause as follows:

1. When DX NetOps Spectrum cannot communicate with the ADES AIM, a proxy unavailable alarm is generated on the ADES Host Manager model. For example, DX NetOps Spectrum cannot communicate with a device when the device is in maintenance or hibernation mode. The reason for the unavailability is identified through the event producing the alarm.

   NOTE
   Proxy management alarms are generated even when their models are in maintenance mode. These alarms are not visible in the Alarm view by default.
2. DX NetOps Spectrum cannot obtain information from the ADES AIM about any of the hosts it manages. As a result, proxy lost alarms are generated for each of the hosts that this AIM manages.
3. The proxy lost alarms are correlated to the proxy unavailable alarm as symptoms, which indicate that the proxy unavailable alarm is the root cause.
4. If DX NetOps Spectrum cannot communicate with the ADES Host Manager, one of the following standard DX NetOps Spectrum communication impairment alarms is also generated:

- Contact lost
- Maintenance
- Hibernation
- Management lost

5. Finally, the proxy unavailable alarm is correlated to the standard communication alarm forming a three-tiered hierarchy of alarm correlation: communication - proxy unavailable - proxy lost. Only the top-level communication alarm indicating the reason why DX NetOps Spectrum cannot communicate with the ADES AIM is visible to the user. This alarm indicates the root cause.

Scenario: Contact between ADES AIM and Active Directory or Exchange Server host is lost

If the ADES AIM loses contact with a managed host, it can no longer obtain Active Directory and Exchange Server metrics for that host. This situation creates outdated or "stale" values in the ADES AIM. As a result, a proxy lost alarm is generated for the host.

Scenario: Active Directory or Exchange Server host is down

When an Active Directory or Exchange Server host is down, DX NetOps Spectrum uses information from both the proxy and directly from the host. DX NetOps Spectrum handles this scenario as follows:

1. Because the management of the device by the ADES AIM is lost, a proxy lost alarm is generated.

   NOTE
   Manage a host by a single ADES AIM only. If, inadvertently, multiple ADES AIMs manage the host, multiple proxy lost alarms are generated. Proxy alarms are generated for each managing ADES Host Manager model.
2. Through direct or standard DX NetOps Spectrum fault management, a contact lost alarm is generated for the managed host.

Both the contact lost alarm and proxy lost alarm is visible to the user. The appearance of both alarms indicates that the proxy and direct methods of communication to the host are impacted.

Troubleshooting ADES Manager

This section describes some of the most common problems that occur with ADES Manager.

SystemEDGE Host Not Modeled as ADES Host Manager

Symptom:

After I model the SystemEDGE host with the ADES AIM installed, the created model is not configured as an ADES Host Manager. I am using the ADES AIM r12.7 with the latest PTFs installed (or later).

Solution:

The ADES AIM must complete its initialization and must have a ready status before DX NetOps Spectrum recognizes it as an ADES Host Manager. If you model the SystemEDGE host after the agent starts but before the ADES AIM finishes loading, the host is not modeled correctly.

To convert the existing SystemEDGE host model to an ADES Host Manager, perform the following procedure.

Follow these steps:

1. Wait for the ADES AIM to complete its initialization and reflect a ready status.
   You can use MIB Tools or another MIB browser to query the SystemEDGE host and view the exchAdAgentStatus variable in the empireExchangeAdMIB MIB. A value of "ready" indicates that initialization is complete.

NOTE
For more information on MIB Tools, see Certifications section.

2. Right-click the SystemEDGE host (Host_systemEDGE) model and select Reconfiguration, Reconfigure Model.
   The SystemEDGE host model is reconfigured as an ADES Host Manager.

Duplicate Models Created After Discovery

Symptom:

After ADES Manager Discovery runs, I see duplicate models in the ADES Manager hierarchy for some of the hosts in my modeled environment.

Solution:

Manage a host by a single ADES Host Manager. If, inadvertently, multiple ADES Host Managers residing in different landscapes are managing a host, duplicate models are created. One host model is created for each landscape where an ADES Host Manager is managing the host. To resolve duplicate models, use the following procedure.

Follow these steps:

1. Search for the host in each landscape. If a host is present:
   a. Unmanage the host in each ADES Host Manager in the landscape by using the Universal Host Table subview.
   b. (optional) After modifying the UHT subview, reconfigure the corresponding ADES Host Manager device to expedite its unmanagement process.
2. Repeat step 1 for every ADES Host Manager across all landscapes except one.

Multiply Managed Alarms

Symptom:

I do not see duplicate hosts in my ADES Manager hierarchy. But, I am getting an alarm on an Active Directory or Exchange Server host with the title "ACTIVE DIRECTORY AND EXCHANGE SERVER HOST MULTIPLY MANAGED".

Solution:

Manage a host by a single ADES Host Manager. If, inadvertently, multiple ADES Host Managers residing in the same landscape are managing a host, this alarm is generated. To avoid multiply managed alarms, use the following procedure.

Follow these steps:

1. Locate the landscape in which the host resides, and do the following steps:
   a. Unmanage the host in each ADES Host Manager in the landscape by using the Universal Host Table subview.
   b. (optional) After modifying the UHT subview, reconfigure the corresponding ADES Host Manager device to expedite its unmanagement process.
2. Repeat step 1 for every ADES Host Manager except for one.
   The alarm automatically clears when a single ADES Host Manager manages the Active Directory or Exchange Server host.

Connections Do Not Appear in Topology

Symptom:

My Active Directory and Exchange Server hosts are not showing connections to other devices in the OneClick topology view.

Solution:

To produce connections between your hosts and the rest of the network, models for any connecting devices must exist before the hosts are modeled.

When discovering and modeling your environment, run a standard DX NetOps Spectrum Discovery first to model upstream routers and switches. Then, ADES Manager Discovery can run, creating models and connections for the Active Directory and Exchange Server components.

To create connections for managed hosts, use the following procedure.

Follow these steps:

1. Verify that devices such as routers and switches that are upstream from your Active Directory and Exchange Server environment are modeled. If not, run a standard DX NetOps Spectrum Discovery to model these connecting devices.
2. If the connecting devices are modeled after your Active Directory and Exchange Server environment is modeled, run Discover Connections on each of the affected devices.

   NOTE
   For information on Discover Connections, see the Modeling and Managing Your IT Infrastructure section.

ADES Managed Hosts Container Not Created

Symptom:

I have modeled an ADES Host Manager, but I do not see a corresponding ADES Managed Hosts container being created for it.

Solution:

DX NetOps Spectrum ADES Manager requires ADES AIM r12.7 or later. Verify that ADES AIM r12.7 or later is running on the ADES Host Manager.

Host Not in ADES Managed Hosts Container

Symptom:

My ADES Managed Hosts container was created but, when I look inside, an expected Active Directory or Exchange Server host is not there.

Solution:

Hosts that were modeled before ADES Manager Discovery are not moved in the topology when brought into management by ADES Manager. To locate the expected host, look in other possible locations in the landscape for the model. In particular, if the Active Directory or Exchange Server host is a virtual machine, it is located in the physical host container.

Unable to Update Attribute

Symptom:

I get the following error when I try to manage or unmanage an Active Directory or Exchange Server host in the Universal Host Table subview:

```
Unable to update attribute exchAdUniversalHostManagedByAgent.  No response from the device.
```

Solution:

The ADES Manager Host must be modeled with a read/write community string. If not, you cannot update the model. To resolve this problem, change the community string of the ADES Host Manager to its read-write value. The SNMP Community String is on the DX NetOps Spectrum Modeling Information subview for the ADES Host Manager model.

Host Subview is Empty

Symptom:

A role-specific subview for my Active Directory or Exchange Server host does not contain any data.

Solution:

A role-specific subview contains data only when the host supports the respective role. Verify that the host supports the role whose data the subview is displaying. Subviews for unsupported roles are empty. For mailbox servers, also verify that the host supports the correct Exchange version, 2007 or 2010; the subview for the unsupported version is empty.

Changes in Environment Not Reflecting

Symptom:

When I modify my Active Directory or Exchange Server environment, the change is not reflected in my modeled environment. For example, after I add or remove a host, I do not see a difference in DX NetOps Spectrum.

Solution:

An ADES AIM Discovery must be run manually before the ADES AIM detects the environment change and models it in DX NetOps Spectrum. To update your modeled environment in DX NetOps Spectrum, initiate the ADES AIM Discovery process manually. ADES AIM Discovery then triggers ADES Manager Discovery, which reflects any changes in DX NetOps Spectrum.

ADES Manager Updates are Slow

Symptom:

The data specific to the Active Directory and Exchange Server technologies is not updating as frequently as I expect it to.

Solution:

Data update delays in DX NetOps Spectrum ADES Manager can be due to ADES AIM performance issues. The number of hosts that the ADES AIM manages can affect performance. The geographic proximity of the ADES AIM to the monitored environment can also affect performance. These factors can contribute to long poll times.

To improve performance by the ADES AIM, use the following procedure.

Follow these steps:

1. Verify that the polling interval is set appropriately.
2. If the polling interval is set as expected, the ADES AIM possibly can be overloaded or located too far from the managed hosts. Check that the recommended limits and configuration for the ADES AIM are adhered to.

   NOTE
   For information on load balancing and sizing guidelines for the ADES AIM, see the *CA Virtual Assurance for Infrastructure Managers* (CA VAIM) documentation.

Cluster Manager

This section explains how DX NetOps Spectrum monitors and manages IBM PowerHA and Microsoft Cluster Service environments.

Introduction to Cluster Manager

Cluster Manager is a DX NetOps Spectrum feature that models and monitors your cluster environment and is intended for administrators. Cluster Manager provides an enterprise-wide view of your cluster environments, showing both topology and the logical relationships among your cluster components. Cluster Manager also provides visibility into useful metrics and helps you pinpoint and effectively troubleshoot problems by applying unique fault isolation techniques.

A key challenge when monitoring your cluster environment is tracking where work is occurring, or identifying the active nodes. Clustering technology is designed to sustain high availability for your server-based applications by providing a fail-safe environment. Resource groups move from one cluster node to another when needed, resulting in the distribution of work and node status changing periodically. Cluster Manager keeps up with these activities by continuously monitoring your cluster components, and quickly notifies you of any changes to your environment.

Cluster Manager Features

Cluster Manager includes the following features:

- Automated device discovery and modeling. Cluster Manager automatically creates models and connections for all managed cluster components, as appropriate.
- A distributed solution that can handle scaling. Cluster management can be distributed across multiple SpectroSERVERs.
- Identification of cluster components in the topology.
- Hierarchical representation of cluster environments.
- Icons that distinguish devices in your cluster environment, including distinct identification of active and inactive nodes.
- Dedicated Cluster Manager views that provide visibility into data specific to cluster environments and respective technologies.
- Events and alarming on cluster entities and activities, provided out-of-box.
- Enhanced fault management. Cluster Manager recognizes and correlates symptomatic alarms and aids fault isolation with proxy management.
- Locater searches specific to cluster components.
- Consistent representation across all supported cluster technologies.

Supported Technologies

Cluster Manager supports the following cluster technologies when all required components are installed and configured properly per solution, as follows:

- **IBM PowerHA**
- 9.2.3 or later
- A dedicated host machine with:
  - SystemEDGE 5.x or later
  - High Availability Cluster Multiprocessing (HACMP) AIM r12.7 or later

    WARNING
    The HACMP AIM must be the only AIM installed on the SystemEDGE host. The SystemEDGE host itself cannot be a node in your managed cluster environment.
- **Microsoft Cluster Service (MSCS)**
- 9.2.3 or later
- A dedicated host machine with:
  - SystemEDGE 5.x or later
  - MSCS AIM r12.7 or later

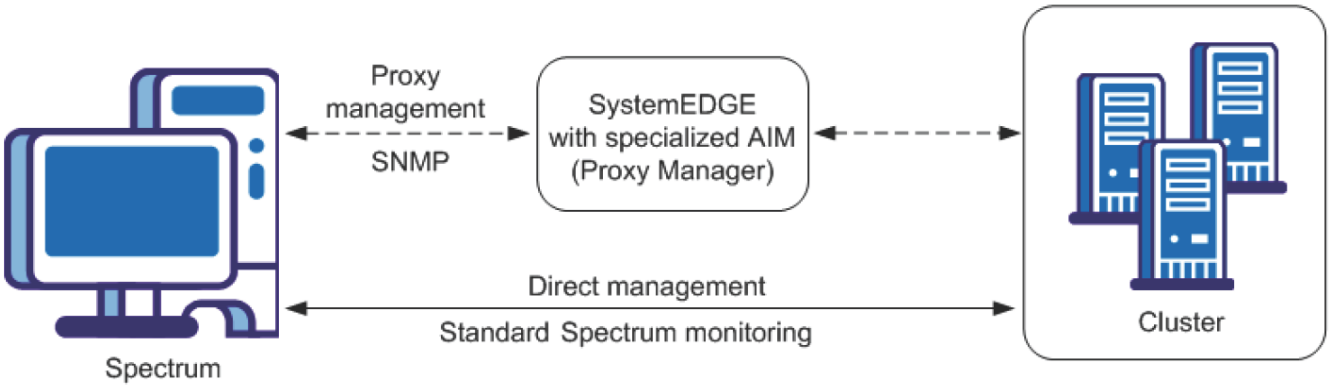
WARNING
The MSCS AIM must be the only AIM installed on the SystemEDGE host. The SystemEDGE host itself cannot be a node in your managed cluster environment.

NOTE
For more information about the SystemEDGE agent and AIM system requirements, see the CA Virtual Assurance for Infrastructure Managers section.

Solution Architecture for Managing Cluster Environments

Cluster Manager monitors your cluster components seamlessly within your network, while providing data that is specific to cluster technologies. DX NetOps Spectrum gathers information about your cluster components using two different methods. As with other DX NetOps Spectrum-managed devices, Cluster Manager uses standard DX NetOps Spectrum monitoring. In addition, Cluster Manager also retrieves specialized information from an alternate (proxy) manager, the SystemEDGE Application Insight Module (AIM).

An AIM is a specialized extension of the SystemEDGE agent and resides on its own host. The proxy manager communicates directly with entities in your cluster environment. DX NetOps Spectrum then uses SNMP to retrieve this information from the proxy manager and uses it to model and monitor your cluster components in OneClick.



The AIMs that work with Cluster Manager include:

- **High Availability Cluster Multiprocessing (HACMP) AIM**
  Provides capabilities to monitor your IBM PowerHA cluster environment.
- **Microsoft Cluster Service (MSCS) AIM**
  Provides capabilities to monitor your Microsoft Cluster Service environment.

NOTE
For more information about the SystemEDGE agent and AIMs, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Cluster Concepts

Administrators organize resources into functional units that are called resource groups, and assign these groups to individual nodes. If a node fails, the resource groups that were being hosted on a particular node move to other nodes in the cluster.

The following terms describe these components of a cluster environment and appear in the Cluster Manager solution:

- **Cluster**

A group of locally attached machines that provide distributed processing power and high availability. A cluster appears to clients as a single system image and IP address.

- **Node**
  An independent computer system that participates in a cluster.
  - **Active node**
    A system in a cluster environment where application processes (as part of a resource group) are currently running. Within Cluster Manager, an active node has resource groups as children.
  - **Inactive node**
    A system that is allocated to a cluster but not currently processing any resources. Within Cluster Manager, an inactive node does not have any resource groups as children.
- **Resource group**
  A collection of resources that forms a functional unit existing on a single node.
- **Resource**
  A logical component or entity that runs on only one node at a time. Resources encompass all elements needed for an application, such as network interfaces, disks, file systems, and application software.
- **Migration**
  Movement of a resource group from one node to another. Different terms are used regarding migration depending on the cluster technology; for example, failover, fall over, failback, and fallback.

Getting Started with Cluster Manager

This section provides the information to get started with understanding your cluster environment, the modeling process, installing the Cluster Manager. This section also provides information about how your cluster environment is organized in OneClick for visibility and management, and cluster fault management is also explained.

NOTE
Unless otherwise noted, the information in this section applies to all supported cluster technologies.

Planning Your Implementation

The purpose of Cluster Manager is to monitor your cluster components and notify you of various activities in your environment. Cluster Manager is highly scalable and can manage cluster nodes under different technologies using multiple AIMs across distributed SpectroSERVERs. Understanding how DX NetOps Spectrum manages the models for the components in your cluster environment provides for a more efficient Cluster Manager implementation.

Before you set up Cluster Manager, review the following topics:

- Environment Management Considerations
- Modeling

Environment Management Considerations

During setup of Cluster Manager, you specify how to organize the management of your environments. With a small environment, you can have a single AIM managing all of your cluster nodes (by vendor) in a single location on one SpectroSERVER. In a complex environment, you can have multiple AIMs across multiple SpectroSERVERs managing various cluster environments in different locations using different vendors.

Although organizational specifications can be changed at any time, knowing the available configuration options allows for a better initial setup.

Consider the following points when setting up your Cluster Manager environment:

- AIMs for Cluster Manager are vendor-specific. If you use cluster technologies from more than one vendor, you need multiple AIMs and dedicated SystemEDGE hosts.
- Each AIM can manage more than one cluster.
- Management of your cluster environment can be distributed across multiple AIMs, which can be supported in a single landscape or across multiple SpectroSERVERs.
- Management of each cluster can be by one cluster technology AIM only.

When deciding how to distribute management of your cluster environment, consider the number and location of nodes in your environment. The number of cluster nodes an AIM manages and the geographic proximity of the AIM to the monitored environment can affect performance. For best performance, size and balance management of the environment appropriately.

NOTE
The clusters that a particular AIM manages are controlled on the AIM and not in DX NetOps Spectrum. For information about defining nodes to manage by an AIM, see the CA Virtual Assurance for Infrastructure Manager section.

Modeling

As with other network elements supported in DX NetOps Spectrum, you discover and model the components of your cluster environment to monitor them. Cluster Manager obtains information about the clusters and nodes to manage from the AIM. DX NetOps Spectrum then uses this information to model each component using AutoDiscovery.

NOTE
Information that is used for the Cluster Manager feature is gathered primarily from the proxy manager (AIM). Additional information is also gathered directly from the nodes.

NOTE
The following topics provide more details about the modeling process:

- What Is Modeled
- Modeling Methods
- Node Management and Multiple Cluster AIMs
- Node Management and Multiple DX NetOps Spectrum AIM Solutions

What Is Modeled

Using information provided in the AIM MIB, DX NetOps Spectrum extracts and models any clusters, nodes, resource groups, and resources that the AIM manages.

Modeling Methods

Cluster nodes are modeled as SNMP-managed elements when possible. SNMP modeling supports enriched device monitoring that can provide added value to your Cluster Manager solution. If an SNMP agent is not installed on the host, it is modeled as an ICMP (Pingable) device.

Model Naming

When modeling cluster nodes, the model name assigned in DX NetOps Spectrum depends on the type of modeling used, as follows:

- For SNMP modeling, DX NetOps Spectrum automatically attempts to supply a name for the model using standard DX NetOps Spectrum naming conventions. Automatic naming is controlled at the SpectroSERVER level by the Model Naming Order value. This field is on the SpectroSERVER Control view for the VNM model.
- For ICMP (Pingable) modeling (when not a virtual device), DX NetOps Spectrum uses the host name provided in the AIM.

WARNING
For ICMP (Pingable) modeling, model names that DX NetOps Spectrum Virtual Host Manager sets take precedence over Cluster Manager.

The administrator can modify the name of a cluster node model at any time. As with other managed network elements, DX NetOps Spectrum automatically updates the model name using established naming rules, which can replace the user-defined value. To retain a user-defined value, lock the model name.

NOTE
You can modify and lock the cluster node model name using the following model attributes: Model_Name (0x1006e) and Lock_Model_Name (0x12a52).

IP Address and MAC Address Determination

When modeling cluster nodes, the IP address and MAC address assigned in DX NetOps Spectrum depend on the type of modeling used, as follows:

- For SNMP modeling, DX NetOps Spectrum automatically attempts to determine the addresses by querying the resident SNMP agent.
- For ICMP (Pingable) modeling (when not a virtual device), DX NetOps Spectrum uses the addresses that the AIM provides.

WARNING
For ICMP (Pingable) modeling, addresses that DX NetOps Spectrum Virtual Host Manager sets take precedence over Cluster Manager.

If the SNMP modeling or Virtual Host Manager cannot supply a valid IP address or MAC address, the AIM value is used.

Node Management and Multiple Cluster AIMs

Manage a cluster node by a single cluster technology AIM only. If you inadvertently manage a cluster node by multiple cluster technology AIMs, Cluster Manager issues the following alarm on the cluster model:

```
UNSUPPORTED CLUSTER AIM CONFIGURATION
```

Children are not created for the cluster model.

Node Management and Multiple DX NetOps Spectrum AIM Solutions

When managing a cluster node model by multiple DX NetOps Spectrum AIM solutions, a defined ranked order of management applies, as follows:

1. Virtual Host Manager
2. Cluster Manager
3. Other technologies (such as Active Directory and Exchange Server Manager)

When a node with a SystemEDGE agent is already modeled in DX NetOps Spectrum, Cluster Manager recognizes the model and a duplicate model is not created. Instead, Cluster Manager pulls the existing model into its own management, abiding by and applying the rules of each solution in the ranked order.

For example, when both Virtual Host Manager and Cluster Manager are managing a node, model parameters that Virtual Host Manager assigns are used. Examples of these parameters include the model name, IP address, and MAC address.

If a node is removed from management by a solution, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.

This defined order of management also affects how models appear in the Universe topology.

How to Install Cluster Manager

When you install DX NetOps Spectrum, the Cluster Manager components are automatically installed and available for use. However, Cluster Manager is operable only after you also install and configure the appropriate proxy manager for your solution.

Refer to the respective section for your solution.

Cluster Manager Discovery and Modeling

After the necessary components have been installed, discover and model any entities that Cluster Manager is going to manage.

Cluster Manager uses the following types of discovery:

- Standard DX NetOps Spectrum Discovery to model the cluster technology AIM and connecting devices
- Cluster Manager discovery to model cluster components

After the cluster technology AIM is modeled successfully, Cluster Manager obtains information about the cluster components in your environment from the AIM. Using a list of machines that is obtained from the AIM, Cluster Manager uses AutoDiscovery to model each cluster node. All supporting cluster components (clusters, resource groups, and resources) are also modeled.

Cluster Manager models cluster nodes as SNMP-managed when possible and when AutoDiscovery parameters are set up correctly.

> **NOTE**
> For information about AutoDiscovery control settings, see the Modeling and Managing Your IT Infrastructure section.

The information provided in this topic applies to all cluster technologies. For more details, refer to the respective section for your solution.

How to Model Your Environment When Using Multiple AIM Solutions

Depending on your environment, you can use Cluster Manager in combination with other DX NetOps Spectrum AIM solutions simultaneously to manage your network entities. Any of the following configurations require the use of multiple solutions for complete management of your environment:

- A cluster node runs on a virtual machine.
- A cluster technology AIM runs on a virtual machine.
- A cluster node is an Active Directory or Exchange Server host.

Each of the DX NetOps Spectrum AIM solutions provides information that is specific to the technology it supports. For example:

- Virtual Host Manager provides details that are specific to virtual technologies.
- Cluster Manager provides details that are specific to cluster technologies.
- Active Directory and Exchange Server Manager (ADES) Manager provides details that are specific to the supported server roles in Active Directory and Exchange Server.

The combination of these features provides a complete monitoring solution. To set up your implementation of multiple AIM solutions effectively, the following approach is recommended.

> **WARNING**
> When using multiple AIMs, only a single AIM can be installed on a given SystemEDGE host.

Follow these steps:

1. Configure the AutoDiscovery settings on the VNM model.
2. Configure the Virtual Host Manager settings that are related to your virtual technology.
3. Set up Virtual Host Manager by modeling the virtual technology manager and all virtual technology components.
4. Set up Cluster Manager by modeling the cluster technology manager and all cluster components.
5. Set up ADES Manager by modeling the ADES Host Manager and all Active Directory and Exchange Server hosts.

NOTE
For more information, see the Virtual Host Manager section and the Active Directory and Exchange Server Manager section.

Viewing Your Cluster Environments

The purpose of Cluster Manager is to provide visibility into your cluster environments. This visibility lets you identify the organization of your environment, where resource groups are allocated, and the status of each node. Most importantly, when a problem occurs in your environment, you can pinpoint its cause.

Cluster Manager provides several methods for viewing your cluster environments, as follows:

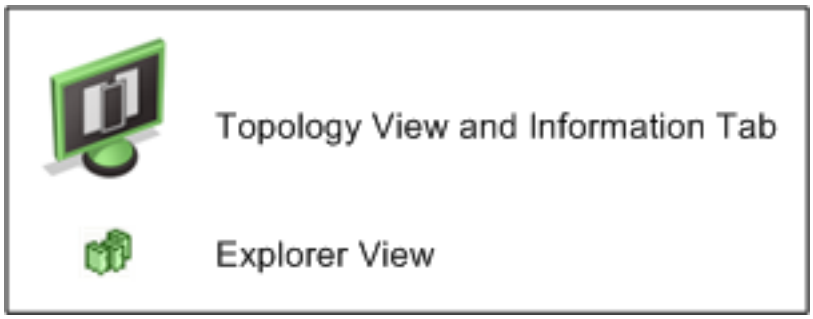
- The Cluster Manager hierarchy in the Navigation panel indicates the logical relationships between components. Examples of hierarchy nodes include clusters, cluster nodes, resource groups, and resources.
- A graphical topology view helps you to group cluster nodes and visualize the connections between them.
- Custom Information views in the Component Detail panel provide details that are specific to cluster technologies and specific vendors.
- Custom searches provide a quick way to find cluster elements.
- Custom icons for individual models provide status and model type information at a glance and are integrated throughout the Cluster Manager feature.

Understanding each of these methods can help you monitor your cluster environments more efficiently, letting you troubleshoot issues more effectively.

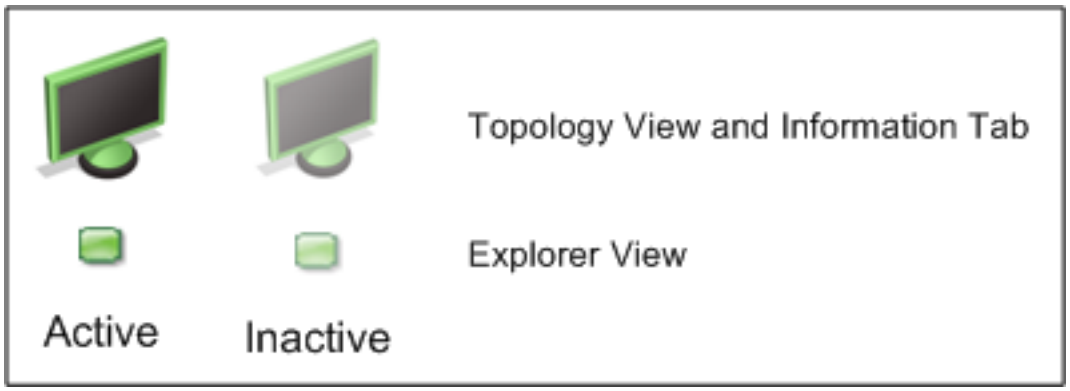
Icons for Cluster Manager

Cluster Manager provides icons that are designed specifically to distinguish devices in your cluster environment. The same icons are used across all cluster vendor technologies.

- **Cluster**
  Cluster icons have a distinctive cluster pattern, representing three workstations that are clustered together, as follows:

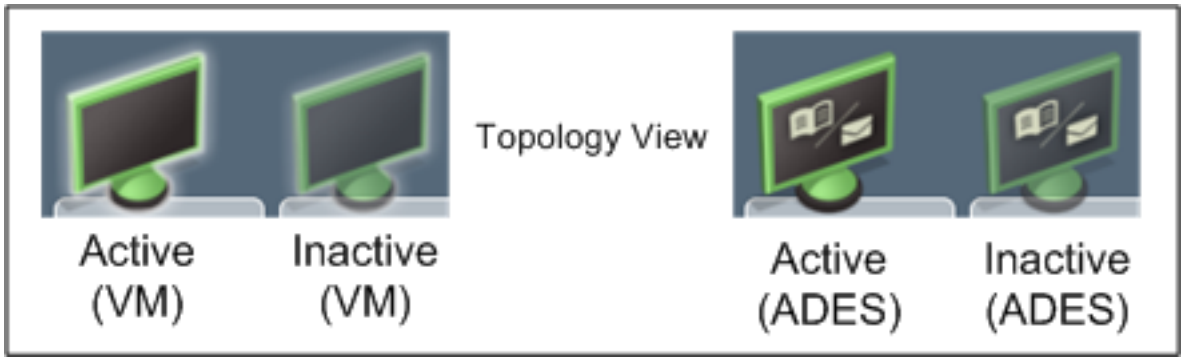


- **Cluster Node**
  Cluster nodes use standard workstation icons. An active node has a solid (nontransparent) representation whereas an inactive node is faded (transparent), as follows:



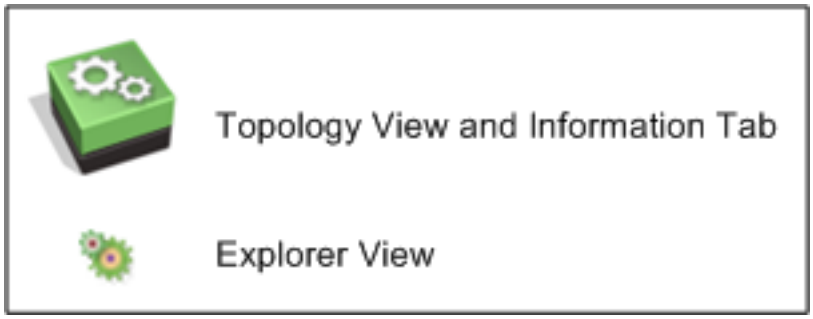
The icon also reflects when Cluster Manager is used in combination with other DX NetOps Spectrum AIM-based solutions. The following example shows:

– An active node and an inactive node in the topology where both nodes are virtual machines that Virtual Host Manager manages. Notice that the virtual halo is brighter for the active node.
– An active node and an inactive node in the topology where both nodes are Active Directory or Exchange Server hosts.



Note: When an inactive node is used with the spotlighting feature, the icon becomes even more transparent.

- **Resource Group**
  Resource groups have an icon that has multiple gears, as follows:



- **Resource**
  Resources have an icon that has a single gear, as follows:

NOTE
Resources are not displayed in the topology view.

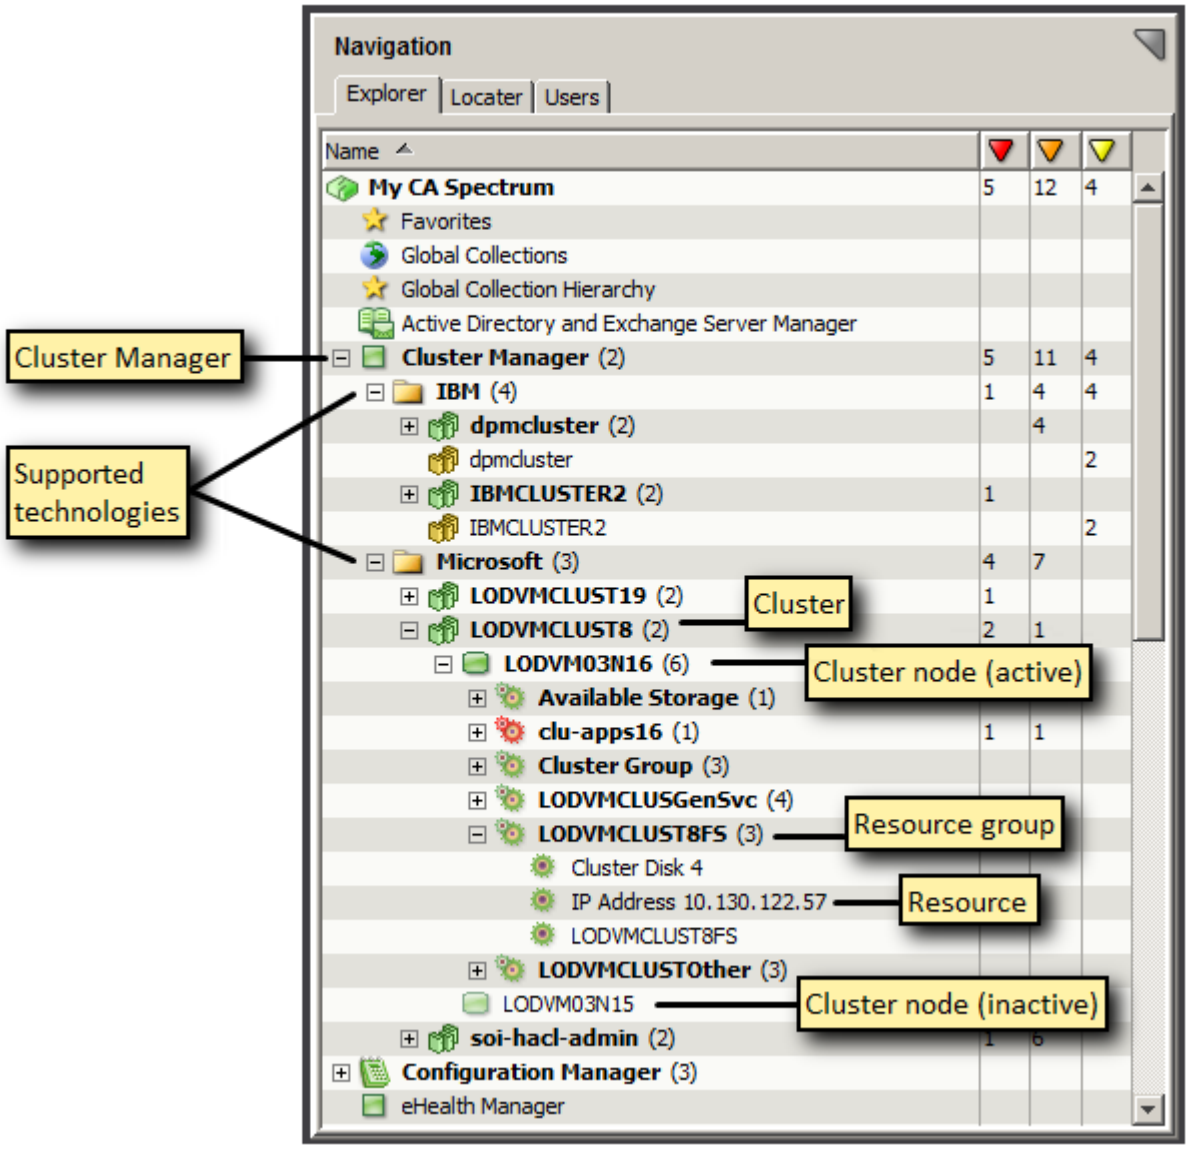
Explorer View

On the Explorer tab of the Navigation panel, Cluster Manager provides a hierarchical tree structure that illustrates the logical organization of your managed cluster environments. Custom icons provide status and model type information for your cluster components at a glance.

Using this information, you can see how the clusters and respective resources are arranged logically in your environment and where they are active.

NOTE
Only users with the appropriate privileges and model security access can view the Cluster Manager hierarchy and components. For more information, see the OneClick Administration section.

The following image is an example of the Cluster Manager hierarchy:



The following elements form the hierarchy. When an element in the hierarchy has children, the label is in bold.

- Cluster Manager
  Denotes the root for the cluster environments that are currently managed. Cluster Manager is a distributed solution that handles multiple landscapes and so appears above the landscape level. Expanding the Cluster Manager element displays the technologies that are supported. The clusters and participating cluster components for each technology are also presented, as depicted in the following diagram:

```
[-] Cluster_technology_1
    [-] Cluster_1
        [-] Cluster_node_1 (active)
            [-] Resource_group_1
                . Resource 1
                . Resource 2
                . Resource 3
            Cluster_node_2 (inactive)
```

```
            Cluster_node_3 (inactive)
      [+] Cluster 2
  [+] Cluster_technology_2
```

NOTE
Only those solutions for which a respective AIM has been installed appear in your implementation. The AIM itself does not appear in the Cluster Manager hierarchy. The Cluster Manager (AIM) model appears in the Universe topology and the Universe hierarchy.

- Cluster technology 
  Represents a vendor cluster technology. The cluster technology folder displays all managed clusters across all landscapes for the respective technology, such as IBM or Microsoft.
  The hierarchy within the vendor folder shows the logical relationships between the participating components. When all cluster components for a cluster technology are deleted, the empty cluster technology folder remains.
- Cluster 
  Represents a cluster. The cluster name that is used is obtained from the AIM and differs based on technology.
- Cluster node 
  Represents a cluster node. The transparency of the icon reflects whether a cluster node is active or inactive. A solid (nontransparent) icon represents an active node; a faded (transparent) icon represents an inactive node. An active node has resource groups as children; an inactive group does not have any resource groups.
- Resource group 
  Represents a resource group.
- Resource 
  Represents a resource.

  NOTE
  Resources are displayed in the hierarchy view only; resources are not displayed in the topology view.

Management by Multiple AIM Solutions

When Cluster Manager and another DX NetOps Spectrum AIM solution simultaneously and successfully manage a cluster node, the following details apply when viewing your environment:

- The Cluster Manager hierarchy provides a complete and accurate view of your cluster environment. The Universe hierarchy presents all models by defined order of solution management. For example, when a cluster node is a virtual machine, it does not appear within its cluster container in the Universe hierarchy. Instead, it appears in its physical host container in the Virtual Host Manager hierarchy.

  NOTE
  When multiple solutions are managing a node, you can quickly locate it in the correct hierarchy from the Contents panel. Locate the model in the List view or Topology view, then right-click the model and select Location.
- In the Explorer view, the icon for the highest ranking solution applies.
- If Virtual Host Manager manages the node, the node name that appears in the Cluster Manager hierarchy and List view is as follows:
  - For ICMP (Pingable) models, the model name that Virtual Host Manager sets is used.
  - For SNMP models, default Cluster Manager model naming is used.

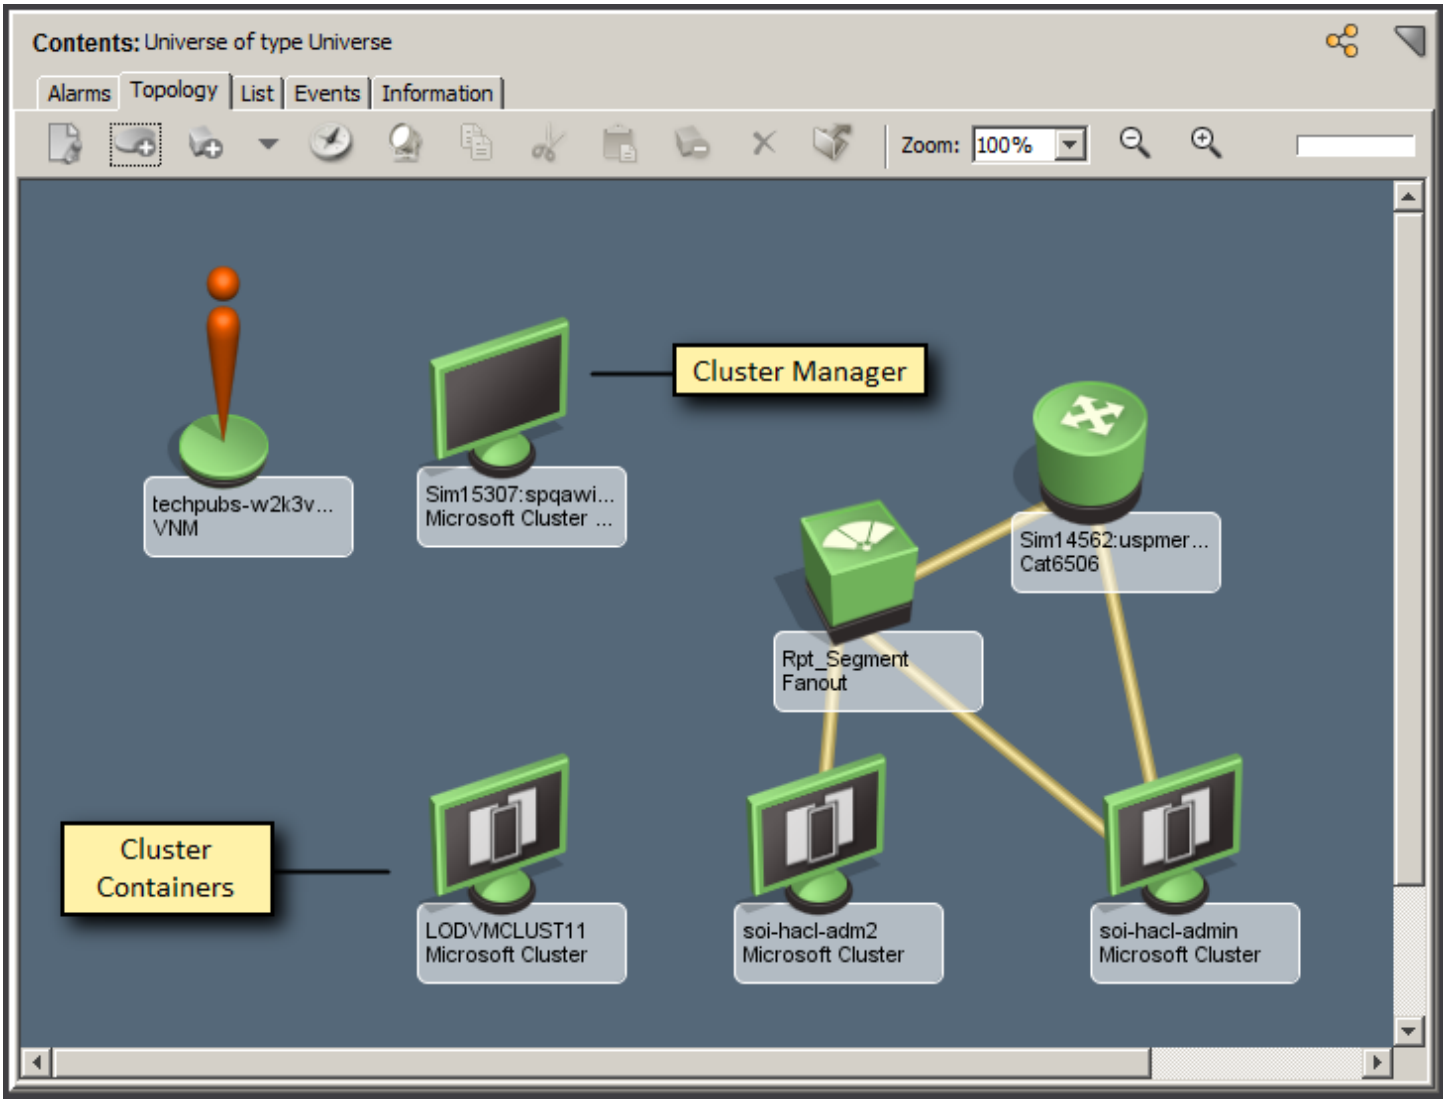
NOTE
Typically, most DX NetOps Spectrum AIM solutions use the Domain Naming System (DNS) name. Regardless, the highest ranking solution applies.

Topology View of a Cluster Environment

The models for your managed cluster environment are organized and integrated into the Universe topology view. These models include the Cluster Manager (SystemEDGE host), cluster, cluster node, and resource group models. This graphical representation helps you visualize the structure of your managed environment, including connections between cluster nodes and other elements of your network.

Cluster node and resource group models are organized in the topology in cluster containers. When possible, the cluster container model is created alongside the Cluster Manager model, as shown in the following Universe topology top view example.

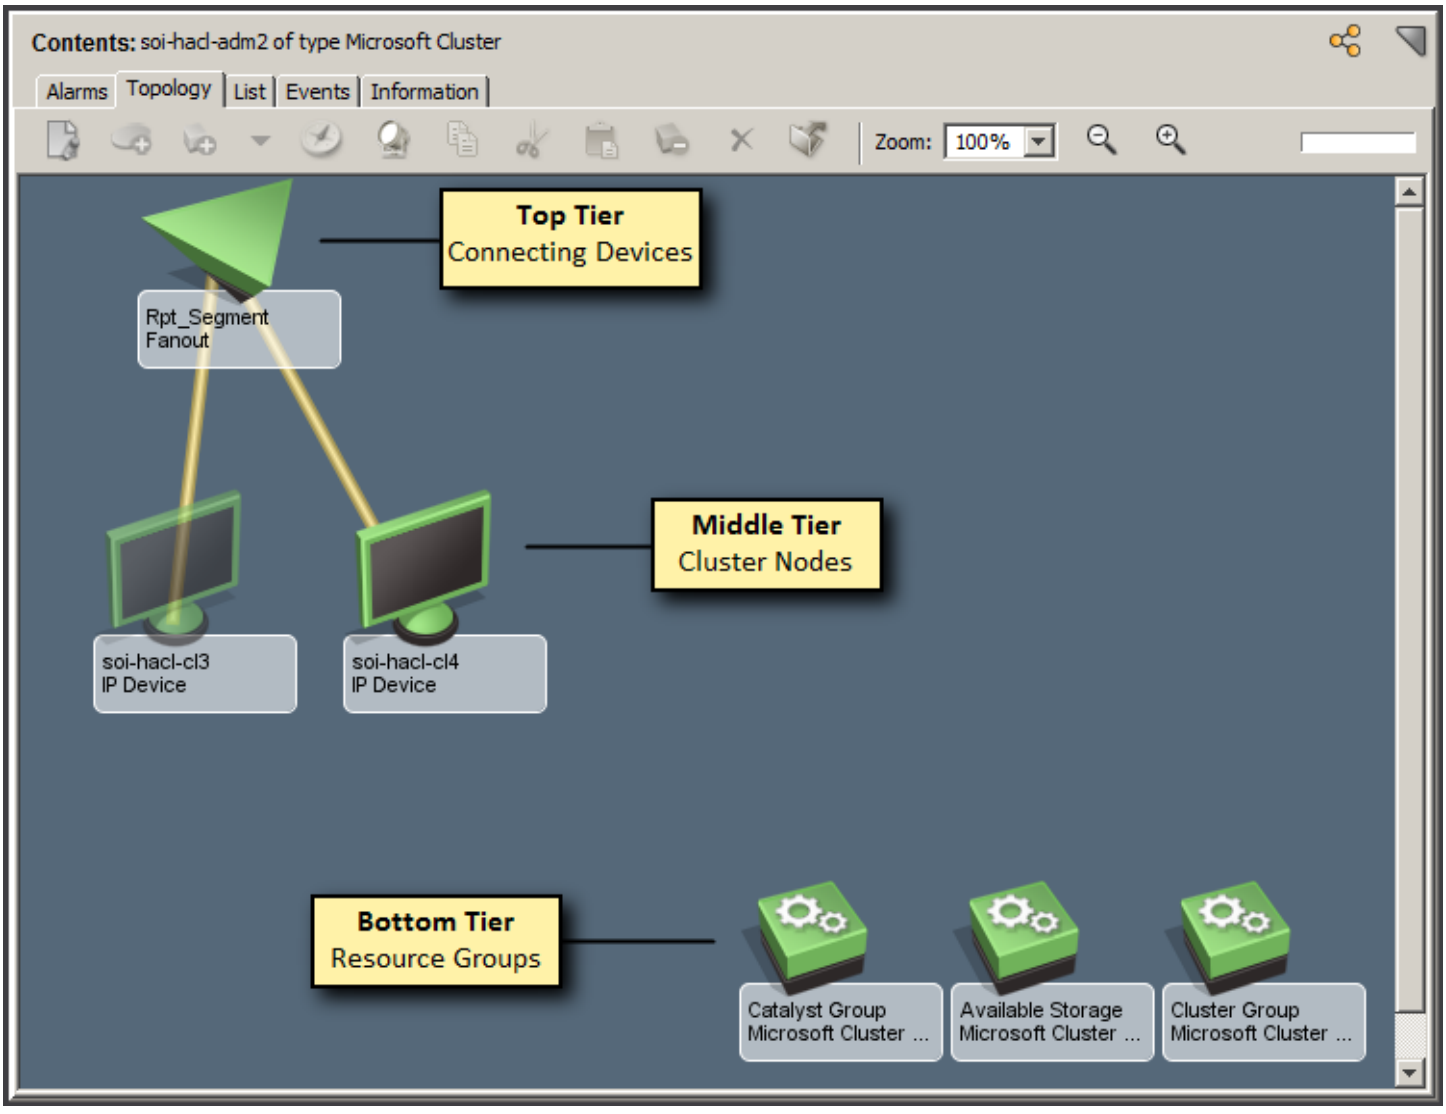
NOTE
If the Cluster Manager is a virtual machine, the cluster container is created in the same topology as the Virtual Host Manager physical host container.



Drilling down into a cluster container reveals its contents. These contents include off-page references to connected network devices, cluster nodes, and active resource groups participating in the cluster.

NOTE
Resources are displayed in the Cluster Manager hierarchy view only; resources are not displayed in the topology view.

The following illustration shows a drill-down view of a cluster container. Cluster components are arranged in three tiers, as shown:



WARNING
Although you can edit the cluster container topology view, DX NetOps Spectrum enforces the placement of the models within the appropriate tiers. If you rearrange the models in this view, their placement is not preserved. Other changes, such as text annotations and background changes, are retained.

- **Top tier**
  Displays any off-page references to connecting devices modeled in other views, such as upstream routers, repeaters, and switches. These elements connect your cluster nodes to your network.
- **Middle tier**

Displays the cluster nodes that participate in the cluster. If a cluster node has already been modeled in Virtual Host Manager before Cluster Manager discovery, it is not modeled again. However, it is included in the cluster container topology to provide a complete view of your cluster environment.

- **Bottom tier**
  Displays the resource groups that participate in the cluster.

  NOTE
  Associations between the resource groups and their respective nodes are not displayed in this view; this information is provided in the Cluster Manager hierarchy view.

The following rules apply to cluster containers:

- You cannot add or remove models from a cluster container. Changes in cluster container contents can occur when components are added or removed from management by an AIM or changes occur in the cluster environment. However, DX NetOps Spectrum controls the placement of models within a cluster container exclusively.
- You cannot destroy a cluster container directly. The cluster container is destroyed only when the respective Cluster Manager model is deleted or when the cluster is removed from management by the AIM. When the cluster container is destroyed, all cluster node models in the container are moved to the Lost and Found (LostFound). An exception is when a cluster node is in a global collection; in this case, the model remains in the global collection.

Placement of Models

The placement of cluster node and resource group models in the topology during Cluster Manager discovery occurs as follows:

- If Cluster Manager discovery creates the model, the model is placed in a cluster container.
- If the model exists and is for a virtual machine that Virtual Host Manager manages, the model remains in the physical host container. And, the model is also included in the cluster container. Within the cluster container, the cluster node icon retains the characteristics of a virtual machine.
- If the model exists and is for a physical machine that another AIM solution manages, the model is moved to the cluster container. An example of another AIM solution is ADES Manager.

  NOTE
  When you remove a model from management by Cluster Manager, it is removed from the cluster container. If ADES Manager continues to manage the host, the model does not appear in the ADES Managed Hosts container automatically. To move the model, cut and paste the model from Lost and Found (LostFound) into the ADES Managed Hosts container.
- If the model exists and no other AIM solution manages the model, the model is moved to the cluster container.

Connectivity

The Topology view displays the connectivity for your cluster environment within your network. Cluster Manager provides the links between your cluster nodes and any connecting devices that have been modeled in your network.

WARNING
Cluster Manager provides the connection to the physical IP address of the cluster node and not to the virtual IP address of the cluster.

In the Universe view, the connections (pipes) represent connections from the connecting devices to the cluster nodes within the cluster containers. By selecting a connection to examine the link more closely, the connections to the specific nodes are displayed, as illustrated in the following example:

Discover Connections runs automatically when the following actions occur:

- A cluster node is initially discovered and modeled.
- The IP address or MAC address of the cluster node has changed.

Discover Connections runs when necessary on the poll cycle. If the Discover Connections process does not complete within a single polling interval, the next Cluster Manager discovery is postponed.

Information Subviews

DX NetOps Spectrum includes several tabs in the Contents and Component Detail panels to provide quick access to information you need for monitoring your cluster environment. The Information tab provides details about a single entity in your environment. These details are displayed in the expandable subviews and vary by solution.

Custom subviews provide detailed information that is specific to the cluster component type. Custom subviews are provided for the following cluster components:

- Cluster Manager
- Cluster
- Cluster Node
- Resource Group
- Resource

Locater Searches for Cluster Manager

DX NetOps Spectrum provides a collection of preconfigured searches on the Locater tab that are designed specifically for your cluster environment. You can use these searches to locate entities in the DX NetOps Spectrum database that are related to the supported cluster technologies. These searches identify specific models or groups of models and can help you obtain details that you can use when monitoring your cluster environment. The searches are grouped under the Cluster Manager folder in the Locater tab of the Navigation panel.

> **NOTE**
> Only users with the appropriate privileges can access Cluster Manager searches. For more information, see OneClick Administration .

Event and Availability Reports

To monitor the cluster environment, you can create event and availability reports. Event reports gather information that helps you make informed decisions about the components in the cluster environment. Using the event filters, you can base the event reports on any of the management events that are generated for the cluster environment in DX NetOps Spectrum.

To report on cluster events, the following event filter files are included with Spectrum Report Manager:

- **Cluster.xml**
  Contains all cluster events, including IBM and Microsoft.
- **IBM-Cluster-all.xml**
  Contains all of the IBM cluster events.
- **IBM-run-status.xml**
  Contains all of the IBM cluster events that are related to Status (such as up, down, offline).
- **MS-Cluster-all.xml**
  Contains all of the Microsoft cluster events.
- **MS-run-status.xml**
  Contains the Microsoft cluster events that are related to Status (such as up, down, offline).
- **ClusterTrap.xml**

Contains only the trap events from IBM and Microsoft clusters.

- **Cluster-spectrum-managing.xml**
  Contains the DX NetOps Spectrum management events, such as cluster proxy events, management events, and polling events.

Availability reports provide historical information about uptime and downtime for assets in the IT infrastructure. The calculation of uptime and downtime depends on the UP and DOWN events that correspond to the cluster model type.

> **NOTE**
> You can use the event codes of the .xml files to generate event reports in Spectrum Report Manager. For more information, see the Report Manager section. You can also generate reports using the predefined event filter files. For more information, see the Install Report Manager section.

Cluster Manager Alarms and Fault Management

Knowing about certain activities, such as a resource group migration or a cluster node failure, can minimize potential problems in your cluster environment. To alert you, DX NetOps Spectrum generates alarms and uses advanced fault management techniques to isolate the root cause.

Problems with a single device can cause several other devices in your network to generate events. Deciding which devices are the root cause of an alarm can be challenging. For example, when you lose contact with the Cluster Manager (the proxy manager), you also lose proxy communication with the cluster nodes that it manages. As a result, alarms are generated for the Cluster Manager and each of its managed components. Sifting through potentially hundreds of simultaneously produced alarms manually to pinpoint the problem could be a tedious and error-prone process. Using fault isolation techniques, Cluster Manager significantly simplifies the troubleshooting process by automatically correlating these alarms to identify a single root cause. As a result, you can identify and correct the problem more quickly.

Alarms and fault isolation vary by cluster technology. Cluster Manager evaluates which devices are issuing alarms and the type of events the devices generate. DX NetOps Spectrum uses all available information to correlate the alarms to the appropriate root cause, only alarming on the isolated faulty device. Cluster Manager relies on the combination of standard DX NetOps Spectrum monitoring, proxy management, state-polling, and traps to create meaningful events and alarms.

> **NOTE**
> In addition to what is provided out-of-box, you can also create your own custom watches to generate events and alarms on other specific metrics. For information about creating watches, see the Watches section.

Cluster Manager Alarms

Alarms are created from information that is obtained from technology-specific traps and polling. To alert you to important activities within your cluster environment, Cluster Manager generates (or clears) alarms for the following conditions:

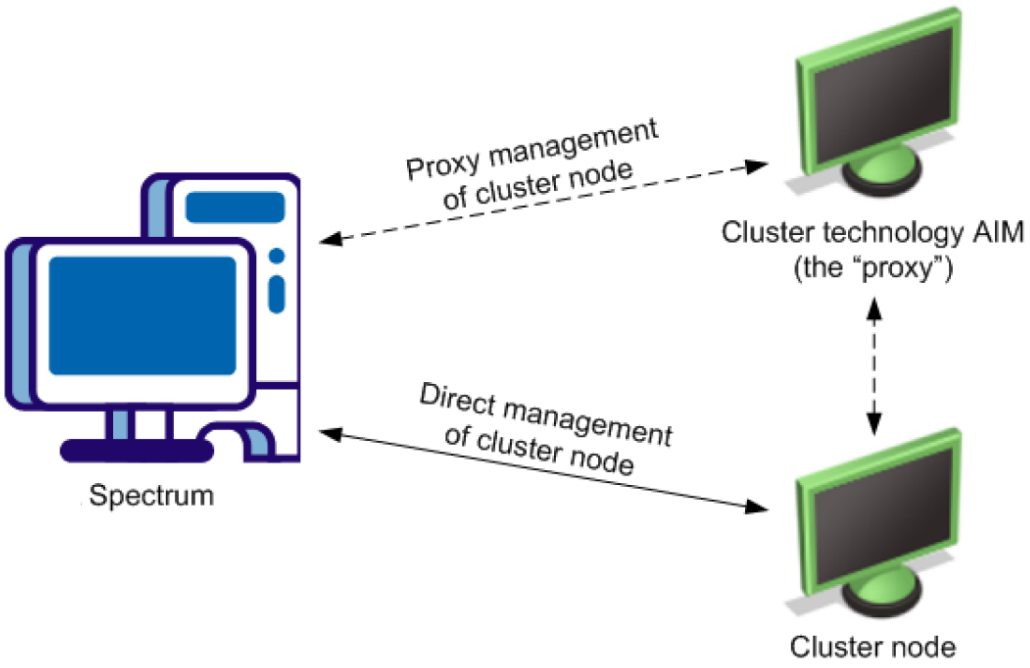
- A Cluster Manager (proxy) is down or communication lost
- Multiple cluster technology AIMs manage the same cluster
- A cluster is up, down, not configured, or in an unknown state
- A cluster node is up, down, joining, leaving, paused, or in an unknown state
- A resource group is online, offline, pending, unmanaged, in an unknown state, in various other states, or has produced an error
- A resource group migrates from one node to another
- A resource is online, online-pending, offline, offline-pending, initializing, pending, inherited, failed, or in an unknown state

> **NOTE**
> Alarms and conditions vary by cluster technology.

Proxy Management

Managing cluster components by a cluster technology AIM provides DX NetOps Spectrum a unique management opportunity. Using this approach, DX NetOps Spectrum has an alternate management perspective in addition to standard device monitoring methods.

Along with gathering information directly from a device, DX NetOps Spectrum also simultaneously gathers information specific to cluster components from the cluster technology AIM. The AIM serves as a "proxy" from which DX NetOps Spectrum gathers information specific to the cluster technologies. Management of a device using an alternate source (such as the AIM) rather than the device directly is called *proxy management*.



DX NetOps Spectrum fault isolation handles this dual management by producing the following alarms:

- **Proxy management alarms**
  By using the cluster technology AIM for management, proxy-related alarms can be generated. These alarms are unique because they alert you when acquisition of cluster-specific information through the proxy is affected, not the state of the device or direct (SNMP) management. When contact through the proxy is lost, you could be missing important cluster-specific information about your environment. Proxy management alarms are of major severity and are not clearable by the user.
  - **Proxy unavailable**
    When DX NetOps Spectrum cannot communicate with the cluster technology AIM, a proxy unavailable alarm is generated on the Cluster Manager model.
    The following text is used for the proxy unavailable alarm:
    ```
    CLUSTER MANAGER UNAVAILABLE
    ```
  - **Proxy lost**
    When DX NetOps Spectrum cannot obtain information about the managed device by way of the proxy, a proxy lost alarm is generated. A proxy lost alarm is generated for the following conditions:
    - When DX NetOps Spectrum cannot communicate with the vendor-specific Cluster Manager model. A proxy unavailable alarm on the Cluster Manager model is generated as well as a proxy lost alarm for each of its managed components.
    - When the cluster technology AIM cannot successfully communicate with the cluster node.

The following text is used for the proxy lost alarm:

```
CLUSTER MANAGER PROXY LOST FOR cluster_entity
```

Cluster entity values include the cluster, cluster node, resource group, and resource.
A proxy lost alarm is generated only for entities that Cluster Manager manages. If the host is removed from management by the proxy, the respective proxy management alarms are cleared.

- **Enhanced contact lost alarms**
  Standard DX NetOps Spectrum alarms that indicate loss of contact with the proxy contain added correlation of Cluster Manager proxy management alarms. These proxy management alarms indicate loss of cluster-specific data acquisition.
  The following text is used for the contact lost alarm:

```
DEVICE HAS STOPPED RESPONDING TO POLLS
```

Alarm Correlation

Using standard DX NetOps Spectrum fault management, state-monitoring data, and added information from the proxy, Cluster Manager automatically correlates the alarms to identify a single root cause. Various state-monitoring and proxy-related alarms are correlated to an alarm on the relevant model to pinpoint the true root cause, such as:

- Contact lost
- Management lost
- Entity down, offline, or in a problem state
- Maintenance
- Hibernation

Cluster Manager provides many default correlations. To view or modify correlations, use the Condition Correlation Editor in OneClick.

NOTE
After an alarm has been issued, use the Impact tab for the alarm to view any correlated or symptomatic alarms.

Maintaining Your Cluster Manager Implementation

This section provides the information that helps you maintain your Cluster Manager implementation after you discover your cluster environment.

Updating Cluster Data

When the DX NetOps Spectrum administrator runs the initial Discovery process, Cluster Manager populates the Explorer tab in the Navigation panel with your cluster environment models. After Cluster Manager builds this initial hierarchy, your cluster environment can change. Cluster Manager continually works to keep this information updated. The information is useful for troubleshooting issues and optimizing performance only when it accurately reflects your environment.

Understanding how and when the information is updated can help you better evaluate the data and how your cluster environment is operating. For example, the following events can change your cluster environment configuration:

- Creating or deleting clusters, cluster nodes, resource groups, and resources
- Migration of cluster components from one entity to another

To keep your information accurate, Cluster Manager detects these changes by polling the AIM. Your modeled cluster environment is updated in DX NetOps Spectrum at each polling cycle. When a change in your cluster environment is detected, DX NetOps Spectrum performs the following tasks:

- Updates the placement of your cluster component models in the Cluster Manager hierarchy in the Explorer view
- Automatically rediscovers connections to the affected components in the Universe topology

DX NetOps Spectrum also receives traps from the AIM and generates the corresponding events. By reviewing the event log, you can find out when changes occur, such as when a resource group has migrated.

WARNING
To reestablish connections to your cluster component models correctly, all interconnecting routers and switches must be modeled. If these models do not exist before connections to your cluster components are rediscovered, DX NetOps Spectrum cannot resolve those connections. As a result, DX NetOps Spectrum cannot display the information correctly in the Universe topology view.

Controlling Polling Intervals on Cluster AIM and Cluster Manager

Polling intervals control how often information is obtained from managed devices. To keep data for your managed cluster environments current, Cluster Manager uses the polling intervals set on the following components:

- **Cluster technology AIM**
  The AIM polling interval indicates how often the AIM queries the cluster components for information. The AIM polling interval exists in the AIM, but you can modify this value from within DX NetOps Spectrum. The default value is 300 seconds with a minimum value of 30 seconds.
- **Cluster Manager model**
  The polling interval on the Cluster Manager model determines how often DX NetOps Spectrum polls the cluster technology AIM. The default value is 300 seconds with a minimum value of 30 seconds. This setting is available on the DX NetOps Spectrum Modeling Information view for the Cluster Manager (Host_systemEDGE) model.

Modifying Cluster Manager Management and Models

When changing your modeled environment, consider the following behaviors:

- When Cluster Manager no longer manages a cluster node, the model moves to the Lost and Found (LostFound), except in the following cases:
  - Virtual Host Manager is managing the host.
  - The host is in a global collection.
- When cluster component names change, Cluster Manager reflects the new values automatically.
- When the IP address or MAC address for a cluster node model is modified, connections to any connecting devices are automatically updated.

How to Convert an ICMP (Pingable) Model to SNMP-Managed

You can model a cluster node as an ICMP (Pingable) model and then later install an SNMP agent on the host. To take advantage of the SNMP capabilities, the cluster node must be remodeled.

Perform a discovery for the node manually to replace the model. A new model is created and then is pulled into Cluster Manager management during the next Cluster Manager discovery.

Deleting Cluster Manager Models

Consider the following behaviors and restrictions regarding the deletion of cluster component models in your DX NetOps Spectrum modeled environment:

- Models typically can be deleted from OneClick at any time for various reasons. However, Cluster Manager restricts your ability to delete models from the Cluster Manager hierarchy in the Navigation panel. To delete models manually, you have the following options:

  - Delete the Cluster Manager model.
  - Remove a cluster component using the vendor-specific cluster management tool.
- In Cluster Manager, models are sometimes deleted automatically. The following circumstances cause DX NetOps Spectrum to delete Cluster Manager models automatically:
  - A Cluster Manager model is deleted. If you delete a Cluster Manager model, DX NetOps Spectrum deletes all associated models.
  - An entity is removed from a supported cluster environment. As you update your cluster environment by modifying cluster, cluster node, resource group, and resource allocation, DX NetOps Spectrum also modifies those models accordingly. This update includes deleting respective models and their children where appropriate.
  - Upgraded models exist. In some cases, a cluster node is first modeled for Cluster Manager without SNMP capabilities. If SNMP capabilities are later added to a node, the previous model is deleted and replaced with the new, manually discovered SNMP-managed model.
- Hosts that both Virtual Host Manager and Cluster Manager manage adhere to all the standard modeling behaviors of virtual machines. These models cannot be deleted from the topology.
- When a Cluster Manager (Host_SystemEDGE) model is deleted, the corresponding cluster containers are destroyed. All cluster node models in the containers are moved to the Lost and Found (LostFound). An exception is when a cluster node is in a global collection, in which case, the model remains in the global collection.
- When all cluster components for a particular cluster technology are deleted, the cluster technology folder remains in the Cluster Manager hierarchy. An unbolded label indicates an empty folder.

Deleting Models When Using Multiple AIM Solutions

If you use Cluster Manager in combination with other DX NetOps Spectrum AIM solutions, consider the following points when deleting models in your environment:

- If you plan to no longer manage models using Virtual Host Manager, configure Virtual Host Manager delete settings to retain models. Otherwise, Virtual Host Manager deletes the cluster node model initially, losing any history or customization on the models. Cluster Manager then recreates the cluster node model during the next Cluster Manager discovery, which occurs on the next poll cycle.
- When Virtual Host Manager unmanages a cluster node and the model is retained, it is pulled back into Cluster Manager management automatically.
- If a node is removed from management by a solution, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.
- When you remove a cluster node model from management by Cluster Manager, it is removed from the cluster container. If ADES Manager continues to manage the host, the model does not appear in the ADES Managed Hosts container automatically. To move the model into the ADES Managed Hosts container, cut and paste the model from the Lost and Found (or global collection, if applicable).

  NOTE
  Cluster node models that are removed from Cluster Manager management are moved to the Lost and Found (LostFound). An exception is when a cluster node is in a global collection, in which case, the model remains in the global collection.
- The Cluster Manager hierarchy synchronizes after the Lost and Found (LostFound) is emptied.

IBM PowerHA

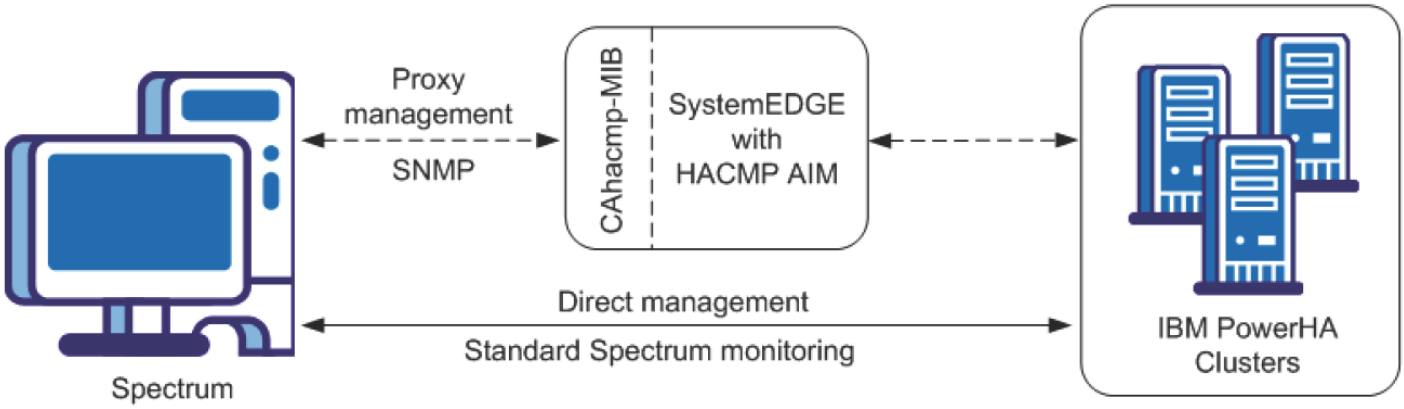
This section describes how DX NetOps Spectrum manages IBM PowerHA cluster environment including its models, the locater search, fault management, subviews in OneClick for visibility.

This section also provides the scenario that guides you in setting up Cluster Manager for IBM PowerHA.

Solution Architecture for IBM PowerHA

DX NetOps Spectrum gathers information about your IBM PowerHA cluster environment using two different methods. As with other DX NetOps Spectrum-managed devices, Cluster Manager uses standard DX NetOps Spectrum monitoring. In addition, Cluster Manager also retrieves specialized information for your IBM PowerHA environment from a proxy manager, the HACMP AIM.

The following diagram shows how DX NetOps Spectrum gathers information about your IBM PowerHA cluster environment:



The SystemEDGE agent with the HACMP AIM resides on its own host. This host is referred to as the IBM PowerHA Cluster Manager. The HACMP AIM obtains information from the IBM PowerHA cluster environment and writes this data to a CA-developed MIB (CAhacmp-MIB). DX NetOps Spectrum then uses SNMP to retrieve this information from the MIB and uses it to model and monitor your IBM PowerHA cluster components in OneClick.

Cluster Manager can support multiple HACMP AIMs either within a single DX NetOps Spectrum or distributed across multiple landscapes.

NOTE
For more information about the HACMP MIB, see the *CA Virtual Assurance for Infrastructure Manager* documentation.

How to Set Up Cluster Manager for IBM PowerHA

The following diagram shows the steps that are required for a DX NetOps Spectrum administrator to set up Cluster Manager to monitor IBM clusters:

Follow these steps:

1. Install DX NetOps Spectrum.
2. Install SystemEDGE agent with HACMP AIM.
3. Discover and Model Your IBM PowerHA Environment.

Install DX NetOps Spectrum

Cluster Manager is included in all DX NetOps Spectrum extraction keys. When you install DX NetOps Spectrum, the Cluster Manager components are automatically installed.

Follow this step:

- Install 9.2.3 or later.

  WARNING
  Do not install the SpectroSERVER on a host that Cluster Manager is going to manage.

  NOTE
  For specific installation instructions, see the Fresh Install section.

Install the SystemEDGE Agent and HACMP AIM

After DX NetOps Spectrum has been installed, install and configure the proxy manager; for IBM clusters, the proxy manager is the HACMP AIM.

The HACMP AIM is a specialized SystemEDGE AIM and resides on its own host. This host is referred to as the IBM PowerHA Cluster Manager.

When configuring the HACMP AIM, you manually specify the IBM PowerHA clusters to manage. Although your implementation can consist of multiple HACMP AIMs, manage each cluster with a single HACMP AIM only.

Follow this step:

- Install the SystemEDGE agent and load and configure the HACMP AIM on a host other than where DX NetOps Spectrum is installed. Note the following requirements:
  - Install only a single AIM on a particular SystemEDGE host.
  - Do not install the SystemEDGE agent and HACMP AIM on a node that Cluster Manager is going to manage.
  - Register each cluster and cluster node with a single HACMP AIM only.

  After the HACMP AIM has been successfully installed and configured, it begins gathering data for its managed components. This information is made available in the MIB.
  You can now discover and model your IBM cluster environment in DX NetOps Spectrum.

Discover and Model Your IBM PowerHA Environment

After you have installed the necessary components, discover and model any entities in your IBM PowerHA cluster environment that Cluster Manager is going to manage.

Follow these steps:

1. Run a Discovery for modeling the IBM PowerHA Cluster Manager and connecting devices.
2. (Optional) Upgrade the SystemEDGE model, if necessary.

   NOTE
   This step is required only if the SystemEDGE host has been modeled in DX NetOps Spectrum before installing the HACMP AIM on the agent.
3. Let Cluster Manager discovery run.

Run DX NetOps Spectrum Discovery to Model the IBM PowerHA Cluster Manager and Connecting Devices

After the SystemEDGE agent and HACMP AIM are set up, model the IBM PowerHA Cluster Manager and any connecting devices in DX NetOps Spectrum. You can use standard DX NetOps Spectrum Discovery to do the following actions:

- Model the IBM PowerHA Cluster Manager, which must be modeled with a read/write community string.
- Model the necessary upstream routers and switches of your IBM PowerHA cluster environment so that connections from the cluster models can later be established.

  WARNING
  Do not include cluster nodes. Clusters, cluster nodes, resource groups, and resources are discovered and modeled automatically using information from the AIM.

NOTE
For details about how to perform a Discovery, see the Modeling and Managing Your IT Infrastructure section.

Gather the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port. Note the following guidelines when configuring your Discovery parameters:

- Include IP addresses for all IBM PowerHA Cluster Managers and interconnecting switches and routers.
- Model the IBM PowerHA Cluster Manager with a read/write community string. If you are modeling the IBM PowerHA Cluster Manager in this Discovery, place its community string appropriately in the SNMP Information ordered list. Alternatively, you can change the community string for the IBM PowerHA Cluster Manager to its read/write value after the discovery.
- Determine pingable MAC addresses during connectivity mapping by using the "ARP Tables for Pingables" option.

  NOTE
  Using this option can increase the time Discover Connections takes to run.
- Add any nonstandard SNMP ports using Advanced Options.

Discovery creates models for the following entities and adds them to your network topology in DX NetOps Spectrum:

- IBM PowerHA Cluster Manager.

  NOTE
  If the Discovery process did not assign the read/write community string to this model, update this setting manually. Use the DX NetOps Spectrum Modeling Information subview for the model.
- The upstream switches and routers that connect the IBM PowerHA cluster nodes to your network.

When Discovery has completed and these models exist in DX NetOps Spectrum, Cluster Manager discovery begins.

NOTE
Instead of using standard DX NetOps Spectrum Discovery, you can manually model your IBM PowerHA Cluster Manager by IP address or host name. If you do, model the upstream devices first (since modeling the IBM PowerHA Cluster Manager automatically triggers a Cluster Manager discovery). Modeling in the proper order allows the correct creation of connections in the topology between your cluster nodes and the remainder of your network. For more information, see the Modeling and Managing Your IT Infrastructure section.

Upgrade the SystemEDGE Host Model (If Necessary)

If the SystemEDGE host model was created before loading the HACMP AIM on the agent, the existing model is not compatible with Cluster Manager. Upgrade the SystemEDGE host (Host_systemEDGE) model so that Cluster Manager can access the HACMP AIM capabilities in SystemEDGE.

To upgrade the SystemEDGE host model, right-click the model and select Reconfiguration, Reconfigure Model.

The SystemEDGE host model is upgraded to support the HACMP AIM.

NOTE
You can also send a reconfigure model action to the SystemEDGE agent using CLI. For instructions on how to send a reconfigure model action to the SystemEDGE agent, see the Modeling and Managing Your IT Infrastructure section.

Cluster Manager Discovery

Cluster Manager discovery is the automatic discovery and modeling process within DX NetOps Spectrum of cluster components. The IBM PowerHA Cluster Manager initiates this process.

With communication between DX NetOps Spectrum and the HACMP AIM established, Cluster Manager gathers information about your IBM PowerHA environment from the HACMP AIM. A list of cluster nodes is passed to AutoDiscovery for modeling. For cluster node models, an SNMP-managed model is created if an SNMP agent exists on the host; otherwise, an ICMP (Pingable) model is created.

New cluster-related models appear in the Cluster Manager hierarchy in the Explorer view and are placed into new cluster containers in the topology view. Connections to any upstream devices are made.

> **NOTE**
> If a cluster node is already modeled in your DX NetOps Spectrum-managed network before Cluster Manager discovery, it is not modeled again. However, the model is included in the cluster container topology.

After the initial modeling, Cluster Manager discovery runs automatically at a frequency that is based on the IBM PowerHA Cluster Manager model poll cycle. During subsequent Cluster Manager discoveries, the modeling within DX NetOps Spectrum is updated with any changes in your cluster environment.

Models Created for IBM PowerHA

Cluster Manager provides several models to represent the components of your IBM PowerHA cluster environment, as follows:

- IBM PowerHA Cluster Manager

  Model Type: Host_systemEDGE
  Represents the host that contains the HACMP AIM. The HACMP AIM monitors the IBM PowerHA cluster elements (clusters, nodes, resource groups, and resources) in your environment.
- IBM PowerHA Cluster

  Model Type: ClusterIBMCluster
  Contains cluster node and resource group models that belong to the cluster. You cannot add or remove models from a cluster container, and you cannot destroy the container itself. When possible, this container model is created alongside the IBM PowerHA Cluster Manager model.

  > **NOTE**
  > If the IBM PowerHA Cluster Manager is a virtual machine, the cluster container is placed in the same topology as the physical host container.
- IBM PowerHA Cluster Node

Represents a cluster node in an IBM PowerHA cluster environment. Cluster nodes are modeled as SNMP-managed elements when possible. A cluster node can be active or inactive.
An active node has resource groups currently running on it and is represented with a solid (nontransparent) icon. An inactive node does not have any resource groups and is represented with a faded (transparent) icon. When resource groups fall over from one node to another, changing the state of the node, the icon transitions automatically.

NOTE
Unlike a model in maintenance mode or hibernation mode, the inactive node model is fully functional. Data is gathered for the node, and any alarm activity or events for the node are generated on the model.

- IBM PowerHA Cluster Resource Group

Model Type: ClusterIBMResourceGroup
Represents a resource group.

- IBM PowerHA Cluster Resource

Model Type: ClusterIBMResource
Represents a resource.

Custom Subviews for IBM PowerHA

Custom subviews in the Component Detail panel provide detailed information about the components in your cluster environment. You can view information specific to IBM PowerHA clusters by:

- IBM PowerHA Cluster Manager
- IBM PowerHA Cluster Component (Cluster, Cluster Node, Resource Group, Resource)

IBM PowerHA Cluster Manager

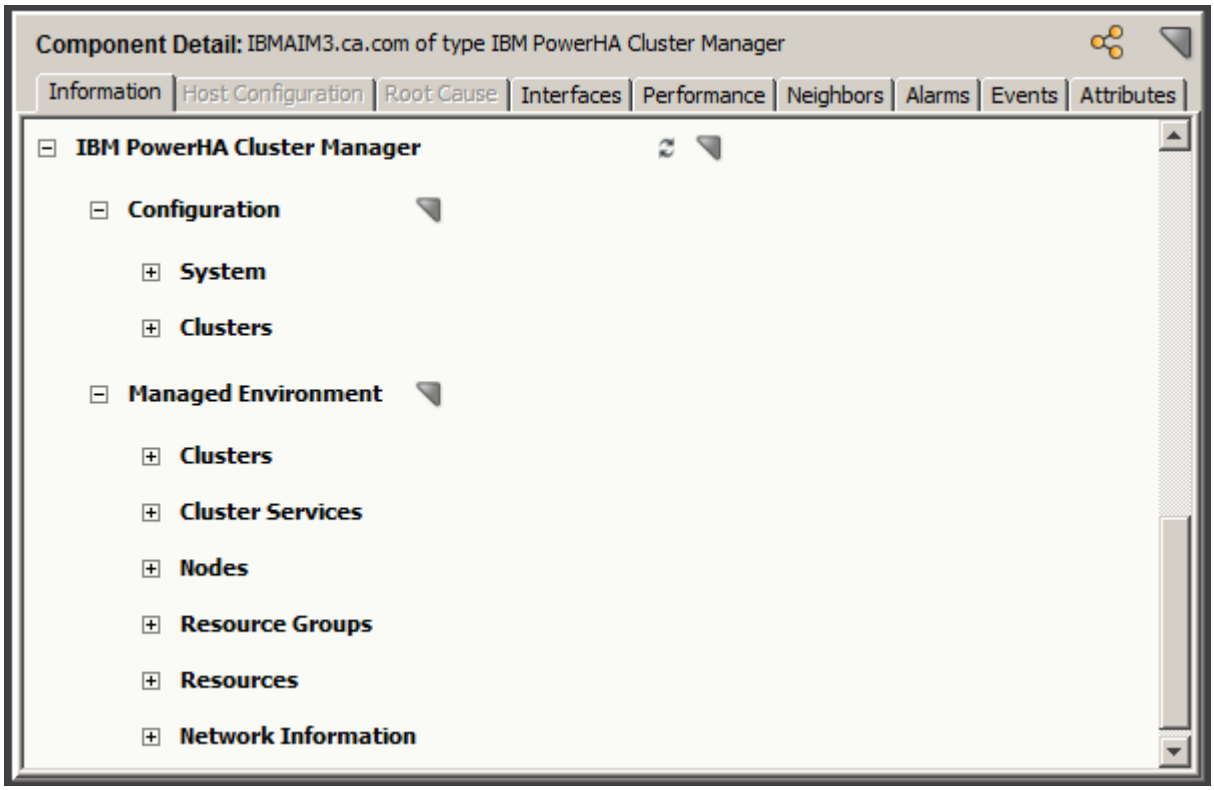
Using subviews that are provided for the IBM PowerHA Cluster Manager (HACMP AIM), you can view the following information:

- Information specific to the IBM PowerHA Cluster Manager host. Data includes the agent version, agent polling interval, and when the HACMP AIM MIB (CAhacmp-MIB) was last updated.
- List of clusters that have been registered to the AIM.
- Consolidated information about all cluster components that this HACMP AIM manages.

The following procedure describes how to view information for an IBM PowerHA Cluster Manager.

Follow these steps:

1. Select the IBM PowerHA Cluster Manager model in the Universe hierarchy or topology.
   The Component Detail panel displays information for the selected IBM PowerHA Cluster Manager.
2. In the Information tab in the Component Detail panel, expand the IBM PowerHA Cluster Manager subview.
   The expanded subview appears, as follows:



The following subviews are available for an IBM PowerHA Cluster Manager:

- **Configuration**
  Provides information specific to the IBM PowerHA Cluster Manager, including:
  – Information about the SystemEDGE agent including version, when the MIB was last updated, and polling interval. You can also modify the polling interval, as described in Controlling the HACMP AIM Polling Interval.
  – List of clusters that have been registered to this AIM and their respective readiness
- **Managed Environment**
  Provides consolidated information about all the entities that this AIM manages, including cluster components, services, resource groups, resources, and network information.

IBM PowerHA Cluster Component

You can view information for any of your clusters or cluster components (cluster node, resource group, resource) in your managed IBM PowerHA cluster environment. Views are tailored to the entity type, providing information that is specific to the component.

The following procedure describes how to view information for an IBM PowerHA cluster or cluster component.

Follow these steps:

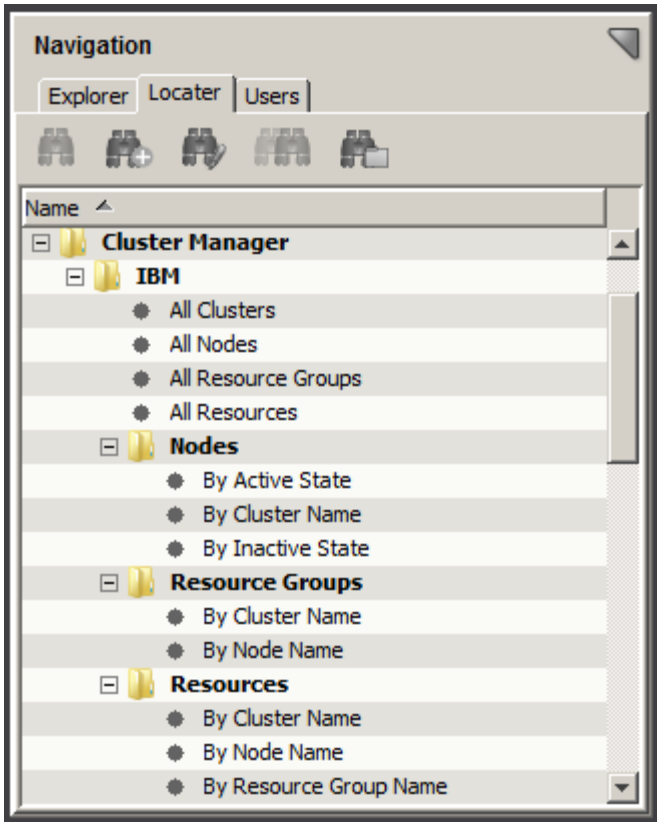
1. Select an IBM PowerHA Cluster, Cluster Node, Resource Group, or Resource model.
   The Component Detail panel displays information for the selected model.
2. In the Information tab in the Component Detail panel, expand the respective cluster-related subview for the model.
   The expanded subview appears, as follows, depending on the model type:
   – **Cluster Information**
   Provides general cluster information for the selected cluster model. Data includes cluster states, number of nodes, and instance name as registered in the AIM.
   – **Node Information**

Provides general node information such as the node state and the number of network interfaces it has. CPU usage and memory statistics are also provided.

- **Resource Group Information**
  Provides statistics such as the number of resources in the group, the node currently owning the group as well as the previous node. The number of startup, fallover, and fallback policies for the group are also provided.
- **Resource Information**
  Provides the resource type and index information.

Locater Searches for IBM PowerHA

You can use the Locater tab to run preconfigured searches. The search options are grouped under the Cluster Manager, IBM folder on the Locater tab, as shown:



These detailed searches can help you investigate information that is related to IBM PowerHA cluster entities that have been modeled in the DX NetOps Spectrum database.

NOTE
Only users with the appropriate privileges can access Cluster Manager searches. For more information, see the OneClick Administration section.

Alarms for IBM PowerHA

To alert you to problems within your IBM PowerHA cluster environment, DX NetOps Spectrum generates alarms. Quickly identifying any device faults helps you to maximize your system up-time and the reliability of your cluster environment and high availability applications. Alarms are created from information that is obtained from technology-specific traps

and polling. The following sections describe the Cluster Manager events and alarms for your IBM PowerHA cluster environment.

NOTE
To view specific event definitions that are related to Cluster Manager, use the Event Configuration application.

Traps for IBM PowerHA

DX NetOps Spectrum supports all traps that the HACMP AIM generates. An event is created for any trap activity and is reported initially on the IBM PowerHA Cluster Manager model. Some events are then forwarded to a corresponding cluster entity type (that is, the "destination" entity), depending on the type of trap.

The following table provides the traps and destination entity type and indicates whether the trap generates an alarm by default.

Trap Name	Trap OID	Alarm?	Destination Entity
hacmpAimInstanceAddedTrap	1.3.6.1.4.1.546.1.1.0.165800	No	Cluster Manager
hacmpAimInstanceRemovedTrap	1.3.6.1.4.1.546.1.1.0.165801	No	Cluster Manager
hacmpAimInstanceDataStatusChanged	1.3.6.1.4.1.546.1.1.0.165802	No	Cluster Manager
hacmpAimNodeAddedTrap	1.3.6.1.4.1.546.1.1.0.165803	No	Cluster Manager
hacmpAimNodeRemovedTrap	1.3.6.1.4.1.546.1.1.0.165804	No	Cluster Manager
hacmpAimResourceGroupAddedTrap	1.3.6.1.4.1.546.1.1.0.16580 5	No	Cluster Manager
hacmpAimResourceGroupRemovedTrap	1.3.6.1.4.1.546.1.1.0.165806	No	Cluster Manager
hacmpAimResourceGroupMigration	1.3.6.1.4.1.546.1.1.0.165807	No	Resource Group
hacmpAimResourceAddedTrap	1.3.6.1.4.1.546.1.1.0.165808	No	Cluster Manager
hacmpAimResourceRemovedTrap	1.3.6.1.4.1.546.1.1.0.165809	No	Cluster Manager
aggregateStateTrap*	1.3.6.1.4.1.546.1.1.0.20	Yes*	various*

* The aggregateStateTrap is a SystemEDGE trap. Alarms are generated for certain aggregateStateTrap conditions. For more information, see Self Monitors for IBM PowerHA.

NOTE
For more information about traps that the HACMP AIM generates, see the CA Virtual Assurance for Infrastructure Managers section. You can also use MIB Tools to view the traps in the "CAhacmp-MIB" MIB. For more information, see the Modeling and Managing Your IT Infrastructure section.

State Monitoring for IBM PowerHA

Cluster Manager monitors the state of various cluster components in your environment and obtains this information from the following sources:

- Polling the "CAhacmp-MIB" MIB. More than 100 objects are monitored regularly about the elements in your cluster environment. This information is updated in DX NetOps Spectrum according to the polling cycle. Cluster Manager derives pertinent information from these objects to create various events and alarms that provide insight into the health and status of your environment.
- Self-monitor traps. When installed, the HACMP AIM configures self monitors on the SystemEDGE agent which track various resources and activities of the managed cluster components. The monitors are threshold-based, and an aggregateState trap is sent when a threshold is violated. DX NetOps Spectrum then generates an event and, depending on the current severity state of the monitor, an applicable alarm. Data that is gathered from self monitors includes CPU or memory usage for a node.

Cluster Manager uses information from both sources to monitor the state of your cluster components. Alarms are generated and, when the condition has been corrected, cleared automatically. All state-based alarms are also user-clearable. When both trap and polling sources reveal the same activity, Cluster Manager identifies the overlap. A single alarm is created, with the alarm that polling generates taking precedence.

When a resource group moves from a primary node to a secondary node, an alarm occurs. When the resource group moves from the secondary node back to the primary, a new alarm is generated for the latest migration. The original alarm does not clear automatically, but it is user-clearable.

The following table lists the state-based alarm information by cluster component:

Entity	State	DX NetOps Spectrum Alarm Severity
Cluster	Up	Clear
Cluster	Down	Critical (Red)
Cluster	Unknown	Major (Orange)
Cluster	Not Configured	Critical (Red)
Cluster	Network state down*	Major (Orange)
Node	Up	Clear
Node	Down	Critical (Red)
Node	Joining	Event only
Node	Leaving	Event only
Node	Unknown	Major (Orange)
Node	High CPU Utilization*	Major (Orange)
Node	High Memory Utilization*	Major (Orange)
Node	Network interface state down*	Major (Orange)
Resource Group	Unknown	Major (Orange)
Resource Group	Online	Clear
Resource Group	Offline	Critical (Red)
Resource Group	Acquiring	Event only
Resource Group	Releasing	Event only
Resource Group	Error	Critical (Red)
Resource Group	Onlinesec	Clear
Resource Group	Acquiringsec	Event only
Resource Group	Releasingsec	Event only
Resource Group	Errorsec	Critical (Red)
Resource Group	Offline_due_to_failover	Minor (Yellow)
Resource Group	Off_line_due_to_parent_off	Critical (Red)
Resource Group	Unmanagedsec	Minor (Yellow)
Resource Group	Offline_due_to_lack_of_node	Critical (Red)
Resource Group	Unmanaged	Minor (Yellow)
Resource Group	Parent changes	Major (Orange)

* Alarms generated from self-monitor aggregateStateTrap.

Self Monitors for IBM PowerHA

Self monitors are threshold-based watches that are configured on the SystemEDGE agent. When installed, the HACMP AIM configures self monitors that are specific to the cluster environment. The HACMP AIM sets the initial severities and threshold values, but you can access and modify the values from within OneClick.

When a configured threshold is violated, the SystemEDGE agent sends the pertinent information to DX NetOps Spectrum using the aggregateStateTrap. DX NetOps Spectrum then generates an event and forwards the event to the respective entity.

For the following monitors only, DX NetOps Spectrum generates alarms by default:

- Node CPU Utilization
- Node Memory Utilization
- Network State
- Network Interface State

HACMP AIM State	DX NetOps Spectrum Alarm Severity
1: None/Unknown	Event only
2: OK	Clear
3: Warning	Clear
4: Minor	Minor (Yellow)
5: Major	Major (Orange)
6: Critical	Major (Orange)
7: Fatal	Major (Orange)

Controlling the HACMP AIM Polling Interval

Cluster Manager uses the HACMP AIM for discovery, modeling, and monitoring of your IBM PowerHA environment. The HACMP AIM has its own polling interval, which can be set from within DX NetOps Spectrum.

> **NOTE**
> For information about other HACMP AIM settings, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Follow these steps:

1. Select the IBM PowerHA Cluster Manager model that represents the HACMP AIM.
   The Component Detail panel displays information for the selected IBM PowerHA Cluster Manager.
2. In the Information tab in the Component Detail panel, expand the IBM PowerHA Cluster Manager, Configuration, System subview.
   The expanded System subview appears.
3. For the Agent Polling Interval, click set, modify the value, and press Enter.
   The polling interval for the HACMP AIM is updated.

Microsoft Cluster Service (MSCS)

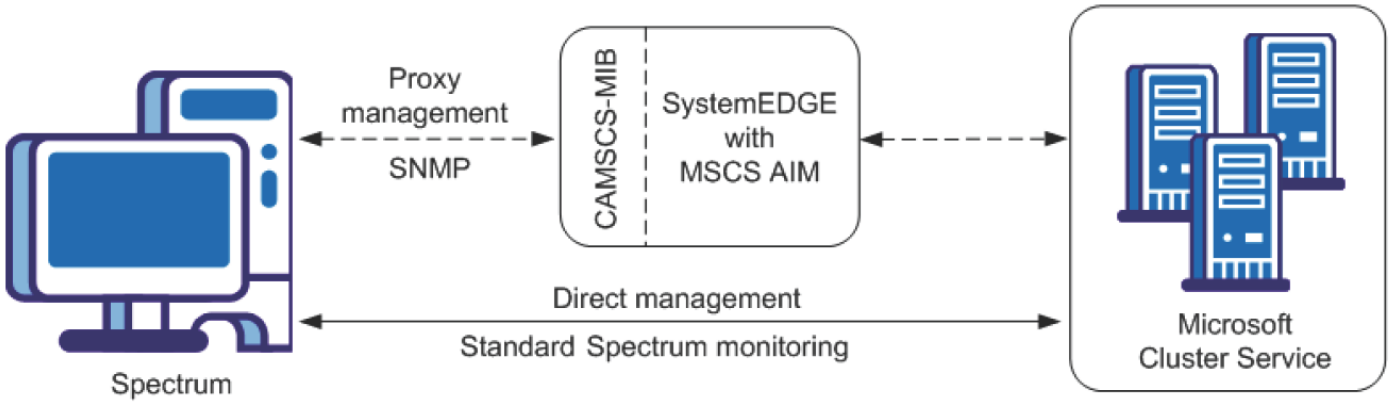
This section describes how DX NetOps Spectrum manages Microsoft Cluster Service (MSCS) including its models, the Locater search, fault management, subviews in OneClick for visibility.

This section also provides the scenario that guides you in setting up Cluster Manager for MSCS.

Solution Architecture for Managing MSCS

DX NetOps Spectrum gathers information about your Microsoft Cluster Service (MSCS) environment using two different methods. As with other DX NetOps Spectrum-managed devices, Cluster Manager uses standard DX NetOps Spectrum monitoring. In addition, Cluster Manager also retrieves specialized information for your MSCS environment from a proxy manager, the MSCS AIM.

The following diagram shows how DX NetOps Spectrum gathers information about your MSCS environment:



The SystemEDGE agent with the MSCS AIM resides on its own host. This host is referred to as the Microsoft Cluster Manager. The MSCS AIM obtains information from the MSCS environment and writes this data to a CA-developed MIB (CAMSCS-MIB). DX NetOps Spectrum then uses SNMP to retrieve this information from the MIB and uses it to model and monitor your MSCS cluster components in OneClick.

Cluster Manager can support multiple MSCS AIMs either within a single SpectroSERVER or distributed across multiple landscapes.

> **NOTE**
> For more information about the MSCS MIB, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

How to Set Up Cluster Manager for MSCS

The following steps are required for a DX NetOps Spectrum administrator to set up Cluster Manager to monitor MSCS clusters:

1. Install DX NetOps Spectrum.
2. Install SystemEDGE agent with MSCS AIM
3. Discover and Model Your MSCS Environment.

Install DX NetOps Spectrum

Cluster Manager is included in all DX NetOps Spectrum extraction keys. When you install DX NetOps Spectrum, the Cluster Manager components are automatically installed.

Follow this step:

- Install 9.2.3 or later.

WARNING
Do not install the SpectroSERVER on a host that Cluster Manager is going to manage.

NOTE
For specific installation instructions, see the Fresh Install section.

Install the SystemEDGE Agent and MSCS AIM

After DX NetOps Spectrum has been installed, install and configure the proxy manager; for MSCS, the proxy manager is the MSCS AIM.

The MSCS AIM is a specialized SystemEDGE AIM and resides on its own host. This host is referred to as the Microsoft Cluster Manager.

When configuring the MSCS AIM, you manually specify the MSCS clusters to manage. Although your implementation can consist of multiple MSCS AIMs, manage each cluster with a single MSCS AIM only.

Follow this step:

- Install the SystemEDGE agent and load and configure the MSCS AIM on a host other than where DX NetOps Spectrum is installed. Note the following requirements:
  - Install only a single AIM on a particular SystemEDGE host.
  - Do not install the SystemEDGE agent and MSCS AIM on a node that Cluster Manager is going to manage.
  - Register each cluster and cluster node with a single MSCS AIM only.

  NOTE
  For more information, see the *CA Virtual Assurance for Infrastructure Managers Installation and Release Notes* section in C*A Virtual Assurance for Infrastructure Managers* documentation.

  After the MSCS AIM has been successfully installed and configured, it begins gathering data for its managed components. This information is made available in the MIB.
  You can now discover and model your MSCS environment in DX NetOps Spectrum.

Discover and Model Your MSCS Environment

After you have installed the necessary components, discover and model any entities in your MSCS environment that Cluster Manager is going to manage.

Follow these steps:

1. Run a DX NetOps Spectrum Discovery for modeling the Microsoft Cluster Manager and connecting devices.
2. (Optional) Upgrade the SystemEDGE model, if necessary.

   NOTE
   This step is required only if the SystemEDGE host has been modeled in DX NetOps Spectrum before installing the MSCS AIM on the agent.
3. Let the Cluster Manager discovery run, see Cluster Manager Discovery section on this page.

Run DX NetOps Spectrum Discovery to Model the Microsoft Cluster Manager and Connecting Devices

After the SystemEDGE agent and MSCS AIM are set up, model the Microsoft Cluster Manager and any connecting devices in DX NetOps Spectrum. You can use standard DX NetOps Spectrum Discovery to do the following actions:

- Model the Microsoft Cluster Manager, which must be modeled with a read/write community string.
- Model the necessary upstream routers and switches of your MSCS environment so that connections from the cluster models can later be established.

WARNING
Do not include cluster nodes. Clusters, cluster nodes, resource groups, and resources are discovered and modeled automatically using information from the AIM.

NOTE
For details about how to perform a Discovery, see the Modeling and Managing Your IT Infrastructure section.

Gather the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port. Note the following guidelines when configuring your Discovery parameters:

- Include IP addresses for all Microsoft Cluster Managers and interconnecting switches and routers.
- Model the Microsoft Cluster Manager with a read/write community string. If you are modeling the Microsoft Cluster Manager in this Discovery, place its community string appropriately in the SNMP Information ordered list. Alternatively, you can change the community string for the Microsoft Cluster Manager to its read/write value after the discovery.
- Determine pingable MAC addresses during connectivity mapping by using the "ARP Tables for Pingables" option.

  NOTE
  Using this option can increase the time Discover Connections takes to run.
- Add any nonstandard SNMP ports using Advanced Options.

Discovery creates models for the following entities and adds them to your network topology in DX NetOps Spectrum:

- Microsoft Cluster Manager.

  NOTE
  If the Discovery process did not assign the read/write community string to this model, update this setting manually. Use the DX NetOps Spectrum Modeling Information subview for the model.
- The upstream switches and routers that connect the MSCS cluster nodes to your network.

When Discovery has completed and these models exist in DX NetOps Spectrum, Cluster Manager discovery begins.

NOTE
Instead of using standard DX NetOps Spectrum Discovery, you can manually model your Microsoft Cluster Manager by IP address or host name. If you do, model the upstream devices first (since modeling the Microsoft Cluster Manager automatically triggers a Cluster Manager discovery). Modeling in the proper order allows the correct creation of connections in the topology between your cluster nodes and the remainder of your network. For more information, see Modeling and Managing Your IT Infrastructure section.

Upgrade the SystemEDGE Host Model (If Necessary)

If the SystemEDGE host model was created before loading the MSCS AIM on the agent, the existing model is not compatible with Cluster Manager. Upgrade the SystemEDGE host (Host_systemEDGE) model so that Cluster Manager can access the MSCS AIM capabilities in SystemEDGE.

To upgrade the SystemEDGE host model, right-click the model and select Reconfiguration, Reconfigure Model.

The SystemEDGE host model is upgraded to support the MSCS AIM.

NOTE
You can also send a reconfigure model action to the SystemEDGE agent using CLI. For instructions on how to send a reconfigure model action to the SystemEDGE agent, see the Modeling and Managing Your IT Infrastructure section.

Cluster Manager Discovery

Cluster Manager discovery is the automatic discovery and modeling process within DX NetOps Spectrum of cluster components. The Microsoft Cluster Manager initiates this process.

With communication between DX NetOps Spectrum and the MSCS AIM established, Cluster Manager gathers information about your MSCS environment from the MSCS AIM. A list of cluster nodes is passed to AutoDiscovery for modeling. For cluster node models, an SNMP-managed model is created if an SNMP agent exists on the host; otherwise, an ICMP (Pingable) model is created.

New cluster-related models appear in the Cluster Manager hierarchy in the Explorer view and are placed into new cluster containers in the topology view. Connections to any upstream devices are made.

> **NOTE**
> If a cluster node is already modeled in your DX NetOps Spectrum-managed network before Cluster Manager discovery, it is not modeled again. However, the model is included in the cluster container topology.

After the initial modeling, Cluster Manager discovery runs automatically at a frequency that is based on the Microsoft Cluster Manager model poll cycle. During subsequent Cluster Manager discoveries, the modeling within DX NetOps Spectrum is updated with any changes in your cluster environment.

Models Created for MSCS

Cluster Manager provides several models to represent the components of your MSCS environment, as follows:

- Microsoft Cluster

  Manager
  Model Type: Host_systemEDGE
  Represents the host that contains the MSCS AIM. The MSCS AIM monitors the MSCS elements (clusters, nodes, resource groups, and resources) in your environment.
- Microsoft

  Cluster
  Model Type: ClusterMSCSCluster
  Contains cluster node and resource group models that belong to the cluster. You cannot add or remove models from a cluster container, and you cannot destroy the container itself. When possible, this container model is created alongside the Microsoft Cluster Manager model.

  > **NOTE**
  > If the Microsoft Cluster Manager is a virtual machine, the cluster container is placed in the same topology as the physical host container.
- Microsoft Cluster

  Node
  Represents a cluster node in an MSCS environment. Cluster nodes are modeled as SNMP-managed elements when possible. A cluster node can be active or inactive.

An active node has resource groups currently running on it and is represented with a solid (nontransparent) icon. An inactive node does not have any resource groups and is represented with a faded (transparent) icon. When resource groups fail over from one node to another, changing the state of the node, the icon transitions automatically.

NOTE
Unlike a model in maintenance mode or hibernation mode, the inactive node model is fully functional. Data is gathered for the node, and any alarm activity or events for the node are generated on the model.

- Microsoft Cluster Resource

Group
Model Type: ClusterMSCSResourceGroup
Represents a resource group.

- Microsoft Cluster

Resource
Model Type: ClusterMSCSResource
Represents a resource.

Custom Subviews for MSCS

Custom subviews in the Component Detail panel provide detailed information about the components in your cluster environment. You can view information specific to MSCS clusters by:

- Microsoft Cluster Manager
- MSCS Component (Cluster, Cluster Node, Resource Group, Resource)

Microsoft Cluster Manager

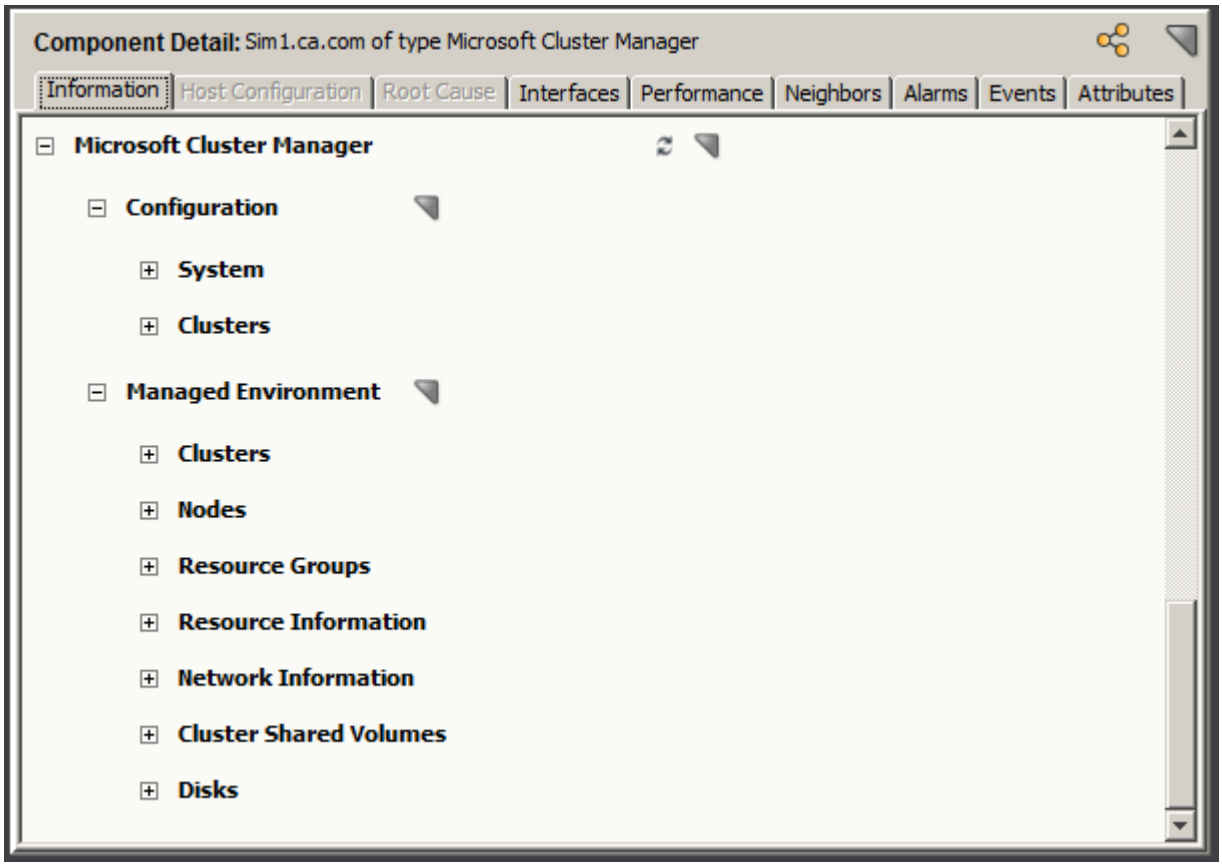
Using subviews that are provided for the Microsoft Cluster Manager (MSCS AIM), you can view the following information:

- Information specific to the Microsoft Cluster Manager host. Data includes the agent version, agent polling interval, and when the MSCS AIM MIB (CAMSCS-MIB) was last updated. You can also control the MSCS AIM polling interval from these views.
- List of clusters that have been registered to the AIM.
- Consolidated information about all cluster components that this MSCS AIM manages.

The following procedure describes how to view information for a Microsoft Cluster Manager.

Follow these steps:

1. Select the Microsoft Cluster Manager model in the Universe hierarchy or topology.
   The Component Detail panel displays information for the selected Microsoft Cluster Manager.
2. In the Information tab in the Component Detail panel, expand the Microsoft Cluster Manager subview.
   The expanded subview appears, as follows:



The following subviews are available for a Microsoft Cluster Manager:

- **Configuration**
  Provides information specific to the Microsoft Cluster Manager, including:
  - Information about the SystemEDGE agent including version, when the MIB was last updated, and polling interval. You can also modify the polling interval, as described in Controlling the MSCS AIM Polling Interval.
  - List of clusters that have been registered to this AIM and their respective readiness
- **Managed Environment**
  Provides consolidated information about all the entities that this AIM manages, including cluster components, resource groups, resources, network information, and storage devices.

MSCS Component

You can view information for any of your clusters or cluster components (cluster node, resource group, resource) in your managed MSCS environment. Views are tailored to the entity type, providing information that is specific to the component.

The following procedure describes how to view information for an MSCS cluster or cluster component.

Follow these steps:

1. Select a Microsoft Cluster, Cluster Node, Resource Group, or Resource model.
   The Component Detail panel displays information for the selected model.
2. In the Information tab in the Component Detail panel, expand the respective cluster-related subview for the model.
   The expanded subview appears, as follows, depending on the model type:
   - **Cluster Information**
     Provides cluster data including:

- The virtual IP address of the cluster
- The number of online and failed node resources
- Log level and the log file size
- Various timeout values
- Statistics on resources, crypto checkpoints, registry checkpoints, messages

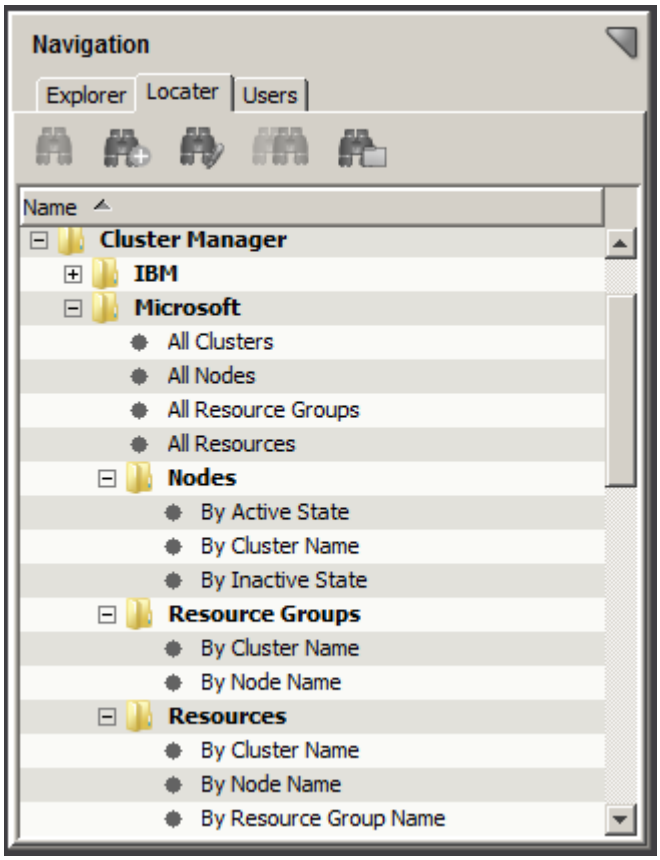
– **Node Information**
Provides cluster node data including:
- General node information including node state, installed Windows details, and the parent cluster
- Host CPU usage and memory statistics
- Data and message information

– **Resource Group Information**
Provides resource group data including:
- The state of the resource group
- The list of its preferred nodes
- Failback and failover threshold values

– **Resource Information**
Provides resource data including:
- The state of the resource
- Possible owners of the resource
- Various timeout, polling, and restart values

Locater Searches for MSCS

You can use the Locater tab to run preconfigured searches. The search options are grouped under the Cluster Manager, Microsoft folder on the Locater tab, as shown:



These detailed searches can help you investigate information that is related to MSCS cluster entities that have been modeled in the DX NetOps Spectrum database.

NOTE
Only users with the appropriate privileges can access Cluster Manager searches. For more information, see the OneClick Administration section.

Alarms for MSCS

To alert you to problems within your MSCS environment, DX NetOps Spectrum generates alarms. Quickly identifying any device faults helps you to maximize your system up-time and the reliability of your cluster environment and high availability applications. Alarms are created from information that is obtained from technology-specific traps and polling. The following sections describe the Cluster Manager events and alarms for your MSCS environment:

NOTE
To view specific event definitions that are related to Cluster Manager, use the Event Configuration application.

Traps for MSCS

DX NetOps Spectrum supports all traps that the MSCS AIM generates. An event is created for any trap activity and is reported initially on the Microsoft Cluster Manager model. Some events are then forwarded to a corresponding cluster entity type (that is, the "destination" entity), depending on the type of trap.

The following table provides the traps and destination entity type and indicates whether the trap generates an alarm by default.

Trap Name	Trap OID	Alarm?	Destination Entity
mscsAimInstanceAddedTrap	1.3.6.1.4.1.546.1.1.0.165100	No	Cluster Manager
mscsAimInstanceRemovedTrap	1.3.6.1.4.1.546.1.1.0.165101	No	Cluster Manager
mscsAimInstanceDataStatusChanged	1.3.6.1.4.1.546.1.1.0.165102	No	Cluster Manager
mscsAimResourceGroupMigration	1.3.6.1.4.1.546.1.1.0.165103	No	Resource Group
aggregateStateTrap*	1.3.6.1.4.1.546.1.1.0.20	Yes*	various*

* The aggregateStateTrap is a SystemEDGE trap. Alarms are generated for certain aggregateStateTrap conditions. For more information, see Self Monitors for MSCS.

NOTE
For more information on MSCS traps, use MIB Tools to view the "CAMSCS-MIB" MIB. For more information, see the Modeling and Managing Your IT Infrastructure section.

State Monitoring for MSCS

Cluster Manager monitors the state of various cluster components in your environment and obtains this information from the following sources:

- Polling the CAMSCS-MIB. Hundreds of objects are monitored regularly about the elements in your cluster environment. This information is updated in DX NetOps Spectrum according to the polling cycle. Cluster Manager derives pertinent information from these objects to create various events and alarms that provide insight into the health and status of your environment.
- Self-monitor traps. When installed, the MSCS AIM configures self monitors on the SystemEDGE agent which track various resources and activities of the managed cluster components. The monitors are threshold-based, and an aggregateState trap is sent when a threshold is violated. DX NetOps Spectrum then generates an event and, depending on the current severity state of the monitor, an applicable alarm. Data that is gathered from self monitors includes CPU or memory usage for a node.

Cluster Manager uses information from both sources to monitor the state of your cluster components. Alarms are generated and, when the condition has been corrected, cleared automatically. All state-based alarms are also user-clearable. When both trap and polling sources reveal the same activity, Cluster Manager identifies the overlap. A single alarm is created, with the alarm that polling generates taking precedence.

The following details apply:

- The MSCS AIM does not provide a state for a cluster. The state is determined by pinging the virtual IP address of the cluster.
- When a resource group moves from a primary node to a secondary node, an alarm occurs. When the resource group moves from the secondary node back to the primary, a new alarm is generated for the latest migration. The original alarm does not clear automatically, but it is user-clearable.

The following table lists the state-based alarm information by cluster component:

Entity	State	DX NetOps Spectrum Alarm Severity
Cluster	Up	Clear
Cluster	Down	Critical (Red)
Node	Up	Clear
Node	Down	Critical (Red)

Node	Joining	Event only
Node	Paused	Event only
Node	Unknown	Major (Orange)
Node	High CPU Utilization*	Major (Orange)
Node	High Memory Utilization*	Major (Orange)
Resource Group	Unknown	Major (Orange)
Resource Group	Online	Clear
Resource Group	Offline	Critical (Red)
Resource Group	Failed	Critical (Red)
Resource Group	Partial_online	Minor (Yellow)
Resource Group	Pending	Event only
Resource Group	Parent changes	Major (Orange)
Resource	Unknown	Major (Orange)
Resource	Inherited	Event only
Resource	Initializing	Event only
Resource	Online	Clear
Resource	Offline	Major (Orange)
Resource	Failed	Critical (Major)
Resource	Pending	Event only
Resource	Online_Pending	Event only
Resource	Offline_Pending	Event only

* Alarms generated from self-monitor aggregateStateTrap.

Self Monitors for MSCS

For the following monitors only, DX NetOps Spectrum generates alarms by default:

- Node CPU Utilization
- Node Memory Utilization

MSCS AIM State	DX NetOps Spectrum Alarm Severity
1: None/Unknown	Event only
2: OK	Clear
3: Warning	Clear
4: Minor	Minor (Yellow)
5: Major	Major (Orange)
6: Critical	Major (Orange)
7: Fatal	Major (Orange)

Controlling the MSCS AIM Polling Interval

Cluster Manager uses the MSCS AIM for discovery, modeling, and monitoring of your MSCS environment. The MSCS AIM has its own polling interval, which can be set from within DX NetOps Spectrum.

NOTE
For information about other MSCS AIM settings, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Follow these steps:

1. Select the Microsoft Cluster Manager model that represents the MSCS AIM.
   The Component Detail panel displays information for the selected Microsoft Cluster Manager.
2. In the Information tab in the Component Detail panel, expand the Microsoft Cluster Manager, Configuration, System subview.
   The expanded System subview appears.
3. For the Agent Polling Interval, click set, modify the value, and press Enter.
   The polling interval for the MSCS AIM is updated.

Viewing and Configuring Events and Alarms

This section explains how to view and modify cluster events, event definitions using the Event Configuration utility in OneClick. This section also explains how to view and modify alarm correlations using the Condition Correlation Editor in OneClick. And how to view and modify self-monitor threshold values in OneClick.

How to View and Modify Cluster Manager Event Definitions

To identify the events that Cluster Manager uses, you can use the Event Configuration application in OneClick. Using this application, you can also modify the generated alarm severity that is associated with the event.

NOTE
Using default settings, Cluster Manager identifies any overlap when multiple monitoring methods reveal the same activity, raising only a single alarm. If you use Event Configuration to add custom alarming, duplicate alarms for the same activity can occur.

Follow these steps:

1. Select Tools, Utilities, Event Configuration.
   The Event Configuration window opens. The Navigation panel displays all events that are defined in your DX NetOps Spectrum installation.
2. Filter for events that apply to Cluster Manager. Using the Show field, enter any of the following event codes one at a time:
   - **0x01169b32 - 0x01169b39, 0x01169c** - Related SystemEDGE events
   - **0x0621** - Cluster Manager events
3. Select an event.
   Event details appear in the Contents panel.
4. (Optional) Use the Details panel to modify any parameter for the event, including alarm severity, and click Save.

NOTE
For more information, see the Event Configuration section.

How to View and Modify Cluster Manager Correlations

To view the correlations that Cluster Manager uses, use the Condition Correlation Editor application in OneClick.

Follow these steps:

1. Select Tools, Utilities, Condition Correlation Editor.

The Condition Correlation Editor opens to the Conditions tab by default. The Conditions tab displays all conditions that are defined in your DX NetOps Spectrum installation.

2. On the Conditions tab, enter **0x0621** in the Show field to display conditions that apply to Cluster Manager.
   Only the conditions that apply to Cluster Manager are displayed. The Condition Name identifies the cluster component and its state. A condition is the basic building block of a correlation. Set Event and Clear Event codes for each condition are also displayed.

   NOTE
   For alarm information associated with a displayed event code, use the Event Configuration application.
3. (Optional) Edit a condition to modify any default settings.
4. Select the Rules tab.
   A list of all correlation rules that are defined for your installation are displayed. The rule defines the relationship between two or more conditions when specific criteria are met.
5. Enter **cluster** in the Show field to filter for rules that apply to Cluster Manager.
6. (Optional) Sort the results by Symptom Condition(s) or Root Cause Condition by selecting the respective column heading.
7. Select a rule.
   The conditions that define the rule are displayed in the Rule Criteria tab.
8. (Optional) Edit a rule to modify any default settings.

   NOTE
   For more information, see the Condition Correlation section.

How to Change Cluster Node Down Alarm Correlation

When a cluster node fails, Cluster Manager correlates the Cluster Node Down alarm to the Contact Lost alarm with Contact Lost as the root cause. You can modify the correlation behavior using the Condition Correlation Editor so that the Cluster Node Down alarm is the root cause. You can also have no correlation and get both alarms.

Modify the Correlation Rule

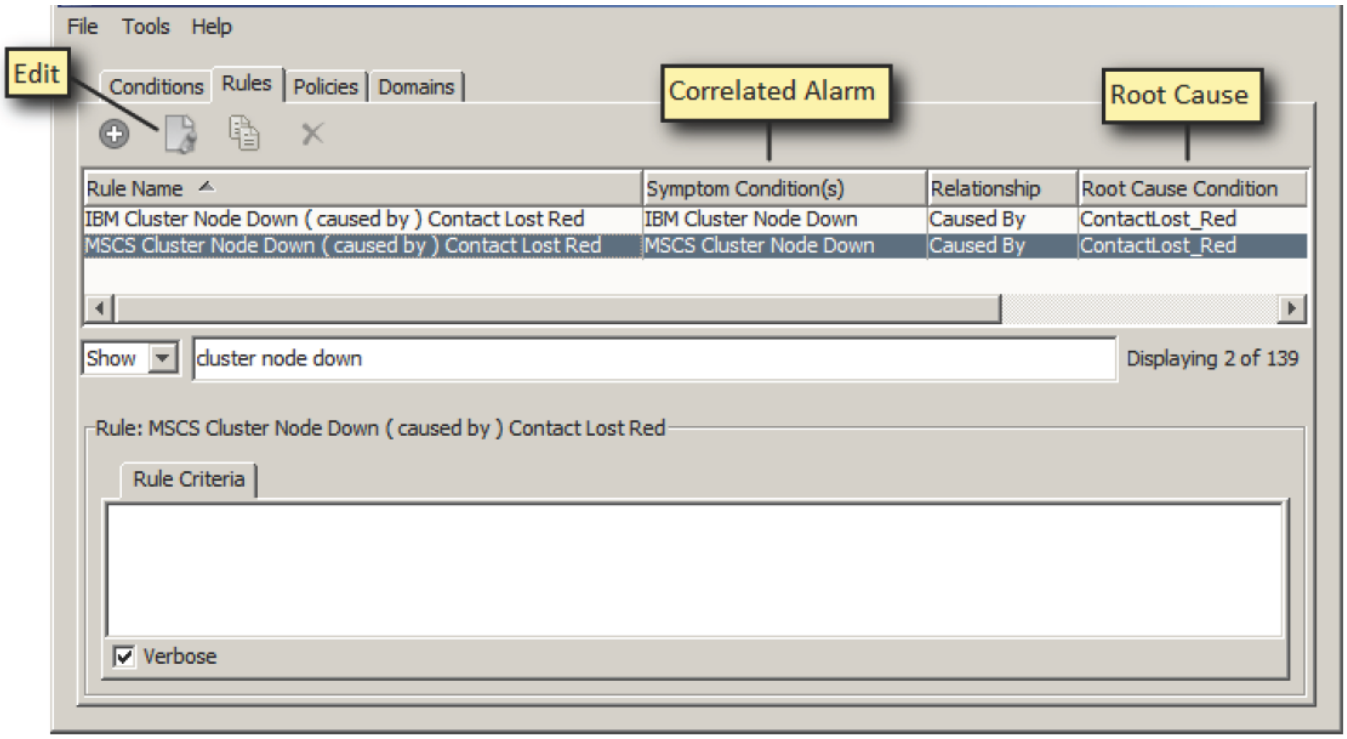
This procedure describes how to change the reported root cause when a cluster node fails by modifying the default correlation behavior.

Follow these steps:

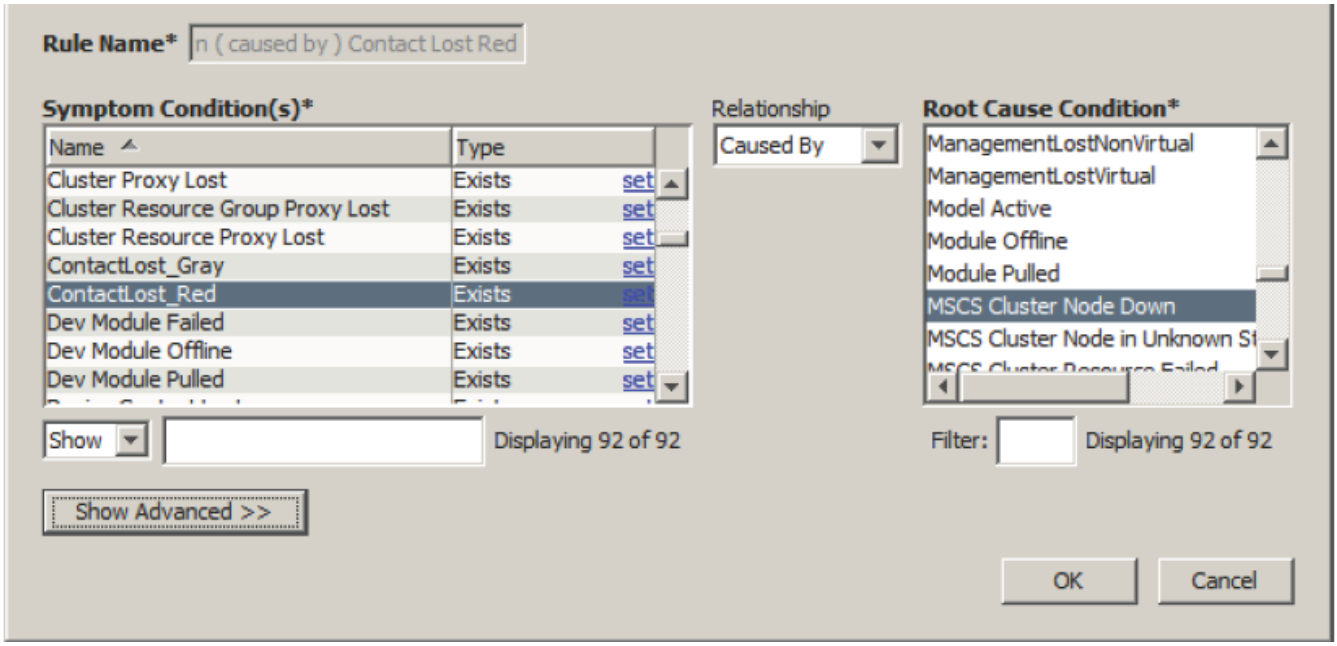
1. Select Tools, Utilities, Condition Correlation Editor.
   The Condition Correlation Editor opens.
2. Select the Rules Tab.
   A list of all correlation rules that are defined for your installation is displayed. The following rules apply to the Cluster Manager and the Cluster Node Down alarm:

   - IBM Cluster Node Down (caused by) Contact Lost Red
   - MSCS Cluster Node Down (caused by) Contact Lost Red

   As shown in the following example, the Symptom Condition of "Cluster Node Down" for each cluster solution correlates to the Root Cause Condition of ContactLost_Red.



3. Select the rule that you want to modify, and click the Edit button.
   The Edit Rule window opens.
4. Modify the values as follows:
   a. Select ContactLost_Red as the new Symptom Condition.
   b. Select the appropriate "Cluster Node Down" value as the Root Cause Condition. As defined in the original out-of-box rules, these values are:
      - IBM Cluster Node Down
      - MSCS Cluster Node Down



5. Click OK.
   Any new alarms for a cluster node failure use Cluster Node Down as the root cause. Existing alarms and symptoms do not change.

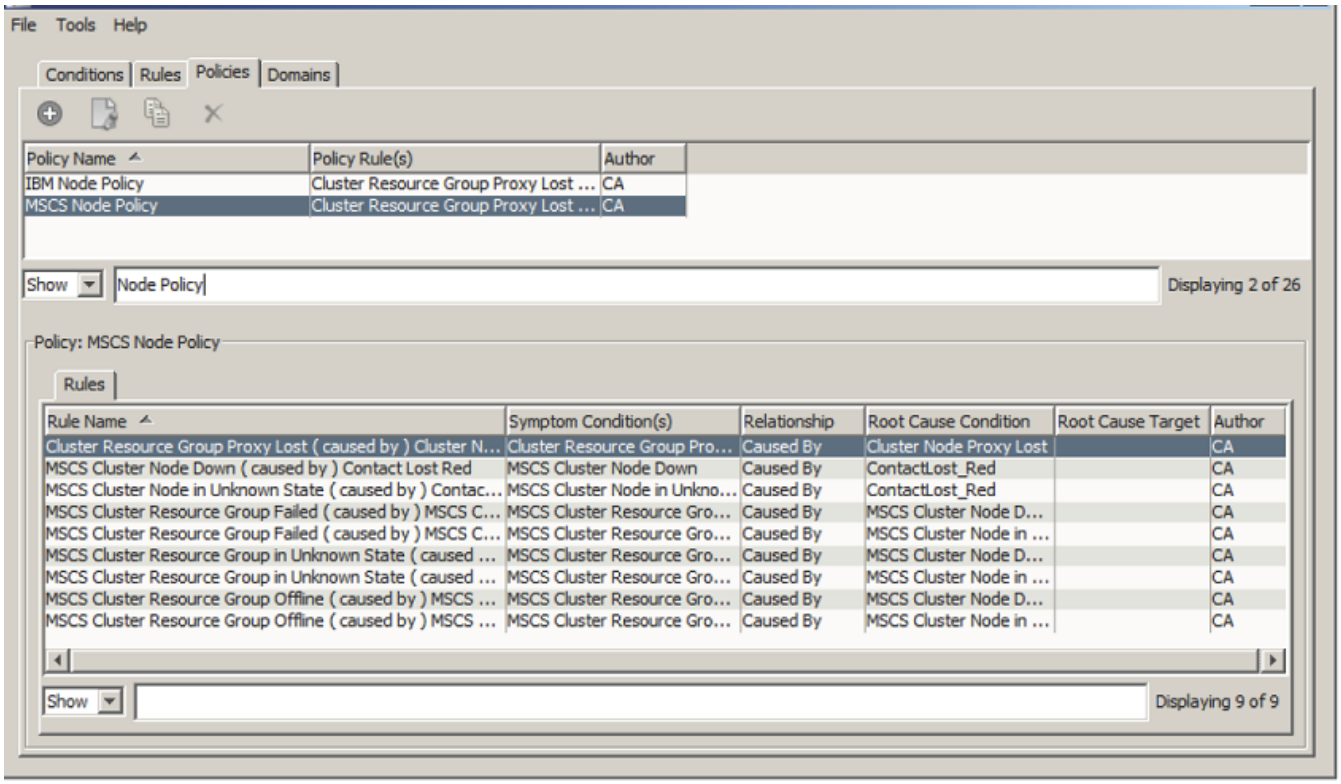
   NOTE
   For more information, see the Condition Correlation section.

Remove the Correlation Rule

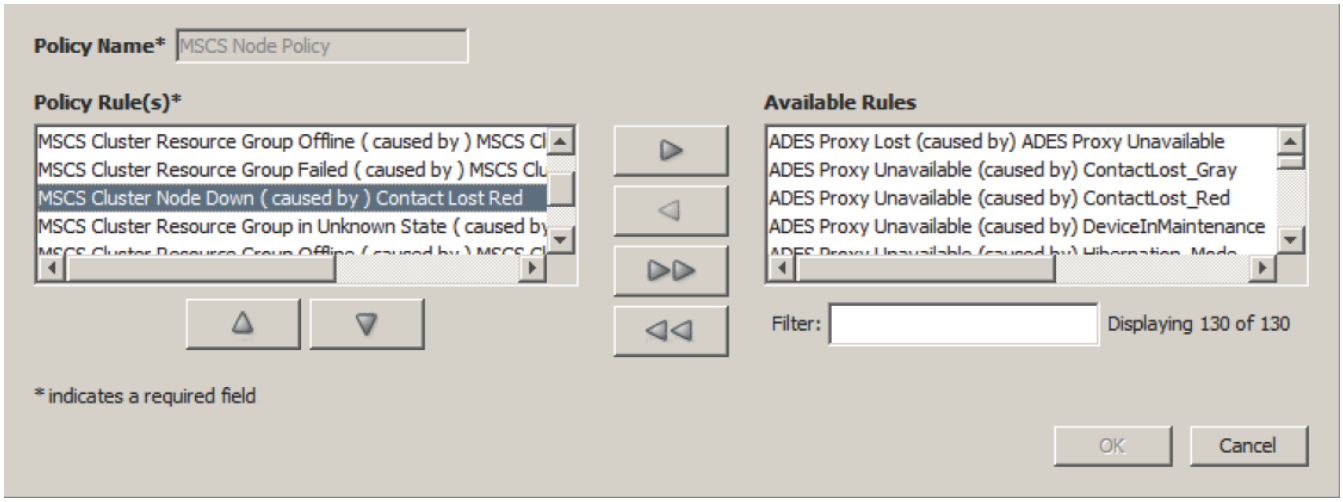
This procedure explains how to remove the correlation rule when a cluster node fails. As a result, both the Cluster Node Down and the Contact Lost alarms are reported.

Follow these steps:

1. Select Tools, Utilities, Condition Correlation Editor.
   The Condition Correlation Editor opens.
2. Select the Policies Tab.
   A list of all correlation policies that are defined for your installation is displayed. The following policies apply to Cluster Manager and the Cluster Node Down alarm:
   - IBM Node Policy
   - MSCS Node Policy



3. Select the policy that you want to modify, and click the Edit button.
   The Edit Policy window opens.
4. Move the appropriate "Cluster Node Down" rule to the right. As defined in the original out-of-box policies, these rules are:
   – IBM Cluster Node Down (caused by) Contact Lost Red
   – MSCS Cluster Node Down (caused by) Contact Lost Red



5. Click OK.
   The Cluster Node Down rule is no longer enabled in the policy. Any new cluster node failures result in both Cluster Node Down and Contact Lost alarms, and no correlation occurs. Existing alarms and symptoms do not change.

   NOTE
   For more information, see the Condition Correlation section.

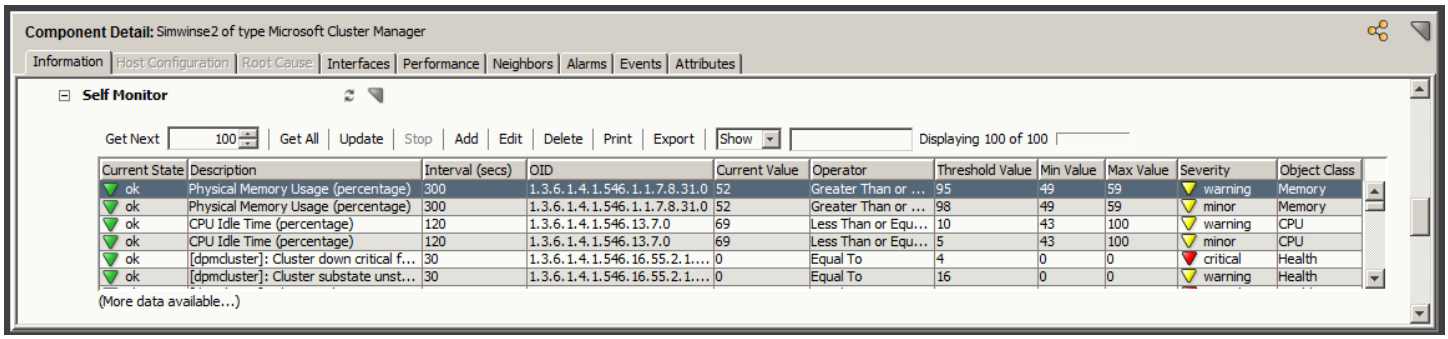
How to View and Modify Threshold Values

Cluster Manager uses self monitors that the cluster technology AIM configures on the SystemEDGE agent. The self monitors are threshold-based and track various resources and activities of the managed cluster components. When a threshold is violated, a DX NetOps Spectrum event and possibly an alarm is created. Configuration parameters for the self monitors are defined and stored on the SystemEDGE agent but can be modified from within DX NetOps Spectrum.

The following procedure describes how to modify self-monitor parameters for your cluster technology AIM from within DX NetOps Spectrum.

Follow these steps:

1. Select the Cluster Manager model in the Universe hierarchy or topology.
   The Component Detail panel displays information for the selected Cluster Manager.
2. In the Information tab in the Component Detail panel, expand the System Resources, Self Monitor subview.
   The expanded subview appears, as follows:



NOTE
Control the columns that appear by right-clicking the table column heading and using the Columns tab. You can also undock the subview.

- Select a row, and click Edit.
  The Edit Self Monitor Table Entry appears.
- Modify the Threshold Value and any other values of interest, and click OK.
  The new values are saved in the table and on the AIM.

Troubleshooting Cluster Manager

This section includes troubleshooting tips for some common problems that are encountered with Cluster Manager.

NetApp Cluster Certification Fixes

This release includes the following fixes:

- The NetApp Cluster Model type is modeled correctly as Modeltype_Name NetAppONTAPDev.
- The Model type Interface data reads from the property mib ie. 1.3.6.1.4.1.789.1.22.1.2
- On clicking the **Interface** tab, the Interface data is displayed.

Unsupported Cluster AIM Configuration

Symptom:

The following alarm message appears after attempting to model the cluster environment 'UNSUPPORTED CLUSTER AIM CONFIGURATION'.

Solution:

You can manage a cluster node by a single cluster technology AIM only. If you inadvertently attempt to manage a cluster node by multiple cluster technology AIMs, Cluster Manager issues this alarm on the cluster model. Children are not created for the cluster model.

Check your AIM configurations. Modify the configuration of your AIMs so that each cluster and cluster node is registered with a single AIM only.

NOTE
For more information, see the *CA Virtual Assurance for Infrastructure Managers* documentation.

Connections Do Not Appear in Topology

Symptom:

Cluster nodes do not show connections to other devices in the OneClick topology view.

Solution:

To produce connections between your cluster nodes and other elements in your network, any connecting devices must be modeled before the cluster nodes are modeled. When discovering and modeling your environment, run a standard DX NetOps Spectrum Discovery first to model upstream routers and switches. Then, Cluster Manager discovery can run, creating models and connections for the cluster components.

Follow these steps:

1. Verify that devices such as routers and switches that are upstream from your cluster nodes are modeled. If not, run a standard DX NetOps Spectrum Discovery to model these connecting devices.
2. If the connecting devices are modeled after your cluster environment is modeled, run Discover Connections on each of the affected devices.

NOTE
For information about Discover Connections, see the Modeling and Managing Your IT Infrastructure section.

Virtual Host Manager

Virtual Host Manager is an application that is provided with DX NetOps Spectrum that models and monitors the health of your virtual network environment. With this application, you can view details about your virtual networking components and the relationships between your physical and virtual components.

This broad view helps you better monitor the health of your network infrastructure, preventing service interruptions to your virtual components. Monitoring your virtual environment, such as monitoring resource utilization on hosts and virtual devices, can help you identify potential performance issues. Virtual Host Manager also helps you pinpoint and effectively troubleshoot problems within your entire network by applying DX NetOps Spectrum fault isolation techniques to virtual environments.

A key challenge when monitoring your virtual environment is keeping the data updated. Virtual environments are designed to optimize resource allocation as needed, so the relationship between the virtual and physical networks can change rapidly. Virtual Host Manager keeps up with these changes and continuously monitors the current state of your virtual network to detect any changes.

Who Should Use Virtual Host Manager

Multiple vendors provide virtual technology solutions. Virtual Host Manager is intended for DX NetOps Spectrum users who create and manage virtual environments. Virtual Host Manager allows the user to monitor the fault and performance of both their physical and virtual network entities.

Virtual Technologies Supported by Virtual Host Manager

Virtual Host Manager can model and manage virtual networks that are created with the following virtual network technologies:

- VMware vCenter Server (part of VMware Infrastructure and vSphere)
- Microsoft Hyper-V
- IBM logical partitions (LPARs)
- Huawei SingleCLOUD

System Requirements for Virtual Host Manager

Virtual Host Manager is an application that works within DX NetOps Spectrum when all required components are configured properly. Virtual Host Manager requires the following components by solution.

VMware

- Release 9.2.3 or later
- VMware vCenter Server
- Latest CA eHealth SystemEDGE agent with vCenter Server AIM

Hyper-V

- Release 9.2.3 or later
- CA eHealth SystemEDGE agent with Hyper-V AIM installed on each physical Microsoft Hyper-V server

IBM LPAR

- Release 9.2.3 or later
- CA eHealth SystemEDGE agent with IBM LPAR AIM installed on a Windows server separate from the HMC managing the IBM LPARs

Huawei SingleCLOUD

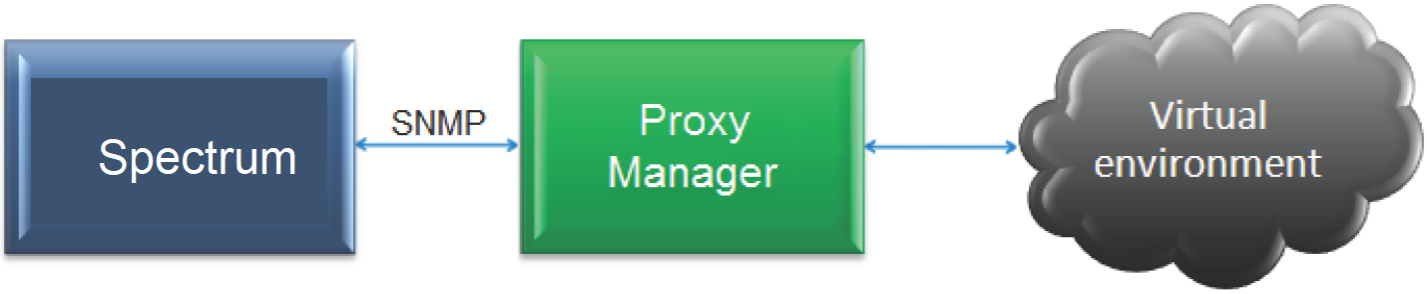
- Release 9.2.3 or later
- CA Mediation Manager with Huawei SingleCLOUD Device Pack

> **NOTE**
> For more information about the CA eHealth SystemEDGE agent and AIM system requirements, see *CA Virtual Assurance for Infrastructure Managers Implementation.* For more information about CA Mediation Manager, see the CA Mediation Manager documentation.

How Virtual Host Manager Works

Virtual Host Manager monitors your virtual network entities seamlessly beside your physical network entities within DX NetOps Spectrum. You get a full view of your network, which facilitates troubleshooting for both types of entities. Although your virtual network entities behave like physical components, the process for monitoring those entities differs from the general DX NetOps Spectrum monitoring process. Understanding how this process works can help you locate and resolve networking issues that are related to your virtual network.

DX NetOps Spectrum typically contacts an SNMP agent on your network devices to gather information. However, some network devices do not have an SNMP agent installed. Without an SNMP agent, it is difficult to gather information that is needed for monitoring status and pinpointing issues using fault isolation. Virtual Host Manager extends basic DX NetOps Spectrum functionality, using a proxy manager to gather the needed information, as shown in the following diagram:



The process to gather information about your virtual network environment is as follows:

1. The proxy manager communicates directly with entities in your virtual environment.

   NOTE
   The proxy manager resides on a server in your network. The location of the server depends on the virtual technology.
2. Using SNMP, DX NetOps Spectrum retrieves this information from the proxy manager and uses it to model and monitor your virtual entities.

Depending on the solution, Virtual Host Manager uses either of the following proxy managers, which are described in the following sections:

- CA eHealth SystemEDGE agent with a CA Virtual Assurance for Infrastructure Managers AIM module
- CA Mediation Manager with a solution-specific device pack

CA eHealth SystemEDGE Agent with CA Virtual Assurance for Infrastructure Managers AIMs

The following CA Virtual Assurance for Infrastructure Managers AIMs work with Virtual Host Manager:

- **vCenter Server AIM:** Provides the capabilities for managing and monitoring systems that are under VMware vCenter Server control. The AIM communicates directly with vCenter Server software to get an entire view of all ESX servers that the associated VMware vCenter Server manages.
- **Hyper-V AIM:** Provides the capabilities for monitoring VMs that are under Hyper-V Server control. The Microsoft Hyper-V AIM requires the CA eHealth SystemEDGE agent on the Microsoft Hyper-V server. The Microsoft Hyper-V AIM communicates with the Microsoft Hyper-V server through WMI. The Microsoft Hyper-V AIM must reside on the Microsoft Hyper-V server to monitor virtual machines.
- **IBM LPAR AIM:** Provides the capabilities for monitoring IBM LPARs managed by the HMC. The IBM LPAR AIM requires the CA eHealth SystemEDGE agent running on a Windows server separate from the HMC. The IBM LPAR AIM uses SSH to communicate with the HMCs, gathering information from the HMC to monitor the IBM LPAR instances.

CA Mediation Manager

The following CA Mediation Manager Device Pack is used with Virtual Host Manager:

- **Huawei SingleCLOUD**
  Provides the capabilities for monitoring the Huawei SingleCLOUD platform. CA Mediation Manager communicates directly with Huawei SingleCLOUD GalaX to obtain information about the Huawei HyperVisor Universal Virtualization Platform (UVP).

Overlapping Virtual Technologies

Your virtual environment has "overlapping" technologies when either of the following conditions exist:

- When two or more virtual technologies are used together in your environment
- When the same virtual technology is nested together

Virtual Host Manager does *not* support overlapping technologies that are modeled within a single SpectroSERVER. The following configuration represents overlapping virtual technologies:

DX NetOps Spectrum

- IBM LPAR AIM running on a VMware virtual machine or Hyper-V virtual machine

When DX NetOps Spectrum discovers an unsupported configuration between virtual technologies, the following behavior occurs:

- During initial modeling of a virtual technology manager, DX NetOps Spectrum prevents the creation of the technology folder. A minor alarm is generated, alerting you to the unsupported configuration.
- When a virtual technology manager monitors the same device that another manager is managing currently, DX NetOps Spectrum creates duplicate models for that device.

If you model the overlapping virtual technology manager on a separate SpectroSERVER, then Virtual Host Manager *can* support the overlapping technology managers.

Virtual Device Management and Multiple DX NetOps Spectrum AIM Solutions

When managing a device by multiple DX NetOps Spectrum AIM solutions, a defined ranked order of management applies, as follows:

1. Virtual Host Manager
2. Cluster Manager
3. Other technologies (such as Active Directory and Exchange Server Manager)

When a host with a CA eHealth SystemEDGE agent is already modeled in , Virtual Host Manager recognizes the model. A duplicate model is not created. Instead, Virtual Host Manager pulls the existing model into its own management, applying the rules for each solution using the ranked order.

For example, when both Virtual Host Manager and Cluster Manager are managing a device, model parameters that Virtual Host Manager assigns are used. Examples of these parameters include the model name, IP address, and MAC address.

When a solution no longer manages a device, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.

The defined order of management also affects how models appear in the Universe topology. Because Virtual Host Manager is the highest in the management ranking, all virtual devices appear in the appropriate virtual host containers automatically.

For more information, see Cluster Manager and Active Directory and Exchange Server Manager.

Install Virtual Host Manager

This section describes the basic information that is required to install and begin using Virtual Host Manager. The information in this section applies to all virtual technologies supported by Virtual Host Manager.

How to Install Virtual Host Manager

When you install DX NetOps Spectrum, the Virtual Host Manager components are automatically installed and available for use. However, Virtual Host Manager is operable only after you also install and configure the appropriate proxy manager for your solution. For Huawei SingleCLOUD, use CA Mediation Manager. For all other supported technologies, use the CA Virtual Assurance for Infrastructure Managers AIM of the CA eHealth SystemEDGE agent.

To manage your virtual devices, DX NetOps Spectrum must be able to contact the proxy manager. And the proxy manager must be able to communicate with your network devices.

To install Virtual Host Manager, complete these tasks:

1. Install the appropriate proxy manager:

- For VMware, Hyper-V, and IBM LPAR solutions, install the CA eHealth SystemEDGE agent and load the appropriate CA Virtual Assurance for Infrastructure Managers AIM. Use the appropriate location for your virtual technology, as follows:
  - VMware: Install on a separate server that can contact vCenter remotely.
  - Hyper-V: Install on each Hyper-V Host.
  - IBM LPAR: Install on a Windows server separate from the HMC that manages the IBM LPARs.

    NOTE
    Monitor only one instance of the IBM LPAR Host with the IBM LPAR AIM. Do not manage a single IBM LPAR Host with multiple HMCs. Monitoring more than one instance can result in duplicate models in DX NetOps Spectrum.

  For installation instructions and more information about the AIM for your virtual technology, see *CA Virtual Assurance for Infrastructure Managers* documentation.
- For Huawei SingleCLOUD, install and configure CA Mediation Manager and the Huawei SingleCLOUD Device Pack. Do not install the CAMM components on the same server where DX NetOps Spectrum is installed.

  WARNING
  When configuring the Huawei SingleCLOUD Device Pack, you set the virtual IP addresses. The primary IP address of the device or virtual machine where the CAMM Presenter is installed cannot be used as a virtual IP address.

  For more information, see the CA Mediation Manager documentation.

2. Install DX NetOps Spectrum with Virtual Host Manager included.

   WARNING
   Do not install SpectroSERVER on a virtual machine (VM) that is managed by Virtual Host Manager. DX NetOps Spectrum identifies that SpectroSERVER machine as the VNM model. As a result, selecting that VM in the navigation hierarchy of OneClick displays the universe topology under that VM. This phenomenon continues in an indefinite loop.

For specific installation instructions, see Installation .

You can now model your virtual network in DX NetOps Spectrum.

How to Model Your Environment When Using Multiple AIM Solutions

Depending on your environment, you can use Virtual Host Manager with other DX NetOps Spectrum AIM solutions to manage your infrastructure. Some configurations, such as the following examples, require multiple solutions for comprehensive management:

- A cluster node is a virtual machine.
- An Active Directory or Exchange Server host is a virtual machine.

Each of the DX NetOps Spectrum AIM solutions provides information that is specific to the technology it supports. For example:

- Virtual Host Manager provides data that is specific to virtual technologies.
- Cluster Manager provides data that is specific to cluster technologies.
- Active Directory and Exchange Server (ADES) Manager data that is specific to the supported Active Directory and Exchange Server roles.

Combined, these features provide a complete monitoring solution. To set up your implementation of multiple AIM solutions, take the following recommended approach.

> **WARNING**
> When using multiple AIMs, only a single AIM can be installed on a CA eHealth SystemEDGE host.

Follow these steps:

1. Configure the AutoDiscovery settings on the VNM model.
2. Configure the Virtual Host Manager settings that are related to your virtual technology.
3. Set up Virtual Host Manager by modeling the virtual technology manager and all virtual technology components.
4. Set up Cluster Manager by modeling the cluster technology manager and all cluster components.
5. Set up ADES Manager by modeling the ADES Host Manager and all Active Directory and Exchange Server hosts.

For more information, see Cluster Manager Solution and Active Directory and Exchange Server Manager Solution.

Viewing the Virtual Environment

VHM Overview

The purpose of Virtual Host Manager is to provide visibility into your virtual environment. This visibility lets you view the logical relationships between devices, view performance data for individual entities, and report on the data you discover. Your virtual environment inevitably connects with your physical environment. Virtual Host Manager can help you visualize where these connections are and how they are performing.

Virtual Host Manager provides several methods for viewing your virtual environment, as follows:

- The Explorer tab hierarchy in the Navigation panel shows logical relationships.
- Icons for individual models provide status and model type information at a glance.
- A graphical topology view helps you visualize connections between virtual and physical entities.
- Information views in the Contents and Component Detail panels provide detailed information about individual entities in your virtual environment.

Understanding each of these methods can help you monitor your virtual environment, letting you troubleshoot issues and optimize performance.

For more information about using the OneClick interface, see Using OneClick .

Cut, Copy, Paste and Delete Functionality for VHM Models

The Cut, Copy, Paste and Delete functionality for VHM models is disabled by default to avoid duplication of models in ESX container. If you move or delete a virtual model from its original parent ESX container, at the next polling cycle the model gets recreated in the original ESX container again. To avoid this and other similar problems with virtual models,

the Cut, Copy, Paste and Delete functionality for VHM models is disabled by default. If required, this functionality can be enabled by changing the ‘editmodemask’ (attribute 0x130cc) value to zero in OneClick.

When you discover devices using SNMP Discovery in DX NetOps Spectrum, Virtual Host Manager creates SNMP models for all new SNMP-capable models and places them in the correct ESX container. It is not supported to move a virtual model from its original parent ESX container to another.

One operation that is supported for virtual models is to copy a model from VHM to the World topology view, as these are separate so do not lead to duplication.

You may need to delete a VM model and recreate it in Virtual Host Manager in the following scenarios:

- To update the DX NetOps Spectrum model type if an SNMP agent type changes from one type to another
- To change a model type from an SNMP-capable type to Pingable

NOTE

Please be aware that moving or deleting VHM models within the Universe can have unexpected consequences as they are automatically modeled in the correct ESX host container.

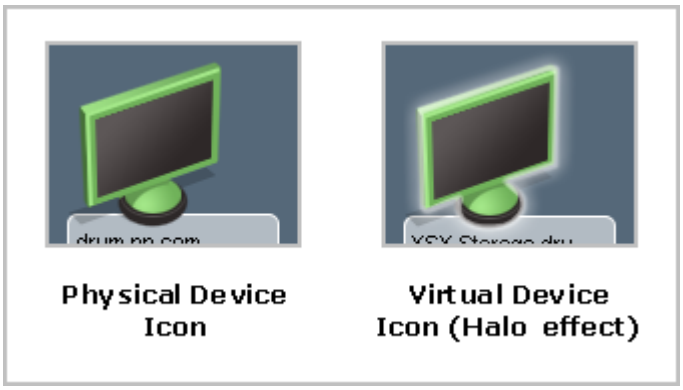
Changing the ‘editmodemask’ (attribute 0x130cc) value:

Follow these steps:

1. From OneClick, select Virtual Server, Component Details panel, Attributes tab.
2. Filter for the "EditModeMask" (0x130cc) attribute in the attribute list.
3. Move the "EditModeMask" attribute to the right side of the window and change the attribute value to '0'. You can cut, copy, paste or delete the device within 10-15 seconds.

Icons for Virtual Devices

Virtual Host Manager provides icons that are designed specifically to distinguish devices in your virtual environment. To distinguish physical and virtual entities, the virtual device icons have a halo-like appearance around the outer edge. For example, a virtual device model icon displays a halo around the perimeter, as follows:



For physical servers that host virtual devices, Virtual Host Manager uses a distinctive honeycomb pattern on the device icon, as follows:

Locating Virtual Models

The models that are created for your virtual environment are integrated into DX NetOps Spectrum in the following three places:

- **Universe group**
  Appears in the Navigation panel and provides a hierarchical tree structure that displays the logical relationships between devices, both physical and virtual.
- **Virtual Host Manager group**
  Appears in the Navigation panel and provides a hierarchical tree structure. This structure helps you to visualize the relationships between your virtual devices, physical devices, and the logical entities that are configured in your virtual technology.
- **Topology tab**
  Appears in the Contents panel, providing a graphical view of your physical network, virtual network, and virtual machines. The topology provides a layer 2 view of the network, showing how your virtual and physical networks are connected. You can use this view to resolve alarms involving these virtual network models.

  NOTE
  This tab is available for only items in the Universe group.

All these views are available from the Explorer tab in the Navigation panel. Understanding how your virtual environment information appears in DX NetOps Spectrum is the key to deciding which view is best for viewing your virtual entities.

For more information about using the OneClick interface, see Using OneClick .

Locate Models on the Explorer tab

As you work with models in the OneClick Console, you can quickly locate a selected model on the Explorer tab. The location feature is provided for items in the Contents and Component Detail panels that reference a single model. These items include rows from the alarms or events tables. The feature is also available from the search results table.

View the same model in different Explorer tab groups to gain insight into its relationships within your physical and virtual networks.

To locate models on the Explorer tab, use the following procedure.

Follow these steps:

1. Locate an item in the Contents panel or Component Detail panel that references a single model.
2. Right-click the item and select from the following options:

- **Location**

Changes the OneClick Console views to locate the selected model within the Explorer tab hierarchy in the Navigation panel. You can select from the following location options**:**

- – **Universe**
  Locates the model in the Universe group hierarchy on the Explorer tab.
- – **Virtual Host Manager**
  Locates the model in the Virtual Host Manager group hierarchy on the Explorer tab.

The OneClick Console locates the related model in the Explorer tab. The Contents and Component Detail panels display details about the selected model.

Topology View

The DX NetOps Spectrum topology views provide a graphical depiction of your physical network, virtual network, and virtual machines. The topology views are available on the Topology tab in the Contents panel. Use the views on the

Topology tab to resolve alarms involving these virtual network models. These views display the Layer 2 connectivity, showing how virtual and physical networks are connected.

DX NetOps Spectrum provides options for arranging the models in most topology views, such as the tree, radial, or manual layout. When selecting the tree layout, the Topology tab for the Universe group includes the following three *unlabeled* tiers of models:

- **Top tier**
  Displays the routers that are discovered with SNMP. These routers are the first level of routers within your virtual network environment that connect your virtual host devices to your physical network.
- **Middle tier**
  Contains any manageable switches that are discovered in your environment. These switches provide connectivity to the virtual host devices within the data center.
- **Bottom tier**
  Contains the virtual host device models and any unmanaged switches. The virtual host devices are the physical servers that run your virtualization technology.

When a server that hosts virtual machines is selected from the Explorer tab, only one layout option is available for the Topology tab. This automatic layout is organized into a tree structure and includes the following three *labeled* tiers:

- **Physical Network**
  Contains an off-page reference to any physical switches that detect traffic for a specific virtual machine. These entities are the components of your physical network that connect to your virtual network.
- **Virtual Network**
  Represents the internal or virtual switching that the virtual machine device provides. When a virtual switch has been configured with multiple virtual machines, DX NetOps Spectrum creates a model in the Virtual Network tier named a "repeater segment" or a "fanout." This fanout model represents the presence of a virtual switch.
- **Virtual Machines**
  Includes the virtual machines that are configured on the virtual host device that you selected in the Navigation panel.

Information Tab and Subviews

The tabs in the Contents and Component Details panels provide information that helps you monitor your virtual environment. The Information tab provides details about a single entity in your environment.

Expand the subviews to see detailed information. Most of the Information tabs include a General Information subview that lists general details about a selected model. Details include the IPv4 address, connection status, and other information.

Updating the Views

When you run the initial Discovery, Virtual Host Manager populates the Explorer tab with virtual device models. After Virtual Host Manager builds this initial hierarchy, your virtual network configuration can change frequently. Therefore, Virtual Host Manager continually updates this information. The information is useful for troubleshooting issues and optimizing performance only when it accurately reflects your virtual environment.

Understanding how and when the information is updated can help you evaluate the data and monitor your virtual environment.

Searching your Virtual Environment

Searching your virtual environment with DX NetOps Spectrum is a fundamental network management task. Virtual Host Manager does not provide a virtual-only topology view. Instead, DX NetOps Spectrum provides a collection of searches on the Locater tab that are designed specifically for your virtual network. These searches identify specific models or

groups of models on your virtual network. Using these searches can help you locate details that you can use to monitor the performance of your virtual environment.

Alarms and Fault Isolation

To alert you to problems within your virtual network, DX NetOps Spectrum generates alarms and uses advanced fault management techniques to isolate the root cause. Virtual networks provide a unique management opportunity because they provide an alternate management perspective in addition to standard device monitoring. While gathering information directly from a device, DX NetOps Spectrum also simultaneously gathers information from the proxy manager. With this extra monitoring capability, in addition to Contact Lost alarms, you can also incur Proxy Lost or Proxy Manager Unavailable alarms.

Alarms and fault isolation vary by virtual technology. The type of fault isolation that Virtual Host Manager uses depends on the devices that generate alarms and the type of events. DX NetOps Spectrum uses all available information to correlate the alarms to the appropriate root cause, avoiding multiple or false alarms.

Alarms on Initial Models

Until DX NetOps Spectrum contacts a model, the model remains in the Initial (blue) condition. Alarms are typically not visible on a model in the Initial condition; however, an exception applies when using Virtual Host Manager. If a virtual machine is brought into Virtual Host Manager management in the powered-down or suspended state, the critical Powered-Down or Suspended alarm overrides the Initial condition.

Creating Event Reports

Use event filters to create event reports in Spectrum Report Manager. You can base these reports on any of the traps and events that are generated for your virtual entities in DX NetOps Spectrum.

To report on Virtual Host Manager events, the following event filter files are included with Spectrum Report Manager:

- vhm.xml
- vhmtrap.xml

For more information about using Spectrum Report Manager to generate event reports from these codes, see Install Report Manager. For information about using the predefined event filter files to generate reports, see Install Report Manager section.

Deleting Models When Using Multiple AIM Solutions

If you use Virtual Host Manager with other DX NetOps Spectrum AIM solutions, consider the following points when deleting models in your environment:

- If you plan to stop managing the device models using Virtual Host Manager, configure Virtual Host Manager delete settings to retain models. Otherwise, Virtual Host Manager deletes the model initially, losing any history or customization. Another AIM solution then recreates the model.

  NOTE
  The Virtual Host Manager setting to retain models when the technology manager is deleted applies to SNMP-enabled device models only. For ICMP (Pingable) models, Virtual Host Manager deletes the model, and then another AIM solution recreates the model.
- When Virtual Host Manager unmanages a device and the model is retained, another AIM solution automatically pulls the model into its management.
- If a solution no longer manages a device, the rules of the remaining solutions are reapplied in the ranked order. Typically, any changes are made at the next polling cycle.
- The Explorer view hierarchy synchronizes after the Lost and Found (LostFound) is emptied.

VMware

This section is for VMware users and describes how to use Virtual Host Manager to manage your virtual entities that are created with VMware vCenter.

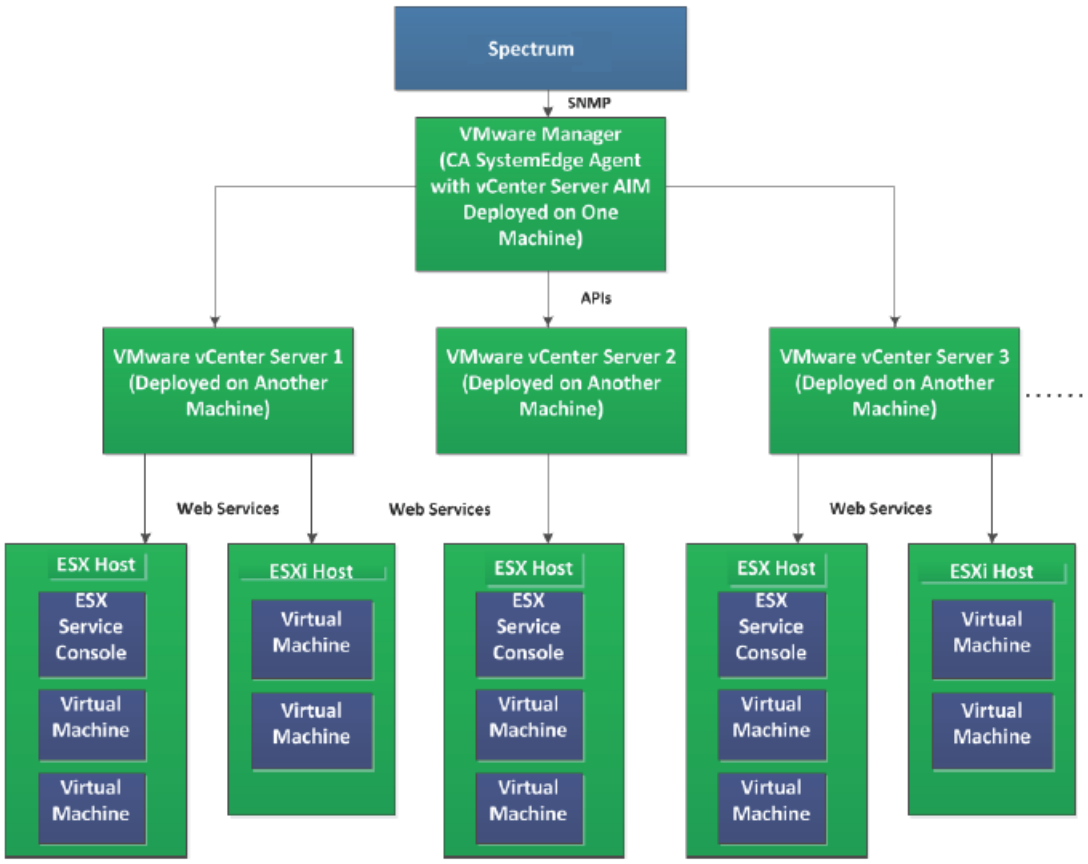
How Virtual Host Manager Works with VMware

Virtual Host Manager monitors your virtual network entities seamlessly with your physical network entities within DX NetOps Spectrum. You get a full view of your network where you can troubleshoot networking issues for both types of entities. Although your virtual network entities behave like physical components, the process for monitoring those entities differs from the general DX NetOps Spectrum monitoring process. Understanding how this process works can help you locate and resolve networking issues that are related to your virtual network.

DX NetOps Spectrum supports only the remote deployments of the latest CA eHealth SystemEDGE. The latest CA eHealth SystemEDGE comes with the latest vCenter Server AIM capable of managing multiple vCenter Server instances (multi-instance). As a result, you can have one or more remote CA eHealth SystemEDGE deployments for managing multiple VMware vCenter Servers. We recommend not to manage the same VMware vCenter Server using more than one remote CA eHealth SystemEDGE deployment.

NOTE
The latest version of CA eHealth SystemEDGE is 5.9. For more information about remotely deploying CA eHealth SystemEDGE, see *CA Virtual Assurance for Infrastructure Managers Implementation Guide*.

The following diagram shows how DX NetOps Spectrum gathers information about your VMware virtual environment using the latest remote CA eHealth SystemEDGE agent:



As shown in the diagram, the process to gather information about your VMware virtual environment is as follows:

1. The VMware vCenter application manages the ESX hosts in your virtual network. The VMware vCenter application stores detailed data about each ESX host and their virtual machines.
2. The CA eHealth SystemEDGE agent communicates with vCenter to gather the details about your virtual network. The CA eHealth SystemEDGE agent must have the vCenter Server AIM loaded.
3. Periodically, DX NetOps Spectrum retrieves information from CA eHealth SystemEDGE and uses it to model and monitor your virtual entities in OneClick.

Because Virtual Host Manager communicates with vCenter, DX NetOps Spectrum is aware of spontaneous network configuration changes. Examples are those changes that are due to VMware VMotion, HA technology, or a DRS scenario. Changes that are associated with these events are quickly reflected in OneClick and factored into the root cause analysis.

Models Created for VMware

Virtual Host Manager provides several models to represent the components of your VMware virtual technology network. Understanding the following basic models can help you better understand Discovery and how the virtual environment interfaces with your physical environment.

> **NOTE**
> Deployment of the CA eHealth SystemEDGE agent and vCenter Server AIM in your environment impacts the models that Virtual Host Manager displays.

Virtual Host Manager includes the following models and icons for VMware devices in the *remote* deployment scenario:

- **VMware Manager**

Represents a physical or virtual host that contains the CA eHealth SystemEDGE agent with vCenter Server AIM loaded. This CA eHealth SystemEDGE agent remotely monitors the vCenter application running on a separate host (represented by the VMware vCenter Server model).
Icon:

or

- **VMware vCenter Server**
  Represents a physical or virtual host that contains the vCenter application to manage your VMware virtual environment. The CA eHealth SystemEDGE agent with vCenter Server AIM monitors the vCenter application remotely. The CA eHealth SystemEDGE agent with vCenter Server AIM is on a separate host (represented by the VMware Manager model).
  Icon:

or

- **ESX Host**
  Represents an ESX host, as configured in your VMware virtualization technology. An *ESX host* is a physical computer that uses ESX Server virtualization software to run virtual machines. Hosts provide the CPU and memory resources that virtual machines use and give virtual machines access to storage and network connectivity. In the Universe topology, these models group your virtual entities into a separate view while showing how the virtual environment interacts with the physical network. The ESX host cannot be contacted directly for status information. Instead, the status of these models is inferred from the status of the items that it contains.
  Icon:

- **ESX Service Console**
  Represents the ESX service console component of your virtual environment. The *ESX service console* is a Linux kernel running on the ESX host that provides a management interface to the hosted virtual machines.

Icon:

- **Virtual Machines**
  Represents a virtual machine, as configured in your VMware virtualization technology. A *virtual machine (VM)* is a software computer that, like a physical computer, runs an operating system and applications. A virtual machine dynamically consumes resources on its physical host, depending on its workload. Because virtual machines are flexible computing units, their deployment comprises a wide range of environments. Examples include environments such as data centers, cloud computing, test environments, or desktops and laptops. In data center implementations, they are used for server consolidation, workload optimization, or higher energy efficiency.
  Icon:

Virtual Host Manager also creates models these additional VMware entities that organize the ESX hosts and their virtual machines:

- **Data Centers**
  Represents a data center, as configured in your VMware virtualization technology. A *data center* serves as a container for your hosts, virtual machines, resource pools, or clusters. Depending on their virtual configuration, data centers can represent organizational structures, such as geographical regions or separate business functions. You can also use data centers to create isolated virtual environments for testing or to organize your infrastructure. Components can interact within data centers, but interaction across data centers is limited. A data center can contain clusters or hosts.
  Icon:

- **Clusters**
  Represents a cluster, as configured in your VMware virtualization technology. A *cluster* is a group of ESX hosts and their associated virtual machines. When a host is added to a cluster, the host resources become part of the cluster resources. The cluster manages the resources of all hosts within it. A cluster can contain hosts, resource pools, or virtual machines.
  Icon:

- **Resource Pools**
  Represents a resource pool, as configured in your VMware virtualization technology. A *resource pool* defines partitions of physical computing and memory resources of a single host or a cluster. You can partition any resource pool into smaller resource pools to divide and assign resources to specific groups or for specific purposes. You can also hierarchically organize and nest resource pools. A resource pool can contain virtual machines or more resource pools.
  Icon:

WARNING
Resource pools that are named "Resources" are skipped during Discovery and modeling. This name is designated for internal use only. Therefore, Virtual Host Manager filters these resource pools out of the Discovery results. You can avoid missing models for resource pools and the devices that they contain by specifying a different name for VMware resource pools.

Discovering VMware Networks

This section describes the Discovery and modeling process for Virtual Host Manager. The Virtual Host Manager administrator typically performs these tasks.

How to Configure Discovery Options

After installation, configure Virtual Host Manager for vCenter Discovery. Selecting preferences helps Virtual Host Manager to model virtual devices correctly.

Select preferences for the following options:

- **Automatically Model New Data Centers**
  Determines whether new data centers that are discovered during vCenter Discovery are modeled automatically.
- **Maintenance Mode for New Virtual Machines**
  Lets you decide which newly discovered virtual machines are placed into maintenance mode until you are ready for DX NetOps Spectrum to manage them.
- **Allow Device Model Deletes During vCenter Discovery**
  Controls how DX NetOps Spectrum handles ESX host, ESX service console, and virtual machine models when vCenter no longer manages them. Controls how these models are handled when you configure DX NetOps Spectrum to disable management of their parent data center.
- **Search for Existing Models**
  Determines the secure domains that Virtual Host Manager searches during a vCenter Discovery.
- **Discover SNMP-Capable Devices**
  Controls how SNMP-capable devices are modeled during vCenter Discovery. By default, new models are initially created as VHM models only. But, this option lets you override the default and immediately create SNMP models for devices that meet the necessary criteria.
- **Retain SNMP-enabled Virtual Machines During VMware Manager Deletion**
  Controls how DX NetOps Spectrum handles SNMP-enabled virtual machine models when a VMware Manager model is deleted.

Configure Automatic Modeling for New Data Centers

For each SpectroSERVER in your networking environment, you can control whether DX NetOps Spectrum automatically models new data centers that are found during vCenter Discovery. Modeling data centers automatically means that DX NetOps Spectrum manages all data centers in your vCenter environment.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery subview.
4. Click Set in the 'Automatically Model New Datacenters' field, and select one of the following options:

- **Yes**
  (Default) Models all data centers that are found during vCenter Discovery. Includes all of the contained clusters, resource pools, ESX hosts, ESX service consoles, and virtual machines.
- **No**
  Prevents the modeling of new data centers that are found during vCenter Discovery. DX NetOps Spectrum does not model the components that are contained within the data center.
  Use this option if your networking environment includes data centers that do not require monitoring. Then model your data centers manually.

Your setting is saved, and new data centers are modeled in Virtual Host Manager according to your selection.

Configure Maintenance Mode for New Virtual Machines

Virtual Host Manager automatically models the virtual machines that vCenter manages. DX NetOps Spectrum attempts to manage all discovered models. However, some virtual machines are not ready for DX NetOps Spectrum management when they are initially modeled. For example, DX NetOps Spectrum generates a Virtual Machine Powered Down alarm when it detects virtual machines that are powered down. To prevent undesired alarms on new models, you can select virtual machine models to be immediately placed into maintenance mode. Later, you can manually disable maintenance mode when you are ready to manage these devices.

Configure the maintenance mode for new virtual machines in OneClick.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery subview.
4. Click Set in the "Maintenance Mode for New Virtual Machines" field, and select one of the following options:
   - **Place only Powered down VMs in Maintenance Mode**
     (Default) Applies maintenance mode only to powered-down or suspended virtual machine models at initial vCenter Discovery.
   - **Place all VMs in Maintenance Mode**
     Applies maintenance mode to all new virtual machine models upon initial vCenter Discovery.

   Your setting is saved, and new virtual machines that are modeled in Virtual Host Manager are placed into maintenance mode according to your selection.

Configure Model Searches Across Secure Domains

Rather than creating new models, vCenter Discovery attempts to locate models that exist in the SpectroSERVER. In an environment with Secure Domain Manager deployed, vCenter Discovery searches for models within the same secure domain as your VMware Manager. This domain is the "local" domain. However, some of your virtual environment devices can exist within a different secure domain. In this case, you can configure vCenter Discovery to search all secure domains for existing models.

You configure model searches across secure domains.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery subview.
4. Click Set in the "Search for Existing Models" field and select from the following options:

- **In vCenter's Secure Domain**
  (Default) Searches for existing models within the same secure domain as the vCenter server.
- **In All Secure Domains**
  Searches for existing models within all secure domains managed by the SpectroSERVER. Select this option only in the following situations:
  - All devices have unique IP addresses.
  - When secure domains are used for security purposes or to isolate network traffic.

  NOTE
  Do not select this option for a NAT environment.

Your setting is saved. vCenter Discovery searches for the specified models in DX NetOps Spectrum. When duplicate models (models with the same IP address) exist in multiple secure domains, Virtual Host Manager handles the situation as follows:

- Virtual Host Manager selects the model in the local secure domain, if available.
- If a duplicate model does not exist in the local domain, Virtual Host Manager randomly selects a model from another secure domain.
- In both cases, Virtual Host Manager generates a minor alarm for the duplicate IP addresses on the VMware Manager model.

Configure SNMP Modeling Preferences

SNMP-capable virtual machines support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. By default, vCenter Discovery creates ESX service consoles and virtual machines as VHM models. You can later upgrade them to SNMP models. However, you can also configure vCenter Discovery to model all new SNMP-capable devices as SNMP models. Although vCenter Discovery can take longer to complete, initially modeling as SNMP models avoids manually upgrading these models later.

WARNING
Enable SNMP modeling *before* you model your vCenter servers. If you model the vCenter servers first, all child models are created as VHM models, which must be manually upgraded to SNMP models.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery, SNMP Discovery subview.

   WARNING
   To prepare your devices and DX NetOps Spectrum for SNMP Discovery, follow the steps in the subview. If devices are not properly prepared before vCenter Discovery, Virtual Host Manager cannot create SNMP models.
4. Click Set in the 'Discover SNMP-Capable Devices' field and select from the following options:
   - **Yes**
     Enables SNMP modeling during vCenter Discovery. Only those devices that meet the specified criteria in the SNMP Discovery subview text are modeled as SNMP devices. Applies to *new* models only.
   - **No**
     (Default) Models all new devices that are found during vCenter Discovery as VHM models. You can manually upgrade these models to SNMP models later.

   Your setting is saved.

Manage Device Models for Devices Deleted from vCenter

The devices and the relationships between them change frequently in virtual networks. DX NetOps Spectrum attempts to reflect these changes accurately. When an ESX host is removed or a virtual machine is deleted in vCenter, DX NetOps Spectrum removes the corresponding device model from the Virtual Host Manager hierarchy. The option to "Allow Device Model Deletes During vCenter Discovery" controls whether DX NetOps Spectrum deletes the model. This option also controls the handling of device models that are contained in a data center when you disable management of the data center in Virtual Host Manager.

WARNING
When models are deleted, all notes or other customizations on those models are lost. You can disable this option if your models are likely to be recreated in vCenter later.

You can manage device models for devices that are deleted from vCenter.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery subview.
4. Click Set in the "Allow Device Model Deletes During vCenter Discovery" field and select one of the following options:
   – **Yes**
   (Default) Deletes the Virtual Host Manager models that correspond to entities that are no longer managed in vCenter. Also deletes data center models for which you disable modeling in Virtual Host Manager.
   – **No**
   Places Virtual Host Manager models in the LostFound container if their corresponding entity is no longer managed in vCenter. Also places data center models in the LostFound container when you disable modeling for the data center in Virtual Host Manager.

   NOTE
   Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

Your setting is saved, and device models are handled as such after the device is deleted from vCenter.

Manage SNMP-Enabled Virtual Machine Models After VMware Manager Deletion

By default, SNMP-enabled devices are deleted from DX NetOps Spectrum when the following items are deleted:

- VMware Manager model for the device
- VMware folder in the Navigation panel

SNMP-enabled device models can include significant customizations that you want to retain. You can adjust your settings to avoid deleting these models. They are placed into the LostFound container for later use.

You can retain SNMP-enabled device models after VMware Manager or VMware folder deletion.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, VMware, vCenter Discovery subview.
4. Click Set in the "Retain SNMP-enabled Virtual Machines During VMware Manager Deletion" field and select one of the following options:
   – **Yes**
   Retains SNMP-enabled virtual machine models in the LostFound container when their VMware Manager or the VMware folder is deleted.

NOTE
Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

- – **No**
  (Default) Deletes all virtual machine models when their VMware Manager or the VMware folder is deleted.

Your setting is saved, and SNMP-enabled device models are handled appropriately when VMware Manager models or the VMware folder is deleted.

How to Discover and Model Your Virtual Environment (VMware)

To monitor your virtual environment, discover and model the virtual entities such as datacenters, resource pools, clusters, ESX hosts, ESX service consoles, and virtual machines. Modeling these entities in Virtual Host Manager lets you view your complete network topology in one tool. You can see the relationships between your physical and virtual components.

The main steps for modeling your virtual environment are as follows:

- **Run a standard Discovery**
  This Discovery ensures that the upstream routers and switches are modeled before vCenter Discovery runs. Or, if the SNMP Modeling option is disabled, this step can also model the SNMP-capable ESX service consoles and virtual machines. When modeling these entities, be sure that your modeling options are set correctly to support Virtual Host Manager.
- Upgrade the CA eHealth SystemEDGE Model
  This step is required only when your CA eHealth SystemEDGE agent on the vCenter server was modeled in a release earlier than r9.1.
- **Let vCenter Discovery run**
  When you model the CA eHealth SystemEDGE agent (with the vCenter Server AIM), vCenter Discovery begins automatically. Each of these vCenter Server models has its own vCenter Discovery process. vCenter Discovery finds the virtual entities that vCenter manages and models the ones that do not exist. vCenter Discovery then places the models in the CA eHealth SystemEDGE view of the Navigation panel.

Run a Standard Discovery

To discover your VMware environment, run the standard DX NetOps Spectrum Discovery. This Discovery ensures that the upstream routers and switches are modeled so that later connections from the virtual entities can be established. You can also model the SNMP-capable ESX service consoles and virtual machines during DX NetOps Spectrum Discovery.

NOTE
Modeling SNMP-capable ESX service consoles and virtual machines is necessary during DX NetOps Spectrum Discovery only when the SNMP Modeling option is disabled during vCenter Discovery.

NOTE
Only an administrator performs this task.

Follow these steps:

1. Open the Discovery console.

   IMPORTANT
   Ensure that you know the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port.

2. In the Navigation panel, click the **Creates a new configuration** icon  .
3. Configure your options for supporting virtual network modeling:
   a. Click **Modeling Options** in the Modeling Options group.
      The Modeling Configuration dialog opens.

b. Click **Protocol Options**.
The Protocol Options dialog opens.
c. Select the **ARP Tables for Pingables** option, and then click **OK**.
The Modeling Configuration dialog opens.
d. (Optional) Click **Advanced Options** in the Advanced Options group. Add your nonstandard SNMP ports (such as the CA eHealth SystemEDGE agent port), and then click **OK**.

4. Enter individual IP addresses or the beginning and ending IP addresses in the IP Boundary List fields, and then click **Add**.

IMPORTANT
Be sure that the range of IP addresses includes all servers with CA eHealth SystemEDGE and vCenter Server AIM installed and the interconnecting switches and routers. Or you can include the SNMP-capable ESX service consoles and virtual machines for which you want to create SNMP models.

5. Enter any additional values in the Discovery console, and then click **Discover**.
The following models are created and are added to your network topology in DX NetOps Spectrum:
– vCenter servers and the switches and routers that connect them to your network -- Information about your virtual environment comes from the vCenter server. When these vCenter Server models exist in DX NetOps Spectrum, vCenter Discovery can begin.
– ESX service consoles and virtual machines -- If you decide not to model these entities with DX NetOps Spectrum Discovery, vCenter Discovery creates them as VHM models.

NOTE
You can also manually model your virtual network by IP address. In this case, we recommend modeling the upstream devices first. Modeling in the correct order ensures that the relationships between these entities are built correctly in the topology. For more information about Discovery, see Modeling and Managing Your IT Infrastructure section.

Upgrade the CA eHealth SystemEDGE Model

The CA eHealth SystemEDGE agent could have been modeled in DX NetOps Spectrum before installing Virtual Host Manager or before the vCenter Server AIM was loaded on the agent. In this case, the existing CA eHealth SystemEDGE model is not compatible with Virtual Host Manager. Upgrade the model so that Virtual Host Manager can access the vCenter Server AIM capabilities in CA eHealth SystemEDGE. *This procedure is not required if the CA eHealth SystemEDGE agent with vCenter Server AIM is modeled after installing DX NetOps Spectrum.*

NOTE
When you are already running the latest remote CA eHealth SystemEDGE with the latest vCenter server AIM, the CA eHealth SystemEDGE model is upgraded automatically.

How vCenter Discovery Works

vCenter Discovery is a specialized discovery process that gathers detailed information about your virtual environment entities. vCenter Discovery finds the virtual entities that vCenter manages and models the ones that do not exist. vCenter Discovery then places the models in the Virtual Host Manager view of the Navigation panel.

A key benefit of vCenter Discovery is that it runs automatically in the background, continually keeping your virtual environment data updated in DX NetOps Spectrum. Understanding how vCenter Discovery works reinforces the importance of properly installing and modeling the various components of Virtual Host Manager.

The vCenter Discovery process works as follows:

1. When the CA eHealth SystemEDGE agent and vCenter Server AIM are operational, the AIM communicates with vCenter servers to gather information about the virtual entities it manages. The vCenter Server AIM stores this information.

WARNING
The CA eHealth SystemEDGE agent and vCenter Server AIM must be installed and configured so that CA eHealth SystemEDGE, vCenter, and DX NetOps Spectrum can communicate. If they cannot, vCenter Discovery cannot run.

2. During DX NetOps Spectrum Discovery, DX NetOps Spectrum creates a vCenter Server model for each server that is referenced in step 1. DX NetOps Spectrum intelligence is enabled to handle communication between DX NetOps Spectrum and the CA eHealth SystemEDGE agent.
3. DX NetOps Spectrum polls the vCenter Server AIM to gather the vCenter information that was stored in Step 1.
4. DX NetOps Spectrum begins vCenter Discovery. The information from the AIM is used to update modeling in the DX NetOps Spectrum Topology tab and the Virtual Host Manager hierarchy in the Navigation panel, as follows:
   a. If you enable SNMP Discovery before Step 2, Virtual Host Manager Discovery creates SNMP models for all new SNMP-capable models meeting the SNMP Discovery criteria.

      NOTE
      By default, SNMP Discovery is disabled during vCenter Discovery.

   b. VHM models are created for data centers, clusters, and resource pools.

      WARNING
      Resource pools that are named "Resources" are skipped during Discovery and modeling. This name is designated for internal use only. Therefore, Virtual Host Manager filters these resource pools out of the Discovery results. You can avoid missing models for resource pools and the devices that they contain by specifying a different name for VMware resource pools.

   c. Previously existing ESX service console and virtual machine models are changed to VHM models.
   d. VHM models are created for the ESX service consoles and virtual machines that are not yet modeled in DX NetOps Spectrum.
   e. VHM models are created for the ESX host models. These models display their associated ESX service console and virtual machine models in the Navigation panel, under Virtual Host Manager and the Universe topology.
   f. All models for your virtual network are added to the Virtual Host Manager portion of the Navigation panel.

      NOTE
      In a virtual environment, devices on separate ESX hosts can have the same IP or MAC address. In this case, DX NetOps Spectrum creates duplicate models for each occurrence of an IP or MAC address.

5. vCenter Discovery automatically repeats this process at each regularly scheduled vCenter polling interval.

NOTE
By default, the vCenter polling interval is controlled by a setting on the VMware Manager model. Or you can control vCenter polling independent of the vCenter Server device model using the vCenter server application model.

Adding SNMP Capabilities to VHM Models (VMware)

SNMP-capable virtual machines support enriched device monitoring, such as process and file system monitoring capabilities, that can provide added value to your solution. However, SNMP agents can be costly and time-consuming to deploy throughout an enterprise. When an SNMP agent is not available or SNMP Discovery is disabled, Virtual Host Manager creates ESX service consoles and virtual machines as VHM models.

Later, you can install an SNMP agent on any virtual machine. You can then upgrade its modeling in DX NetOps Spectrum. Depending on your needs, you can upgrade to SNMP models as follows:

- **Upgrade only selected devices**
  This method works quickly when you have a small selection of models that require an upgrade. This method first deletes the VHM models and child models. After DX NetOps Spectrum deletes the models, the new SNMP models are

created during the next vCenter Discovery and placed in Virtual Host Manager. This method requires you to know the IP addresses for the models to upgrade.

- **Upgrade all SNMP-capable VHM models**
  This method upgrades models in batch, and this method is preferred when upgrading Virtual Host Manager to a new release. For this method, you are not required to know the IP addresses of individual models. Another advantage is that after DX NetOps Spectrum deletes the VHM models, the upgraded SNMP models are immediately placed in the Virtual Host Manager hierarchy. You do not have to wait for the next polling cycle. Therefore, child models are not left unmanaged. The drawback to this method is that it can take a long time to complete. The time that is required to complete this upgrade depends on how many community strings and SNMP ports Virtual Host Manager must search when locating SNMP-capable devices.

  NOTE

  Virtual Host Manager attempts to identify SNMP agents on powered-up pingable virtual machines only.

  WARNING

  When models are deleted, all notes or other customizations on those models are lost.

Upgrade Selected VHM Models to SNMP Models

When an SNMP agent is not available or SNMP Discovery is disabled during vCenter Discovery, Virtual Host Manager creates VHM models. This modeling applies to ESX service consoles and virtual machines. Later, you can install an SNMP agent on any virtual machine. You can then upgrade its modeling in DX NetOps Spectrum. You are required to know the IP addresses for the device models you want to upgrade. Manually selecting models to upgrade works quickly, but all notes or customizations on these models are lost during the upgrade.

Follow these steps:

1. Deploy or enable an SNMP agent on the device, if required.
2. Model the device again using one of the following methods:
   - DX NetOps Spectrum Discovery
   - Model individual devices by IP address

   When the new SNMP-capable model is created, DX NetOps Spectrum removes the previous model from Virtual Host Manager and deletes the model. At the next vCenter Server AIM polling cycle, DX NetOps Spectrum adds the SNMP-capable model to Virtual Host Manager in the Navigation panel.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Upgrade All VHM Models to SNMP Models

Virtual Host Manager creates ESX service consoles and virtual machines as VHM models in the following cases:

- When an SNMP agent is not available.
- When SNMP Discovery is disabled during vCenter Discovery.

Later, you can install an SNMP agent on any virtual machine and then upgrade its modeling in DX NetOps Spectrum. When upgrading in batch, DX NetOps Spectrum searches your VHM models, locating those models that are now SNMP-capable devices. Then DX NetOps Spectrum converts them to SNMP models. This method can take a long time, depending on how many community strings and ports Virtual Host Manager must search. However, this method ensures that child models are not unmanaged while parent models are upgrading.

You can upgrade all VHM models for VMware to SNMP models.

Follow these steps:

1. Deploy or enable an SNMP agent on your devices, as required.
2. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
3. Select the VMware Manager model in the Navigation panel that manages the models to upgrade.
4. Click the Information tab.
5. Expand the VMware Manager Modeling Control, ICMP-Only Device Upgrades subview.
6. Click the Upgrade ICMP-Only Devices button.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Virtual Host Manager searches the devices that the vCenter Server AIM manages on the selected VMware Manager device. Virtual Host Manager upgrades all ICMP-only devices that meet the criteria for SNMP devices and places them within the Virtual Host Manager hierarchy.

Move an ESX Host to a Different vCenter

Moving an ESX host from one DX NetOps Spectrum managed vCenter to another can cause modeling problems when both vCenter hosts are modeled on the same SpectroSERVER. Some possible symptoms of these modeling problems are as follows:

- DX NetOps Spectrum deletes the models that are associated with the ESX host and does not recreate them after the move.
- False Proxy Lost alarms are created and remain, even though the new vCenter can contact the ESX host and all hosted virtual machines.

If you move your ESX host in the correct order, you can avoid these problems.

To move an ESX host to a different vCenter server, use the following procedure.

Follow these steps:

1. (Optional) Change the "Allow Device Model Deletes During vCenter Discovery" option to No.

   NOTE
   Perform this step only if both the originating and destination vCenters are modeled in the same SpectroSERVER. This setting keeps the existing ESX host, ESX service console, and virtual machine models when they become unmanaged by the first vCenter server. Therefore, customizations or historical details for the models are preserved and available after the move.
2. Open VMware and remove the ESX host from the management of the first vCenter server.
3. Wait for Virtual Host Manager in the Navigation panel to reflect the changes.
4. Open VMware and add the ESX host into the destination vCenter server.

   NOTE
   Virtual Host Manager is not DSS aware. Therefore, when moving the ESX host to a vCenter server modeled on a different SpectroSERVER, a new set of models are created. These models represent the ESX host, ESX service console, and the hosted virtual machines.
5. (Optional) Change the "Allow Device Model Deletes During vCenter Discovery" option back to Yes on the originating vCenter server model.
   The ESX host is successfully moved from one vCenter server to a second vCenter server.

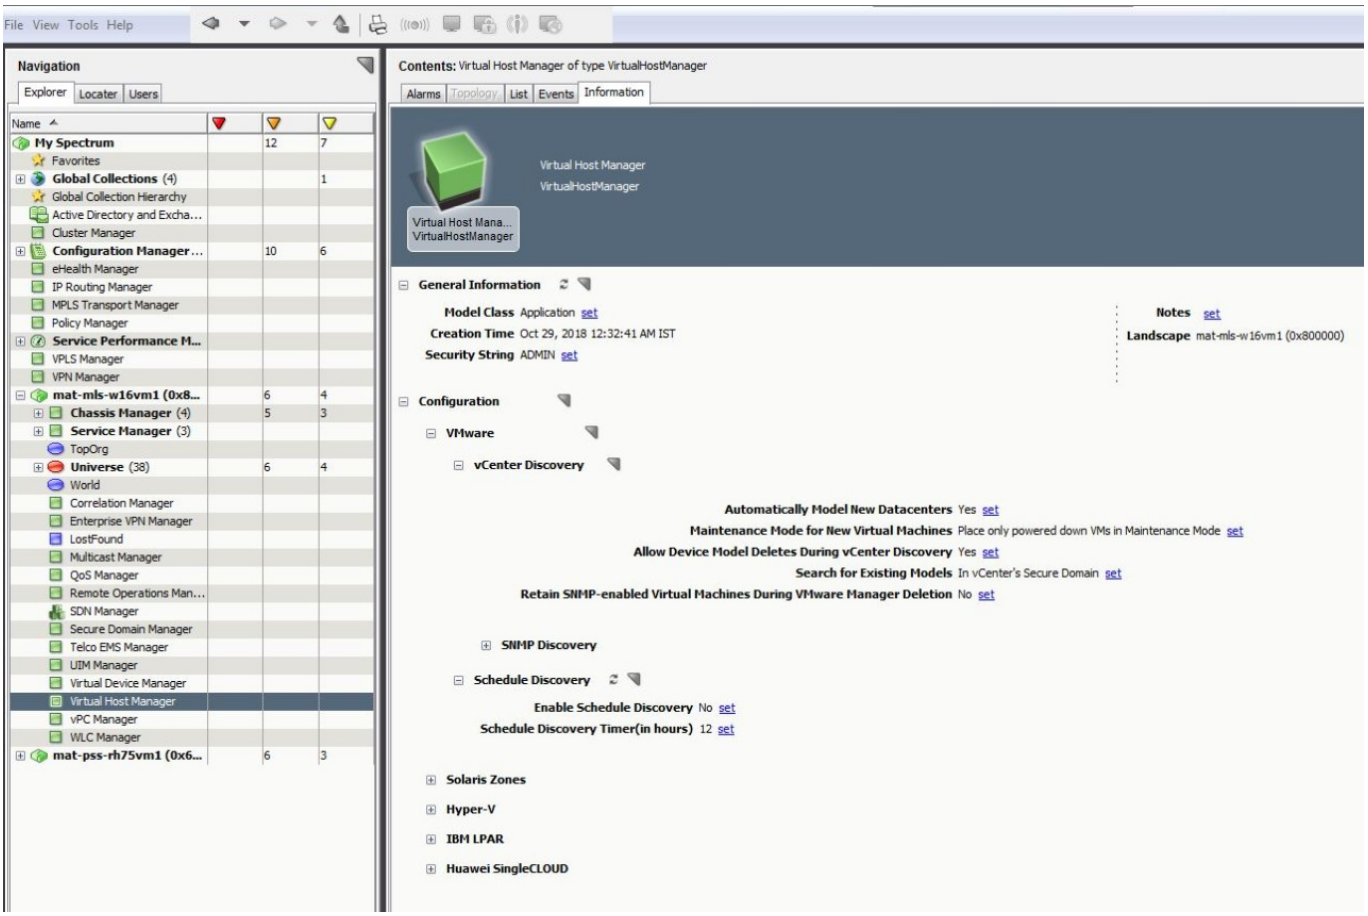
Schedule Discovery

Scheduling discovery jobs for VHM VMs addresses performance issues with the continuous discovery requests which are triggered from VMware. With an increase in the capacity that is the number of models, performance issues are prevalent, and scheduling discovery jobs can prove to be beneficial in managing large customer environments. This interim solution is introduced to schedule time (default of 12 hours) and queue up all the discovery jobs to run them post schedule expiry time.

Users can now **set** the '**Enable Schedule Discovery**' feature to '**Yes**' to enable scheduling of discovery jobs, then **set** the '**Schedule Discovery Timer**' (in hours) to the time they want, for queuing up all the discovery jobs. Users can also specify any given time (in hours) between 1 hour and 24 hours *only*. If a user does not specify a time, then by default the 'Timer' is set to 12 hours.

> **NOTE**
>
> If the schedule discovery option is enabled on an active server, that goes down and does not come up back until the scheduled discovery time, then the scheduled discovery does not run on the backup server.

Following is a screenshot of the VHM Vmware Configuration Settings Tab:

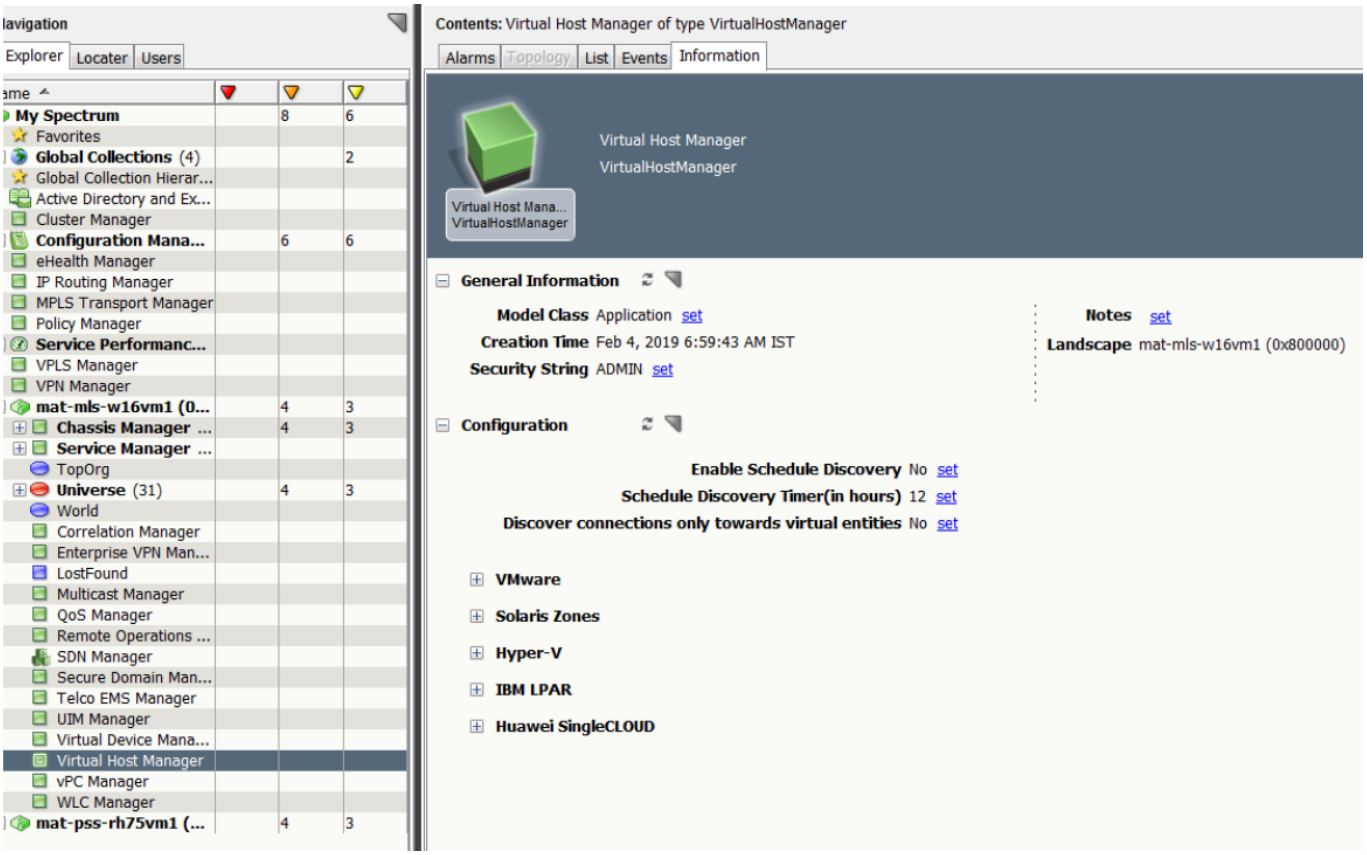


Discover Connections Only toward Acess Points

Previously VHM discovered connections on all the subnet switches corresponding to the VM. From 10.3.1 onwards there is an option under the VHM Manager to discover connections with the right upstream switches of the VM. This

feature skips creating other neighboring connections for the subnet switches, and uses the mac address (SAT Table) or IP address (CDP Table) of the VM to discover connections toward its upstream switch.

Following is a screenshot of the new 'Discover connections only towards virtual entities' option:



Viewing Your VMware Virtual Environment

This section describes concepts for viewing your VMware virtual environment and the associated alarms. The basic steps are no different from the standard DX NetOps Spectrum procedures. However, this section describes conceptual differences and details that only apply to the VMware virtual technology.

Viewing Your VMware Virtual Network

On the Explorer tab, the Virtual Host Manager node provides a hierarchical tree structure. This layout helps you visualize the logical relationships between your virtual environment resources.

Using this information, you can see how resources are shared among your virtual hosts. This information can help you identify opportunities to reorganize and optimize your virtual environment. The hierarchy also provides a quick way to monitor the performance of your resources and troubleshoot alarms.

Because Virtual Host Manager is not aware of a DSS environment, it is located within a landscape hierarchy. The following example, showing where Virtual Host Manager appears on the Explorer tab in the Navigation panel, illustrates the virtual environment hierarchy:

```
[-] <ss> host
    [+] Universe
    [-] Virtual Host Manager
        [-] VMware
            [-] VMware Manager 1
                [-] vCenter server 1
                    [-] Datacenter 1
                        [-] ESX host 1
                         .  ESX service console 1
                         .  Virtual machine 1
                         .  Virtual machine 2
                [-] vCenter server 2
                    [-] Datacenter 2
                        [-] ESX host 2
                             .  ESX service console 2
                             .  Virtual machine 3
                             .  Virtual machine 4
                                [+] Resource pool 1
                                 .  Virtual machine A
                                 .  Virtual machine B
                        [+] Cluster 1
                        [-] Cluster 2
                            [-] ESX host A
                                 .  ESX service console A
                             .  Virtual machine 3
                             .  Virtual machine 4
                            [-] Resource Pool 2
                                 .  Virtual machine C
                                [+] Resource Pool A
                                [+] Resource Pool B
                    [+] Datacenter 3
            [-] VMware Manager 2
                [-] vCenter server 3
                    [-] Datacenter 4
                        [-] ESX host 1
                         .  ESX service console 1
                         .  Virtual machine 1
                         .  Virtual machine 2
                [-] vCenter server 4
                    [-] Datacenter 5
                        [-] ESX host 2
                             .  ESX service console 2
                             .  Virtual machine 3
                             .  Virtual machine 4
```

Virtual Host Manager is the root node for the entire virtual environment that this SpectroSERVER manages. Selecting this node in the Navigation panel displays Virtual Host Manager details in the Contents panel. You can view details such as events and alarms that are related to your virtual environment.

Directly under Virtual Host Manager, virtual environments are organized within folders that represent the associated technology. In the example hierarchy above, the VMware folder contains the portion of the virtual environment that was created using VMware virtualization technology. In this folder, Virtual Host Manager lists all CA eHealth SystemEDGE servers with the vCenter Server AIM and the vCenter servers that this SpectroSERVER manages. These entities are represented separately as a VMware Manager model with a vCenter Server model directly beneath it in the hierarchy.

Selecting a VMware Manager in the Navigation panel displays details in the Contents panel, such as the Configuration, Managed Environment, and Events.

Each vCenter server contains only the portion of the entire virtual environment that it manages. Selecting a vCenter server in the Navigation panel displays details in the Contents panel, such as Configuration and Utilization of the selected vCenter servers.

Under each vCenter server, the hierarchy represents the logical relationships among the following virtual entities:

- **Data Centers**
  A data center can contain clusters or hosts. Selecting a data center in the Navigation panel displays details in the Contents panel. These details include events and alarms that are related to the data center or a list of clusters. Components can interact within data centers, but interaction across data centers is limited.
- **Clusters**
  Clusters can contain ESX hosts, resource pools, or virtual machines. Selecting a cluster in the Navigation panel displays details in the Contents panel, which include:
  – Events and alarms that are related to the cluster.
  – A list of ESX hosts and virtual machines that are contained in the cluster.
  – The DRS and HA settings.
- **Resource pools**
  A resource pool can contain virtual machines or other resource pools. Selecting a resource pool in the Navigation panel displays details in the Contents panel, which include:
  – Overall CPU usage.
  – Events and alarms that are related to the resource pool.
  – A list of other virtual network objects that are contained in the resource pool.

    WARNING
    Resource pools that are named "Resources" are skipped during Discovery and modeling. This name is designated for internal use only. Therefore, Virtual Host Manager filters these resource pools out of the Discovery results. You can avoid missing models for resource pools and the devices that they contain by specifying a different name for VMware resource pools.

- **ESX hosts**
  An ESX host can contain an ESX service console, resource pools, or virtual machines. Selecting an ESX host in the Navigation panel displays details in the Contents panel, which include:
  – Total virtual machine memory.
  – CPU state.
  – A list of virtual machines that the ESX host manages.

    NOTE
    When a cluster contains an ESX host, the virtual machines that are associated with the host are not grouped under the host. Instead, they appear under the cluster beside the ESX host on the Explorer tab.
- **ESX service consoles**
  The ESX service console model appears as a child to its corresponding ESX host model. The ESX service console model is always a leaf node on the Virtual Host Manager hierarchy tree. This model has the same name as its parent. The model icon in the Contents and Component Detail panels distinguishes the ESX service console models from their parent ESX host model. The DeviceType attribute also distinguishes these models. Selecting an ESX service console in the Navigation panel displays details in the Contents panel.

NOTE
The ESX service console model is the only VMware model type within Virtual Host Manager that does not provide a Virtual Host Manager-specific subview on the Information tab.

- **Virtual machines**
  A virtual machine is always a leaf node on the Virtual Host Manager hierarchy tree. Selecting a virtual machine in the Navigation panel displays details in the Contents panel, including power status, memory usage, and related events and alarms.

Understanding the VMware Virtual Topology

The vCenter server, ESX host, ESX service console, and virtual machine models that are created for your virtual environment are integrated into the topology views. ESX host models automatically group their associated ESX service console and virtual machines. The topology shows how these ESX service consoles and virtual machines are connected to your physical network entities.

The following example shows how these models can appear on the Explorer tab in the Navigation panel under the Universe group:

```
[-] Universe
     .  Physical switch 1
     .  Physical switch 2
    [-] ESX host
         .  ESX service console
         .  Fanout 1
         .  Fanout 2
         .  Virtual machine 1
         .  Virtual machine 2
         .  Virtual machine 3
```

Selecting one of these models displays these relationships graphically on the Topology tab in the Contents panel.

How the VMware Data is Updated in Virtual Host Manager

During your initial vCenter Discovery, DX NetOps Spectrum populates the Virtual Host Manager hierarchy in the Navigation panel with your virtual device models. After DX NetOps Spectrum builds this initial hierarchy, your virtual network configuration can change frequently. Virtual Host Manager continually works to keep this information accurate in DX NetOps Spectrum. For example, the following events can change your virtual network configuration:

- Adding a new vCenter server to be managed by an existing CA eHealth SystemEDGE.
- Creating or deleting datacenters, clusters, resource pools, ESX hosts, or virtual machines in the vCenter application
- HA or DRS settings in VMware, which can cause virtual machines to move spontaneously to a new ESX host
- Manually migrating a virtual machine from one ESX host to another

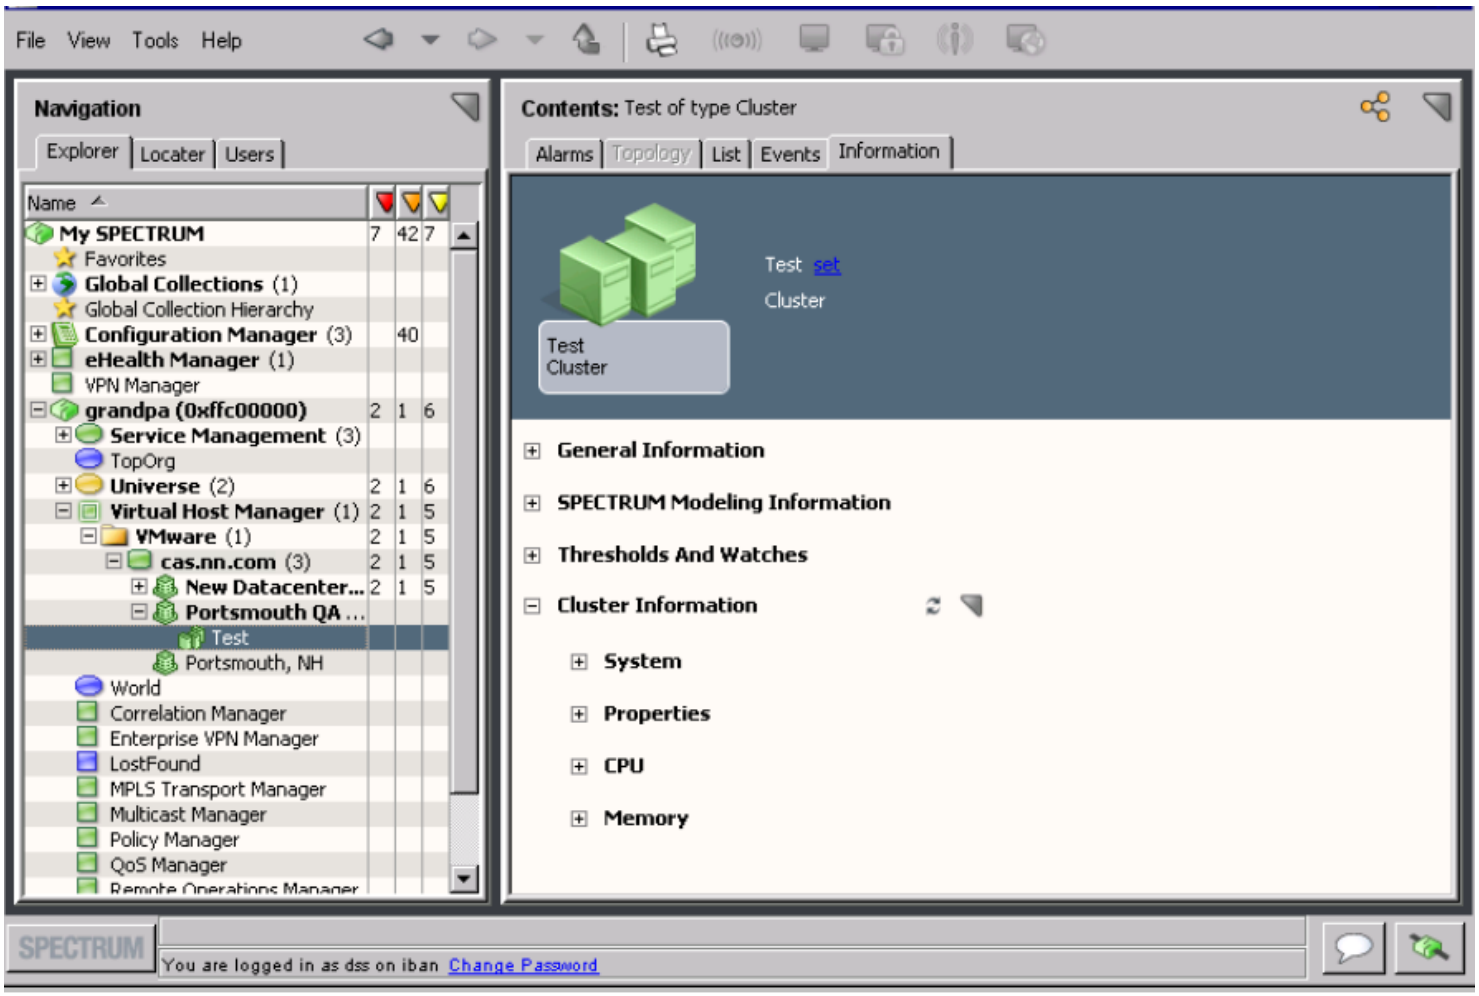
To keep your information accurate, Virtual Host Manager detects these changes by polling the vCenter Server AIM. Therefore, your virtual network configuration changes, if any, are reflected in DX NetOps Spectrum at each polling cycle. DX NetOps Spectrum also receives traps from the AIM and generates the corresponding events. By reviewing the event log, you can find out when configuration changes occur. Example configuration changes include when a virtual device is migrated because of HA or DRS. When it detects a change in your virtual network configuration, DX NetOps Spectrum performs the following tasks:

- Updates the placement of your virtual entity models in the Virtual Host Manager hierarchy of the Explorer tab
- *Automatically* rediscovers connections to the affected ESX service console and virtual machine models and associates them with the correct ESX host in the Universe topology

WARNING
To reestablish connections to your virtual models correctly, all interconnecting routers and switches in your physical network must be modeled. If these models do not exist before connections to your virtual devices are rediscovered, DX NetOps Spectrum cannot resolve those connections in the Universe topology view. The ESX hosts are placed in the same LAN container as the CA eHealth SystemEDGE model.

Custom Subviews for Virtual Entity Types

Your Virtual Host Manager models collectively provide information about your virtual environment. Individually, each model provides unique information or configuration settings, depending on the virtual entity type it represents. This custom subview appears on the Information tab in the Contents panel. These subviews can contain real-time data, such as disk space available or memory utilization. Also, these subviews provide access to threshold settings. For example, the custom subview for a cluster is the "Cluster Information" subview, as shown:



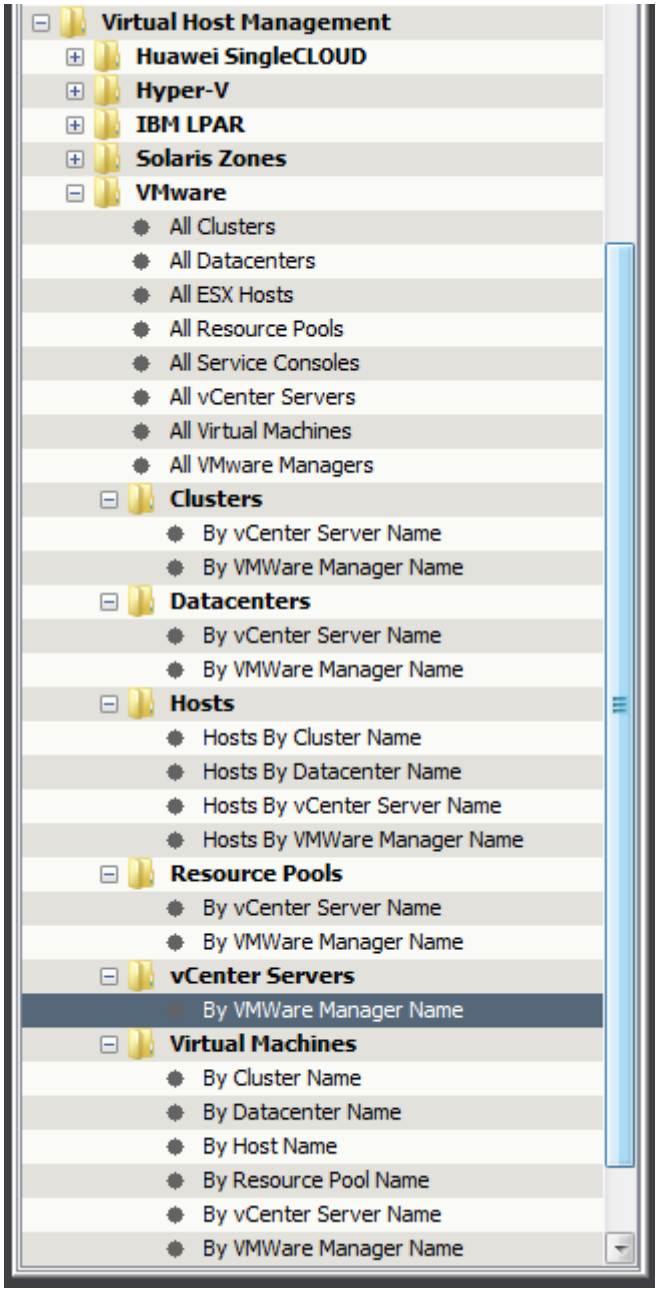
The ESX service console model is the only VMware model type within Virtual Host Manager that does not provide a Virtual Host Manager-specific subview.

NOTE
The vCenter model provides combined information for all virtual devices that the vCenter server manages. Select the VMware Manager model in the Navigation panel to see information about the selected manager and combined information about all of its entities. These entities include vCenter server, ESX hosts, ESX

service consoles, virtual machines, virtual switches, NICs, and datastores. This information is the same data that is displayed on the Information tab for each individual entity model. The combined subview in the VMware Manager model can provide a good overview about all of the virtual entities that it manages.

Locater Tab for VMware Searches

In addition to viewing details about your virtual environment on the Explorer tab, you can also use the Locater tab to run preconfigured Virtual Host Manager searches. The search options are grouped under the Virtual Host Management, VMware folder on the Locater tab, as shown:



These detailed searches can help you investigate information that is related to virtual entities only, such as a specific resource pool or ESX host. For example, if you know the name of a specific ESX host, you can search for all virtual

machines that it manages. Creating this list of virtual machines can be useful when checking the status of a group of virtual machines. Or, you can use the list to determine which machines require management changes in VMware. Example management changes include moving the virtual machines to a different ESX or placing them in maintenance mode.

NOTE
Although Virtual Host Manager is not DSS aware, these preconfigured searches let you select multiple landscapes to search in the search parameters.

The Locater tab in the Navigation panel includes the following searches for Virtual Host Manager information:

- **All Clusters**
  Locates all clusters that have been modeled in the DX NetOps Spectrum database for the virtual network.
- **All Datacenters**
  Locates all datacenters that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All ESX Hosts**
  Locates all ESX host servers that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All Resource Pools**
  Locates all resource pools that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All Service Consoles**
  Locates all ESX service consoles that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All vCenter Servers**
  Locates all VMware vCenter host servers that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All Virtual Machines**
  Locates all virtual machines that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All VMware Managers**
  Locates all servers hosting the CA eHealth SystemEDGE agent with vCenter Server AIM enabled and that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **Clusters**
  Locates Clusters in the DX NetOps Spectrum database. Results are limited to only those entities that the containers that are specified in one of the following searches manage:
  – By Vmware Manager Name
  – By vCenter Server Name
- **Datacenters**

Locates Datacenters in the DX NetOps Spectrum database. Results are limited to only those entities that the containers that are specified in one of the following searches manage:

By Vmware Manager Name

- By vCenter Server Name

Hosts

Locates ESX host servers or ESX service consoles in the DX NetOps Spectrum database. Results are limited to only those entities that the containers that are specified in one of the following searches manage:

- ESX Hosts By Cluster Name
- ESX Hosts By Datacenter Name
- By VMware Manager Name
- By vCenter Server Name

Resource Pools

Locates Resource Pools in the DX NetOps Spectrum database. Results are limited to only those entities that the containers that are specified in one of the following searches manage:

By Vmware Manager Name

- By vCenter Server Name

vCenter Servers

Locates vCenter Servers in the DX NetOps Spectrum database. Results are limited to only those entities that the containers that are specified in one of the following searche manage:

By Vmware Manager Name

Virtual Machines

Locates virtual machines in the DX NetOps Spectrum database. Results are limited to only the virtual machines that the containers that are specified in one of the following searches manage:

- By Cluster Name
- By Datacenter Name
- By Host Name
- By Resource Pool Name
- By VMware Manager Name
- By vCenter Server Name

Status Monitoring Options

DX NetOps Spectrum provides a wide range of options for monitoring the state of your virtual network resources. The status information available for a resource varies, depending on the type of virtual entity you are monitoring. Also, your ability to configure a status option depends on its type. For example, some status options are read-only, but others let you configure threshold values, enable behaviors, or select an alarm severity. Providing this range of options and levels of customization, DX NetOps Spectrum lets you decide how best to monitor the performance of your virtual network.

Status fields are located in the OneClick subviews. All status information for a given virtual environment is available on the VMware Manager model in a tabular format. Also, each virtual entity type that has a unique model in DX NetOps Spectrum provides a subset of the same status information for easy viewing. Status-related settings, including the alert type, monitor, and thresholds, can be set from either subview location.

The following tables outline the type of status information available for each virtual entity type. The Subview Location column describes where the corresponding status fields are located in OneClick. For example, DX NetOps Spectrum lets you monitor "memory" information for your resource pool models. Thus, the corresponding status fields are available from the Resource Pool and VMware Manager subviews on the Information tab in OneClick. To explore the exact status options available for each status information type, locate the subview in OneClick.

Datacenter

Status Information Type	Subview Location
Overall	Datacenter and VMware Manager

Resource Pool

Status Information Type	Subview Location
Overall	Resource Pool and VMware Manager
CPU	Resource Pool and VMware Manager

Memory	Resource Pool and VMware Manager

Virtual Machine

Status Information Type	Subview Location
Percent ready	Virtual Machine and VMware Manager
CPU	Virtual Machine and VMware Manager
Memory	Virtual Machine and VMware Manager
Heartbeat	Virtual Machine and VMware Manager
Power	Virtual Machine and VMware Manager
OS state	Virtual Machine and VMware Manager
Connected	Virtual Machine and VMware Manager
VMware tools	Virtual Machine and VMware Manager
Virtual NICs	VMware Manager only

ESX Host

Status Information Type	Subview Location

Memory	vCenter

How to Configure Management Options (VMware)

After your virtual network is modeled, you can configure Virtual Host Manager options for viewing and managing your device models. Configuring your preferences helps ensure that Virtual Host Manager handles your virtual device models correctly and monitors only the information that is important to you.

To configure your installation of Virtual Host Manager, perform the following procedures after you discover and model your virtual network:

- Configure the vCenter Server AIM
  These options let you select settings for the CA eHealth SystemEDGE vCenter Server AIM, such as the vCenter Server AIM polling interval and various traps.
- Configure and Monitor Resource Status
  These options let you determine the information that you want to monitor and how DX NetOps Spectrum manages the various events that occur in your virtual network.

Configure the vCenter Server AIM

The vCenter Server AIM communicates with vCenter to manage and collect information about your virtual network. In Virtual Host Manager, you can configure the AIM to determine how it handles traps, and events. The AIM settings let you balance the information to gather against the amount of required resources.

To configure the vCenter Server AIM in Virtual Host Manager, use the following procedure.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Locate and click your VMware Manager on the Explorer tab in the Navigation panel.
   The tabs in the Contents panel are populated with details about all vCenter servers.
3. Click the Information tab.
4. Expand the SystemEDGE Application Insight Modules (AIMs), VMware vCenter, Configuration subview.
5. Click Set to change the settings for the following fields, as needed:
   – **Trap Enable Mask**
   Determines which class of traps the vCenter Server AIM sends. The value that is entered in this field determines the class. The values are as follows:
   - **0**
     Sends no traps.
   - **1**
     Sends detected vCenter change traps.
   - **2**
     Sends detected AIM state change traps.
   - **3**
     Sends detected vCenter change traps and detected AIM state change traps.
   - **4**
     Sends AIM configuration change traps only.
   - **5**
     Sends AIM configuration change and detected vCenter change traps.
   - **6**
     Sends AIM configuration change traps and detected AIM state change traps.
   - **7**
     (Default) Sends all traps.

NOTE
Default: 7**Limits:** 0-7

– **Log Level**
Specifies the level of information that is written to the vCenter Server AIM log file. The levels are cumulative (for example, log level 4 writes all messages at levels 0 through 4). The following log levels are available:
- 0: Fatal
- 1: Critical
- 2: Warning
- 3: Info
- 4: Debug
- 5: Debug Low
- 6: Debug Lower
- 7: Debug Lowest

NOTE
Default: 2 Specifying a debug level greater than 4 is not recommended.

6. Expand Configuration, Instances subview.
A table containing all vCenter server instances and their corresponding parameters are displayed.
7. In the Instances table, set any of the following parameters on the required vCenter server instance.
– **Poll Interval (Seconds)**
Specifies the time interval (in seconds) when the vCenter Server AIM polls and caches status and modeling information from the vCenter server. This polling retrieves the following status and modeling updates and more:
- Virtual machine powered down status
- ESX host disconnected
- New data center available
- New ESX host
- New virtual machine

Default: 120
Limits: Numbers greater than or equal to 30
Note: For best results, we recommend that you set this interval no larger than the DX NetOps Spectrum poll cycle interval.

– **VC Event Poll (Seconds)**
Specifies the time interval (in seconds) when the vCenter Server AIM polls and caches event information from the vCenter server. This polling interval affects the polling of the vCenter event queue.
Default: 120
Limits: Numbers greater than or equal to 120

– **VC Event Enable**
Determines how Virtual Host Manager handles events that are collected from the vCenter server and from the vCenter Server AIM. The following options are available:
- **Disable**
Specifies that no events are collected.
- **Collect**
Specifies that events are gathered but no traps are sent for those events having traps.
- **Collect and trap**
Specifies that the events are gathered and traps are sent.

Default: Disable

– **VC Event Monitor Info**
Determines whether vCenter information events are collected. The options are Enable and Disable.
Default: Disable

– **VC Event Monitor User**

Determines whether vCenter user events are collected. The options are Enable and Disable.
Default: Disable

- **VC Event Monitor Error**
  Determines whether vCenter error events are collected. The options are Enable and Disable.
  Default: Disable
- **VC Event Monitor Warning**
  Determines whether vCenter warning events are collected. The options are Enable and Disable.
  Default: Disable

Your vCenter Server AIM is configured with your selections.

Configure and Monitor Resource Status

You can monitor the status of virtual resources in OneClick. For example, you can view the total physical memory, used physical memory, percent of free space on a datastore, and more. Also, you can set monitoring options, such as enabling alerts and setting threshold values for traps. This information can help you optimize your virtual network performance and troubleshoot alarms.

> **NOTE**
> The vCenter Server AIM sets and manages the traps, but you can configure these threshold values from the OneClick subviews. A read/write community string is required to change any threshold values or settings.

You can view or configure resource status options and information for virtual devices on the Information tab.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Locate and click the virtual device on the Explorer tab in the Navigation panel.
   The device details display in the Contents panel.
3. Click the Information tab.
   Multiple subviews are available for viewing. Generally, the subview at the bottom of the tab includes the resource allocation and utilization information for the selected model. For example, a datacenter model displays a subview that is named "Datacenter Information". This subview includes details for the specific datacenter model that you selected in the Navigation panel.
4. Expand the appropriate subview.
   All available resource status details and monitoring options for the selected device model are displayed.

> **NOTE**
> The VMware Manager model provides combined information for all virtual devices that the VMware Manager manages. Select the VMware Manager model in the Navigation panel to see information about all the vCenter servers and combined information about all of its entities. These entities include ESX hosts, ESX service consoles, virtual machines, virtual switches, NICs, and datastores. This information is the same data that is displayed on the Information tab for each individual entity model. The combined subview in the VMware Manager model can provide a good overview about all of the virtual entities that it manages.

Controlling vCenter Server AIM Polling (VMware)

When tuning Virtual Host Manager performance, you can change the vCenter server polling rate or you can disable vCenter polling. By default, the polling attributes on the vCenter Server device model control the VMware-related polling behavior. Or you can change this VMware-related polling behavior independently. The vCenter application model, VMWareVCAIMApp, controls your VMware-related polling.

The following two attribute values on the application specifically control the VMware polling logic:

- PollingStatus
- Polling_Interval

Both the vCenter server and the VMWareVCAIMApp application model contain these attributes. PollingStatus enables and disables polling, while Polling_Interval controls the polling frequency. If their values are different, the VMWareVCAIMApp application model attribute values take precedence.

As stated, DX NetOps Spectrum allows you to set the values for the device model and application model separately. This capability lets you fine-tune your VMware-related polling independently of the vCenter server device polling. For both attributes, modifying the attribute on the vCenter Server device model also changes the corresponding application model attribute if their values are the same.

Configure the vCenter Server Polling Interval

You can change the vCenter server polling rate to increase or decrease the frequency. Configure the polling interval by setting the Polling_Interval attribute on the vCenter application model.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'
   A search dialog opens.
3. Enter the IP address for your vCenter server in the Device IP Address field and click OK.
   A list of application models for the vCenter server appears in the Contents panel.
4. Select the VMWareVCAIMApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Double-click the DX NetOps Spectrum Modeling Information subview.
7. Click Set in the Polling Interval (sec) field, enter a new value.
   NOTE
   A value of 0 disables vCenter server polling.
   The vCenter server polling interval setting is configured.

Disable vCenter Server Polling

You can disable vCenter polling. Disabling vCenter polling is the same as disabling Virtual Host Manager. You can disable polling by setting the PollingStatus attribute on the vCenter application model.

To disable vCenter server polling on the application model, use the following procedure.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'
   A search dialog opens.
3. Enter the IP address for your vCenter server in the Device IP Address field, and click OK.
   A list of application models for the vCenter server appears in the Contents panel.
4. Select the VMWareVCAIMApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Click the DX NetOps Spectrum Modeling Information subview.
7. Click 'set' in the Polling field and select Off.
   Polling is disabled for the selected vCenter server.

Disabling DNS Lookup for Virtual Machines

Starting with 9.4 release, you can disable the DNS lookup for a virtual machine that has a blank IP address. You can have scenarios when you do not want DX NetOps Spectrum the DNS lookup for a virtual machine with a blank IP address. In such scenarios, you can set the attribute "VMWare_vmDNSLookuponBlankIPAddr" to "No" at the Virtual Host Manager level in OneClick. When this attribute is set to "No", DX NetOps Spectrum skips the DNS lookup for a virtual machine with a blank IP address. As a result, the IP address of such a virtual machine is not populated in OneClick.

If this attribute is set to "Yes", DX NetOps Spectrum performs a DNS lookup to find the IP address of a virtual machine without an IP address. If DX NetOps Spectrum finds the IP address of that virtual machine, that IP address is populated in the OneClick.

WARNING

If you do not want to perform the DNS lookup after a SpectroSERVER restart, set the **'VMWare_vmDNSLookonVNMRestart'** attribute value to **'No'.**

Deleting Virtual Host Manager Models

Generally, models can be deleted from OneClick at any time. However, Virtual Host Manager restricts your ability to delete models from the Virtual Host Manager hierarchy in the Navigation panel. To delete models manually, you have the following two options:

- Delete the VMware folder or a vCenter server model in Virtual Host Manager
- Remove a virtual entity from your VMware virtual environment using vCenter

In Virtual Host Manager, models are sometimes deleted automatically. The following circumstances cause DX NetOps Spectrum to delete Virtual Host Manager models automatically:

- **VMware folder or VMware Manager model is deleted**
  If you delete a VMware Manager model or the VMware folder, DX NetOps Spectrum deletes all related child models. The set of deleted models includes the vCenter Server model that is related to the remote VMware Manager model.
- **An entity is removed from VMware**
  As you delete data centers, resource pools, clusters, ESX hosts, and virtual machines in VMware, DX NetOps Spectrum also deletes those models and their child models from Virtual Host Manager.
- **Disabled data center in Virtual Host Manager**
  If you disable management of a data center, DX NetOps Spectrum deletes the child models that are related to that data center.
- **Upgraded models exist** -- In some cases, an ESX service console or virtual machine is first modeled for Virtual Host Manager without SNMP capabilities. If SNMP capabilities are later added to a VHM model, the previous model is deleted and replaced with the new SNMP-capable model.

NOTE

Although the default setting is to delete models, you can configure Virtual Host Manager to retain the models instead. In this case, Virtual Host Manager places the ESX host, ESX service console, and virtual machine models in the LostFound container when they are removed from Virtual Host Manager. This setting is respected when you remove an entity from VMware or you disable a data center in Virtual Host Manager. This setting does not apply when you delete the VMware folder or you delete a VMware Manager model. The setting also does not apply when you remove a VMware Manager and vCenter Server model or upgrade a VHM model.

Distributed and Selective Management

This section describes the concepts and procedures for selectively managing individual data centers on your vCenter servers. This section also describes how to distribute the management of data centers across multiple SpectroSERVERs.

Selective Data Center Modeling

By default, each vCenter Server model monitors all data centers that it manages within your virtual environment. Virtual Host Manager lets you selectively monitor only a subset of these data centers. To perform selective modeling, you can configure each vCenter Server model to enable or disable modeling for the individual data centers that it manages.

This feature offers the following benefits:

- Organizations can disable management for data centers that do not require monitoring, such as a lab environment.
- Virtual Host Manager can distribute management of your virtual environment.

How to Selectively Manage Your Datacenters

By default, each vCenter server model monitors all data centers that it manages within your virtual environment. However, you can configure your vCenter server models to monitor a subset of data centers. This feature is useful when you have data centers that do not require monitoring, such as a lab environment.

The following process describes how to configure your vCenter server to monitor only selected data centers:

1. Select your preference for automatically modeling data centers in Virtual Host Manager. This setting is used as the default for your data center models in Step 3.
2. Model your vCenter server.
3. Enable on each vCenter server the selected data centers for monitoring. The vCenter server models only the data centers and its contained components for which you enable modeling.

Distributed Management of Your Virtual Environment

Using the selective data center modeling feature, you can distribute the management of your data centers across multiple SpectroSERVERs. For large organizations with geographically dispersed networks or large virtual environments, the potential benefits include the following:

- Improved Virtual Host Manager performance -- Resources that are required to model each data center can be spread across multiple SpectroSERVERs. Ideally, we recommend modeling using a single SpectroSERVER to reduce resources that are required to poll from multiple servers. However, if a single SpectroSERVER cannot effectively manage your virtual environment, a distributed environment can improve your Virtual Host Manager performance despite the additional polling resources required.
- Organizational flexibility -- Because of organizational or geographical boundaries, you may prefer to distribute the management of data centers across multiple SpectroSERVERs.

You can accomplish distributed management by first modeling your vCenter servers on separate SpectroSERVERs. In each SpectroSERVER environment, you can then selectively enable or disable the data centers managed by each vCenter server.

For example, you model the 'cas' vCenter server on two SpectroSERVERs: SS_1 and SS_2. After vCenter Discovery, Virtual Host Manager discovers that 'cas' manages the following three data centers:

- DCenter-A
- DCenter-B
- DCenter-C

On each SpectroSERVER, you can configure data center modeling for 'cas' as follows:

Data Center	cas on SS_1	cas on SS_2
DCenter-A	enabled	disabled
DCenter-B	enabled	disabled

DCenter-C	disabled	enabled

In this scenario, management of the data centers for 'cas' is distributed across the two SpectroSERVERs.

WARNING
Distributed data center management is not a scalable solution. For every vCenter server that is modeled on a SpectroSERVER, Virtual Host Manager must poll *all* data center data during each polling interval. Therefore, even if you disable modeling for a data center, Virtual Host Manager polls the data center. To minimize duplication of effort when polling, be mindful of how many SpectroSERVERs model the same vCenter server.

How to Distribute Management of Your Virtual Environment

To help improve Virtual Host Manager performance or organization, you can use the selective data center modeling feature. Distributed management spreads your data center modeling across multiple SpectroSERVERs.

The process for distributing management is similar to the selective data center modeling process, with a few additional steps, as follows:

1. Select your preference for automatically modeling data centers in Virtual Host Manager. In a distributed data center management environment, you must decide how to handle new data centers added to VMware. When configuring Virtual Host Manager for data center management, you have the following two options:
   - Disable automatic data center modeling for all SpectroSERVERs -- In this case, you must manually model all new data centers that you want Virtual Host Manager to monitor. Although it requires manual modeling, this option ensures that Virtual Host Manager is monitoring only the data centers that require management.
   - Enable automatic data center modeling on *one* SpectroSERVER, and disable for all others -- This option ensures that all new data centers are modeled on one SpectroSERVER. We recommend this option so that important network components are not forgotten. After your data center models appear in Virtual Host Manager, you can manually move their management to a different SpectroSERVER, if needed.

     WARNING
     Do not enable automatic data center modeling on multiple SpectroSERVERs. Virtual Host Manager models all new data centers on multiple SpectroSERVERs, resulting in duplicate effort, which can affect Virtual Host Manager performance.
2. Model your vCenter server. Be sure to model this vCenter server on each SpectroSERVER where you manage one or more of its data centers.
3. On each SpectroSERVER, enable on each vCenter server the selected data centers to monitor. The vCenter server models only the data centers and its contained components for which you enable modeling.
4. Configure the CA eHealth SystemEDGE agent to send traps to each SpectroSERVER. To ensure that data centers are properly monitored, traps must be sent to all SpectroSERVERs where your vCenter servers are modeled. For more information, see Trap Management in a Distributed Data Center Environment.

Trap Management in a Distributed Data Center Environment

To monitor data centers and their components, the related traps must reach the SpectroSERVER where each data center is managed. In a distributed data center management scenario, configure the CA eHealth SystemEDGE agent to send traps to each SpectroSERVER where your vCenter servers are modeled.

When properly configured, DX NetOps Spectrum sends all traps that are generated by the vCenter Server AIM to these SpectroSERVERs. Each SpectroSERVER filters the traps and drops the traps that are generated for data centers and their components that are *not* modeled on that SpectroSERVER. Only the traps that are related to modeled data center components generate events and alarms.

NOTE
For more information about configuring traps on the vCenter Server AIM, see *CA Virtual Assurance for Infrastructure Managers Implementation*.

Alarms and Fault Isolation for VMWare

This section describes the traps used by Virtual Host Manager and the resulting alarms. The following topics explains how Virtual Host Manager fault isolation differs from basic DX NetOps Spectrum fault isolation:

Virtual Host Manager Alarms for VMware

To alert you to problems within your virtual network, DX NetOps Spectrum generates alarms. Alarms are created in two ways:

- Traps sent from the CA eHealth SystemEDGE agent
- Polling

Two alarms are generated from polling: Powered Down/Suspended and Proxy Lost/Unavailable. However, several traps can generate alarms on your virtual devices. DX NetOps Spectrum supports all traps that are sent by the vCenter Server AIM from the CA eHealth SystemEDGE agent. To optimize these traps, you can configure the threshold values for each virtual device individually.

If a trap breaches your threshold value and generates an alarm, DX NetOps Spectrum uses the value of the “state” varbind passed with the trap to determine the alarm severity. All state varbinds have the following possible values, which receive the same DX NetOps Spectrum alarms:

- 0: Unknown
- 1: OK
- 2: Warning
- 3: Critical

DX NetOps Spectrum maps these vCenter states to a DX NetOps Spectrum alarm severity, as shown:

vCenter State	DX NetOps Spectrum Alarm Severity
0: Unknown	Clear
1: OK	Clear
2: Warning	Minor (Yellow)
3: Critical	Major (Orange)

Forwarding Traps from CA SystemEDGE

DX NetOps Spectrum supports all traps that the vCenter Server AIM sends. These traps are initially sent to the vCenter CA eHealth SystemEDGE model. If the destination for a trap is not the vCenter model, DX NetOps Spectrum forwards the trap to the correct virtual model.

NOTE
For specific event codes related to the traps, use the Event Configuration application and filter on “0x056e.” Or you can launch MIB tools to view the traps in the Trap Support table for the “EMPIRE-CAVMVCA-MIB” MIB. For more information about using the Event Configuration application, see Event Configuration. For more information about using MIB tools, see Modeling and Managing Your IT Infrastructure .

DX NetOps Spectrum determines where to forward the trap by using the following process:

1. When DX NetOps Spectrum receives a trap, it maps the UID of the entity type to a well-known varbind location.

   NOTE
   For the Host Sensor traps, DX NetOps Spectrum uses the virtual entity name, not the UID. If multiple hosts have the same vCenter name, DX NetOps Spectrum maps to the first entry.

2. DX NetOps Spectrum uses this UID to look up and locate the DX NetOps Spectrum model that is tied to a given UID. The entity type of all traps is predetermined. Depending on the results of the look-up, DX NetOps Spectrum forwards the trap as follows:
   – If it finds a DX NetOps Spectrum model of a specific type with a given UID, DX NetOps Spectrum forwards the event and corresponding alarm to the destination model.
   – If it cannot find a DX NetOps Spectrum model for a given UID, DX NetOps Spectrum generates a new generic event (0x56e109f) on the vCenter model. This new event includes the following details:
     • Trap details
     • Entity type searched for
     • Additional information from attempts to find the information about a model

NOTE
DX NetOps Spectrum often cannot find a related model when a trap is sent immediately after changing your virtual network entities in vCenter. vCenter Discovery has not yet identified and created the corresponding model in DX NetOps Spectrum.

Traps Supported in Virtual Host Manager

All traps that the vCenter Server AIM generates are supported in DX NetOps Spectrum. The traps are initially sent to the vCenter model. Then they are forwarded to a corresponding virtual entity type (that is, the "destination" entity), depending on the type of trap. Using these traps, you can monitor the performance of your virtual network, resolve any resulting alarms, or trigger events.

NOTE
For more information about traps that are generated by the vCenter Server AIM, see *CA Virtual Assurance for Infrastructure Managers Administration*.

The following tables list the traps for a specific destination entity type and specify whether the trap generates an alarm.

NOTE

Information!

*The vCenter ESX host name is used to locate the ESX host model in DX NetOps Spectrum. If two ESX host models exist with the same name, DX NetOps Spectrum alarms on the first model matching the name.

**These traps do not generate alarms because DX NetOps Spectrum vCenter polling intelligence detects and generates these alarms on the next vCenter polling cycle.

***These events are generated on the vCenter server because vCenter Discovery generates similar events on each entity that is discovered or removed from DX NetOps Spectrum management.

Trap Name	Trap OID	Alarm?
vmvcAimClusterHADRSChangeTrap	1.3.6.1.4.1.546.1.1.0.165253	No

Fault Management for Virtual Networks

The goal of fault isolation is to narrow down the root cause of a networking problem. Finding the root cause can help you to troubleshoot and quickly correct the problem or to correct the problem programmatically with automated scripts. Deciding which devices are the root cause of an alarm can be difficult, because problems with a single device can cause several devices in your network to generate events.

For example, losing contact with an ESX host often means that you have also lost contact with the virtual machines that the ESX manages. Therefore, the ESX device model and all affected virtual machines generate alarms. Using fault isolation techniques, Virtual Host Manager correlates these alarms to identify a single root cause.

Virtual networks provide a unique management opportunity because they provide DX NetOps Spectrum an alternate management perspective. DX NetOps Spectrum can gather information through direct contact with your virtual devices or through the virtual network management application, VMware vCenter. This alternate management perspective enhances standard DX NetOps Spectrum fault management in two ways:

- **Enhanced contact lost alarms** -- Two sources of information about a device mean Virtual Host Manager can pinpoint the cause and more easily correlate events to a single root cause.
- **Proxy failure alarms** -- *Proxy management* is the act of managing network devices using an alternate management source in place of or in addition to the primary manager. For example, DX NetOps Spectrum can manage virtual network devices by contacting them directly or through the virtual technology application's contact with the devices. When vCenter loses contact with a virtual network device, Virtual Host Manager generates a Proxy Management

Lost alarm for each device. These alarms are unique,alerting you that *management* of the device through the *proxy* is affected, not the state of the device or direct (SNMP) management.

How Fault Isolation Works when Device Contact is Lost

To help you troubleshoot networking problems with your devices, DX NetOps Spectrum uses fault isolation to narrow down the root cause of an alarm. For virtual networks, Virtual Host Manager uses information from direct contact with the device plus information provided by vCenter through the vCenter Server AIM. In many cases, standard DX NetOps Spectrum fault management can pinpoint the root cause. But in special circumstances, the method for isolating problems in a virtual network goes beyond the standard methods.

The type of fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe two unique fault management situations and how DX NetOps Spectrum isolates the networking error in your virtual network.

Scenario 1: Virtual machine is powered down or suspended

In a virtual environment, the virtual management application can provide more details than DX NetOps Spectrum can discover through standard device monitoring. For example, the management application is aware when a virtual machine is placed into one of the following modes:

- Powered down
- Suspended

If a virtual machine is in one of these modes and DX NetOps Spectrum loses contact with it, but proxy management of the ESX host is uninterrupted, DX NetOps Spectrum determines the root cause as follows:

1. When DX NetOps Spectrum loses contact with the virtual machine, it generates a Contact Lost alarm.
2. During its next polling cycle, the vCenter server model polls the vCenter Server AIM to gather information about the virtual machines. Because vCenter manages the virtual machines, it can provide a unique view into the possible cause of alarms generated by a virtual machine.
3. If vCenter finds that a virtual machine is powered down or suspended, it generates the appropriate alarm.

   NOTE
   The Powered Down and Suspend alarms are cleared upon the first vCenter polling cycle after the virtual machine is powered on.
4. Virtual Host Manager correlates these Powered Down and Suspend alarms to the corresponding Contact Lost alarm created by DX NetOps Spectrum. Virtual Host Manager makes the Contact Lost alarm appear as a symptom of the Powered Down or Suspend alarms.

Scenario 2: ESX host is down

If DX NetOps Spectrum loses contact with a modeled ESX service console and all virtual machines running on that host, DX NetOps Spectrum checks the status of the upstream routers and switches. Depending on their status, DX NetOps Spectrum determines the root cause as follows:

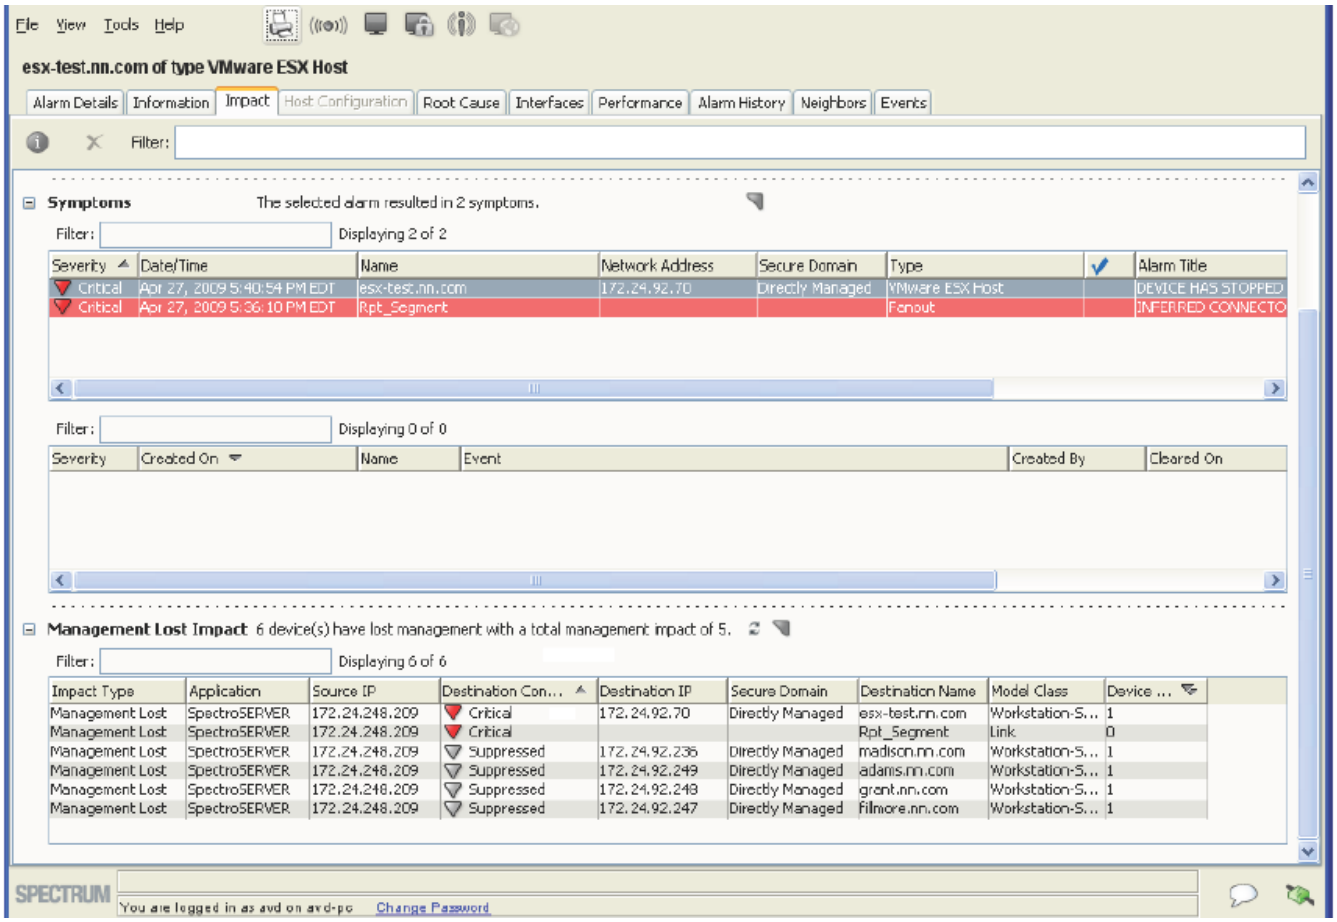
- All upstream devices for one or more virtual machines or the ESX service console are unavailable -- Standard DX NetOps Spectrum fault isolation techniques determine the root cause, as follows:
  - Device Stopped Responding to Polls alarm -- Generated on the ESX host when at least one upstream connected device for any virtual machine or ESX service console is up.
  - Gateway Unreachable alarm -- Generated on the ESX host when *all* upstream connected devices are down.
- At least one upstream device is available for every virtual machine and ESX service console model connected to the ESX host -- DX NetOps Spectrum infers that the ESX host is the root cause and responds as follows:
  a. The ESX service console model and all virtual machines, ports, and fanouts that are directly connected to the ESX service console model or virtual machine models generate the standard fault isolation alarms.
  b. Virtual Host Manager creates a Physical Host Down alarm for the ESX host model.

c. All fault isolation-related alarms that are created for the impacted devices (such as virtual machines, ESX service consoles, ports, and fanouts) are correlated to the Physical Host Down alarm, making them symptoms of the Physical Host Down alarm. These symptom alarms appear in the Symptoms table on the Impact tab for the Physical Host Down alarm.

NOTE
For each ESX host model, Virtual Host Manager creates a "virtual fault domain." This domain includes the ESX host, ESX service console, and virtual machines, plus all ports and fanouts directly connected to the ESX service console model or virtual machines. When the ESX host generates the Physical Host Down alarm, all standard fault isolation alarms within the domain are correlated to it. Correlating these alarms as symptoms indicates that the Physical Host Down alarm on the ESX host is the root cause.

d. All impacted devices are listed in the Management Lost Impact table on the Impact tab for the Physical Host Down alarm.

NOTE
Devices that are suppressed do not have a corresponding alarm in the Symptoms table, which is why the following example shows only two alarms but six impacted devices:



If all upstream devices for one or more virtual machines or the ESX service console go down, DX NetOps Spectrum can no longer reliably state that the fault lies with the ESX host. Therefore, DX NetOps Spectrum clears the Physical Host Down alarm and applies the standard DX NetOps Spectrum fault isolation techniques.

How Fault Isolation Works when Proxy Management is Lost

The VMware vCenter application used to create your virtual network provides DX NetOps Spectrum a unique management opportunity. DX NetOps Spectrum can use the standard methods to contact your virtual devices directly,

plus DX NetOps Spectrum can simultaneously gather virtual device information from vCenter. In this sense, vCenter is a "proxy" from which DX NetOps Spectrum gathers virtual device information. If DX NetOps Spectrum loses direct contact with a device, it generates alarms. Likewise, if vCenter loses contact with a virtual device or if Virtual Host Manager loses contact with the vCenter application, Virtual Host Manager generates alarms -- Proxy Management Lost alarms.

In response, DX NetOps Spectrum attempts to isolate the cause of the proxy management failure. Proxy fault isolation is similar to the standard DX NetOps Spectrum fault isolation, except that these alarms alert you to the fact that *proxy* management of a virtual device is affected. Proxy management fault isolation cannot tell you whether a virtual device is up or down. However, it is important to know when contact through the proxy is lost, because you could be missing important virtual information about a device.

The type of proxy fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe two unique proxy fault management situations and how Virtual Host Manager isolates the networking error in your virtual network.

Scenario 1: Contact between vCenter and ESX is lost

If vCenter loses contact with one of the ESX hosts it is managing, the vCenter data about that ESX and all hosted virtual devices is lost. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. A Proxy Management Lost alarm is generated on the ESX host, ESX service console, all hosted virtual machines, and any resource pools defined in that ESX.
2. The virtual machine alarms are correlated to the ESX Proxy Management Lost alarm, making them symptoms of the ESX alarm. Correlating these alarms as symptoms indicates that the ESX alarm is the root cause.
3. If DX NetOps Spectrum also loses contact with the ESX host and generates a Physical Host Down alarm, the Proxy Management Lost alarm generated for the ESX is correlated to the Physical Host Down alarm. In this case, the Proxy Management Lost alarm becomes a symptom of the Physical Host Down alarm. Correlating this alarm as a symptom indicates that the Physical Host Down alarm on the ESX is the root cause.

Scenario 2: Contact between DX NetOps Spectrum and vCenter is lost

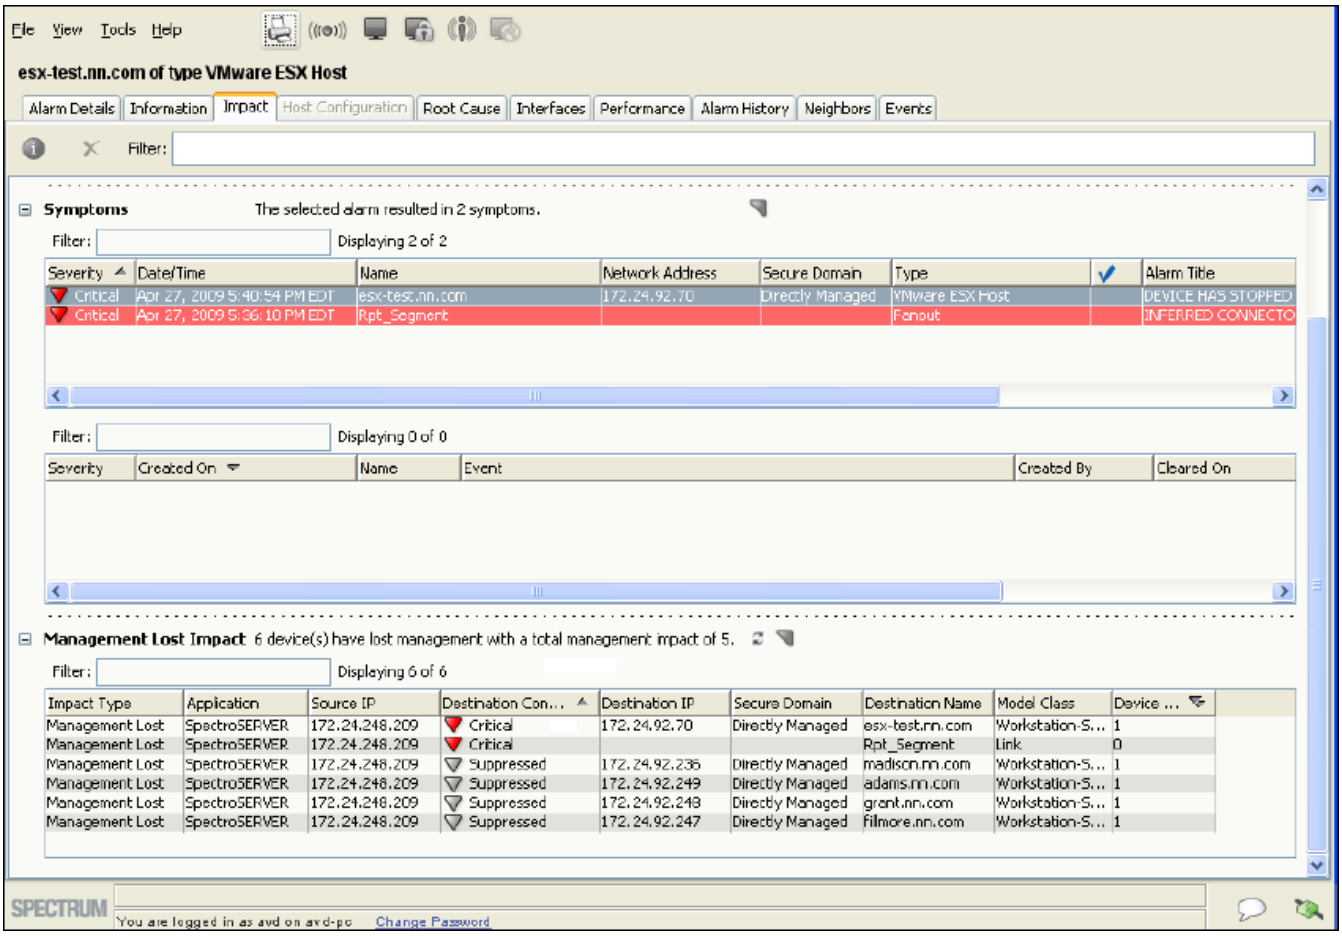
If DX NetOps Spectrum loses contact with a vCenter model, DX NetOps Spectrum loses vCenter data about all virtual models managed by that vCenter server. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. DX NetOps Spectrum generates Proxy Management Lost alarms for all virtual models managed by that vCenter server, including virtual machines, ESX hosts, ESX service consoles, datacenters, resource pools, and clusters. DX NetOps Spectrum also generates a separate Proxy Unavailable alarm that vCenter server model.
2. The virtual machine alarms are correlated to their corresponding ESX model alarm.
3. The ESX, datacenter, resource pool, and cluster alarms are correlated to the vCenter model Proxy Unavailable alarm.
4. The vCenter alarm is correlated to another alarm generated by standard DX NetOps Spectrum fault management, such as the alarms created for the following situations:
   - Lost management of vCenter (that is, a problem occurred with the remote SystemEDGE agent)
   - Machine contact is lost
   - vCenter is in maintenance mode

Determining Virtual Machines Affected by ESX Outages

When contact with an ESX is interrupted or the ESX goes down, all virtual machines hosted by the ESX are affected. Because vCenter cannot communicate with the ESX to get usage information, you might not receive alarms for a critical virtual machine that is hosted on that ESX. To find out whether a critical virtual machine is affected, access a list of affected virtual machines on the Impact tab of the alarm. The following views are available:

- Symptoms view -- displays all symptom alarms that the affected virtual machines generate
- Management Lost Impact view -- lists the virtual machines that are affected by the alarm



Microsoft Hyper-V

This section is for Microsoft Hyper-V virtualization technology users and describes how to use Virtual Host Manager to manage your virtual entities created with Hyper-V.

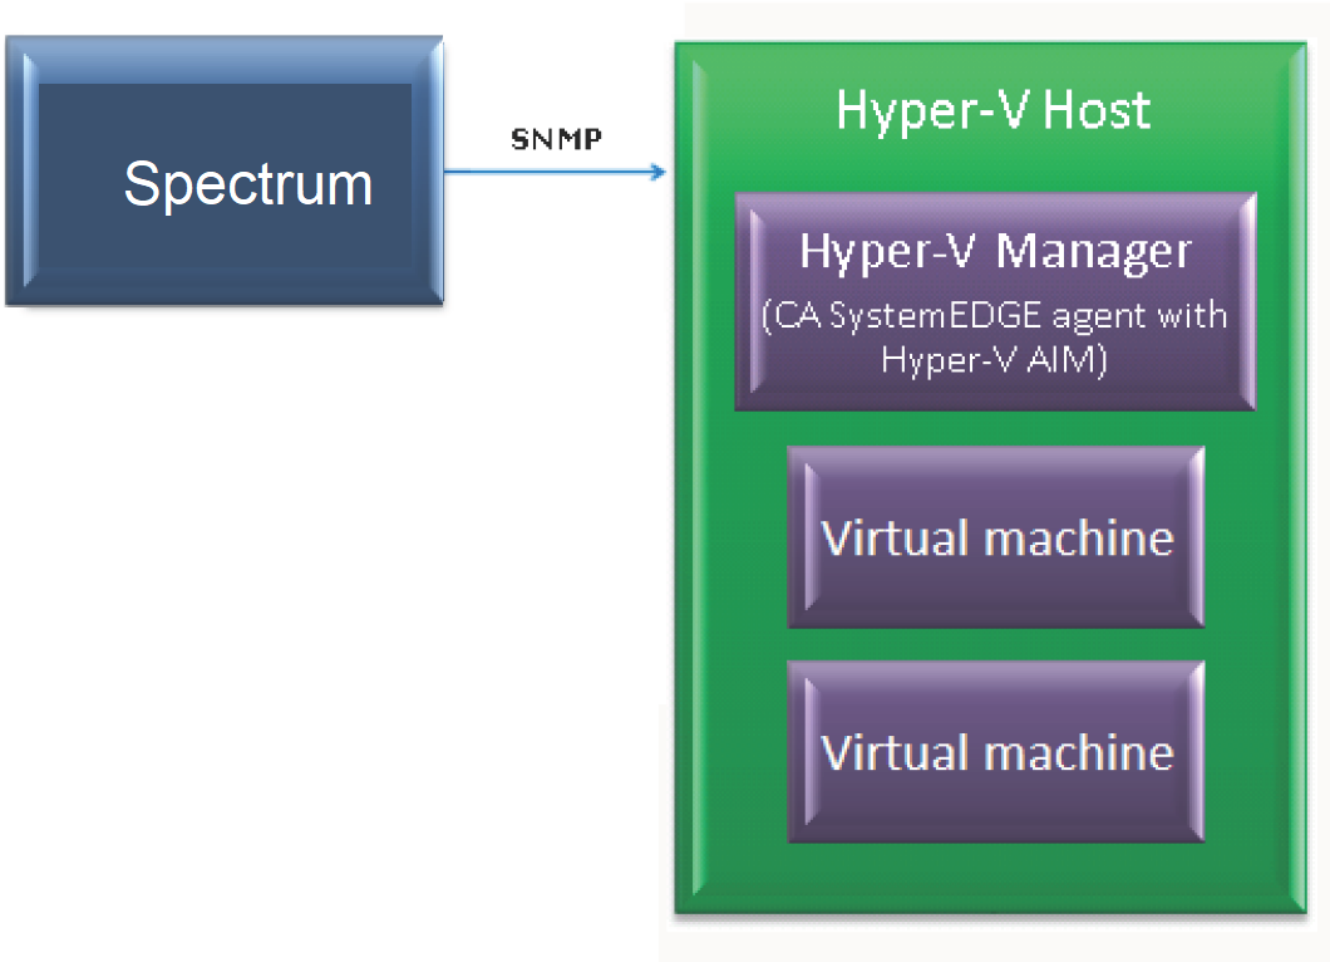
How Virtual Host Manager Works with Hyper-V

The Microsoft Hyper-V AIM collects the data of the monitored Hyper-V resources through server-internal queries without accessing the network. Therefore, the CA eHealth SystemEDGE agent and the Hyper-V AIM must run on each Microsoft Hyper-V Server that you want to monitor through DX NetOps Spectrum.

If your Microsoft Hyper-V virtual machine is a Windows platform virtual machine, we recommend installing the Microsoft Hyper-V integration services on each virtual machine in your Microsoft Hyper-V environment. The Hyper-V integration services optimize the virtualization of virtual machines. Without these tools, many features are not available.

The Microsoft Hyper-V Server provides the functionality to create, run, and manage virtual machines. The Hyper-V AIM and CA eHealth SystemEDGE agent integrates with the Microsoft Hyper-V Server and collects data for Hyper-V monitoring through DX NetOps Spectrum.

The following diagram shows how DX NetOps Spectrum gathers information about your Microsoft Hyper-V virtual environment using the CA eHealth SystemEDGE agent with the Hyper-V AIM loaded:



As shown in the diagram, the process to gather information about your Microsoft Hyper-V virtual environment is as follows:

1. The Microsoft Hyper-V management operating system resides on the Microsoft Hyper-V Host in your virtual environment, storing detailed data about each host and their virtual machines.
2. The Microsoft Hyper-V Manager, which contains the CA eHealth SystemEDGE agent with the Microsoft Hyper-V AIM loaded, resides on the Hyper-V host server. With that AIM loaded, the CA eHealth SystemEDGE agent communicates with the Microsoft Hyper-V management operating system to gather the details about your virtual environment.
3. Periodically, DX NetOps Spectrum retrieves the information from the Hyper-V Manager and uses it to model and monitor your virtual entities.

Models Created for Hyper-V

Virtual Host Manager provides several models to represent the components of your Microsoft Hyper-V virtual technology network. Understanding the following basic models can help you better understand Discovery and how the virtual environment interfaces with your physical environment.

Virtual Host Manager includes the following models and icons for Hyper-V devices:

- **Hyper-V Manager**
  Represents a server that contains the CA eHealth SystemEDGE agent with the Hyper-V AIM loaded. There can be only one Hyper-V Manager per Hyper-V Host.

Icon:

NOTE
The Hyper-V management operating system is represented in the virtual topology as part of the Hyper-V Manager model. The *Hyper-V management operating system* is the original operating system running on the Hyper-V Host. Microsoft Hyper-V uses this operating system to configure the hosted Hyper-V virtual machines. As appropriate, this Hyper-V Manager model is repeated in the hierarchy and topology views to represent the Hyper-V management operating system.

- **Hyper-V Host**
  Represents a Hyper-V Host, as configured in your Hyper-V virtualization technology. A *Hyper-V Host* is a physical computer that uses Microsoft Hyper-V virtualization software to run virtual machines. Hosts provide the CPUs and memory resources that Hyper-V virtual machines use. They also give these virtual machines access to storage and network connectivity. These models serve as container models within the topology views, helping to group your virtual entities into a separate view while showing where the virtual environment interfaces with your physical network. The Hyper-V Host cannot be contacted directly for status information. Instead, the status of these models is inferred from the status of its contained items.
  Icon:

- **Hyper-V virtual machine**
  Represents a Hyper-V virtual machine, as configured in your Hyper-V virtualization technology. A Hyper-V *virtual machine* is a software computer that, like a physical computer, runs an operating system and applications. A virtual machine dynamically consumes resources on its physical host, depending on its workload.
  Icon:

Discovering Hyper-V Networks

This section describes the Discovery and modeling process for Virtual Host Manager. These tasks are typically performed by the Virtual Host Manager administrator.

How to Configure Discovery Options

After Virtual Host Manager is installed, you can configure Virtual Host Manager for Hyper-V Discovery. Configuring your preferences helps ensure that Virtual Host Manager models your virtual devices correctly.

To configure your installation of Virtual Host Manager for Hyper-V Discovery, select your preferences for the following options:

- Maintenance Mode for New Virtual Machines -- Lets you decide which newly discovered virtual machines to place into maintenance mode until you are ready for DX NetOps Spectrum to manage them.
- Allow Device Model Deletes During Hyper-V Discovery -- Controls how DX NetOps Spectrum handles Hyper-V host and Hyper-V virtual machine models when Microsoft Hyper-V no longer manages them.
- Search for Existing Models -- Determines which secure domains Virtual Host Manager searches during a Hyper-V Discovery.
- Discover SNMP-Capable Devices -- Controls how SNMP-capable devices are modeled during Hyper-V Discovery. By default, new models are initially created as VHM models only. But, this option lets you override the default and immediately create SNMP models for devices that meet the necessary criteria.
- Retain SNMP-enabled Virtual Machines During Hyper-V Manager Deletion -- Controls how DX NetOps Spectrum handles SNMP-enabled virtual machine models when a Hyper-V Manager model is deleted.

Configure Maintenance Mode for New Hyper-V Virtual Machines

Virtual Host Manager automatically models the virtual machines that are managed by Microsoft Hyper-V. DX NetOps Spectrum attempts to manage all models discovered. However, some newly discovered Hyper-V virtual machines are not ready for DX NetOps Spectrum management when they are initially modeled. To prevent undesired alarms on new Hyper-V virtual machine models, you can decide which new models are immediately placed into maintenance mode. Later, you can manually disable maintenance mode on individual models when you are ready for DX NetOps Spectrum to manage these devices.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   A details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, Hyper-V, Hyper-V Discovery subview.
4. Click Set in the 'Maintenance Mode for New Hyper-V Virtual Machines' field and select one of the following options:
   - **Place non-enabled VMs in Maintenance Mode**
     (Default) Applies maintenance mode to only non-enabled Hyper-V virtual machine models on initial Hyper-V Discovery.
   - **Place all VMs in Maintenance Mode**
     Applies maintenance mode to all newly discovered Hyper-V virtual machine models upon initial Hyper-V Discovery.

   Your setting is saved and newly discovered Hyper-V virtual machine models created by Virtual Host Manager are placed into maintenance mode per your selection.

Manage Device Models for Devices Deleted from Microsoft Hyper-V

The devices and the relationships among them change frequently in virtual environments. Maintaining accurate and timely data about your virtual environment in DX NetOps Spectrum is challenging. For example, when a Hyper-V virtual machine is removed, DX NetOps Spectrum removes the corresponding device models from Virtual Host Manager in the Navigation panel. However, should DX NetOps Spectrum keep or delete the model? You can select settings to control model deletion.

> **WARNING**
> When models are deleted, all notes or other customizations on those models are lost. Disable this option if models are likely to be recreated in your Hyper-V environment later.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.

3. Expand the Configuration, Hyper-V, Hyper-V Discovery subview.
4. Click Set in the 'Allow Device Model Deletes During Hyper-V Discovery' field and select one of the following options:
   – **Yes**
   (Default) Deletes the models that correspond to entities no longer managed by your Microsoft Hyper-V environment.
   – **No**
   Places Virtual Host Manager models in the LostFound container when their corresponding entity is no longer managed by your Hyper-V environment, but the models are not deleted from DX NetOps Spectrum.

   NOTE
   Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

Your setting is saved, and device models are handled accordingly after the device is deleted from your Hyper-V environment.

Configure Model Searches Across Secure Domains (Hyper-V)

Before creating new models, Hyper-V Discovery attempts to locate models in the SpectroSERVER. In an environment with Secure Domain Manager deployed, Hyper-V Discovery searches for models within the same secure domain as your Hyper-V Manager. This domain is the "local" domain. However, some of your virtual environment devices can exist within a different secure domain. In this case, you can configure Hyper-V Discovery to search all secure domains for existing models.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   A details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, Hyper-V, Hyper-V Discovery subview.
4. Click Set in the 'Search for Existing Models' field and select from the following options:
   – **In Hyper-V Manager's Secure Domain**
   (Default) Searches for existing models within the same secure domain as the Hyper-V Manager server.
   – **In All Secure Domains**
   Searches for existing models within all secure domains managed by the SpectroSERVER. Select this option only in the following situations:
   • All devices have unique IP addresses
   • When secure domains are used for security purposes or to isolate network traffic

   NOTE
   Do not select this option for a NAT environment.

   Your setting is saved and Hyper-V Discovery searches for existing models in DX NetOps Spectrum according to your selection. If duplicate models (that is, models that share the same IP address) exist in multiple secure domains, Virtual Host Manager does the following:
   – Selects the model in the local secure domain, if available.
   – If a duplicate model does not exist in the local domain, Virtual Host Manager randomly selects a model from another secure domain.
   – In both cases, Virtual Host Manager generates a minor alarm for the duplicate IP addresses on the Hyper-V Manager model.

Configure SNMP Modeling Preferences (Hyper-V)

SNMP-capable virtual machines support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. By default, Hyper-V Discovery creates

virtual machines as VHM models, which you can later upgrade to SNMP models. However, you can configure Hyper-V Discovery to model all new SNMP-capable devices as SNMP models. Although Hyper-V Discovery may take longer to complete, initially modeling these as SNMP models avoids manually upgrading these models later.

> **WARNING**
> Enable SNMP modeling *before* you model your Hyper-V Manager servers. If you model the Hyper-V Manager servers first, all child models are created as VHM models, which must be manually upgraded to SNMP models.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, Hyper-V, Hyper-V Discovery, SNMP Discovery subview.

   > **WARNING**
   > Follow the steps in the subview to prepare your devices and DX NetOps Spectrum for SNMP Discovery. If devices are not properly prepared before Hyper-V Discovery, Virtual Host Manager cannot create SNMP models.
4. Click Set in the 'Discover SNMP-Capable Devices' field and select from the following options:
   - **Yes**
     Enables SNMP modeling during Hyper-V Discovery. Only devices that meet the criteria specified in the SNMP Discovery subview text are modeled as SNMP devices. Applies to *new* models only.
   - **No**
     (Default) Models all new devices found during Hyper-V Discovery as VHM models. You can manually upgrade these models to SNMP models later.

   Your setting is saved and new devices are modeled in Virtual Host Manager according to your selection.

Manage SNMP-Enabled Virtual Machine Models After Hyper-V Manager Deletion

By default, SNMP-enabled devices are deleted from DX NetOps Spectrum when the following items are deleted:

- Hyper-V Manager model for the device
- Hyper-V folder in the Navigation panel

SNMP-enabled device models can include significant customizations that you want to retain. You can adjust your settings to avoid deleting these models. They are placed into the LostFound container for later use.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, Hyper-V, Hyper-V Discovery subview.
4. Click Set in the ‘Retain SNMP-enabled Virtual Machines During Hyper-V Manager Deletion' field and select one of the following options:
   - **Yes**
     Retains SNMP-enabled virtual machine models in the LostFound container when their Hyper-V Manager or the Hyper-V folder is deleted.

     > **NOTE**
     > Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.
   - **NO**
     (Default) Deletes all virtual machine models when their Hyper-V Manager or the Hyper-V folder is deleted.

Your setting is saved. SNMP-enabled device models are handled according to your selection when Hyper-V Manager models or the Hyper-V folder is deleted.

How to Discover and Model Your Virtual Environment (Hyper-V)

To monitor your virtual environment, discover and model your virtual entities -- Hyper-V Managers, Hyper-V Hosts, and Hyper-V virtual machines. Modeling these entities in Virtual Host Manager lets you view your complete network topology in one tool, showing the relationships between your physical and virtual components.

The main steps for modeling your virtual environment are as follows:

1. Run a standard Discovery.
   The purpose of this Discovery is to ensure that the upstream routers and switches are modeled before Hyper-V Discovery runs. Or, if the SNMP Modeling option is disabled, this step can also model the SNMP-capable virtual machines and Hyper-V servers. When modeling these entities, be sure that your modeling options are set correctly to support Virtual Host Manager.
2. Upgrade the CA eHealth SystemEDGE model.
   This step is required only when your CA eHealth SystemEDGE agent on the Hyper-V server was modeled in a release before 9.2.1.
3. Let Hyper-V Discovery run.
   When you model the CA eHealth SystemEDGE agent (with the Hyper-V AIM) on the Hyper-V server, Hyper-V Discovery begins automatically. Each of these Hyper-V Server models has its own Hyper-V Discovery process. The purpose of Hyper-V Discovery is to find the virtual entities managed by Hyper-V, model the ones that do not exist, and place them in the Virtual Host Manager view of the Navigation panel.

Run Discovery (Hyper-V)

To discover your Hyper-V environment, run the standard DX NetOps Spectrum Discovery. This Discovery ensures that the upstream routers and switches are modeled so that later connections from the virtual entities can be established. You can also model the SNMP-capable Hyper-V virtual machines during DX NetOps Spectrum Discovery.

NOTE
Modeling SNMP-capable Hyper-V virtual machines is necessary during DX NetOps Spectrum Discovery only when the SNMP Modeling option is disabled during Hyper-V Discovery.

NOTE
Only an administrator performs this task.

Follow these steps:

1. Open the Discovery console.

   NOTE
   Before modeling, be sure that you know the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port.
2. In the Navigation panel, click the Creates a new configuration icon  .
3. Configure your options to support virtual network modeling, as follows:
   a. Click the Modeling Options button in the Modeling Options group.
      The Modeling Configuration dialog opens.
   b. Click the Protocol Options button.
      The Protocol Options dialog opens.
   c. Select the ARP Tables for Pingables option, and click OK.

The Modeling Configuration dialog opens.

d. (Optional) Click the Advanced Options button in the Advanced Options group. Add your nonstandard SNMP ports (such as, the CA eHealth SystemEDGE agent port), and click OK.

4. Enter individual IP addresses or the beginning and ending IP addresses in the IP Boundary List fields and click Add.

NOTE
Be sure that the range of IP addresses includes all servers with CA eHealth SystemEDGE and Hyper-V AIM installed and the interconnecting switches and routers. Or you can include the SNMP-capable Hyper-V virtual machines that require SNMP models.

5. Enter any additional values in the Discovery console, and click Discover.
The following models are created and added to your network topology in DX NetOps Spectrum:
   - Hyper-V Manager servers and the switches and routers that connect them to your network -- Information about your virtual environment comes from the Hyper-V Manager. When these Hyper-V Manager models exist in DX NetOps Spectrum, Hyper-V Discovery can begin.
   - Hyper-V Hosts and Hyper-V virtual machines -- If you decide not to model these entities with DX NetOps Spectrum Discovery, Hyper-V Discovery creates them as VHM models.

NOTE
You can also manually model your virtual network by IP address. In this case, we recommend modeling the upstream devices first. Modeling in the correct order ensures that the relationships among these entities are built correctly in the topology. For more information about how to perform a Discovery, see Modeling and Managing Your IT Infrastructure section.

Upgrade the CA SystemEDGE Model (Hyper-V)

The CA eHealth SystemEDGE agent could have been modeled in DX NetOps Spectrum before installing Virtual Host Manager or before the Hyper-V AIM was loaded on the agent. In this case, the existing CA eHealth SystemEDGE model is not compatible with Virtual Host Manager. Upgrade the model so that Virtual Host Manager can access the Hyper-V AIM capabilities in CA eHealth SystemEDGE. *This procedure is not required if the CA eHealth SystemEDGE agent with Hyper-V AIM is modeled after installing DX NetOps Spectrum.*

To upgrade the CA eHealth SystemEDGE model, right-click the model and select Reconfiguration, Reconfigure Model.

The CA eHealth SystemEDGE model is upgraded to support the Hyper-V AIM.

NOTE
You can also send a reconfigure model action to CA eHealth SystemEDGE using the CLI. For more information, see Modeling and Managing Your IT Infrastructure section.

How Hyper-V Discovery Works

Hyper-V Discovery is a specialized discovery process that gathers detailed information about your virtual environment. The purpose of Hyper-V Discovery is to obtain the virtual entities managed by Microsoft Hyper-V, model the ones that do not exist in DX NetOps Spectrum, and place them under Virtual Host Manager in the Navigation panel.

A key benefit of Hyper-V Discovery is that it runs automatically in the background, continually keeping your virtual environment data updated in DX NetOps Spectrum. Understanding how Hyper-V Discovery works reinforces the importance of properly installing and modeling the various components of Virtual Host Manager.

The Hyper-V Discovery process works as follows:

1. Immediately after the CA eHealth SystemEDGE agent and Hyper-V AIM are installed, the Hyper-V AIM communicates with the Hyper-V Host to gather information about the virtual entities it manages. The Hyper-V AIM stores this information.

WARNING
The CA eHealth SystemEDGE agent and Hyper-V AIM must be installed so that CA eHealth SystemEDGE, Hyper-V virtualization technology, and DX NetOps Spectrum can communicate. If they cannot, Hyper-V Discovery cannot run.

2. During DX NetOps Spectrum Discovery, DX NetOps Spectrum creates a Hyper-V Manager model for each server in Step 1 and enables DX NetOps Spectrum to handle communication between DX NetOps Spectrum and the CA eHealth SystemEDGE agent.
3. DX NetOps Spectrum polls the Hyper-V AIM to gather the Hyper-V information that is stored in Step 1.
4. DX NetOps Spectrum begins Hyper-V Discovery and uses this information from the AIM to update modeling in the DX NetOps Spectrum Topology tab and the Virtual Host Manager hierarchy in the Navigation panel, as follows:
   a. If you enable SNMP Discovery before Step 2, Virtual Host Manager Discovery creates SNMP models for all new SNMP-capable models that meet the SNMP Discovery criteria.

      NOTE
      By default, SNMP Discovery is disabled during Hyper-V Discovery.

   b. VHM models are created for the Hyper-V Managers.
   c. Previously existing Hyper-V virtual machine models are changed to VHM models.
   d. VHM models are created for the Hyper-V virtual machines that do not exist in DX NetOps Spectrum.
   e. VHM models are created for the Hyper-V Host models, and these models group their associated Hyper-V virtual machine models in the Navigation panel, under Virtual Host Manager and the Universe topology.
   f. All models for your virtual network are added to the Virtual Host Manager portion of the Navigation panel.

      NOTE
      In a virtual environment, devices on separate ESX hosts can have the same IP address or MAC address. In this case, DX NetOps Spectrum creates duplicate models for each occurrence of an IP address or MAC address.

5. Hyper-V Discovery automatically repeats this process at each regularly scheduled Hyper-V polling interval.

   NOTE
   By default, the Hyper-V polling interval is controlled by setting the polling interval on the Hyper-V Manager model. Or you can control Hyper-V polling by using the Hyper-V server application model.

Adding SNMP Capabilities to VHM Models

SNMP-capable virtual machines support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. When an SNMP agent is not available or SNMP Discovery is disabled, Virtual Host Manager creates Hyper-V virtual machines as VHM models.

Later, you can install an SNMP agent on any virtual machine and upgrade its modeling in DX NetOps Spectrum. Options for upgrading to SNMP models are as follows:

- **Upgrade only selected devices** -- This method works quickly when you have a small selection of models to upgrade. The VHM models and child models are deleted first. A drawback of this method is that after DX NetOps Spectrum deletes the models, you must wait for the next Hyper-V Discovery to create the new SNMP models and place them in Virtual Host Manager. Knowledge of the IP addresses for the models to upgrade is required.
- **Upgrade all SNMP-capable VHM models** -- This method upgrades models in batch. It is preferred when upgrading Virtual Host Manager to a new release. For this method, knowledge of the IP addresses of individual models is not required. Another advantage is that after DX NetOps Spectrum deletes the VHM models, the upgraded SNMP models are immediately placed in the Virtual Host Manager hierarchy without waiting for the next polling cycle. Therefore, the child models are not left unmanaged.
  One drawback of this method is that it can take a long time to complete. The time required to complete this upgrade depends on how many community strings and SNMP ports Virtual Host Manager must search when locating SNMP-capable devices.

NOTE
Virtual Host Manager attempts to identify SNMP agents on powered-up pingable virtual machines only.

WARNING
When models are deleted, all notes or other customizations on those models are lost.

Upgrade Selected VHM Models to SNMP Models

When an SNMP agent is not available or SNMP Discovery is disabled during Hyper-V Discovery, Virtual Host Manager creates Hyper-V virtual machines as VHM models. Later, you can install an SNMP agent on any virtual machine and upgrade its modeling in DX NetOps Spectrum. You must know the IP addresses for the device models to upgrade. Manually selecting models to upgrade works quickly, but all notes or customizations on these models are lost during the upgrade.

Follow these steps:

1. Deploy or enable an SNMP agent on the device, if required.
2. Model the device again using one of the following methods:
   – DX NetOps Spectrum Discovery
   – Model individual devices by IP address

   When the new SNMP-capable model is created, DX NetOps Spectrum removes the previous model from Virtual Host Manager and deletes it. At the next Hyper-V AIM polling cycle, DX NetOps Spectrum adds the SNMP-capable model to Virtual Host Manager in the Navigation panel.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Upgrade All VHM Models to SNMP Models (Hyper-V)

When an SNMP agent is not available or SNMP Discovery is disabled during Hyper-V Discovery, Virtual Host Manager creates Hyper-V virtual machines as VHM models. Later, you can install an SNMP agent on any virtual machine and upgrade its modeling in DX NetOps Spectrum. When upgrading in batch, DX NetOps Spectrum searches all VHM models to find models that are now SNMP-capable devices. DX NetOps Spectrum converts them to SNMP models. This method can take a long time to complete, depending on how many community strings and ports Virtual Host Manager must search.

Follow these steps:

1. Deploy or enable an SNMP agent on your devices, as required.
2. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
3. Select the Hyper-V Manager model in the Navigation panel that manages the models that you want to upgrade.
4. Click the Information tab.
5. Expand the Hyper-V Manager, DX NetOps Spectrum Modeling Control subview.
6. Click Upgrade ICMP-Only Devices.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Virtual Host Manager searches for VHM models managed by the Hyper-V AIM on the selected Hyper-V Manager device. Virtual Host Manager upgrades the ICMP-only devices that meet the criteria for SNMP devices and places them within the Virtual Host Manager hierarchy.

Move a Hyper-V Virtual Machine to a Different Hyper-V Host

Moving a Hyper-V virtual machine from one Hyper-V Host to another can result in lost data. The risk depends on your Virtual Host Manager configuration. The Hyper-V AIM does not support virtual machine migration. To Virtual Host Manager, a move is two events -- the virtual machine is deleted from the original Hyper-V Host, and a new virtual machine is added to the new Hyper-V Host. In this case, Virtual Host Manager deletes the original virtual machine model and creates a new one. If you customized the original model, deleting it can result in lost data. You can avoid this data loss when you configure your Virtual Host Manager settings correctly before moving the virtual machine.

Follow these steps:

1. Change the 'Allow Device Model Deletes During Hyper-V Discovery' option to No.

   NOTE
   Disabling this option means that DX NetOps Spectrum does not delete the virtual machine model from DX NetOps Spectrum when the model is removed from Virtual Host Manager management.
2. Use the Microsoft Hyper-V virtualization technology to remove the virtual machine from the original Hyper-V Host.
3. Wait for Virtual Host Manager to reflect the changes in the Navigation panel.
4. Use the Microsoft Hyper-V virtualization technology to add the virtual machine to the other Hyper-V Host.
   When Hyper-V Discovery finds the new virtual machine, Virtual Host Manager reconciles it with the existing model. Virtual Host Manager places that model into Virtual Host Manager management.
5. (Optional) Change the 'Allow Device Model Deletes During Hyper-V Discovery' option back to Yes on the originating Hyper-V Manager model.
   The virtual machine is successfully moved.

Viewing Your Hyper-V Virtual Environment

This section describes concepts for viewing your Hyper-V virtual environment and the associated alarms. The basic steps are no different from the standard DX NetOps Spectrum procedures. However, this section describes conceptual differences and details that only apply to the Hyper-V virtual technology.

Viewing Your Hyper-V Virtual Network

On the Explorer tab, the Virtual Host Manager node displays a hierarchical tree structure that helps you visualize the logical relationships among your virtual environment resources.

Using this information, you can see how resources are shared among your Hyper-V Managers. This information can help you identify opportunities to reorganize and optimize your virtual environment. The hierarchy also provides a quick way to monitor the performance of resources and troubleshoot alarms.

Because Virtual Host Manager is not aware of a DSS environment, it is located within a landscape hierarchy. The following example shows where Virtual Host Manager appears on the Explorer tab in the Navigation panel and illustrates the virtual environment hierarchy:

```
[-] <ss> host
    [+] Universe
    [-] Virtual Host Manager
        [-] Hyper-V
            [+] Hyper-V Manager 1
            [-] Hyper-V Manager 2
                [-] Hyper-V Host
                     .  Hyper-V Manager 2 (management operating system)
                     .  Hyper-V virtual machine 1
                     .  Hyper-V virtual machine 2
```

NOTE
The Hyper-V management operating system is represented in the virtual topology as part of the Hyper-V Manager model.

Virtual Host Manager is the root node for the entire virtual environment that is managed by this SpectroSERVER. Selecting this node in the Navigation panel displays Virtual Host Manager details in the Contents panel. You can view details such as events and alarms related to your virtual environment.

Directly under Virtual Host Manager, virtual environments are organized within folders that represent the associated technology. In the example hierarchy above, the Hyper-V folder contains the portion of the virtual environment that was created using Microsoft Hyper-V virtualization technology. In this folder, Virtual Host Manager lists all Hyper-V Manager hosts managed by this SpectroSERVER.

Each Hyper-V Manager contains only the portion of the entire virtual environment that it manages. Selecting a Hyper-V Manager in the Navigation panel displays details in the Contents panel, such as the Hyper-V Hosts or Hyper-V virtual machines managed by the selected Hyper-V Manager.

Under each Hyper-V Manager, the hierarchy represents the logical relationships between the following entities:

- **Hyper-V Hosts**
  A Hyper-V Host contains the Hyper-V virtual machines that it manages. Selecting a Hyper-V Host in the Navigation panel displays details in the Contents panel such as events and alarms related to the Hyper-V Host, memory usage, status, and more.
- **Hyper-V Management Operating System**
  The Hyper-V Management Operating System model appears as a child to its corresponding Hyper-V Host model and is always a leaf node on the Virtual Host Manager hierarchy tree. This model shares the name and model type of its parent. Although this model appears to be the same as the Hyper-V Manager model, the instance that appears under the Hyper-V Host model represents the management operating system running on the Hyper-V Host. Hyper-V uses this operating system to configure the hosted Hyper-V virtual machines. Selecting a Hyper-V Management Operating System model in the Navigation panel displays details in the Contents panel, including system status and CPU and memory usage.
- **Hyper-V Virtual Machines**
  A Hyper-V virtual machine is always a leaf node on the Virtual Host Manager hierarchy tree. Selecting a Hyper-V virtual machine in the Navigation panel displays details in the Contents panel, such as events and alarms that are related to the virtual machine, memory usage, and status.

Understanding the Hyper-V Virtual Topology

The Hyper-V Manager/Management Operating System, Hyper-V Host, and Hyper-V virtual machine models created for your virtual environment are integrated into the topology view. Hyper-V Host models automatically group their associated Hyper-V virtual machines. The topology shows how these Hyper-V virtual machines are connected to your physical network entities.

NOTE
The Hyper-V management operating system is represented in the virtual topology as part of the Hyper-V Manager model.

The following example shows how these models can appear on the Explorer tab in the Navigation panel under the Universe group:

```
[-] Universe
     .  Physical switch 1
     .  Physical switch 2
    [-] Hyper-V Host
         .  Fanout 1
```

```
. Fanout 2
. Hyper-V Manager (management operating system)
. Hyper-V virtual machine 1
. Hyper-V virtual machine 2
. Hyper-V virtual machine 3
```

Selecting one of these models displays these relationships graphically on the Topology tab in the Contents panel.

How the Hyper-V Data is Updated in Virtual Host Manager

After DX NetOps Spectrum builds your initial Hyper-V hierarchy, your virtual network configuration can change. Virtual Host Manager continually works to keep this information accurate in DX NetOps Spectrum. For example, the following events can change your virtual network configuration:

- Creating or deleting a Hyper-V virtual machine on a Hyper-V Host
- Manually moving a Hyper-V virtual machine from one Hyper-V Host to another

To keep your information accurate, Virtual Host Manager detects these changes by polling the Hyper-V AIM. Therefore, your virtual network configuration changes, if any, are reflected in DX NetOps Spectrum at each polling cycle. DX NetOps Spectrum also receives traps from the AIM and generates the corresponding events. By reviewing the event log, you can find out when configuration changes occur, such as when a new virtual machine is created.

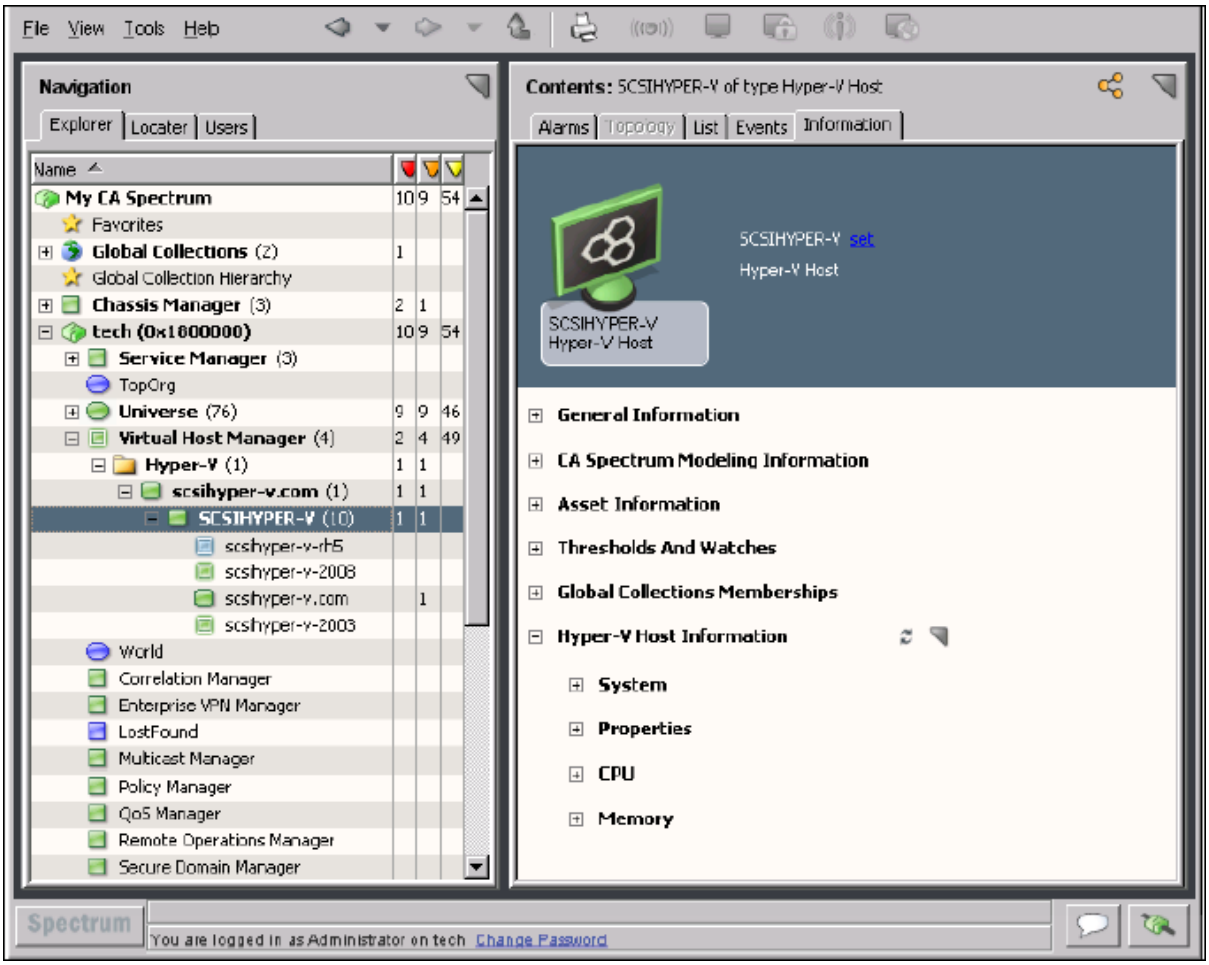
When a virtual machine is deleted, DX NetOps Spectrum removes the models from the Virtual Host Manager hierarchy on the Explorer tab. When the AIM detects an addition to your virtual network configuration, such as creating a new virtual machine or placing one into management, DX NetOps Spectrum performs the following tasks:

- Updates the placement of your virtual device models in the hierarchy of the Explorer tab
- *Automatically* rediscovers connections to the affected Hyper-V Manager and virtual machine models and associates them with the correct Hyper-V Host in the topology

> **NOTE**
> Although most components of your virtual environment are discovered automatically, the DX NetOps Spectrum administrator should initiate a new SNMP discovery to model *new* switches or routers. This discovery is necessary only when a new virtual host is configured that does not share connections with the existing virtual network models.

Custom Subviews for Virtual Entity Types (Hyper-V)

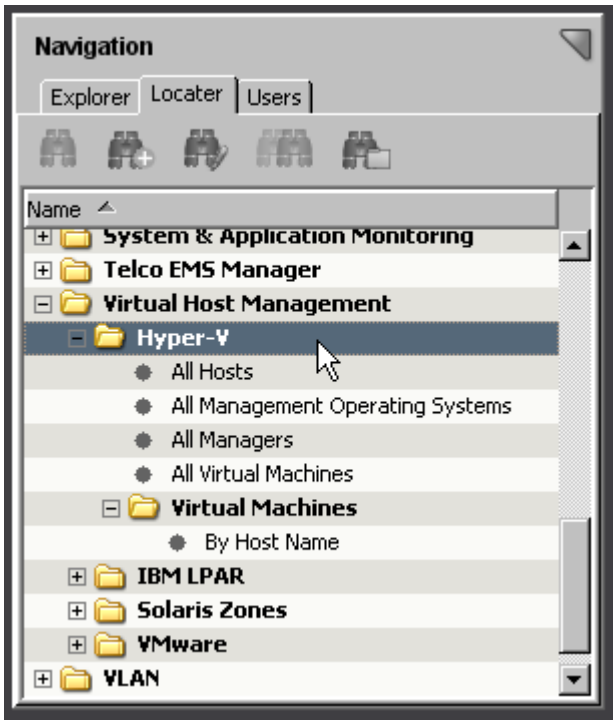
Your Virtual Host Manager models collectively provide information about your virtual environment. Individually, each model provides unique information or configuration settings, depending on the virtual entity type it represents. This custom subview appears on the Information tab in the Contents panel. These subviews can contain real-time data, such as CPU status or memory utilization. For example, the custom subview for a Hyper-V Manager is the "Hyper-V Manager" subview, as shown:



NOTE
The Hyper-V Manager model provides combined information for all virtual devices managed by the Hyper-V Manager. That is, selecting the Hyper-V Manager model in the Navigation panel displays information about the selected Hyper-V Manager host *and* combined information about all Hyper-V Hosts and Hyper-V virtual machines. This information is the same data displayed on the Information tab for each individual entity model. The combined view in the Hyper-V Manager model can provide a good overview about all of the virtual entities it manages.

Locater Tab for Hyper-V Searches

In addition to viewing details about your virtual environment on the Explorer tab, you can also use the Locater tab to run preconfigured Virtual Host Manager searches. The search options are grouped under the Virtual Host Management, Hyper-V folder on the Locater tab, as shown:



These detailed searches can help you investigate information related to virtual entities only, such as locating all Hyper-V virtual machines within a landscape.

NOTE
Although Virtual Host Manager is not DSS aware, these preconfigured searches let you select multiple landscapes to search in the search parameters.

The Locater tab in the Navigation panel includes the following searches for Virtual Host Manager information:

- **All Hosts**
  Locates all Hyper-V Host servers that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All Management Operating Systems**
  Locates all Hyper-V management operating systems that have been modeled in the DX NetOps Spectrum database for your virtual network.

  NOTE
  The Hyper-V management operating system is represented in the virtual topology as part of the Hyper-V Manager model.
- **All Managers**
  Locates servers hosting the CA eHealth SystemEDGE agent with Hyper-V AIM enabled that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All Virtual Machines**
  Locates all Hyper-V virtual machines that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **Virtual Machines, By Host Name**
  Locates virtual machines in the DX NetOps Spectrum database managed by only one or a select group of Hyper-V Hosts.

Status Monitoring Options (Hyper-V)

DX NetOps Spectrum provides a wide range of options for monitoring the state of your virtual network resources. The status information available for a resource varies, depending on the type of virtual entity you are monitoring. Also, your ability to configure a status option depends on its type. For example, some status options are read-only, but others let you enable behaviors or select an alarm severity. Providing this range of options and levels of customization, DX NetOps Spectrum lets you decide how to best monitor the performance of your virtual network.

Status fields are located in the OneClick subviews. All status information for a given virtual environment is available on the Hyper-V Manager model in a tabular format. Also, each virtual entity type that has a unique model in DX NetOps Spectrum provides a subset of the same status information for easy viewing. Status-related settings, including the alert type and monitor settings, can be set from either view location.

The following tables outline the type of status information available for each virtual entity type. The Subview Locations column describes where the corresponding status fields are located in OneClick. For example, "memory" information for a Hyper-V virtual machine model is available on the Information tab in the following two locations:

- Virtual Machine Information subview for the Hyper-V virtual machine model
- Hyper-V Manager, Managed Environment, Virtual Machines subview for the Hyper-V Manager model

To explore the exact status options available for each status information type, locate the subview in OneClick.

Hyper-V Manager

Status Information Type	Subview Locations
Overall	Hyper-V Manager

Hyper-V Host

Status Information Type	Subview Locations
Overall	Hyper-V Host
CPU	Hyper-V Host, Hyper-V Manager
Memory	Hyper-V Host, Hyper-V Manager

Hyper-V Virtual Machine

Status Information Type	Subview Locations
Overall	Hyper-V virtual machine, Hyper-V Manager
Memory	Hyper-V virtual machine, Hyper-V Manager
CPU	Hyper-V virtual machine, Hyper-V Manager

How to Configure Management Options (Hyper-V)

After your virtual network is modeled, you can configure Virtual Host Manager options for viewing and managing your device models. Configuring your preferences helps ensure that Virtual Host Manager handles your virtual device models correctly and monitors only the information that is important to you.

To configure your installation of Virtual Host Manager, perform the following procedure after you discover and model your virtual network:

- Configure threshold values and other status monitoring options -- These options let you determine which information you want to monitor and how DX NetOps Spectrum manages the various events that occur in your virtual network.

Configure and Monitor Resource Status (Hyper-V)

You can monitor the status of virtual resources in OneClick. For example, you can view the total physical memory or used physical memory, and more. You can also set monitoring options, such as enabling alerts. This information can help you optimize your virtual network performance and troubleshoot alarms.

NOTE
Traps are set on and managed by the Hyper-V AIM.

You can view or configure resource status options and information for virtual devices on the Information tab.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Locate and click the virtual device on the Explorer tab in the Navigation panel.
   The device details display in the Contents panel.
3. Click the Information tab.
   Multiple subviews are available for viewing. Generally, the subview at the bottom of the tab includes the resource allocation and utilization information for the selected model. For example, a Hyper-V Host model displays a subview named "Hyper-V Host Information" that includes details for the specific Hyper-V Host model you selected in the Navigation panel.
4. Expand the appropriate subview.
   All available resource status details and monitoring options for the selected device model are displayed.

   NOTE
   The Hyper-V Manager model provides combined information for all virtual devices managed by the Hyper-V Manager. That is, selecting the Hyper-V Manager model in the Navigation panel displays information about the selected Hyper-V Manager host *and* combined information about all Hyper-V Hosts and Hyper-V virtual machines. This information is the same data displayed on the Information tab for each individual entity model. The combined view in the Hyper-V Manager model can provide a good overview about all of the virtual entities it manages.

Controlling Hyper-V AIM Polling

When you are tuning Virtual Host Manager performance, you can change the Hyper-V Manager polling rate or disable Hyper-V technology polling. By default, the polling attributes on the Hyper-V Manager model control the Hyper-V polling behavior. Or you can change this Hyper-V polling behavior independently. The Hyper-V technology application model, HyperVAimApp, controls your Hyper-V polling.

The following two attribute values on the application specifically control the Hyper-V polling logic:

- PollingStatus
- Polling_Interval

Both the Hyper-V Manager model and the HyperVAimApp application model contain these attributes. PollingStatus disables and enables polling while Polling_Interval controls the polling frequency. If their values are different, the HyperVAimApp application model attribute values take precedence when determining Hyper-V technology polling behavior.

This ability to set the value for the device model and application model lets you fine-tune your Hyper-V technology polling. For both PollingStatus and Polling_Interval, modifying the attribute on the Hyper-V Manager device model also changes the corresponding application model attribute when their values are the same.

Configure the Hyper-V AIM Polling Interval

You can change the Hyper-V AIM polling rate. Configure the polling interval by setting the Polling_Interval attribute on the Hyper-V technology application model.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'
   A search dialog opens.
3. Enter the IP address for your Hyper-V Manager device in the Device IP Address field, and click OK.
   A list of application models for the Hyper-V Manager appears in the Contents panel.
4. Select the HyperVAimApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Open the Modeling Information subview.
7. Click set in the Polling Interval (sec) field, enter a new value.

   NOTE
   Changing the Polling Interval value from any number to 0 also sets the Polling field to Off, disabling Hyper-V AIM polling. However, if you set the Polling Interval to 0 and set the Polling field to On, Hyper-V AIM polling continues, using the polling interval for the Hyper-V Manager device.

   The Hyper-V AIM polling interval setting is modified.

Disable Hyper-V AIM Polling

You can disable Hyper-V AIM polling. Disabling Hyper-V polling is the same as disabling Virtual Host Manager. Disable polling by setting the PollingStatus attribute on the Hyper-V virtual technology application model.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'
   A search dialog opens.
3. Enter the IP address for your Hyper-V Manager device in the Device IP Address field and click OK.
   A list of application models for the Hyper-V Manager appears in the Contents panel.
4. Select the HyperVAimApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Open the DX NetOps Spectrum Modeling Information subview.
7. Click set in the Polling field and select Off.
   Polling is disabled for the Hyper-V AIM on the selected Hyper-V Manager.

Deleting Virtual Host Manager Models (Hyper-V)

Models can be deleted from OneClick at any time for various reasons. However, Virtual Host Manager restricts your ability to delete models from the Virtual Host Manager hierarchy in the Navigation panel. To delete models manually, you have the following two options:

- Delete the Hyper-V folder or a Hyper-V Manager model in Virtual Host Manager
- Remove a virtual entity using your Microsoft Hyper-V virtualization technology

In Virtual Host Manager, models are sometimes deleted automatically. The following circumstances cause DX NetOps Spectrum to delete Virtual Host Manager models automatically:

- **Hyper-V folder deleted or Hyper-V Manager model removed from Virtual Host Manager**
  If you remove a Hyper-V Manager model or delete the Hyper-V folder from the Navigation panel, DX NetOps Spectrum deletes all related child models.
- **An entity removed from Hyper-V virtual environment**

As you delete Hyper-V Hosts and the Hyper-V Manager using your Microsoft Hyper-V virtualization technology, DX NetOps Spectrum may also delete those models and their child models from Virtual Host Manager, according to your configuration settings.

- **Upgraded models exist** -- In some cases, a Hyper-V Host is first modeled for Virtual Host Manager without SNMP capabilities. If SNMP capabilities are later added to a VHM model, the previous model is deleted and replaced with the new SNMP-capable model.

  NOTE
  Although the default setting is to delete the models, you can configure Virtual Host Manager to place the Hyper-V Host and Hyper-V virtual machine models in the LostFound container when they are removed from Virtual Host Manager. This setting is respected only when you remove an entity using your Microsoft Hyper-V virtual environment. However, this setting does not apply when you delete the Hyper-V folder, remove a Hyper-V Manager model, or upgrade a VHM model.

Alarms and Fault Isolation for Hyper-V

This section describes the traps used by Virtual Host Manager and the resulting alarms. This section also explains how Virtual Host Manager fault isolation differs from basic DX NetOps Spectrum fault isolation.

Virtual Host Manager Alarms for Hyper-V

To alert you to problems within your virtual network, DX NetOps Spectrum generates alarms during polling. Polling generates four alarms: Hyper-V Proxy Lost, Hyper-V Host Proxy Lost, Hyper-V Manager Unavailable, and Hyper-V Virtual Machine Not Running.

Forwarding Traps from CA SystemEDGE (Hyper-V)

DX NetOps Spectrum supports all traps that the Hyper-V AIM sends. These traps are initially sent to Hyper-V CA eHealth SystemEDGE model. If the destination for a trap is not the Hyper-V model, DX NetOps Spectrum forwards the trap to the correct virtual model.

NOTE
For specific event codes related to the traps, use the Event Configuration application and filter on “0x056e.” Alternately, you can launch MIB tools to view the traps in the Trap Support table for the “CAHYPERV-AIM-MIB” MIB.

DX NetOps Spectrum determines where to forward the trap by using the following process:

1. When DX NetOps Spectrum receives a trap, it uses varbind information in the trap to identify the UID for the target device.
2. DX NetOps Spectrum uses this UID to look up and locate the DX NetOps Spectrum model that is tied to a given UID. The entity type of all traps is predetermined. Depending on the results of the look-up, DX NetOps Spectrum forwards the trap as follows:
   – If it finds a DX NetOps Spectrum model of a specific type with a given UID, DX NetOps Spectrum forwards the event and corresponding alarm to the destination model.
   – If it cannot find a DX NetOps Spectrum model for a given UID, DX NetOps Spectrum generates a new generic event on the Hyper-V Manager model. This new event includes details about the trap.

     NOTE
     DX NetOps Spectrum often cannot find a related model when a trap is sent immediately after changing your virtual network entities in the Hyper-V virtualization technology. Hyper-V Discovery has not yet identified and created the corresponding model in DX NetOps Spectrum.

Traps Supported in Virtual Host Manager (Hyper-V)

All traps that are generated by the Hyper-V AIM are supported in DX NetOps Spectrum. The traps are initially sent to the Hyper-V Manager model. Then, the traps are forwarded to a corresponding virtual entity type (that is, the "destination" entity), depending on the type of trap. Using these traps, you can monitor the performance of your virtual network, resolve any resulting alarms, or trigger events.

NOTE
For more information about traps that are generated by the Hyper-V AIM, see *CA Virtual Assurance for Infrastructure Managers Administration*.

The following tables list the traps for a specific destination entity type and specify whether the trap generates an alarm.

Trap Name	Trap OID	Alarm?
hypervAimStatVMAddTrap	1.3.6.1.4.1.546.1.1.6.16501	No
hypervAimStatVMRemoveTrap	1.3.6.1.4.1.546.1.1.6.16502	No
hypervAimStatVMMigrateTrap	1.3.6.1.4.1.546.1.1.6.16505	No

Trap Name	Trap OID	Alarm?
hypervAimStatVMEnabledTrap	1.3.6.1.4.1.546.1.1.6.16504	No

Fault Management for Virtual Networks (Hyper-V)

The goal of fault isolation is to narrow down the root cause of a networking problem. Finding the root cause can help you to troubleshoot and quickly correct the problem or to correct the problem programmatically with automated scripts. Deciding which devices are the root cause of an alarm can be difficult, because problems with a single device can cause several devices in your network to generate events.

For example, losing contact with a Hyper-V Host often means that you have also lost contact with the Hyper-V virtual machines it manages. Therefore, the Hyper-V Host device model and all affected virtual machines generate alarms. Using fault isolation techniques, Virtual Host Manager correlates these alarms in an attempt to identify a single root cause.

Virtual networks provide a unique management opportunity, because they provide DX NetOps Spectrum an alternate management perspective. That is, DX NetOps Spectrum can gather information through direct contact with your virtual devices or through the virtual network management technology, Microsoft Hyper-V. This alternate management perspective enhances standard DX NetOps Spectrum fault management in two ways:

- **Enhanced Contact Lost alarms** -- Two sources of information about a device means Virtual Host Manager can pinpoint the cause and more easily correlate events to a single root cause.
- **Proxy Failure alarms** -- *Proxy management* is the act of managing network devices using an alternate management source in place of or in addition to the primary manager. For example, DX NetOps Spectrum can manage virtual network devices by contacting them directly or through the virtual technology application's contact with the devices. When Hyper-V virtualization technology loses contact with a virtual network device, Virtual Host Manager generates one of the Proxy Management Lost alarms for each device. These alarms are unique, because they are alerting you to the fact that *management* of the device through the *proxy* is affected, not the state of the device or direct (SNMP) management.

How Fault Isolation Works when Device Contact is Lost

To help you troubleshoot networking problems with your devices, DX NetOps Spectrum uses fault isolation to narrow down the root cause of an alarm. For virtual networks, Virtual Host Manager uses information from direct contact with the device plus information provided by Hyper-V virtualization technology through the Hyper-V AIM. In many cases, standard DX NetOps Spectrum fault management can pinpoint the root cause. But in special circumstances, the method for isolating problems in a virtual network go beyond the standard methods.

The type of fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe two unique fault management situations and how DX NetOps Spectrum isolates the networking error in your virtual network.

Scenario 1: Hyper-V virtual machine is not running

In a virtual environment, the virtual management application can provide more details than DX NetOps Spectrum can discover through standard device monitoring. For example, the Hyper-V virtualization technology is aware when a Hyper-V virtual machine changes from the "running" state to something else, such as the "not running" state.

If a Hyper-V virtual machine is no longer running and DX NetOps Spectrum loses contact with it, but proxy management of the Hyper-V Manager is uninterrupted, DX NetOps Spectrum determines the root cause as follows:

1. When DX NetOps Spectrum loses contact with a Hyper-V virtual machine, it generates a Contact Lost alarm.
2. During its next polling cycle, the Hyper-V Manager model polls the Hyper-V AIM to gather information about the virtual machine. Because Hyper-V technology manages the virtual machine, it can provide a unique view into the possible cause of alarms generated by a Hyper-V virtual machine.
3. If the Hyper-V virtualization technology finds that the virtual machine is in the not-running mode, it generates a Virtual Machine Not Running alarm.

   NOTE
   This alarm is cleared upon the first Hyper-V AIM polling cycle after the virtual machine is running again.
4. Virtual Host Manager correlates the Contact Lost alarm to the corresponding Virtual Machine Not Running alarm created by DX NetOps Spectrum. Virtual Host Manager makes the Contact Lost alarm appear as a symptom of the Virtual Machine Not Running alarm.

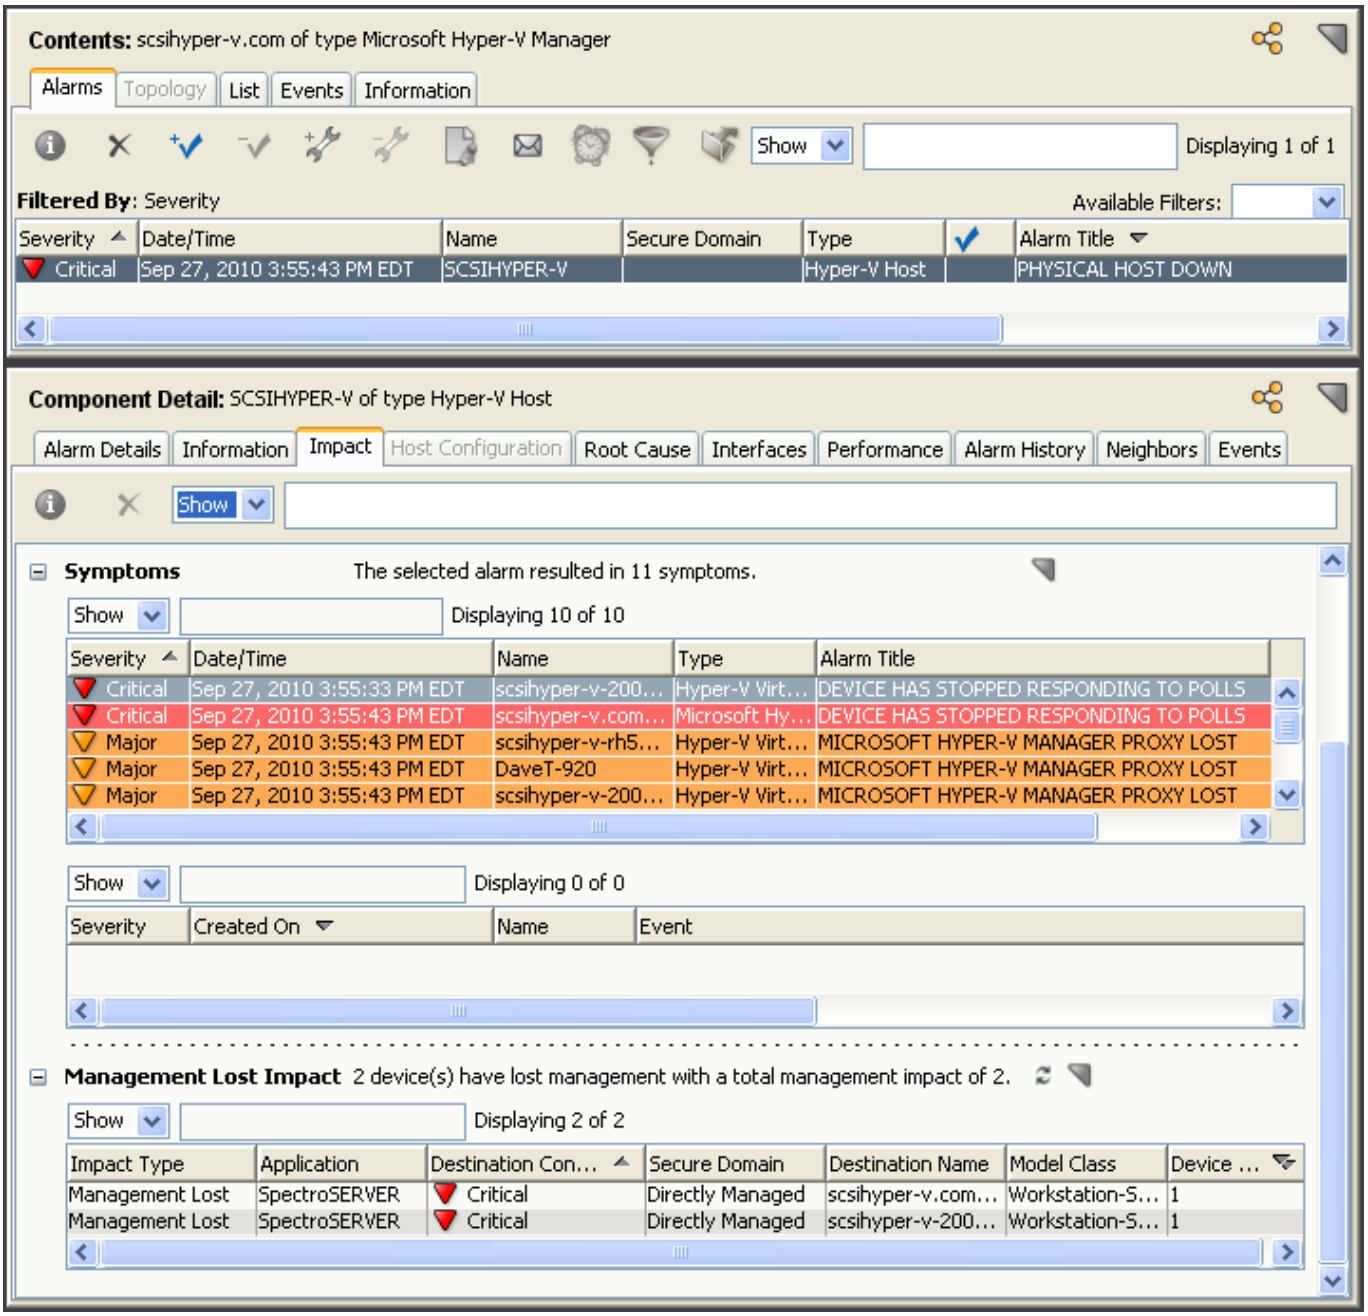
Scenario 2: Hyper-V Host is down

If DX NetOps Spectrum loses contact with a modeled Hyper-V Manager and all Hyper-V virtual machines running on that host, DX NetOps Spectrum checks the status of the upstream routers and switches. Depending on their status, DX NetOps Spectrum determines the root cause as follows:

- All upstream devices for one or more virtual machines or the Hyper-V Manager are unavailable -- Standard DX NetOps Spectrum fault isolation techniques determine the root cause, as follows:
  - Device Stopped Responding to Polls alarm -- Generated on the Hyper-V Host when at least one upstream connected device for any virtual machine or Hyper-V Manager is up.
  - Gateway Unreachable alarm -- Generated on the Hyper-V Host when *all* upstream connected devices are down.
- At least one upstream device is available for every virtual machine and Hyper-V Manager model connected to the Hyper-V Host -- DX NetOps Spectrum infers that the Hyper-V Host is the root cause and responds as follows:
  a. The Hyper-V Manager model and all Hyper-V virtual machines, ports, and fanouts that are directly connected to the Hyper-V Manager model or virtual machine models generate the standard fault isolation alarms.
  b. Virtual Host Manager creates a Physical Host Down alarm for the Hyper-V Host model.
  c. All fault isolation-related alarms that are created for the impacted devices (such as virtual machines, ports, and fanouts) are correlated to the Physical Host Down alarm, making them symptoms of the Physical Host Down alarm. These symptom alarms appear in the Symptoms table on the Impact tab for the Physical Host Down alarm.

     NOTE
     For each Hyper-V Host model, Virtual Host Manager creates a "virtual fault domain." This domain includes the Hyper-V Host, Hyper-V Manager, and virtual machines, plus all ports and fanouts directly connected to the Hyper-V Manager model or virtual machines. When the Hyper-V Host generates the Physical Host Down alarm, all standard fault isolation alarms within the domain are correlated to it. Correlating these alarms as symptoms indicates that the Physical Host Down alarm on the Hyper-V Host is the root cause.
  d. All impacted devices are listed in the Management Lost Impact table on the Impact tab for the Physical Host Down alarm.

NOTE
Devices that are suppressed do not have a corresponding alarm in the Symptoms table.



If all upstream devices for one or more virtual machines or the Hyper-V Manager go down, DX NetOps Spectrum can no longer reliably state that the fault lies with the Hyper-V Host. Therefore, DX NetOps Spectrum clears the Physical Host Down alarm and applies the standard DX NetOps Spectrum fault isolation techniques.

How Fault Isolation Works when Proxy Management is Lost (Hyper-V)

The Microsoft Hyper-V virtualization technology used to create your virtual network provides DX NetOps Spectrum a unique management opportunity. DX NetOps Spectrum can use the standard methods to contact your virtual devices directly, plus DX NetOps Spectrum can simultaneously gather virtual device information from Hyper-V technology. In this sense, the Hyper-V technology is a "proxy" from which DX NetOps Spectrum gathers virtual device information. If DX NetOps Spectrum loses direct contact with a device, it generates alarms. Likewise, if Hyper-V technology loses contact with a virtual device or if Virtual Host Manager loses contact with the Hyper-V Manager, Virtual Host Manager generates alarms -- Proxy Management Lost alarms.

In response, DX NetOps Spectrum attempts to isolate the cause of the proxy management failure. Proxy fault isolation is similar to the standard DX NetOps Spectrum fault isolation, except that these alarms alert you to the fact that *proxy* management of a virtual device is affected. Proxy management fault isolation cannot tell you whether a virtual device is up or down. However, it is important to know when contact through the proxy is lost, because you could be missing important virtual information about a device.

The type of proxy fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenario describes a unique proxy fault management situation and how Virtual Host Manager isolates the networking error in your virtual network.

Scenario: Contact between DX NetOps Spectrum and Hyper-V Manager is lost

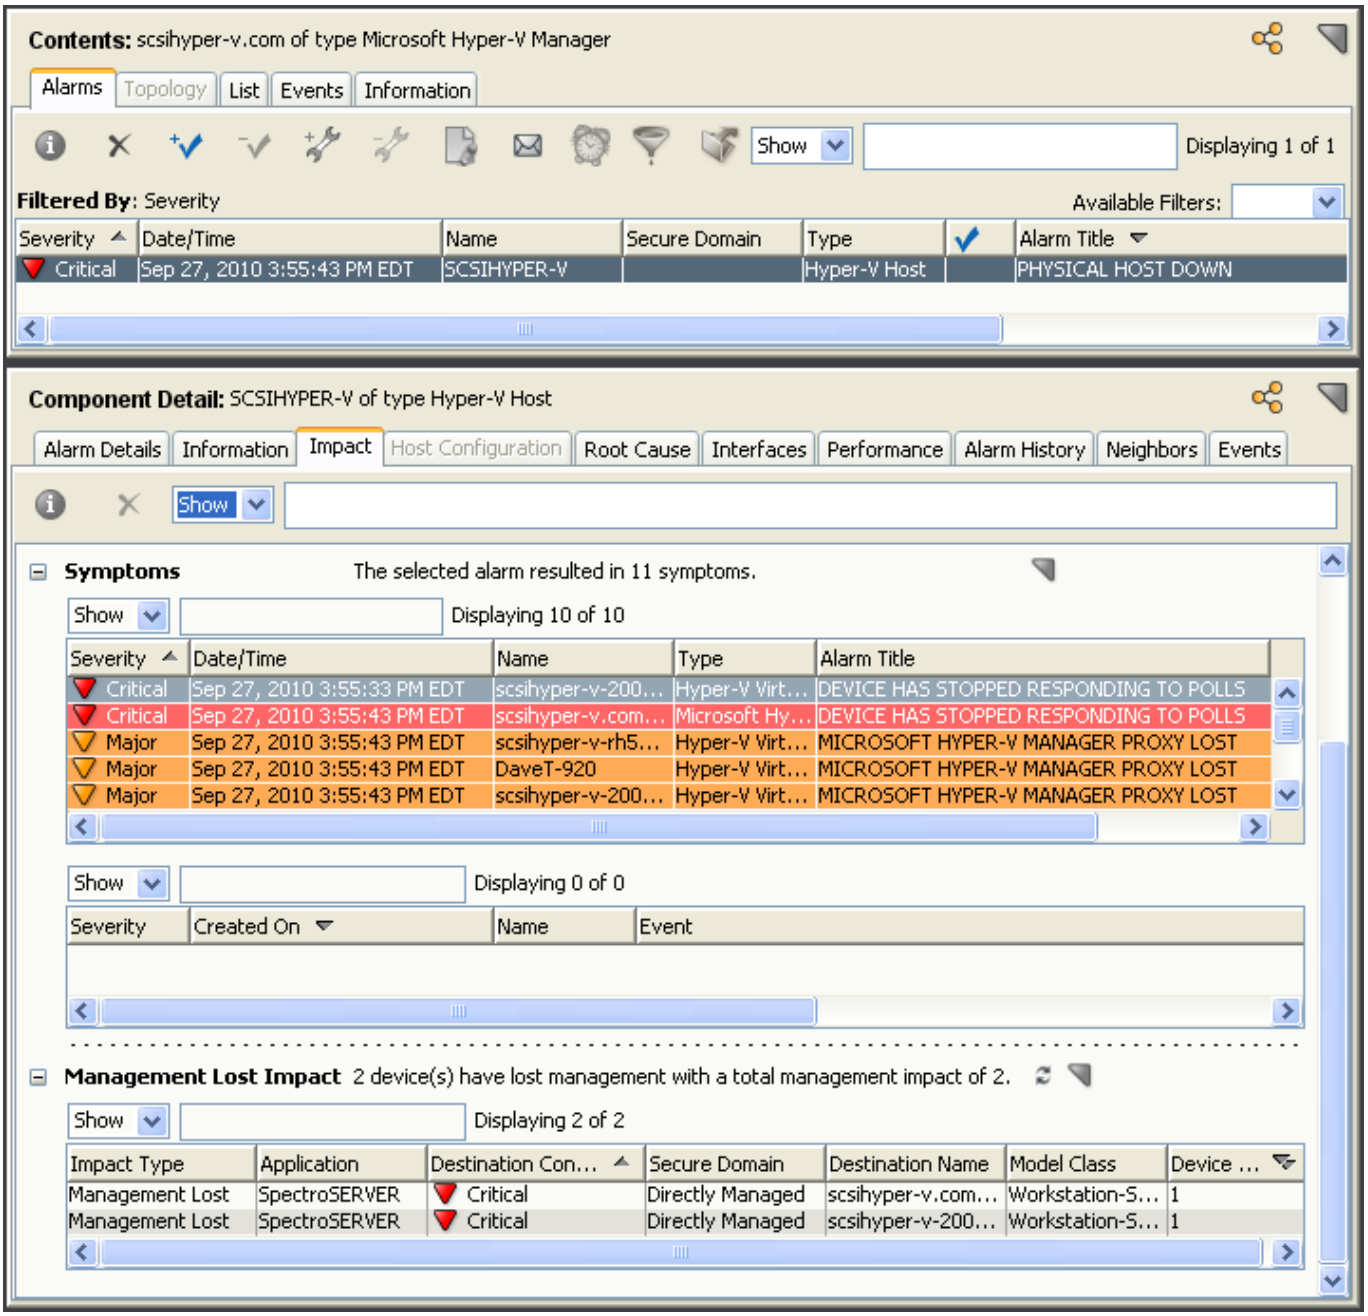
If DX NetOps Spectrum loses contact with or stops polling the Hyper-V Manager model, DX NetOps Spectrum loses the Hyper-V virtualization technology data about all virtual models managed by that Hyper-V Manager. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. DX NetOps Spectrum generates Proxy Lost alarms for all virtual models managed by that Hyper-V Manager, including virtual machines and Hyper-V Hosts. DX NetOps Spectrum also generates a separate Proxy Unavailable alarm on the Hyper-V Manager model.
2. The virtual machine alarms are correlated to their corresponding Hyper-V Host model alarm.
3. The Hyper-V Host model alarms are correlated to a Proxy Unavailable alarm for the Hyper-V Manager model.
4. This Proxy Unavailable alarm is then correlated to the root cause of the Hyper-V Manager being down. The root cause is typically an alarm generated by standard DX NetOps Spectrum fault management, such as the alarms created for the following situations:
   – Lost management of Hyper-V Manager (that is, a problem occurred with the CA eHealth SystemEDGE agent on the Hyper-V Manager host)
   – Machine contact is lost
   – Hyper-V Manager model is in maintenance mode

Determining Hyper-V Virtual Machines Affected by Hyper-V Host Outages

When contact with a Hyper-V Host is interrupted or the Hyper-V Host goes down, all Hyper-V virtual machines hosted by the Hyper-V Host are affected. Because Hyper-V technology cannot communicate with the Hyper-V Host to get usage information, you might not receive alarms for a critical virtual machine on that Hyper-V Host. To find out if a critical virtual machine is impacted, you can view a list of affected virtual machines on the Impact tab of the alarm, as follows:

- Symptoms subview -- displays all symptom alarms generated by the affected Hyper-V virtual machines
- Management Lost Impact subview -- lists the Hyper-V virtual machines impacted by the alarm



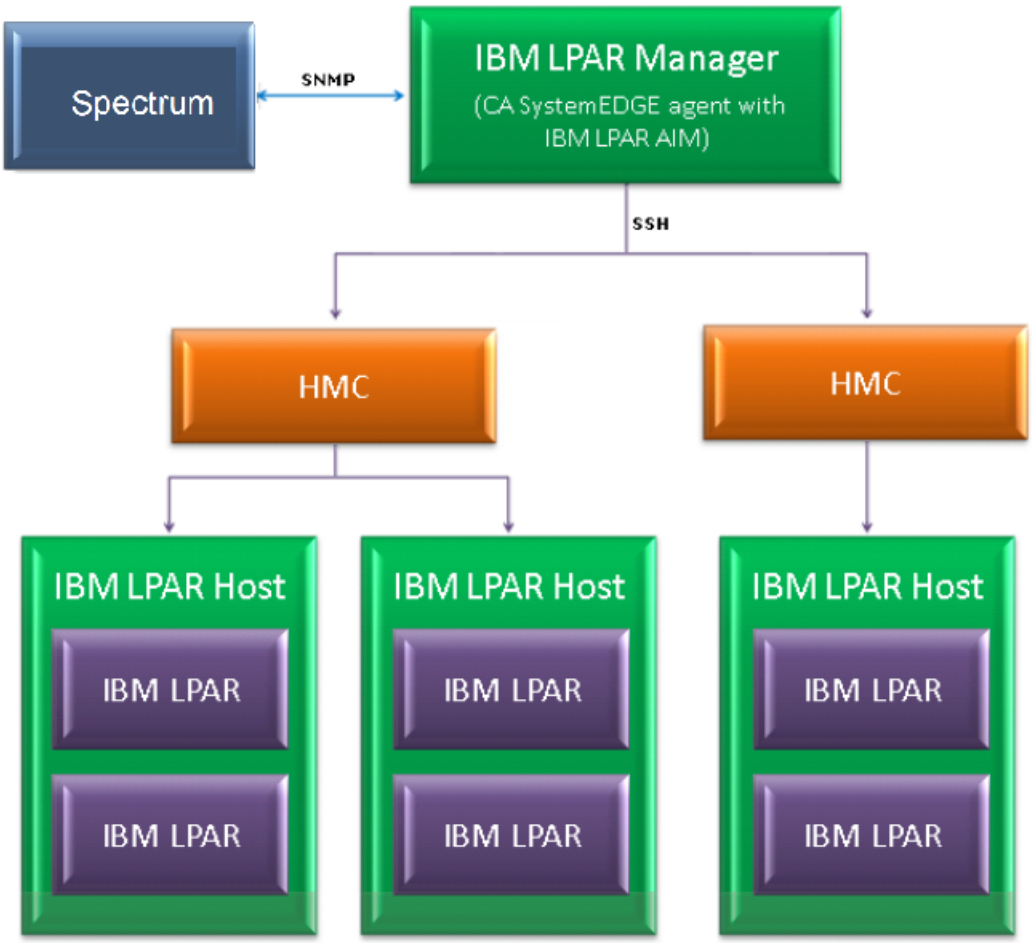
IBM LPAR

This section is for IBM LPAR virtualization technology users and describes how to use Virtual Host Manager to manage your virtual entities created with IBM LPAR technology.

How Virtual Host Manager Works with IBM LPARs

Virtual Host Manager monitors your virtual network entities seamlessly with your physical network entities. You get a full view of your network where you can troubleshoot networking issues for both types of entity. Although your virtual network entities behave like physical components, the process for monitoring those entities differs from the general DX NetOps Spectrum monitoring process. Understanding how this process works can help you locate and resolve networking issues related to your virtual network.

The *IBM LPAR Manager* in Virtual Host Manager is the CA eHealth SystemEDGE agent with the IBM LPAR AIM enabled. The IBM LPAR Managers are responsible for reporting on all of the configured IBM LPARs. Virtual Host Manager communicates with the IBM LPAR Managers to gather details about your IBM LPAR virtual environment. The following diagram shows how DX NetOps Spectrum gathers information about your IBM LPAR virtual environment using the IBM LPAR Manager:



As shown in the diagram, the process to gather information about your IBM LPAR virtual environment is as follows:

1. The HMC communicates with each IBM LPAR Host that it manages.
2. The IBM LPAR Manager uses SSH to communicate with each of its managed HMCs to gather details about your virtual environment.

NOTE
Monitor only one instance of the IBM LPAR Host with the IBM LPAR AIM. Do not manage a single IBM LPAR Host with multiple HMCs. Monitoring more than one instance can result in duplicate models in DX NetOps Spectrum.

3. Periodically, DX NetOps Spectrum communicates with the IBM LPAR Manager to retrieve these details. The IBM LPAR Manager has the CA eHealth SystemEDGE agent installed with the IBM LPAR AIM enabled. DX NetOps Spectrum uses SNMP to communicate with the CA eHealth SystemEDGE agent and uses the information to model and monitor your virtual environment in DX NetOps Spectrum.

Models Created for IBM LPARs

Virtual Host Manager provides several models to represent the components of your IBM LPAR virtual technology network. Understanding the following basic models can help you better understand Discovery and how the virtual environment interfaces with your physical environment.

Virtual Host Manager includes the following models and icons for IBM LPAR devices:

- **IBM LPAR Manager**
  Represents a server that contains the CA eHealth SystemEDGE agent with the IBM LPAR AIM loaded.
  Icon:
  
- **IBM LPAR Host**
  Represents an IBM LPAR Host, as configured in the HMC. An *IBM LPAR Host* is a physical computer that uses IBM LPAR virtualization software to host IBM LPAR instances. IBM LPAR Hosts provide the CPU and memory resources that IBM LPARs use. They also give these IBM LPARs access to storage and network connectivity. These models serve as container models within the Universe topology, helping to group your virtual entities into a separate view while showing where the virtual environment interfaces with your physical network. The IBM LPAR Host cannot be contacted directly for status information. Instead, the status of these models is inferred from the status of its contained items.
  Icon:
  
- **IBM LPAR**
  Represents an IBM LPAR, as configured in the HMC. An *IBM LPAR* is a logical partition instance configured on the IBM LPAR Host that, like a physical computer, runs an operating system and applications. An IBM LPAR dynamically consumes resources on its physical host, depending on its workload and configuration.
  Icon:
  

Discovering IBM LPAR Networks

This section describes the Discovery and modeling process for Virtual Host Manager. These tasks are typically performed by the Virtual Host Manager administrator.

How to Configure Discovery Options

After Virtual Host Manager is installed, you can configure Virtual Host Manager for IBM LPAR Discovery. Configuring your preferences helps ensure that Virtual Host Manager models your virtual devices correctly.

To configure your installation of Virtual Host Manager for IBM LPAR Discovery, select your preferences from the following options:

- Maintenance Mode for New IBM LPARs -- Lets you decide which newly discovered IBM LPAR instances to place into maintenance mode until you are ready for DX NetOps Spectrum to manage them.
- Allow Device Model Deletes During IBM LPAR Discovery -- Controls how DX NetOps Spectrum handles IBM LPAR virtualization technology models when Virtual Host Manager no longer manages them.
- Search for Existing Models -- Determines which secure domains Virtual Host Manager searches during an IBM LPAR Discovery.
- Discover SNMP-Capable Devices -- Controls how SNMP-capable devices are modeled during IBM LPAR Discovery. By default, new models are initially created as VHM models only. But, this option lets you override the default and immediately create SNMP models for devices that meet the necessary criteria.
- Retain SNMP-enabled LPARs During IBM LPAR Manager Deletion -- Controls how DX NetOps Spectrum handles SNMP-enabled LPAR models when an IBM LPAR Manager model is deleted.

Configure Maintenance Mode for New IBM LPARs

Virtual Host Manager automatically models the IBM LPAR instances in your IBM LPAR virtual environment. DX NetOps Spectrum attempts to manage all models that are discovered. However, some new IBM LPARs are not ready for DX NetOps Spectrum management when they are initially modeled. For example, a non-running IBM LPAR causes DX NetOps Spectrum to generate a Contact Lost alarm. To prevent undesired alarms on new IBM LPAR models, you can decide which new models are immediately placed into maintenance mode. Later, you can manually disable maintenance mode when you are ready for DX NetOps Spectrum to manage these devices.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   A details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, IBM LPAR, IBM LPAR Discovery subview.
4. Click Set in the 'Maintenance Mode for New IBM LPARs' field and select one of the following options:
   - **Place non-enabled LPARs in Maintenance Mode**
     (Default) Applies maintenance mode to only non-enabled IBM LPAR models upon initial IBM LPAR Discovery.
   - **Place all LPARs in Maintenance Mode**
     Applies maintenance mode to all new IBM LPAR models upon initial IBM LPAR Discovery.

   Your setting is saved and new IBM LPAR instances created by Virtual Host Manager are placed into maintenance mode per your selection.

Manage Device Models for Devices Deleted from IBM LPAR Manager

The devices and the relationships among them change frequently in virtual environments. Maintaining accurate and timely data about your virtual environment in DX NetOps Spectrum is challenging. For example, when an IBM LPAR Host or IBM LPAR instance is removed, DX NetOps Spectrum knows to remove the corresponding device models from Virtual

Host Manager in the Navigation panel. However, should DX NetOps Spectrum keep or delete the model? You can select settings to control model deletion.

> **WARNING**
> When models are deleted, all notes or other customizations on those models are lost. You can disable this option if your models are likely to be recreated in your IBM LPAR environment later.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, IBM LPAR, IBM LPAR Discovery subview.
4. Click Set in the 'Allow Device Model Deletes During IBM LPAR Discovery' field and select one of the following options:
   - **Yes**
     (Default) Deletes the Virtual Host Manager models that correspond to entities no longer managed by your IBM LPAR environment.
   - **No**
     Places Virtual Host Manager models in the LostFound container if their corresponding entity is no longer managed by your IBM LPAR environment.

     > **NOTE**
     > Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

Your setting is saved, and device models are handled accordingly after the device is deleted from your IBM LPAR environment.

Configure Model Searches Across Secure Domains (IBM LPAR)

Rather than creating new models, IBM LPAR Discovery attempts to locate models in the SpectroSERVER. In an environment with Secure Domain Manager deployed, IBM LPAR Discovery searches for models within the same secure domain as your IBM LPAR Manager. This domain is the "local" domain. However, some of your virtual environment devices can exist within a different secure domain. In this case, you can configure IBM LPAR Discovery to search all secure domains for existing models.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, IBM LPAR, IBM LPAR Discovery subview.
4. Click Set in the 'Search for Existing Models' field and select from the following options:
   - **In IBM LPAR Manager's Secure Domain**
     (Default) Searches for existing models within the same secure domain as the IBM LPAR Manager server.
   - **In All Secure Domains**
     Searches for existing models within all secure domains managed by the SpectroSERVER. Select this option only in the following situations:
     - All devices have unique IP addresses
     - When secure domains are used for security purposes or to isolate network traffic

       > **NOTE**
       > Do not select this option for a NAT environment.

Your setting is saved and IBM LPAR Discovery searches for existing models in DX NetOps Spectrum according to your selection. If duplicate models (that is, models that share the same IP address) exist in multiple secure domains, Virtual Host Manager does the following:

- Selects the model in the local secure domain, if available.
- If a duplicate model does not exist in the local domain, Virtual Host Manager randomly selects a model from another secure domain.
- In both cases, Virtual Host Manager generates a minor alarm for the duplicate IP addresses on the IBM LPAR Manager model.

Configure SNMP Modeling Preferences (IBM LPAR)

SNMP-capable devices support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. By default, IBM LPAR Discovery creates IBM LPAR instances as VHM models. You can later upgrade them to SNMP models. However, you can also configure IBM LPAR Discovery to model all new SNMP-capable devices as SNMP models. Although IBM LPAR Discovery can take longer to complete, initially modeling these as SNMP models avoids manually upgrading these models later.

WARNING
Enable SNMP modeling *before* you model your IBM LPAR Hosts. If you model the IBM LPAR Hosts first, all child models are created as VHM models, which must be manually upgraded to SNMP models.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Click the Information tab.
3. Expand the Configuration, IBM LPAR, IBM LPAR Discovery, SNMP Discovery subview.

   WARNING
   Follow the steps in the subview to prepare your devices and DX NetOps Spectrum for SNMP Discovery. If devices are not properly prepared prior to IBM LPAR Discovery, Virtual Host Manager cannot create SNMP models.
4. Click Set in the 'Discover SNMP-Capable Devices' field and select from the following options:
   - **Yes**
     Enables SNMP modeling during IBM LPAR Discovery. Only devices that meet the criteria specified in the SNMP Discovery subview text are modeled as SNMP devices. Applies to *new* models only.
   - **No**
     (Default) Models all new devices found during IBM LPAR Discovery as VHM models. You can manually upgrade these models to SNMP models later.

   Your setting is saved and new devices are modeled in Virtual Host Manager according to your selection.

Manage SNMP-Enabled LPAR Models After IBM LPAR Manager Deletion

By default, SNMP-enabled devices are deleted from DX NetOps Spectrum when the following items are deleted:

- IBM LPAR Manager model for the device
- IBM LPAR folder in the Navigation panel

SNMP-enabled device models can include significant customizations that you want to retain. You can adjust your settings to avoid deleting these models. They are placed into the LostFound container for later use.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.

2. Click the Information tab.
3. Expand the Configuration, IBM LPAR, IBM LPAR Discovery subview.
4. Click Set in the ‘Retain SNMP-enabled LPARs During IBM LPAR Manager Deletion' field and select one of the following options:
   – **Yes**
   Retains SNMP-enabled LPAR models in the LostFound container when their IBM LPAR Manager or the IBM LPAR folder is deleted.

   NOTE
   Models with more associations, such as a model that is included in a Global Collection, are handled differently. These models are removed from the Universe, but they are not moved to the LostFound container.

No

(Default) Deletes all LPAR models when their IBM LPAR Manager or the IBM LPAR folder is deleted.

Your setting is saved, and SNMP-enabled device models are handled accordingly when IBM LPAR Manager models or the IBM LPAR folder is deleted.

How to Discover and Model Your Virtual Environment (IBM LPAR)

To monitor your virtual environment, you must discover and model your virtual entities -- IBM LPAR Hosts and IBM LPAR instances. Modeling these entities in Virtual Host Manager lets you view your complete network topology in one tool, showing the relationships between your physical and virtual components.

The main steps for modeling your virtual environment are as follows:

1. Run a standard Discovery.
   The purpose of this Discovery is to help ensure the upstream routers and switches are modeled before IBM LPAR Discovery runs. Optionally, if the SNMP Modeling option is disabled, this step can also model the SNMP-capable IBM LPAR Managers. When modeling these entities, be sure that your modeling options are set correctly to support Virtual Host Manager.
2. Upgrade the CA eHealth SystemEDGE model.
   This step is required only when your CA eHealth SystemEDGE agent on the IBM LPAR Manager host was modeled in a release before 9.2.1.
3. Let IBM LPAR Discovery run.
   When you model the CA eHealth SystemEDGE agent with IBM LPAR AIM on the IBM LPAR Manager host, IBM LPAR Discovery begins automatically. Each of these IBM LPAR Manager models has its own IBM LPAR Discovery process. The purpose of IBM LPAR Discovery is to find the virtual entities in your IBM LPAR environment, model the ones that do not exist, and place them in the Virtual Host Manager view of the Navigation panel.

Run Discovery (IBM LPAR)

To discover your IBM LPAR environment, run the standard DX NetOps Spectrum Discovery. This Discovery ensures that the upstream routers and switches are modeled so that later connections from the virtual entities can be established. You can also model the SNMP-capable IBM LPAR Hosts and IBM LPAR instances during DX NetOps Spectrum Discovery.

NOTE
Modeling SNMP-capable IBM LPAR Hosts and IBM LPAR instances is necessary during DX NetOps Spectrum Discovery only when the SNMP Modeling option is disabled during IBM LPAR Discovery.

NOTE
Only an administrator performs this task.

Follow these steps:

1. Open the Discovery console.

   NOTE
   Before modeling, be sure that you know the correct community strings, IP addresses, and port numbers for any SNMP agents that run on a nonstandard port.
2. In the Navigation panel, click the Creates a new configuration icon  .
3. Configure your options to support virtual network modeling, as follows:
   a. Click the Modeling Options button in the Modeling Options group.
      The Modeling Configuration dialog opens.
   b. Click the Protocol Options button.
      The Protocol Options dialog opens.
   c. Select the ARP Tables for Pingables option, and click OK.
      The Modeling Configuration dialog opens.
   d. (Optional) Click the Advanced Options button in the Advanced Options group, add your nonstandard SNMP ports (such as, the CA eHealth SystemEDGE agent port), and click OK.
4. Enter individual IP addresses or the beginning and ending IP addresses in the IP Boundary List fields and click Add.

   NOTE
   Be sure that the range of IP addresses includes all servers with CA eHealth SystemEDGE and the IBM LPAR AIM installed and the interconnecting switches and routers. Or you can include the SNMP-capable IBM LPAR Hosts and IBM LPAR instances that require SNMP models.
5. Enter any additional values in the Discovery console, and click the Discover button.
   The following models are created and are added to your network topology in DX NetOps Spectrum:
   – IBM LPAR Managers and the switches and routers that connect them to your network -- Information about your virtual environment comes from the IBM LPAR Manager. When these IBM LPAR Manager models exist in DX NetOps Spectrum, IBM LPAR Discovery can begin.
   – IBM LPAR instances -- If you decide not to model these entities with DX NetOps Spectrum Discovery, IBM LPAR Discovery creates them as VHM models.

   NOTE
   You can also manually model your virtual network by IP address. In this case, we recommend modeling the upstream devices first. Modeling in the correct order ensures that the relationships among these entities are built correctly in the topology. For more information about how to perform a Discovery, see Modeling and Managing Your IT Infrastructure section.

Upgrade the CA SystemEDGE Model (IBM LPAR)

The CA eHealth SystemEDGE agent could have been modeled in DX NetOps Spectrum before installing Virtual Host Manager or before the IBM LPAR AIM was loaded on the agent. In this case, the existing CA eHealth SystemEDGE model is not compatible with Virtual Host Manager. Upgrade the model so Virtual Host Manager can access the IBM LPAR AIM capabilities in CA eHealth SystemEDGE. *This procedure is not required if the CA eHealth SystemEDGE agent with IBM LPAR AIM is loaded and is modeled after installing DX NetOps Spectrum.*

To upgrade the CA eHealth SystemEDGE model, right-click the model and select Reconfiguration, Reconfigure Model.

The CA eHealth SystemEDGE model is upgraded to support the IBM LPAR AIM.

NOTE
You can also send a reconfigure model action to CA eHealth SystemEDGE using the CLI. For more information, see Modeling and Managing Your IT Infrastructure Administrator *section*.

.

How IBM LPAR Discovery Works

IBM LPAR Discovery is a specialized discovery process that gathers detailed information about your virtual environment. The purpose of IBM LPAR Discovery is to obtain the virtual entities managed by the HMC, model the ones that do not exist in DX NetOps Spectrum, and place them under Virtual Host Manager in the Navigation panel.

A key benefit of IBM LPAR Discovery is that it runs automatically in the background, keeping your virtual environment data updated in DX NetOps Spectrum. Understanding how IBM LPAR Discovery works reinforces the importance of properly installing and modeling the various components of Virtual Host Manager.

The IBM LPAR Discovery process works as follows:

1. Immediately after the IBM LPAR Manager is configured (the CA eHealth SystemEDGE agent is installed with the IBM LPAR AIM enabled), the IBM LPAR Manager uses SSH to contact each HMC that it monitors. The IBM LPAR Manager gathers and stores information from the HMC about your virtual environment.

   NOTE
   Monitor only one instance of the IBM LPAR Host with the IBM LPAR AIM. Do not manage a single IBM LPAR Host with multiple HMCs. Monitoring more than one instance can result in duplicate models in DX NetOps Spectrum.

   WARNING
   The CA eHealth SystemEDGE agent and IBM LPAR AIM must be installed so that CA eHealth SystemEDGE, the HMCs, and DX NetOps Spectrum can communicate. If they cannot, IBM LPAR Discovery cannot run.

- During DX NetOps Spectrum Discovery, DX NetOps Spectrum creates a model for each IBM LPAR Manager in Step 1 and enables DX NetOps Spectrum to handle communication between DX NetOps Spectrum and the CA eHealth SystemEDGE agent.
- DX NetOps Spectrum polls the IBM LPAR AIM to gather the IBM LPAR Manager information that is stored in Step 1.
- DX NetOps Spectrum begins IBM LPAR Discovery and uses this information from the AIM to update modeling in the DX NetOps Spectrum Topology tab and the Virtual Host Manager hierarchy in the Navigation panel, as follows:
  a. If you enable SNMP Discovery before Step 2, Virtual Host Manager Discovery creates SNMP models for all new SNMP-capable models that meet the SNMP Discovery criteria.

     NOTE
     By default, SNMP Discovery is disabled during IBM LPAR Discovery.

  b. VHM models are created for the remaining non-SNMP IBM LPAR Hosts and IBM LPAR instances, as follows:
     - Previously existing IBM LPAR models are changed to VHM models.
     - VHM models are created for the IBM LPAR instances that *do not* previously exist in DX NetOps Spectrum.
     - VHM models are created for the IBM LPAR Host models, and these models group their associated IBM LPAR instance models in the Navigation panel, under Virtual Host Manager and the Universe topology.
  c. All models for your virtual network are added to the Virtual Host Manager portion of the Navigation panel.

     NOTE
     In a virtual environment, devices on separate IBM LPAR Hosts can have the same IP address or MAC address. In this case, DX NetOps Spectrum creates duplicate models for each occurrence of an IP address or MAC address.
- IBM LPAR Discovery automatically repeats this process at each regularly scheduled IBM LPAR technology polling interval.

NOTE
By default, the IBM LPAR polling interval is controlled by setting the polling interval on the IBM LPAR Manager model. Or you can control IBM LPAR polling independently using the IBM LPAR virtualization technology application model.

Adding SNMP Capabalities to VHM Models (IBM LPAR)

SNMP-capable devices support enriched device monitoring, such as process and file system monitoring capabilities. However, SNMP agents can be costly and time-consuming to deploy. When an SNMP agent is not available or SNMP Discovery is disabled, Virtual Host Manager creates IBM LPARs as VHM models.

Later, you can install an SNMP agent on any IBM LPAR Host or IBM LPAR and upgrade its modeling in DX NetOps Spectrum. Options for upgrading to SNMP models are as follows:

- **Upgrade only selected devices** -- This method works quickly when you have a small selection of models to upgrade. The VHM models are deleted first. One drawback of this method is that after DX NetOps Spectrum deletes the models, you must wait for the next IBM LPAR Discovery to create the SNMP models and place them in Virtual Host Manager. Knowledge of the IP addresses for the models to upgrade is required.
- **Upgrade all SNMP-capable VHM models** -- This method upgrades models in batch. It is preferred when upgrading Virtual Host Manager to a new release. Knowledge of the IP addresses of individual models is not required. Another advantage is that after DX NetOps Spectrum deletes the VHM models, the upgraded SNMP models are immediately placed in the Virtual Host Manager hierarchy without waiting for the next polling cycle. Therefore, Virtual Host Manager manages the models more quickly. The drawback to this method is that it can take a long time to complete. The time required to complete this upgrade depends on how many community strings and SNMP ports Virtual Host Manager must search when locating SNMP-capable devices.

  NOTE
  Virtual Host Manager attempts to identify SNMP agents on powered-up pingable devices only.

  WARNING
  When models are deleted, all notes or other customizations on those models are lost.

Upgrade Selected VHM Models to SNMP Models (IBM LPAR)

When an SNMP agent is not available or SNMP Discovery is disabled during IBM LPAR Discovery, Virtual Host Manager creates IBM LPAR instances as VHM models. Later, you can install an SNMP agent on these devices and upgrade their modeling in DX NetOps Spectrum. You must know the IP addresses for the device models to upgrade. Manually selecting models to upgrade works quickly, but all notes or customizations on these models are lost during the upgrade.

Follow these steps:

1. Deploy or enable an SNMP agent on the device, if required.
2. Model the device again using one of the following methods:
   - DX NetOps Spectrum Discovery
   - Model individual devices by IP address

   When the new SNMP-capable model is created, DX NetOps Spectrum removes the previous model from Virtual Host Manager and deletes it. At the next IBM LPAR AIM polling cycle, DX NetOps Spectrum adds the SNMP-capable model to Virtual Host Manager in the Navigation panel.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Upgrade All VHM Models to SNMP Models (IBM LPAR)

When an SNMP agent is not available or SNMP Discovery is disabled during IBM LPAR Discovery, Virtual Host Manager creates IBM LPAR instances as VHM models. Later, you can install an SNMP agent on any IBM LPAR and upgrade its

modeling in DX NetOps Spectrum. When upgrading in batch, DX NetOps Spectrum searches your VHM models and locates models that are now SNMP-capable devices. Then, DX NetOps Spectrum converts these to SNMP models. This method can take a long time to complete, depending on how many community strings and ports Virtual Host Manager must search.

Follow these steps:

1. Deploy or enable an SNMP agent on your devices, as required.
2. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
3. Select the IBM LPAR Manager model in the Navigation panel that manages the models you want to upgrade.
4. Click the Information tab.
5. Expand the IBM LPAR Manager, DX NetOps Spectrum Modeling Control subview.
6. Click the Upgrade ICMP-Only Devices button.

   WARNING
   When models are deleted, all notes or other customizations on those models are lost.

Virtual Host Manager searches for VHM models managed by the IBM LPAR AIM on the selected IBM LPAR Manager device. Virtual Host Manager upgrades the ICMP-only devices that meet the criteria for SNMP devices and places them within the Virtual Host Manager hierarchy.

Move IBM LPAR to a Different Host

Moving an IBM LPAR from one IBM LPAR Host to another can potentially result in lost data, depending on your configuration settings in Virtual Host Manager and the HMC. The IBM LPAR AIM does not support IBM LPAR migration. To Virtual Host Manager, a move is treated as two events -- an IBM LPAR is deleted in the HMC and a new IBM LPAR is created. Based on your Virtual Host Manager configuration, DX NetOps Spectrum can delete the original IBM LPAR model and create a new one. If you customized the original model, deleting it can result in lost data. You can avoid this data loss when you configure your Virtual Host Manager settings correctly before moving the IBM LPAR in the HMC.

Follow these steps:

1. Change the 'Allow Device Model Deletes During IBM LPAR Discovery' option to No.

   NOTE
   With this option disabled, DX NetOps Spectrum does not delete the IBM LPAR model from DX NetOps Spectrum, even though the model is removed from Virtual Host Manager management.
2. Using the HMC, remove the IBM LPAR from the original IBM LPAR Host.
3. Wait for Virtual Host Manager in the Navigation panel to reflect the changes.
   DX NetOps Spectrum places the IBM LPAR model into the LostFound container.

   WARNING
   For Virtual Host Manager to reconcile the new IBM LPAR with the existing model in the LostFound container, the IBM LPAR name, MAC address, *and* IP address must remain the same after migrating the IBM LPAR in the HMC. If any of these values change, Virtual Host Manager cannot use the existing model.
4. Using the HMC, add the IBM LPAR to the other IBM LPAR Host.
   When IBM LPAR Discovery finds the new IBM LPAR, Virtual Host Manager reconciles it with the existing model, removes it from the LostFound container, and places that model into Virtual Host Manager management.
5. (Optional) Change the 'Allow Device Model Deletes During IBM LPAR Discovery' option back to Yes on the originating IBM LPAR Manager model.
   The IBM LPAR is moved from one IBM LPAR Host to another.

Viewing Your IBM LPAR Virtual Environment

This section describes concepts for viewing your IBM LPAR virtual environment and the associated alarms. The basic steps are no different from the standard DX NetOps Spectrum procedures. However, this section describes conceptual differences and details that only apply to the IBM LPAR virtual technology.

Viewing Your IBM LPAR Virtual Network

On the Explorer tab, the Virtual Host Manager node displays a hierarchical tree structure that helps you visualize the logical relationships among your virtual environment resources.

Using this information, you can see how resources are shared among your IBM LPAR Managers, which can help you identify opportunities to reorganize and optimize your virtual environment. This hierarchy also provides a quick way to monitor the performance of your resources and troubleshoot their alarms.

Because Virtual Host Manager is not aware of a DSS environment, it is located within a landscape hierarchy. The following example shows where Virtual Host Manager appears on the Explorer tab in the Navigation panel and illustrates the virtual environment hierarchy:

```
[-] <ss> host
    [+] Universe
    [-] Virtual Host Manager
        [-] IBM LPAR
            [+] IBM LPAR Manager 1
            [-] IBM LPAR Manager 2
                [-] IBM LPAR Host 1
                     .  IBM LPAR 1
                     .  IBM LPAR 2
                [+] IBM LPAR Host 2
                [+] IBM LPAR Host 3
```

Virtual Host Manager is the root node for the entire virtual environment managed by this SpectroSERVER. Selecting this node in the Navigation panel displays Virtual Host Manager details in the Contents panel. You can view details such as events and alarms that are related to your virtual environment.

Directly under Virtual Host Manager, virtual environments are organized within folders that represent the associated technology. In the example hierarchy above, the IBM LPAR folder contains the portion of the virtual environment that was created using IBM LPAR virtualization technology. In this folder, Virtual Host Manager lists all IBM LPAR Manager hosts that are managed by this SpectroSERVER.

Each IBM LPAR Manager contains only the portion of the entire virtual environment that it manages. Selecting an IBM LPAR Manager in the Navigation panel displays details in the Contents panel, such as the IBM LPAR Hosts or IBM LPAR instances that are managed by the selected IBM LPAR Manager. You can also view general statistics and view details about other components that are not modeled in DX NetOps Spectrum, such as the following:

- System profiles
- Profiles
- Slots
- Virtual Ethernet devices
- Virtual SCSI devices
- Virtual serial devices
- Physical disks

Under each IBM LPAR Manager, the hierarchy represents the logical relationships between the following entities:

- **IBM LPAR Hosts**

An IBM LPAR Host contains the IBM LPAR instances that it manages. Selecting an IBM LPAR Host in the Navigation panel displays details in the Contents panel, such as events and alarms that are related to the IBM LPAR Host and CPU usage.

- **IBM LPAR instances**
  An IBM LPAR instance is always a leaf node on the Virtual Host Manager hierarchy tree. Selecting an IBM LPAR in the Navigation panel displays details in the Contents panel, including events and alarms, memory usage, and status.

Understanding the IBM LPAR Virtual Topology

The IBM LPAR Manager, IBM LPAR Host, and IBM LPAR instance models created for your virtual environment are integrated into the topology view. IBM LPAR Host models automatically group their associated IBM LPAR instances. The topology shows how these IBM LPARs are connected to your physical network entities.

The following example shows how these models can appear on the Explorer tab in the Navigation panel under the Universe group:

```
[-] Universe
     .  Physical switch 1
     .  Physical switch 2
     .  IBM LPAR Manager
    [-] IBM LPAR Host
         .  Fanout A
         .  Fanout B
         .  IBM LPAR A
         .  IBM LPAR B
         .  IBM LPAR C
```

Selecting one of these models displays these relationships graphically on the Topology tab in the Contents panel.

How the IBM LPAR Data is Updated in Virtual Host Manager

During your initial IBM LPAR Discovery, DX NetOps Spectrum populates Virtual Host Manager hierarchy in the Navigation panel with your virtual device models. After DX NetOps Spectrum builds this initial hierarchy, your virtual network configuration can change, and Virtual Host Manager must continually work to keep this information accurate in DX NetOps Spectrum. For example, the following events can change your virtual network configuration:

- Creating or deleting an IBM LPAR on an IBM LPAR Host
- Moving an IBM LPAR from one IBM LPAR Host to another

To keep your information accurate, Virtual Host Manager detects these changes by polling the IBM LPAR AIM. Therefore, your virtual network configuration is updated in DX NetOps Spectrum at each polling cycle. DX NetOps Spectrum also receives traps from the AIM and generates the corresponding events. By reviewing the event log, you can find out when configuration changes occur, such as when a new IBM LPAR is created.

When an IBM LPAR is deleted, DX NetOps Spectrum removes the models from the Virtual Host Manager hierarchy in the Navigation panel. When the AIM detects an addition to your virtual network configuration, such as provisioning a new IBM LPAR or placing one into management, DX NetOps Spectrum performs the following tasks:

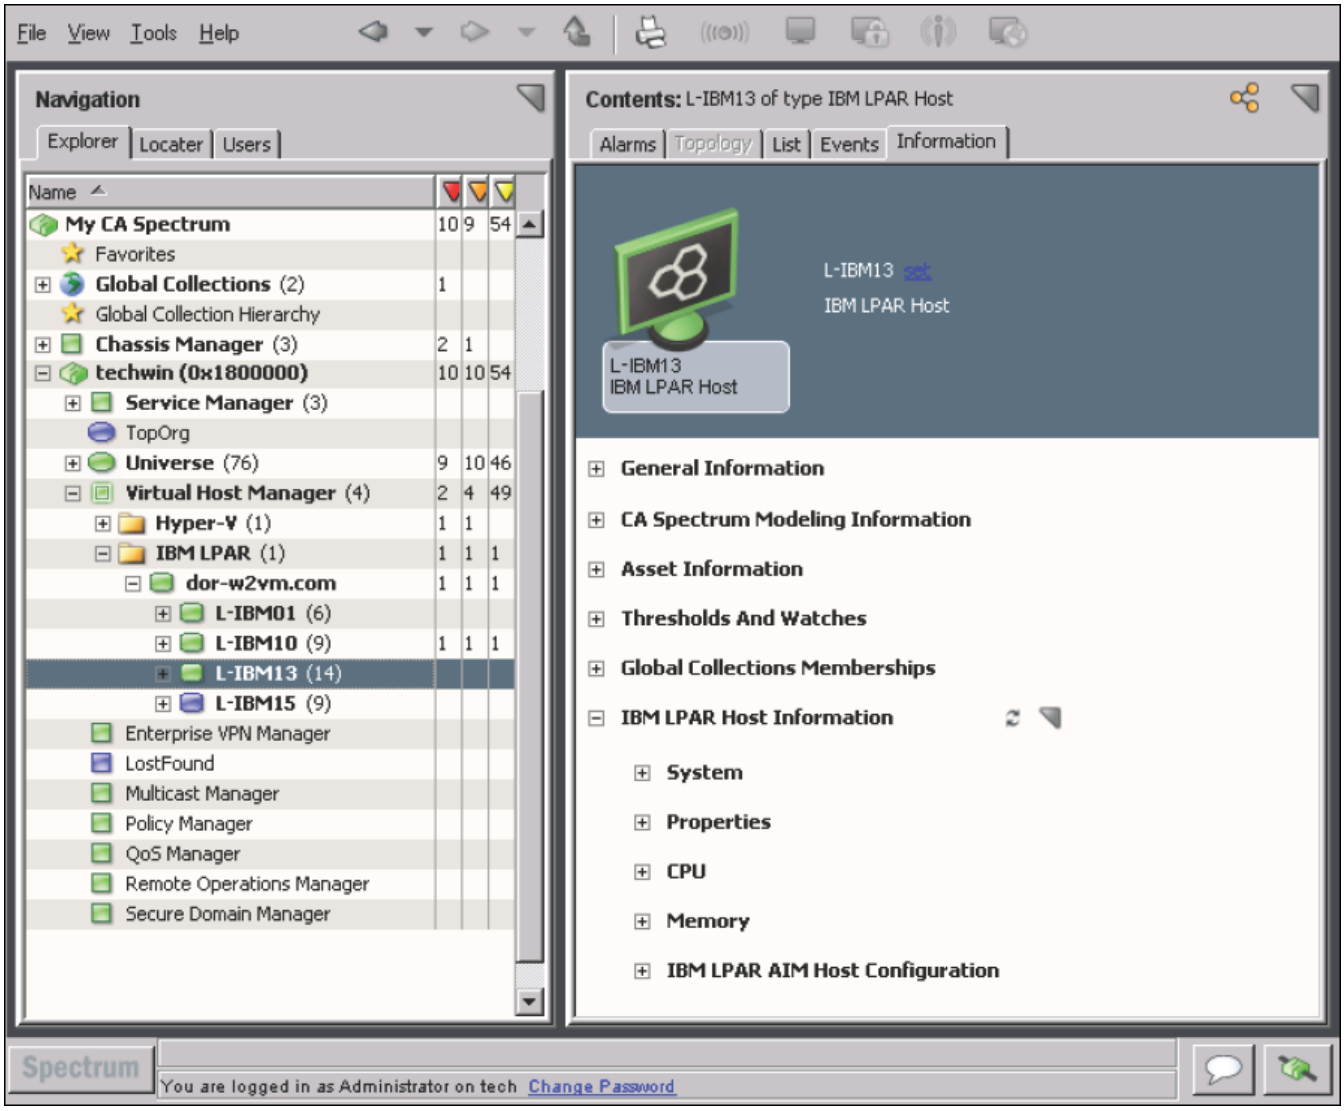
- Updates the placement of your virtual device models in the Virtual Host Manager hierarchy of the Navigation panel
- *Automatically* rediscovers connections to the affected IBM LPAR models and associates them with the correct IBM LPAR Host in the Universe topology.

  WARNING
  To reestablish connections to your virtual models correctly, all interconnecting routers and switches in your physical network must be modeled. If these models do not exist before connections to your virtual devices are rediscovered, DX NetOps Spectrum cannot resolve those connections and display the information

correctly in the Universe topology view. The IBM LPAR Hosts are placed in the same LAN container as the CA eHealth SystemEDGE model.

Custom Subviews for Virtual Entity Types (IBM LPAR)

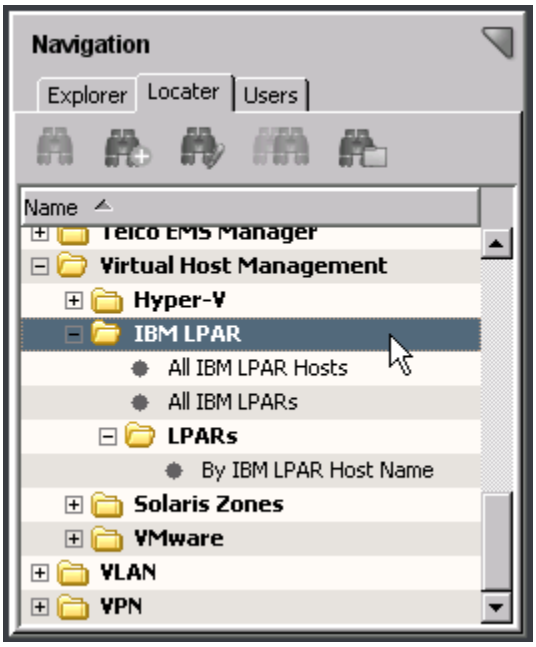
Your Virtual Host Manager models collectively provide information about your virtual environment. Individually, each model provides unique information or configuration settings, depending on the virtual entity type it represents. This custom subview appears on the Information tab in the Contents panel. These subviews can contain real-time data, such as CPU status or memory utilization, and provide access to threshold settings. For example, the custom subview for IBM LPAR Host is the "IBM LPAR Host Information" subview, as shown:



NOTE
The IBM LPAR Manager model provides combined information for all virtual devices managed by the IBM LPAR Manager. That is, selecting the IBM LPAR Manager model in the Navigation panel displays information about the selected IBM LPAR Manager host *and* combined information about all IBM LPAR Hosts, IBM LPAR instances, system profiles, virtual Ethernet devices, and more. This information contains the same data displayed on the Information tab for each individual entity model. The combined view in the IBM LPAR Manager model can provide a good overview about all of the virtual entities it manages.

Locater Tab for IBM LPAR Searches

In addition to viewing details about your virtual environment on the Explorer tab, you can also use the Locater tab to run preconfigured Virtual Host Manager searches. The search options are grouped under the Virtual Host Management, IBM LPAR folder on the Locater tab, as shown:



These detailed searches can help you investigate information related to virtual entities only, such as locating all IBM LPAR instances within a landscape.

> **NOTE**
> Although Virtual Host Manager is not DSS aware, these preconfigured searches let you select multiple landscapes to search in the search parameters.

The Locater tab in the Navigation panel includes the following searches for Virtual Host Manager information:

- **All IBM LPAR Hosts**
  Locates all IBM LPAR Hosts that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **All IBM LPARs**
  Locates all IBM LPAR instances that have been modeled in the DX NetOps Spectrum database for your virtual network.
- **LPARs, By IBM LPAR Host Name**
  Locates all IBM LPAR instances that have been modeled in the DX NetOps Spectrum database for your virtual network, limited to only those IBM LPARs managed by a selected IBM LPAR Host.

Status Monitoring Options (IBM LPAR)

DX NetOps Spectrum provides a wide range of options for monitoring the state of your virtual network resources. The status information available for a resource varies, depending on the type of virtual entity you are monitoring. Also, your ability to configure a status option depends on its type. For example, some status options are read-only, but others let you configure threshold values, enable behaviors, or select an alarm severity. Providing this range of options and levels of customization, DX NetOps Spectrum lets you decide how to best monitor the performance of your virtual network.

Status fields are located in the OneClick subviews. All status information for a given virtual environment is available on the IBM LPAR Manager model in a tabular format. Also, each virtual entity type that has a unique model in DX NetOps Spectrum provides a subset of the same status information for easy viewing. Status-related settings, including the alert type, monitor, and thresholds, can be set from either view location.

The following tables outline the type of status information available for each virtual entity type. The Subview Locations column describes where the corresponding status fields are located in OneClick. For example, "memory" information for your IBM LPAR models is available on the Information tab in the following two locations:

- IBM LPAR Information, Memory subview for the IBM LPAR model
- IBM LPAR Manager, Managed Environment, LPARs subview for the IBM LPAR Manager model

To explore the exact status options available for each status information type, locate the subview in OneClick.

IBM LPAR Host

Status Information Type	Subview Locations
Overall	IBM LPAR Host, IBM LPAR Manager
CPU	IBM LPAR Host, IBM LPAR Manager

IBM LPAR

Status Information Type	Subview Locations
System	IBM LPAR, IBM LPAR Manager
CPU	IBM LPAR, IBM LPAR Manager
Memory	IBM LPAR, IBM LPAR Manager

How to Configure Management Options (IBM LPAR)

After your virtual network is modeled, you can configure Virtual Host Manager options for viewing and managing your device models. Configuring your preferences helps ensure that Virtual Host Manager handles your virtual device models correctly and monitors only the information that is important to you.

To configure your installation of Virtual Host Manager, perform the following procedures after you discover and model your virtual network:

- Configure the IBM LPAR AIM options -- These options let you select settings for the CA eHealth SystemEDGE IBM LPAR AIM, such as the AIM polling interval and various traps.
- Configure threshold values and other status monitoring options -- These options let you determine which information you want to monitor and how DX NetOps Spectrum manages the various events that occur in your virtual environment.

Configure the IBM LPAR AIM

The IBM LPAR AIM communicates with the IBM LPAR Manager to manage and collect information about your virtual environment. In Virtual Host Manager, you can configure the AIM to determine how it handles polling, traps, and events. The IBM LPAR AIM configuration settings let you determine the right balance of information to gather against the amount of required resources.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Locate and click your IBM LPAR Manager on the Explorer tab in the Navigation panel.
   The tabs in the Contents panel are populated with details about your IBM LPAR Manager.

3. Click the Information tab.
4. Expand the IBM LPAR Manager, IBM LPAR AIM, Configuration subview.
5. Click set to change the settings for the following fields, as needed:
   - **Polling Interval (Seconds)**
     Specifies the time interval (in seconds) when the IBM LPAR AIM polls and caches status and modeling information from the configured IBM LPAR Hosts. This polling retrieves status and modeling updates, such as an IBM LPAR not-running status, IBM LPAR Host disconnected, new IBM LPAR available, new IBM LPAR Host, and more.
     Default: 300
     Limits: Values greater than or equal to 300.
     Note: For best results, we recommend setting this interval lower than the DX NetOps Spectrum poll cycle interval.
   - **Log Level**
     Specifies the level of information written to the IBM LPAR AIM log file. The levels are cumulative (for example, log level 4 writes all messages at levels 0 through 4). The log levels are as follows:
     - 0: Fatal
     - 1: Critical
     - 2: Warning
     - 3: Info
     - 4: Debug
     - 5: Debug Low
     - 6: Debug Lower
     - 7: Debug Lowest

     NOTE
     Default: 2 Specifying a debug level greater than 4 is discouraged.
   - **Events Max**
     Specifies the maximum number of events to store in the Events table. When the maximum rows are reached, DX NetOps Spectrum begins overwriting event rows, beginning with the oldest recorded events.
     Default: 500
     Limits: 1 - 2147483647
   - **History (days)**
     Specifies the amount of history information that is available in the Events table, in days. Events older than the specified number of days are purged from the Events table.
     Note: The value in the Events Max field also affects this setting. When the max is reached, the Events table cannot always store events that span the number of days that you specify in the History (days) field. For example, 800 events occur in the past 30 days. The most recent 500 events occurred within the past 10 days. If the Events Max field specifies 500, only 10 days of history are available in the Events table.
     Default: 30
     Limits: 1 - 365
   - **Clear Events**
     Determines whether to clear events from the Events table. Select from the following options:
     - **do-not-clear**
       (Default) Retains all events in the Event table until the Events Max or History (days) values are reached.
     - **clear**
       Clears all events from the Event table when you start the IBM LPAR AIM.

   Your IBM LPAR AIM is configured with your selections.

Configure and Monitor Resource Status (IBM LPAR)

Yu can monitor the status of virtual resources in OneClick. For example, you can view the total memory, used memory, percent of CPU usage, and more. Also, you can set monitoring options, such as enabling alerts and setting threshold values for traps. This information can help you optimize your virtual network performance and troubleshoot alarms.

NOTE
Traps are set on and managed by the IBM LPAR AIM, but you can configure these threshold values from the OneClick subviews. A read/write community string is required to change any threshold values or settings.

You can view or configure resource status options and information for virtual devices on the Information tab.

Follow these steps:

1. Open Virtual Host Manager in the Navigation panel.
   The main details page opens in the Contents panel for the selected Virtual Host Manager.
2. Locate and click the virtual device on the Explorer tab in the Navigation panel.
   The device details display in the Contents panel.
3. Click the Information tab.
   Multiple subviews are available for viewing. Generally, the subview at the bottom of the tab includes the resource allocation and utilization information for the selected model. For example, an IBM LPAR Host model displays a subview named "IBM LPAR Host Information" that includes details for the specific model you selected in the Navigation panel.
4. Expand the appropriate subview.
   All available resource status details and monitoring options for the selected device model are displayed.

   NOTE
   The IBM LPAR Manager model provides combined information for all virtual devices managed by the IBM LPAR Manager. That is, selecting the IBM LPAR Manager model in the Navigation panel displays information about the selected IBM LPAR Manager host *and* combined information about all IBM LPAR Hosts, IBM LPAR instances, system profiles, virtual Ethernet devices, and more. This information contains the same data displayed on the Information tab for each individual entity model. The combined view in the IBM LPAR Manager model can provide a good overview about all of the virtual entities it manages.

Controlling IBM LPAR AIM Polling

When tuning Virtual Host Manager performance, you can change the IBM LPAR Manager polling rate or disable IBM LPAR technology polling. By default, the polling attributes on the IBM LPAR Manager model control the IBM LPAR-related polling behavior. Or you can change this IBM LPAR-related polling behavior independently. The IBM LPAR virtual technology application model, IBMLPARAIMApp, controls your IBM LPAR-related polling.

The following two attribute values on the application specifically control the IBM LPAR technology polling logic:

- PollingStatus
- Polling_Interval

Both the IBM LPAR Manager device model and the IBMLPARAIMApp application model contain these attributes. PollingStatus disables and enables polling, while Polling_Interval controls the polling frequency. If the values are different, the IBMLPARAIMApp application model attribute values take precedence.

This ability to set the value for the device model and application model lets you fine-tune your IBM LPAR-related polling. For both PollingStatus and Polling_Interval, modifying the attribute on the IBM LPAR Manager device model also changes the corresponding application model attribute if their values are the same.

Configure the IBM LPAR Polling Interval

You can change the IBM LPAR AIM polling rate. Configure the polling interval by setting the Polling_Interval attribute on the IBM LPAR virtual technology application model.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'

A search dialog opens.
3. Enter the IP address for your IBM LPAR Manager in the Device IP Address field and click OK.
   A list of application models for the IBM LPAR Manager appears in the Contents panel.
4. Select the IBMLPARAIMApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Click the Modeling Information subview.
7. Click set in the Poll Interval (sec) field, enter a new value.

   NOTE

   Changing the Poll Interval (sec) value from any number to 0 also sets the Polling field to Off, disabling IBM LPAR AIM polling. However, if you set the Poll Interval (sec) to 0 and set the Polling field to On, IBM LPAR AIM polling continues, using the polling interval set for the IBM LPAR Manager device.

   The IBM LPAR AIM polling interval setting is configured.

Disable IBM LPAR Polling

You can disable IBM LPAR AIM polling. Disabling IBM LPAR polling is the same as disabling Virtual Host Manager. Disable polling by setting the PollingStatus attribute on the IBM LPAR virtual technology application model.

Follow these steps:

1. Open OneClick and click the Locater tab in the Navigation panel.
2. Expand the Application Models folder and double-click 'By Device IP Address.'
   A search dialog opens.
3. Enter the IP address for your IBM LPAR Manager in the Device IP Address field and click OK.
   A list of application models for the IBM LPAR Manager appears in the Contents panel.
4. Select the IBMLPARAIMApp application model.
   The application model details appear in the Component Details panel.
5. Click the Information tab in the Component Details panel.
6. Click the DX NetOps Spectrum Modeling Information subview.
7. Click set in the Polling field and select Off.
   Polling is disabled for the IBM LPAR AIM on the selected IBM LPAR Manager.

Deleting Virtual Host Manager Models (IBM LPAR)

Models can be deleted from OneClick at any time for various reasons. However, Virtual Host Manager restricts your ability to delete models from the Virtual Host Manager hierarchy in the Navigation panel. To delete models manually, you have the following two options:

- Delete the IBM LPAR folder or an IBM LPAR Manager model in Virtual Host Manager
- Remove a virtual entity using the HMC

In Virtual Host Manager, models are sometimes deleted automatically. The following circumstances cause DX NetOps Spectrum to automatically delete Virtual Host Manager models:

- **IBM LPAR folder deleted or IBM LPAR Manager model removed from Virtual Host Manager**
  If you remove an IBM LPAR Manager model or delete the IBM LPAR folder from the Navigation panel, DX NetOps Spectrum deletes all related child models.
- **An entity removed from IBM LPAR virtual environment**

As you delete IBM LPAR Hosts and IBM LPAR instances using the HMC, DX NetOps Spectrum also deletes those models and their child models from Virtual Host Manager.

- **Upgraded models exist** -- In some cases, an IBM LPAR instance is first modeled for Virtual Host Manager without SNMP capabilities. If SNMP capabilities are later added to a VHM model, the previous model is deleted and replaced with the new SNMP-capable model.

  NOTE
  Although the default setting is to delete the models, you can configure Virtual Host Manager to place the IBM LPAR Host and IBM LPAR instances in the LostFound container when they are removed from Virtual Host Manager. This configuration setting applies only when you remove devices using your HMC. However, this setting does not apply when you delete the IBM LPAR folder, remove an IBM LPAR Manager model, or upgrade a VHM model.

Alarms and Fault Isolation for IBM LPAR

This section describes the traps used by Virtual Host Manager and the resulting alarms. This section also explains how Virtual Host Manager fault isolation differs from basic DX NetOps Spectrum fault isolation.

Virtual Host Manager Alarms for IBM LPAR

To alert you to problems within your virtual network, DX NetOps Spectrum generates alarms. Alarms are created in two ways:

- Traps sent from the CA eHealth SystemEDGE agent
- Polling

Polling generates four alarms: IBM LPAR Proxy Lost, IBM LPAR Host Proxy Lost, IBM LPAR Manager Unavailable, and IBM LPAR Not Running. However, several traps can generate alarms on your virtual devices. DX NetOps Spectrum supports all traps sent by the IBM LPAR AIM from the CA eHealth SystemEDGE agent. To get the greatest value from these traps when monitoring your devices, you can configure the threshold values for each virtual device individually.

If a trap breaches your threshold value and generates an alarm, DX NetOps Spectrum uses the value of the “state” varbind passed with the trap to determine the alarm severity. All state varbinds have the following possible values, which DX NetOps Spectrum alarms on the same way:

- 0: Unknown
- 1: OK
- 2: Warning
- 3: Critical

The "Unknown" state does not have an associated alarm severity and does not change the alarm severity of a device. DX NetOps Spectrum maps the other IBM LPAR technology states to a DX NetOps Spectrum alarm severity:

IBM LPAR State	DX NetOps Spectrum Alarm Severity
1: OK	Normal (Green)
2: Warning	Minor (Yellow)
3: Critical	Major (Orange)

Forwarding Traps from CA SystemEDGE (IBM LPAR)

DX NetOps Spectrum supports all traps sent by the IBM LPAR AIM. These traps are initially sent to the IBM LPAR CA eHealth SystemEDGE model. If the destination for a trap is not this model, DX NetOps Spectrum forwards the trap to the correct virtual model.

NOTE
For specific event codes related to the traps, use the Event Configuration application and filter on “0x056e.” Or you can launch MIB tools to view the traps in the Trap Support table for the “EMPIRE-CALPARA-MIB” MIB.

DX NetOps Spectrum determines where to forward the trap by using the following process:

1. When DX NetOps Spectrum receives a trap, it uses varbind information in the trap to locate the correct virtual entity, as follows:
   – For traps that are forwarded to an IBM LPAR Host, DX NetOps Spectrum uses the UID to locate the correct host.
   – For traps that are forwarded to an IBM LPAR instance, DX NetOps Spectrum uses the UID to determine first the correct IBM LPAR Host. Based on the UID or the IBM LPAR name, DX NetOps Spectrum locates the correct IBM LPAR instance within the list of IBM LPARs managed by this IBM LPAR Host.
2. DX NetOps Spectrum uses this UID to look up and locate the DX NetOps Spectrum model that is tied to a given UID. The entity type of all traps is predetermined. Depending on the results of the look-up, DX NetOps Spectrum forwards the trap as follows:
   – If it finds a DX NetOps Spectrum model of a specific type with a given UID and in some cases an IBM LPAR name, DX NetOps Spectrum forwards the event and corresponding alarm to the destination model.
   – If it cannot find a DX NetOps Spectrum model for a given UID and in some cases an IBM LPAR name, DX NetOps Spectrum generates a new generic event on the IBM LPAR Manager model. This new event includes details about the trap.

NOTE
DX NetOps Spectrum often cannot find a related model when a trap is sent immediately after changing your virtual network entities in the HMC. IBM LPAR Discovery has not yet identified and created the corresponding model in DX NetOps Spectrum.

Traps Supported in Virtual Host Manager (IBM LPAR)

All traps that are generated by the IBM LPAR AIM are supported in DX NetOps Spectrum. The traps are initially sent to the IBM LPAR Manager model. Then, the traps are forwarded to a corresponding virtual entity type (that is, the "destination" entity), depending on the type of trap. Using these traps, you can monitor the performance of your virtual network, resolve any resulting alarms, or trigger events.

NOTE
For more information about traps that are generated by the IBM LPAR AIM, see *CA Virtual Assurance for Infrastructure Managers Implementation*.

The following tables list the traps for a specific destination entity type and specify whether the trap generates an alarm.

Trap Name	Trap OID	Alarm?
lparAimSysAdded	1.3.6.1.4.1.546.1.1.0.165317	No
lparAimSysRemove	1.3.6.1.4.1.546.1.1.0.165316	No

Trap Name	Trap OID	Alarm?
lparAimLPAdded	1.3.6.1.4.1.546.1.1.0.165321	No
lparAimLPDeleted	1.3.6.1.4.1.546.1.1.0.165322	No
lparAimSlotAdd	1.3.6.1.4.1.546.1.1.0.165340	No

lparAimVIOvSerialAdd	1.3.6.1.4.1.546.1.1.0.165375	No
lparAimVIOvSerialRemoved	1.3.6.1.4.1.546.1.1.0.165376	No

Fault Management for Virtual Networks (IBM LPAR)

The goal of fault isolation is to narrow down the root cause of a networking problem. Finding the root cause can help you to troubleshoot and quickly correct the problem or to correct the problem programmatically with automated scripts. Deciding which devices are the root cause of an alarm can be difficult, because problems with a single device can cause several devices in your network to generate events.

For example, losing contact with an IBM LPAR Host often means that you have also lost contact with the IBM LPAR instances it manages. Therefore, the IBM LPAR Host device model and all affected IBM LPAR instances generate alarms. Using fault isolation techniques, Virtual Host Manager correlates these alarms in an attempt to identify a single root cause.

Virtual networks provide a unique management opportunity, because they provide DX NetOps Spectrum an alternate management perspective. That is, DX NetOps Spectrum can gather information through direct contact with your virtual devices or through the virtual network management technology, IBM LPAR. This alternate management perspective enhances standard DX NetOps Spectrum fault management in two ways:

- **Enhanced Contact Lost alarms** -- Two sources of information about a device means Virtual Host Manager can pinpoint the cause and more easily correlate events to a single root cause.
- **Proxy Failure alarms** -- *Proxy management* is the act of managing network devices using an alternate management source in place of or in addition to the primary manager. For example, DX NetOps Spectrum can manage virtual network devices by contacting them directly or through the virtual technology application's contact with the devices. When IBM LPAR virtualization technology loses contact with a virtual network device, Virtual Host Manager generates one of the Proxy Management Lost alarms for each device. These alarms are unique, because they are alerting you to the fact that *management* of the device through the *proxy* is affected, not the state of the device or direct (SNMP) management.

How Fault Isolation Works when Device Contact is Lost (IBM LPAR)

To help you troubleshoot networking problems with your devices, DX NetOps Spectrum uses fault isolation to narrow down the root cause of an alarm. For virtual networks, Virtual Host Manager uses information from direct contact with the device plus information provided by IBM LPAR technology through the IBM LPAR AIM. In many cases, standard DX NetOps Spectrum fault management can pinpoint the root cause. But in special circumstances, the method for isolating problems in a virtual network go beyond the standard methods.

The type of fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe two unique fault management situations and how DX NetOps Spectrum isolates the networking error in your virtual network.

Scenario 1: IBM LPAR instance is not running

In a virtual environment, the virtual management application can provide more details than DX NetOps Spectrum can discover through standard device monitoring. For example, the IBM LPAR virtualization technology is aware when an IBM LPAR changes from the "running" state to something else, such as the "open-firmware" state.

If an IBM LPAR is no longer running and DX NetOps Spectrum loses contact with it, but proxy management of the IBM LPAR Manager is uninterrupted, DX NetOps Spectrum determines the root cause as follows:

1. When DX NetOps Spectrum loses contact with an IBM LPAR, it generates a Contact Lost alarm.
2. During its next polling cycle, the IBM LPAR Manager model polls the IBM LPAR AIM to gather information about the IBM LPAR instance. Because IBM LPAR technology manages the IBM LPAR instances, it can provide a unique view into the possible cause of alarms generated by an IBM LPAR.
3. If the IBM LPAR technology finds that the IBM LPAR is in the not-running mode, it generates an IBM LPAR Not Running alarm.

   NOTE
   This alarm is cleared upon the first IBM LPAR AIM polling cycle after the IBM LPAR is running again.
4. Virtual Host Manager correlates the Contact Lost alarm to the corresponding IBM LPAR Not Running alarm created by DX NetOps Spectrum. Virtual Host Manager makes the Contact Lost alarm appear as a symptom of the IBM LPAR Not Running alarm.

Scenario 2: IBM LPAR Host is down

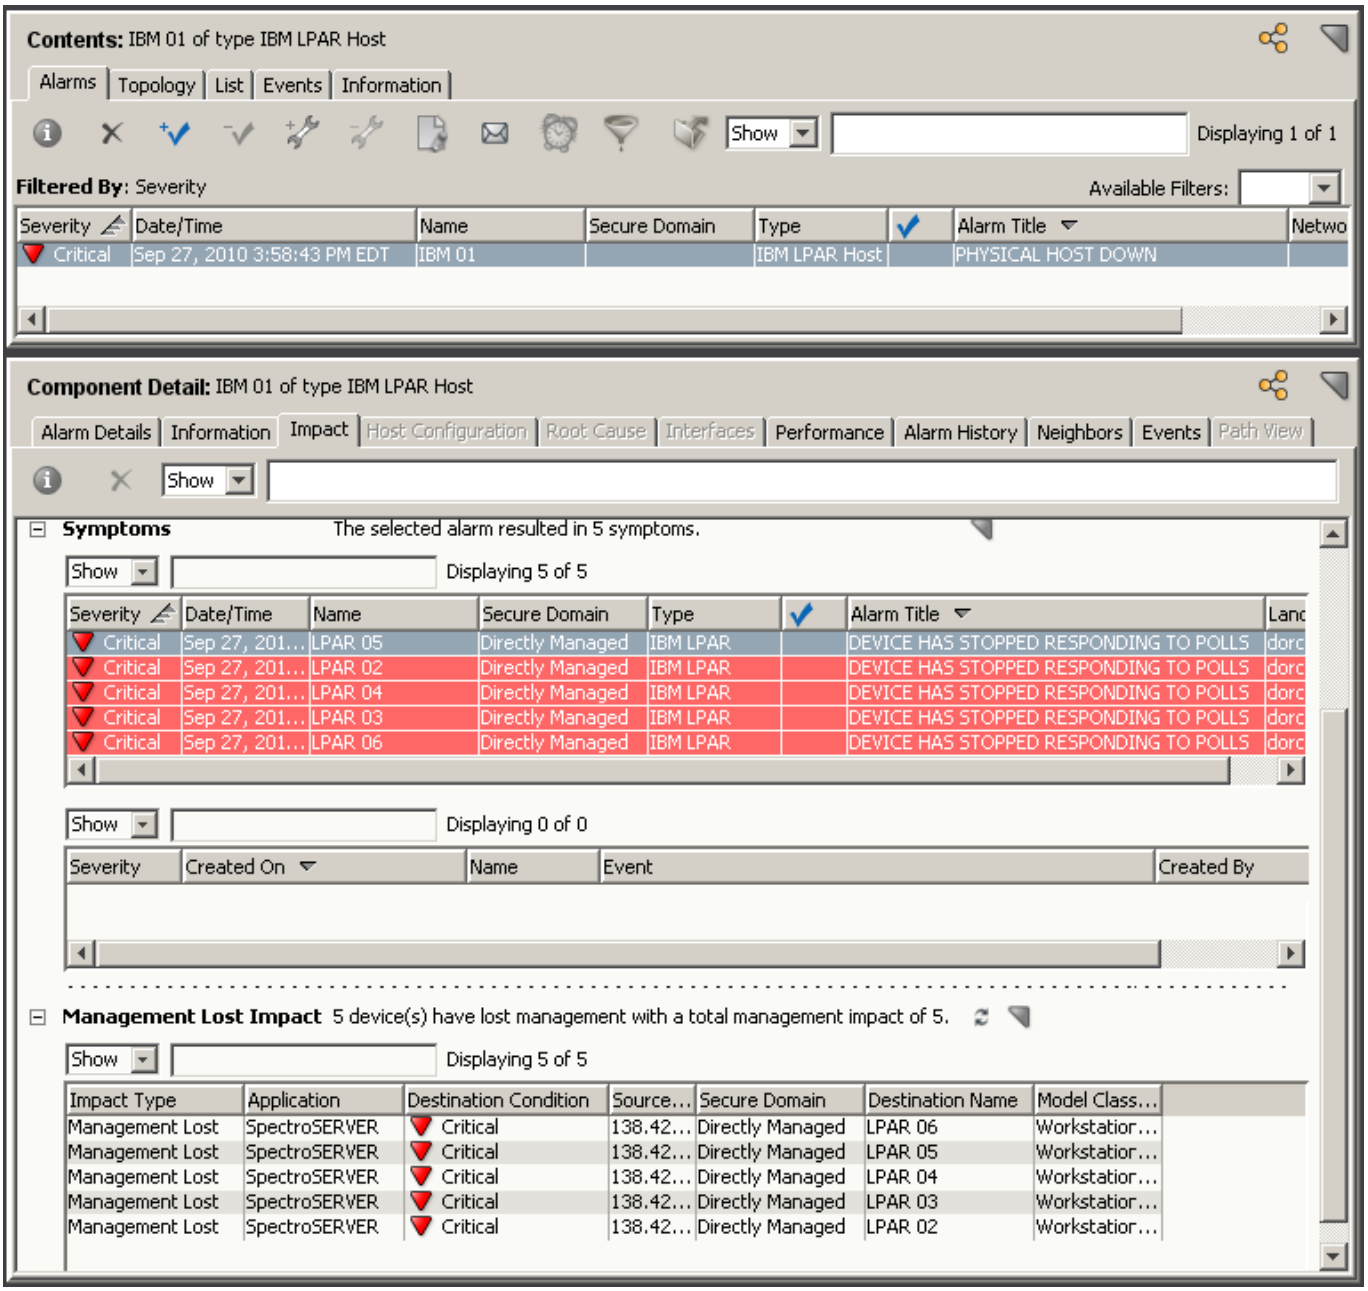
If DX NetOps Spectrum loses contact with all IBM LPARs running on an IBM LPAR Host, DX NetOps Spectrum checks the status of the upstream routers and switches. Depending on their status, DX NetOps Spectrum determines the root cause as follows:

- All upstream devices for one or more IBM LPAR instances are unavailable -- Standard DX NetOps Spectrum fault isolation techniques determine the root cause, as follows:

  - Device Stopped Responding to Polls alarm -- Generated on the IBM LPAR Host when at least ne upstream connected device for any IBM LPAR is up.
  - Gateway Unreachable alarm -- Generated on the IBM LPAR Host when *all* upstream connected devices are down.
- At least one upstream device is available for every IBM LPAR instance connected to the IBM LPAR Host -- DX NetOps Spectrum infers that the IBM LPAR Host is the root cause and responds as follows:
  a. All IBM LPARs, ports, and fanouts that are directly connected to the IBM LPAR models generate the standard fault isolation alarms.
  b. Virtual Host Manager creates a Physical Host Down alarm for the IBM LPAR Host model.
  c. All fault isolation-related alarms that are created for the impacted devices (such as IBM LPARs, ports, and fanouts) are correlated to the Physical Host Down alarm, making them symptoms of the Physical Host Down alarm. These symptom alarms appear in the Symptoms table on the Impact tab for the Physical Host Down alarm.

     NOTE
     For each IBM LPAR Host model, Virtual Host Manager creates a "virtual fault domain." This domain includes the IBM LPAR Host and IBM LPAR instances, plus all ports and fanouts directly connected to the IBM LPARs. When the IBM LPAR Host generates the Physical Host Down alarm, all standard fault isolation alarms within the domain are correlated to it. Correlating these alarms as symptoms indicates that the Physical Host Down alarm on the IBM LPAR Host is the root cause.
  d. All impacted devices are listed in the Management Lost Impact table on the Impact tab for the Physical Host Down alarm.

     NOTE
     Devices that are suppressed do not have a corresponding alarm in the Symptoms table.



If all upstream devices for one or more IBM LPAR instances go down, DX NetOps Spectrum can no longer reliably state that the fault lies with the IBM LPAR Host. Therefore, DX NetOps Spectrum clears the Physical Host Down alarm and applies the standard DX NetOps Spectrum fault isolation techniques.

How Fault Isolation Works when Proxy Management is Lost (IBM LPAR)

The IBM LPAR virtualization technology used to create your virtual network provides DX NetOps Spectrum a unique management opportunity. DX NetOps Spectrum can use the standard methods to contact your virtual devices directly, plus DX NetOps Spectrum can simultaneously gather virtual device information from IBM LPAR technology. In this sense, the IBM LPAR technology is a "proxy" from which DX NetOps Spectrum gathers virtual device information. If DX NetOps Spectrum loses direct contact with a device, it generates alarms. Likewise, if IBM LPAR technology loses contact with

a virtual device or if Virtual Host Manager loses contact with the IBM LPAR Manager, Virtual Host Manager generates alarms -- Proxy Management Lost alarms.

In response, DX NetOps Spectrum attempts to isolate the cause of the proxy management failure. Proxy fault isolation is similar to the standard DX NetOps Spectrum fault isolation, except that these alarms alert you to the fact that *proxy* management of a virtual device is affected. Proxy management fault isolation cannot tell you whether a virtual device is up or down. However, it is important to know when contact through the proxy is lost, because you could be missing important virtual information about a device.

The type of proxy fault isolation Virtual Host Manager uses to discover the root cause depends on which devices are alarming and the type of events the devices generate. The following scenarios describe two unique proxy fault management situations and how Virtual Host Manager isolates the networking error in your virtual network.

Scenario 1: Contact between IBM LPAR Manager and HMC is lost

If the IBM LPAR Manager loses contact with an HMC and all IBM LPAR Hosts and IBM LPARs the HMC is managing, the IBM LPAR Manager data about the IBM LPAR Hosts and all hosted IBM LPAR instances is lost. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. A Proxy Lost alarm is generated on the IBM LPAR Hosts and all hosted IBM LPARs.
2. The IBM LPAR alarms are correlated to the Proxy Lost alarm for the IBM LPAR Host, making these IBM LPAR alarms symptoms of the IBM LPAR Host alarm. Correlating these alarms as symptoms indicates that the IBM LPAR Host alarm is the root cause.
3. If DX NetOps Spectrum also loses contact with the IBM LPAR Host and generates a Physical Host Down alarm, the Proxy Lost alarm generated for the IBM LPAR Host is correlated to the Physical Host Down alarm. In this case, the Proxy Lost alarm becomes a symptom of the Physical Host Down alarm. Correlating this alarm as a symptom indicates that the Physical Host Down alarm on the IBM LPAR Host is the root cause.

Scenario 2: Contact between DX NetOps Spectrum and IBM LPAR Manager is lost

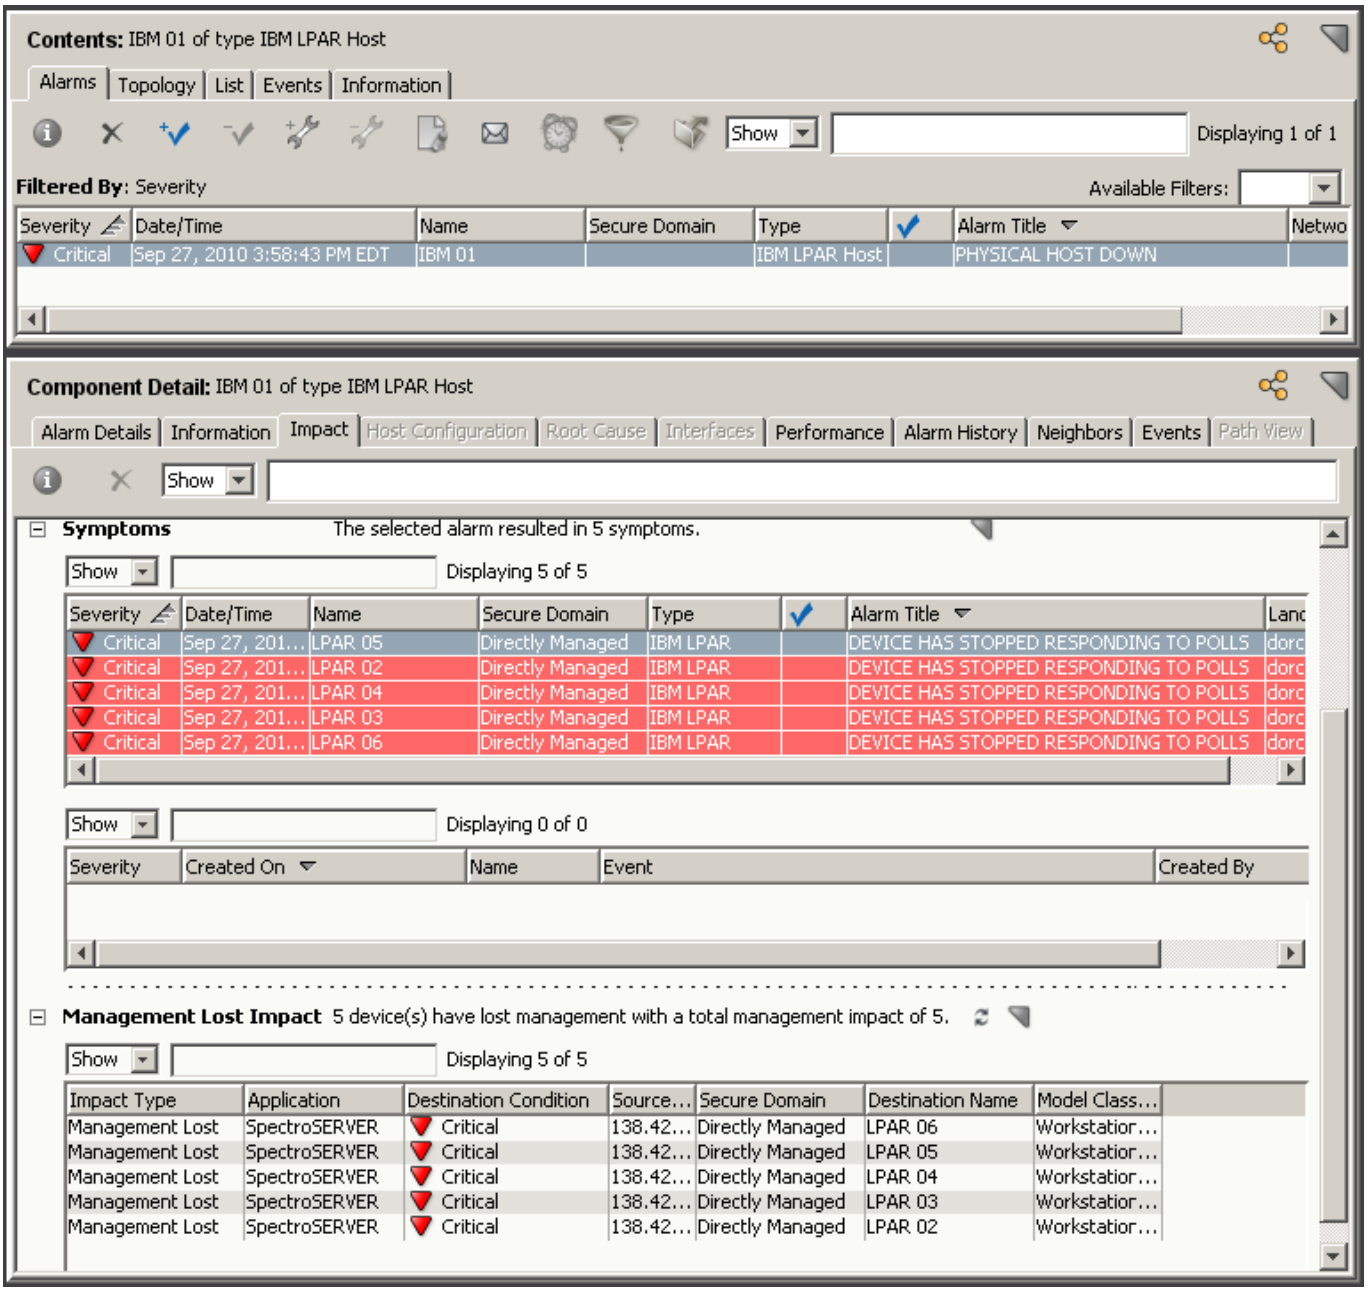
If DX NetOps Spectrum loses contact with or stops polling the IBM LPAR Manager model, DX NetOps Spectrum loses the IBM LPAR technology data about all virtual models managed by that IBM LPAR Manager. To isolate the problem, Virtual Host Manager determines the root cause as follows:

1. DX NetOps Spectrum generates Proxy Lost alarms for all virtual models managed by that IBM LPAR Manager, including IBM LPAR instances and IBM LPAR Hosts. DX NetOps Spectrum also generates a separate Proxy Unavailable alarm on the IBM LPAR Manager model.
2. The IBM LPAR alarms are correlated to their corresponding IBM LPAR Host model alarm.
3. The IBM LPAR Host model alarms are correlated to a Proxy Unavailable alarm for the IBM LPAR Manager model.
4. This Proxy Unavailable alarm is then correlated to the root cause of the IBM LPAR Manager being down. The root cause is typically an alarm generated by standard DX NetOps Spectrum fault management, such as the alarms created for the following situations:
   - Lost management of IBM LPAR Manager (that is, a problem occurred with the CA eHealth SystemEDGE agent on the IBM LPAR Manager host)
   - Machine contact is lost
   - IBM LPAR Manager model is in maintenance mode

Determining IBM LPARs Affected by Host Outages

When contact with an IBM LPAR Host is interrupted or the IBM LPAR Host goes down, all IBM LPAR instances hosted by the IBM LPAR Host are affected. Because IBM LPAR technology cannot communicate with the IBM LPAR Host to get usage information, you might not receive alarms for a critical IBM LPAR hosted on that IBM LPAR Host. To find out if a critical IBM LPAR is impacted, you can view a list of affected IBM LPAR instances on the Impact tab of the alarm, as follows:

- Symptoms subview -- displays all symptom alarms generated by the affected IBM LPAR instances
- Management Lost Impact subview -- lists the IBM LPAR instances impacted by the alarm



Huawei SingleCLOUD

This section is for Huawei SingleCLOUD virtualization technology users and describes how to use Virtual Host Manager to manage the virtual entities in your Huawei SingleCLOUD platform.

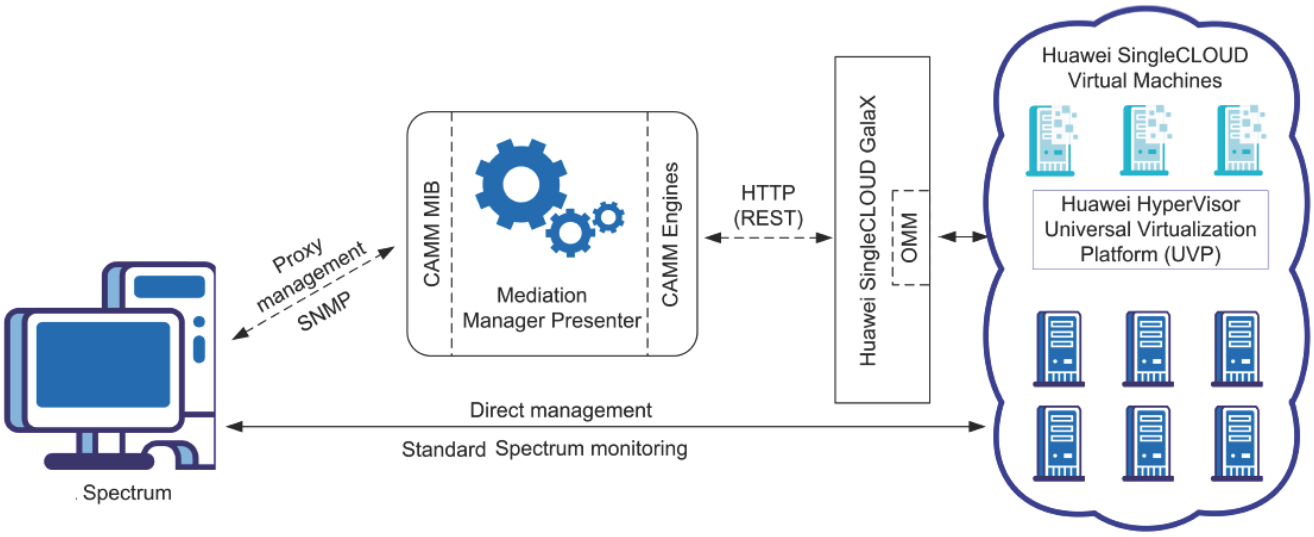
How Virtual Host Manager Works with Huawei SingleCLOUD

Virtual Host Manager monitors your virtual network entities seamlessly with your physical network entities. You get a full view of your network where you can troubleshoot networking issues for both types of entities. Although your virtual network entities behave like physical components, the process for monitoring those entities differs from the general DX NetOps Spectrum monitoring process. Understanding how this process works can help you locate and resolve networking issues related to your virtual network.

The Huawei SingleCLOUD platform consists of a complete system of network, storage, servers, and software for creating private or public clouds. Virtual Host Manager helps you to manage and monitor your Huawei SingleCLOUD virtual environment.

DX NetOps Spectrum gathers information about your Huawei SingleCLOUD virtual environment by two different methods. As with other DX NetOps Spectrum managed devices, Virtual Host Manager uses standard DX NetOps Spectrum monitoring methods. In addition, Virtual Host Manager for Huawei SingleCLOUD also retrieves specialized information from an alternate (proxy) manager, DX Mediation Manager (DX MM).

The following diagram shows how DX NetOps Spectrum gathers information about your Huawei SingleCLOUD environment:



DX Mediation Manager resides on its own host and obtains information from the Huawei SingleCLOUD environment by using HTTP (REST) services to communicate with Huawei SingleCLOUD GalaX, a software suite that collectively manages Huawei SingleCLOUD.

DX MM uses the following components:

- The Engine. The Engine is DX MM's polling engine which gathers information from the Huawei SingleCLOUD platform. The CAMM Engine communicates directly with the Huawei SingleCLOUD GalaX Operation and Management Module (OMM) to obtain information about the Huawei HyperVisor Universal Virtualization Platform (UVP).
- The Presenter. The Presenter receives the information from the Engine and uses it to populate a CA-developed MIB (CAMEDIATIONMANAGER-ENTERPRISES-HUAWEI-SINGLECLOUD-MIB).

DX NetOps Spectrum uses SNMP to retrieve data from the CAMM MIB and uses this information to model and monitor your Huawei SingleCLOUD environment in OneClick.

Models Created for Huawei SingleCLOUD

Virtual Host Manager provides several models to represent the components of your Huawei SingleCLOUD virtual network. Understanding the following basic models can help you better understand Discovery and how the virtual environment interfaces with your physical environment.

Virtual Host Manager includes the following models and icons for Huawei SingleCLOUD entities:

- **Huawei SingleCLOUD CAMM Presenter**
  Represents a CA Mediation Manager (CAMM) Presenter. The CAMM Presenter model allows configuration of the virtual IP addresses used by the CAMM Engines to communicate with Huawei SingleCLOUD GalaX. Each CAMM Presenter can support multiple virtual IP addresses.
  Icon:
  
- **Huawei SingleCLOUD Manager**
  Represents a virtual IP address on the CAMM Presenter. CAMM communicates with Huawei SingleCLOUD GalaX, which is responsible for managing the Huawei SingleCLOUD virtual platform. Information for each Huawei SingleCLOUD GalaX being monitored by CAMM is provided through a virtual IP address on the CAMM Presenter and is represented by a Huawei SingleCLOUD Manager model.
  Icon:
  
- **Huawei SingleCLOUD Cloud**
  Represents a collection of physical and virtual hosts that make up a private or public cloud network.
  Icon:
  
- **Huawei SingleCLOUD Host**
  Represents the Computing Node Agent (CNA) that hosts the virtual machines. In the Universe topology, these models group your virtual entities into a separate view while showing where the virtual environment interfaces with your physical network. The Huawei SingleCLOUD Host cannot be contacted directly for status information. Instead, the status of this model is inferred from the status of its contained items.
  Icon:
  
- **Huawei SingleCLOUD CNA FIP**
  Represents the management interface of the CNA that is hosting the virtual machines. This model is assigned the IP address of the CNA FIP and lives within the host container.

Icon:

- **Huawei SingleCLOUD Virtual Machine**
  Represents a virtual machine, as configured in your Huawei SingleCLOUD platform.
  Icon:

Discovering Huawei SingleCLOUD Networks

Before you can use Virtual Host Manager to monitor your Huawei SingleCLOUD virtual environment, you have to discover and model any network elements that are to be managed. This section describes the discovery and modeling process for Virtual Host Manager for Huawei SingleCLOUD. These tasks are typically performed by the Virtual Host Manager administrator.

Follow these steps:

1. Perform the following pre-Discovery steps:
   a. Define CA Mediation Manager Presenters.
   b. Configure Discovery Options.
2. Discover and model your Huawei SingleCLOUD network.

Define CA Mediation Manager Presenters

After Virtual Host Manager is installed, you define the CA Mediation Manager Presenters to DX NetOps Spectrum. The Huawei SingleCLOUD CAMM Presenter model allows configuration of the virtual IP addresses associated with Huawei SingleCLOUD GalaX. Defining a CAMM Presenter creates a container model that will later be used to organize and contain Huawei SingleCLOUD Manager models.

NOTE
Creating a Huawei SingleCLOUD CAMM Presenter model does not trigger Discovery.

Follow these steps:

1. Select the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Select the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, CA Mediation Manager Presenters subview.
   The CA Mediation Manager Presenters table appears.
4. Click Add.
   The 'Create Model Of Type HuaweiSCCAMMPresenter' dialog appears.
5. Enter a Name and Description, and click OK.
   The Huawei SingleCLOUD CAMM Presenter model is created and appears in the table.

Configure Discovery Options

Before you perform Discovery to create models for your Huawei SingleCLOUD entities, specify options to control aspects of the Discovery process. Configuring your preferences helps Virtual Host Manager model your virtual devices as expected.

To configure your installation of Virtual Host Manager for Huawei SingleCLOUD Discovery, select your preferences from the following options:

- Maintenance Mode for New Huawei SingleCLOUD Virtual Machines -- Lets you decide whether to place newly discovered virtual machines into maintenance mode until you are ready for DX NetOps Spectrum to manage them.
- Allow Device Model Deletes During Huawei SingleCLOUD Discovery -- Controls how DX NetOps Spectrum handles Huawei SingleCLOUD models when Virtual Host Manager no longer manages them.
- Search for Existing Models -- Determines which secure domains Virtual Host Manager searches during a Huawei SingleCLOUD Discovery.
- Retain SNMP-enabled Virtual Machines During Huawei SingleCLOUD Manager Deletion -- Controls how DX NetOps Spectrum handles SNMP-enabled Huawei SingleCLOUD models when a Huawei SingleCLOUD Manager model is deleted.
- Discover SNMP-Capable Devices -- Controls how SNMP-capable devices are modeled during Huawei SingleCLOUD Discovery. By default, new models are initially created as VHM models only. But this option lets you override the default and immediately create SNMP models for devices that meet the criteria.

Configure Maintenance Mode for New Huawei SingleCLOUD Devices

areVirtual Host Manager automatically models the virtual machines that make up the Huawei SingleCLOUD virtual environment. DX NetOps Spectrum attempts to manage all models that are discovered. However, some newly discovered Huawei SingleCLOUD virtual machines are not ready for DX NetOps Spectrum management when they are initially modeled. To prevent undesired alarms on new Huawei SingleCLOUD Virtual Machine models, you can decide which new models are immediately placed into maintenance mode. Later, you can manually disable maintenance mode when you are ready for DX NetOps Spectrum to manage these devices.

Follow these steps:

1. Click the Virtual Host Manager node in the Explorer tab in the Navigation panel.
   The Contents panel displays information for the Virtual Host Manager feature.
2. Click the Information tab.
3. Expand the Configuration, Huawei SingleCLOUD, Huawei SingleCLOUD Discovery subview.
   Configurable Discovery options appear.
4. Click Set in the 'Maintenance Mode for New Huawei SingleCLOUD Virtual Machines' field and select one of the following options:
   - **Place non-enabled VMs in Maintenance Mode**
     (Default) Applies maintenance mode to only non-enabled Huawei SingleCLOUD Virtual Machine models upon initial Huawei SingleCLOUD Discovery.
   - **Place all VMs in Maintenance Mode**
     Applies maintenance mode to all newly discovered Huawei SingleCLOUD Virtual Machine models upon initial Huawei SingleCLOUD Discovery.

   Your setting is saved and newly discovered Huawei SingleCLOUD Virtual Machine models created by Virtual Host Manager are placed into maintenance mode per your selection.

Manage Device Models for Deleted Huawei SingleCLOUD Devices
